When a frame arrives at the queue, its size will be *ImmediateEgressEncap+Data*. This size is stored as the *OfferedFrameSize* so that the queue offered stats used in HQoS calculations are correct. Let us refer to the HQoS offered statistics as Offered.

This size is then adjusted by removing the *ImmediateEgressEncap* and adding the *LastMileFrameOverWireEncap*. This new adjusted frame size, let us refer to it as *LastMileOfferedFrameSize*, is then used for checking compliance of the frame against the queue PIR and CIR bucket sizes and for updating the queue forwarded and dropped stats.

The *LastMileOfferedFrameSize* value is computed dynamically for each packet serviced by the queue.

A new HQoS stat counter *OfferedLastMileAdjusted* is maintained for the purpose of calculating the running average frame expansion ratio, which is the ratio of the accumulated *OfferedLastMileAdjusted* and Offered of each queue:

$\text{RunningAverageFrameExpansionRatio} = \text{OfferedLastMileAdjusted} / \text{Offered}$

The vport/port scheduler will hand out its **FoW** bandwidth in terms of Fair Information Rate (FIR) bandwidth to each subscriber queue. This queue FIR must be converted into **LM-FoW** format to cap it by the queue PIR (*adminPIR*) and to make sure the sum of *FIRs* of all queues of the same subscriber does not exceed the subscriber **agg-rate-limit** which is also expressed in **LM-FoW** format. The conversion between these two rates makes use of the cumulative *RunningAverageFrameExpansionRatio* value.

Note that a queue **LM-foW** AdminPIR value will always be capped to the value of the local port **FoW** rate even if the conversion based on the current *RunningAverageFrameExpansionRatio* value indicates that a higher AdminPIR may be able to fill in the full line rate of the local port.

#### 9.4.12.3.6 Vport Determination and Evaluation

In the BNG application, host queues of all subscribers destined to the same downstream BSAN, for example, all SAPs on the egress port matching the same S-VLAN tag value, are parented to the same vport which matches the destination ID of the BSAN.

The BNG determines the parent vport of a subscriber host queue, which has the **port-parent** option enabled, by matching the destination string **dest** string associated with the subscriber with the string defined under a vport on the port associated with the subscriber.

The user configures the dest string match under the egress context of the Ethernet port associated with the subscriber:

**CLI Syntax:** `config>port>ethernet>access>egress>vport>host-match dest string create`

If a given subscriber host queue does not have the **port-parent** option enabled, it will be foster-parented to the vport used by this subscriber and which is based on matching the **dest** string. If the subscriber could not be matched with a vport on the egress port, the host queue will not be bandwidth controlled and will compete for bandwidth directly based on its own PIR and CIR parameters.

By default, a subscriber host queue with the **port-parent** option enabled is scheduled within the context of the port's port scheduler policy. In order to indicate the option to schedule the queue in the context of a port scheduler policy associated with a vport, the user enters the following command in SLA profile used by the subscriber host:

**CLI Syntax:** `config>subscr-mgmt>sla-profile>egress>qos sap-egress-qos-policy-id vport-scheduler`

This command is persistent meaning that the user can re-enter the **qos** node without specifying the **vport-scheduler** argument each time and the system will remember it. The user can revert to the default setting without deleting the association of the SLA profile with the SAP egress QoS policy by explicitly re-entering the command with the following new argument:

**CLI Syntax:** `config>subscr-mgmt>sla-profile>egress>qos sap-egress-qos-policy-id vport-scheduler`

#### 9.4.12.3.7 Applying Aggregate Rate Limit to a Vport

The user can apply an aggregate rate limit to the vport and apply a port scheduler policy to the port.

This model allows the user to oversubscribe the Ethernet port. The application of the **agg-rate** option is mutually exclusive with the application of a port scheduler policy, or a scheduler policy to a vport.

When using this model, a subscriber host queue with the **port-parent** option enabled is scheduled within the context of the port's port scheduler policy. However, the user must still indicate to the system that the queues are managed by the aggregate rate limit instance of a vport by enabling the **vport-scheduler** option in the subscriber host SLA profile:

**CLI Syntax:** `config>subscr-mgmt>sla-profile>egress>qos sap-egress-qos-policy-id vport-scheduler`

A subscriber host-queue which is port-parented will be parented to the port scheduler policy of the port used by the subscriber and aggregate rate limited within the instance of the vport used by this subscriber and which is based on matching the **dest** string and **org** string. If the vport exists but the port does not have a port scheduler policy applied, then the host queue will be orphaned and no aggregate rate limit can be enforced.

If a given subscriber host queue does not have the port-parent option enabled, it will be foster-parented to the port used by this subscriber and aggregate rate limited within the instance of the vport used by this subscriber. If the vport exists but the port does not have a port scheduler policy applied, then the host queue will be orphaned and no aggregate rate limit can be enforced.

#### 9.4.12.3.8 Applying a Scheduler Policy to a Vport

The user can apply a scheduler policy to the vport. This allows scheduling control of subscriber tier 1 schedulers in a scheduler policy applied to the egress of a subscriber or SLA profile, or to a PW SAP in an IES or VPRN service.

The advantage of using a scheduler policy under a vport, compared to the use of a port scheduler (with or without an agg-rate rate), is that it allows a port parent to be configured at the vport level.

Bandwidth distribution from an egress port scheduler to a vport configured with a scheduler policy can be performed based on the level/cir-level and weight/cir-weight configured under the scheduler's port parent. The result is in allowing multiple vports, for example representing different DSLAMs, to share the port bandwidth capacity in a flexible way that is under the control of the user.

The configuration of a scheduler policy under a vport is mutually exclusive with the configuration of a port scheduler policy or an aggregate rate limit.

A scheduler policy is configured under a vport as follows:

**CLI Syntax:** `config>port>ethernet>access>egress>vport# scheduler-policy scheduler-policy-name`

When using this model, a tier 1 scheduler in a scheduling policy applied to a subscriber profile or SLA profiles must be configured as follows:

**CLI Syntax:** `config>qos>scheduler-policy>tier# parent-location vport`

If the vport exists, but port does not have a scheduler policy applied, then its schedulers will be orphaned and no port level QOS control can be enforced.

The following **show/monitor/clear** commands are available related to the vport scheduler:

```
show qos scheduler-hierarchy port port-id vport name [scheduler scheduler-name]
[detail]
```

```
show qos scheduler-stats port port-id vport name [scheduler scheduler-name] [detail]
```

```
monitor qos scheduler-stats port port-id vport name [interval seconds] [repeat
repeat] [absolute|rate]
```

```
clear qos scheduler-stats port port-id vport name [scheduler scheduler-
name] [detail]
```

HQoS adjustment and host tracking are not supported on schedulers that are configured in a scheduler policy on a vport, so the configuration of a scheduler policy under a vport is mutually exclusive with the configuration of the egress-rate-modify parameter.

ESM over MPLS pseudowires are not supported when a scheduler policy is configured on a vport.

#### **9.4.12.3.9 Signaling of Last Mile Encapsulation Type**

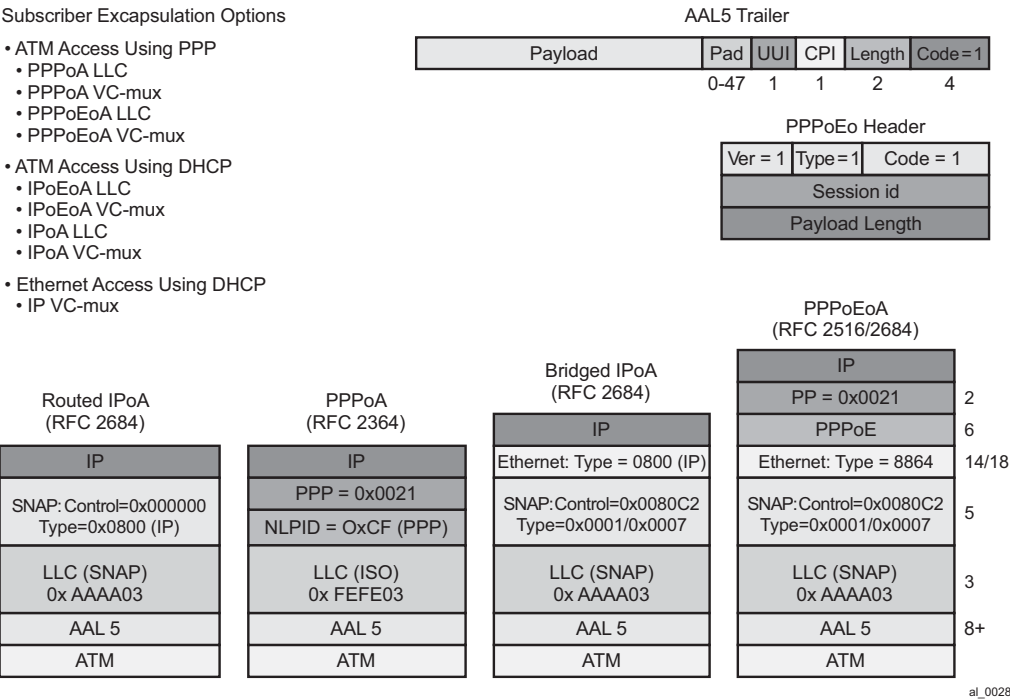

A subscriber host session can signal one of many encapsulation types each with a different fixed offset in the last mile. These encapsulation types are described in RFC 4679 and are illustrated in [Figure 82](#) and [Figure 83](#). The BNG node learns the encapsulation type of each subscriber host session by inspecting the Access-loop-encapsulation sub-TLV in the Vendor-Specific PPPoE Tags as specified in RFC 4679. When Ethernet is the last mile, the encapsulation type will result in a fixed offset for all packet sizes. When ATM/DSL is the last mile, there will be an additional expansion due to AAL5 padding to next multiple of 48 bytes and which varies depending on the packet size.

Both ATM and Ethernet access using PPP encapsulation options are supported in the software and hardware based implementations. Thus both provide support for the Access-loop-encapsulation sub-TLV in the Vendor-Specific PPPoEv4/PPPoEv6 Tags with the ATM encapsulation values and Ethernet encapsulation values.

ATM and Ethernet access using IP encapsulation are only supported using default encapsulation offset configuration in the subscriber profile in the software based implementation. Support for signaling the Access-loop-encapsulation sub-TLV in the DHCPv4/DHCPv6 Relay Options is included in the hardware based implementation. There is no support for DHCPv6 relay options.

Figure 82      Subscriber Host Session Encapsulation Types

**Figure 83 Access-Loop-Encapsulation Sub-TLV**

Encapsulation combinations (RFC 4679)

Valid values for the sub-fields are as follows:

## Data Link

0x00 AAL5  
0x01 Ethernet

## Encaps 1

0x00 NA - Not Available  
0x01 Untagged Ethernet  
0x02 Single-Tagged Ethernet

## Encaps 2

0x00 NA - Not Available  
0x01 PPPoA LLC  
0x02 PPPoA Null  
0x03 IPoA LLC  
0x04 IPoA Null  
0x05 Ethernet over AAL5 LLC with FCS  
0x06 Ethernet over AAL5 LLC without FCS  
0x07 Ethernet over AAL5 Null with FCS  
0x08 Ethernet over AAL5 Null without FCS

## Encapsulation combinations

- AAL5
  - PPPoA LLC/Null
  - IPoA LLC/Null
  - Ethernet over ATM x 4
    - Tagged/Untagged PPP
    - Tagged/Untagged DHCP
  - Total of 20 AAL5 combinations
- Ethernet
  - Tagged/Untagged PPP
  - Tagged/Untagged DHCP
  - Total of four Ethernet combinations
- *Total of 24 access combinations*

The operational last-mile values for hosts on the same sap, having the same SLA profile are displayed in following the show-command:

**CLI Syntax:** `show>service active-subscribers>ale-adjust`

The data-link can have values: atm, other and unknown. If no offset is supplied it will be set to unknown. Other is used when the data-link is non-atm, otherwise it will state atm.

Operational per-queue values can also be found in the show-command:

**CLI Syntax:** `show>qos>scheduler-hierarchy`

Here, one can see whether the queue is operating in last-mile mode. Note that this command is not available on HSMDAv2,

### 9.4.13 Subscriber Volume Statistics

Subscriber volume statistics or octet and packet counters are available through the queues and policers that are instantiated for the subscriber. The queue and policer configuration is defined in the SLA profile via ingress and egress qos policy associations with optional overrides. Subscriber hosts that belong to the same subscriber, that are active on the same SAP and that have the same sla-profile will share the set of queues and policers defined by that SLA profile instance. For HSMDB hardware, the ingress policer/queue and egress queue configuration is defined in the subscriber profile via ingress and egress qos policy associations with optional overrides. All hosts belonging to the subscriber share the same set of queues and policers.

#### 9.4.13.1 IP (Layer 3) Volume Accounting

Subscriber volume statistics by default count Layer 2 frame sizes optionally modified by configuration such as packet-byte-offset, last mile aware shaping, etc.

To report subscriber volume statistics as Layer 3 (IP) packet sizes, the volume-stats-type can be configured to **ip** in the subscriber profile:

```
configure
 subscriber-mgmt
 sub-profile <subscriber-profile-name>
 volume-stats-type ip
```

**volume-stats-type ip** affects the subscriber statistics in SNMP, CLI, RADIUS accounting, XML accounting and Diameter Gx usage monitoring. Volume quota for RADIUS or Diameter Credit Control applications are interpreted as Layer 3 quota.

The following restrictions apply for **volume-stats-type ip**:

- Layer-3/IP accounting is not supported in combination with last-mile-aware shaping on HSMDA
- Layer-3/IP accounting is not supported in combination with ESMoPW on HSMDA
- Layer-3/IP accounting is not supported in combination with MLPPP
- Layer-3/IP accounting in combination with ESMoPW and last-mile-aware shaping may be inaccurate if the MPLS encapsulation overhead changes during the lifetime of a subscriber.
- Layer-3/IP accounting is restricted to a single encap per sla-profile instance (queue instance). The first host associated with the sla-profile instance (queue instance) determines the allowed encap. Conflicting encaps are:
  - PPPoE and IPoE on regular Ethernet SAPs
  - PPPoE and IPoE on PW SAPs
  - PPPoA and PPPoEoA on ATM ports
- PPPoE keep alive packets do not contain IP payload and introduce an error in Layer-3/IP accounting when enabled in combination with L2TP-LAC. A workaround is to isolate the keep alives in a separate queue/policer.
- Padding of frames smaller than the Ethernet minimum frame size (64B) may introduce an inaccuracy in Layer-3/IP accounting.
- With ATM in the last mile, last-mile-aware shaping may introduce an inaccuracy in Layer-3/IP accounting.
- Packet-Byte-Offset (PBO) changes during the lifetime of a subscriber introduces an inaccuracy in Layer-3/IP accounting.

### 9.4.13.2 Separate IPv4 and IPv6 Counters

IPv4 and IPv6 forwarded and dropped subscriber traffic can be counted separately via a **stat-mode v4-v6** command that is configured as a policer or queue qos override in the sla-profile. The **stat-mode v4-v6** command is only applicable for Enhanced Subscriber Management (ESM).

```
configure subscriber-mgmt
 sla-profile "sla-profile-1" create
 ingress
 qos 10
 queue 1
 stat-mode v4-v6
 exit
 policer 1
 stat-mode v4-v6
 exit
 exit
exit
```

```

 egress
 qos 10
 queue 1
 stat-mode v4-v6
 exit
 policer 1
 stat-mode v4-v6
 exit
 exit
 exit
exit

```

For policers, the `stat-mode` command overrides the policer `stat-mode` configuration as defined in the `sap-ingress` or `sap-egress` qos policy. For details on `sap-ingress` and `sap-egress` policer `stat-mode`, refer to the Quality of Service Guide. For a policer in `stat-mode v4-v6`, following counters are available:

- Offered IPv4 octets and packets
- Offered IPv6 octets and packets
- Dropped IPv4 octets and packets
- Dropped IPv6 octets and packets
- Forwarded IPv4 octets and packets
- Forwarded IPv6 octets and packets

When a policer's `stat-mode` is changed while the sla profile is in use, any previous counter values are lost and any new counters are set to zero.

For queues, a `stat-mode` is only available for use in Enhanced Subscriber Management (ESM) context to enable separate IPv4/IPv6 counters. For a queue in `stat-mode v4-v6`, following counters are available:

- Offered High Priority, Low Priority, Uncolored, Managed octets and packets
- Dropped IPv4 octets and packets
- Dropped IPv6 octets and packets
- Forwarded IPv4 octets and packets
- Forwarded IPv6 octets and packets

A queue's `stat-mode` cannot be changed while the sla profile is in use.

Note that there will be no in-profile/out-of-profile forwarded and dropped counters for policers and queues in **stat-mode v4-v6**.

Non IP traffic (for example PPPoE LCP frames) is counted against the IPv4 counters.

The separate IPv4 and IPv6 forwarded and dropped counters are reported in

- RADIUS accounting

When a queue or policer is configured in stat-mode v4-v6, existing VSA's are re-used in RADIUS detailed per queue / per policer accounting (**configure subscriber-mgmt radius-accounting-policy <name> include-radius-attribute detailed-acct-attributes**):

- in-profile counter VSA's map to IPv4 octets/packets
- ingress queue high priority dropped counter VSA's map to IPv4 octets/packets
- out-of-profile counter VSA's map to IPv6 octets/packets
- ingress queue low priority dropped counter VSA's map to IPv6 octets/packets

In addition the [26-6527-107] Alc-Acct-I-statmode / [26-6527-127] Alc-Acct-O-statmode is sent with value set to "v4-v6".

Optionally a set of VSA's can be included in RADIUS accounting to report the aggregate IPv6 forwarded octets and packets of queues and policers with stat-mode v4-v6 enabled (configure subscriber-mgmt radius-accounting-policy <name> include-radius-attribute detailed-acct-attributes v6-aggregate-stats):

[26-6527-194] Alc-IPv6-Acct-Input-Packets

[26-6527-195] Alc-IPv6-Acct-Input-Octets

[26-6527-196] Alc-IPv6-Acct-Input-GigaWords

[26-6527-197] Alc-IPv6-Acct-Output-Packets

[26-6527-198] Alc-IPv6-Acct-Output-Octets

[26-6527-199] Alc-IPv6-Acct-Output-Gigawords

Refer to the 7750 SR RADIUS Attributes Reference Guide for a detailed description of all counter attributes.

- XML accounting

The complete-subscriber-ingress-egress and custom-record-subscriber XML records use following fields to represent IPv4 and IPv6 forwarded/dropped octets and packets for queues or policers with **stat-mode v4-v6** enabled:

v4po - IPv4PktsOffered (policer only)  
v4oo - IPv4OctetsOffered (policer only)  
v6po - IPv6PktsOffered (policer only)  
v6oo - IPv6OctetsOffered (policer only)  
v4pf - IPv4PktsForwarded  
v6pf - IPv6PktsForwarded  
v4pd - IPv4PktsDropped  
v6pd - IPv4PktsDropped  
v4of - IPv4OctetsForwarded  
v6of - IPv6OctetsForwarded  
v4od - IPv4OctetsDropped  
v6od - IPv4OctetsDropped

For custom records, the following CLI is re-used to include v4/v6 counters if the queue is configured in **stat-mode v4-v6**:

i-counters

|                                  |       |
|----------------------------------|-------|
| all-packets-offered-count        | # n/a |
| all-octets-offered-count         | # n/a |
| high-packets-offered-count       | # n/a |
| low-packets-offered-count        | # n/a |
| uncoloured-packets-offered-count | # n/a |
| high-octets-offered-count        | # n/a |

| out-profile-octets-forwarded-count  | # IPv6 |
| out-profile-octets-discarded-count  | # IPv6 |

On HSM DA, **stat-mode v4-v6** is configured as a policer or queue qos override in the subscriber profile:

```
configure subscriber-mgmt
 sub-profile "sub-profile-2" create
 hsmda
 egress-qos
 qos 10
 queue 1
 stat-mode v4-v6
 exit
 exit
 exit
 ingress-qos
 qos 10
 policer 1
 stat-mode v4-v6
 exit
 queue 1
 stat-mode v4-v6
 exit
 exit
 exit
exit
```

The stat-mode on egress hsmda queues is always enabled per subscriber: when enabling **stat-mode v4-v6** for one hsmda queue, it is automatically enabled for all hsmda queues for that subscriber profile.

## 9.4.14 Configuring IP and IPv6 Filter Policies for Subscriber Hosts

Access Control Lists (ACLs) for subscriber traffic are defined as IP and IPv6 filter policies and are configured in the SLA-profile associated with the subscriber. For information about IP and IPv6 filter policy configurations, refer to the Router Configuration Guide.

```
config>subscr-mgmt>sla-prof
 sla-profile sla-profile-1 create
 ingress
 ip-filter 100
 ipv6-filter 300
 exit
 egress
 ip-filter 200
 ipv6-filter 400
 exit
 exit
```

Traffic from different hosts of a single subscriber and associated with the same sla-profile instance, is subject to the filter policies defined in the SLA profile.

The IP or IPv6 filter policy configuration of subscriber hosts can be dynamically updated using different mechanisms:

1. Assign a new SLA profile.

This can be done dynamically by, for example, a RADIUS CoA message. As the SLA profile also defines the QoS configuration for the subscriber hosts, this change may result in a discontinuity in accounting.

Note: changing the ip-filter policy in an SLA profile in use by an active subscriber is allowed in the CLI, but not recommended. Changing the IPv6 filter policy in an SLA profile in use by an active subscriber is prevented in the CLI.

2. Override the IP and IPv6 filter policies

Alternatively, it is also possible to dynamically override the IP and IPv6 filter policies per subscriber-host through a RADIUS Access-Accept or CoA message. Following VSA should be included in the RADIUS message:

3. Insert subscriber host specific filter entries

A subscriber host specific entry is dynamically created from a RADIUS access accept or CoA message using the NAS-Filter-Rule or Alc-Ascend-Data-Filter-Host-Spec attribute (see also [IP Filter Attribute Format Details](#) for a detailed description of the attribute format):

**Table 57** NAS-Filter-Rule or Alc-Ascend-Data-Filter-Host-Spec Attributes

| Attribute ID | Attribute Name  | Type   | Limits                                                               | SR OS Format                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------|-----------------|--------|----------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 92           | NAS-Filter-Rule | String | max. 10 attributes per message or max. 10 filter entries per message | <p>The format of a NAS-Filter-Rule is defined in rfc-3588 section-4.3. A single filter rule is a string of format "&lt;action&gt; &lt;direction&gt; &lt;protocol&gt; from &lt;source&gt; to &lt;destination&gt; &lt;options&gt;". Multiple rules should be separated by a NUL (0x00). A NAS-Filter-Rule attribute may contain a partial rule, one rule, or more than one rule. Filter rules may be continued across attribute boundaries.</p> <p>A RADIUS message with NAS-Filter-Rule attribute value equal to 0x00 or " " (a space) removes all host specific filter entries for that host.</p> <p>See also <a href="#">IP Filter Attribute Format Details</a>.</p> <p>For example:</p> <p>Nas-Filter-Rule = "permit in ip from any to 10.1.1.1/32"</p> |

**Table 57 NAS-Filter-Rule or Alc-Ascend-Data-Filter-Host-Spec Attributes (Continued)**

| Attribute ID | Attribute Name                   | Type   | Limits                                                                                                                                                                   | SR OS Format                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------|----------------------------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 26-6527-159  | Alc-Ascend-Data-Filter-Host-Spec | octets | max. 10 attributes per message or max. 10 filter entries per message.<br>min. length 22 bytes (IPv4), 46 bytes (IPv6)<br>max. length: 110 bytes (IPv4), 140 bytes (IPv6) | a string of octets with fixed field length (type (ipv4/ipv6), direction (ingress/egress), src-ip, dst-ip, ...). Each attribute represents a single filter entry. See <a href="#">IP Filter Attribute Format Details</a> for a description of the format.<br>For example:<br># "permit in ip from any to 10.1.1.1/32"<br>Alc-Ascend-Data-Filter-Host-Spec =<br>0x010101000000000000a0101010020000000000000000000 |

The Alc-Subscriber-Filter VSA is a comma separated list of strings:

**Table 58 Alc-Subscriber-Filter VSA Fields**

| Field            | Use                 |
|------------------|---------------------|
| Ingr-v4:<number> | Ingress ipv4 filter |
| Egr-v4:<number>  | Egress ipv4 filter  |
| Ingr-v6:<number> | Ingress ipv6 filter |
| Egr-v6:<number>  | Egress ipv6 filter  |

The filter number can have following values:

**Table 59 Filter Number Results**

| <number> | Result                                                                                                                                              |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| 1..65535 | Ignore filter from sla-profile configuration and assign corresponding pre-configured filter                                                         |
| 0        | Ignore filter from sla-profile configuration and do not assign a new filter (only allowed if no dynamic subscriber host specific rules are present) |
| -1       | No change in filter configuration                                                                                                                   |

**Table 59** Filter Number Results (Continued)

| <number> | Result                                        |
|----------|-----------------------------------------------|
| -2       | Restore filter from sla-profile configuration |

**Notes:**

- Not relevant fields (IPv4 filters for an IPv6 host) will be ignored.
- RADIUS CoA message: if the ingress or egress field is missing in the VSA, there will be no change for that direction.
- RADIUS Access-Accept message: if the ingress or egress field is missing in the VSA, then the IP filters as specified in the SLA profile will be active for that direction.

An SLA profile IP filter override is applicable to all dynamic host types, including L2TP LNS but excluding L2TP LAC.

- Insert subscriber host specific filter entries

A subscriber host specific entry is a filter entry where the match criteria is automatically extended with the subscriber host IP or IPv6 address as source (ingress) or destination (egress) IP. They represent a per host customization of a generic filter policy: only traffic to/from the subscriber host will match against these entries.

A subscriber host specific entry is dynamically created from a RADIUS access accept or CoA message using the NAS-Filter-Rule attribute:

The format used to specify host specific filter entries (NAS-Filter-Rule format or Alcatel-Data-Filter-Host-Spec format) cannot change during the lifetime of the subscriber host. A RADIUS message can only contain a single format for host specific filter entries.

Up to 10 host specific filter rules can be specified in a single RADIUS message. Each new RADIUS CoA message containing host specific filter attributes overwrites the previous subscriber host-specific filter entries for that host provided that there are enough free entries in the reserved range.

Subscriber host specific filter entries can be removed with a RADIUS CoA message with NAS-Filter-Rule attribute value equal to 0x00 or " " (a space).

When the subscriber host session terminates or is disconnected the corresponding subscriber host specific filter entries are also deleted.

Note that subscriber host-specific filter entries are moved if the subscriber host filter policy is changed (new SLA profile or ip filter policy override) and the new filter policy contains enough free reserved entries (sub-insert-RADIUS).

A range of entries must be reserved for subscriber host specific entries in a filter policy:

```
config>filter
 ip-filter 100 create
 sub-insert-radius start-entry 1000 count
 100
```

High and low watermarks can be configured to raise an event when the thresholds of free entries in the reserved range are reached:

```
config>filter>ip-filter# sub-insert-wmark ?
- no sub-insert-wmark
- sub-insert-wmark low <low-watermark> high <high-
 watermark>
```

<low-watermark> : [0..100]

<high-watermark> : [0..100]

Use following show commands to check filter policy details and the filter configuration for a subscriber host:

```
show filter ip <ip-filter-id> type <entry-type>
show filter ipv6 <ipv6-filter-id> type <entry-type>
 <entry-type> : fixed|radius-insert|credit-control-insert

show service active-subscribers filter [subscriber <sub-ident-string>] [origin
<origin>]
 <sub-ident-string> : [32 chars max]
 <origin> : radius|credit-control
```

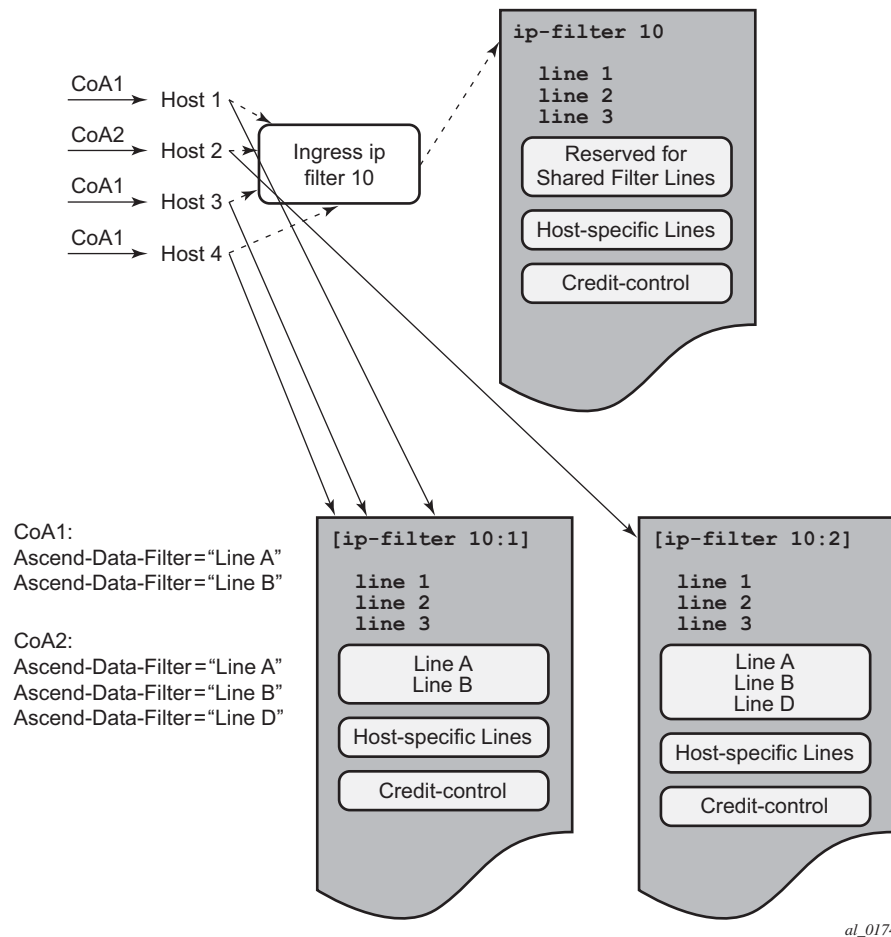

- Insert shared filter entries

The target application for RADIUS shared filter entries is operators that have a predefined limited number of different filter lists that each are shared with multiple subscriber hosts and that are to be managed and activated from RADIUS at authentication.

A local configured ip or ipv6 filter associated with a host (sla-profile or host filter override) can be enhanced with dynamic filter entries that can be shared with multiple subscriber hosts. The shared dynamic filter entries are inserted with a set of RADIUS attributes "[242] Ascend-Data-Filter" or "[26-6527-158] Alc-Nas-Filter-Rule-Shared" received in a RADIUS Access-Accept or CoA message. A CoA message containing a set of one of those attributes overrides the previous set of shared filter entries active for that subscriber host.

For each unique set of dynamic filter entries received per type (ipv4/ipv6) and direction (ingress/egress), a copy is made of the local filter with the dynamic entries included at a preconfigured insert point. If the same set of dynamic filter entries is sent to subscriber hosts that have the same associated local filter, then they will share the same filter copy. When there are no more subscriber hosts associated with a filter copy, then the filter copy is deleted. A filter copy is identified as *local filter id:number*. For example: show filter ip 10:2

Shared filter entries are moved if the subscriber host filter policy is changed (new SLA profile or ip filter policy override) and if the new filter policy contains enough free reserved entries.

**Figure 84** Insert Shared Filters

A range of entries must be reserved for shared entries in a filter policy:

```
config>filter
ip-filter 10 create
 sub-insert-shared-radius start-entry 100 count
 10
```

High and low watermarks can be configured to raise an event when the thresholds of dynamic filter copies are reached:

```
config>filter>ip-filter# shared-radius-filter-wmark ?
- no shared-radius-filter-wmark
- shared-radius-filter-wmark low low-watermark
 high high-watermark
 low-watermark : [0..8000]
```

high-watermark : [0..8000]

The format used to specify shared filter entries (Alc-Nas-Filter-Rule-Shared format or Ascend-Data-Filter format) cannot change during the lifetime of the subscriber host. A RADIUS message can only contain a single format for shared filter entries.

Shared filter entries can be removed with a RADIUS CoA message with Alc-Nas-Filter-Rule-Shared attribute value equal to 0x00 or " " (a space).

**Table 60** Alc-Nas-Filter-Rule-Shared Attributes

| Attribute ID | Attribute Name             | Type   | Limits                                                                                                                                             | SR OS Format                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------|----------------------------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 242          | Ascend-Data-Filter         | Octets | multiple attributes per RADIUS message allowed.<br>min. length 22 bytes (IPv4), 46 bytes (IPv6)<br>max. length: 110 bytes (IPv4), 140 bytes (IPv6) | a string of octets with fixed field length (type (ipv4/ipv6), direction (ingress/egress), src-ip, dst-ip, ...). Each attribute represents a single filter entry. See <a href="#">IP Filter Attribute Format Details</a> for a description of the format.<br>For example:<br># "permit in ip from any to 10.1.1.1/32"<br>Ascend-Data-Filter =<br>0x010101000000000000a0101010020000000000000000000                                                                                                                                                                                                                                                                                                                                              |
| 26-6527-158  | Alc-Nas-Filter-Rule-Shared | string | Multiple attributes per RADIUS message allowed.                                                                                                    | The format is identical to [92] NAS-Filter-Rule and is defined in rfc-3588 section-4.3. A single filter rule is a string of format "<action> <direction> <protocol> from <source> to <destination> <options>". Multiple rules should be separated by a NUL (0x00). An Alc-Nas-Filter-Rule-Shared attribute may contain a partial rule, one rule, or more than one rule. Filter rules may be continued across attribute boundaries.<br>A RADIUS message with Alc-Nas-Filter-Rule-Shared attribute value equal to 0x00 or " " (a space) removes the shared filter entries for that host.<br>See also <a href="#">IP Filter Attribute Format Details</a> .<br>For example:<br>Alc-Nas-Filter-Rule-Shared = "permit in ip from any to 10.1.1.1/32" |

### 9.4.14.1 IP Filter Attribute Format Details

The format for [92] Nas-Filter-Rule and [26-6527-158] Alc-Nas-Filter-Rule-Shared is a string formatted as: “*action direction protocol from source to destination options*”. Refer to the table below for details on the respective fields.

**Table 61 Nas-Filter-Rule and Alc-Nas-Filter-Rule-Shared Fields**

| Action or Classifier | Value                        |           | Corresponding SR-OS Filter Function                                                                                        |
|----------------------|------------------------------|-----------|----------------------------------------------------------------------------------------------------------------------------|
| <direction>          | in                           |           | ingress                                                                                                                    |
|                      | out                          |           | egress                                                                                                                     |

|                        | address mask request    |  | protocol 1 / icmp-type 17           |
|                        | address mask reply      |  | protocol 1 / icmp-type 18           |
|                        | -                       |  | protocol 1 / icmp-type [0..255]     |
|                        | 3-9 ( range)            |  | not supported                       |

**Table 61 Nas-Filter-Rule and Alc-Nas-Filter-Rule-Shared Fields (Continued)**

| Action or Classifier   | Value                      | Corresponding SR-OS Filter Function |
|------------------------|----------------------------|-------------------------------------|
|                        | 3,5,8,9 ( comma separated) | not supported                       |
| <options: icmptypesv6> | destination unreachable    | icmp-type 1                         |
|                        | time-to-live exceeded      | icmp-type 3                         |
|                        | IP header bad              | icmp-type 4                         |
|                        | echo request               | icmp-type 128                       |
|                        | echo reply                 | icmp-type129                        |
|                        | router solicitation        | icmp-type 133                       |
|                        | router advertisement       | icmp-type 134                       |
|                        | redirect                   | icmp-type 137                       |

The format for [242] Ascend-Data-Filter and [26-6527-159] Alc-Ascend-Data-Filter-Host-Spec is an octet string with fixed length fields. Refer to the table below for details on the respective fields.

**Table 62 Ascend-Data-Filter and Alc-Ascend-Data-Filter-Host-Spec Fields**

| Field                  | Length          | Value                                   |
|------------------------|-----------------|-----------------------------------------|
| Type                   | byte            | 1 = IPv4                                |
|                        |                 | 3 = IPv6                                |
| Filter or forward      | 1 byte          | 0 = drop                                |
|                        |                 | 1 = accept                              |
| Indirection            | 1 byte          | 0 = egress                              |
|                        |                 | 1 = ingress                             |
| Spare                  | 1 byte          | ignored                                 |
| Source IP address      | IPv4 = 4 bytes  | IP address of the source interface      |
|                        | IPv6 = 16 bytes |                                         |
| Destination IP address | IPv4 = 4 bytes  | IP address of the destination interface |
|                        | IPv6 = 16 bytes |                                         |
| Source IP prefix       | 1 byte          | Number of bits in the network portion   |

**Table 62** Ascend-Data-Filter and Alc-A ascend-Data-Filter-Host-Spec Fields (Continued)

| Field                      | Length  | Value                                                               |
|----------------------------|---------|---------------------------------------------------------------------|
| Destination IP prefix      | 1 byte  | Number of bits in the network portion                               |
| Protocol                   | 1 byte  | Protocol number.<br>Note: match the inner most header only for IPv6 |
| Established                | 1 byte  | ignored (not implemented)                                           |
| Source port                | 2 bytes | Port number of the source port                                      |
| Destination port           | 2 bytes | Port number of the destination port                                 |
| Source port qualifier      | 1 byte  | 0 = no compare                                                      |
|                            |         | 1 = less than                                                       |
|                            |         | 2 = equal to                                                        |
|                            |         | 3 = greater than                                                    |
|                            |         | 4 = not equal to (not supported)                                    |
| destination port qualifier | 1 byte  | 0 = no compare                                                      |
|                            |         | 1 = less than                                                       |
|                            |         | 2 = equal to                                                        |
|                            |         | 3 = greater than                                                    |
|                            |         | 4 = not equal to (not supported)                                    |
| Reserved                   | 2 bytes | ignored                                                             |

### 9.4.14.2 Checking Filter Policy Details

Use following show commands to check filter policy details and the filter configuration for a subscriber host:

```
show filter ip ip-filter-id detail
show filter ipv6 ip-filter-id detail
show filter ip ip-filter-id type entry-type
show filter ipv6 ipv6-filter-id type entry-type
 entry-type : fixed | radius-insert | credit-control-
 insert | radius-shared
show service active-subscribers filter [subscriber sub-
 ident-string] [origin origin]
```

---

```
sub-ident-string : [32 chars max]
origin : radius | credit-control"
```

## 9.4.15 ESM PPPoA/PPPoEoA

The main goal of PPP in the subscriber context is to provide authentication, to negotiate link layer parameters (such as MTU) and to negotiate IP parameters (IP address, WINS, DNS, Default Gateway, etc.).

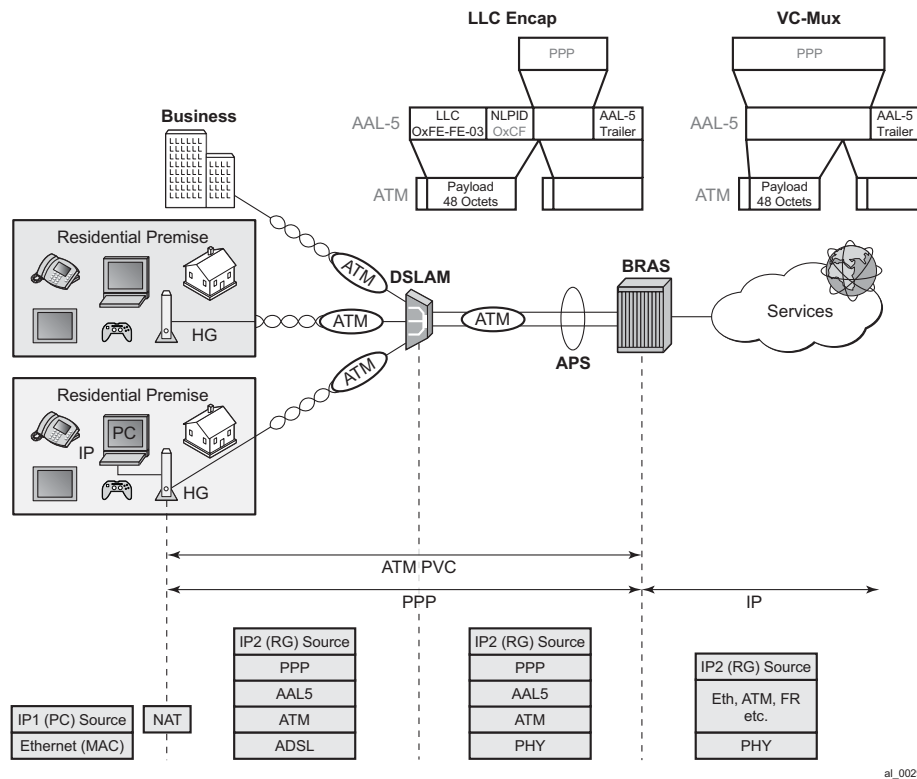

Each PPP session is carried over a single ATM VC over to the BNG. In PPPoA environment, PPP session is directly encapsulated over ATM transport on a DSL Customer Premise Equipment (CPE).

In the PPPoEoA environment, an additional layer is added to accommodate Ethernet medium. In this fashion, a PPP session can be directly terminated on any host within the customer Ethernet network and then transported over an ATM network to the BNG. Multiple PPPoE sessions can be carried over a single ATM PVC.

However, the majority of current implementations in ATM transport networks have PPPoE session terminated at the DSL CPE and not on a host within the customer network. This PPPoE session is then transported over ATM to the BNG. Although it seems unnecessary to add the overhead associated with Ethernet on an ATM-equipped DSL CPE, mainly for historical reasons PPPoE became ingrained in the home network and as such has moved into DSL CPE.

### 9.4.15.1 PPPoA

In a PPPoA environment, services are offered to residential and business customers. DSL CPE and BNG are the originating and terminating points of a PPP connection. In a residential example, a DSL CPE is a Home Gateway (HG) as shown in [Figure 85](#).

**Figure 85 PPPoA Architecture and Packet Encapsulation**

An ATM VC must exist between a CPE and a BNG before a PPP session can be established. From a QoS perspective, this VC is one of the following service categories: CBR, rt-VBR, nrt-VBR or UBR(+). CPE starts negotiating PPP link/session parameters over the VC. Once the IP address is obtained from the Service Provider (SP) side, the customer is ready for data transfer. There is a 1:1 mapping between a PPPoA session and a VC.

There is no need for the customer to run PPP within its own network. CPE, as a default gateway, accepts Ethernet IP packets, strips off the Ethernet header, performs a NAT function, and encapsulates the IP packets into PPPoA before it sends them on to the BNG.

In most residential cases, this PPPoA session is used for pure data transport (Internet access). As such, the BNG side would require a single service queue per VC.

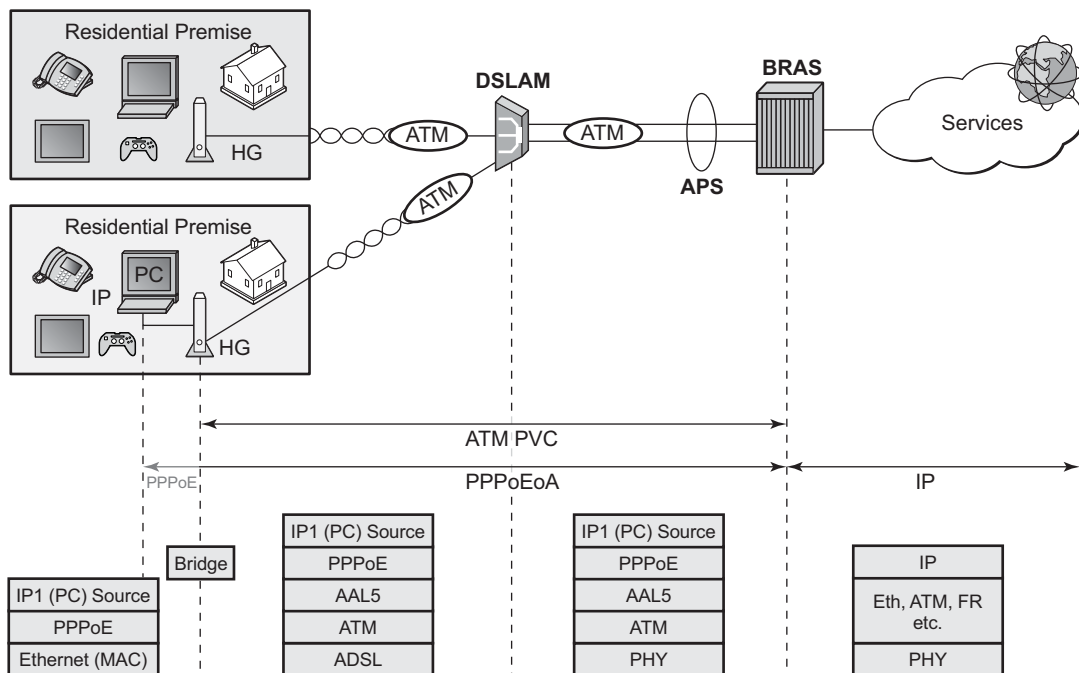

In certain cases, customers use PPPoA for VoIP. In this case, they use an IAD (Integrated Access Device) to gain access to the ATM network.

It must be noted here that nothing in this architecture precludes customers from using multiple services over a single PPPoA session. Services would be differentiated through DSCP bits and each service in this case would require a separate queue. This is most likely a scenario with business customers where a customer runs multiple services over a PPPoA session. DSL CPE would play a role here in differentiating and appropriately marking the services, either through a separate physical port per service or through some other means.

### 9.4.15.2 PPPoEoA

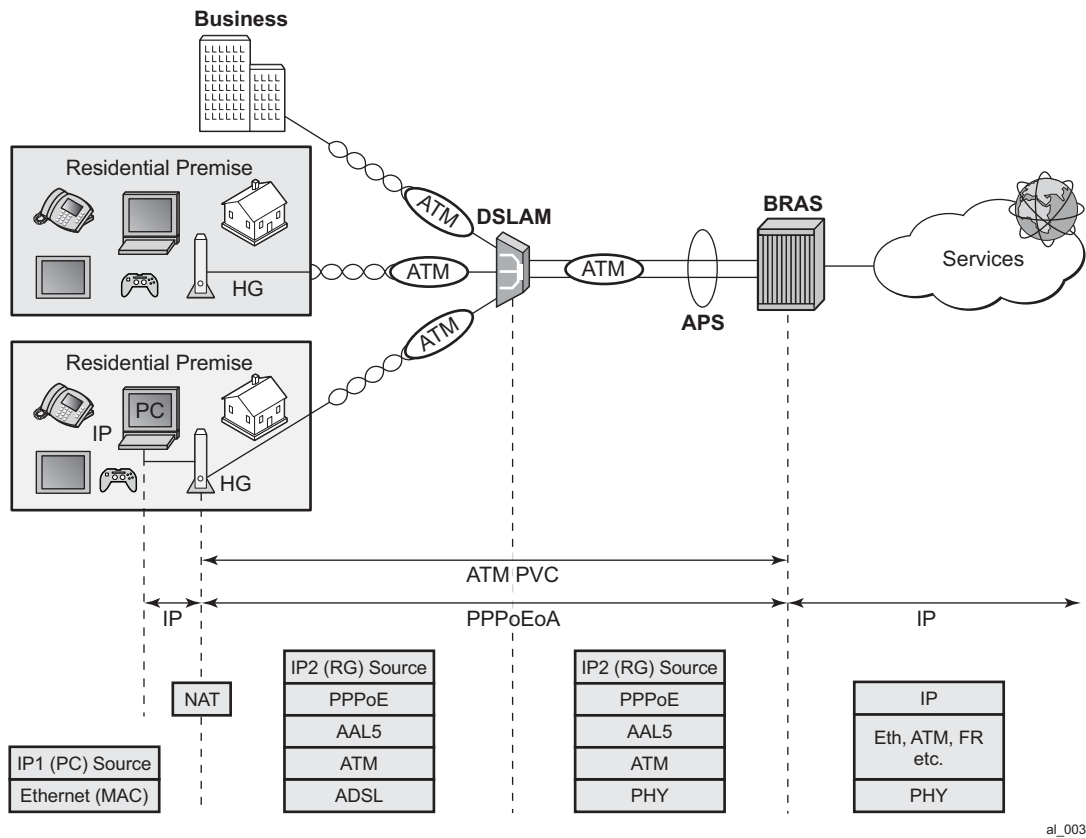

In the PPPoE model the originating PPP point could extend beyond the DSL CPE and into the customer Ethernet network where any host can originate a PPP session. In such case, ATM is generally used as a transport to carry PPPoE sessions that are originated by hosts within the customer network (beyond DSL CPE). The DSL CPE would operate in a bridged mode. This is shown in [Figure 86](#).

**Figure 86 PPPoEoA Host Terminated Session**

al\_0030

However, the majority of deployments have PPPoE sessions terminated in DSL CPE. Although it is inefficient to add an extra Ethernet encapsulation layer over ATM-equipped DSL CPE, the evolution of PPP in broadband is the chief reason for this deployment scenario as shown in [Figure 87](#).

**Figure 87 PPPoEoA DSL CPE Terminated Session**

al\_0031

PPPoEoA implementation must allow multiple PPPoE sessions of the same subscriber to be carried over a single ATM PVC.

### 9.4.15.3 Hardware Support

This feature is supported on ATM MDA on:

- 7750 SR (SR-12, SR-7) platforms
- 7750 SR-c4/12 platforms
- 7450 ESS platforms in Mixed Mode.

This feature is implemented only on IOM3 based hardware.

ATM MDAs:

- 16 port ATM OC-3/STM-1 (single rate)

- 4 port ATM OC-3/12c/STM-1/4c (dual rate on a per port basis; oc3/stm1 or oc12/stm4; port speed can only be changed in groups of four ports).

Chassis modes B,C and D are supported.

PPPoEoA/PPPoA will NOT be supported on the following modules:

ASAP MDAs:

- 4 port channelized OC-3/STM-1 (IOM2-20G and IOM3-XP)
- 1 port channelized OC-12/STM-4
- 12 port channelized DS3/E3 (coax)
- 4 port channelized DS3/E3 (coax)

ATM CMA:

- 8 port T1/E1 ATM (RJ-48)

The 7750-c4/12 currently supports only the four port ATM MDA.

#### **9.4.15.4 Termination Points within 7450 ESS and 7750 SR**

PPPoA/PPPoEoA sessions are terminated on the access ATM SAP in IES and IP-VPN service context through subscriber/group interfaces.

However, for the wholesale/retail deployment scenarios, the ATM VCs are terminated on the LAC while the PPP(oE) sessions will be terminated on the LNS.

PPPoA/PPPoEoA is not supported in the wholesale/retail VRF model (wholesale VRF + retailer VRF). However it is supported in wholesale/retail MSAP model (capture SAP in VPLS that is mapped into a VRF).

### 9.4.15.5 PPPoA Encapsulation

PPP frames are transported over ATM using ATM AAL5 framing mechanism. This is defined in RFC 2364. In short, each PPP packet is appended by an 8-octet AAL5 trailer with some control information (16-bit length field and a 32-bit CRC being the most important). This new frame is not self-identifying, in other words, kind of payload it carries (PPP, IPv4, IPv6, ARP, MPLS, etc.) can not be identified. This means that if you want to send it as such, it can carry only a single protocol type which must be agreed upon in advance by configuration at each side of a PVC connection. Only then will both ends of the connection be able to recognize the payload type inside of it.

To add more flexibility to the payload type and allow multiple protocol types to be multiplexed within a single VC session, an additional header must be defined in the AAL-5 packet. This header which allows protocol multiplexing over ATM VC is called Link Layer Control (LLC) header. PPP transport over ATM using LLC is defined in RFC 2364, *PPP over AAL5*. A more extensive version for multiplexing protocols over VC is defined in RFC 2684 "Multiprotocol Encapsulation over ATM AAL5" (LLC/ SNAP encap).

7450 ESS and 7750 SR supports these two types of PPPoA encapsulation:

1. LLC (RFC 2364)

LLC header is extended with a NLPID (Network Layer Protocol Identifier) which identifies the protocol type inside of the AAL5 frame. NLPID for PPP in LLC is 0xCF.

**Figure 88 PPPoA LLC Encapsulation**

Possible CLI syntax:

```
encapsulation aal5nlpid-ppp
```

The **ppp** keyword in the **aal5nlpid-ppp** command is used to indicate that ppp is the only encapsulation that currently supported in NLPID.

SNAP is an extension to LLC for protocols that are not defined in LLC NLPID. PPP protocol identifier is defined within NLPID and therefore it does not need additional SNAP header (this reduces the overall AAL5 header overhead).

LLC/SNAP encapsulation is defined in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*, and it is needed for PPPoEoA encapsulation.

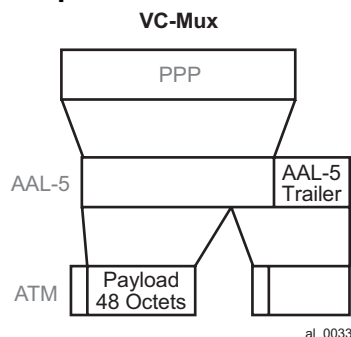

## 2. VC-MUX

In VC-MUX mode there is no additional (LLC/SNAP) header used for protocol multiplexing. Instead, VC endpoints must agree before hand on the payload type that they will transport. For PVCs this is done during the provisioning phase on each side of the connection. For example:

encapsulation aal5mux-ppp

aal5mux-ppp will tell each end of the VC in advance that the payload inside of the AAL5 frame is PPP.

**Figure 89 PPPoA AAL5MUX Encapsulation**

### 9.4.15.5.1 PPPoEoA Encapsulation

Similar to PPPoA, two types of encapsulation are defined for PPPoEoA:

- Protocol multiplexing (Layer 2 bridging defined by additional headers - LLC/SNAP).
- VC-Multiplexing where payload type within a VC is agreed upon in advance by static configuration.

Both types are supported in our implementation:

1. "Multiprotocol Encapsulation over ATM AAL5" (LLC/SNAP) defined in RFC 2684.

This encapsulation adds support for protocols that are currently not defined in the LLC header. There are two basic types of encapsulations defined under this RFC:

- Routed
- Bridged

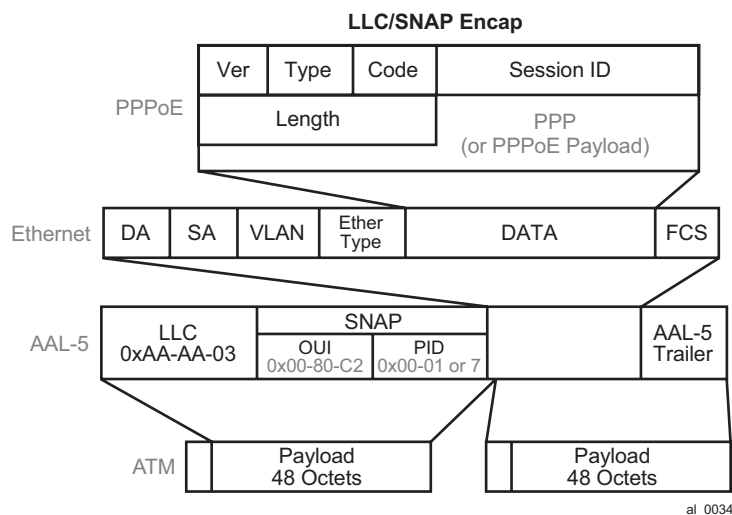

PPPoEoA encapsulation is defined as 'Bridged' where Layer 2 information is preserved through transitioning between two different Layer 2 network types (Ethernet -> ATM) which is shown in [Figure 90](#).

0xAA-AA-03 in the LLC header indicates the presence of the SNAP header.

0x00-80-C2 in the OUI indicates that a bridged PDU is encapsulated.

0x00-01 or 0x00-07 in PID indicates that the encapsulated Layer 2 network type is 802.3 Ethernet with or without preserved FCS.

**Figure 90**      **PPPoEoA Bridged LLC/SNAP Encapsulation**

The CLI syntax is:

encapsulation aal5snap-bridged

- VC-MUX

In the VC-MUX mode there is no additional (LLC/SNAP) header used for protocol multiplexing. Instead, the VC endpoints must agree before hand on the payload type that they will transport. For PVCs this is done during the provisioning phase on each side of the connection. For example:

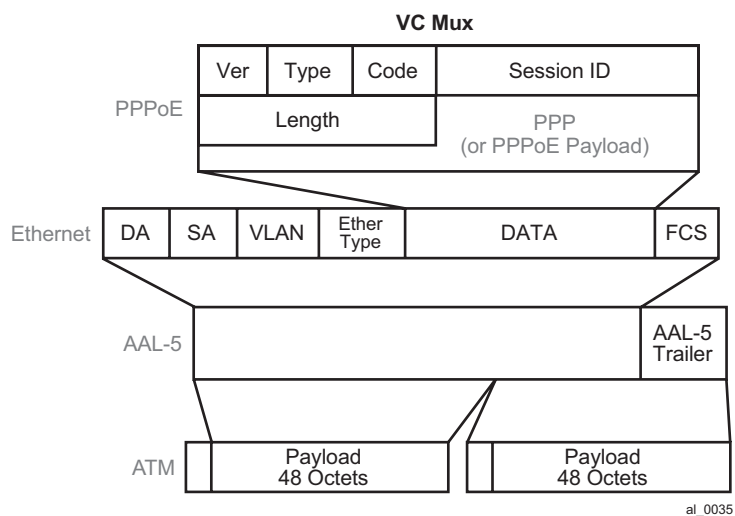

encapsulation aal5mux-bridged-eth-nofcs

aal5mux-bridged-eth-nofcs tells each end of the VC in advance that the payload inside of the AAL5 frame is an Ethernet frame. In this case, it accepts the frame and treat it as an Ethernet frame inside AAL5. The EtherType within the frame must be set to 0x8863 (PPPoE Discovey Phase) or 0x8864 (PPPoE Session Phase).

The '-nofcs' portion indicates that the FCS is not supported on those Ethernet frames.

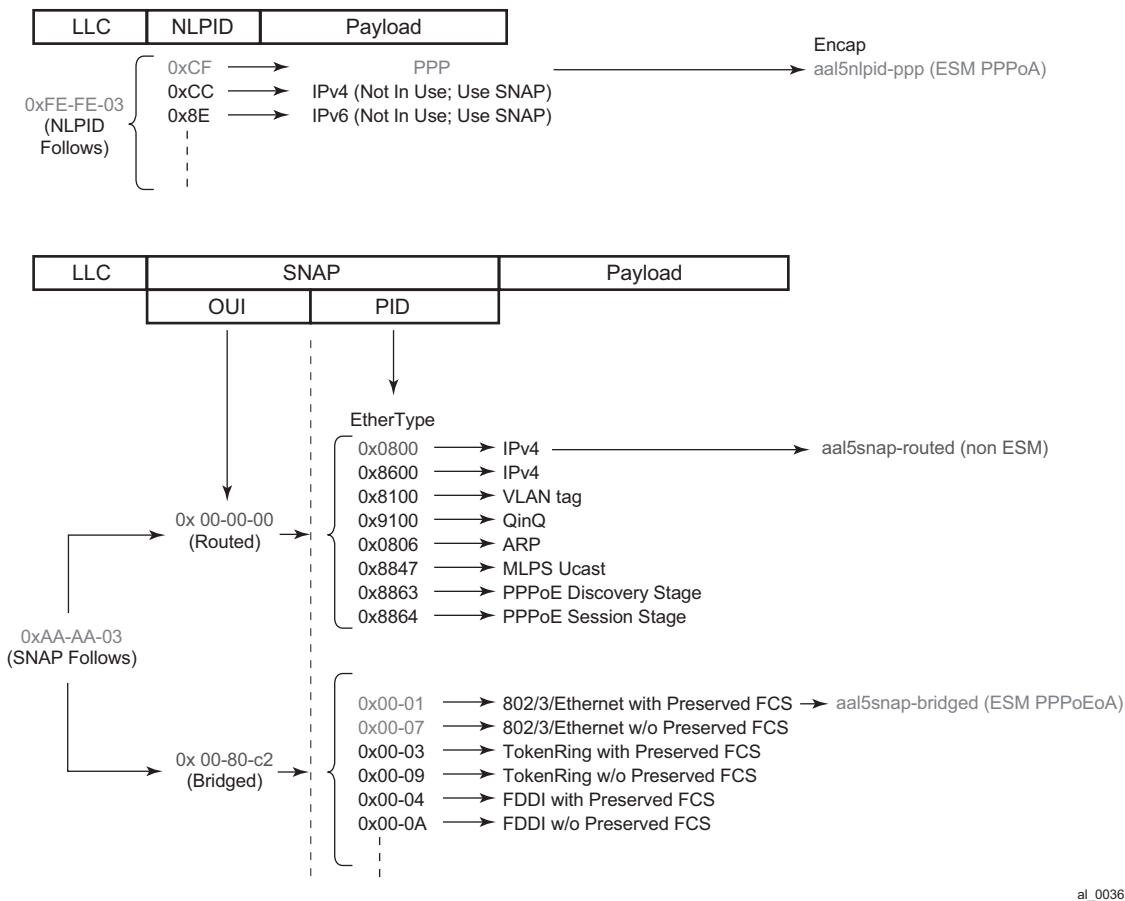

PPPoEoA encapsulation is shown in [Figure 91](#).

**Figure 91 PPPoA AAL5MUX Encapsulation**

### 9.4.15.6 Encapsulation Summary

**Figure 92 LLC/SNAP Encapsulation**

al\_0036

There is a 0-2Byte additional padding (optional) in the SNAP Bridged encapsulation header that is not shown in Figure 92. This padding, according to RFC 2684, is necessary to align the info field (payload of the Layer 2 encapsulated frame) on a 4-Byte boundary.

At the end the following types of ATM encapsulation are supported on 7450 ESS and 7750 SR in ESM:

#### aal5snap-bridged

This encapsulation type is used for PPPoEoA encapsulation with FCS or without FCS on ingress. On egress only frames without MAC FCS can be sent. PPPoE session type will be determined based on the EtherType in the Ethernet frame.

aal5mux-bridged-eth-nofcs

This encapsulation type is used for mux PPPoEoA sessions without MAC FCS.

aal5nlpid-ppp

This encapsulation type is used for LLC/NLPID PPPoA encapsulated packets.

aal5mux-ppp

This type encapsulation is used for PPPoA traffic without LLC/SNAP header (VC-MUX).

aal5auto (new command)

This encapsulation type is supported in ESM and it is used for auto detecting the encapsulation type. This is also called autosensing.

All hosts for the same subscriber will use the same encapsulation type.

#### 9.4.15.7 Concurrent Support for Different Service Types on the Same Port

An ATM port on 7450 ESS and 7750 SR can concurrently support various service types. One service type can be mapped only to one VC. This would normally be the case if there is an aggregation network in front of 7450 ESS and 7750 SR. A Service Provider could run a variety of services over this aggregation network (ATM switches) connected on the same physical port within the routers.

For example, the following services can be run on the same physical port:

- PPPoA/PPPoEoA sessions connecting residential/business customers through a DSLAM to 7450 ESS and 7750 SR
- Providing access for xPIPE services
- Plain aal5snap-ip or vc-mux-ip PVC for Internet access

#### 9.4.15.8 Restrictions in Scaled ATM MDA Mode

**Note:** ATM concatenation mode for Apipe is not supported in the 16K VC mode.

In the concatenated mode, cells are delayed so that they can be concatenated and delivered in a single packet over to pseudowires to the other side. Without concatenation, each cell is transported individually. The implication is that each cell is individually encapsulated into Eth/MPLS which results in wasted bandwidth on the link.

Support for the concatenated ATM pseudowires is not removed from the CLI in the 16K mode of operation:

```
configure
service apipe <id> [vc-type <cell-type>]
 spoke-sdp <sdp:pw> cell-concatenation
 [no] aal5-frame-aware
 [no] clp-change
 [no] max-cells
 [no] max-delay
```

Instead:

- Adding an ATM port or a connection profile on an MDA in 16-VC mode to an APIPE is disabled if the vc-type is set to atm-cell AND cell-concatenation is enabled.

```
A:BNG>config>service>apipe# sap x/y/z:cp.w create
```

```
MINOR: SVCMGR #2603 Cell-concatenation is not allowed on 16k VC-mode
ATM MDAs
```

- cell-concatenation on an APIPE of the vc-type atm-cell is disabled if it already contains an ATM port or a connection profile.

```
A:BNG>config>service>apipe>spoke-sdp>cell-concat# max-delay X
```

```
MINOR: SVCMGR #2603 Cell-concatenation is not allowed on 16k VC-mode
ATM MDAs
```

Note that regular VPI/VCI SAPs (sap:vpi/vci) are not allowed to be configured on an Apipe of vc-type atm-cell.

Cell-concatenation is supported on Apipe services with a VC on an ATM MDA in the 8-VC mode.

AAL5 SDU mode is continued to be supported.

### 9.4.15.9 QoS Implementation

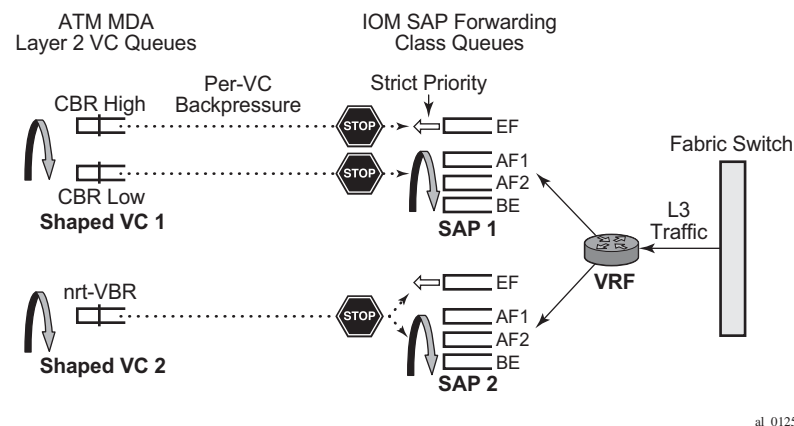

In addition to our system QoS that is provided in the “Q” chip on IOM, the ATM MDA offers QoS capabilities at the ATM cell level. In the context of this document, the system QoS is referred to as ‘IOM QoS’ and to ATM MDA provided QoS simply as ‘ATM QoS’.

Both, IOM QoS as well as ATM QoS defined by Traffic Descriptors working at the cell level, play a role in the overall QoS for the SAP (or virtual circuit). ATM QoS defines rates of each VC stream and defines the behavior under port congestion. IOM QoS defines bandwidth allotment and the scheduling scheme for each service within a VC stream.

In general, both MDAs, ATM and ASAP, support four traffic categories:

- CBR
- Rt-VBR
- Nrt-VBR
- UBR

**Figure 93 Scheduling on ATM MDA**

al\_0125

Each ATM traffic category is defined by a set of parameters, such as PIR, SIR, MIR, MBS and CDTV.

Currently, policing is supported only on ingress for CBR and VBR traffic classes. CBR traffic class police at PIR, while rt/nrt-VBR police at SIR.

Shaping is supported only on egress for CBR and rt/nrt-VBR traffic classes. CBR shapes traffic at PIR, while rt/nrt-VBR shape traffic at SIR. Egress shaping can be disabled only for nrt-VBR traffic class.

Scheduling at the ATM layer is shown in [Figure 93](#). Shaped CBR and VBR traffic classes have two queues, an HP and an LP queue. Packets from IOM are marked according to scheduling priority of the Forwarding Class (expedited or best-effort) from which they were sent and are accepted into the ATM VC queue (HP | LP) accordingly. For example, at the IOM level packets from an expedited FC (queue) are marked as HP, and the packets from a best-effort FC (queue) are marked as LP. When these packets arrive to MDA, they will be admitted into appropriate queues, pending VC (or port) buffer availability.

Non-shaped VBR and UBR have only one queue at the MDA level.

In terms of the ATM QoS scheduling, CBR has the highest scheduling priority (strict priority) followed by rt-VBR (also strict priority). The remaining traffic classes (non-shaped VBR and UBR) are serviced in WRR fashion, the weight being their configured SIR (non shaped nrt-VBR) or MIR (UBR) rate.

There are several areas of QoS that are addressed in relation to integration of IOM QoS and ATM QoS:

- Association between the subscriber and ATM VC traffic descriptor.
- Rate adjustments between Layer 3 and ATM QoS rates due to difference in frame/cell sizes on which they operate.
- Per VP shaping.

#### **9.4.15.10 Association Between the Subscriber and ATM VC Traffic Descriptor (QoS)**

Each PPPoA PVC is of a certain traffic class – CBR, rt/nrt-VBR or UBR/UBR+MIR which along with other parameters is defined in the ATM traffic descriptor profile. For ATM service categories and traffic descriptors. There should be a uniform mapping between service offered and Layer 3 and ATM QoS.

**Figure 94 ATM Traffic Descriptor Association with Subscriber**

al\_0037

The ATM traffic descriptor (atm-td) is applied to a VC under the SAP CLI hierarchy. In this fashion, MDA related QoS (ATM QoS) is referenced outside of the subscriber context (SUB/SLA-profiles).

The following describes the operability:

atm-td for the VC is applied under the SAP:

```
configure
 services ies/vprn
 subscriber-interface <sub-if-name>
 group-interface <grp-if-name>
 sap <sap-id>
 atm
 ingress
 traffic-desc <id>
 egress
 traffic-desc <id>
```

and for MSAP:

```
configure
 subscriber-management
 msap-policy <name>
 atm
 ingress
 traffic-desc <id>
 egress
 traffic-desc <id>
```

The msap-policy is then invoked via LUDB, RADIUS or the default-msap-policy under the capture SAP.

This allows router to have preconfigured MSAP policies, each corresponding to a specific VC type with its own traffic-class parameters (CBR/rt-nrt-VBR/UBR.). Each subscriber with corresponding hosts is then associated with a msap-policy that determines the VC type.

A more flexible way to go about this would be to allow the subscriber to reference the atm-td directly by the sub-host at the host creation time, independently of the msap-policy. This is supported in the following manner:

- atm-td is referenced via a RADIUS VSA in the Access-Accept message.
- There are two VSAs, one for ingress and one for egress atm-td:
  - alc-ingress-atm-td  
(ATTRIBUTE Alc-ATM-Ingress-TD-Profile 128 integer)
  - alc-egress-atm-td  
(ATTRIBUTE Alc-ATM-Egress-TD-Profile 129 integer)
- Only the first host of the subscriber can overwrite the atm-td that is defined under the msap-policy or under the static SAP.
- Consecutive hosts (second, third, and so on) of the same subscriber will not have any effect on the atm-td of the VC. For example, if the second host tries to overwrite the existing atm-td with a different atm-td, it will fail. Once the atm-td is set via the Access-Accept message for the first host, it cannot be changed as long as the subscriber is active in the system. This implies that all hosts of the same subscriber will have the same atm-td.
- If another hosts of the same subscriber initiates a session with a different atm-td name in the Access-Accept message, the host will be created but the atm-td for the VC will not be changed. A trap/syslog will be generated with a 'VC-parameter-mismatch:VSA ignored' info message.
- atm-td change will not be supported through CoA.

The following guidelines should be followed in configuring ATM traffic descriptors:

- ATM policing is the only function that can discard ATM cells on an ATM MDA
- Ingress:
  - ATM policing can only be enabled on ingress.
  - Policing is disabled by default.
  - Policing can only be enabled for the following traffic categories: CBT, rt-VBR and nrt-VBR.
  - CBR police at PIR. CBR is CLP transparent (it does not look at the CLP bit – aggregate traffic policing).

- rt-VBR and nrt-VBR police at SIR and can operate either in CLP Significant (CLP marking) or CLP transparent mode (only relevant for Apipes and not for ESM).
- In CLP significant mode with policing enabled, traffic is policed at the PIR value, but it can be marked with CLP 1 if it exceeds the SIR rate (only relevant for Apipes and not for ESM).
- Ingress classification: the service category and CLP bits only affect Apipe traffic. If ATM traffic is terminated in the BNG, rely on the existing QoS classification implemented in the IOM.
- Egress:
  - Shaping is supported only on egress. Traffic shaping is supported for CBR, rt/nrt-VBR service categories.
  - ATM MDA is cell “lossless” — It sends backpressure to IOM which drops packets.

#### **9.4.15.11 Per VP Shaping**

VCs traversing the same DSLAMs will typically use the same VPI. To prevent overrunning DSLAM capacity (intermediate destinations) in case an aggregation network is in place (between BNG and a DSLAM), per VP shaping will be implemented.

**Figure 95** VP Shaper

al\_0038

The shaping rate per VP and the VP service type is provisioned manually via a traffic descriptor on a per port level. The CLI syntax is:

```
config
 port <port-id>
 sonet-sdh
 path
 atm
 vp <vpi> egress-traffic-desc <atm-td-profile-id>
```

Where the vpi is a VPI identifier and the egress-traffic-desc is the traffic descriptor id. Only traffic descriptors with service-category of cbr, rt-vbr and nrt-vbr can be used in VP Shapers. However, only the rate in the traffic descriptor can be changed on-the-fly, and not the service category (nrtVBR, rtVBR, CBR). A VP shaper can be added to or removed from active VCs.

CBR VP Shaper shapes cells at the exact PCR rate. There is no burst concept in CBR shaping. Excessive traffic is back-pressured towards the IOM (Q-chip).

The IOM will never send more frames to the ATM MDA than the MDA cannot buffer. This is implemented through a combination of software and hardware backpressure mechanisms. This backpressure mechanism utilizes a combination of hardware and software. Software backpressure aims to have around 100ms of traffic queued against a VC based on its configured shaping/scheduling rate, but being a software mechanism that is only a guideline. As ATM MDA detects more traffic that it can accept, a hardware backpressure is exerted.

A rt/nrt-VBR type VP Shaper has three parameters associated with it: PCR (peak cell rate), SCR (sustained cell rate) and MBS (maximum burst size at a peak rate). As long as there is enough MBR credit, traffic will be shaped at the PCR rate. Once all MBR credit (burst) is exhausted, traffic will be shaped at the SCR rate. Bursting above the SCR is configurable via the MBS parameter.

In both cases cells will be spaced at 1/PCR or 1/SCR as perfectly as possible with minimum jitter.

VP shaping is supported only when the ATM MDA is in max16k-vc mode. The maximum number of VP shapers per MDA is 128.

The maximum number of VCs that can feed into a single VP shaper is 16K. This includes the sum of all VC-ranges on the VP plus any statically configured VC on that VP.

VCs within the VP tunnel is serviced by a single scheduler assigned to each VP tunnel. The ATM VP shaper will condition the aggregate traffic for all ATM VCs within the VP tunnel. VCs within the shaped VP tunnel are degraded from the originally assigned service category to a common UBR service category (default traffic descriptor). If the VP shaper is removed from the VCs, the VCs will be reverted to their original service category. Scheduling between VCs will be WRR based with a weight parameter that is explicitly configured. The weights assigned to VCs within the VP tunnel are in range 1-255. By default, VCs are assigned a priority based on the originally assigned service category:

- VC degraded from CBR = weight 10
- VC degraded from rt-VBR = weight 7
- VC degraded from nrt-VBR = weight 5
- VC degraded from UBR+ = weight 2
- VC degraded from UBR = weight 1

The weight parameter is user configurable under the traffic descriptor hierarchy.

```
configure
 qos
 atm-td-profile <td-profile-id> [create]
 weight <weight>
```

<weight> : 1-255.

If weight is not specifically configured, the defaults are taken as described above.

The explicitly configured weight parameter is honored only on ATM MDA in the max16k-vc mode. On all other ATM capable MDAs (ASAP or ATM MDA in max8K-VC mode), the weight parameter is ignored.

Note that in the current ATM implementation there is already a WRR scheme in place based on internally calculated weights. This WRR scheme is used to service traffic from the VC queues of equal priority (where there are two queues per VC - a HiPrio and a LowPrio queue). Weights are assigned to VCs automatically based on the rate of the VC,

#### **9.4.15.12 ATM/IOM QoS Integration**

There are major differences between the QoS mode of operation at the ATM MDA level and the IOM level.

ATM QoS operates on fixed size cells that contain additional transport overhead. In addition, ATM shaping is very accurate so that traffic is paced into the ATM network with nodes that are sensitive to bursts (ingress policing). Buffering and service differentiation (number of queues) at the ATM layer is not as flexible as it is on the IOM level.

On the other hand, HQoS in the IOM is less accurate and less responsive to sudden traffic fluctuations (bursts). It operates on Layer 2 frame lengths. Bursts of traffic are usually let into the network more freely than the ATM network would like to accept.

To combine the extensibility of IOM HQoS with the stringent ATM QoS requirements, the two modes of operation are integrated.

The congestion in the ATM network is treated by using extensive IOM HQoS.

When the VC ATM queue becomes congested, it exerts backpressure to the subscriber queues in the IOM on the corresponding VC.

To avoid the condition where a VC becomes overly oversubscribed and excessive in exerting the backpressure, our HQoS in IOM has to be proactive and has to be able to detect congestion on the IOM level based on the ATM VC configured rate or the VP configured rate. IOM HQoS must deal with this congestion before it actually becomes the problem in the ATM layer. Occasional and short-lived backpressure

from VCs, but persistent QoS backpressure and congestion at the ATM layer is avoided. A prerequisite for treating ATM congestion at the IOM level is to adjust the frame size in HQoS calculations (on all levels - including queues and aggregate rate limits) so that it reflects the ATM overhead associated with ATM transport (AAL5 encap, cellification).

#### 9.4.15.12.1 Intermediate Node Rate Limit/Shaper

In many cases it is desired or even necessary to shape traffic per DSLAM. In the ATM network, a DSLAM corresponds to a VP (Virtual Path) which is at the ATM cell level identified by a Virtual Path Identifier (VPI). The VPI/VCID pair represents the addressing mechanism in the ATM network.

Another level of hierarchy is introduced into our HQoS model - an aggregate rate limit in the IOM that will correspond to the ATM VP shaper. The purpose of this new construct in the IOM is to help detect congestion at the IOM level before it becomes a severe problem at the ATM layer.

As a final solution, the HQoS hierarchy in the IOM is a 4-tier hierarchy consisting of:

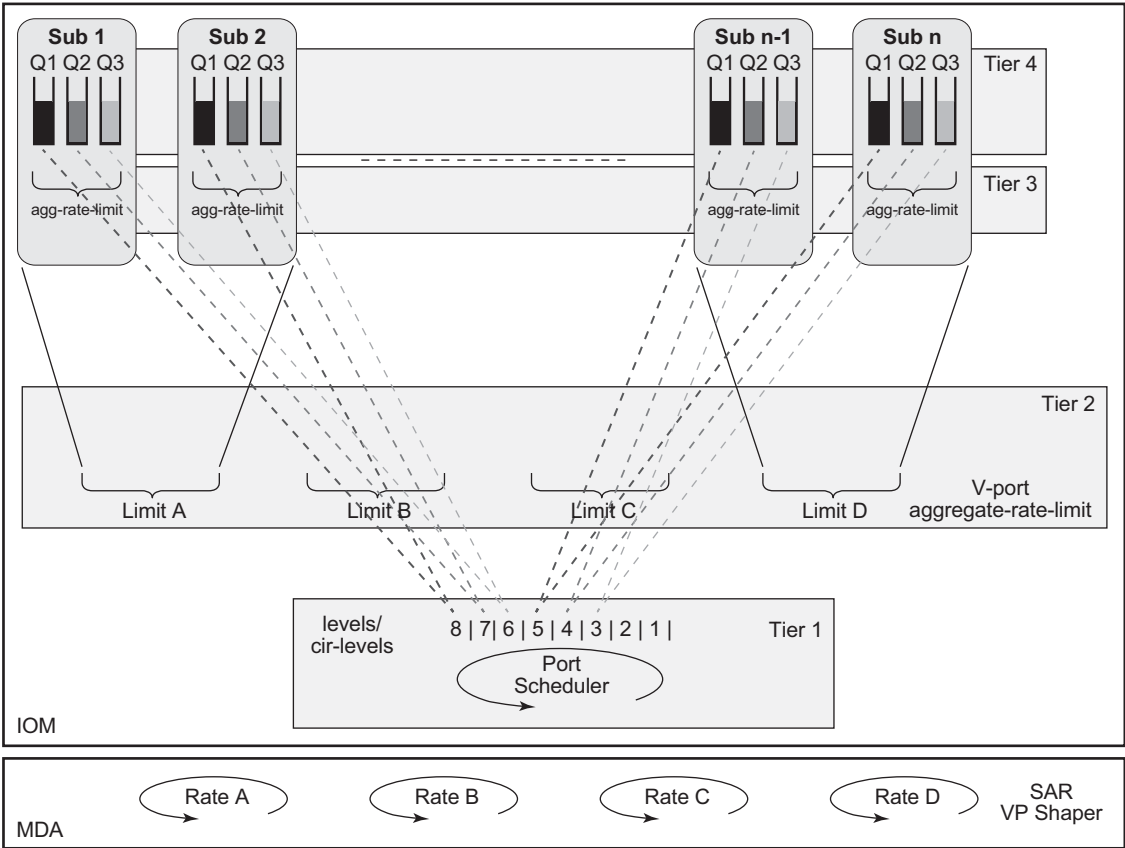

- subscriber queues that are parented to the port scheduler
- egress agg-rate-limit that represents the egress aggregate subscriber rate
- tier-2 aggregate-rate-limit that represents the ATM VP rate limiter (related to DSLAM). This is a pure rate limiter and not a scheduler (it does not receive any scheduling opportunity).
- port-scheduler to which are subscriber queues parented. The port-scheduler delegates bandwidth to its children based on the priority levels associated with the children queues.

The four tiered hierarchy is needed to deal with:

- port congestion. The port bandwidth can be overbooked the desired service levels can still be ensured.
- ATM VP congestion. An ATM VP can be effectively protected from prolonged congestion that would result into significant backpressure to the IOM queues.
- subscriber congestion. Within the subscriber, bandwidth is managed within the subscriber bandwidth limit.

The four-tiered hierarchy looks like [Figure 96](#).

Figure 96 Tier HQoS

al\_0039

The key point in such HQoS model is that the port-scheduler delegates its available bandwidth to the subscriber queues directly according to the queue priority on a configured level. Higher priority queue are served over all subscribers before any lower priority queues, up to the limits imposed by the tier 1 and tier 2 aggregate rate limits.

### 9.4.15.12.2 Provisioning Aspects

The tier 2 aggregate rate limit that corresponds to the VP shaper on the IOM level is provisioned in the context of a vport. The vport is a container that is configured directly under the port and it can contain either an aggregate rate limit or another port scheduling policy (port scheduler). These two constructs (vport aggregate and V-port port scheduling policy) are mutually exclusive. In addition, if a V-port port scheduling policy is configured instead of the V-port aggregate, then the port scheduler cannot be used (currently two port schedulers applied under the same port cannot be used in a parent/children relationship).

The V-port aggregate have to have the agg-rate-limit defined explicitly. In other words, the rate **cannot** be implicitly inherited by configuration from the VP shaper traffic descriptor.

Example:

```
config
 port <port-id>
 sonet-sdh
 path
 egress-scheduler-policy <port-scheduler-policy-name>
 access
 egress
 vport <vport-name>
 description <description-string>
 host-match dest <dest-string>
 agg-rate-limit <agg-rate>
 port-scheduler-policy <port-scheduler-policy-name>
 atm
 vp <vpi> egress-traffic-desc <atm-td-profile-id>
```

The association between the vport aggregate and the subscriber host is done in three ways:

- RADIUS attribute — a dest-string VSA that is matched against the string defined under the corresponding vport. This dest string VSA is returned via RADIUS at the subhost instantiation time.
- LUDB – similar to the RADIUS method. The dest-string comes from the LUDB instead from RADIUS.
- VP identifier (VPI) - The VPI is known to the CPM from the beginning of the session initiation process – raw (unknown encapsulation) packets and passed to the CPM. These raw packets contain VPI,VCI identifiers. The vport container for the subscriber is referenced implicitly via the VPI in the following fashion (Figure 97):
  - CPM determines the VPI from the first packet for the session.

- ATM VP Shaper mapping: The VPI is used to make the subscriber association with the VP Shaper which is defined under the VP Shaping node: **port>sonet-sdh>path>atm>vp**. The VP Shaping node name must be the VPI number.
- Vport mapping: The vport-name in the **port>sonet-sdh>path>access>egress>vport <vport-name>** hierarchy is matched against the VPI number.

**Figure 97 VPI Based V-Port <-> Subscriber Association**

The association method (automatic via VPI or based on RADIUS/LUDB) between the subscriber host and the vport is defined under the SAP (or MSAP) where the subscriber resides. In most cases subscriber management is used with MSAPs.

This is the syntax:

```
configure
 subscriber-mgmt
 msap-policy <name>
 sub-sla-mgmt
 def-inter-dest-id string <inter-dest-string>
 def-inter-dest-id {use-top-q | use-vpi}

configure
 services ies/vprn
```

```
subscriber-interface <sub-if-name>
 group-interface <grp-if-name>
 sap <sap-id>
 sub-sla-mgmt
 def-inter-dest-id string <inter-dest-string>
 def-inter-dest-id {use-top-q | use-vpi}
```

The **def-inter-dest-id** stand for a 'default inter-destination identifier'.

If the use-vpi method is used and the VPI derived from the incoming traffic points to a non-existing VP container, the association between the subhost and the V-port container will fail and a message/trap is logged. This however will not prevent the creation of the subhost that can be parented to the port-scheduler.

If the use-vpi is used on an Ethernet port where this parameter is not applicable, the parameter is ignored and defaulted to 'string'. A message/trap is logged.

Note that if the vport contains an aggregate-rate-limit, then there is no need for the indication of a vport construct in the sub-profile or sla-profile of the subscriber. On the contrary, in case that the vport contains a port-scheduling-policy, the sla-profile template must contain the indication that the subscriber is tied to a vport (**config>subscr-mgmt>sla-profile>egress>qos sap-egress-qos-policy-id vport-scheduler.**)

#### 9.4.15.12.3 HQoS Combinations

These are the possible HQoS combinations that are supported:

- port-scheduler assigned to path, agg-rate-limit assigned to vport, agg-rate-limit assigned to subscriber.
- port-scheduler assigned to path, no vport, agg-rate-limit or scheduler-policy assigned to subscriber.
- no port-scheduler assigned to path, port-scheduler assigned to V-port, agg-rate-limit or scheduler-policy assigned to subscriber.
- no port-scheduler assigned to path, no vport, scheduler-policy assigned to subscriber.

In case that the vport contains the agg-rate-limit, any subscriber host queue that is parented to a virtual scheduler will not be rate-limited by the vport aggregate rate. The queue will compete for bandwidth directly on the port's port scheduler, at the priority level and weighted scheduler group the virtual scheduler is port-parented to. If the virtual scheduler is not port-parented or if there is no port scheduler policy on the port, the host queue will be orphaned and will compete for bandwidth directly based on its own PIR and CIR parameters.

#### 9.4.15.12.4 ATM Rate Adjustment

The difference in cell/frame overhead on the ATM level and IOM Level (Layer 2) lead to inconsistent behavior in integrated QoS. For example, IOM based QoS operates on Layer 2 frames (PPP header is included in rate calculations). On the other hand, ATM QoS operates on ATM 53byte cells. Each PPP frame with AAL5 overhead is segmented into 48-byte chunk cells prepended by a 5 byte ATM header. Assuming that ATM QoS operates on 53-octet cells, a significant rate discrepancy might arise from this difference.

For example, consider two flows:

Flow 1, 1000pps, PPP+IP packet size 190Bytes => L2 (IOM) QoS rate is 1520 kb/s

Flow 2, 1000pps, PPP+IP Packet size 232Bytes => L2 (IOM) QoS rate is 1856 kb/s

Assuming that VC MUX encap is used, and that AAL5 trailer (8 octets + padding) is used:

Flow 1 = AAL5 length is  $190+8+48B_{\text{boundary\_padding}}$ = 240Bytes => 5 ATM cells

Flow 2 = AAL5 length is  $232+8+48B_{\text{boundary\_padding}}$ = 240Bytes=>5 ATM cells

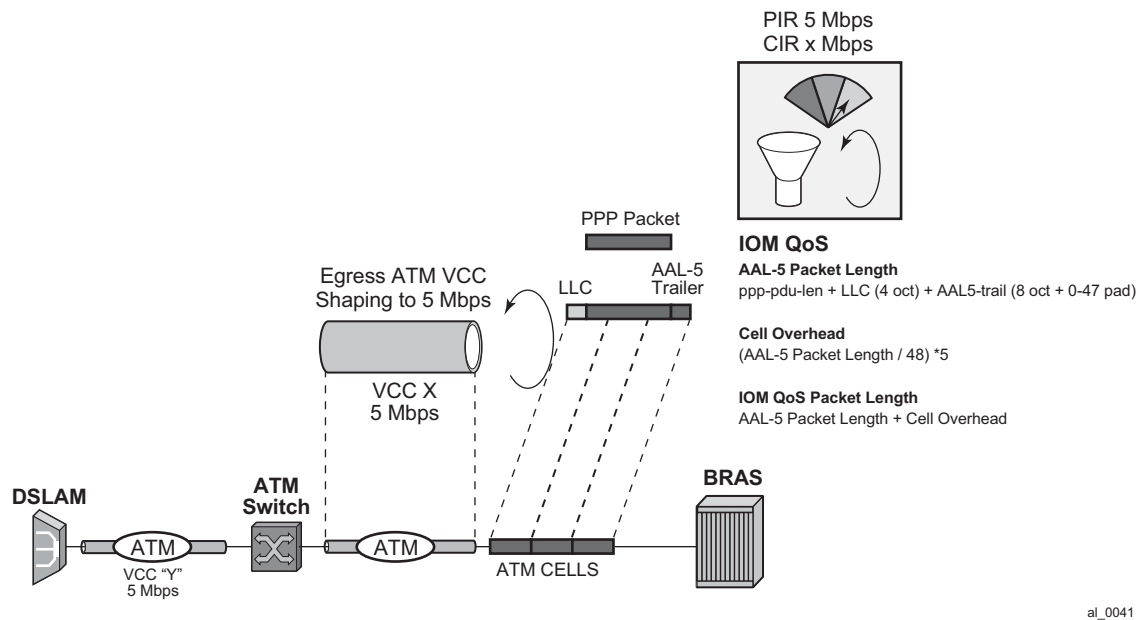

Each cell has a 5 byte header which translates into a 2120 kb/s rate for each flow.

As a result, more bandwidth is required at the ATM layer than the QoS on the IOM level has budgeted. Moreover, the two flows appear to be of the same rate at the ATM layer, even though the IP rate of flow 1 is ~20% less than the flow 2.

From the example above, Flow 1 consumes 40% more bandwidth configured at the ATM layer than it is given in IOM QoS. The rate adjustment depends on the packet size which additionally complicates conversion. This issue is more pronounced with smaller packet sizes.

An example is shown in [Figure 98](#).

**Figure 98 QoS Adjustment**

Depending on the session encapsulation (VC-MUX, LLC/SNAP) the packet length on which IOM QoS operates is adjusted.

The rates are adjusted on a per queue level, per subscriber egress agg-rate-limit level, per V-port aggregate level and on per port-scheduler level. Because the ATM termination points are on the BNG, there is a direct view of the encapsulation. The encapsulation information is supplied to the forwarding plane via the control plane.

The rate adjustment are examined in the following commands:

- **frame-based-accounting** under the qos>scheduler-policy hierarchy
- **queue-frame-based-accounting** under the sub-profile>agg-rate-limit hierarchy
- **avg-frame-overhead** under the queue hierarchy
- **encap-offset** under the sub-profile hierarchy

In PPPoA/PPPoEoA scenario there is no last mile rate adjustment (due to the difference in encapsulation) performed. It is assumed that the encapsulation in the last mile and in the intermediate mile is the same. In other words, it is assumed that the DSLAM does not add/change any encapsulation but instead it only acts as a VPI/VCI cross-connect. If the last mile encapsulation is PPPoA, then the intermediate encapsulation is considered to be PPPoA as well. Similar is valid for PPPoEoA encapsulation.

There are two configuration scenarios possible:

1. The **encap-offset** command in the sub-profile is configured. This command overwrites any other command related to rate conversion that might be configured (**frame-based-accounting**, **queue-frame-based-accounting**, **avg-frame-overhead**, or **avg-frame-size**).

The *encap-offset* command forces dynamic wire rates calculation in the intermediate mile (directly connected ports) on all levels in the QoS hierarchy. The wire overhead in the intermediate mile takes into account the length of the fixed ATM encapsulation, the variable length of AAL5 encapsulation (including AAL5 48bit boundary padding) and the ATM cellification overhead. The queue stats are also wire based. All calculations are performed in the data plane using the actual packet size. In other words, this command will ensure that the rates on the queue level and the subscriber aggregate level (either through virtual schedulers or egress aggregate-rate limits) are wire based. Port-scheduler and V-port rates are already by default wire based rates and this cannot be changed.

2. The **encap-offset** command is not configured by default. In this case the other rate conversion related commands are in effect (**frame-based-accounting**, **queue-frame-based-accounting**, **avg-frame-overhead**, or **avg-frame-size**).

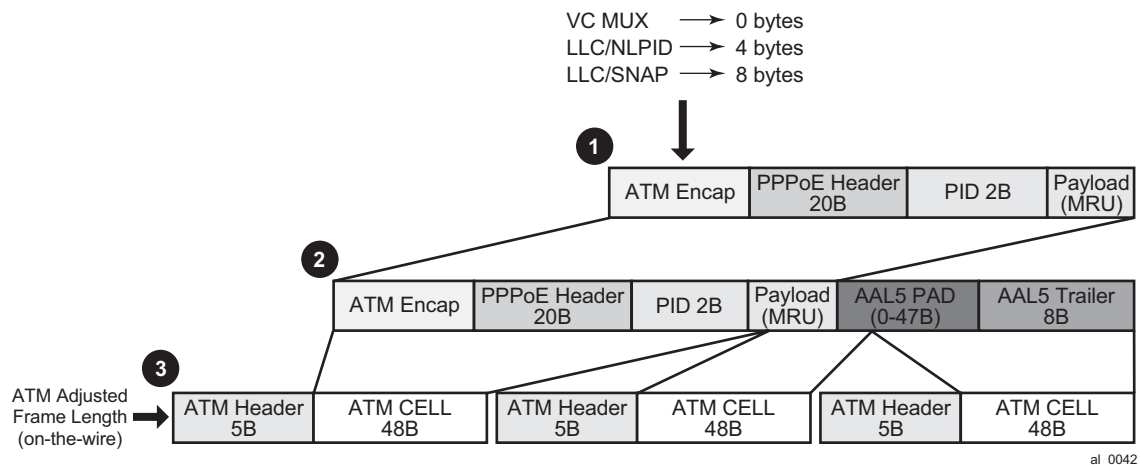

The behavior is the following:

- Wire rates in the intermediate mile (directly connected ports) are based on the **avg-frame-overhead** command which is provisioned via CLI. If *avg-frame-overhead* is not provisioned via CLI, by default it is assumed to be 0[%] and the wire rates effectively become data rates (IP payload + IP header + PPP(oE) header + fixed ATM encapsulation).
- Queue stats (used in accounting) are always 'data' stats. This includes the IP Payload + IP header + PPP(oE) header + fixed ATM encapsulation.
- *agg-rate-limit* (subscriber or vport) rates are always wire rates (as defined in the first bullet – based on the *avg-frame-overhead*).
- Rates in the *port-scheduler-policy* (vport or physical port) are always wire based (rates (as defined in the first bullet – based on the *avg-frame-overhead*).
- The **frame-based-accounting** command under the scheduler-policy will affect rate calculation for virtual schedulers and queues:
  - If this option is configured, the virtual scheduler and queue rates will be wire based.
  - if this option is NOT configured, the virtual scheduler and queue rates will be data rates
- *queue-frame-based-accounting* configuration option under the subscriber *agg-rate-limit* command (in sub-profile) will affect rate calculations for queues. If this command is configured, the queue rates will be wire rates, otherwise they will be data rates

Avg-frame-size command in PPPoA/PPPoEoA is ignored.

Currently queue rates and subscriber virtual scheduler rates are allowed to be either data rates (one in Figure 99) or *on-the-wire-rates* (three in Figure 99). *Port-scheduler* rates, vport rates and the subscriber *agg-rate-limit* (in sub-profile) are always on *on-the-wire* rates.

**Figure 99 ATM Wire Overhead**

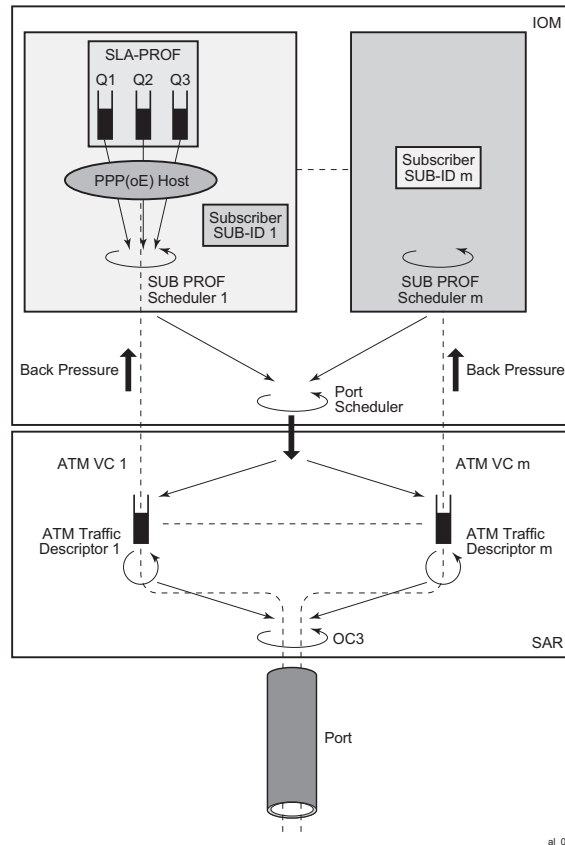

### 9.4.15.13 Subscriber Instantiation Use Cases

Note that multiple subscribers per single VC are not supported. However, multiple VCs per subscriber are supported.

The following displays examples of how subscriber hosts could be instantiated in PPPoA/PPPoEoA environment.

#### Case 1

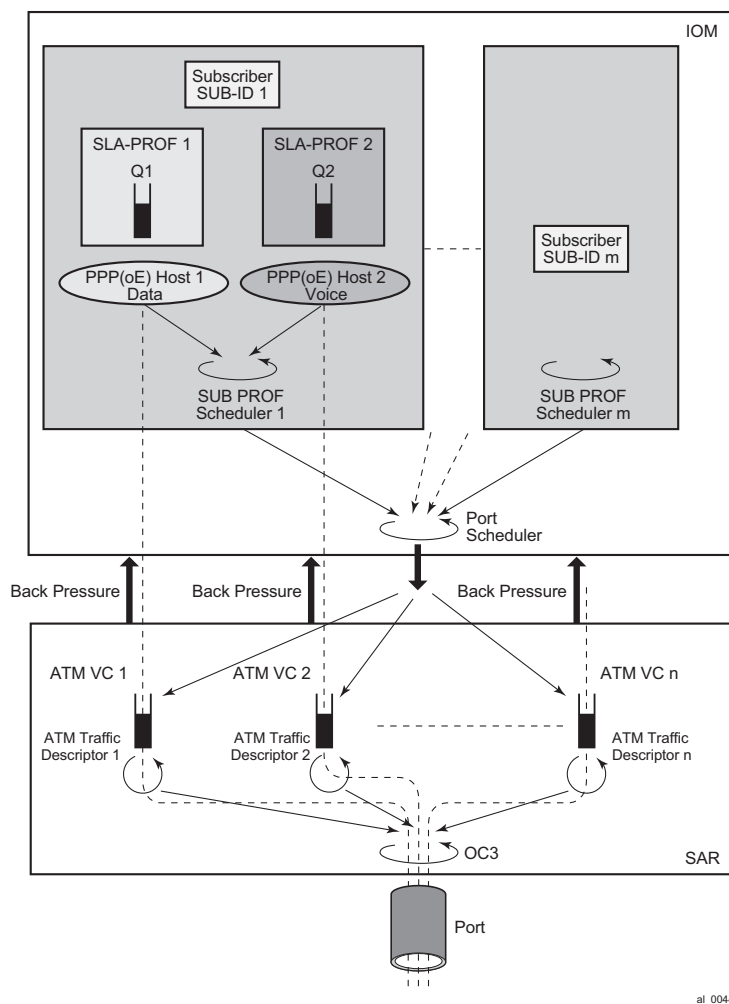

- One host per subscriber.
- One ATM VC per subscriber.
- Authentication is done via RADIUS or LUDB.
- Authentication methods: PAP/CHAP or PADI for PPPoE.
- If there is no RADIUS/LUDB authentication, the subscriber-id should be by default the SAP (with VPI:VCI) with default sub-strings. For MSAP this would be configured under the msap-policy – all subs would have the same service in this case (SLA/SUB profiles).

**Figure 100 Subhost per VC****Case 2**

- Multiple hosts per subscriber
- Single VC per host
- Multiple VCs per subscriber
- PPPoA or PPPoEoA
- Subhosts for the same subscriber can authenticate using a unique username or the same username

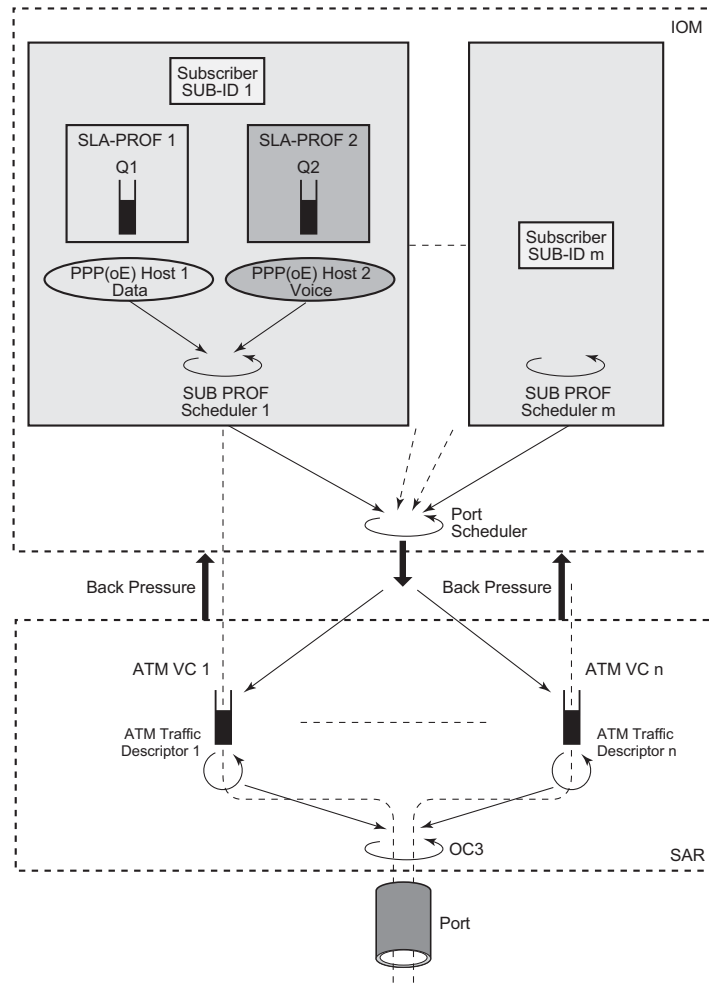

**Figure 101 Multiple VCs per Subscriber**

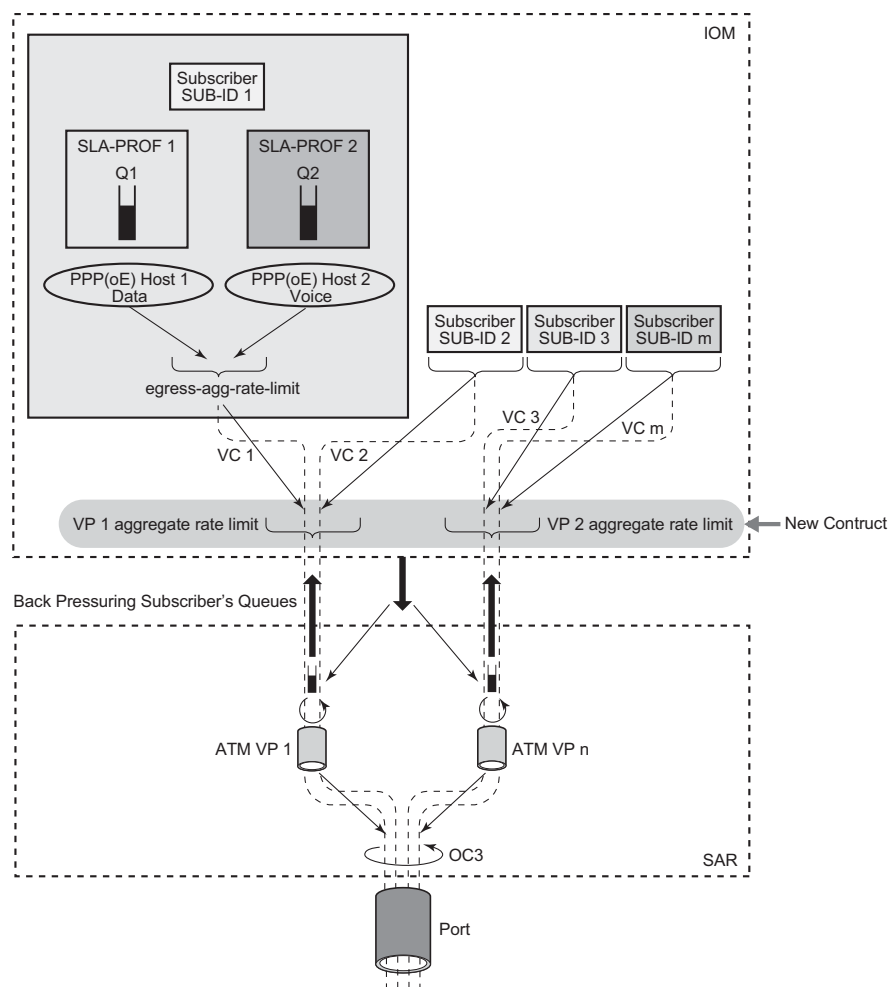

### Case 3

- Multiple hosts per subscriber
- Single VC
- PPPoEoA only
- Per host SLA-PROFILE instantiation

**Figure 102 Multiple Hosts per Subscriber, Single VC****Case 4**

- VP Shaping

**Figure 103** VP Shaping

at\_0046

#### 9.4.15.14 Authentication

Authentication for PPPoEoA is the same as in PPPoE:

- based on PADI
- based on PAP/CHAP
- No authentication

Authentication in PPPoA is based on:

- PAP/CHAP
- No Authentication — There is a small percentage of cases where this might be required.

An example of no authentication configuration for PPPoEoA would be:

```
configure
 service ies/vprn
 subscriber-interface <sub-if-name>
 group-interface <grp-if-name>
 dhcp
 server <ip-address>
 client-application pppoe => make PPPoE session the client of
 DHCP server
 local-dhcp-server <dhcp-server-name>
 user-db <ludb-name> => allow DHCP server to query LUDB

configure
 subscriber-management
 local-user-db <ludb-name>
 pppoe
 host <host-name>
 host-identification [circuit-id|mac|remote-id|service-name|username]
 options
 address
 identification-strings
```

In the case that there is no PAP/CHAP authentication, a PPPoE host can be identified by a MAC address, circuit/remote-id (inserted by the BNG) or service-name in PPPoE.

#### 9.4.15.15 LUDB Access via Capture SAP

Access to LUDB via a capture SAP is enabled for this feature:

```
configure
 service vpls <id>
 sap <sap-id> capture-sap
 pppoe-user-db <ludb-name>
 ppp-user-db <ludb-name>
```

Note that if the authentication-policy (RADIUS authentication) is specified under the capture SAP, it (the RADIUS authentication) will take precedence over LUDB.

### 9.4.15.16 Encapsulation Autosensing

As previously discussed, these four static encapsulation types will be supported:

1. aal5nlpid-ppp (LLC/SNAP for PPPoA)
2. aal5snap-bridged (LLC/SNAP for PPPoEoA)
3. aal5mux-ppp (mux PPPoA)
4. aal5-mux-bridged-eth-nofcs (mux PPPoEoA)

These four types of encapsulation are supported for ATM MSAPs as well as for fixed configuration ATM SAPs.

In addition, the LLC/SNAP encapsulation type can be autosensed. This is called autosensing. The keyword for autosensing is **aal5auto**. An option is given to provision encapsulation statically, if needed.

```
sap x/y/z:* capture-sap
atm
encapsulation aal5auto | aal5mux-ppp | aal5nlpid-ppp | aal5mux-pppoe | aal5snap-
bridged-eth-nofcs

sap x/y/z:w/z
atm
encapsulation aal5auto | aal5mux-ppp | aal5nlpid-ppp | aal5mux-pppoe | aal5snap-
bridged-eth-nofcs
```

The aforementioned encapsulation options (including autosensing) is visible only under the SAP hierarchy on group-interfaces and on capture SAPs in VPLS. This is allowed only in 16K-VP mode ATM MDA.

### 9.4.15.17 SAP Autoprovisioning

In order to simplify the provisioning of the subscriber access ports in the ESM context, a concept similar to managed SAP (MSAP) on Ethernet is introduced. In Ethernet MSAP, an ingress access SAP is automatically created upon receipt of the first (VLAN) tagged packet from the customer side (pending the authentication process).

In our ESM over PPPoA/PPPoEoA case, a number of PVCs is pre-provisioned that will initially be only in a provisioned (or listening, passive) state. This is sometimes referred as a bulk configuration of VC ranges. Once the initial ESM processing in the CPM is completed (for example, the user is authenticated), the ATM SAP is created in the appropriate context (VRF or GRT) and the ATM VC is activated. ATM VC activation means that the ATM VC is associated with a SAP.

The ratio between the maximum number of provisioned VCs vs the maximum number of active VCs on an MDA supporting PPPoA/PPPoEoA is 2:1. This amounts to 32K ATM VCs in the listening state. Out of the total 32K ATM VCs, 16K ATM VCs can be active simultaneously.

Obviously, there are some differences between the Ethernet MSAP processing and the ATM MSAP processing. On Ethernet there is not need to pre-configure VCs, while on ATM this is necessary due to complexity of ATM layer comparing to Ethernet.

Our current Ethernet based MSAP is configured under VPLS. The same approach is adopted for ATM capture SAP.

Since a combination of ESM over PPPoA/PPPoEoA VCs and other non PPPoA/PPPoEoA VCs on a single physical port is supported, ranges of VCs that will be supported in autoconfiguration are defined. ATM VCs outside this range are available for manual creation. Multiple ranges are necessary in order to address non-contiguous sets of VPI/VCI.

The following is the CLI syntax:

```
configure
 service vpls <id> customer <customer-id> [create]
 sap x/y/x:*/* capture-sap [create]
 atm
 vc-range <num> vpi-range <vpi-range> vci-range <vci-range>
```

Note that the capture SAP must be configured as ‘\*/’ in place of the VPI/VCI identifiers. Any other combination for the VPI/VCI identifiers is not allowed.

Up to 5 ranges are allowed per capture SAP. VCs configured in this way can carry a single PPP session per VC or multiple PPPoE sessions per VC. Ranges are not allowed unless the ATM MDA is in the 16K-VCs mode.

The total number of VCs that can be fed into a VP is 16K. This includes all VC ranges associated with the VP plus any statically configured VC on the VP.

### 9.4.15.18 PPP Nodes and ppp-policy

Differences in operation between PPP and PPPoE warrant creation of a new ppp node under the *group-interface* in the CLI that will cover PPP aspects of operation. The existing pppoe node under the *group-interface* is preserved in the CLI. This allows referencing different *user-dbs* for authentication purposes and different session parameters defined in the *ppp-policy* for each session type (pppoe or plain ppp).

PPP node under the *group-interface* is used to cover PPPoA operation while PPPoE node is used to cover PPPoE and PPPoEoA operation. ATM in PPPoEoA is just a transport and as such does not carry any information relevant to PPP operation (like PADx does in PPPoE).

For dynamic SAPs (managed SAPs), the same PPP(oE) related structures are referenced under the capture SAP hierarchy. Under the capture SAP there are no ppp/pppoe nodes (like they are under the group-interface hierarchy). In order to differentiate between *ppp* and *pppoe* clients, a new ppp-policy command is introduced in addition to the *pppoe-policy* command. The *ppp-policy* under the capture SAP is needed for the definition of session parameters before the *group-interface* (where normally session parameters are referenced) is determined.

Two commands for LUDB access are available under the same *capture-sap* hierarchy (*pppoe-user-db* and *ppp-user-db*).

The **ppp-policy** under the **subscr-mgmt** hierarchy contains PPP and PPPoE session parameters. PPP parameters are applicable to both session types (PPP and PPPoE) while PPPoE parameters are applicable only to PPPoE session type. The PPPoE parameters are ignored for PPP sessions.

### 9.4.15.19 MTU Considerations

MRU configuration option negotiated during the LCP phase in PPPoA is based on the following command:

```
config>subscr-mgmt>ppp-policy#
ppp-mtu
```

By default, this command is disabled and consequently will negotiate the default MRU of 1500B, as long as the ATM port's MTU can accommodate at least 1500B:

```
config>port>sonnet-sdh>path#
mtu
```

The MRU option in PPPoA refers to the PPP packet length (PID+Information+Padding) that is ATM encapsulated.

#### 9.4.15.19.1 PPP(oE) Session Antispoofing

Antispoofing filters need to be in place in order to prevent the hijacking of a PPPoA/PPPoEoA session. For successful anti-spoofing, the following fields are accessible:

- Source IP address (PPPoA and PPPoEoA)
- VPI/VCI pair which is equivalent to the SAP (PPPoA/PPPoEoA)
- Source MAC Address (PPPoEoA only)
- session-ID (PPPoEoA only)

For locally terminated PPPoEoA subscriber hosts, access to all fields are required (a, b, c and d). Antispoofing is defined under the following hierarchy:

```
config
 service <svc-name>
 subscriber-interface <sub-if-name>
 group-interface <grp-if-name>
 pppoe
 anti-spoof [mac-sid | mac-sid-ip]
```

This behavior matches our current PPPoE behavior. The default antispoofing option is set to mac-sid, which means that the incoming traffic is checked against the source MAC address and the session-ID. Antispoofing under this hierarchy cannot be disabled.

The source IP address can be added to the source MAC and session-ID (mac-sid-ip).

Note that the group-interface is the lowest granularity at which options can be enabled. In other words, these two options (mac+sid or mac+sid+ip) cannot be changed at the SAP level.

The VPI/VCI pair is always be checked against the incoming traffic, regardless of the configuration option as the VPI/VCI pair is an intrinsic part of the SAP (similar to VLAN tags on Ethernet).

In case that a subscriber host is a routed host (managed routes), the nh-mac antispoofing option must be enabled under the managed sap (msap-policy) or **group-interface->sap** level. Otherwise, managed routes for the host would **not** be installed. The nh-mac option forces a lookup of the incoming packet based on the mac+sid of the originally created host (CPE device). Note that only the **group-interface->sap>anti-spoof** and msap-policy hierarchies contain the **nh-mac** option, and NOT the pppoe->anti-spoof hierarchy.

For locally terminated PPPoA subscriber hosts, only access to source IP address is available (src mac and session-ID fields are non-existent in PPP).

The default antispoofing is based on the VPI/VCI pair + IP. This cannot be changed by configuration, except when the session has managed routes or is a LAC session. In the case of managed routes (routed host) a lookup will be done based on the SAP (VPI/VCI) only. The anti-spoofing for PPPoA should be set to anti-spoof nh-mac, under msap-policy or grp-if>sap hierarchy even though PPPoA has no MAC address.

For LAC, the behavior is the following:

- For PPPoE traffic, antispoofing is always done based only on the SAP+mac+session-id.
- For PPP traffic, antispoofing is always based on VPI/VCI pair (SAP only). The IOM automatically determines whether IP based antispoofing can be done (e.g. no IP based antispoofing for LAC and managed routes).

There are two other nodes on which antispoofing can be configured:

```
configure
 service ies/vprn
 subscriber-interface <sub-if-name>
 group-interface <grp-if-name>
 sap <sap-id>
 anti-spoofing [ip|ip-mac|nh-mac]
```

A few points in regards to the above hierarchy:

- **ip** - This option can be only used in BSM mode. This is used only for IPoE.
- **ip-mac** – Lookup is performed based on the combination of the IP address and MAC address (incipient host). This is used for IPoE. For PPPoE, it will be overwritten by the configuration option under the group-interface-> ppp node (mac+sid or mac-sid+ip).
- **nh-mac** – Lookup is based on the MAC only for IPoE or mac+sid for PPPoE.

```
configure
 subscriber-managemnt
 msap-policy <msap-pol-name>
 ies-vprn-only-sap-parameters
 anti-spoof [ip-mac|nh-mac]
```

This is similar to the previous case (under the group-interface>sap hierarchy) with the exception that the pure IP option is not supported under the MSAP. The reason is that the IP option can only be used in BSM (under the SAP node) whereas MSAP can only be used in ESM (PPPoX).

Note that for IPoE, the entire control over antispoofing under the (M)SAP node, while for PPPoE, the anti-spoofing control is distributed between the (M)SAP node and the **group-interface>ppp** node.

## 9.4.16 Multi-Chassis Synchronization

Figure 104 shows the configuration under which synchronization of subscriber management information is performed. As depicted, a single access node aggregating several subscriber lines is dual-homed to redundant-pair of nodes.

**Figure 104 Dual-Homing Configuration**

Enabling subscriber management features (whether basic subscriber-management (BSM) or enhanced subscriber management (ESM)) causes the node to create and maintain state information related to a given subscriber-host. This information is synchronized between redundant-pair nodes to secure non-stop service delivery in case of the switchover.

### 9.4.16.1 Overview

The synchronization process provides the means to manage distributed database (the Multi-Chassis Synchronization (MCS) database), which contains the dynamic state information created on any of the nodes by any application using its services. The individual entries in the MCS database are always paired by peering-relation, sync-tag and application-id. At any time the given entry is related two the single redundant-pair objects (two SAPs on two different nodes) and hence stored in a local MCS database of the respective nodes.

Internally, peering-relation and sync-tag are translated into a port and encapsulation value identifying the object (SAP) that the given entry is associated with. The application-id then identifies the application which created the entry on one of the nodes. There are three basic operations that the application can perform on MCS database. The MCS database will always synchronize these operations with its respective peer for the given entry.

The following principles apply:

- **add-operation** — Any dynamic-state created in the application is pushed to the MCS database. MCS then creates and synchronizes with the corresponding peer provided (if configured). The application in the peer node is then notified as soon as the entry has been created. Similarly, the application in the local node (the node where the state has been created) is notified that entry has been synchronized (MCS is “in-sync” state). This operation will be also used to modify existing MCS database entry.
- **local-delete** — The MCS database entry is marked as no longer in use locally and this information is sent to the peer node. If the information is no longer used by applications on both nodes (the application in remote-node has already issued local-delete before), it is removed from database.
- **global-delete** — The MCS database entry is removed from both nodes and from the application in the remote node.

The choice of the operation in corresponding situation is driven by the application. The following general guidelines are observed:

- An event which leads to a dynamic-state deletion on a standby chassis will be handled as “local-delete”.
- An event which leads to a dynamic-state deletion on an active chassis will be handled as “global-delete”.
- An exception to above the rules is an explicit “clear” command which will be handled as “global-delete” regardless of where the command was executed.

As previously stated, the MCS process automatically synchronizes any database operation with the corresponding peer. During this time, the MCS process maintains state per peer indicating to the applications (and network operator) the current status, such as in-sync, synchronizing or sync\_down. These states are indicated by corresponding traps.

#### **9.4.16.1.1 Loss of Synchronization and Reconciliation**

Each time the connection between the redundant pair nodes is (re)established the MCS database will be re-synchronized. There are several levels of connectivity loss which may have different effect on amount of data being lost. To prevent massive retransmissions when the synchronization connection experiences loss or excessive delay, the MCS process implementation will take provisions to ensure following:

- In the case of a reboot of one or both nodes or establishing the peering for the first time, the full MCS database will be reconciled.
- In the case that the MCS communication is lost and then re-established but neither node rebooted during the connection loss, only the information not synchronized during this time will be reconciled (using sequence numbers helps identify information which was not synchronized).
- In the case that MCS communication is lost because of excessive delay in ACK messages but no information has been effectively lost, the MCS process indicates a loss of synchronization but no reconciliation is performed.

### **9.4.17 Subscriber Routed Redundancy Protocol (SRRP)**

#### **9.4.17.1 SRRP Messaging**

SRRP uses the same messaging format as VRRP with slight modifications. The source IP address is derived from the system IP address assigned to the local router. The destination IP address and IP protocol are the same as VRRP (224.0.0.18 and 112, respectively).

The message type field is set to 1 (advertisement) and the protocol version is set to 8 to differentiate SRRP message processing from VRRP message processing.

The vr-id field has been expanded to support an SRRP instance ID of 32 bits.

Due to the large number of subnets backed up by SRRP, only one message every minute carries the gateway IP addresses associated with the SRRP instance. These gateway addresses are stored by the local SRRP instance and are compared with the gateway addresses associated with the local subscriber IP interface.

Unlike VRRP, only two nodes may participate in an SRRP instance due the explicit association between the SRRP instance group IP interface, the associated redundant IP interface and the multi-chassis synchronization (MCS) peering. Since only two nodes are participating, the VRRP skew timer is not utilized when waiting to enter the master state. Also, SRRP always preempts when the local priority is better than the current master and the backup SRRP instance always inherits the master's advertisement interval from the SRRP advertisement messaging.

SRRP advertisement messages carry a *becoming-master* indicator flag. The *becoming-master* flag is set by a node that is attempting to usurp the master state from an existing SRRP master router. When receiving an SRRP advertisement message with a better priority and with the *becoming-master* flag set, the local master initiates its *becoming-backup* state, stops routing with the SRRP gateway MAC and sends an SRRP advertisement message with a priority set to zero. The new master continues to send SRRP advertisement messages with the *becoming-master* flag set until it either receives a return priority zero SRRP advertisement message from the previous master or its *becoming-master* state timer expires. The new backup node continues to send zero priority SRRP advertisement messages every time it receives an SRRP advertisement message with the *becoming-master* flag set. After the new master either receives the old master's priority zero SRRP advertisement message or the *become-master* state timer expires, it enters the *master* state. The *become-master* state timer is set to 10 seconds upon entering the *become-master* state.

The SRRP advertisement message is always evaluated to see if it has higher priority than the SRRP advertisement that would be sent by the local node. If the advertised priority is equal to the current local priority, the source IP address of the received SRRP advertisement is used as a tie breaker. The node with the lowest IP address is considered to have the highest priority.

The SRRP instance maintains the source IP address of the current master. If an advertisement is received with the current masters source IP address and the local priority is higher priority than the masters advertised priority, the local node immediately enters the *becoming-master* state unless the advertised priority is zero. If the advertised priority is zero, the local node bypasses the *becoming-master* state and immediately enters the *master* state. Priority zero is a special case and is sent when an SRRP instance is relinquishing the master state.

### 9.4.17.2 SRRP and Multi-Chassis Synchronization

In order to take full advantage of SRRP resiliency and diagnostic capabilities, the SRRP instance should be tied to a MCS peering that terminates on the redundant node. The SRRP instance is tied to the peering using the **srrp srrp-id** command within the appropriate MCS peering configuration. Once the peering is associated with the SRRP instance, MCS will synchronize the local information about the SRRP instance with the neighbor router. MCS automatically derives the MCS key for the SRRP instance based on the SRRP instance ID. For example, an SRRP instance ID of 1 would appear in the MCS peering database with a MCS-key srrp-0000000001.

The SRRP instance information stored and sent to the neighbor router consists of:

- The SRRP instance MCS key
- Containing service type and ID
- Containing subscriber IP interface name
- Subscriber subnet information
- Containing group IP interface information
- The SRRP group IP interface redundant IP interface name, IP address and mask
- The SRRP advertisement message SAP
- The local system IP address (SRRP advertisement message source IP address)
- The Group IP interface MAC address
- The SRRP gateway MAC address
- The SRRP instance administration state (up/down)
- The SRRP instance operational state (disabled/becoming-backup / becoming-master/master)
- The current SRRP priority
- Remote redundant IP interface availability (available/unavailable)
- Local receive SRRP advertisement SAP availability (available/unavailable)

### 9.4.17.3 SRRP Instance

The SRRP instance uses the received information to verify provisioning and obtain operational status of the SRRP instance on the neighboring router.

- [SRRP Instance MCS Key](#)
- [Containing Service Type and ID](#)
- [Containing Subscriber IP Interface Name](#)

- [Subscriber Subnet Information](#)

#### 9.4.17.3.1 SRRP Instance MCS Key

The SRRP instance MCS key ties the received MCS information to the local SRRP instance with the same MCS key. If the received key does not match an existing SRRP instance, the MCS information associated with the key is ignored. Once an SRRP instance is created and mapped to an MCS peering, the SRRP instance evaluates received information with the same MCS key to verify it corresponds to the same peering. If the received MCS key is on a different peering than the local MCS key an SRRP peering mismatch event is generated detailing the SRRP instance ID, the IP address of the peering the MCS key is received on and the IP address to which the local MCS key is mapped. If the peering association mismatch is corrected, an SRRP peering mismatch clear event is generated.

#### 9.4.17.3.2 Containing Service Type and ID

The Containing Service Type is the service type (IES or VPRN) that contains the local SRRP instance. The Containing Service ID is the service ID of that service. This information is supplied for troubleshooting purposes only and is not required to be the same on both nodes.

#### 9.4.17.3.3 Containing Subscriber IP Interface Name

The containing subscriber IP interface name is the subscriber IP interface name that contains the SRRP instance and its group IP interface. This information is supplied for troubleshooting purposes only and is not required to be the same on both nodes.

#### 9.4.17.3.4 Subscriber Subnet Information

The subscriber subnet information includes all subscriber subnets backed up by the SRRP instance. The information for each subnet includes the Owned IP address, the mask and the gateway IP address. If the received subscriber subnet information does not match the local subscriber subnet information, an SRRP Subscriber Subnet Mismatch event is generated describing the SRRP instance ID and the local and remote node IP addresses. Once the subscriber subnet information matches, an SRRP Subscriber Subnet Mismatch Clear event is generated.

#### **9.4.17.3.5 Containing Group IP Interface Information**

The containing group IP interface information is the information about the group IP interface that contains the SRRP instance. The information includes the name of the group IP interface, the list of all SAPs created on the group IP interface, the administrative and operational state of each SAP and the MCS key and the peering destination IP address associated with each SAP. To obtain the MCS information, the SRRP instance queries MCS to determine the peering association of the SRRP instance and then queries MCS for each SAP on the group IP interface. If the local SRRP instance is associated with a different MCS peering than any of the SAPs or if one or more SAPs are not tied to an MCS peering, an SRRP group interface SAP peering mismatch event is generated detailing the SRRP instance ID, and the group IP interface name.

When receiving the remote containing group IP interface information, the local node compares the received SAP information with the local group IP interface SAP information. If a local SAP is not included in the SAP information or a remote SAP is not included in the local group IP interface, an SRRP Remote SAP mismatch event is generated detailing the SRRP instance ID and the local and remote group IP interface names. If a received SAP's MCS key does not match a local SAP's MCS Key, an SRRP SAP MCS key mismatch event is generated detailing the SRRP instance ID, the local and remote group IP interface names, the SAP-ID and the local and remote MCS keys.

#### **9.4.17.3.6 Remote Redundant IP Interface Mismatch**

If the group IP remote redundant IP interface address space does not exist, is not within the local routing context for the SRRP instances group IP interface or is not on a redundant IP interface, the local node sends redundant IP interface unavailable to prevent the remote neighbor from using its redundant IP interface. An SRRP redundant IP interface mismatch event is generated for the SRRP instance detailing the SRRP instance, the local and remote system IP addresses, the local and remote group IP interface names and the local and remote redundant IP interface names and IP addresses and masks. The local redundant IP interface may still be used if the remote node is not sending redundant IP interface unavailable.

#### **9.4.17.3.7 Remote Sending Redundant IP Interface Unavailable**

If the remote node is sending redundant IP interface unavailable, the local node will treat the local redundant IP interface associated with the SRRP instances group IP interface as down. A Local Redundant IP Interface Unavailable event is generated detailing the SRRP instance ID, the local and remote system IP addresses, the local group IP interface name, the local redundant IP interface name and the redundant IP interface IP address and mask.

#### **9.4.17.3.8 Remote SRRP Advertisement SAP Non-existent**

If the remote node's SRRP advertisement SAP does not exist on the local SRRP instances group IP interface, the local node sends local receive SRRP advertisement SAP unavailable to the remote node. An SRRP receive advertisement SAP non-existent event is generated detailing the SRRP instance ID, the local and remote system IP addresses, the local group IP interface name and the received remote SRRP advertisement SAP. Since SRRP advertisement messages cannot be received, the local node will immediately become master if it has the lower system IP address.

#### **9.4.17.3.9 Remote Sending Local Receive SRRP Advertisement SAP Unavailable**

If the local node is receiving local receive SRRP advertisements stating that the SAP is unavailable from the remote node, an SRRP Remote Receive advertisement SAP Unavailable event will be generated. This details the SRRP instance ID, the local and remote system IP addresses, the remote group IP interface name and the local SRRP advertisement SAP. Since the remote node cannot receive SRRP advertisement messages, the local node will immediately become master if it has the lower system IP address.

#### **9.4.17.3.10 Local and Remote Dual Master Detected**

If the local SRRP state is master and the remote SRRP state is master, an SRRP dual master event is generated detailing the SRRP instance ID and the local, remote system IP addresses and the local and remote group IP interface names and port numbers.

#### **9.4.17.4 Subscriber Subnet Owned IP Address Connectivity**

In order for the network to reliably reach the owned IP addresses on a subscriber subnet, the owning node must advertise the IP addresses as /32 host routes into the core. This is important since the subscriber subnet is advertised into the core by multiple routers and the network will follow the shortest path to the closest available router which may not own the IP address if the /32 is not advertised within the IGP.

#### **9.4.17.5 Subscriber Subnet SRRP Gateway IP Address Connectivity**

The SRRP gateway IP addresses on the subscriber subnets cannot be advertised as /32 host routes since they may be active (master) on multiple group IP interfaces on multiple SRRP routers. Without a /32 host route path, the network will forward any packet destined to an SRRP gateway IP address to the closest router advertising the subscriber subnet. While a case may be made that only a node that is currently forwarding for the gateway IP address in a master state should respond to ping or other diagnostic messages, the distribution of the subnet and the case of multiple masters make any resulting response or non-response inconclusive at best. To provide some ability to ping the SRRP gateway address from the network side reliably, any node receiving the ICMP ping request will respond if the gateway IP address is defined on its subscriber subnet.

#### **9.4.17.6 Receive SRRP Advertisement SAP and Anti-Spoof**

The group IP interface SAPs are designed to support subscriber hosts and perform an ingress anti-spoof function that ensures that any IP packet received on the group IP interface is coming in the correct SAP with the correct MAC address. If the IP and MAC are not registered as valid subscriber hosts on the SAP, the packet is silently discarded. Since the SRRP advertisement source IP addresses are not subscriber hosts, an anti-spoof entry will not exist and SRRP advertisement messages would normally be silently discarded. To avoid this issue, when a group IP interface SAP is configured to send and receive SRRP advertisement messages, anti-spoof processing on the SAP is disabled. This precludes subscriber host management on the SRRP messaging SAP.

### **9.4.18 PPPoE MC Redundancy**

This feature minimizes the downtime for PPPoE clients in an ESM environment when a single node fails.

But it is not necessary that an entire BNG fails before it triggers the corrective action. The solution outlined in this document will natively include protection against interfaces and line card failures within the BNG. The redundant (protective) entity, however, does not reside within the same BNG on which the failure occurs but instead it is on a separate BNG node.

The PPPoE MC Redundancy is based on SRRP and MC-LAG because SRRP is already established in ESM providing IPoE MC Redundancy. With some modifications, SRRP approach is adopted to PPPoE deployments.

### 9.4.18.1 Hardware Support

This feature is supported on the following platforms:

- 7750 SR-7/12
- 7750 SR-c4/12
- 7450 ESS in mixed chassis mode.

MCS across different platform types (7750 SR-7/12, 7750-c4/12, 7450 ESS) is not supported. For example, MCS between 7750 SR-7/12 and 7750-c12 is not supported.

This feature is supported in the following chassis modes: B, C, D and SR Mixed Mode (IPv6 on IOM3 while IOM1 cards can be present in the same system).

IPv4 functionality is supported on IOM2 cards and IPv4/IPv6 on IOM3 cards.

**Note:** ESM v6 is supported only on IOM3 cards. IPv6 forwarding in ESM between IOM3 and IOM2 cards is not supported for example, if the access side is IOM3 and the network side is IOM2. However, plain routing (non-ESM related) is supported between these two cards.

### 9.4.18.2 SRRP Considerations for PPPoE

SRRP is based on VRRP whose purpose is to provide a default gateway redundancy for clients sharing the transport medium such as Ethernet. IPoE would be a typical example of this where IPoE clients use a virtual IP and MAC address that is shared between two default gateway nodes in the Master/Backup configuration. SRRP supports only two nodes in a cluster but VRRP allows multiple nodes to be configured in a cluster with a priority that will determine which node will assume Mastership. Although it is mandatory for the proper operation of IPoE clients that the same SRRP IP address is shared between the two BNG nodes providing

redundancy, having the same SRRP IP address is not necessary for the operation of SRRP itself. In other words, SRRP itself (Master/Backup states) will work with different SRRP IP addresses on each node. Same is valid for MAC addressing. It is possible by configuration that the redundant BNG nodes use different IP/MAC addresses on a pair of SRRP instances.

Upon a switchover, a gratuitous ARP is sent from a newly selected active node so that each IPoE client can update the ARP table, if the MAC address has indeed changed (it does not have to). More importantly, if an Layer 2 aggregation network is in place between the BNG and the IPoE client, all intermediate Layer 2 devices will have to update their port-to-mac mappings (Layer 2 FIB). The above described process will ensure proper packet addressing on the IPoE client side as well as the proper forwarding path through Layer 2 aggregation network to the newly activated BNG.

When considering PPPoE in conjunction with SRRP, keep in mind that PPP protocol (point-to-point protocol) is adopted for the Ethernet (shared medium) by enabling an extra Ethernet related layer in PPP that allows sharing of point-to-point sessions over Ethernet (shared medium). The result is a PPPoE protocol designed to 'tunnel' each PPP session over Ethernet.

PPPoE is not aware of ARP (Address Resolution Protocol) and it will not react to gratuitous ARP packets sent by a newly active BNG. The destination MAC address that PPPoE clients will use when sending traffic is determined not by ARP but by the PPPoE Discovery phase at the beginning of the session establishment. This originally discovered destination MAC is used throughout the lifetime of the session. This has a couple of consequences:

1. If SRRP is used for PPPoE then the 'SRRP' MAC address between the redundant BNG nodes must be shared. It is not allowed to use a unique 'SRRP' MAC address per BNG in the redundant pair of BNG nodes (as it is allowed today for IPoE). Every PADx conversation is based on the SRRP shared MAC address, that is, the PADO reply must have the shared SRRP MAC address as the source MAC. This has a significant impact on the operation of MSAP in conjunction with this feature.
2. Since PPPoE sessions are not ARP aware, the only purpose of the gratuitous ARP would be to update the Layer 2 FIB in the aggregation network (and not the PPPoE client destination MAC address). For IPoE, the gratuitous ARP is sent for ALL subnet gateway IP addresses found under the subscriber interface over either all SAPs (default) or top-tags only. For PPPoE, the gratuitous ARP is sent only for the system IP address. The purpose of the gratuitous ARP in PPPoE scenario is only to update Layer 2 network path which is otherwise IP unaware. It is not necessary to send the gratuitous ARP for every default-gateway address found under the subscriber-interface. Since this feature is only applicable to PPPoE deployments, therefore, only PPPoE is present under the group interface. This is indicated by the following command under the SRRP node:

```
group-interface <name>
 srrp <id>
 one-garp-per-sap
```

#### 9.4.18.2.1 SRRP Fact-Checks

1. Once Multi-chassis Synchronization (MCS) for subscriber management and SRRP is enabled, both BNG nodes, Master and Backup will in general forward packets (for subscribers) in both directions.
2. Traffic flows through an SRRP enabled node according to the entries in the SRRP sync database and the SRRP state of the node:
  - Backup SRRP directs downstream traffic over the redundant-interface towards the Master SRRP node. If the redundant interface is unavailable, traffic is sent directly to the subscriber.
  - Master SRRP always directly forwards the downstream traffic towards the subscriber.
  - In the upstream direction, the active SRRP node accepts subscriber traffic addressed either to the MAC address of the SRRP active group OR the native interface MAC address.
  - The standby node accepts in the upstream direction only packets addressed to its native interface MAC address.
3. If both SRRP nodes become Masters then both forward traffic to/from subscribers unaware of the link failure somewhere in the Layer 2 network. As a result, downstream traffic can be blackholed. Whether downstream traffic will be lost depends on the native routing on the network side, which is unaware of the failures in the aggregation network.

#### 9.4.18.3 State Synchronization

PPPoE sessions are synchronized between the redundant BNG nodes. The subscriber synchronization is achieved through Multi-Chassis Synchronization (MCS) protocol in a similar way it is performed for IPoE.

```
multi-chassis
 peer <IP@>create
 sync
 local-dhcp-server
 SRRP
 sub-mgmt [ipoe | pppoe]
 :
 :
 no shutdown
exit
no shutdown
```

---

`exit`

Two keywords, **ipoe** and **pppoe** enable a more granular control over which type of subscribers the MCS should be enabled.

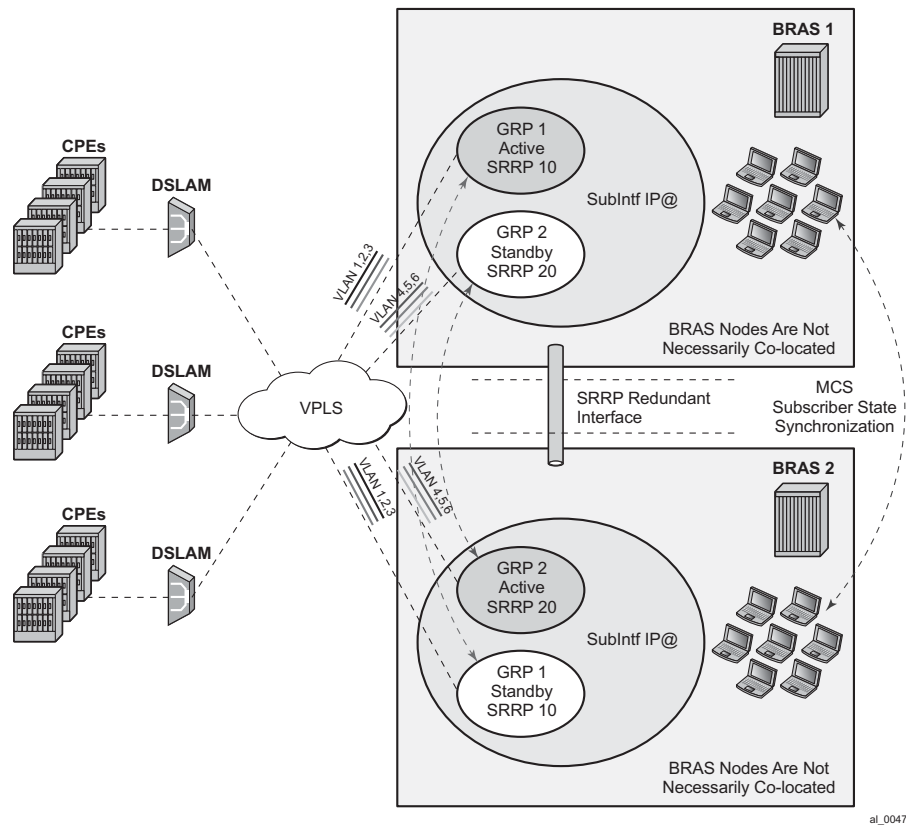

Subscriber synchronization is important for following reasons:

1. Forwarding of downstream traffic between the redundant BNG nodes through a redundant interface is an artifact of how natural routing steers traffic through the network.
2. Subscriber instantiation on the node which did not originally create subscriber session. This drastically reduces downtime during the SRRP switchover.
3. Monitors operational aspects of the subscriber management through show commands.

#### 9.4.18.3.1 PPPoE Multi-chassis Synchronization (MCS) Model

PPPoE MCS model is based on SRRP synchronization and can be used in a centralized or distributed environment with or without Layer 2 aggregation network in-between DSLAMs and BNG nodes. The failure detection speed is dependent on SRRP timers. Traffic load can be balanced per SRRP group over the two links. In this model ([Figure 105](#)), PPPoE states are synchronized between the redundant BNG nodes. If one BNG fails, the newly activated BNG sends out a 'MAC update' (gratuitous ARP) message prompting the intermediate Layer 2 nodes to update their forwarding tables so that forwarding can resume. The SRRP timers can be configured in the sub-second range. In reality, the limiting factor for timer values is the scale of the deployment, in particular the number of SRRP groups per node.

**Figure 105 Fully Redundant “Statefull 1:1” Model**

#### 9.4.18.4 Traffic Control and Redundant Interface

To preserve QoS and Accounting, subscriber's traffic must flow in both directions through the Master BNG node.

In the upstream direction, this is always true as traffic is steered to the master SRRP node just by the virtue of SRRP operation.

In the downstream direction which represents bulk of traffic, SRRP can not be relied up on to steer traffic through the Master node. This poses a problem in a very common environment where IP subnets are shared over multiple group-interfaces with SRRP enabled. A particular subnet will be advertised to the network side from both BNG nodes, Master and Backup. Natural routing on the network side will determine which BNG node will receive subscriber's traffic in the downstream direction. If the Backup SRRP node receives the traffic, it cannot simply send the traffic directly to the access network where the subscriber resides by just inserting

the source MAC address of the SRRP instance in the outgoing packet. This would break the operation of SRRP. Instead, the Backup BNG node must send the traffic to the Master BNG node via a redundant-interface. The Master SRRP node would then forward traffic directly to the subscriber. Source MAC address of this traffic would then be the MAC address of SRRP instance. This traffic shunting over the redundant interface can result in a substantial load on the link between the two BNG nodes.

The increase in shunted traffic can quickly become an issue if the redundant BNG nodes that are not collocated. To minimize the shunt traffic, more granular routing information must be presented to the network core. This would lead to more optimal routing where downstream subscriber traffic would be directed towards the Master BNG node, without the need to cross the redundant interface. The downside of this approach is that this would further fragment the IP address space within the network core. In the extreme case where /32 (subscriber) IP addresses are advertised, the churn that /32s can cause in the core routing would most likely be unsustainable. In this case, routing updates in the core would be triggered by subscribers coming on/off-line.

Optimal operation would call for the shunt traffic to be eliminated and at the same time, a high IP route aggregation on the network side is achieved. The existence of the shunt traffic stems from the fact that routing protocols advertise subscriber subnets into the network with no awareness of the SRRP activity state (Master/Standby). To address this problem along with better aggregation of advertised subnets, two SRRP enhancements are introduced:

- SRRP fate-sharing
- SRRP aware routing

Both of these concepts are described in the '[SRRP Enhancement on page 1214](#)' section.

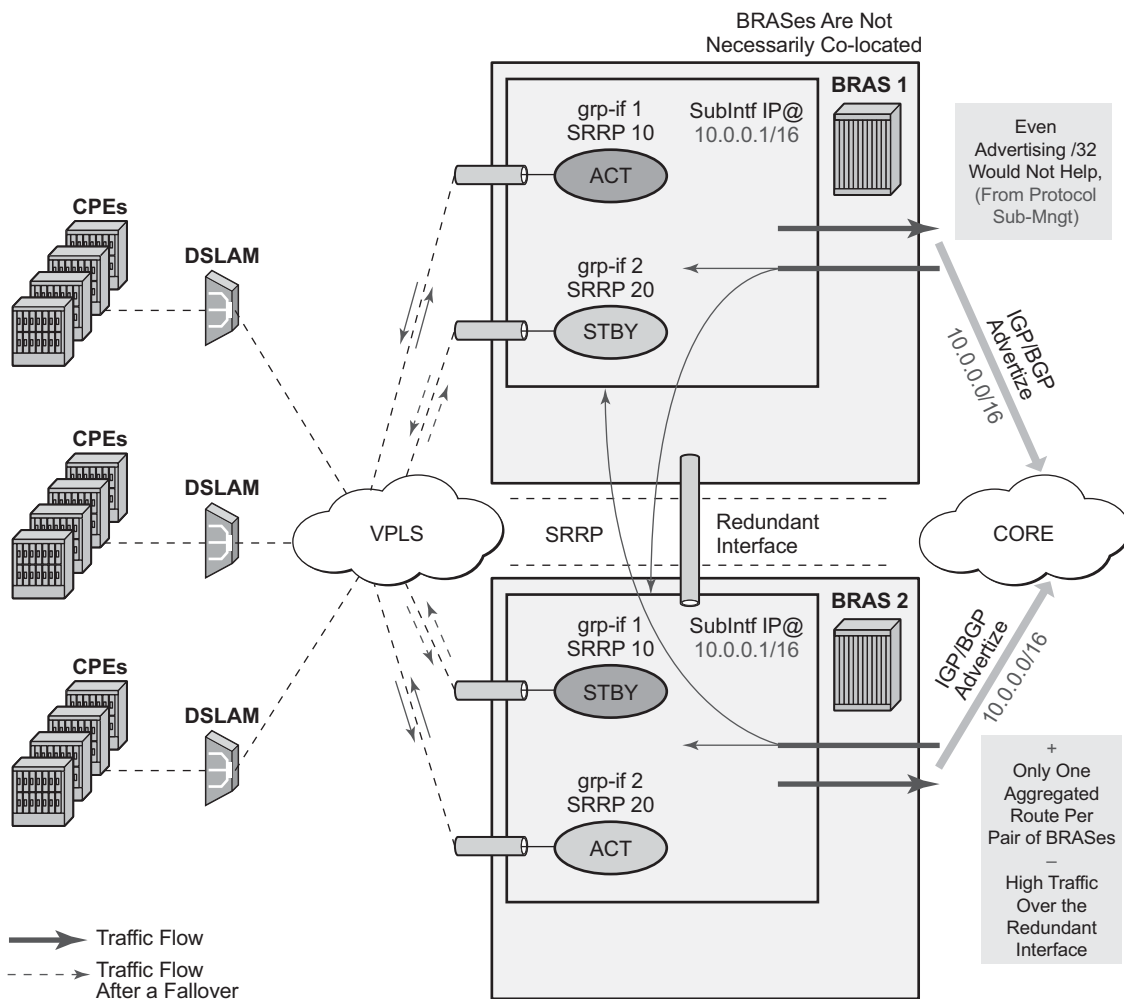

Traffic destined to/from the subscriber is forwarded under the condition that the subscriber-interface is operationally UP. This applies also to shunting of downstream subscriber traffic from the STANDBY to MASTER node. It is always necessary to keep the subscriber-interface operationally UP by configuring a dummy group-interface with a **oper-up-while-empty** command under it. This is especially true for the MC-LAG which causes the messaging SAP on the STANDBY node always to be in the INIT state. In case that MSAPs are used on such group-interfaces, the group-interfaces would be also operationally DOWN, causing the subscriber-interface to be operationally DOWN.

#### 9.4.18.4.1 Subnet Assignment and Advertisement - Option 'A'

A single IP subnet is used for all subscribers terminated within the redundant BNG nodes. The upside of the Option 'A' is that it offers aggregated IP addressing in the network core per pair of redundant BNG nodes. The downside is that the subscriber termination point (active BNG for the SRRP group) is hidden from the network core. Since both BNG nodes share the same IP subnet for the subscribers, the natural routing can cause downstream traffic to be sent to the standby BNG which in turn will have to shunt the traffic to the active BNG. It is likely that half of the traffic will be shunted over the redundant-interface with this approach. This scenario is shown in Figure 106.

**Figure 106 Shared Subscriber IP Space**

al\_0048

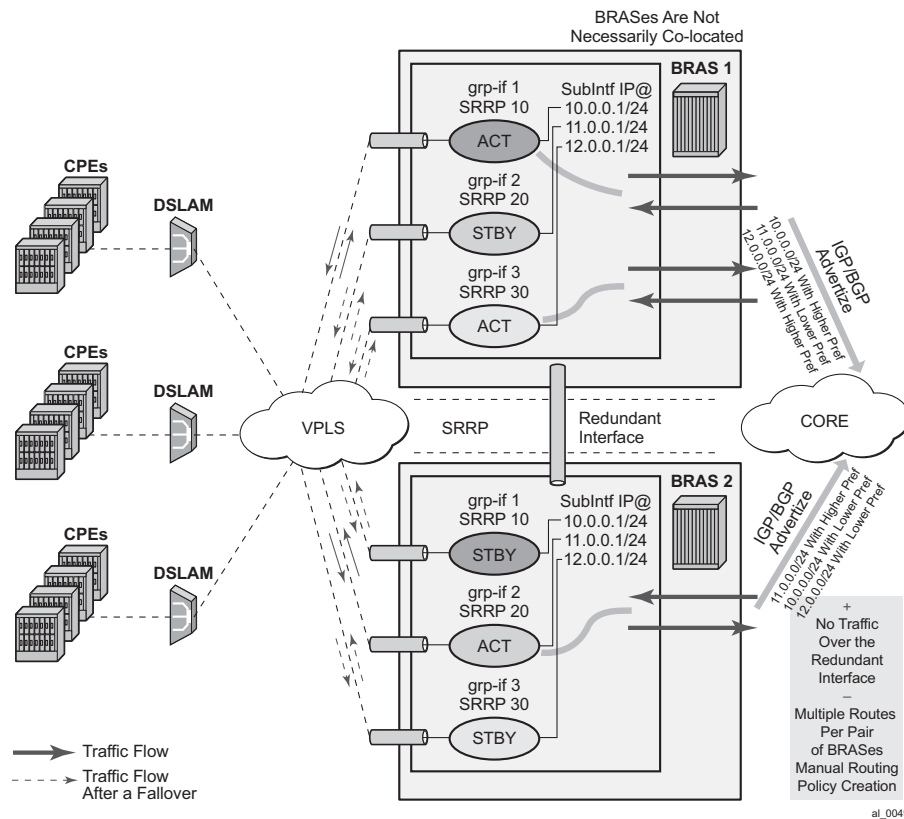

#### 9.4.18.4.2 Subnet Assignment and Advertisement - Option 'B'

With the option 'B', an IP address pool (or subnet) can be allocated per group of SRRP instances that are in the Master state. The routing decision on the network side is further influenced by the static increase of the metric of the advertised route on the BNG node hosting the active SRRP groups ([Figure 107](#)).

This approach would cause greater IP space segmentation in the network core, but at the same time, it would indirectly provide more information about the subscriber whereabouts and thus minimize or eliminate the shunt traffic during the normal operation. However, in the case of a SRRP switchover, the shunt traffic would ensue. The amount of the shunted traffic would depend on the scale of the failure. From the [Figure 107](#), it can be concluded that:

- In the depicted scenario on [Figure 107](#), there is no shunted traffic.
- If any of the SRRP instances transitions out of the Master state, traffic for an entire IP network associated with this failed SRRP instance would be shunted. The reason for this is that the advertised route metric is static and it does not follow changes in SRRP state.

**Figure 107 Option 'B' – IP Subnet per Active SRRP Group**

### 9.4.18.5 MSAP Considerations

As per RFC 2516 (PPPoE), this has the implications on the operation of the capture SAP. In IPoE environment, the initial DHCP traffic related to host establishment will use its native MAC of the physical port on the router. Once the group-interface is learned (later in the process, via RADIUS or msap-policy), the MAC address is switched to SRRP MAC address (virtual MAC). The IPoE client will adapt easily to this change. On the contrary, for the proper operation of PPPoE with SRRP, the initial destination MAC address learned by the PPPoE client does not change during the lifetime of the session.

This is ensured by indirectly referencing the grp-if under the capture SAP:

```
config>service>vpls
 sap 1/1/1:1.* capture-sap
 track-srrp 10
 sap 1/1/1:2.* capture-sap
 track-srrp 20
```

```
config>service>vprn>
 subscriber-interface <if-name>
 group-interface <grp-if-name>
 sap 1/1/1:1.1
 srrp 10
 message-path 1/1/1:1.1

 group-interface <grp-if-name>
 sap 1/1/1:2.1
 srrp 20
 message-path 1/1/1:2.1
```

With this approach the grp-if is nailed during the session initiation phase by referencing the SRRP instance in track-srrp statement (SRRP is a group interface-wide concept). RADIUS returned grp-if name must match the one on which referenced SRRP instance runs.

The capture SAP of the form

```
sap port-id:.* capture-sap
 track-srrp X
```

assumes that there is only one grp-if associated with all msaps under this capture SAP.

A check is put in place to make sure that the MAC addresses associated with the SRRP instance is the same as the MAC address of the associated capture SAP. A log is raised if there is a discrepancy between the MAC addresses while the grp-if is operationally UP. If there is a MAC address change (user misconfiguration) then the existing PPPoE sessions will time out and the new sessions will fail to establish until the condition is corrected.

## 9.4.18.6 Unnumbered Interface Support

For unnumbered subscriber-interface support in PPPoE, the gateway IP address that is used to send gratuitous ARP is not available. For this reason, the system IP address is used to send gratuitous ARPs. Gratuitous ARP is used to update the Layer 2 network forwarding path towards the BNG node in the upstream direction.

The system IP address is used automatically if the subscriber interface is unnumbered.

### 9.4.18.7 Compatibility with MC-LAG

SRRP for PPPoE works in an environment where MC-LAG is enabled. For example, the standby LAG link automatically puts the SRRP node in a Backup state and the SRRP becomes master on the active MC-LAG link. It is important that the SRRP on the standby leg of the MC-LAG is forced into a Backup state, or any new state that will force the downstream traffic to use the redundant interface.

Traffic destined to/from the subscriber is forwarded under the condition that the subscriber-interface is operationally UP. This applies also to shunting of downstream subscriber traffic from the STANDBY to MASTER node. It is always necessary to keep the subscriber-interface operationally UP by configuring a dummy group-interface with a command `oper-up-while-empty` under it. This is especially true for the MC-LAG which causes the messaging SAP on the STANDBY node always to be in the INIT state. In case that MSAPs are used on such group-interfaces, the group-interfaces would be also operationally DOWN, causing the subscriber-interface to be operationally DOWN.

### 9.4.18.8 IPv6 Support

Prerequisite for MC IPv6 Redundancy is to synchronize PPPoEv6 and IPoEv6 subscribers between the nodes via MCS.

In PPPoE environment, SRRP is used to refresh the forwarding path (MAC addresses) in the access aggregation network (via gratuitous ARP). SRRP ensures that the upstream traffic is steered to the Master BNG node. In the downstream direction, the Backup BNG directs traffic over to the Master BNG node via redundant-interface.

The IPv6 functionality currently relies on IPv4 based SRRP and IPv4 based redundant-interface. In other words, IPv4 is required to run on the access side as well as on the redundant-interface.

The redundant-interface is used in the downstream direction. Traffic arriving on the network links on the Standby node is shunted over to the Master node over the redundant-interface. This is required to ensure consistent QoS and accounting functionality across the nodes (upstream and downstream traffic on the access links for a subscriber must traverse the same BNG node). There is no IPv6 related CLI associated with the redundant-interface.

All IPv6 subscriber traffic that arrives on the Standby node in the downstream direction is automatically shunted over the IPv4 redundant-interface to the Master node. When IPv6 traffic arrives over the redundant-interface on the Master node, it is either PPPoEv6 encapsulated or left as plain IPoEv6 before it is forwarded to the subscriber.

In the upstream direction (AN->BNG) the behavior is the following:

- PPPoEv6

On the switchover, gratuitous ARPs (gARP) is sent from the new Master on each vlan. The IP address in gARP is the IPv4 gw-ip address or the system IP in the case of unnumbered interfaces. This updates the Layer 2 network path with the proper SRRP MAC address.

- IPoEv6

IPv4 based SRRP is used to update the Layer 2 forwarding path in the case of a switchover. A gratuitous ARP is sent in the same fashion as it is used for IPoEv4 hosts. Router Advertisements (RA) are not sent out in the case of the switchover.

However, the two BNG nodes share the same virtual Link Local (LL) IPv6 address. This address is used by the clients as a default-gw and only the Master BNG advertises this LL address in RAs. RAs are suppressed on the Standby node. As already mentioned, RAs are not sent during the switchover. RAs are sent:

- When the client first gets established – this is how the client learns its default-gw (in PPPoE case RA can also be used for SLAAC – stateless address configuration).
- As a reply to Router Solicitations messages sent by the clients.
- Periodically to each client.

Note that RAs are unicasted to each client.

Neighbor Advertisements (NA) used for address resolution are sent only from the Master. NA has the SRRP MAC address in the target link layer option on SRRP enabled group interfaces (on non-SRRP enabled group-interfaces, NAs contains the group interface MAC address).

The LL IPv6 address must be the same on both nodes. In addition, the gw-mac address must be the same on both nodes. The IPv6 clients will not be aware of the switchover and therefore they will not send NS to solicit the update of its neighbor cache with the possibly different gw-mac address.

The syntax to configure the LL address on the subscriber interface is the following:

```
config>service>ies | vprn>
 subscriber-interface <if-name>
 ipv6
 [no] link-local-address <ipv6-address>
```

```
<ipv6-address> : ipv6-address - x:x:x:x:x:x:x:x:x:x:x:d.d.d.d
x [0..FFFF]H
d[0..255]D
```

Note that the current version of SRRP relies only on IPv4 routes. The connection between SRRP and IPv4 routes is done via the subnets with gw IP addresses defined under the subscriber-interfaces in the ESM context. This connection is needed so that SRRP can send Gratuitous ARP properly.

These are the cases for PPPoEv6 MC Redundancy that are supported:

- unnumbered subscriber-interfaces (**config>service>subscriber-interface** hierarchy)
- numbered IPv4 subscriber-interfaces (**config>service>subscriber-interface** hierarchy)
- numbered IPv4 AND IPv6 subscriber-interfaces (**config>service>subscriber-interface** and **config>service>sub-if>ipv6** hierarchy)

numbered IPv6 only subscriber-interfaces (config>service>sub-if>ipv6 hierarchy) is not supported

## 9.4.18.9 Considerations with Local DHCP Server

When local DHCP Server redundancy/synchronization is used, using address-range failover local | remote, in conjunction with PPPoE in multi-chassis environment, both DHCP servers must be referenced under the corresponding group-interface on each node. For address-range failover access-driven configurations only one DHCP server must be referenced.

```
subscriber-interface <sub-if>
 group-interface <grp-if>
 dhcp
 server <local-dhcp-ip-address> <remote-dhcp-ip-address>
```

Otherwise, the PPPoE clients will not be synchronized via MCS.

Note that this is not the requirement in the IPoE environment. In the IPoE environment, it is enough that the DHCP server points to the IP address of the local DHCP server. If the IP lease is originally assigned by the peer DHCP server, the request for renewal is automatically forwarded to the remote DHCP server by the virtue of the IP address of the original DHCP server that is included in the renewal request.

It is necessary for the successful renewal of the IP address on the remote DHCP server, that the remote DHCP server has a valid return path back to the gi-address of the forwarder of the renewal request.

#### **9.4.18.10 Redundant Interface Considerations**

In PPPoE dual-chassis environment without the redundant-interface in place, SRRP aware routing should always be used. Otherwise, if the downstream traffic arrives on the backup node, it will get forwarded directly to the client over the access network (assuming that the access network is operational) with the source MAC address of the group-interface (instead of gw-mac). This grp-if MAC address is different from the MAC address (gw-mac) negotiated during the initial PPPoE phase, and therefore, this traffic will be dropped by the client. It must be ensured that the downstream traffic is always attracted to the Master node in the absence of redundant.

---

## 9.4.19 Routed Central Office (CO)

### 9.4.19.1 Layer 3 Subscriber Interfaces

On regular interfaces in an IES or VPRN service, only one SAP can be associated. A group-interface allows multiple SAPs to be configured as part of a single interface. All SAPs in a single group-interface must be within the same port. Since broadcast is not allowed in this mode, forwarding to the subscriber is based on IP/MAC addresses information gathered by the subscriber management module and stored in the subscriber management table. These entries are based on both static and dynamic DHCP hosts. Routed CO must be used with standard subscriber management or enhanced subscriber management. DSLAMs are typically deployed with Ethernet interfaces.

This model is a combination of two key technologies, subscriber interfaces and group interfaces. While the subscriber interface define the subscriber subnets, the group interfaces are responsible for aggregating the SAPs.

As depicted in [Figure 108](#), an operator can create a new subscriber interface in the IES or VPRN service. A subscriber interface allows for the creation of multiple group interfaces. The IP space is defined by the subnets of the subscriber interface's addresses. [Figure 108](#) shows the details of group interface A.

Figure 108    Subscriber Interface in an IES/VRN Service

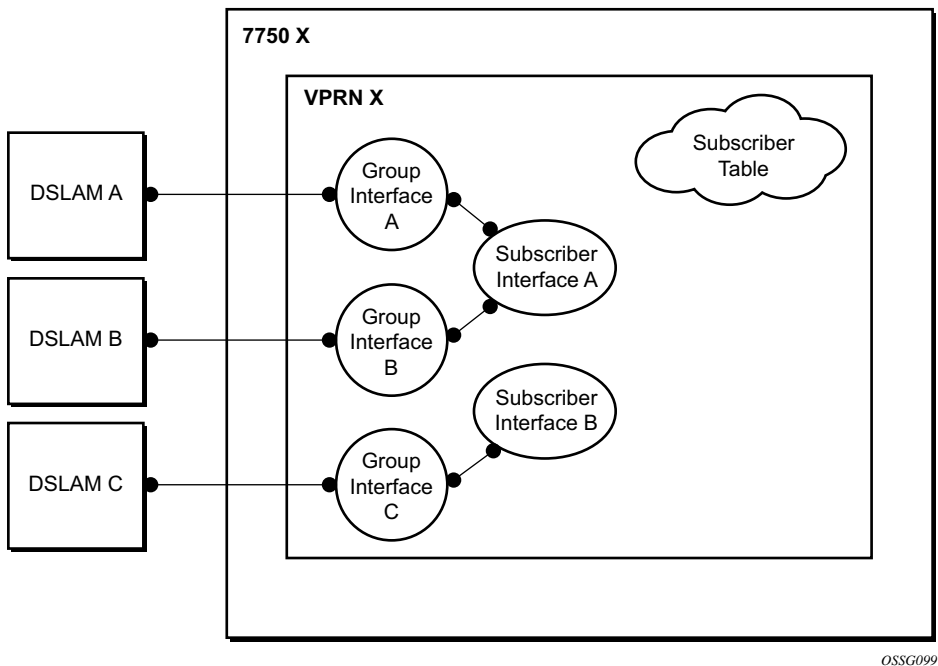

Figure 109    Details of a Group Interface

Figure 110 shows a network diagram where the DSLAM are connected directly to a Broadband Service Router (BSR) providing access to an IP subnet. Subscribers from multiple DSLAMs can be part of the same subnet. Note that BSR is also referred to as Broadband Network Gateway (BNG).

**Figure 110 Aggregation Network with Direct DSLAM-BSE Connection**

OSSG089

The BSR can be configured with multiple subnets, allowing subscribers to be part of a single subnet as well as providing mechanisms for re-addressing or expanding existing services without affecting existing users.

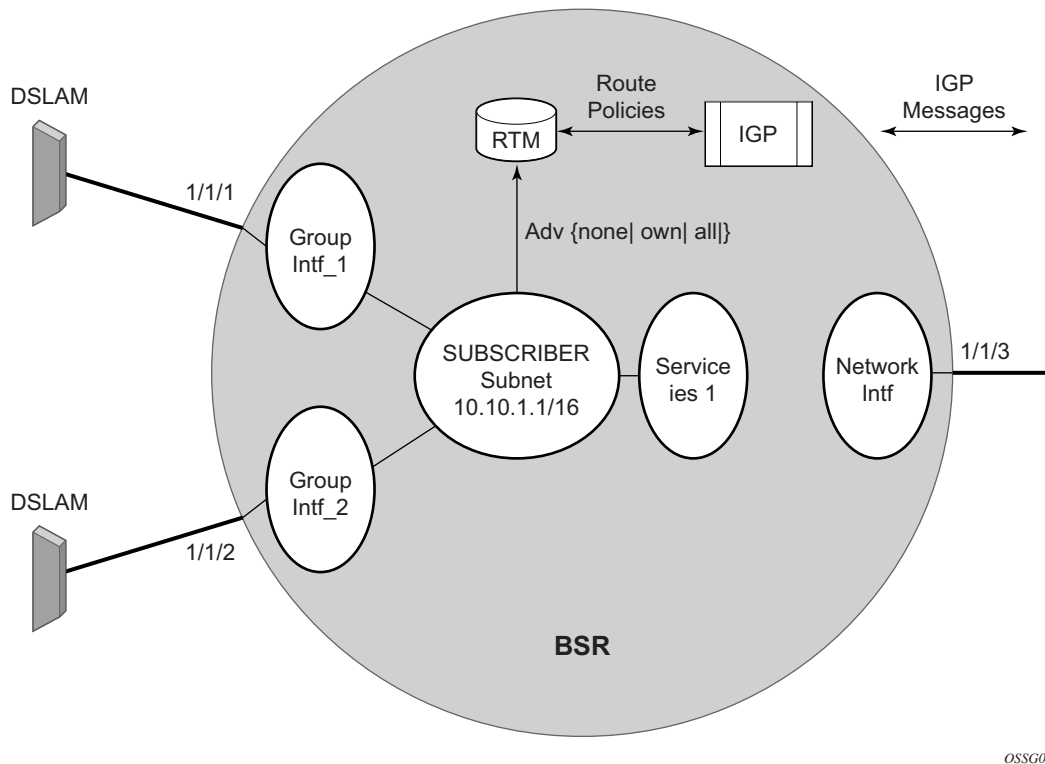

**Figure 111 Detailed View of Configurable Objects Related to Layer 3 Subscriber Interfaces**

Figure 111 shows a detailed view of a router and the configuration objects implemented to support Layer 3 subscriber interfaces.

- A subscriber service is defined by an IES Service. One or more IES services can be created.
- Each IES service concentrates a number of subscriber-interfaces. The operator can create multiple subscriber interfaces (represented as a subscriber subnet). A subscriber interface will define at least one subnet.
- A group-interface will be provisioned within the subscriber interface for each DSLAM connected. All group interfaces created under the subscriber interface will share the same subnet (or subnets). Group interfaces (shown as intf\_1 and intf\_2 in Figure 111) are configured as unnumbered and are associated with the subscriber-interface under which they are configured.
- SAPs can be configured under the group-interface. In a VLAN-per-DSLAM model only, one SAP per group-interface is needed, while in the VLAN-per-subscriber model, a subscriber of the DSLAM will require its own SAP. All SAPs on a group-interface must be on the same physical port or LAG.

The individual features related to subscribers, such as DHCP relay, DHCP snooping and anti-spoofing filters, are enabled at group-interface level. For a Routed CO model of subscriber management, and when enhanced subscriber management (if sub-sla-mgmt is configured). Then, hashing will be based on an internally assigned subscriber-ID. Having a unique subscriber ID configured in CLI will ensure that each subscriber is assigned a unique internal subscriber ID.

It is assumed that individual end-user devices (further referred to as subscriber hosts) get their IP address assigned through either DHCP or static configuration. The management of individual subscriber hosts (such as creation, queue allocation, etc.) is performed by Enhanced Subscriber Management.

The operator can provision how the system advertises routes. While most deployments will advertise the full subnet it is possible to have the system advertise only the active, discovered or static host routes.

The distribution of this information into routing protocols will be driven by import/export route policies configured by the operator.

#### 9.4.19.1.1 DHCP Interactions

The DHCP relay process has been enhanced to record incoming DHCP discover and request messages. Since forwarding to the SAPs is done by the information in the subscriber management table and multiple SAPs are allowed in one interface it was impossible to know which SAP will be used to forward the DHCP replies. The node maintains a cache of the DHCP requests. The cache can be viewed using the **tools>dump>router>dhcp>group-if-mapping** command. The cache holds an entry for 30 seconds. If an ACK/NAK packet was not received from the server within the timeout the node discards the cache entry. The node can use the Option 82 circuit-id field as part of the temporary host entry. If used, the ACK must contain the same circuit-id field in Option 82 to be found in the cache only if the match-circuit-id is specified at the DHCP level of the group- interface. When the match-circuit-id command is enabled a check is performed for option 82 circuit-id.

#### 9.4.19.1.2 Routed CO for IES Service

The routed CO model depends on subscriber management to maintain the subscriber host information. To create a group-interface the operator must first create a subscriber interface within the service (**config>service>ies>subscriber-interface ip-int-name**). The subscriber interface maintains up to 256 subscriber subnets and is configured with a host address for each subnet.

When a DHCP ACK is received the IP address provided to the client will be verified to be in one of the subscriber subnets associated with the egress SAP. It will be noted that when DHCP snooping is enabled for regular IES interfaces the same rule will apply.

The subscriber interface is an internal loopback interface. The operational state is driven from the child's group-interface states and the configuration of an address in the RTM.

The group interface is an unnumbered interface. The interface will be operationally up if it is in the no shutdown state and if at least one SAP has been defined and is up and the parent subscriber interface is administratively up. The first SAP defined will determine the port for the group- interface. If the user attempts to define a subsequent SAP that is on a different port will result in an error. When the subscriber-interface or the group-interface is in shutdown state no packets will be delivered/received to/from the subscriber hosts but the subscriber hosts, both dynamic and static, will be maintained based on the lease time.

In the routed CO model, the router acts as a DHCP relay agent and also serves as the subscriber- identification agent. The DHCP actions are defined in the group-interface. All SAPs in that interface inherit these definitions. The group-interface DHCP definition are a template for all SAPs.

Lease-populate is enabled by default with the number-of-entries set to 1. This enables DHCP lease state for each SAP in the group-interface.

Since the group-interface can aggregate subscribers in different subnets a GI address must be defined for the DHCP relay process. The address must be in one of the host addresses defined for the subscriber interface. The GI address can be defined at the subscriber interface level which will cause all child group interface to inherit that route. The GI address can then be overridden at the group interface level. A GI address must be defined in order for DHCP relay to function.

Because of the nature of the group-interface, local-proxy-arp, as well as arp-populate, should be enabled. This would allow the system to respond to subscriber ARP requests if the ARP request contains an IP address which is in the same subnet as one of the subscriber interface subnets.

When an authentication policy is specified for a SAP under a group interface, DHCP will intercept DHCP discover messages for RADIUS authentication. If the system is a DHCP-relay defined in a group-interface and the GI address was not configured the operational state of DHCP will be down.

### 9.4.19.1.3 Routed CO for VPRN Service

Much like in Routed CO for IES service, the Routed CO model for VPRN depends on subscriber management to maintain the subscriber host information. To create a group-interface, the operator must first create a subscriber interface in the `config>service>vprn` context. The subscriber interface can maintain up to 256 subscriber subnets and can be configured with a host address for each subnet. The host IP address can be installed as a result of both relaying to a DHCP server and proxy to a RADIUS server. In both cases the host IP address must be in the subnet defined by the VPRN's subscriber interface.

Basic subscriber management is allowed only in a subscriber/SAP model and can be used only in a dedicated VPRN architecture. A RADIUS service selection (using Managed SAPs) will require Enhanced Subscriber Management. The subscriber interface's subnets are allowed to be advertised to both IGPs and BGP within a VPRN.

When an authentication policy is specified for a group-interface, DHCP snooping must be enabled to intercept DHCP discover and renew messages for RADIUS authentication. Subscriber management RADIUS extensions are allowed if the operator chooses to have the RADIUS server return the subscriber identification, subscriber profile and sla-profile strings using RADIUS.

The node can be defined with both a DHCP relay or proxy function. If the user configures a DHCP relay, the `local-proxy-server` command will enable DHCP split leases. In that configuration the node will provide the configured DHCP lease to the client using either RADIUS or the real DHCP server as the source of the IP address to be provided.

The RADIUS server can send a Change of Authorization (CoA) message containing the DHCP `forcerenew` VSA which prompts the `local-proxy-server` to send a `forcerenew` message to the client. The node ACKs when the Force-Renew has been sent, regardless of whether the subscriber responds. If the client fails to respond or if a new session cannot be established due to resource management issues or otherwise the node must respond with a NACK to the RADIUS server.

If the CoA message contains an IP address that is different than the configured IP address (when RADIUS was providing IP addresses) the node must send a `forcerenew` message to the client and NAK the request and provide a new IP address. If the node fails to receive a request the CoA is ACK'd when the force-renew has been sent

The operational state of group and subscriber interfaces are dependent on the state of active SAPs. A group interface can become operationally up only if at least one SAP is configured and is in an operationally up state. A subscriber interface becomes operationally up if at least one group interface is operationally up or the associated wholesale forwarding interface is operationally up. This ensures that, in a failure scenario that affects all group interfaces in a given subscriber subnet, the node will stop advertising the subnet to the network. The SRRP state will affect this behavior as well and can cause the subnet to be removed if all group interfaces (and SRRP instances) are in backup state.

### 9.4.19.2 Wholesale Retail Routed CO

VPRN Routed CO allows a provider to resell wholesaler services (from a carrier) while providing direct DSLAM connectivity. An operator can create a VPRN service for the retailer and configure the access from subscribers as well as to the retailer network. Any further action will be as if the VPRN is a standalone router running the Routed CO model. All forwarding to these servers must be done within the VPRN service. The operator can leak routes from the base routing instance. In this model, the operator can use RADIUS for subscriber host authentication, DHCP relay and DHCP proxy. This provides maximum flexibility to the retailer while minimizing the involvement of the wholesaler. Access cannot be shared among retailers unless a subscriber SAP is used. This requires that the wholesaler maintain a different access node (DSLAM) for each retailer that does not scale well. The wholesale retail model described in this section overcomes these limitations.

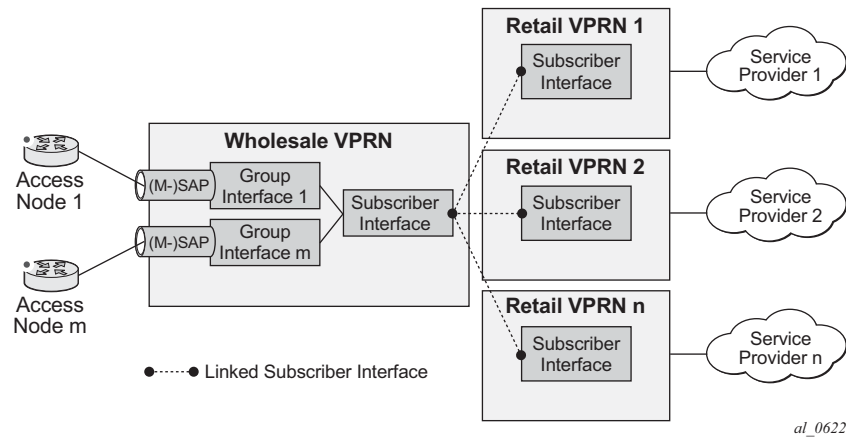

#### 9.4.19.2.1 Wholesale Retail Model

In the wholesale retail model ([Figure 112](#)), the wholesaler instance connections that are common to the access nodes are distributed to many retail instances. A subscriber host attached to an access node connected in the wholesaler service can be instantiated in a retail service and obtain IP addresses from the retailers address space. The service context of the retailer is determined during the subscriber host authentication phase (for example via the Alc-Retail-Serv-Id attribute in RADIUS or the retail-service-id CLI in the local user database).

Upstream subscriber traffic ingresses into the wholesaler instance and after identification is then forwarded into the retail instance. The reverse will occur for traffic in the downstream direction.

**Figure 112 Wholesale Retail Model**

In a wholesale retail model, two subscriber interfaces must be configured and linked together: one in the wholesale VPRN and one in the retail service.

The wholesale subscriber interface defines the IP subnets and host specific configuration parameters for subscriber hosts belonging to the wholesaler. There are associated group interfaces that contain the SAPs which connect to the access nodes.

The retail subscriber interface defines the IP subnets and host specific configuration parameters for subscriber hosts belonging to the retailer. The retail subscriber interface is linked to a wholesale subscriber interface for forwarding via explicit configuration. There are no associated group interfaces.

For example:

```
config>service
 vprn 1000 customer 1 create
 subscriber-interface "sub-int-ws-1" create
 # wholesale subscriber interface
 --- snip ---
 group-interface "group-int-1-1" create
 --- snip ---
 sap 1/1/1:1 create
 --- snip ---
 exit
 exit
exit
exit

vprn 1001 customer 1 create
```

```
subscriber-interface "sub-int-rt-1" fwd-service 1000 \\
 fwd-subscriber-interface "sub-int-ws-1" create
linked retail subscriber interface
--- snip ---
exit
exit
```

A retail subscriber interface can be linked to a single wholesale subscriber interface and context only. Subscriber interface chaining (linking a retail subscriber interface to another retail subscriber interface) is not supported. Multiple retail subscriber interfaces belonging to different retail contexts can be associated with a single wholesale subscriber interface. When a retail subscriber interface is linked to a wholesale context, all other retail subscriber interfaces from the same retailer must be linked to the same wholesale context.

#### 9.4.19.2.2 Configuration and Applicability

As explained in the previous section, the wholesale retail model is provisioned with the linking of a subscriber interface in a retail service to a subscriber interface in the wholesale VPRN service.

Because a retail subscriber interface does not have a group-interface context, some group-interface-specific CLI parameters such as to **configure dhcp relay** are made available at the retail subscriber interface level. Other CLI parameters such as to provision Radius or local user database authentication are configured at the wholesale subscriber or group interface and apply to both wholesale and retail subscriber hosts.

The DHCP lease-populate configuration is special in wholesale retail as it is configured in both wholesale and retail context. The lease-populate value in the wholesale group-interface dhcp context controls the per SAP limits while the lease-populate value configured in the retail subscriber interface dhcp context controls the limits for the retailer subscriber interface. Both limits must be satisfied before a new subscriber host can be instantiated.

The sample configurations below enable dual stack IPoE devices to connect to wholesale service VPRN 4000 and retail service VPRN 4001. Hosts connected in VPRN 4000 get their IP address assigned from RADIUS, hence the proxy server configuration. Hosts connected in VPRN 4001 get their IP address from a DHCP server, hence the DHCP relay configuration.

Only the service configurations are shown. They have to be completed with authentication policies and subscriber management configuration such as radius-server-policies, sub- and sla-profiles, and so on.

### Sample configuration – Wholesale VPRN Service:

```
config>service
 vprn 4000 customer 1 create
 autonomous-system 64500
 route-distinguisher 64500:4000
 auto-bind-tunnel
 resolution-filter
 ldp
 rsvp
 exit
 resolution filter
 exit
 vrf-target target:64500:4000
 subscriber-interface "sub-int-1" create
 address 10.10.1.254/24
 address 10.10.2.254/24
 ipv6
 delegated-prefix-len variable
 subscriber-prefixes

The wholesale retail model applies to all IPoE, PPPoE PTA, IPv4 and IPv6 host types.

The wholesale service type must be VPRN. For IPEv4 hosts, the retail service type must be a VPRN. For all other host types, the retail service type can be IES or VPRN.

Multicast-per-host replication can be enabled without support for multi-chassis redundancy.

The wholesale retail model can be deployed in combination with managed SAPs.

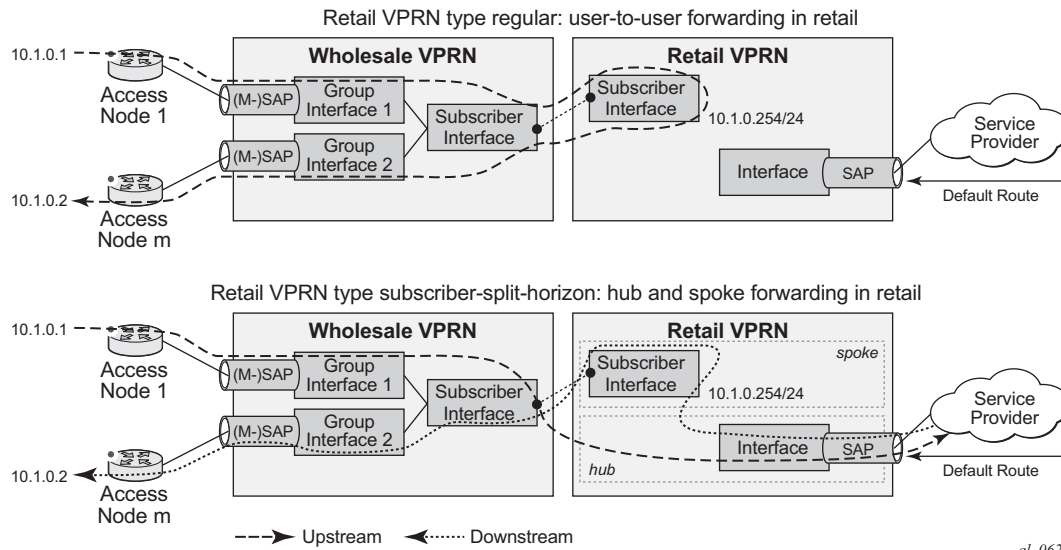

Overlapping subscriber subnets and prefixes in retail VPRN services associated with the same wholesale forwarding service are supported for PPPoE (IPv4 and IPv6) and IPEv6. This is enabled by configuring private retail subnets on the retail subscriber interface. Private retail subnets cannot be configured when multi-chassis redundancy is needed.

#### 9.4.19.2.3 Hub-and-Spoke Forwarding

In some cases, hub-and-spoke-type forwarding is needed for the retailer's VPRN. When the retailer expects all subscriber traffic to reach its router (for accounting, monitoring, wiretapping, and so on) normal best-hop behavior within the retailer VPRN is not desired. Any subscriber-to-subscriber traffic will be forwarded within the VPRN preventing the retailer from receiving these packets. To force all subscriber packets to the retailer network, a new type of hub-and-spoke topology is defined: "type subscriber-split-horizon". It can be used to force all subscriber traffic (upstream) to the retailer's network. The system requires that the operator shutdown the VPRN service to enable this flag.

With retail VPRN type configured to subscriber-split-horizon, routes learned from MBGP, IGP through a regular interface, static routes through regular interfaces and locally attached regular interface routes are considered hub routes and are used for upstream traffic forwarding. Subscriber subnets cannot be used for upstream traffic forwarding. Downstream traffic will use routes in both hub and spoke routing instances.

[Figure 113](#) shows user-to-user traffic forwarding for both retail VPRN types: regular and subscriber-split-horizon.

**Figure 113 Wholesale Retail – Hub-and-Spoke Forwarding**

al\_0623

Hub-and-spoke forwarding can also be used in combination with wholesale unicast RPF (uRPF) check. The uRPF is performed on upstream traffic on spoke routes (subscriber subnets) and the forwarding uses hub routes only.

### 9.4.19.3 Routed Subscriber Hosts

**Figure 114 Router Subscriber Hosts**

A routed subscriber host associated route is a global routable subnet/prefix behind a routed CPE or Home Gateway. The routed CPE is identified in the BNG as an ESM subscriber host: QoS, accounting and anti-spoofing is enforced per CPE. The associated routes are installed in the BNG route table with next-hop pointing to the routed subscriber host's WAN address.

Routed subscriber host associated routes are supported on IES/VPDN subscriber interfaces in a routed CO configuration. To put a SAP or MSAP in routed subscriber mode, the anti-spoof type for the SAP or MSAP must be configured to nh-mac:

```
configure
 service ies/vprn <service-id>
 subscriber-interface <ip-int-name>
 group-interface <ip-int-name>
 sap <sap-id>
 anti-spoof nh-mac

configure
 subscriber-mgmt
 msap-policy <msap-policy-name>
 ies-vprn-only-sap-parameters
 anti-spoof nh-mac
```

There are three ways to learn about a routed subscriber host associated IPv4 route:

1. Configuration for a static host
2. A dynamic BGP peer
3. The RADIUS [22] Framed-Route attribute

A routed subscriber host associated IPv6 route can only be learned with the RADIUS [99] Framed-IPv6-Route attribute.

#### 9.4.19.3.1 Static Configured IPv4 Managed Route

The routes associated with a static host are populated in the routing table as "Remote Managed" routes. Up to sixteen managed routes can be configured for a static host.

```
config>service>ies>sub-if>grp-if>sap
config>service>vprn>sub-if>grp-if>sap

static-host ip 10.1.1.20 create
 sla-profile "sla-profile-1"
 sub-profile "sub-profile-1"
 subscriber "static-host-1"
 managed-routes
 route 172.20.1.0/24
```

```

. . .
route 172.20.16.0/24
exit
no shutdown
exit

```

To display the managed routes associated with a routed subscriber host, use following commands:

**show service id *service-id* static-host detail**

#### 9.4.19.3.2 Static Configured IPv6 Managed Route

The routes associated with a static host are populated in the routing table as “Remote Managed” routes. Up to sixteen managed routes can be configured for a static host.

```

config>service>ies>sub-if>grp-if>sap
config>service>vprn>sub-if>grp-if>sap
 anti-spoof nh-mac
 static-host ip 2001::1/128 create
 sla-profile "sla-profile-1"
 sub-profile "sub-profile-1"
 subscriber "static-host-1"
 managed-routes
 route 2000::/56
. . .
 route 3000::/56
 exit
 no shutdown
 exit

 static-host ip 2001:1::/64 create
 sla-profile "sla-profile-1"
 sub-profile "sub-profile-1"
 subscriber "static-host-1"
 managed-routes
 route 4000::/56
. . .
 route 5000::/56
 exit
 no shutdown
 exit

```

To display the managed routes associated with a routed subscriber host, use following commands:

**show service id *service-id* static-host detail**

### 9.4.19.3.3 Dynamic BGP Peering

Routed subscriber host associated IPv4 routes can be learned over a dynamic BGP IPv4 peer that is automatically set up when a subscriber host is instantiated. The parameters for the BGP peer are configured in a BGP peering policy or obtained in Radius VSA attributes. The subscriber-host IPv4 address is used as the BGP peer IP address. The BGP peering is torn down and the associated routes removed from the routing table as soon as the subscriber-host is removed.

Dynamic BGP peering is supported for routed subscriber hosts terminated in a VPRN service and is not supported for routed subscriber hosts terminated in an IES service. The BGP learned routes scaling is limited by the BGP scaling limits. The routes learned via a dynamic BGP peer are populated in the routing table as “Remote BGP” routes.

To display the BGP learned routes associated with a routed subscriber host, use the regular BGP commands. For example:

**show router *service-id* bgp neighbor *ip-address* received-routes**

An ESM dynamic BGP group must be configured in the BGP cli context of the VPRN service where the subscriber host is started:

**config>service>vprn>bgp**

```
group "dynamic-peer-1" esm-dynamic-peer
exit
```

The BGP peering policy to be used must be configured in the subscriber-mgmt CLI context:

```
config>subscr-mgmt
```

```
bgp-peering-policy "bgp-policy-1" create
exit
```

An ESM dynamic BGP peer is established for a subscriber host if the RADIUS attribute [26-6527-55] “Alc-BGP-Policy” returned in the Access-Accept contains the name of a local configured bgp-peering-policy and if an ESM dynamic peer group is configured in the VPRN BGP context.

BGP peering parameters can be specified from multiple sources:

- Use BGP peering parameters returned in RADIUS VSA attributes
- If not available from RADIUS, use BGP peering parameters configured in the bgp-peering-policy

- If not configured in the bgp-peering-policy, use BGP peering parameters configured for the esm-dynamic-peer group
- If not configured in the esm-dynamic-peer group, use the BGP peering parameters configured in the VPRN service BGP CLI context.
- If not configured in the VPRN service BGP CLI context, use the defaults

The import and export policies to be used for the dynamic bgp peer are determined in following priority order:

1. Use import/export policies returned in RADIUS VSA attributes and append policies configured in the bgp-peering-policy.
2. If not available from RADIUS AND not configured in the bgp-peering-policy, use the policies configured in the esm-dynamic-peer group.
3. If not configured in the esm-dynamic-peer group, use the policies configured in the VPRN service BGP CLI context.

[Table 63](#) details the RADIUS VSA attributes that can be used to setup dynamic BGP peering.

**Table 63 RADIUS VSA Attributes to Setup Dynamic BGP Peering**

| Attribute-ID | Attribute Name        | Description                                                                                                                                                                  |
|--------------|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 26-6527-55   | Alc-BGP-Policy        | Mandatory attribute to setup a dynamic BGP peer. References a bgp peering policy configured in the “configure subscriber-mgmt bgp-peering-policy <policy-name>” CLI context. |
| 26-6527-56   | Alc-BGP-Auth-Keychain | Optional. References a keychain configured in the “configure system security keychain <keychain-name>” CLI context.                                                          |
| 26-6527-57   | Alc-BGP-Auth-Key      | Optional. The MD5 authentication key used between BGP peers for BGP session establishment.                                                                                   |
| 26-6527-58   | Alc-BGP-Export-Policy | Optional. References a pre-configured BGP export routing policy.                                                                                                             |
| 26-6527-59   | Alc-BGP-Import-Policy | Optional. References a pre-configured BGP import routing policy.                                                                                                             |
| 26-6527-60   | Alc-BGP-PeerAS        | Optional. Specifies the Autonomous System number for the remote peer                                                                                                         |

#### 9.4.19.3.4 RIP Listener

If a routed subscriber host is associated with a RIP policy, the host's IPv4 routes can be learned over RIP. The BNG only supports RIP listener and does not support sending RIP routes to subscribers. To enable RIP for a subscriber, the subscriber must first be associated with a **rip-policy**. The group interface of the subscriber must also be configured as a RIP neighbor. The rip-policy can be associated to the subscriber during authentication from LUDB or via RADIUS. It can also be configured directly for static hosts. The RIP routes learned from a subscriber is removed as a subscriber is purged or shutdown from the system. RIP listening for ESM host is supported on both IES and VPRN.

To display the RIP learned routes associated with a routed subscriber host, use the regular RIP commands. For example:

```
show router service-id rip neighbor interface advertised-routes
```

The group interface must be configured in the RIP CLI context of the routed instance where the subscriber host is created:

```
config>router/service vprn>rip
 group "rip-listener"
 neighbor "group-interface-01"
```

The RIP policy is configured in the subscriber-mgmt CLI context:

```
config>sub-mgmt
 rip-policy "rip-policy-01" create
```

A RIP neighbor is established for a subscriber host if the RADIUS attribute [26-6527-207] "Alc-RIP-Policy" is returned in the Access-Accept or in LUDB. RIP parameters such as **authentication key** and **type** can be specified in the RIP policy.

For more information about RIP, refer to the Unicast Routing Protocols Guide.

### 9.4.19.3.5 RADIUS: Framed-Route and Framed-IPv6-Route

RADIUS attribute [22] Framed-Route can be specified in a RADIUS Access-Accept message to associate an IPv4 route with an IPv4 routed subscriber host and Radius attribute [99] Framed-IPv6-Route can be used to associate an IPv6 route with an IPv6 routed subscriber wan host (DHCPv6 IA-NA or SLAAC). These routes are populated in the routing table as “Remote Managed” routes. Up to sixteen managed routes can be installed for a routed subscriber host; this corresponds with up to sixteen Framed-Routes and sixteen Framed-IPv6-Routes for a dual stack routed subscriber. Framed-IPv6-Routes cannot be associated with a Prefix Delegation host (DHCP IA-PD).

The Framed-Route and Framed-IPv6-Route attributes should be formatted as:

```
"<ip-prefix>[/<prefix-length>] <space> <gateway-address> [<space> <metric>]
[<space> tag <space> <tag-value>] [<space> pref <space> <preference-value>]"
```

where:

<space> — is a white space or blank character.

<ip-prefix>[/prefix-length] — is the managed route to be associated with the routed subscriber host. The prefix-length is optional for an IPv4 managed route. When not specified, a class-full class A,B or C subnet is assumed. The prefix-length is mandatory for an IPv6 managed route.

<gateway-address> — must be the routed subscriber host IP address.  
“0.0.0.0” is automatically interpreted as the host IPv4 address for managed IPv4 routes.

“::” and “0:0:0:0:0:0:0:0” are automatically interpreted as the wan-host IPv6 address for managed IPv6 routes.

[<metric>] — Optional. Installed in the routing table as the metric of the managed route. If not specified, metric zero is used. Value = [0.. 65535].

[tag <tag-value>] — Optional. The managed route will be tagged for use in routing policies. If not specified, or tag-value = 0, then the route is not tagged. Value = [0..4294967295].

[pref <preference-value>] — Optional. Installed in the routing table as protocol preference for this managed route. If not specified, preference zero is used. Value = [0..255].

If the optional metrics (metric, tag and/or preference) are specified in a wrong format or with out of range values, then the defaults are used for all metrics: metric=0, no tag and preference=0. No event is logged.

If the Framed-Route or Framed-IPv6-Route is invalid (for example because the gateway address specified does not match the host wan IP address or because the host bits are not zero) then the routed subscriber host is instantiated without the ill defined managed route. An event is logged in this case.

Equal Cost Multi-Path (ECMP) is supported for Framed-Route and Framed-IPv6-Route:

The maximum number of equal cost paths in a routing instance is configured with:

```
config>router>
config>service>vprn>
 ecmp <max-ecmp-routes>
```

If an identical managed route is associated with different routed subscriber hosts in the context of the same IES/VPNRN service, up to <max-ecmp-routes> managed routes are installed in the routing table. Candidate ECMP Framed-Routes/Framed-IPv6-Routes have:

- Identical prefix
- Equal lowest preference
- Equal lowest metric

A tie breaker determines if more candidate ECMP Framed-Routes/Framed-IPv6-Routes are available than the configured <max-ecmp-routes> is: Lowest ip next-hop.

Other identical managed routes are shadowed and an event is logged.

Note that Candidate ECMP Framed-Routes/Framed-IPv6-Routes can belong to hosts of the same or different subscriber.

Valid Framed-Routes and Framed-IPv6-Routes are persistent (stored in the persistency file for recovery after reboot) and synchronized in a Multi-Chassis Redundancy configuration.

RADIUS-learned Framed-Route/Framed-IPv6-Route and static host associated managed routes that are installed in the routing table can be identified in routing policies for redistribution as protocol "managed".

To display the managed routes associated with a routed subscriber host, use following commands:

**show service id *service-id* dhcp lease-state detail**

**show service id *service-id* dhcp6 lease-state detail**

**show service id *service-id* slaac host detail**

**show service id *service-id* ppp session detail**

**show service id *service-id* pppoe session detail**

**show service id *service-id* arp-host detail**

Valid RADIUS-learned managed routes can be included in RADIUS accounting messages with the following configuration:

```
configure
 subscriber-mgmt
 radius-accounting-policy <name>
 include-radius-attribute
 framed-route
 framed-ipv6-route
```

Associated managed routes for an instantiated routed subscriber host are included in RADIUS accounting messages independent of the state of the managed route (Installed, Shadowed, HostInactive, etc.)

For a PPP session, when a Framed-Route or Framed-IPv6-Route is available while the corresponding routed subscriber host is not yet instantiated, the managed route is in the state “notYetInstalled” and will not be included in RADIUS accounting messages.

#### 9.4.19.3.6 GRT Lookup and Routed CO in a VPRN

GRT lookup allows routing from a VPRN to the GRT, and GRT leaking allows routing from the GRT to a VPRN. These features are particularly useful when VPRNs require routing to the Internet and the GRT already contains the Internet routing table. Wholesale/retail VPRNs and the routed CO VPRN have both GRT lookup and GRT leaking support.

The **config>service>vprn>grt-lookup>export-grt** command exports subscriber-related routes and protocols to the GRT. This allows traffic arriving from the network port to be routed downstream to the subscriber. The following configurations are supported in the downstream direction.

- For an IPv4 numbered subscriber interface inside a routed CO VPRN, an IPv4 subscriber subnet can be exported as a policy using the **config>service>vprn>grp-lookup>export-grt** command, where the policy is configured with the **config>router>policy-options>policy-statement** command.

- For an IPv6 numbered subscriber interface inside a routed CO VPRN, an IPv6 subscriber subnet/prefix can be exported as a policy using the **config>service>vprn>grp-lookup>export-grt** command, where the policy is configured with the **config>router>policy-options>policy-statement** command.
- Subscriber-related protocols (managed routes and subscriber management routes) inside a routed CO VPRN can be exported to the GRT.
- For an IPv4 unnumbered subscriber interface inside a routed CO VPRN, subscriber host /32 routes are exported individually to the GRT using the “sub-mgmt” protocol.
- For an IPv6 unnumbered subscriber interface inside a routed CO VPRN, subscriber host /128 routes and/or prefixes are exported individually to the GRT using the “sub-mgmt” protocol.
- The retail VPRN supports all items listed above for a routed CO VPRN (exporting subscriber routes and protocols to the GRT via the **config>service>vprn>grp-lookup>export-grt** command). The retail VPRN does not export host routes by default. Therefore, the **export-host-routes** command may be required for a retail VPRN unnumbered subscriber interface.
- The wholesale VPRN supports all items listed above for a routed CO VPRN (exporting subscriber routes and protocols to the GRT via a route policy). However, retail-related routes that appear in the FIB of the wholesale VPRNs, cannot be exported. Retail-related routes must be exported individually within the VPRN to the GRT. This provides control over which retail VPRNs route to the GRT.

GRT lookup supports traffic from the subscriber to be routed upstream to the GRT. The following configurations are supported in an upstream direction:

- routed CO VPRN and **grt-lookup**
- wholesale VPRN and **grt-lookup**
- retail VPRN and **grt-lookup**

#### Not Supported

- SRRP setup in routed CO VPRN
- SRRP setup in wholesale/retail VPRN

## 9.4.20 Dual Homing

All residential networks are based on two models: Layer 2 CO and Layer 3 CO. Dual homing methods for Layer 2 CO include MC-LAG and MC-Ring. Dual homing for Layer 3 CO is based on SRRP and can be done in ring-topologies (I3-mc-ring or with directly attached nodes). All methods use multi-chassis synchronization protocol to sync subscriber state.

### 9.4.20.1 Dual Homing to Two PEs (Redundant-Pair Nodes) in Triple Play Aggregation

**Figure 115** Dual-Homing to Two PEs

Fig\_40

Figure 115 depicts dual-homing to two different PE nodes. The actual architecture can be based on a single DSLAM having two connections to two different PEs (using MC-LAG) or ring of DSLAMs dual-connected to redundant pair of PEs.

Similarly to previous configuration, both aggregation models (VLAN-per-subscriber or VLAN-per-service) are applicable.

Configurations include:

- Loop resolution and failure recovery — Can be based on MC-LAG or mVPLS.
- DHCP-lease-state persistency — Stores all required information to recover from node failure.
- DHCP-lease-state synchronization — A mechanism to synchronize the DHCP lease-state between two PE nodes in the scope of redundancy groups (a group of SAPs used for dual homing).
- IGMP snooping state synchronization — Similarly to DHCP lease-state synchronization, IGMP snooping state is synchronized to ensure fast switchover between PE nodes. In a VPLS network, a BTV stream is typically available in all PE nodes (the ring interconnecting all PEs with Mcast routers is typically used) so the switch over can be purely driven by RSTP or MC-LAG.
- ARP reply agent responses — The ARP reply agent can response to ARP requests addressing a host behind the given SAP if the SAP is in a forwarding state. This prevents the FDB table in the VPLS from being “poisoned” by ARP responses generated by the node with a SAP in a blocking state (see [Figure 116](#)).

[Figure 116](#) shows a typical configuration of network model based on Layer 2 CO model. Individual rings of access nodes are aggregated at BSA level in one (or multiple) VPLS services. At higher aggregation levels (the BSR), individual BSAs are connected to Layer 3 interfaces (IES or VPRN) by spoke SDP termination. Every Layer 3 interface at BSR level aggregates all subscribers in one subnet.

**Figure 116 Layer 2 CO Dual Homing - Network Diagram**

Fig\_39

Typically, BTV service distribution is implemented in a separate VPLS service with a separate SAP per access-node. This extra VPLS is not explicitly indicated in [Figure 116](#) (and subsequent figures) but the descriptions refer to its presence.

From a configuration point of view in this model, it is assumed that all subscriber management features are enabled at the BSA level and that synchronization of the information (using multi-chassis synchronization) is configured between redundant pair nodes (BSA-1 and BSA-2 shown in [Layer 2 CO Dual Homing - Network Diagram](#)). The multi-chassis synchronization connection is used only for synchronizing active subscriber host database and will operate independently from dual-homing connectivity control. At the BSR level, there are no subscriber management features enabled.

The operation of redundancy at the BSR level through VRRP is the same as dual homing based on MC-LAG. The operation of dual homing at BSA level is based on two mechanisms. Ring control connection between two BSAs have two components, in-band and out-of-band communication. With in-band communication, BFD session between BSA-1 and BSA-2 running through the access ring and using dedicated IES/VPDN interface configured on both nodes. This connection uses a separate VLAN throughout the ring. The access nodes provides transparent bridging for this VLAN. The BFD session is used to continuously verify the integrity of the ring and to detect a failure somewhere in the ring.

With out-of-band communication, the communication channel is used by BSA nodes to exchange information about the reachability of individual access nodes as well as basic configurations in order to verify the consistency of the ring. The configuration information is synchronized through multi-chassis synchronization and therefore it is mandatory to enable multi-chassis synchronization between two nodes using the multi-chassis-ring concept.

In addition, the communication channel used by MC-LAG or MC-APS control protocol is used to exchange some event information. The use of this channel is transparent to the user.

Ring node connectivity check continuously checks the reachability of individual access nodes in the ring. The session carrying the connection is conducted on separate VLAN, typically common for all access nodes. SHCV causes no interoperability problems.

#### 9.4.20.2 Steady-State Operation of Dual-homed Ring

[Figure 117](#) illustrates the operation of the dual-homed ring. The steady state is achieved when both nodes are configured in a consistent way and the peering relation is up. The multi-chassis ring must be provisioned consistently between two nodes.

In-Band Ring Control Connection (IB-RCC) is in operational UP state. Note that this connection is set up using a bi-directional forwarding session between IP interfaces on BSA-1 and BSA-2.

**Figure 117 Dual Homing Ring Under Steady-State Condition**

In [Figure 117](#), the ring is fully closed and every access node has two possible paths towards the VPLS core. [Figure 117](#) refers to these as **path-a** and **path-b**. In order to avoid the loop created by the ring, only one of the paths can be used by any given ring node for any given VLAN. The assignment of the individual VLANs to path-a or path-b, respectively, has to be provisioned on both BSAs.

The selection of the BSA master for both paths will be based on the IP address of the interface used for IB-RCC communication (bi-directional forwarding session). The BSA with the lower IP address of the interface used as IB-RCC channel will become master for ring nodes and their respective VLANs assigned to path-a. The master of path-b will be other BSA.

In this example, each path in the ring has a master and standby BSA. The functionality of both devices in steady state are as follows:

In the master BSA:

- All SAPs that belong to the path where the given BSA is a master, are operationally UP and all FDB entries of subscriber hosts associated with these SAPs point to their respective SAPs.
- The master of a path performs periodical Ring Node Connectivity Verification (RNCV) check to all ring nodes.

- In case of a RNCV failure, the respective alarm will be raised. Note that the loss of RNCV to the given ring node does not trigger any switchover action even if the other BSA appears to have the connection to that ring node. As long as the BFD session is up, the ring is considered closed and the master/standby behavior is driven solely by provisioning of the individual paths.
- The ARP reply agent replies to ARP requests addressing subscriber hosts where the BSA master.

In the standby BSA:

All SAPs that belong to a BSA's path, the standby will be operationally down and all FDB entries of subscriber hosts associated with those SAPs will be pointing towards SDP connecting to master BSA (also called a shunt SDP).

In both BSAs:

- The information on individual paths assignment is exchanged between both BSAs through multi-chassis synchronization communication channel and conflicting SAPs (being assigned to different paths on both BSA nodes) will be forced to path-a (the default behavior).
- For IGMP snooping, the corresponding multi-chassis IDs are targeting all subscriber-facing SAPs on both nodes. On the standby BSA node, the corresponding SAPs are in an operationally down state to prevent the MC traffic be injected on the ring twice.

### 9.4.20.3 Broken-Ring Operation and the Transition to this State

[Figure 118](#) illustrates the model with a broken ring (link failure or ring node failure). This state is reached in following conditions:

- Both nodes are configured similarly.
- Peering is up.
- The multi-chassis ring is provisioned similarly between two nodes
- IB-RCC is operationally down.

In this scenario, every ring node has only one access path towards the VPLS core and hence, the Path-a and Path-b notion has no meaning in this situation.

Functionally, both BSAs are now the master for the reachable ring nodes and will take action as described in [Steady-State Operation of Dual-homed Ring](#). For all hosts behind the unreachable ring nodes, the corresponding subscriber host FDB entries point to the shunt SDP.

**Figure 118 Broken Ring State**

Fig\_38

The mapping of individual subscriber hosts into the individual ring nodes is complicated, especially in the VLAN-per-service model where a single SAP can represent all nodes on the ring. In this case, a given BSA can have subscriber hosts associated with the given SAP that are behind reachable ring nodes as well as subscriber hosts behind un-reachable ring nodes. This means that the given SAP cannot be placed in an operationally down state (as in a closed ring state), but rather, selectively re-direct unreachable subscriber states to the shunt SDP.

All SAPs remain in an operationally up state as long as the ring remains broken. This mainly applies for BTV SAPs that do not have any subscriber hosts associated with and do not belong to any particular ring node.

In order to make the mapping of the subscriber-hosts on the given ring node automatically provisioned, the ring node identity will be extracted during subscriber authentication process from RADIUS or from a Python script. The subscriber hosts which are mapped to non-existing ring node will remain attached to the SAP.

At the time both BSA detect the break in IB-RCC communication (if BFD session goes down) following actions are taken:

- Both nodes trigger a RNCV check towards all ring nodes. The node, which receives the reply first, will assume a master functionality and will inform the other BSA through an out-of-band channel. This way, the other node can immediately take actions related to the standby functionality without waiting for an RNCV timeout. Even if the other node receives an RNCV response from the given ring node later, the master functionality remains with the node the received the response first.
- After assuming the master functionality for hosts associated with the given SAP(s), the node will send out FIB population messages to ensure that new path towards the VPLS core is established. The FIB population messages are sourced from the MAC address of the default gateway used by all subscriber hosts (such as the VRRP MAC address) which is provisioned at the service level.

#### 9.4.20.4 Transition from Broken to Closed Ring State

By its definition, the multi-chassis ring operates in a revertive mode. This means that whenever the ring connectivity is restored, the BSA with lower IP address in the IB-RCC communication channel will become master of the path-a and vice versa for path-b.

After restoration of BFD session, the master functionality, as described in [Steady-State Operation of Dual-homed Ring](#), is assumed by respective BSAs. The FDB tables are updated according to the master/standby role of the given BSA and FDB population messages is sent accordingly.

#### 9.4.20.5 Provisioning Aspects and Error Cases

The multi-chassis ring can operate only if both nodes similarly configured. The peering relation must be configured and both nodes must be reachable at IP level. The multi-chassis ring with a corresponding sync-tag as a ring-name identifying a local port ID must be provision on both nodes. And, BFD session and corresponding interfaces needs to be configured in a consistent way.

In case the multi-chassis rings are not provisioned consistently, the ring will not become operational and the SAP managed by it will be in operationally up state on both nodes.

The assignment of individual SAPs to path-a and path-b is controlled by configuration of VLAN ranges according to the following rules:

- By default, all SAPs (and hence all VLANs on the given port) are assigned to path-a.
- An explicit statement defining the given VLAN range assigns all SAPs falling into this range to the path-b.
- An explicit statement defining the given VLAN range defines all SAPs that are excluded from the multi-chassis ring control.
- In case of a conflict in the configuration of VLAN ranges between two redundant nodes is detected, all SAPs falling into the “conflict-range” will be assigned to path-a, on both nodes regardless the local configuration.
- For QinQ-encapsulated ports the VLAN range refers to the outer VLAN.

### 9.4.20.6 Dual Homing to Two BSR Nodes

Figure 119 depicts a single DSLAM dual-homed to two BSRs.

**Figure 119** Low

In order to provide dual-homing in the context of subscriber interfaces, the following items must be configured on both BSRs:

- Group interface (dslam-1) with corresponding SAPs (vlan 1-100)
- SRRP instance controlling given group interface
- Redundant interface between BSRs to provide “shunt” connectivity
- MCS connection to provide synchronization of dynamic subscriber-host entries

During the operation, BSR-1 and BSR-2 will resolve master-backup relation and populate respective FIBs in such a way that at master side, subscriber-host entries point to corresponding group-interface while at the back-up side, subscriber-host entries point to the redundant interface. Note that the logical operation of the ring in the Layer 3 CO model is driven by SRRP. For more details on SRRP operation, refer to [Subscriber Routed Redundancy Protocol \(SRRP\)](#).

### 9.4.20.7 MC Services

The typical implementation of MC services at the network level is shown in [Figure 120](#).

**Figure 120 MC Services in a Layer 3-Ring Topology (a)**

The IGMP is used to register joins and leaves of the user. IGMP messaging between BSRs is used to determine which router performs the querier role (BSR2 in [Figure 120](#)). PIM is used to determine which router will be the designated router and the router that sends MC streams on the ring.

The access nodes have IGMP snooping enabled and from IGMP messaging between BSR, they are aware which router is the querier. In the most generic case, IGMP snooping agents (in access nodes) send the IGMP-joins messages only to IGMP-querier. The synchronization of the IGMP entries can be then be performed through MCS. In some cases, access nodes can be configured in such a way that both ring ports are considered as m-router ports and IGMP joins are sent in both directions.

All of the above is a steady state operation which is transparent to the topology used in a Layer 2 domain.

A ring-broken state is shown in [Figure 121](#).

In this case, IGMP and PIM messaging between BSRs is broken and both router assume role of querier and role of designated router. By the virtue of ring topology, both routers will see only IGMP joins/leaves generated by host attached to a particular “half” of the ring. This means that both routers will have “different” view on dynamic IGMP state.

**Figure 121 MC Services on a Layer 3-Ring Topology (b)**

OSSG254

In principle, MCS could be used to synchronize both routers, but in case of a Layer 2 ring, the implementation sends all IGMP messages to a “ring-master: which then performs IGMP processing and consequently, MCS sync. As a result, any race conditions are avoided.

Another ring-specific aspect is related to ring healing. The ring continuity check is driven by BFD which then drives SRRP and PIM messaging. BFD is optimized for fast detection of ring-down events while ring-up events are announced more slowly. There is a time window when routers are not aware that the ring is recovered. In the case of MC, this means traffic will be duplicated on the ring.

To avoid this, the implementation of BFD provides a “raw mode” which provides visibility on “ring-up” events. The protocols, such as SRRP and PIM, use this raw mode rather than the BFD API.

#### 9.4.20.8 Routed CO Dual Homing

Routed CO dual homing is a solution that allows seamless failover between nodes for all models of routed CO. In the dual homed environment, only one node will forward downstream traffic to a given subscriber at a time. Dual homing involves several components:

- Redundant Interface — This is used to shunt traffic to the active node for a given subscriber for downstream traffic.
- SRRP — This is used to monitor the state of connectivity to the DSLAM. Refer to the SRRP section for more detail.
- MCS — This is used to exchange subscriber host and SRRP information between the dual homed nodes.

Routed CO dual homing can be configured for both wholesaling models. Dual homing is configured by creating a redundant interface that is associated with the protected group interfaces. The failure detection mechanism can be VRRP. If VRRP is used, each node monitors the VRRP state to determine the priority of its own interface.

Dual homing is used to aggregate a large number of subscribers in order to support a redundancy mechanism that will allow a seamless failover between nodes. Because of the Layer 3 nature of the model, forwarding is performed for the full subscriber subnet.

#### 9.4.20.8.1 Redundant Interfaces

In dual homing, a redundant interface must be created. A redundant interface is a Layer 3 spoke SDP-based interface that allows delivery of packets between the two nodes. The redundant interface is required to allow a node with a failed link to deliver packets destined to subscribers behind that link to the redundant node. Since subscriber subnets can span multiple ports it is not possible to stop advertising the subnet, thus, without this interface the node would black hole.

The redundant interface is associated with one or more group interfaces. An interface in backup state will use the redundant interface to send traffic to the active interface (in the active node). The SAP structure under the group interface must be the same on both nodes as the synchronization of subscriber information is enabled on a group interface basis. Traffic can be forwarded through the redundant interface during normal operation even when there are no failed paths. See [Figure 122](#).

#### 9.4.20.8.2 SRRP in Dual Homing

Subscriber Router Redundancy Protocol (SRRP) allows two separate connections to a DSLAM to operate in an active/standby fashion similar to how VRRP interfaces operate. Since the SRRP state is associated with the group-interface, multiple group-interfaces may be created for a given port such that some of the SAPs will be active in one node and others active on the other node. While each SRRP pair is still allowed to be active/backup, the described configuration is allowed for load balancing between the nodes. Note that in a failure scenario subscriber bandwidth will be affected. For more information about SRRP, refer to [Subscriber Routed Redundancy Protocol \(SRRP\)](#).

If SRRP is configured before the redundant interface is up, and in backup state the router will forward packets to the access node via the backup interface but will not use the gateway MAC address. This applies to failures in the redundant interface as well. If the redundant interface exists and up the router will send downstream packets to the redundant interface and will not use the backup group interface.

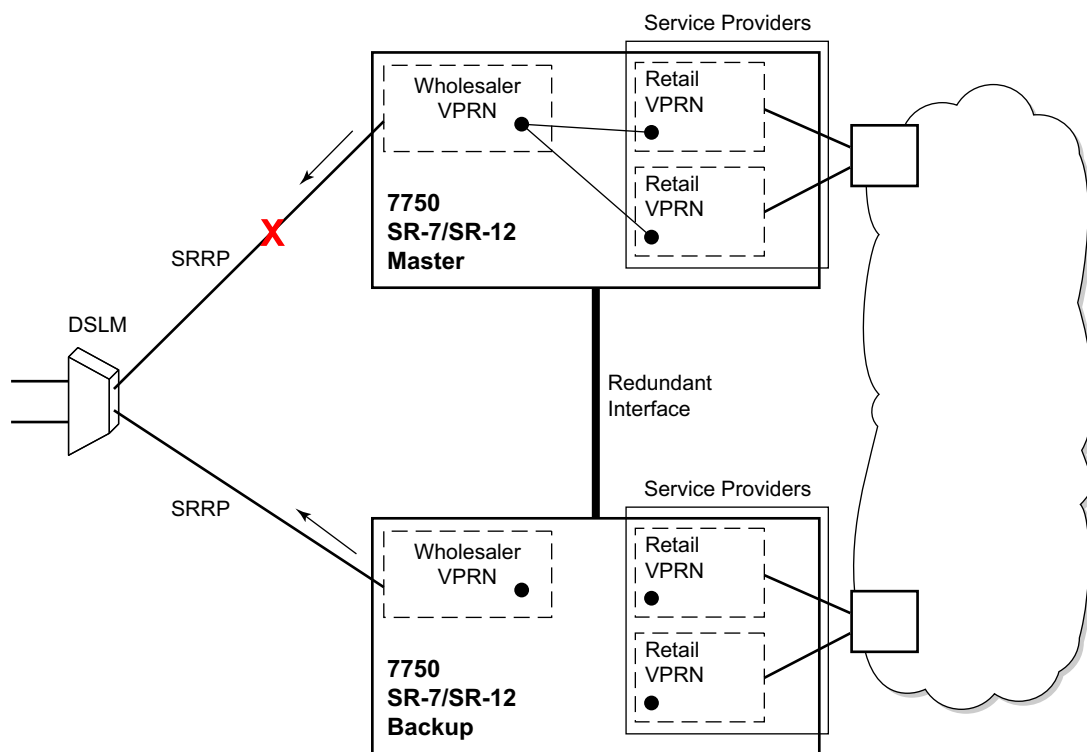

In a dual homing architecture the nodes must be configured with SRRP to support redundant paths to the access node. The nodes must also be configured to synchronize subscriber data and IGMP state. To facilitate data forwarding between the nodes in case some of the ports in a given subscriber subnet are affected a redundant interface must be created and configured with a spoke. The redundant interface is associated with one or more group interfaces.

The service IDs for both the wholesale VPRN and the retailer VPRN must be the same in both nodes.

An interface in backup state will use the redundant interface to send traffic to the active interface (in the active node). The SAP structure under the group interface must be the same on both nodes as the synchronization of subscriber information is enabled on a group interface basis.

SRRP is associated a group-interface. Multiple group-interfaces can be created for a given port such that some of the SAPs will be active in one node and others active on the other node. While every SRRP pair is still allowed to be active/backup the described configuration will allow for load balancing between the nodes. Note that in a failure scenario subscriber bandwidth will be affected.

**Figure 122 Dual Homing Example**

OSSG127

#### 9.4.20.8.3 Synchronization

To establish subscriber state the nodes must synchronize subscriber information. Refer to the Basic Configuration Guide for multi-chassis synchronization configuration information. The operator must complete the configuration and the system must have data synchronized before the backup node may deliver downstream packets to the subscriber.

If dual homing is used with regular interfaces that run IGMP the nodes must be configured to synchronize the Layer 3 IGMP state.

The service IDs for both the wholesale VPRN and the retailer VPRN must be the same in both nodes.

#### 9.4.20.8.4 Wholesale-Retail Multi-Chassis Redundancy

Multi-Chassis Redundancy for a retail service is enabled with the SRRP and redundant interface configuration on the wholesale group-interface parented by the forwarding subscriber interface. The Multi-Chassis state (active or standby) of the retail subscriber host is determined from the SRRP state (master / non-master) of the group-interface that parents the SAP of the retail subscriber host. The retail service id must be equal on both nodes.

Sample wholesale service configuration:

```
vprn 3000 customer 1 create
 description "Wholesale service"
 route-distinguisher 64500:3000
 auto-bind mpls
 vrf-target import target:64500:3000
 redundant-interface "red-int-1" create
 address 192.168.100.0/31
 ip-mtu 1500
 spoke-sdp 12:3000 create
 no shutdown
 exit
 exit
 subscriber-interface "sub-int-1" create
 address 10.1.1.253/24 gw-ip-address 10.1.1.254
 address 10.1.2.253/24 gw-ip-address 10.1.2.254
 group-interface "group-int-1-1" create
 dhcp
 --- snip ---
 exit
 redundant-interface "red-int-1"
 sap 1/1/6:1.4001 create
 description "SRRP 1 message path"
 exit
 srrp 1 create
 message-path 1/1/6:1.4001
 send-fib-population-packets outer-tag-only
 no shutdown
 exit
 pppoe
 --- snip ---
 exit
 exit
 group-interface "group-int-1-2" create
 dhcp
 --- snip ---
 exit
```

```

 redundant-interface "red-int-1"
 sap 1/1/6:2.4001 create
 description "SRRP 2 message path"
 exit
 srrp 2 create
 message-path 1/1/6:2.4001
 priority 50
 send-fib-population-packets outer-tag-only
 no shutdown
 exit
 pppoe
 --- snip ---
 exit
 exit
exit
no shutdown
exit

```

### Sample retail service configuration:

```

vprn 3001 customer 1 create
 description "Retail service"
 route-distinguisher 64500:3001
 auto-bind mpls
 vrf-target target:64500:3001
 subscriber-interface "sub-int-rt-3000-1" fwd-service 3000 fwd-
subscriber-
interface "sub-int-1" create
 address 10.1.11.253/24 gw-ip-address 10.1.11.254
 address 10.1.12.253/24 gw-ip-address 10.1.12.254
 dhcp
 --- snip ---
 exit
 pppoe
 --- snip ---
 exit
exit
no shutdown
exit

```

Overlapping addresses in retail subscriber interfaces (enabled with **private-retail-subnets**) cannot be used in combination with multi-chassis redundancy. This is because retail subscriber subnets and prefixes leaked in the wholesale service are needed to forward downstream shunted traffic over the redundant interface. For the same reason, retail unnumbered host routes must be leaked in the wholesale service:

- The address of an IPv4 unnumbered subscriber host (enabled with **unnumbered** *ip-int-name* | *ip-address* or **allow-unmatching-subnets** on the retail subscriber interface) is not contained in the subnets configured on the retail subscriber interface. The export of the IPv4 retail subscriber host routes to the wholesale service must be explicitly enabled with the **export-host-routes** command:

```
vprn 3001 customer 1 create
 subscriber-interface "sub-int-rt-3000-1" fwd-service 3000 fwd-
subscriber-
interface "sub-int-1" create
 allow-unmatching-subnets
 address 10.1.11.253/24 gw-ip-address 10.1.11.254
 address 10.1.12.253/24 gw-ip-address 10.1.12.254
 export-host-routes
 --- snip ---
```

- The address of an IPv6 unnumbered subscriber host (enabled with **ipv6 allow-unmatching-prefixes** on the retail subscriber interface) is not contained in the IPv6 prefixes configured on the retail subscriber interface. IPv6 retail subscriber host routes are automatically exported to the wholesale service.

Downstream traffic arriving on an SRRP non-master node must be shunted over the redundant interface. Downstream traffic shunting can be reduced by advertising the retail subscriber subnets and prefixes from the master SRRP node with a more favorable metric using routing policies. To make retail subscriber subnets and prefixes SRRP state-aware, they have to be configured to track an SRRP instance that is active on a group interface of the connected wholesale subscriber interface:

```
vprn 3001 customer 1 create
 subscriber-interface "sub-int-rt-3000-1" fwd-service 3000 fwd-
subscriber-
interface "sub-int-1" create
 address 10.1.11.253/24 gw-ip-address 10.1.11.254 track-srrp 1
 address 10.1.12.253/24 gw-ip-address 10.1.12.254 track-srrp 2
 ---snip---
 ipv6
 subscriber-prefixes
 prefix 2001:db8:d001::/48 pd track-srrp 1
 prefix 2001:db8:d002::/48 pd track-srrp 2
 prefix 2001:db8:1:100::/56 wan-host track-srrp 1
 prefix 2001:db8:1:200::/56 wan-host track-srrp 2
 exit
 exit
```

Multi-Chassis Redundancy is supported for IPoE (IPv4 and IPv6) and PPPoE (IPv4 and IPv6) retail subscriber hosts and sessions.

---

### 9.4.20.9 SRRP and Multi-Chassis Synchronization

In order to take full advantage of SRRP resiliency and diagnostic capabilities, the SRRP instance will be tied to a MCS peering that terminates on the redundant node. Once the peering is associated with the SRRP instance, MCS will synchronize the local information about the SRRP instance with the neighbor router. MCS automatically derives the MCS key for the SRRP instance based on the SRRP instance ID. An SRRP instance ID of 1 would appear in the MCS peering database with a MCS-key srrp-0000000001.

The SRRP instance information stored and sent to the neighbor router consists of:

- The SRRP instance MCS key
- Containing service type and ID
- Containing subscriber IP interface name
- Subscriber subnet information
- Containing group IP interface information
- The SRRP group IP interface redundant IP interface name, IP address and mask
- The SRRP advertisement message SAP
- The local system IP address (SRRP advertisement message source IP address)
- The group IP interface MAC address
- The SRRP gateway MAC address
- The SRRP instance administration state (up/down)
- The SRRP instance operational state (disabled/becoming-backup/backup/becoming-master/ master)
- The current SRRP priority
- Remote redundant IP interface availability (available/unavailable)
- Local receive SRRP advertisement SAP availability (available/unavailable)

### 9.4.20.10 Dual Homing and ANCP

The routers provide a feature related to exchange of control information between DSLAM and BRAS (BSA is described in this model). This exchange of information is implemented by in-band control connection between DSLAM and BSA, also referred to as ANCP connection.

In case of dual homing, two separate connections will be set. As a consequence, there is no need to provide synchronization of ANCP state. Instead every node of the redundant-pair obtains this information from the DSLAM and creates corresponding an ANCP state independently.

## 9.4.21 SRRP Enhancement

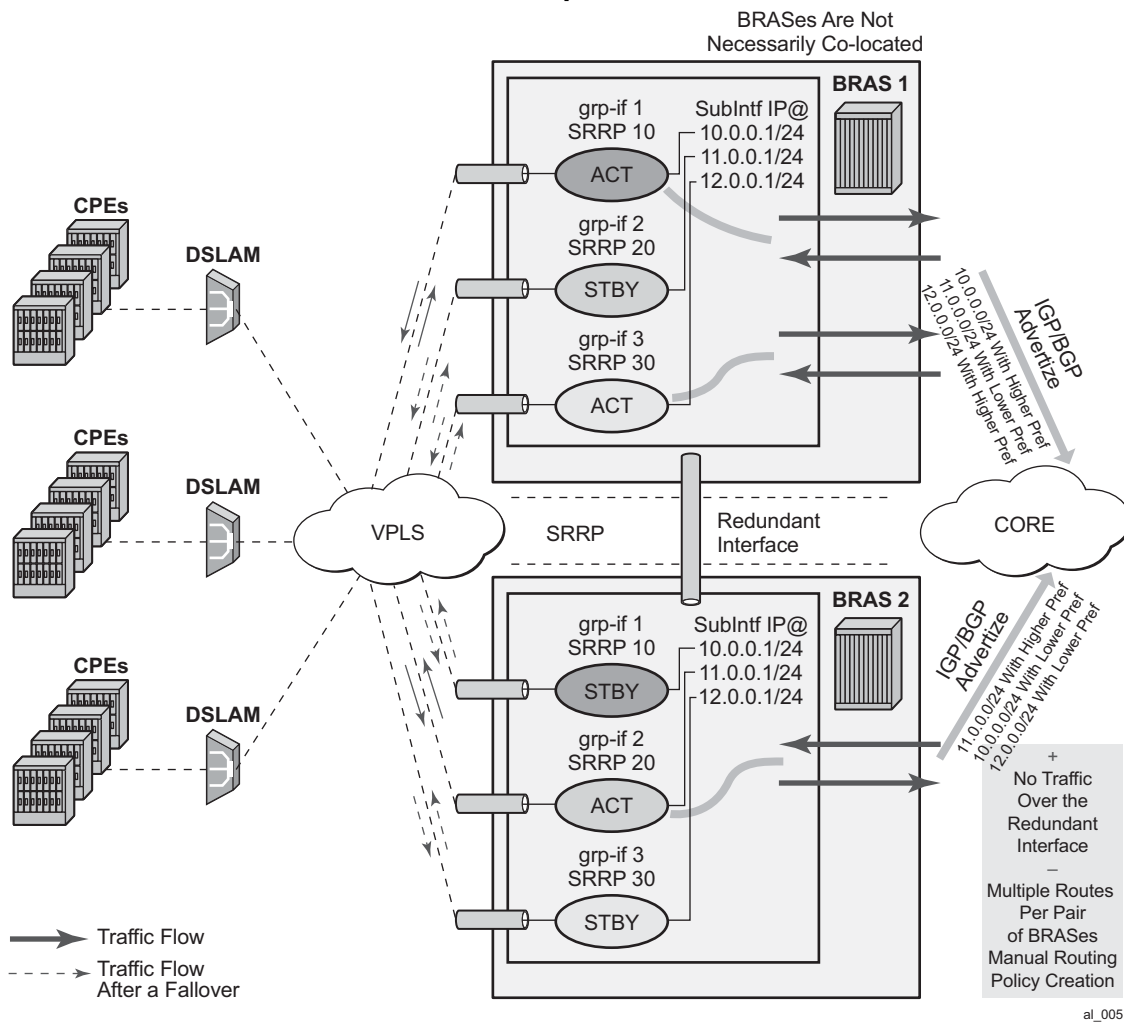

The SRRP enhancements addressed in this section is to reduce the need for redundant-interface between the pair of redundant nodes without sacrificing the subnet aggregation on the back-end.

Redundant BNG nodes are not always colocated. This means that the logical link associated with the redundant (shunt) interfaces is taking the uplink path thus wasting valuable bandwidth (downstream traffic that arrives to the Standby node is routed via uplinks for the second time over to the Master node).

To meet the requirement to reduce the existence of shunted traffic only to the short transitioning period between SRRP switchovers while the routing on the network side is converging, the following was required (referring to [Figure 123](#)):

1. Share IP subnets over multiple SRRP instances. This is not mandatory, but it would helps to load balance traffic over the two nodes. For example, IP subnets 10 and 11 can be shared over SRRP instances 10 and 20 on node 1, and the IP subnet 12 can be associated with the SRRP instance 30 on node 2.
2. *SRRP aware routing* – this allows to dynamically increase routing metric on the IP subnets advertised from the Master SRRP node in comparison to the Standby SRRP node. It also allows to advertise/withdraw routes from a routing protocol based on the SRRP state. In this fashion, downstream traffic is routed in a predictable manner towards the Master SRRP node.
3. *SRRP Fate Sharing* for SRRP instances 10 and 11. This ensures congruency of SRRP states on the same node. This is a necessary step towards *SRRP aware routing*.

**Figure 123 IP Subnet Per SRRP Master Group**

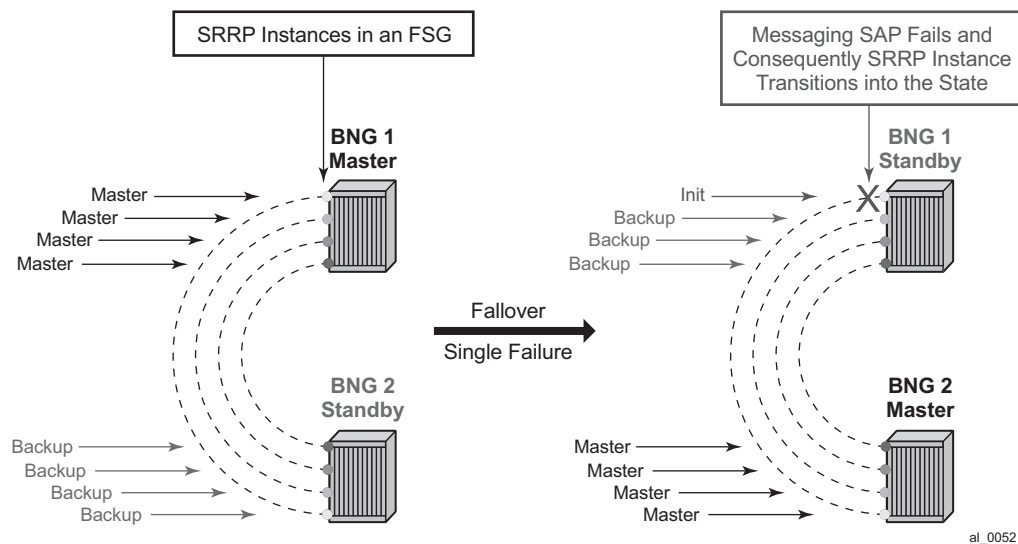

### 9.4.21.1 SRRP Fate Sharing

SRRP Fate Sharing is a concept in which a group of SRRP instances track a single operational-object comprised of SRRP messaging SAPs. The SRRP instances behave as one (in the single failure case) with regards to SRRP mastership. The group of SRRP instances that are sharing fate on a paired node are referred as a Fate Sharing Group (FSG).

Transition of a single messaging SAP within the FSG into a DOWN state forces the SRRP instance on top of it into the INIT state. Consequently, all other SRRP instances within the same FSG transitions into a Backup state. In other words, SRRP instances within the FSG all share the same fate as the failed SRRP instance as shown in [Figure 124](#). SRRP Fate Sharing provides optimal protection in the context of a single failure in the network.

**Figure 124 FSG — Single Network Failure**

In the case of multiple network failures, the concept of the FSG breaks as there is a possibility that a 'FSG' contains SRRP instances that are in any of the three possible SRRP states: Master, Backup, or Init. This Fate Sharing feature may not provide optimal protection when there are multiple network failures distributed over both redundant nodes.

**Figure 125 Multiple Network Failures**

The whereabouts of the failure in the network path that SRRP is designed to monitor are not always clearly reflected through SRRP states. For example, if the network failure is somewhere in the aggregation network beyond the direct reach of our BNG, SRRP assumes Mastership on both BNG nodes. This is a faulty condition and the reason why solely monitoring of the SRRP states is not enough to protect against failures. On the other hand, the SRRP messaging SAP states are more indicative of the network failure since they can be tied into Eth-OAM.

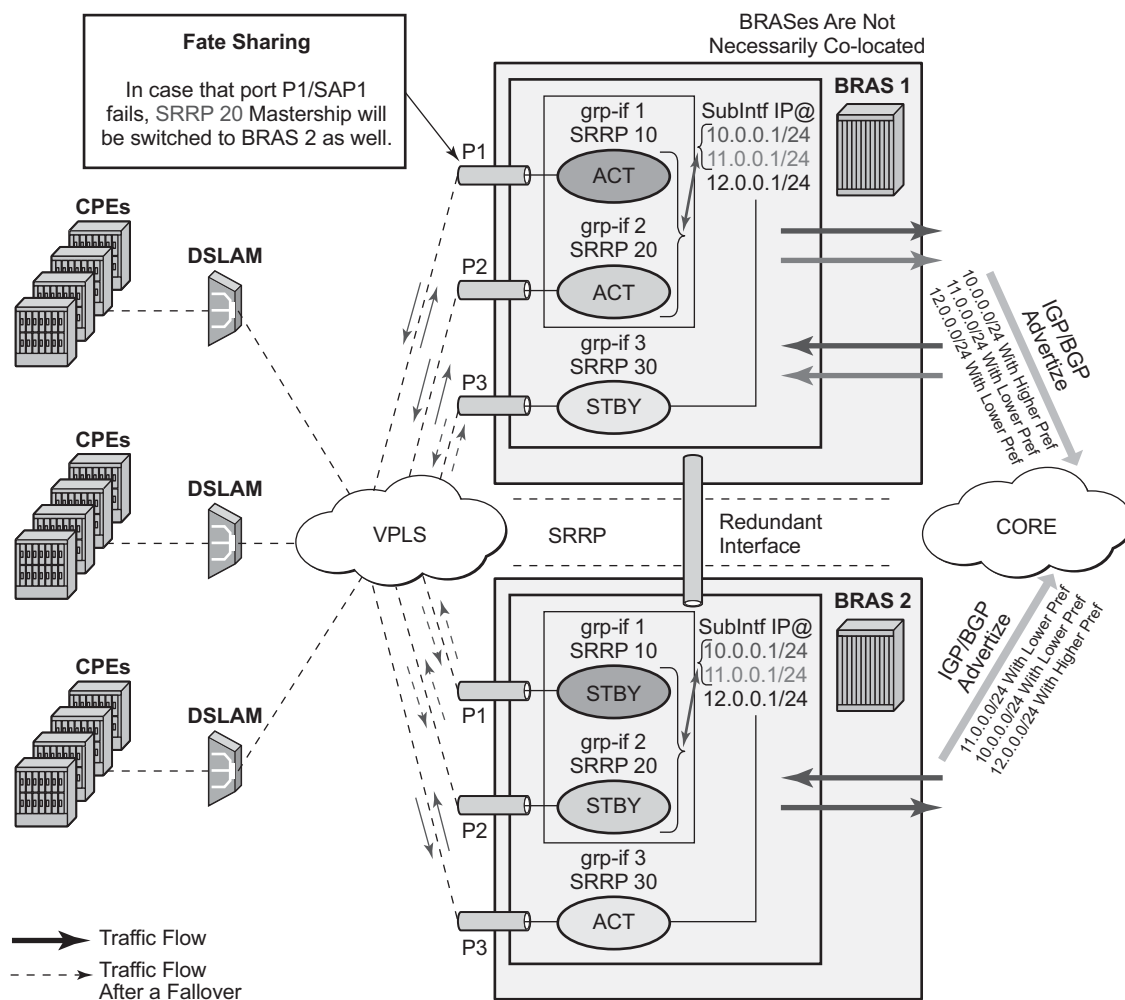

Once a single network failure is detected and as a result an SRRP instance transitions into a non-Master state, the remaining SRRP instances in the FSG are forced into a Backup state. This is achieved by changing the priority of each individual SRRP instance in the FSG.

In the case of simultaneous multiple failures (multiple ports fail at the same time), it is possible that the SRRP instances within the FSG settle in any of the three possible SRRP states: Master, Backup, or Init. In such scenario shunted traffic will ensue.

In the premise of SRRP Fate Sharing, the network failure will be reflected in the operational state of the messaging SAP over which SRRP runs. This will certainly be the case if the failure is localized to the BNG (somewhere on the directly connected link). In the case of non-localized failure (beyond the direct reach of the BNG node), Eth-OAM might be needed in to detect the remote end failure and consequently bring the SAP operationally into a DOWN state.

Once the single network failure is detected, all instance within the FSG transitions into a non-Master state.

If there are no failures in the network, all SAPs are UP and SRRP instances within the FSG are in a homogeneous and deterministic state based on their configured priorities.

**Figure 126 SRRP Fate Sharing**

al\_0054

**Failure Detection in a Fate Sharing Group**

1. Dual homing over directly connected ports.  
No Eth-OAM is needed, AN is directly connected to the BNG.

**Figure 127 Scenario 1**

2. Dual homing with aggregation network - aggregation network has no redundancy between Layer 2 switches (STP). To determine whereabouts of failure at point 1 in the figure below, Eth-OAM is needed.

**Figure 128 Scenario 2**

3. Dual homing with aggregation network - aggregation network with redundancy between Layer 2 switches (STP).  
No Eth-OAM is needed in this case for successful operation. However, the failure detection is based on the failure of the directly attached ports.

Figure 129 Scenario 3

4. Single homing with aggregation network.  
In this case, SRRP can protect only against direct failures. Any remote failure leaves a part of the network isolated from the subscriber point of view.

Figure 130 Scenario 4

### 9.4.21.2 Fate Sharing Algorithm

Fate Sharing Algorithm (FSG) is relying on tracking the state of messaging SAPs over which SRRP instances run. An SRRP instance with the messaging SAP operationally DOWN will transition into the Init state.

The transitioning of any messaging SAP in a FSG into an UP/DOWN state will trigger SRRP priority adjustment within the FSG. The SRRP priorities should be chosen carefully to achieve the desired behavior. They are modified dynamically as the SAP states change. The range in which SRRP priorities can be modified is from 1 to the SRRP priority that is initially configured under the SRRP node. Here are some general guidelines for choosing SRRP priorities in a FSG:

- Initially configured SRRP priorities for all SRRP instance within the FSG within the node should be the same.
- Initially configured SRRP priorities should be different between pairing FSGs. For example, SRRP instances in the BNG node A within an FSG will all have the same SRRP priority 'X', while corresponding SRRP instances on the paired node within corresponding FSG will all have SRRP priority 'Y'. This ensures that SRRP mastership is clearly defined between the two BNG nodes. Note that this step is not mandatory as SRRP will naturally break the Mastership tie in the case that all SRRP priorities are the same. However, following this step may provide a clearer view from an operational perspective.
- The priority-step used for dynamic SRRP priority adjustment must be greater than the difference in initially configured SRRP priorities between two BNG nodes. This ensures that a single failure event triggers the SRRP switchover. Otherwise, if the dynamically lowered SRRP priority is still greater than the one from the SRRP peer, the switchover would not be triggered. Therefore, the fate sharing concept would not function as intended.
- Initially configured SRRP priority of each SRRP instance should be greater than the (anticipated) number of SRRP instances in a FSG multiplied by the SRRP priority-step. This ensures that the dynamically priority never tries to go below 1. There is a code check that prevents SRRP priority going below 1. Nonetheless, it is recommended not to get into a situation where this needs to be enforced in the code.

**Note:** The priorities will never be less than 1 or greater than initially configured SRRP priority.

Example scenarios:

Assume 3 SRRP instances in a FSG. The SRRP instances in the FSG-1 on BNG 1 have the priority of 100, while the SRRP instances in the FSG-2 on BNG 2 have the priority of 95. The priority-step is 6. The SRRP instances and underlying messaging SAPs will be referred as SRRP 1, 2, 3 and SAP 1,2,3, respectively.

#### Initialization:

Scenario 1 – all SAPs are operationally UP.

BNG 1 boots up and all messaging SAPs transition into the UP state. When the first SRRP instance in FSG-1 comes up, it looks under the FSG to find out how many messaging SAPs are operationally UP. Since all messaging SAPs are operationally UP, this first SRRP instance assumes its initially configured priority of 100. The other two SRRP instances in the same FSG follow the same sequence of events.

BNG 2 follows the same flow of events. As a result, BNG 2 assumes mastership over BNG 1 for all SRRP instances within the corresponding FSG.

Scenario 2 – messaging SAP 1 is operationally DOWN on BNG 1, the rest of the messaging SAPs are operationally UP.

SRRP 2 and 3, during the initialization, pick up SRRP priority of 94 ( $100 - 1 \times \text{priority-step}$ ).

On BNG 2, all messaging SAPs are UP and consequently all SRRP instances within the FSG on BNG 2 have SRRP priority of 95. The SRRP instances on BNG 2 assume Mastership.

Scenario 3 – Continuing from scenario 2, the SAP 1 on BNG 1 transitions into the UP state. SRRP priority of each SRRP instance in FSG-1 is increased by 6, bringing it to 100, enough to assume Mastership.

#### Adding a New Instance into an FSG

To introduce minimal network disruption, first create messaging SAPs in both BNG nodes and ensure that both SAPs are operationally UP. Then a new SRRP 4 instance should be created on both BNG nodes. The next step would be to include this new messaging SAP into a SAP monitoring group. And finally, the SRRP-4 is added into the FSG (1 and 2). This triggers the recalculation of SRRP priorities for the existing FSG-1 and FSG-2. Since all SRRP priorities are at the max (initially configured priority), nothing changes.

There are more disruptive ways of adding an SRRP instance into a FSG. One such example would be in the case where SRRP priorities are not at their maximum (initially configured) priority. If an SRRP instance is first added into an FSG that is in a 'Backup' state, this would increase the FSG priority and potentially cause a switchover. If the SRRP instance is then added in a FSG on the peer BNG (previously Master), the priority of this FSG would be increased again and the switchover would unnecessarily occur for the second time. The new SRRP instances, once operational, should always be added in the Master FSG first.

SRRP priority re-calculation within the FSG is triggered by the following events:

- SRRP initialization
- addition of a SAP under the monitoring group
- messaging SAP failure

This priority calculation looks into how many SAPs are in the DOWN state within the monitored SAP group. Based on this number, the priority is calculated as follows:

$\text{SRRP priority} = \text{configured-priority} - \text{priority-step} * \text{num\_down\_SAPs}$ .

### 9.4.21.3 SRRP Aware Routing - IPv4/IPv6 Route Advertisement Based on SRRP State

There are three cases that need to be covered, each case with its own specifics:

- Subscriber Interface Routes (IPv4/IPv6)
- Managed Routes
- Subscriber Management Routes (/32 IPv4 hosts routes and IPv6 PD wan-host routes)

Depending on the route type, the action is to either modify the route metric based on the SRRP state that the route is tracking, OR to advertise/withdraw the route based on the SRRP state that the route is tracking. The action is defined in the routing policy and it is based on the new attributes with which the routes are associated.

To achieve a better granularity of the routes that are advertised, an origin attribute is added to the subscriber management routes (/32 IPv4 routes and IPv6 PD wan-host) with three possible values:

**aaa**

IPv4

*subscriber-management* /32 host routes that are originated through RADIUS framed-ip-address VSA other than 255.255.255.254. The 255.255.255.254 returned by the RADIUS indicates that the BNG (NAS) should assign an IP address from its own pool.

IPv6

*subscriber-management* routes that are originated through framed-ipv6-prefix (SLAAC), delegated-ipv6-prefix (IA\_PD) or alc-ipv6-address (IA\_NA) RADIUS attributes. This is valid for IPoE and PPPoE type host.

**dhcp**

**IPv4**

*subscriber-management* /32 host routes that are originated via DHCP server (local or remote) and also RADIUS framed-ip-address=255.255.255.254 (RFC 2865).

**IPv6**

*subscriber-management* routes that are assigned via local DHCPv6 server pools whose name is obtained through Alc-Delegated-IPv6-Pool (PD pool) and Framed-IPv6-Pool (NA pool) RADIUS attributes. This is valid for IPoE and PPPoE type hosts.

In addition, for IPoEv6 only, the pool name can be also obtained via ipv6-delegated-prefix-pool (PD pool) and ipv6-wan-address-pool (NA pool) from LUDb.

**ludb****IPv4**

*subscriber-management* /32 host routes that are originated via LUDb. This also covers RADIUS fallback category (RADIUS falls back to system-defaults or to LUDb).

**IPv6**

*subscriber-management* routes obtained from LUDb via ipv6-address (IA\_NA) or ipv6-prefix (IA\_PD). This is supported only for IPoE.

Overall, the following new route attribute is added:

*state: srrp-master, srrp-non-master*

The existing origin attribute is expanded to contain the following values:

*origin: aaa, dhcp, ludb*

These two attribute types are applied in the following fashion:

The state attribute is applied to all three route types: *subscriber interface routes*, *managed routes* and *subscriber management routes*. Each route listens to the SRRP state.

If an attribute is defined in the routing policy as a match condition (from statement) but the route itself does not have this attribute, the route is evaluated into a non-match condition.

The origin attribute is always applied only to subscriber management routes. No additional statement is needed to explicitly apply this attribute as it may be the case for the state attribute.

Every time there is a change in the attribute associated with the route, the route is re-evaluated in the RTM by the routing policy and corresponding action is taken.

#### 9.4.21.3.1 Subscriber Interface Routes (IPv4 and IPv6)

Optimized routing and elimination of downstream shunt traffic during normal operation can be achieved by **statically** favoring the routes on the network side that are advertised with an increased metric by Master SRRP nodes.

The downside of this static approach is that during the port/card failure and consequently a SRRP switchover, the node with the failed port/card will continue to advertise routes with the same high metric as long as the subscriber interface is in the 'UP' state (or a single SAP under it). That is, the network side will not be aware of the switchover. It will continue to forward traffic to the standby node, and as a result, heavy shunt traffic will ensue. To effectively deal with this, the network side must be aware of the routing change that occurred in the access layer.

When failure is detected, the metric for the route is changed automatically based on the following configuration:

```
configure
 service <type> <id>
 subscriber-interface <intf-name>
 address <ip-address> gw-ip-address <gw-address> track-srrp <srrp-
inst> holdup-time <msec>
 ipv6
 subscriber-prefixes
 prefix <ipv6-prefix> pd track-srrp <srrp-id> holdup-time <msec>
 prefix <ipv6-prefix> wan-host track-srrp <srrp-id> holdup-
time <msec>

 policy-options
 begin
 policy-statement <name>
 entry 1
 from
 protocol direct
 state 'srrp-master'
 exit
 action accept
 metric set 100
 exit
 exit
 entry 2
 from
 protocol direct
 state 'srrp-non-master'
 exit
 action accept
 metric subtract 10
 exit
```

```
exit
entry 3
 from
 protocol direct
 exit
 action accept
 exit
exit
```

This configuration ensures that the route metric is changed for the subscriber interface routes based on the SRRP state while the other, non-subscriber directly attached routes are unaffected by SRRP.

The **Route Advertisement based on SRRP State** requirement is applicable to BGP (IPv4, IPv4-IPVPN) and IGP.

The routing policy also provides the flexibility to prevent route advertisement (*action reject*) instead of changing the route metric.

Although this feature is designed to minimize or eliminate the use of the redundant-interface, it is important to note that the redundant-interfaces would still be used in the case of transient conditions. An example of such condition would be:

1. Messaging SAP Fails
2. SRRP switches over
3. Stale routing in the core is still in the effect while the metric is being propagated (or the route is being advertised/withdrawn). During this time, traffic is flowing over the redundant interface.
4. Network convergence is complete
5. Traffic in the network core is redirected to the new Master SRRP node

#### 9.4.21.3.2 Managed Routes

Only the state attribute is applicable to managed routes, and only to the ones that are synchronized (static and RADIUS obtained – framed-route and framed-ipv6-route). The managed routes obtained via BGP are not synchronized and this feature is not applicable to them.

Based on the SRRP state, the managed route can be either advertised with a modified metric or be withdrawn altogether.

For example:

*Managed routes* that are tracking SRRP state are only advertised from the Master node and denied from Backup node. All other managed routes that are not tracking SRRP state are advertised regardless of the SRRP state.

```
policy-options
 begin
 policy-statement <name>
 entry 1
 from
 protocol managed
 state 'srrp-master'
 exit
 action accept
 exit
 exit
 entry 2
 from
 protocol managed
 state 'srrp-non-master'
 exit
 action reject
 exit
 exit
 entry 3
 from
 protocol managed
 exit
 action accept
 exit
 exit
 exit
```

#### 9.4.21.3.3 Subscriber Management Routes (/32 IPv4 Host Routes, IPv6 PD WAN-Host Routes)

Both attributes (state and origin) are applicable to the subscriber management routes.

For Example:

A Service Provider wants to advertise only subscriber-management routes with the origin DHCP and AAA from the Master node. Routes with the LUDB origin are not advertised. Standby node is not advertising any /32 subscriber management routes.

```
policy-options
 begin
 policy-statement <name>
 entry 1
 from
 origin dhcp
 origin aaa
 state 'srrp-master'
 exit
```

```

 action accept
 exit
 exit
exit

```

Default action is reject.

#### 9.4.21.3.4 Activating SRRP State Tracking

The SRRP state tracking by routes is turned on only when desired.

For subscriber-interface routes (IPv4 and IPv6), this is performed explicitly.

```

subscriber-interface <intf-name>
 address <ip-address> gw-ip-address <gw-address> track-srrp <inst-name> holdup-
time <msec>
 ipv6
 subscriber-prefixes
 prefix <ipv6-prefix> pd track-srrp <srrp-id> holdup-time <msec>
 prefix <ipv6-prefix> wan-host track-srrp <srrp-id> holdup-time <msec>

```

For managed and subscriber management routes, this is explicitly enabled under the group interface:

```

group-interface <name>
 srrp-enabled-routing holdup-time <msec>

```

#### 9.4.21.4 SRRP in Conjunction with a PW in ESM Environment – Use Case

In certain cases, subscriber traffic is terminated on the BNG via an Epipe. In this case, the subscriber traffic can be offloaded onto a plain Ethernet port via a VSM module (a 'loop') so that it can be terminated in ESM. Epipes can be configured in A/S configuration and terminated on two BNG nodes in multihomed environment.

In such multi-homed environment with Epipes and 'loops', the ESM itself would be detached from the Epipe, which brings the subscriber traffic to the BNG. Because of that, the ESM would not know if the PW's state is Active or Standby. As a result, in the downstream direction, traffic could end up being forwarded towards the Standby PW, effectively being black-holed.

To overcome this, SRRP can be used in conjunction with an additional mechanism to help monitor the activity of the PWs. This monitoring mechanism is very similar to Fate-sharing. The difference in this case is that the messaging SAP (instead of SRRP instance) is monitoring the activity of the PW. As a result, the SRRP messaging SAP reflects the state of the PW. For example, the PW in a Standby mode would cause the messaging SAP to be in the DOWN state while the PW Active state would cause the messaging SAP to be in the UP state. That is, the SRRP instance reflects the operational state of the messaging SAP. SRRP is indirectly tied into PW state.

Modifying the priority of SRRP instance based on PW's state as a mean of mapping the Master SRRP into the Active PW would not help here as SRRP messages are not flowing over standby PWs. This is why SRRP state must be enforced via the messaging SAP.

Fate-sharing for PW termination in conjunction with SRRP is not supported.

Metric adjustment for the subscriber routes is supported. Once the tracked SRRP instance transitions into a non-Master state, the state attribute of the route changes and the appropriate action defined in the routing-policy is taken.

#### 9.4.21.5 Group Monitor

The failure detection mechanism to trigger an action within FSG relies on the operational state of the messaging SAP. Such failure detection mechanism is referred as a group monitor.

Group monitor can also be used to detect the state change of the PW. PW state change is reflected in the messaging SAP which in turn triggers the state change of an SRRP instance.

All this is implemented through an oper-group object which is described in the Services Guide. All entities that needs to be monitored (messaging SAPs and PWs) are associated with this oper-group object. Finally, an SRRP instance (in case of FSG) or a messaging SAP (in case of PW) is instructed to monitor the entities in the oper-group object. State transitions of objects in a oper-group object trigger state transitions of entities that are monitoring them (messaging SAPs and SRRP instances). State transitions of monitored objects in a oper-group will cause the following actions:

- In the case of an FSG, priorities of SRRP instances are recalculated
- In the case of PW termination on BNG, the operational state of the messaging SAP is changed.

This is an overview of the CLI syntax showing the principles of how should this work (for exact description of commands and full syntax, please see the command reference):

```
config>service
 oper-group <name> //oper-group creation

config>service(IES | VPRN)>sub-if>grp-if>sap
 oper-group <name> //adds the SAP to the oper-group
 monitor-oper-group <name> // links the status of the oper-
group to the SAP. In this fashion a messaging SAP can monitor the state of a PW.

config>service(IES | VPRN)>sub-if>grp-if>srrp x
 monitor-oper-group <name> priority-step [0-253] //
with this, a state transition of the objects in the oper-
group should trigger SRRP priority recalculation. The state of the oper-
group is not important but in the state of the objects within. If an object within t
he oper-group goes down, the SRRP priority is lowered by a priority-
step. The SRRP priority will be adjusted on every state transition of member objects
.

config>service>epipe>spoke-sdp
 oper-group <name> // this will add a PW to the oper-
group. A messaging SAP monitors
this PW and it assumes the state according to the state of the PW in the oper-
group.
A standby or a DOWN PW state causes the messaging SAP to assume a DOWN state. Otherw
ise
the messaging SAP would be in the UP state. In order for the SAP to assume the DOWN
state, both RX and TX side of the PW must be shut. In other words, a PW in standby
mode also must have the local TX disabled by the virtue of the 'slave' flag (standby
-
signaling-slave command under the spoke-
sdp hierarchy). Without the TX disabled, the
SAP monitoring the PW would not transition in the down state.
```

A hold timer is provided within the **oper-group** command to suppress flapping of the monitored object (SAP or pseudowire).

Example with ESM over pseudowire through a VSM 'loop'.

## 9.4.22 Subscriber Override

This feature provides the ability to override queue and policer parameters (CIR, PIR, CBS, MBS) as well as HQoS parameters (egress aggregate-rate and root-arbiter rate) configured at sla-profile and sub-profile level in order to provide per-subscriber-(host) customizations. The goal is to avoid an explosion of the sub-profiles and sla-profiles to cover all service level combinations. This customization of QoS related parameters can in principle occur during authentication (auth-response message) or during sub-host life time by RADIUS CoA messages.

The QoS parameter customizations are communicated by RADIUS server in form of RADIUS VSAs which can be included in RADIUS-authentication response message or in CoA message.

The Alc-Subscriber-QoS-Override VSA (126) is a string with following layout “direction:type:[key:]values” where:

- Object-type:

- **direction** represents single character indicating **i** for ingress and **e** for egress.
- **type** represents single character indicating **q** for queue, **p** for policer, **r** for aggregate-rate and **a** for arbiter.
- **key** is indicated the queue or policer-id. It is not used in case of aggregate-rate and root-arbiter.
- **values** indicates actual values preceded with keywords used in CLI (e.g., `cir`).

Aspects, such as parent, priority level, stats- mode are not accessible through this customization. Instead, a new policy should be created on the node.

The key identifying the subscriber-host in the RADIUS CoA message is accounting-session-id This is different in previous releases, where the *service-id* and *ip-address* are mandatory fields in RADIUS CoA message.

The operational value of the QoS objects (queues or schedulers) are derived from different inputs. As in queue/policer parameters, the following hierarchy of inputs are respected (highest priority is the first):

- On-line charging overrides
- RADIUS response/CoA overrides
- Queue overrides configured at sla-profile level
- Queue parameters set in QoS policy level

In the case of scheduler/arbiter-overrides, the following hierarchy of inputs apply:

- ANCP overrides
- RADIUS response overrides
- Scheduler/arbiter parameters as configured in scheduling/policer-control-policy.

The above rules are generic. If any given override mechanism is not yet applicable to policers (or arbiters) it will be skipped. The above rules indicate the priority if all mechanisms are supported.

The QoS overrides received in RADIUS message (in the form of a VSA) are per definition related to a given subscriber-host the given message is referring to. Internally, the overrides are applied on per SLA instance level (queue/policer-overrides) and per-subscriber-level (scheduler/arbiter overrides). The subscriber-overrides are applicable to PPPoE hosts only.

In a dual-homing environment, the adapted values are synchronized through MCS, but they do not need to be persistent.

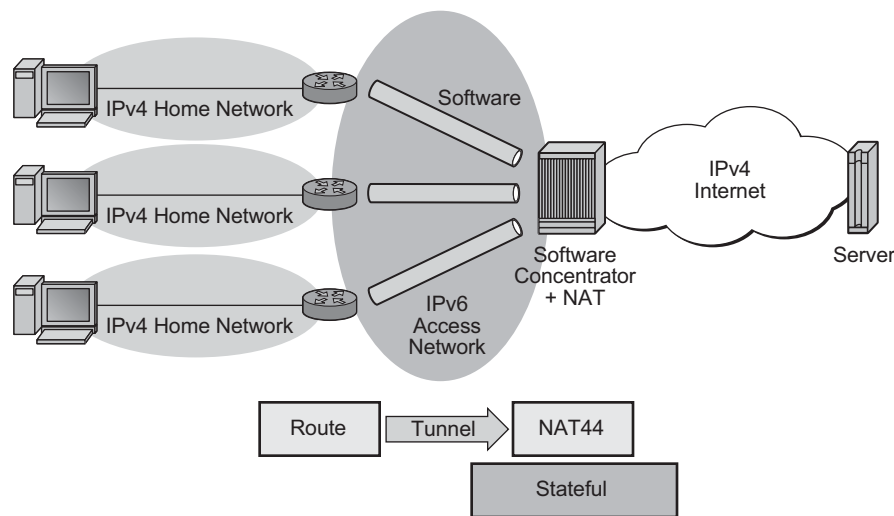

### 9.4.23 Dual Stack Lite

Dual Stack Lite feature is supported on the 7710 SR-Series in combination with the MS-ISA to function as a DS-Lite Address Family Transition Router (AFTR).

Dual Stack Lite is an IPv6 transition technique that allows tunneling of IPv4 traffic across an IPv6-only network. Dual-stack IPv6 transition strategies allow service providers to offer IPv4 and IPv6 services and save on OPEX by allowing the use of a single IPv6 access network instead of running concurrent IPv6 and IPv4 access networks. Dual-Stack Lite has two components: the client in the customer network, known as the Basic Bridging BroadBand element (B4) and an Address Family Transition Router (AFTR) deployed in the service provider network.

Dual-Stack Lite leverages a network address and port translation (NAPT) function in the service-provider AFTR element to translate traffic tunneled from the private addresses in the home network into public addresses maintained by the service provider. On the 7750 SR, this is facilitated through the Carrier Grade NAT function.

**Figure 132 Dual-Stack Lite**

al\_0060

As shown in [Figure 132](#), Dual-Stack Lite has two components, a software initiator in the RG and a software concentrator, deployed in the service provider network, where control-less IP-in-IP (using protocol 4 - IPv4 in IPv6) is used for tunneling. When using control-less protocol, packets are sent on the wire for the remote software endpoint without prior setup of a tunnel.

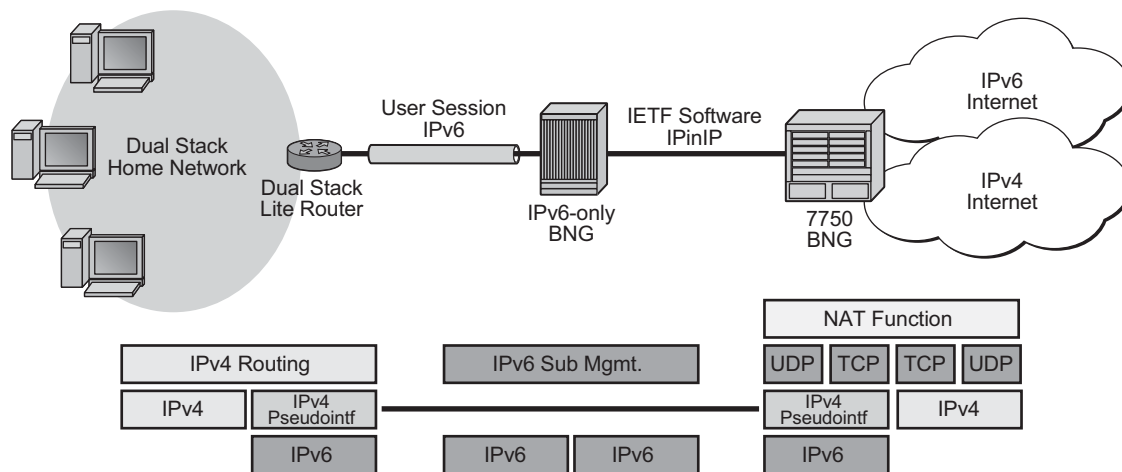

The software initiator in the home network is combined with a routing function, where the default route is passed to the software pseudo-interface. Note that there is no NAT function, therefore, the private IP addresses of the home network are encapsulated without source address modification, and forwarded to the software concentrator where all NAT is performed. The software pseudo-interface unicasts all IPv4 traffic to the IPv6 address of the software concentrator, which was pre-configured.

When encapsulated traffic reaches the software concentrator, the device treats the source-IP of the tunnel to represent a unique subscriber. The software concentrator performs IPv4 network address and port translation on the embedded packet by re-using Large Scale NAT and L2-Aware NAT concepts.

### 9.4.23.1 IP-in-IP

As shown in [Figure 133](#), IP-in-IP uses IP protocol 4 (IPv4) to encapsulate IPv4 traffic from the home network across an IPv6 access network. The IPv4 traffic tunneling is treated as best-effort with no subscriber management or policy, and does not use ESM. The scale is dependent only on the internal structures of the MS-ISA and CPM, that is, the IP-in-IP model can support more subscribers than an ESM-based approach.

**Figure 133 IP-in-IP**

al\_0061

Dual-Stack Lite IP-in-IP is configured through the existing **nat** command that is inside the CLI statements that are within the base router or VPRN. A service performing large scale NAT supports Dual-Stack Lite.

Dual-Stack Lite expects a routing (non-NATing) gateway in the home, where many different IPv4 inside addresses exist for each subscriber. These inside addresses may overlap other subscriber's address, especially given the heavy use of RFC 1918 address space.

The lack of control of protocol for the IP-in-IP tunnels simplifies the functional model, since any received IPv4 packet to the ISA dual-stack-lite address can simply be:

- Checked for protocol 4 in the IPv6 header.
- Checked that the embedded IP packet is IPv4.
- Processed as if it were L2-Aware, where the source-IP of the tunnel (the source IPv6 address) is used as the subscriber identifier.

Note that the inside IP address in the NAT, tables must not be the IPv6 address of the tunnel, but the true IPv4 address of any host within the home. The subscriber-id must be the literal IPv6 address (appreciating this may be 34 characters in length).

### 9.4.23.2 Configuring Dual Stack Lite

Dual Stack Lite is configured on an inside service and uses the existing Large Scale NAT nat-policies and outside pools. Dual-Stack Lite and NAT44 Large Scale NAT can operate concurrently on the same inside and outside services.

Dual Stack Lite is configured using the following CLI:

```
configure {router | service vprn service-id}
- [no] nat
- inside
- [no] dual-stack-lite
- [no] *address ipv6-address
```

### 9.4.23.3 L2TP over IPv6

In this mode, L2TP provides the transport for IPv4 that allows full ESM capabilities on the 7750 SR. From the node's perspective, the L2TP tunnel is no different in capability to those already supported. Only the underlying transport (IPv6 instead of IPv4) distinguishes this approach.

To support legacy IPv4 access, L2TP over IPv6 is combined with the existing L2-Aware NAT feature as shown in [Figure 134](#).

As ESM is used, scale is limited by the number of ESM hosts supported on a chassis and any associated resources like queues.

**Figure 134 L2TP over IPv6**

L2TP LNS over IPv6 is supported in both the base routing instance and VPRN that has 6VPE configured.

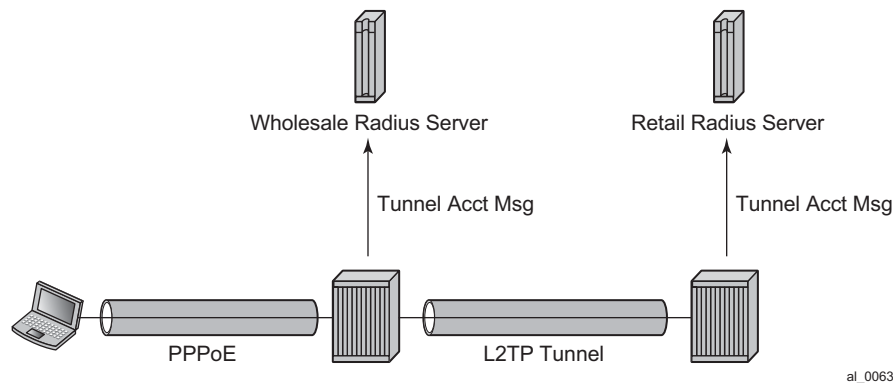

Like the SR-OS 8.0 LNS implementation, tunnels are terminated on any routing interface, including loopback, SAP, or network port. A single interface simultaneously supports IPv4 and IPv6 L2TP tunnel termination by having two different addresses configured.

For greater scalability, L2TP tunnel and session count per chassis are increased to allow 1 tunnel per session.

NAT capabilities are supported via existing L2-Aware NAT methods. Note that the L2TP LNS over IPv6 may be used without NAT as well and the L2TP sessions may be either IPv6-only or dual-stack.

## 9.5 L2TP Tunnel RADIUS Accounting

**Figure 135** L2TP Tunnel Accounting

When L2TP tunnel accounting is enabled, except for **host** or **sla-profile**-based accounting packets and attributes, the following are additional accounting packets and attributes:

- Accounting packets: tunnel-start/stop/reject; tunnel-link-start/stop/reject — There are no interim updates for L2TP tunnel/session accounting.
- RADIUS accounting attributes:
  - Tunnel-Assignment-Id (LAC only)
  - Acct-Tunnel-Connection
  - Acct-Tunnel-Packets-Lost

These attributes were added into current account-start/stop/interim-update packets (host accounting/sla-profile accounting)

Tunnel level accounting and session level accounting can be enabled or disabled independently.

New accounting packets and related RADIUS attribute list are described in [Table 64](#).

Some considerations of RADIUS attributes are described in [RADIUS Attributes Value Considerations](#)

## 9.5.1 Accounting Packets List

Table 64 describes L2TP tunnel accounting behavior along with some key RADIUS attributes (apply for both LAC and LNS):

**Table 64** L2TP Tunnel Accounting Behavior

| Act-Packet    | When                                  | Key Attributes           | Remark |
|---------------|---------------------------------------|--------------------------|--------|
| Tunnel-Start  | A new L2TP tunnel is created          | Acct-Session-ID          | —      |
|               |                                       | Event-Timestamp          | —      |
|               |                                       | Tunnel-Type:0            | —      |
|               |                                       | Tunnel-Medium-Type:0     | —      |
|               |                                       | Tunnel-Assignment-Id:0   | —      |
|               |                                       | Tunnel-Client-Endpoint:0 | —      |
|               |                                       | Tunnel-Client-Auth-Id:0  | —      |
|               |                                       | Tunnel-Server-Endpoint:0 | —      |
|               |                                       | Tunnel-Server-Auth-Id:0  | —      |
| Tunnel-Reject | A new L2TP tunnel creation failed     | Acct-Session-Id          | —      |
|               |                                       | Event-Timestamp          | —      |
|               |                                       | Tunnel-Type:0            | —      |
|               |                                       | Tunnel-Medium-Type:0     | —      |
|               |                                       | Tunnel-Assignment-Id:0   | —      |
|               |                                       | Tunnel-Client-Endpoint:0 | —      |
|               |                                       | Tunnel-Client-Auth-Id:0  | —      |
|               |                                       | Tunnel-Server-Endpoint:0 | —      |
|               |                                       | Acct-Terminate-Cause     | —      |
| Tunnel-Stop   | An established L2TP tunnel is removed | Acct-Session-Id          | —      |
|               |                                       | Event-Timestamp          | —      |
|               |                                       | Tunnel-Type:0            | —      |
|               |                                       | Tunnel-Medium-Type:0     | —      |
|               |                                       | Tunnel-Assignment-Id:0   | —      |

**Table 64 L2TP Tunnel Accounting Behavior (Continued)**

| Act-Packet        | When                       | Key Attributes           | Remark                                                             |
|-------------------|----------------------------|--------------------------|--------------------------------------------------------------------|

|                    |                                       | Tunnel-Client-Endpoint:0 | —                                                                   |
|                    |                                       | Tunnel-Client-Auth-Id:0  | —                                                                   |
|                    |                                       | Tunnel-Server-Endpoint:0 | —                                                                   |
|                    |                                       | Tunnel-Server-Auth-Id:0  | —                                                                   |

**Table 64 L2TP Tunnel Accounting Behavior (Continued)**

| Act-Packet | When | Key Attributes           | Remark |
|------------|------|--------------------------|--------|
|            |      | Acct-Tunnel-Connection   | —      |
|            |      | Acct-Session-Time        | —      |
|            |      | Acct-Input-Gigawords     | —      |
|            |      | Acct-Input-Octets        | —      |
|            |      | Acct-Output-Gigawords    | —      |
|            |      | Acct-Output-Octets       | —      |
|            |      | Acct-Input-Packets       | —      |
|            |      | Acct-Output-Packets      | —      |
|            |      | Acct-Tunnel-Packets-Lost | —      |
|            |      | Acct-Terminate-Cause     | —      |

Notes:

- Errors will occur if there are multiple hosts sharing the same sla-profile instance and then these hosts go to different tunnel.
- 7750 SRs have an internal limitation of 500 pps for accounting messages. This feature shares the same limitation

## 9.5.2 RADIUS Attributes Value Considerations

- The value of Acct-Tunnel-Connection uniquely identify a L2TP session, and in order to match LAC and LNS accounting record, the value of Acct-Tunnel-Connection is determined by a method shared by LAC and LNS. This means for a given L2TP session, Acct-Tunnel-Connection from the LAC and LNS are the same.
- Current ESM stats are used in Tunnel-Link and tunnel level accounting. This applies for both standard attribute and the 7750's own VSA.
- Tunnel level accounting stats need to aggregate all sessions stats that belong to the tunnel. Note: there could be sessions come and go before tunnel is down, so system need to remember the stats of every session that has been created within the tunnel.

This applies for both standard attribute and 7750's own VSA.

- The value of Acct-Tunnel-Packets-Lost is the aggregation of all discarded packets on both ingress and egress.

## 9.5.3 Other Optional RADIUS Attributes

Table 65 lists the optional attributes that could be optionally included in tunnel accounting packet, some of them are applied for link level accounting only.

**Table 65** Optional RADIUS Attributes

| Attribute      | Tunnel/Link     |
|----------------|-----------------|
| nas-identifier | Both            |
| nas-port       | Link level only |
| nas-port-id    | Link level only |
| nas-port-type  | Link level only |

## 9.5.4 RADIUS VSA to Enable L2TP Tunnel Accounting

In order to support pure RADIUS-enabled L2TP tunnel accounting on LAC side, the following RADIUS VSA are supported:

**Table 66** Supported RADIUS VSAs

| VSA                          | Type   | Value                                                                                                         |
|------------------------------|--------|---------------------------------------------------------------------------------------------------------------|
| ALC-Tunnel-Accounting-Policy | String | Policy-name; if the name is <b>disable</b> then this means L2TP tunnel accounting is disabled for this tunnel |

Note: ALC-Tunnel-Accounting-Policy takes precedence over what has been defined in CLI when Alc-Tunnel-Group is also returned.

### 9.5.5 MLPPP on the LNS Side

With MLPPP, the counter on LNS side is only available for the bundle, not for each link, so the SR OS's behavior is:

- For each new link session system sends a tunnel-link-start.
- For each link session that is deleted system sends a tunnel-link-stop.
- For all link sessions except the last one system reports 0 for all counters.
- For the last link session, system reports the actual counters for the bundle.

## 9.6 RADIUS Route Download

The RADIUS route download mechanism periodically polls a RADIUS server for routes to download. The main objective of this feature is to download, in advance, customer-assigned subnets so that they can be re-advertised to the corresponding routing protocols. In this way, subscriber bring up can potentially be done faster (as the routes are already in place and advertised) and, most importantly, reduce the routing protocol churn as subscribers connect and disconnect. The routes being learned through this mechanism could be both managed routes/delegated prefixes as well as the WAN IP assigned to the subscriber in the case PPPoE and un-numbered interfaces are being used.

The route download process requests the routes to a configured RADIUS server by triggering an access-request message. The key identifier for this message is the username, which is a combination of the system's name (or an optionally configured value), appended by a dash ( "-") and then a monotonically increasing integer. The download process sends an access request starting with 1 (such as "hostname-1") and the RADIUS server replies with an access-accept message and a number of

routes embedded within the message. The system then increases the counter and sends another access request (this time being hostname-2) and receive a reply with the next batch of routes to download. The process continues, incrementing the counter by 1 each time until the system gets an access-reject or the maximum number of routes that can be downloaded is reached.

The routes to be accepted are in the following format:

```
[vrf {vprn-name | vprn-service-id}] prefix-mask {null0 | null 0 | black-hole} [metric] [tag tag-value]
```

The prefix-mask could be in any form as 'prefix/length', 'prefix mask' or 'prefix' (in the latter case, for IPv4 routes, the mask shall be derived from the IP class of the prefix).

The route formats are supported:

- Framed-Route (RADIUS attribute 22)  
Framed-Route = "192.168.3.0 255.255.255.0 null0"  
Framed-Route = "vrf vrfboston 192.168.1.0/24 null 0 0 tag 6"  
Framed-Route = "vrf 2001 192.168.10.0/24 black-hole 0 tag 8"
- Cisco-AVPair (Cisco VSA 26-1)  
cisco-avpair = "ip:route = 192.168.3.0 255.255.255.0 null0"  
cisco-avpair = "ip:route = vrf vrfboston 192.168.1.0/24 null 0 0 tag 6"

IPv6 routes are also supported. The format is based on using the IETF-defined IPv6 Framed-IPv6-Route (attribute 99). The following text shows the supported formats.

- Framed-IPv6-Route (RADIUS attribute 99)  
Framed-Route = "2001:100:bad:cafe::/64 null0"  
Framed-Route = "vrf vrfboston 2100:5aaa:dead:beaf::/96 null 0 0 tag 6"  
Framed-Route = "vrf 3000 2200:1bbbb:dead::/48 black-hole 0 tag 6"

All the routes downloaded will be a new protocol type "**periodic**". The downloader process re-starts the AAA requests after a given interval (a configurable value but target refresh rate is 15 minutes) and routes shall be updated according to the following process:

- When the router initiates a new download process, the routes are kept in a temporary table until the download process completes (receives an access-reject from the AAA). The temporary download table is then checked for errors and finally, any changes reflected to the actual routing table.
- Routes no longer present in the download will be removed from the routing table.

- If the AAA server responds with an access-reject for the first username (that is, an implicit empty route-download table), all routes will be removed from the routing table.
- If there are any protocol errors (at the RADIUS level), such as time-out, no response, bad record format, too many records, etc., the download process is suspended and retried after a configurable timer. The minimum retry timer is at least 1 minute and given the light load this represents control-plane-wise (concurrent downloads are not supported) the retries can continue infinitely until the next refresh period occurs, where the download restarts from the beginning. An exponential backoff algorithm with a configured minimum and maximum delay will be used to determine the retry timer.
- In any case, the routes are only purged from the routing table after a complete download process was achieved (properly terminated with an access-reject message). Under any other failure condition, the routes shall remain active. Shutting down the download process should not remove the downloaded routes. A clear command will be provided to clear the periodic routes.
- All the imported routes (blackholes) will be imported into the line-card FIBs to avoid the routing loops caused by announcing the prefixes but not installing the actual blackholes.

## 9.7 Managed SAP (MSAP)

Managed SAPs allow the use of policies and a SAP template for the creation of a SAP. Although the router supports automatic creation of subscriber hosts in a shared SAP, the most secure mode of operation and common mode is the subscriber per SAP model. In this model, each subscriber is defined with its own VLAN. This feature uses authentication mechanisms supported by the node to provide a SAP.

The reception of a trigger packet initiates a RADIUS or local user database authentication to provide the service context in which the MSAP should be created. The VLAN of the created MSAP is the same as the trigger packet. An MSAP is similar to a regular SAP but its configuration is not user editable and not maintained in the configuration file. The managed SAP remains active as long as the session is active.

The following trigger types are supported:

- DHCP discover (or requests if configured) for DHCP clients. The managed SAP lifetime is defined by the lease time.
- PPPoE PADI for the PPPoE client. The managed SAP lifetime is defined by the session time. The MSAP is installed after the IP address is provided. A short temporary state handles packets between the PADO and ACK.

- ARP defines the managed SAP lifetime. The ARP entry refresh behavior is maintained.
- DHCP6
- PPP
- rtr-solicit (SLAAC hosts)

Multiple trigger types can be enabled on a single capture-sap.

Trigger packets are received on a capture SAP that must be configured in a VPLS service. A capture SAP is defined in a similar way as a regular default SAP but it does not forward traffic. It's sole purpose is to capture trigger packets for authentication. Refer to the following configuration example:

```
vpls 10 customer 1 create
 sap 1/1/1:.* capture-sap create
 description "capture sap"
 trigger-packet arp dhcp dhcp6 pppoe
 authentication-policy "auth-policy-1"
 exit
 no shutdown
exit
```

A capture SAP and default SAP cannot be configured at the same time for a single port with the dot1q encapsulation or for a single port:topq combination with qinq encap. The capture SAP is used if a more specific match for the Q or Q-in-Q tags is not found by the IOM. If a capturing SAP is defined, triggering packets are sent to the CPM. Non-triggering packets captured by the capturing SAP are dropped.

An ingress VLAN ID (VID) type mac filter can be configured on a capture-sap to have additional control on the VLANs that are allowed to initiate a host setup. Other filter types are not supported on a capture-sap.

Capture-sap on a dot1q encapsulated port:

- <port-id>.\*

Captures any valid single tagged trigger packet on <port-id> for which no more specific SAP or MSAP is found.

A single q-tag (<port-id>:tag) is available for authentication.

The corresponding Managed SAP is created as: <port-id>:tag

Capture-sap on a qinq encapsulated port:

- <port-id>:.\*

Captures any valid double tagged trigger packet on <port-id> for which no more specific SAP or MSAP is found.

Both q-tags (<port-id>:tag1.tag2) are available for authentication.

The corresponding Managed SAP is created as: <port-id>:tag1.tag2.

The optional allow-dot1q-msaps CLI command configured at the capture SAP enables additional support for single tagged trigger packets:

- also valid single tagged trigger packets for which no more specific SAP or MSAP is found are captured on <port-id>
- A single q-tag is available for authentication, the second tag is set to zero (<port-id>:tag.0)
- The corresponding Managed SAP is created as: <port-id>:tag.0
- The **config>system>ethernet>new-qinq-untagged-sap** command should be configured where a combination of <port-id>:tag1.0 and <port-id>:tag1.tag2 MSAPs co-exist. When not configured, <port-id>:tag1.0 MSAPs attract double tagged <port-id>:tag1.tag2 encapsulated traffic which is either dropped (IPoE traffic) or handled as single tagged traffic causing PPPoE sessions to fail.

- <port-id>:tag1.\*

Captures any valid double tagged trigger packet with outer tag = tag1 on <port-id> and for which no more specific SAP or MSAP is found.

Both q-tags (<port-id>:tag1.tag2) are available for authentication.

The corresponding Managed SAP is created as: <port-id>:tag1.tag2.

The optional allow-dot1q-msaps CLI command configured at the capture SAP enables additional support for single tagged trigger packets:

- also valid single tagged trigger packets with tag=tag1 and for which no more specific SAP or MSAP is found are captured on <port-id>
- A single q-tag is available for authentication, the second tag is set to zero (<port-id>:tag1.0).
- The corresponding Managed SAP is created as: <port-id>:tag1.0
- It is a prerequisite to have the **config>system>ethernet>new-qinq-untagged-sap** command configured to enable both <port-id>:tag1.\* capture-sap and <port-id>:tag1.0 MSAP to co-exist. The <port-id>:tag1.0 capture-sap cannot be created when not configured.

- <port-id>:\*.tag2

Captures any valid double tagged trigger packet with inner tag tag2 on <port-id> for which no more specific SAP or MSAP is found.

Both q-tags (<port-id>:tag1.tag2) are available for authentication.

The corresponding Managed SAP is created as: <port-id>:tag1.tag2.

This is an inverse capture-sap that matches on a fixed inner tag with the outer tag identifying the user. The following restrictions apply when an inverse capture-sap is configured on a port:

- Ethernet ports only

- It is not possible to create y.\* saps when there is a \*.x capture sap present on the port (y=0,1..4094,\* and x=1..4094).
- It is not possible to create a y.\* network interface when there is a \*.x capture SAP present on the port (y=0,1..4094,\* and x=1..4094).
- No support for single tagged managed SAP creation

To enable the creation of single and double tagged managed SAPs via a qinq encapsulated capture SAP, following CLI command should be specified:

```
config service
 vpls 10 customer 1 create
 sap 1/1/1:*. * capture-sap create
 allow-dot1q-msaps
```

In addition, new-qinq-untagged-sap should be configured for scenarios as explained previously:

```
config system
 ethernet
 new-qinq-untagged-sap
```

Note that enabling the **new-qinq-untagged-sap** command affects the behavior of existing <port-id>:tag1.0 SAPs.

Valid single tagged trigger packets will result in the creation of a <port-id>:tag.0 managed sap. With **encap-tag-range** matching in a local user database, it is possible to specify different MSAP defaults for single or double tagged MSAPs. For example:

```
config subscriber-mgmt
 local-user-db "ludb-1" create
 ipoe
 host "single-tagged" create
 host-identification
 encap-tag-range start-tag *.0 end-tag *.0
 exit
 msap-defaults # defaults for dot1q MSAPs
 group-interface "group-int-2"
 policy "msap-policy-2"
 service 2000
 exit
 no shutdown
 exit
 exit
 exit

config service
 vpls 10 customer 1 create
 sap 1/1/1:*. * capture-sap create
 trigger-packet dhcp dhcp6
 allow-dot1q-msaps
 ipoe-session
 ipoe-session-policy "ipoe-policy-1"
```

```

 user-db "ludb-1"
 no shutdown
 exit
 msap-defaults # defaults for qinq MSAPs
 group-interface "group-int-1"
 policy "msap-policy-1"
 service 1000
 exit
exit

```

A set of mandatory parameters should be provisioned for MSAP creation are as follows:

- **Service id:** The service context in which the MSAP will be created.
- **Interface id:** The name of the group-interface context in which the MSAP will be created. The group-interface must exist in the provided service for the MSAP to be installed (routed CO scenario only).
- **MSAP policy:** The name of the policy that defines the MSAP parameters. The policy must exist in the subscriber-mgmt context.

These parameters can be obtained from the following order of preference:

1. Local user database lookup.
2. RADIUS attributes.
3. Defaults configured at the capture-sap context.

The MSAP parameters can be obtained from a local user database. The local user database should be configured at the capture SAP and group interface context. For example,

#### # IPoEv4 hosts

```

config>service>vpls>sap# dhcp-user-db <local-user-db-name>
config>service>ies>sub-if>grp-if>dhcp# user-db <local-user-db-name>

```

#### # IPoEv6 hosts

```

config>service>vpls>sap# dhcp6-user-db <local-user-db-name>
config>service>ies>sub-if>grp-if>ipv6>dhcp6# user-db <local-user-db-name>

```

#### # PPP hosts

```

config>service>vpls>sap# pppoe-user-db <local-user-db-name>
config>service>ies>sub-if>grp-if>pppoe# user-db <local-user-db-name>

```

When RADIUS authentication is still required after local user database authentication, then the authentication policy must be specified in the local user database. In this case no authentication policy may be configured at the group-interface context. For example,

#### # I PoE hosts

```
config>subscr-mgmt>loc-user-db>ipoe>host# auth-policy <policy-name>
```

#### # PPP hosts

```
config>subscr-mgmt>loc-user-db>ppp>host# auth-policy <policy-name>
```

The MSAP parameters are configured at the local user database host context. For example,

```
config>subscr-mgmt>loc-user-db>ipoe>host# msap-defaults
config>subscr-mgmt>loc-user-db>ppp>host# msap-defaults
```

```
- msap-defaults
```

```
[no] group-interface - Configure the group interface
[no] policy - Configure the MSAP policy
[no] service - Configure the service
```

When RADIUS authentication is required to return the MSAP parameters without prior local user database authentication, then the authentication policy should be configured at the capture-sap context. In a Bridged CO model, the authentication policy specified in the capture-sap will also be used for the MSAP in the VPLS service. In a Routed CO model, the same authentication policy must also be configured at the group-interface context. For example,

```
config>service>vpls>sap# authentication-policy <auth-policy-name>
config>service>ies>sub-if>grp-if# authentication-policy <auth-policy-name>
```

The MSAP will not be created if the group-interface name returned from RADIUS has a different authentication policy than the authentication policy configured at the capture-sap.

The following table lists the RADIUS attributes (VSAs) to include in a RADIUS access accept message to obtain MSAP parameters in the RADIUS authentication phase.

**Table 67 RADIUS Attributes**

| Attribute Name                     | Type    | Purpose and Format                                                     |
|------------------------------------|---------|------------------------------------------------------------------------|
| Alc-MSAP-Serv-Id<br>[26-6527-31]   | Integer | Service ID of the service context in which the MSAP will be created.   |
| Alc-MSAP-Policy<br>[26-6527-32]    | String  | Name of the policy that defines the MSAP parameters.                   |
| Alc-MSAP-Interface<br>[26-6527-33] | String  | Name of the group-interface context in which the MSAP will be created. |

MSAP parameters that are not obtained from a local user database lookup, and that are not returned from RADIUS can be specified in the default-msap section of the capture-sap context (last resort):

```
>config>service>vpls>sap# msap-defaults ?
- msap-defaults

[no] group-interface - Configure the group interface
[no] policy - Configure the MSAP policy
[no] service - Configure the service
```

MSAPs can be created in IES or VPRN group interfaces (Routed CO model) and in a VPLS service (Bridged CO model).

The managed SAP configuration can be persistent. The template MSAP policy is stored with the subscriber host which in turn can be made persistent.

If local user database or RADIUS authentication did not provide all the required information to create the subscriber host (no IP address for example), then the MSAP is created with a short timer while waiting for the host to acquire the missing information. If no host is instantiated when the timer expires, the MSAP is deleted.

Multiple subscribers and/or subscriber hosts can share a single MSAP. The MSAP is created with the first instantiated subscriber host and deleted when the last associated subscriber host is removed from the system. Note that only a single MSAP policy is allowed to be specified for a given MSAP. An attempt to change the MSAP policy by a new subscriber host for an existing MSAP will result in a host setup failure.

MSAPs can be created in a wholesale VPRN service while the corresponding subscriber host or session is terminated in a retail VPRN or IES service. Both wholesale MSAP data (service, group-interface and policy) and retail service id must be provided during authentication.

## 9.7.1 Sticky MSAP

After a subscriber session ends, the MSAP is removed from the system and the historical data of the subscriber is deleted. Sticky MSAP allows the MSAP to remain even when the subscriber session ends. This feature is only recommended for service providers who do not oversubscribe MSAPs in the network.

Sticky MSAP provides the following benefits.

- Because the sticky MSAP is never deleted, the subscriber can start a session faster; processing time is reduced because the MSAP does not have to be recreated.
- The MSAP may contain valuable historical information for the service provider. Keeping the MSAP provides a means for the service provider to look up subscriber historical data.

The MSAP is only be eligible for stickiness if it was successfully created. The sticky MSAP introduces a new state: idle. An idle MSAP indicates that the subscriber on the MSAP has disconnected and the MSAP is ready for a new subscriber connection. An example is shown below:

```
A:BNG> # show service sap-using
=====
Service Access Points
=====
PortId SvcId Ing. Ing. Egr. Egr. Adm Opr
 QoS Fltr QoS Fltr

[1/1/20:1841] (I) 1000 1 none 1 none Up Up
1/1/1:4000 1000 1 none 1 none Up Up

Number of SAPs : 20

Number of Managed SAPs : 1, indicated by [<sap-id>]
Flags : (I) = Idle MSAP

=====
```

The command **clear service id id msap** removes MSAPs.

**Note:** This command can remove MSAPs with active subscribers. To clear only MSAPs without any active subscriber, use the keyword **idle-only**.

## 9.7.2 ESM Identification Process

### 9.7.2.1 SAP-ID ESM Identifier

Providers migrating from Basic Subscriber Management (BSM) can assign a subscriber to a SAP. The SAP ID ESM identifier makes the transition easier by allowing the operator to continue using the *sap-id* as a subscriber-ID.

An ESM SAP ID provides the system the ability to:

- Provide access to the SAP ID string in the Python script.
- Allow the automatic assignment of the SAP-ID to a static subscriber or subscriber host.

### 9.7.2.2 DSLAM-ID

A DSLAM ID provides the system the ability to define a DSLAM-ID string provided through the Python script, RADIUS, or local user database. If the DSLAM-ID was provided, but the subscriber host is instantiated on a regular MDA (a non-HSMDA), the DSLAM-ID will be ignored.

The HSMDA and the ability to aggregate subscribers into DSLAMs for the purpose of QoS, can use the SAP ID to identify subscribers and associated DSLAMs.

### 9.7.3 Default-Subscriber

This feature provides a default subscriber definition under the SAP. If the object was configured the operator may use ESM without enabling a processing script or a RADIUS authentication policy. In the event both have been disabled any host that was installed for the SAP will be installed with the configured default subscriber ID. If a RADIUS policy was used or if a script was enabled but a subscriber ID was not returned the default subscriber ID will be used.

### 9.7.4 Multicast Management

The multicast-management CLI node contains the bandwidth-policy and multicast-info-policy definitions. The bandwidth-policy is used to manage the ingress multicast paths into the switch fabric. The multicast-info-policy is used to define how each multicast channel is handled by the system. The policy may be used by the ingress multicast bandwidth manager, the ECMP path manager and the egress multicast CAC manager.

### 9.7.5 Subscriber Mirroring

This section describes mirroring based on a subscriber match. Enhanced subscriber management provides the mechanism to associate subscriber hosts with queuing and filtering resources in a shared SAP environment. Mirroring used in subscriber aggregation networks for lawful intercept and debugging is required. With this feature, the mirroring capability allows the match criteria to include a subscriber-id.

Subscriber mirroring provides the ability to create a mirror source with subscriber information as match criteria. Specific subscriber packets can be mirrored mirror when using ESM with a shared SAP without prior knowledge of their IP or MAC addresses and without concern that they may change. The subscriber mirroring decision is more specific than a SAP. If a SAP (or port) is placed in a mirror and a subscriber host of which a mirror was configured is mirrored on that SAP packets matching the subscriber host will be mirrored to the subscriber mirror destination.

The mirroring configuration can be limited to specific forwarding classes used by the subscriber. When a forwarding class (FC) map is placed on the mirror only packets that match the specified FCs are mirrored. A subscriber can be referenced in maximum 2 different mirror-destinations: 1 for ingress and 1 for egress.

## 9.8 Volume and Time Based Accounting

Time and volume-based accounting includes the following components:

- Metering function performing stateful monitoring of the service delivery to the subscriber.
- Communication with an external management system that gets and updates credit per subscriber, notifications of credit exhaustion, and so on.
- Action on credit exhaustion takes pre-defined action when the credit has been exhausted.

### 9.8.1 Metering

Metering represents the core of time and volume-based accounting. Service usage is typically measured by performing an accounting of the traffic passing through corresponding subscriber-host queues (volume usage) or by keeping lease-state while the given subscriber-host is connected to the network (time usage).

- Statefulness — The accounting information is compared with pre-defined credit expressed in terms of time or volume to monitor service usage.
- Sensitivity — Defining so called activity-threshold allows distinction between subscriber-host being connected and subscriber-host effectively using the service. This is particularly of interest in cases of time based charging.
- Aggregated usage per-category per-subscriber-host — Accounting information can be reported on per-queue per-sla instance of the given subscriber. In many situations, a certain level of aggregation (such as a per-subscriber or HSI ingress and egress traffic) is required to perform meaningful mechanism for pre-paid services.

#### 9.8.1.1 Categories Map and Categories

This feature introduces a new object category-map which defines individual aggregates (such as data in and out, video and data, etc.) and their mapping to individual forwarding queues.

The following output depicts a category-map configured in the subscriber management context.

```
*A:ALA-48>config>subscr-mgmt# info
```

```

```

```

...
 category-map "triple-play" create
 category "data" create
 queue 1 ingress-egress
 exit
 category "video" create
 queue 2 egress-only
 exit
 category "voice" create
 queue 3 ingress-egress
 exit
 exit
 category-map "aggr-subscriber-service" create
 category "data-services" create
 queue 1 ingress-egress
 queue 3 egress-only
 exit
 exit
...

*A:ALA-48>config>subscr-mgmt#

```

Based on a category-map the system gathers usage information (volume/time) on a per-sla-instance-per-category basis. In order to do so, statistics of all queues and/or policers forming the category of the given sla-instance are aggregated.

- Single subscriber host (routed CPE) — Single SLA instance.
- Multiple subscriber hosts on the same SAP (bridged CPE) — Single SLA instance. Note that several hosts use the same credit and the renewal of one will cause renewal for all.
- Multiple subscriber hosts on different SAP (bridged CPE) — SLA instance per host.

The per-category usage gathered as described above is compared with per-subscriber-host-per-category credit and when credit is exhausted several actions can be taken.

There are several category-maps pre-configured on the system. The category-map applicable to a given subscriber-host will be derived at the host creation from the RADIUS VSA in an authentication-response, Python script, or static configuration in the local-user-database. All subscriber-hosts belonging to the same subscriber and created on the same SAP (hence, sharing the same sla-instance) must use the same category-map. In case of conflict, (an existing subscriber host has a different category-map than the one derived for the new host) the category-map of the last host will be applied to a given sla-instance. As a consequence, all previous information related to the status of the credit will be lost.

There can be multiple queues and/or policers aggregated into one category. There can be up to sixteen categories in a category map.

### 9.8.1.2 Quota Consumption

There are two types of quota (credit), volume and time. In volume usage monitoring, the system accumulates byte counters per category-sla-instance and compares it with the assigned quota. Once the credit is exhausted (or threshold for renewal is met) the system attempts to renew it with corresponding management system.

In time-based credit, the distinction between active-usage and active-connection is made by defining an activity-threshold, where an object defines an average data rate under which the subscriber-host is considered silent.

As long as the effective rate of the application usage does not exceed the rate defined by the activity-threshold, the given subscriber host will be considered silent and its corresponding credit will not be used. As long as the application usage exceeds the rate, the application-credit will be consumed (in terms of time).

### 9.8.1.3 Minimum Credit Control Quota Values

The minimum credit control quota values are one second for time quota and one byte for volume quota. These minimum values are not realistic deployment values for multiple reasons such as effective sampling periods, statistics processing time, RADIUS message load, subscriber scale, etc.

For typical deployment scenarios it is not recommended to implement Credit Control quota values smaller than 60 seconds for time quota and for volume quota the volume that can be consumed in 60 seconds for that category (function of number of queues/policers monitored and their respective rates).

### 9.8.1.4 RADIUS VSA Alc-Credit-Control-Quota

The quota in the RADIUS VSA Credit-Control-Quota uses this fixed format:

Alc-Credit-Control-Quota = "<volume quota>|<time quota>|<category name>"

- <volume-quota> is specified in bytes (B), in kilobytes (K or KB), in megabytes (M or MB), in gigabytes (G or GB)
- <time-quota> is specified in seconds (s), in minutes (m), in hours (h), in days (d) or a combination (5m30s). A lower unity may never exceed the higher unity: 5m60s is not allowed and should be specified as 6m.

Both volume and time quota should be specified in the attribute but only one credit type (volume or time) is applied per category. The credit-type of a category is configured in the category-map CLI context.

For example, use `Alc-Credit-Control-Quota = "0|1h30m|cat1"` to grant time quota and `Alc-Credit-Control-Quota = "1G|0|cat2"` to grant volume quota.

## 9.8.2 Credit Negotiation Mechanisms

The per-subscriber per-category credit can be obtained by several ways:

- RADIUS during authentication process.
- Static configuration - configured in the **config>subscr-mgmt>category-map>category** context.

Credit can be expressed by either

- Volume
- Time

The renewal of the credit using RADIUS authentication is triggered by credit exhaustion or (if configured) by depletion of the credit to exhausted-credit-threshold level. If this occurs, the system will send a RADIUS authentication message indicating the corresponding category and usage. The following are several possibilities for the RADIUS server response (as shown in [Figure 136](#)):

**Figure 136 Threshold Configured/Not Configured**

al 0064

1. No authentication response — The system will install out-of-credit action after the original credit has been used.
2. Authentication response with reject — The corresponding host is removed after the original credit has been used.
3. Authentication response with accept and no credit VSA included — The system will install out-of-credit action.
4. Authentication response with accept and credit VSA included — The credit will be installed.

The new installed credit is reduced by the amount of credit consumed during credit renewal (i.e. between the start of the credit renewal and reception of an authentication-response). In case the new received credit is less than the credit consumed during credit renewal, then the out-of-credit-action is installed instead.

5. Authentication response with accept and credit VSA included — The out-of-credit will be installed.

Note that the new credit is always reduced by the amount of credit consumed in time between renewal has been initiated and authentication-response has been received. In case of a negative result (the newly receive credit is smaller than the amount consumed in the meantime) the test is installed.

In order to identify that the given RADIUS-auth request is related to credit renewal rather than to plain authentication, the node will include empty credit VSAs, depending on categories which has been exhausted. The RADIUS server can identify which category has requested credit renewal.

### 9.8.3 Action on Credit Exhaustion

System supports configurable actions once the credit for given subscriber is exhausted:

- Sends an SNMP trap and continue (the credit-usage counter is reset).
- Disconnect.
- Changes to a pre-defined service level (such as adjusting the queue rate).
- Blocks the category.

### 9.8.4 Action on Error-Conditions

During credit negotiation, the number of errors can occur which can lead to a given subscriber-host category with no new credit renewed. This is different from credit exhaustion where a separate configurable action will be taken. The following occurs:

- Sends an SNMP trap and continues.
- Sends a trap and blocks the category.

### 9.8.5 Applicability of Volume and Time Based Accounting

Volume and time based accounting is applicable to the ESM mode of operation only. Using credit control concept is not mutually exclusive with other accounting methods. In many network implementations the more traditional accounting methods such as XML file or RADIUS accounting will be still used in a combination with the credit concept but with larger intervals. This is helpful when providing overviews of the average usage and service utilization.

## 9.9 Subscriber Host Idle Timeout

An idle timeout is the maximum time that a subscriber session can be idle before the session is terminated or a connectivity check is started. Idle timeout applies to PPPoE, PPPoEoA, PPPoA and IPoE hosts.

The time/volume based accounting model is used to configure an idle timeout:

- Create a category-map (see [Categories Map and Categories](#))
  - Define a category with queues and/or policers to be monitored for activity (packets being forwarded).
  - An activity threshold (in kb/s) must be configured for idle timeout to take effect. The activity threshold suppresses background traffic (for example control flows) from activity monitoring.

Example:

```
config>subscr-mgmt
 category-map "idle-timeout" create
 activity-threshold 25
 category "cat-1" create
 queue 1 ingress-egress
 exit
 exit
```

In the sla-profile, associate the category-map and optionally define

- An idle-timeout (60 to 15552000 seconds). The default is infinite (no idle-timeout).

The idle-timeout can also be specified from RADIUS in an access-accept or CoA message with the [28] Idle-Timeout attribute. A RADIUS specified idle-timeout overrides the CLI- configured value. The values outside the limits are accepted but rounded to these boundaries.

**Table 68** Idle-Timeout Attribute

| Attribute ID | Attribute name | Type    | Limits                    | Purpose and Format                                                                                 |
|--------------|----------------|---------|---------------------------|----------------------------------------------------------------------------------------------------|
| 28           | Idle-Timeout   | integer | [60..15552000]<br>seconds | 0 = infinite (no idle-timeout)<br>[60..15552000] in seconds<br>For example:<br>Idle-Timeout = 3600 |

- An idle-action:

- **shcv-check** — Perform a subscriber host connectivity check (IPoE hosts only). Host connectivity verification should be enabled on the corresponding group-interface for the **idle-action shcv-check** to take effect:

**config service ies|vprn service-id subscriber-interface ip-int-name group-interface ip-int-name host-connectivity-verify**

If the shcv check is successful, the subscriber host is not disconnected and the idle-timeout timer is reset to zero. If the shcv check fails, the subscriber host is disconnected (same as terminate).

For PPP hosts, the **idle-action shcv-check** is ignored and has the same effect as “idle-action terminate”

- Terminate (default): disconnect the subscriber hosts
  - IPoE:
    - Delete the subscriber host
    - Send a DHCP release message to the DHCP server
    - Send an Accounting Stop message to the RADIUS accounting server
  - PPP:
    - Delete the subscriber host
    - Send a terminate request message to the CPE
    - Send an Accounting Stop message to the RADIUS accounting server

### Example

```
config>subscr-mgmt
 sla-profile "sla-profile-1" create
 category-map "idle-timeout"
 category "cat-1" create
 idle-timeout 3600
 idle-timeout-action terminate
 exit
 exit
 exit
exit
```

At host instantiation, a timer is initialized to the idle-timeout value (one timer per sla-profile instance). Each queue or policer in the category is monitored for activity over a fixed polling interval:

- During the polling interval:
  - if the forwarding rate falls below the configured activity threshold then the timer is deducted by the polling interval (time elapsed).
  - If the forwarding rate is above the configured activity threshold then the timer is initialized to the idle-timeout value.

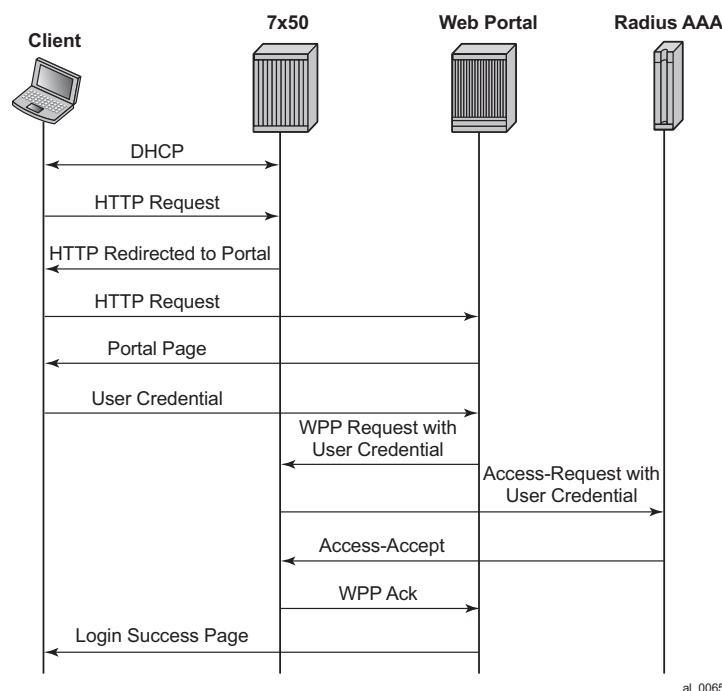

When the timer becomes zero, the idle-timeout-action is performed for all hosts associated with the SLA-profile-instance (all hosts from a subscriber on a single sap and that share the same sla-profile).

## 9.10 Web Authentication Protocol (WPP)

The Web Authentication Protocol (WPP) is a protocol running between a BNG and a Web portal server. WPP is used for web portal authentication of WLAN users (DHCP Host). It can function like a web portal that can trigger BNG to perform RADIUS authentication for WLAN users, or send user disconnection notification to BNG.

The [Figure 137](#) illustrates high level of call flow of WPP authentication.

**Figure 137 WPP Authentication**

The following describes WPP authentication call flow:

1. When the WLAN user starts a DHCP exchange with a 7750 SR, the router will create a DHCP host from following configurations:
  - Sub-id is the default sub-id configured in the **sap>sub-sla-mgmt** context.

- sla-profile/sub-profile/aa-profile will take the configuration from CLI command **grp-if>wpp>initial-sla-profile/initial-sub-profile/initial-app-profile**.
  - IP address from local or external DHCP server will be assigned to the host.
2. When the user sends an HTTP request to visit a web site by browser, the router redirects the HTTP request to the web portal.
  3. The portal server sends an authentication page to the WLAN user.
  4. WLAN user enters username and password in the authentication page and submit to the Portal Server.
  5. The portal server sends a WPP request to router together with the user credentials.
  6. The 7750 sends an access-request to RADIUS server with user credentials.
  7. RADIUS returns an access-accept if authentication succeeds.
  8. The 7750 returns a WPP ack to portal server.
  9. If it was access-accept, then the router can optionally override the following host properties:
    - Sub-id: sub-id from RADIUS. If there is no sub-id from RADIUS, then the host will keep using current sub-id.
    - Sla-profile/sub-profile/aa-profile: The system will use the RADIUS server returned values. If the RADIUS server did not return these then the system will try to use the LUDB (in local DHCP server) return values if they are available. If not, the system will try to use the default values configured under SAP.

### 9.10.1 WPP Configurations

A minimal WPP configurations must include the following:

- WPP portal server — Specifies the name and IP address of the WPP portal server.
- Enable WPP under the group-interface:
  - WPP portal server that system should listen to.
  - **authentication-policy** on **group-interface** that specifies address of RADIUS server.
  - **def-sub-id** under **sap>sub-sla-mgmt** that is used for DHCP host before user is authenticated by portal server.

- **initial-sla-profile** and **initial-sub-profile** that are used for the DHCP host before user is authenticated by portal server.

**Note:** **initial-sla-profile** should include a ingress filter that has **http-redirection** entry.

The following is an example configuration:

```
#-----
echo "Web Portal Protocol Configuration"
#-----

wpp
 portals
 portal "portal-1" address 9.9.9.9 create
 no shutdown
 exit
 exit
 no shutdown
exit
config>service>vprn# info

subscriber-interface "sub-if" create
address 192.168.10.1/24
group-interface "grp-if" create
 dhcp
 server 1.1.1.1
 gi-address 192.168.10.1
 no shutdown
 exit
 authentication-policy "radius-auth"
 sap 1/1/9 create
 sub-sla-mgmt
 def-sub-id "WLAN-User-Unauth"
 no shutdown
 exit
 wpp
 initial-sla-profile "webportal"
 initial-sub-profile "webportal"
 portal router "Base" name "portal-1"
 no shutdown
 exit
exit
exit
...
```

## 9.10.2 WPP Triggered Host Creation

In some cases, a 7750 SR can sit behind a Layer 3 device (such as an CMTS), where the router does not participate in client's DHCP process. Such a use case is different from a normal WPP use case where the routers rely on getting client's DHCP request to create an initial ESM host.

This feature allows the system to create an ESM host upon successful WPP authentication without creating an initial host.

In the above use case (behind a Layer 3 device) the user also need to configure one or more default hosts on the SAP to allow HTTP redirection without an ESM host. The default-host subnet is the user's source subnet and the nexthop address is the Layer 3 device's interface address that connect to the SAP. Users also need to configure the **lease-populate l2-header** command in the **grp-if>dhcp** context to make HTTP redirection with default-host work. The **grp-if>dhcp** context could be shutdown in the meantime.

This feature does not work with wholesale/retail

### 9.10.2.1 LUDB Support For WPP

The SR OS supports LUDB lookup for WPP authentication. Users can optionally configure LUDB using the **grp-if>wpp** context to return the WPP-related configuration attributes (such as a portal name, initial-sla-profile, initial-sub-profile, and so on) for an IPoE host. The system can access LUDB when creating the initial host before WPP authentication. The LUDB returned attribute overrides the corresponding configuration under the **group-interface** context.

A LUDB lookup is performed by the system in the following cases.

- when a host is created
- when the system restores a host after a disconnect

If the WPP LUDB lookup returns an authentication policy, it will be used for WPP RADIUS authentication. When WPP LUDB is configured, the authentication policy on **group-interface** is optional and only used by the WPP if there is no authentication policy returned from the WPP LUDB lookup.

### 9.10.3 WPP Multi-Chassis Redundancy Support

The SR OS supports multi-chassis redundancy to WPP. This can be achieved by doing following:

- Create a loopback interface on both 7750 SRs with the same IP address X.
- Use the **track-srrp** parameter while configuring address X to track the corresponding SRRP instance.

- Configure a portal with the same name and same service-id on both nodes to send WPP packets to the destination address.
- Use an route-policy to export X to the routing protocol. The metric the route X can be set is based on the a specified SRRP state (master or non-master) so that master node can advertise route X with a better metric. Then the WPP packet from the portal will be attracted to the master.
- Only the master process WPP packet, however in case of standby node receives (such as routing is still re-converging) the WPP packet, then standby will shunt the WPP back to master.
- WPP hosts will be synced via MCS.

## 9.11 One-time HTTP Redirection Overview

With this feature enabled, after an ESM host is created, only the FIRST HTTP request from the host will be redirected to a configured URL with specified parameters. Subsequent HTTP request will go through without being redirected.

This feature could be used by service providers to push a web-page to broadband users for purpose of advertisement, announcements, and such.

A **one-time-http-redirection** filter could be configured in **sla-profile**, this filter will be replaced by ingress filter in **sla-profile** after 1st HTTP request is redirected. There is also a RADIUS VSA (ALC-Onetime-Http-Redirection-Filter-Id) that could be included in access-accept or CoA request to override CLI configuration. The format of ALC-Onetime-Http-Redirection-Filter-Id is

**Ingr-v4:***filter-id*; for example, **Ingr-v4:1000**. If the the filter-id is 0, then system will replace the current **one-time-http-redirection** filter with ingress filter.

**Note:** In case of CoA, if the host's **one-time-http-filter** has already been replaced then system will just ignore the ALC-Onetime-Http-Redirection-Filter-Id.

If a 7750 SR receives filter insertion via CoA or access-accept when **one-time-http-redirection** filter is still active then the received filter entries will only be applied to the ingress filter. And after 1st http redirection, the update ingress filter will replace the one-time-http-redirection filter.

This feature only supports IPv4 filter.

## 9.12 ESM over MPLS Pseudowires

This feature allows IPoE and PPPoE (terminated or L2TP tunneled) subscriber sessions to be backhauled through an Ethernet aggregation network using MPLS pseudowires terminating directly on the BNG. The MPLS pseudowire originates from the first hop aggregation PE (referred to as access PE) upstream of the Access-Node (or directly from a multi-service AN), and terminates on the BNG. Multiple subscriber sessions from a given access-port on the Access-PE can be backhauled over a single P2P MPLS pseudowire towards the BNG. This capability allows the network to scale and does not require a MPLS pseudowire per subscriber between Access-PE and the BNG. The access-port on the Access-PE can be dot1q, q-in-q or NULL encapsulated. The BNG terminates the MPLS pseudowire, decapsulates the received frames, and provides ESM functions including HQoS, without requiring an internal or external loopback. Each MPLS pseudowire is represented on the BNG as a “PW-port” for which SAPs are created. A PW-port can be configured with capture SAP. Both static and managed SAPs are supported. The underlying Ethernet port is required to be in hybrid mode. The feature set is supported for IOM3-XP and HSMDAv2. This feature is supported on the 7750 SR and 7450 ESS in mixed mode.

**Figure 138 ESM over MPLS Pseudowire Example**

al\_0066

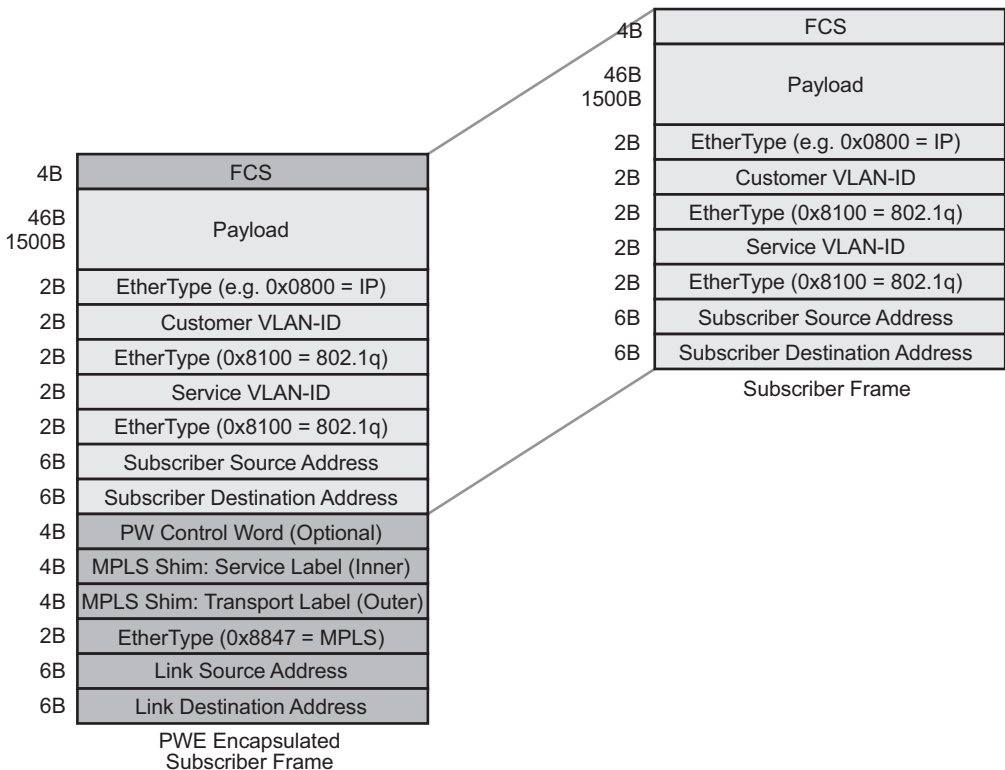

Figure 139 Group Interface Example

### 9.12.1 Encapsulation

The subscriber frame encapsulated within the pseudowire is shown in [Figure 140](#). Optional control word is not supported. The SDP could be LDP, RSVP or LDP over RSVP. Hash labels are not supported. SDP is bound to a port or a LAG. In case the SDP is re-routed, the corresponding PW-ports are operationally brought down. The PW-ports are associated with the SDP by configuration.

**Figure 140**    **Subscriber Frame with PWE Encapsulation**

al\_0068

### 9.12.2 ESM and PW Ports

In BNG deployments, PWs are typically terminated on PW-ports where payload is extracted and processed by ESM on PW-SAPs. There are two modes of operation for PW-ports in SR OS:

- When a PW-port is bound to a specific physical port. A successful mapping between the PW and PW-port requires that the PW terminates on the same physical port (I/O port) to which the PW-port is bound. In this mode of operation, PW-ports do not support re-routing of PWs between the I/O ports. For example, if a PW is rerouted to an alternate physical port due to a network failure, the PW-port will become non-operational.
- When a PW-port is independent of the physical port (I/O ports) on which the PW is terminated. The PXC based PW-port is anchored/bound on the termination side of a port cross connect PXC (which can be either a pxc sub-port or a pxc lag) under an internally created fwd-path-ext (FPE) PW. The benefit of peer 10.20.1.2 create such PW-Port is that it continues to provide services in cases where PW is switched between the I/O ports due to a network failure.

### 9.12.2.1 ESM on PW-Port Bound to a Physical Port

#### 9.12.2.1.1 QoS Support

QoS is supported for ESM over PW SAPs as with ESM over regular SAPs, and includes currently supported models.

- FC to queue mapping
- H-QOS
  - Per-subscriber HQOS (service scheduler child to port-scheduler parent).
  - PW SAP queues attached to H-QOS scheduler by a **parent** statement.
  - Scheduler attached to port scheduler by a **port-parent** statement.
- Direct service queue to port-scheduler.
  - Aggregate-rate-limit.

#### Bandwidth Control at PW Port Level via Vport

Bandwidth control per PW-port (per AN or per AN/ per service), via vport.

- The vport can be created on the binding port.
- The vport can be associated with the PW port either via static assignment or dynamic selection via inter-dest-id (returned from RADIUS or DHCP for a host).
- Aggregate-rate-limit can be configured to shape the egress traffic across all hosts associated with the vport via inter-dest-sting match or via static association of underlying PW port with the vport.

The following output displays a dynamic vport selection based on an inter-dest-id configuration.

```
config>
 Port 1/1/1
 ethernet
 mode hybrid
 encap-type dot1Q
 mtu 1540
 access
 egress
 vport "v1" create
 agg-rate-limit 1000
 host-match dest "dslam-1" ##### hosts will be associated with
 exit ##### vport based on inter-dest-id
 exit
 exit
 exit
 exit

config>service>sdp>binding
 pw-port 11 vc-id 11 create
 egress
 shaping int-dest-id "dslam-1" ##### dynamic vport selection based on
 ##### int-dest-id.
```

The following output displays a static assignment of PW port to vport configuration.

```
config>
 Port 1/1/2
 ethernet
 mode hybrid
 encap-type dot1Q
 access
 egress
 vport "v2" create
 agg-rate-limit 1000
 exit
 exit
 exit
 exit
 exit

config>service>sdp>binding
 pw-port 20 vc-id 20 create
 egress
 shaping vport "v2" ##### static assignment of pw-port to vport.
 exit
 exit
```

### Last Mile Shaping

With normal Ethernet aggregation in the next-mile, when last-mile shaping is on, fixed encapsulation-offset is calculate based on the last-mile encapsulation type and the next-mile encapsulation (26 Bytes with q-in-q). This offset is applied to the frame, and the ATM overhead is then dynamically calculated on the adjusted size. The resulting dynamically calculated overhead in the data-path is then applied to the queue-rates and the subscriber aggregate-rate.

With this feature of backhauling subscriber sessions using MPLS PW in the aggregation network. The last mile does not see any MPLS PW overhead. The next-mile includes overhead due to the PW encapsulation shown in [Figure 140](#). Therefore, when last mile shaping is enabled, the fixed encapsulation-offset is calculated based on the difference between last-mile encapsulation type and next-mile encapsulation, The next-mile encapsulation takes into account the additional PW overhead, which includes:

14B Ethernet header + [4B] (optional network interface Q-tag) + MPLS Labels (variable)

In the data-path the actual PW encapsulation overhead, taking into account the MPLS labels which could be variable (with FRR or PHP) is tracked, and is applied to the computed “encapsulation offset”. This adjusted “encapsulation offset” is applied to the frame. The ATM overhead is then dynamically calculated on the adjusted size, and applied for last mile shaping (to queue-rates and subscriber-aggregate-rate). Note that there is no change from ESM over normal SAPs, in how last-mile shaping is triggered or how the last mile encapsulation type is determined (via configuration in egress context of subscriber profile or dynamically learned from Access-Loop-Encapsulation sub-TLV in vendor specific PPPoE tags).

#### 9.12.2.1.2 BNG Redundancy with ESM over Pseudowire

This feature provides support for stateful BNG redundancy (when the far-end aggregation PE (A-PE) is dual-homed to two BNGs terminating subscriber sessions over MPLS pseudowires (PWs) that are initiated from the A-PE and provides ESM). Subscriber state between BNGs is synced using MCS.

### Epipipe-Based Aggregation Service

For an Epipipe based aggregation service, the redundancy is based on active/standby PWs from A-PE to dual BNGs. A-PE signals active/standby pseudowire status to peer BNGs. An SRRP instance per PW port (group-interface) is required on the BNG with messaging SAP on each PW port. BNG terminating active PW assumes the mastership for the SRRP instance on the corresponding PW port. SRRP state is tied to the state of the messaging SAP. The messaging SAP goes down when the underlying PW-port goes down, based on PW status bit signaled by the A-PE.

In this model, there is no SRRP message exchange between the two BNGs, as there is no Layer 2 path between the BNGs. The purpose of SRRP is to get SRRP-aware routing for subscriber routes and managed routes, and/or to be able to use the redundant (shunt) interface. Downstream traffic for a subscriber that ingresses the backup BNG can only be shunted to the active BNG, if the corresponding subscriber-interface on the backup BNG is operationally UP. This can be achieved by creating a second empty group-interface (without SAPs) on the same subscriber-interface with the knob 'oper-up-while-empty' configured. Multiple PWs with endpoint configuration is not supported on the BNG.

**Figure 141 BNG Redundancy Based on Active/Standby PW Signaling**

### Sample Configuration on Master BNG

```

```

## VPLS-Based Aggregation Service

With VPLS based aggregation service from A-PE, normal SRRP message exchange can take place between the primary and backup BNGs. Master-ship decision and switch-over is based on SRRP. SRRP instance is configured per group-interface corresponding to PW port. Fate-sharing groups (FSG) can be configured for a set of SRRP instances (for example, SRRP instances corresponding to PW ports sharing the same subnet). Standard **oper-group** *grp-id* would need to be configured with messaging SAPs for all PW ports that are in the same FSG, and **monitor-oper-group** *grp-id* would need to be configured under each SRRP instance in same FSG. Existing SRRP support defined in Triple-play services guide for ESM over regular group-interfaces and subscriber SAPs is applicable identically to ESM over PW ports and PW SAPs.

**Note:** With PW over ESM, redundancy in the aggregation network based on MC-LAG between A-PE and dual BNGs is not supported.

**Figure 142 BNG Redundancy with VPLS Based Aggregation Service**

al 0069

### 9.12.2.2 ESM on PXC-Based PW-Ports

This section provides an example on how to configure PW-Port based capture SAP that is used in ESM. For more information on PXC Based PW-Ports, refer to the SR OS Services Overview Guide.

#### PXC Configuration

The following is a PXC configuration example:

```
configure
 port-xc
 pxc 1 create
 port 1/1/1
 no shutdown
 pxc 2 create
 port 2/1/1
 no shutdown
```

With this configuration, ports 1/1/1 and 2/1/1 are auto-provisioned in hybrid mode operating as individual loopback ports. The SR OS system will automatically create a pair of sub-ports per PXC. Those sub-ports are by default in shutdown state:

```
configure
 port pxc-1.a
 shutdown
 port pxc-1.b
 shutdown

 port pxc-2.a
 shutdown
 port pxc-2.b
 shutdown
```

For redundancy purposes and/or increased bandwidth, the PXC sub-ports are aggregated in a LAG:

```
configure
 lag 1 create
 port pxc-1.a
 port pxc-2.a
 lag 2 create
 port pxc-1.b
 port pxc-2.b
```

#### FPE Configuration

A PW-port is associated with PXC via an FPE configuration. FPE configuration facilitates creation of an internal tunnel over PXC. This tunnel is used to map the external PW to the PW-port. For more information on FPE, refer to SR OS Interface Configuration Guide.

The following is an FPE configuration example:

```
configure
 fwd-path-ext
 fpe 1 create
 path xc-a lag-1 xc-b lag-2
 pw-port
```

The association between xc-a/b (cross-connects) and LAG IDs is performed arbitrarily by the operator. For example, it is allowed to associate xc-a with lag-id 2 (which includes PXC sub-ports on the .b side) and xc-b with lag-id 1 (which includes PXC sub-ports on the .a side). However, the FPE will always assign the .a side of the pxc sub-ports to the transit side of the cross-connect, while the .b side of the pxc subport will be assigned to the termination side of the cross-connect. Refer to the PXC Based PW-Ports section in the Layer 2 Services and EVPN Guide: VLL, VPLS, PBB, and EVPN, for further information about transit/termination side of the cross-connect.

### PW-Port Creation

The PW-port must be explicitly created in the SR OS, before mapping between PW and PW-port can be performed.

```
pw-port 100 create
 encap-type qinq
```

### SDP Creation for the External PW

The following displays an SDP configuration for the external PW.

```
configure
 service
 sdp 1 create
 signaling tldp
 far-end 1.1.1.1
```

The PW can be static or dynamically signaled, with MPLS or GRE transport.

### Mapping Between the External PW and the PW-Port

The stitching of the external PW and PW-port is configured through an Epipe in vc-switching mode.

```
configure
 service
 epipe 10 customer 1 vc-switching create
 spoke-sdp 1:100 create
 pw-port 100 fpe 1
```

### Capture PW-SAP Creation

PW-SAPs can be configured as capture SAPs. In this example, a capture PW-SAP with s-tag 3 is created on the pw-port 100.

```
configure
 service vpls 2 create
 sap pw-port-100:3.* capture-sap create
```

From here, ESM functionality is applied to the PW-SAP in the same manner as on any other regular SAP.

### Cross-Connecting SAPs to PW-Ports

In addition to PW termination, a PW-port can become a terminating point for a regular SAP. For example:

```
configure
 service
 epipe 10 customer 1 vc-switching create
 sap 1/1/1:10.* create
 pw-port 100 fpe 1
```

In this example, the outer VLAN tag 10 in the payload is removed on ingress and the payload is delivered to the PW-Port where it can be mapped to a capture PW-SAP. This scenario allows traffic distribution from a single I/O port to different EMS termination points (anchor line cards) based on outer VLANs.

## 9.13 Logical Link Identifier (LLID)

This feature enables service providers to track subscribers on the basis of a virtual-port known as logical line ID (LLID). The LLID (an alphanumeric string) is a logical identification of a subscriber line. Mapping of physical line of a subscriber to LLID is performed via pre-authentication with a separate AAA server than the AAA server used for authenticating the subscriber session during normal access authentication.

LLID serves the purpose of abstracting the physical line of the user from the ISP. If the user moves to a new physical line, the RADIUS server database maintaining the physical line of the subscriber to LLID is updated. Because a subscriber's LLID remains same regardless of subscriber's physical location, using LLID gives service provider a stable and secure identifier for tracking subscriber.

The local user database assigned to the PPPoE node under the group interface can have both a pre-authentication policy and an authentication policy. The purpose of the pre-authentication policy is to retrieve the LLID from the AAA server. The pre-authentication will only extract the calling-station-id attribute (0x31) which is used as the LLID, anything else returned during pre-authentication are simply ignored. If the pre-authentication is missing the LLID, the session will move on to the authentication policy. In the authentication policy that follows, it is possible to use the LLID as the calling-station ID.

It is possible to convey LLID from the LAC to the LNS. The LLID is retrieved through PPPoE pre-authentication where the returned RADIUS attribute calling station ID is used as the LLID. This LLID is selectable attribute in L2TP as a calling-number (AVP 22) to be passed from LAC to LNS. At the LNS, the subscriber calling station number is retrieved from AVP 22 and can be included as an attribute during authentication.

## 9.14 Open Authentication Model for DHCP and PPPoE Hosts

### 9.14.1 Terminology

LUDB – Local User Database configured within the 7450 ESS and 7750 SR

- IP Address Assignment via DHCP Relay — IP address assignment request (DHCP or IPCP) from the host is relayed to an internal or external DHCP server. Gi-address must be present in this relayed request while the pool name is optional. The internal DHCP server may select the IP address from its local pool based on the gi-address or based on the pool-name present in the request. The IP address selection method is configuration dependent. Third party DHCP servers may consider additional fields in IP address selection process (mac address, circuit-id, and so on).
- IP Address Assignment via DHCP Proxy — A preconfigured IP address in LUDB or RADIUS server is handed out to the host via a DHCP proxy function. This proxy function responds natively using DHCP protocol to the IPoE host. Although PPPoE hosts are not utilizing DHCP protocol, the DHCP proxy functionality within the server is still needed for successful IP address delegation to PPPoE hosts.

### 9.14.2 LUDB and RADIUS Access Models

During the subscriber-host instantiation phase, various parameters for the hosts are gathered from a single or multiple sources. These parameters represent the level of service within the router to which the host is entitled. Some of the parameters are mandatory for subscriber instantiation while others are optional. The following lists the parameter sources in the order of priority:

- LUDB
- RADIUS
- DHCP Server — The DHCP server directly queries LUDB
- DHCP option processed on DHCP ACK that is indicated in subscriber identification policy.
- Extraction from the DHCP Ack via Python (IPv4 only)
- Defaults that are statically configured on the node (SAP, msap-policy, capture-sap, and subscriber-identification-policy).

In most cases, the host IP address assignment process is controlled by the parameters returned via LUDB or RADIUS. As such, the IP address delegation is integral part of the host instantiation process and will consequently be described in the following sections.

### 9.14.3 No Authentication

IPoE and PPPoE v4/v6 hosts on static SAPs can be instantiated without the need to access LUDB or RADIUS server. In this case, the default subscriber host parameters (sla-profile, sub-profile, subscriber-id) must be provisioned statically under the SAP. The IP address assignment is provided by internal or external DHCP server. The IP address selection on the router based DHCP server is based on the gi-address while third party DHCP servers may provide additional means to select the IP address (*mac-address*, *circuit-id*, and so on).

A DHCP pool name cannot be provided by an SR-series router DHCP relay agent, since the LUDB and/or RADIUS are not utilized.

This model does not support IP address delegation via DHCP Proxy function since there is no LUDB or RADIUS server available that can supply pre-configured IP address.

Host instantiation without LUDB or RADIUS access on dynamic VLANs (capture SAP and consequently mSAP) is not supported.

### 9.14.4 LUDB Only Access

Subscriber-host authentication, identification and IP address assignment can be performed via LUDB without the need to access the RADIUS server.

The LUDB is normally configured under the **group-interface>ppp/dhcp** hierarchy and can provide subscriber-identification parameters as well as IP addressing parameters:

Pool names for DHCP relay function (IPv4, IPv6 IA-NA, IPv6 IA-PD)

Fixed IP addresses – IPv4, IPv6 IA-NA, IPv6 IA-PD and IPv6 SLAAC prefix.

In case of capture SAP, the LUDB name configured under the capture SAP must match the LUDB name under the **group-interface>dhcp/ppp** hierarchy. If the LUDB names do not match, the subscriber-host instantiation will fail.

### 9.14.5 LUDB Access via DHCPv4 Server

In case that the IPv4 addressing assignment is facilitated by the DHCPv4 relay and an internal DHCPv4 server, the DHCPv4 server itself can query the LUDB for IPv4 address information. LUDB can provide a v4 pool name and IPv4 DHCP options to the DHCPv4 server or it can instruct it to use the gi-address as the IPv4 address selection mechanism.

ESM strings can also be provided via LUDB queried by the DHCPv4 server.

If LUDB access via DHCPv4 server is provided in addition to other authentication means (another LUDB under the group-interface, or RADIUS server), the ESM strings from the LUDB under the grp-interface or from the RADIUS server will have priority over the ESM strings configured under the LUDB accessed by the DHCPv4 server. On the other hand, the IPv4 addressing information will have the highest priority from the LUDB accessed directly by the DHCPv4 server.

Accessing LUDB directly via DHCPv4 server should be used in rare and exceptional cases.

LUDB access under the group-interface, possibly complemented by the RADIUS server will provide necessary means for subscriber-host instantiation in majority of use cases.

### 9.14.6 RADIUS Only Access

Similar to LUDB-only access, RADIUS server can provide all the necessary information for subscriber-host instantiation, including the IP addressing parameters (pool names or IP addresses/prefixes). Authentication-policy which defines the RADIUS access must be applied to the group-interface.

In case of capture SAP, the authentication policy must be applied under the capture SAP. This authentication policy name must match the authentication policy name that is configured under the group-interface. Otherwise, the host instantiation will fail.

### 9.14.7 Consecutive Access to LUDB and RADIUS

LUDB and RADIUS access can be combined during subscriber-host instantiation phase.

Configuration wise, LUDB must be referenced under the **group-interface>dhcp/ppp/pppoe** hierarchy (and possibly under the capture SAP), while the authentication-policy is specified within the LUDB. In this fashion, LUDB access is followed by RADIUS access. The subscriber-host parameters retrieved from both sources are combined with LUDB parameters being prioritized over RADIUS parameters in case that both sources return the same parameters.

In case that LUDB and authentication policy are configured simultaneously under the group-interface (and possibly under the capture SAP), the RADIUS authentication policy will be evaluated and LUDB will be ignored.

### 9.14.8 RADIUS Fallback

In case that RADIUS server is not accessible (non-responsive), the host instantiation phase can be:

Terminated in the case the there is no fallback action within authentication policy specified.

Continued within LUDB if the fallback action within the authentication-policy references LUDB.

Continued without any response from RADIUS. Subscriber-host will be instantiated if defaults parameters are statically configured or the instantiation will fail in case that the defaults are not available.

The fallback action takes effect once the preconfigured RADIUS timeout period expires.

RADIUS fallback is currently not supported for DHCPv6 hosts.

## **9.15 Flexible Subscriber-Interface Addressing (Unnumbered Subscriber-Interfaces)**

### **9.15.1 Terminology**

Subscriber host — A representation of an external host requesting a service. Each such host is fully instantiated within the 7450 ESS and 7750 SR for the purpose of providing traffic control and billing services (for example, QoS, filtering, antispoofing, accounting). The external hosts may represent variety of devices such as regular PCs, STBs, residential gateways, CPEs, VoIP devices. In most cases, the external host will run a DHCPv4/v6 or PPPoEv4/v6 client. DHCP and PPPoE initiation messages from such clients will trigger host instantiation within the router. For this the subscriber host term can be interchangeably used with a term DHCP client or PPPoE client.

### **9.15.2 Flexible Subscriber-Interface Addressing for IPOE/ PPPOE v4/v6 Subscribers**

In certain wholesale/retail environments, the wholesale provider that own the 7450 ESS and 7750 SR -BNG does not know the IP addresses that the retailers will assign to their clients in advance. For this reason, wholesaler's BNG must accept any IP address from retailers and consequently pass it to the client during subscriber-host initiation phase.

**Figure 143 Use Case for Flexible IP Addressing Model**

Flexible addressing of the subscriber-interface assumes two deployment scenarios:

1. Subscriber-interface is unnumbered — For example, there is no explicit assigned IP address. Instead the subscriber-interface borrows the IP address from an existing interface that is operationally UP and is located in the same routing instance (router | vprn).

Note that an interface must have an IP address assigned in order to be operationally UP. Therefore, an unnumbered subscriber-interface must reference another existing interface that is operationally UP in the same routing instance. The subscriber-interface will borrow the IP address from the referenced interface.

In this case any IP address can be assigned to the subscriber host under the unnumbered subscriber-interface. The subscriber IPv4 address will be installed in the FIB as /32 route while IPv6 address will be installed as an entry of the length anywhere between 64 and 128 bits.

2. Subscriber-interface is numbered — The IP address/prefix is explicitly configured and solely owned by the subscriber-interface.

In this case, all subscriber IP addresses/prefixes that fall under the subnet/prefix dictated by the configured subscriber-interface IP address/prefix will be directly aggregated under the subscriber-interface subnet. As such they will occupy a single entry in the FIB. The rest of the subscriber hosts with IP addresses/prefixes that fall outside of the configured range will be installed in the FIB as individual entries (/32 for IPv4 and an entry of the length anywhere between 64 and 128 bits for IPv6 hosts).

### 9.15.3 Default Gateway in IPv4 Flexible Addressing

In scenarios where subscriber host IPv4 address lies within the configured subscriber-interface subnet, the default-gw IPv4 address for the host will be one of the subscriber-interface IPv4 addresses. In this case, the service provider is aware of the IPv4 addressing scheme in the BNG and as such it will supply the DHCP client with the appropriate default-gw IPv4 address via LUDB, RADIUS or DHCP Server (in that order of priority).

In scenarios where the retail service provider wants to maintain independence from the IPv4 addressing scheme deployed in the BNG (that is controlled by wholesaler), the retailer can always supply its own IPv4 address, the subnet mask and the default-gw IPv4 address. But if the default-gw IPv4 address and/or subnet mask is not supplied by the retailer, then they will be auto-generated by the BNG. Once the default-gw IPv4 address is auto-generated, it will be sent to the requesting DHCP client via DHCP offer in option 3 (RFC 2132, Router Option, section 3.5). There is no additional configuration needed for this action. The BNG will automatically detect whether the default-gw IPv4 address is supplied via LUDB, RADIUS or DHCP server and it will act correspondingly.

The default-gw IPv4 address is auto-generated based on the assigned IPv4 address/mask by setting the last bit of the assigned host IPv4 address to binary 01 or binary 10. For example if the subscriber host's assigned IPv4 address is 10.10.10.10 255.255.255.0, then the default-gw IPv4 address is set to 10.10.10.1. If the assigned IPv4 address is 10.10.10.1 255.255.255.0, then the auto-generated default gateway IPv4 is set to 10.10.10.2.

The default gateway IPv4 address will always have to be within the subscriber's subnet. If it is not, the behavior might be inconsistent. For example:

1. RADIUS (or DHCP) returns IP@, mask and def-gw:
  - IP 10.10.10.1
  - Subnet mask 255.255.255.0
  - Def-gw 10.10.0.254

The subscriber will be successfully instantiated in the BNG but the client may not ARP for a default-gw outside of its configured subnet. Whether the client will or will not ARP for a default-gw outside of its configured subnet will depend on the implementation in the RG and CPE.

- RADIUS returns IP@ and subnet mask.
  - In this case the auto-generated default-gw IPv4 address will always be within subscriber's subnet.

Flexible IPv4 addressing with auto-generated default-gw is supported only in Routed Central Office (RCO) model with routed residential gateways (RGs) or CPEs. In RCO model with bridged residential gateways or CPEs, the default-gw IPv4 addresses and the assigned IPv4 addresses may overlap. Once the IPv4 address of the default-gw is auto-generated, it is possible that the second host behind the bridged residential gateway or CPE is assigned the same IPv4 address as the IPv4 address of the default gateway of the first host. Such hosts would not be able to communicate with outside world.

For example:

RADIUS or DHCP server assigns IPv4 address and subnet mask to the first host in a bridged environment:

IP1: 10.10.10.1

Auto-generated default-gw IPv4 address: 10.10.10.2

Since the RADIUS and DHCP Server are not aware of the auto-generated default-gw, they may assign the following IPv4 address to the second host that comes on-line:

IP 2: 10.10.10.2 (same IPv4 address as the default-gw IPv4 address of the first host)

Auto-generated default-gw IPv4 address: 10.10.10.1

Now the first host will forward all traffic outside of the configured subnet to the second hosts which will discard this traffic, effectively rendering this operation model non-deployable. And vice versa.

## 9.15.4 IPv4 Subnet Sharing

Subnet sharing between the hosts in flexible IPv4 addressing model is supported. In other words, in flexible IPv4 addressing model the operator can assign all IPv4 addresses (minus one – the default-gw IPv4 address) from a given subnet. In this fashion, all subscribers (routed RGs or CPEs) within a single subnet can share the same default gateway.

For example if the operator owns the IPv4 subnet 10.10.10.0/24, then one IPv4 address can be set aside for the default-gw (for example 10.10.10.254) and the remaining addresses can be assigned to the subscriber (routed RGs or CPEs). An example would be:

RG1: IP=10.10.10.1/24 def-gw 10.10.10.254

RG2: IP=10.10.10.2/24 def-gw 10.10.10.254

RG3: IP=10.10.10.3/24 def-gw 10.10.10.254

:

RG100: IP=10.10.10.100/24 def-gw 10.10.10.254

The subnet sharing is also supported in conjunction with auto-generated default-gw IPv4 address. The implication of this is that the IPv4 address of the default-gw can collide with the same IPv4 address already assigned to an existing subscriber. This is not an issue for routed RGs or CPEs since the BNG will always answers ARPs for the IPv4 address of the default-gw with its own MAC address. However, local-proxy ARP functionality in the 7450 ESS and 7750 SR -BNG must be enabled to support this.

This behavior can be further clarified with the following example.

Let's assume that we have scenario with two routed RGs:

RG-1, IP=10.10.10.0/24, default-gw IP=10.10.10.1

RG-2, IP=10.10.10.1/24, default-gw IP=10.10.10.0

Once RG-1 ARPs for its default gateway of 10.10.10.1, the BNG will reply with its own MAC address.

Now that host RG-1 has resolved ARP for its default-gw (MAC address pointing to the router), it can send traffic to the outside world via the BNG. When such traffic arrives to the router, the destination IPv4 address of the received packet will determine the forwarding decision within the router. If the destination IPv4 address matches the IPv4 address of any subscriber (RG) instantiated within the system, the traffic will be forwarded to that RG. This also includes the case where the destination IPv4 address is the default-gw IPv4 address (10.10.10.1), which represents just another RG within the router. The traffic will be consequently passed from RG-1 via 7450 ESS and 7750 SR to RG-2.

### 9.15.5 IPv4 Subnet Mask Auto-Generation

The subnet mask corresponding to the IPv4 address assigned to the subscriber is auto-generated in case that the IPv4 addressing authority (LUDB, RADIUS or DHCP Server) does not supply it. The subnet mask is derived from the IPv4 address of the subscriber and possibly the default-gw IPv4 address and it is the smallest subnet that contains both, the IPv4 address of the subscriber and the default-gw.

For example if the RADIUS received IPv4 address is 10.10.10.138 and the received default-gw IPv4 address is 10.10.10.170, then the subnet mask will be auto-generated and set to 255.255.255.192 (/26).

138 = 10001010

170 = 10101010

192 = 11000000

In case that neither the subnet mask nor the default-gw are returned, then both would be auto-generated:

1. Subnet mask would be set to /31
2. Default-gateway which must belong to the subscriber's subnet would be set to 10.10.10.139.

In cases where the host IPv4 address and the default-gw are directly supplied by the addressing authority but the subnet mask is missing, the subnet mask auto-generation may cause the host part of the default-gw IPv4 address to become a broadcast IPv4 address. If this is an issue, then it can be avoided by directly providing the subnet mask via the addressing authority.

## 9.15.6 Local-proxy-arp and arp-populate

Local-proxy-arp and arp-populate are two commands that are relevant only to IPoEv4 hosts.

Local-proxy-arp command ensures that the router answers ARP Requests with its own MAC address for any 'active' IPv4 address under the subnet on which the ARP request arrived. The 'active' IPv4 address is considered the one that is assigned to an already instantiated hosts or the default-gw (even auto-generated).

In absence of local-proxy-arp command, the only ARP Request that the router will answer is the one for the statically configured IPv4 addresses of the subscriber-interface. In flexible IPv4 addressing, the IPv4 address of the default-gw does not necessarily match any of the configured subscriber-interface IPv4 addresses. The ARP Request for such default-gw IPv4 address would go unanswered. Consequently, the subscriber hosts would not be able to communicate with outside world. Therefore, the flexible IPv4 addressing requires that the local-proxy-arp command is configured.

Arp-populate command disables dynamic learning of ARP entries (IPv4<->MAC mapping) on an interface based on the ARP protocol. In this case, the ARP table is populated based on the DHCPv4 lease state table which contains IPv4<->MAC mappings obtained via DHCP processing during the host instantiation phase. Arp-populate functionality is highly desirable in case of flexible IPv4 addressing.

When the **arp-populate** command is disabled the ARP entries are dynamically learned based on the ARP protocol. This, in conjunction with flexible IPv4 addressing may cause certain issues. Consider the following example:

- The subscriber-host is instantiated in the 7450 ESS and 7750 SR
- The subscriber-interface is unnumbered
- The ARP table does not contain an ARP entry for the subscriber-host

In this case, downstream traffic towards the subscriber host will trigger the router to send ARP Request for the subscriber host IPv4 address. The router needs to know the MAC address of the subscriber-host in order to forward traffic. Since the subscriber-interface is unnumbered, the source IPv4 address of the ARP request is unknown and consequently the ARP request will not be sent. As a result, downstream traffic is dropped.

Note however that the above example is an unlikely scenario. If the subscriber host sends the ARP request for the default-gw first, the router would create an entry in the ARP table for it and the issue would be resolved. This is the most likely outcome since the subscriber host will always try to initiate communication with the outside and therefor ARP for the IPv4 address of the default-gw (which is a 7450 ESS and 7750 SR ).

## 9.15.7 Gi-address Configuration Consideration

With flexible IPv4 address assignment, the gi-address can be configured as any IPv4 address that is already assigned to an interface (loopback interface, regular interface attached to physical port or subscriber interface) within the same routing instance (VRF or GRT).

## 9.15.8 PPPoE Considerations

PPPoE subscriber hosts do not have the concept of default-gw. Consequently the default-gw auto-generation concept does not apply to PPPoE hosts.

## 9.15.9 IPoEv6 Considerations

The default-gw for IPoEv6 hosts is link-local IPv6 address. Since this address is always present, there is no need for auto-generation during the subscriber instantiation time.

SLAAC hosts are installed as /64 entries, the length of the installed DHCP-PD prefix is dictated by the prefix-length and the DHCP-NA hosts are installed as /128 entries.

## 9.15.10 General Configuration Guidelines for Flexible IP Address Assignment

Flexible IP addressing for IPoE/PPPoE v4 and v6 hosts is by default disabled. In other words, the subscriber hosts will be instantiated in the BNG with ability to forward traffic only if their assigned IP addresses belong to one of the configured subnets/prefixes that are associated with the subscriber-interfaces. IPv4 and IPv6 cases will be examined separately:

### IPv4:

By default, IPoE and PPPoE subscriber host creation will fail in the following two cases:

1. The subscriber-interface does not have an IPv4 address configured, and therefore it will be operationally down. This configuration is also known as unnumbered subscriber-interface.
2. The subscriber-interface does have an IPv4 address configured but the IPv4 address assigned to the subscriber host itself is outside of the subscriber-interface configured subnet(s). In such case the host will be instantiated but the forwarding will be disabled.

Subscriber host instantiation and forwarding can be explicitly enabled for both cases above with flexible IP addressing functionality.

For case 1, this can be achieved by borrowing an IP address for the subscriber-interface from any interface that is operationally up within the given routing context. This functionality can be enabled with the following command:

```
configure service ies <id>
configure service vprn <id>
subscriber-interface <intf-name>
unnumbered <ip-addr | interface-name >
```

To enable forwarding for the subscribers whose IP address falls outside of the configured subnet under the subscriber-interface (case 2), the following command must be entered:

```
configure service ies <id>
configure service vprn <id>
 subscriber-interface <intf-name>
 allow-unmatching-subnets
```

The above commands (**unnumbered** and **allow-unmatching-subnets**) are mutually exclusive. In addition, the unnumbered command can be configured only if the subscriber-interface does not have an IP address already configured. Otherwise the execution of this command will fail.

In both of these cases the host will be installed in the routing table as /32.

### IPv6:

For IPv6 there is a single command that will enable flexible IP addressing for both cases:

1. IPv6 prefixes are not configured under the **subscriber-interface>ipv6** node
2. IPv6 prefixes are configured but the actual address or prefix assigned to the subscriber (via DHCP, LUDB or RADIUS) is outside any prefix that is configured under the **subscriber-interface>ipv6** hierarchy.

This single command is:

```
configure service ies <id>
configure service vprn <id>
 subscriber-interface <name>
 ipv6
 allow-unmatching-prefixes
```

To summarize, the following scenarios are possible:

- PPPoEv4

- An IPv4 address under the subscriber-interface is configured

- By default hosts outside of the sub-intf subnet are instantiated but they are in a non-forwarding-state. Traffic is dropped.
    - **allow-unmatching-subnets** is configured. This command is allowed only if subscriber-interface has also configured its own IPv4 address(es). In this case the IP address for IPCP negotiation is one of the sub-intf addresses. Hosts outside of the sub-intf subnets are instantiated and forwarded.

- The **unnumbered** `<ip-address | intf>` command is not allowed in this scenario.
- An IPv4 address under the subscriber-interface is not configured
  - By default, the subscriber-interface is operationally down. Subscribers cannot be instantiated.
  - The **allow-unmatching-subnets** command has no effect since subscriber-interface does not have an IPv4 address configured and is therefore operationally down. No subscribers can be instantiated.
  - The **unnumbered** `<ip-address | intf>` command is the only viable option in this case. The subscriber-interface borrows an IPv4 address from another interface that is operationally UP and consequently this allows subscribers to be instantiated. This command is mutually exclusive with **allow-unmatching-subnets**. In addition, this command can only be configured if the subscriber-interface itself does not have explicitly configured an IPv4 address.
- IPoEv4

Similar to the PPPoE case above.

- IPoEv6 and PPPoEv6 — the **allow-unmatching-prefixes** command is independent of any IPv4 command related to flexible IP address assignment (**unnumbered** or **allow-unmatching-subnets**). This command can always be enabled, regardless of the v6 prefixes configured under the **subscriber-interface>ipv6** hierarchy. Any subscriber, regardless of the subscriber-interface prefix configuration will be instantiated and forwarded.

### 9.15.11 Caveats

- Auto-generation of the default-gw IPv4 address is supported only in RCO model with routed RGs/CPEs. Bridged RGs/CPEs are not supported.
- A configured IPv4 address cannot be removed from the subscriber-interface when DHCPv4 hosts under the corresponding subnet are instantiated in the system.
- An IPv4 address cannot be configured under the subscriber-interface while (unnumbered) DHCPv4 hosts under that subnet are already instantiated.
- Executing the **no allow-unmatching-subnets** command is only allowed when there are no unnumbered DHCPv4 hosts instantiated under the subscriber-interface.

## 9.16 uRPF for Subscriber Management

uRPF is supported for IPv4 and IPv6 dual-stack subscribers with framed routes.

For IPv4, uRPF is supported on group interfaces using anti-spoofing filters. A group interface configured for NATed subscribers will be configured with MAC/IP/PPPoE Session-ID anti-spoofing filters.

IPv6 subscribers, which are non-NAT, are always treated as being on a local subnet. For such subscribers, a BNG will install a FIB entry for local routes that match either the wan-host prefix, or the delegated prefix, or both. In strict mode for IPv6 ESM, the uRPF check will check not just that the route matching the SA (which should be a local route, i.e. a subnet) would route the packet back out of the interface it came in on, but in addition that we would route the packet out to the same SAP it was received on.

SROS supports the ability to configure a NH-MAC anti-spoof type for non-NATed subscribers. When configured, the datapath performs ingress anti-spoofing based on source MAC address and egress anti-spoof (also referred to as egress subscriber-host look-up) based on the nh-ip address.

The NH-MAC anti-spoof type is configured under the following context:

```
config>service>vprn>if>sap
```

```
config>service>ies>sub-if>grp-if>sap
```

```
config>service>vprn>sub-if>grp-if>sap
```

```
config>subscr-mgmt>msap-policy
```

A uRPF check is also performed that prefixes delegated to a subscriber on that MAC address exist in the FIB.

## 9.17 IPoE Sessions

The IP stacks of dual stack IPoE devices are set up and configured independently using different protocols such as DHCPv4, DHCPv6 or SLAAC. As opposed to PPPoE, there is no single protocol that binds the IP stacks from a single end device together.

To facilitate subscriber management of dual stack IPoE devices as a single entity similar as for PPPoE sessions instead of handling individual IPoE subscriber hosts, there is a need for a logical IPoE session construct. An IPoE session enables single authentication, session accounting and policy management (mid-session changes) for dual stack IPoE devices.

An IPoE session is a logical grouping of IPoEv4 and IPoEv6 subscriber hosts that represent the different IP stacks of a single end device and that share authentication data such as subscriber id, subscriber and SLA profile, session-timeout, etc. The grouping of subscriber hosts in an IPoE session is based on a configurable session key per group-interface. The IPoE session key includes by default the SAP identifier and MAC address and can be extended with Circuit-Id/Interface-Id or Remote-Id. For DHCPv6 Remote-Id, the enterprise number is excluded from the session-key. Circuit-id/Interface-Id or Remote-id should only be used in the IPoE session key if all subscriber host associated with the IPoE session have this field in their protocol trigger packets. The IPoE session creation or subscriber host association to an IPoE session fails if the Circuit-Id/Interface-Id or Remote-id is not present in a trigger packet while the field is part of the session-key.

**Figure 144 IPoE Session**

al\_0631

An IPoE session represents a single end device and can have following associated IP stacks:

- IPv4 — A single DHCPv4 host.
- IPv6 WAN — One DHCPv6 IA-NA host and/or one SLAAC host.
- IPv6 PD — One DHCPv6 IA-PD host or PD as managed route.

A violation of the above rules will result in a setup failure of the subscriber host when an attempt is made to associate it to the IPoE session.

## 9.17.1 Enabling IPoE Sessions

IPoE sessions are supported in a Routed CO environment with Enhanced Subscriber Management (ESM) enabled. To enable the IPoE session instantiation, the **ipoe-session** CLI context on the capture SAP (managed SAP scenario) and/or group-interface must be configured to no shutdown. See also the configuration steps below.

### Important Notes:

- Enabling IPoE sessions on a group-interface with active subscriber hosts will trigger a migration. Use one of the following CLI command to determine if there are active hosts on a group-interface:
  - Check the number of subscriber hosts on a group-interface:  
Note that DHCPv6 IA-PD modeled as a managed route are not counted with this command.  
`show service id <service-id> subscriber-hosts detail | match <group-int-name> | count`
  - Check the number of IP stacks (Client types) attached on a group-interface.  
`tools dump router <router-instance> ipoe-session migration interface <group-int-name>`  
The active number of IP stacks (Client types) on the group-interface are listed per type as well as if they are associated with an IPoE session or not.  
Note that DHCPv6 IA-PD modeled as a managed route is also counted in the DHCPv6 type counter.
  - Check the number of DHCPv4 leases, DHCPv6 leases and SLAAC hosts on the group-interface that are not attached to a session:  
`# show service id <service-id> dhcp4 lease-state interface <group-int-name> session none`  
`# show service id <service-id> dhcp6 lease-state interface <group-int-name> session none`  
`# show service id <service-id> slaac host interface <group-int-name> session none`  
Note that DHCPv6 IA-PD modeled as a managed route is also counted in the DHCPv6 lease state counter.
- If there are active hosts on the group-interface, make sure you have read the “IPoE session migration” section prior to enabling IPoE sessions.
- Disabling IPoE sessions by executing an ipoe-session shutdown or no ipoe-session CLI command on a group-interface will delete all active sessions and associated hosts on that group interface, resulting in service impact for these subscribers. Use one of the following CLI commands to determine if there are active ipoe-sessions on a group-interface:

```
show service id <service-id> ipoe session interface <group-int-name>
```

```
tools dump router <router-instance> ipoe-session migration interface <ip-int-name>
```

If there are active IPoE sessions on the group-interface, be aware that disabling IPoE sessions on the group-interface will result in service impact for those sessions.

## 9.17.2 IPoE Session Authentication

A single authentication is performed for all subscriber hosts that belong to the same IPoE session. The table below lists the packets that trigger an IPoE session authentication.

**Table 69** IPoE Session Authentication Trigger Packets

| IP stack | Trigger packets                |
|----------|--------------------------------|
| IPv4     | DHCPv4 Discover                |
|          | DHCPv4 Request                 |
| IPv6 WAN | DHCPv6 Solicit                 |
|          | DHCPv6 Request                 |
|          | DHCPv6 Relay Forward (Solicit) |
|          | DHCPv6 Relay Request (Solicit) |
|          | Router Solicitation            |
| IPv6 PD  | DHCPv6 Solicit                 |
|          | DHCPv6 Request                 |
|          | DHCPv6 Relay Forward (Solicit) |
|          | DHCPv6 Relay Request (Solicit) |

When a trigger packet is received on a capture SAP or group-interface with IPoE sessions enabled, an IPoE session lookup is performed based on the configured IPoE session key:

- If no IPoE session is found, a new session is created and authenticated following the ESM authentication configuration such as local user database lookup, Radius or Diameter authentication, defaults, and such. After successful authentication, the authentication data is stored in the IPoE session state. The subscriber host is created and associated with the session.

- If an IPoE session already exists, and no re-authentication must be performed then the subscriber host is created using the stored IPoE session data. The subscriber host is associated with the session.
- If an IPoE session already exists, and re-authentication must be performed then the session is re-authenticated. When successful, the authentication data for the IPoE session is updated and applied to all associated hosts. The subscriber host is created and associated with the session. When unsuccessful, existing hosts associated with the session are not impacted and the session data is kept unchanged.

Re-authentication is by default disabled for IPoE sessions. To enable re-authentication, a minimum authentication interval must be configured. The min-auth-interval CLI parameter configures the maximum frequency of re-authentications by specifying a minimum interval between two non-forced authentications for the same IPoE session. A re-authentication is triggered by the renewal of any host belonging to the IPoE session. Setting the min-auth-interval to zero seconds, will always re-authenticate on each trigger packet. The re-authentication CLI knob in a Radius authentication policy is ignored for IPoE session authentication.

A forced authentication is performed when the Circuit-Id/Interface-Id or Remote-Id in the trigger packet has changed. An empty or absent Circuit-Id/Interface-Id or Remote-Id is not considered as a change. The default forced authentication behavior is changed with the force-auth CLI command in the group-interface ipoe-session context: only force authenticate on Circuit-Id/Interface-Id change or only force authenticate on Remote-Id change or disable forced authentications.

A new local user database config in the ipoe-session CLI context on a capture SAP or group interface ensures that all subscriber hosts associated with an IPoE session are using the same database and therefore common match criteria. The per subscriber host type user-db configs, such as **ipv6 dhcp6 user-db**, **dhcp user-db** and **rtr-solicit-user-db** are ignored when IPoE sessions are enabled.

### 9.17.3 IPoE Session Accounting

All Radius accounting modes can be enabled for IPoE sessions: queue instance accounting, host accounting or session accounting.

With session accounting, a Radius accounting start is generated when the first host of the session is created and an accounting stop when the last host of the session is deleted. The generation and interval of periodic interim updates can be configured. Optionally, triggered interim update messages can be generated when a host is deleted from the session or an additional host is associated.

A unique accounting session id is generated for the IPoE session and is used in RADIUS session accounting. The IPoE session accounting session id can be included in the Radius Access Request message via CLI **config>subscriber-mgmt>auth-plcy# include-radius-attribute acct-session-id session**.

This accounting session ID can also be used in RADIUS CoA or Disconnect Messages to target the IPoE session.

## 9.17.4 IPoE Session Mid-Session Changes

Mid-session changes such as those initiated via RADIUS CoA or Diameter Gx RAR are applied to all hosts associated with the IPoE session.

A RADIUS CoA message targeting any host of an IPoE session has the same effect as a Radius CoA message targeting the IPoE session using the IPoE session Acct-Session-Id as key: all host of the session are targeted and the session state is updated with the new data.

The following tools commands are available to manually enforce a mid-session change:

```
tools perform subscriber-mgmt edit-ipoe-session sap <sap-id> mac <mac-address>
[subscriber <sub-ident-string>] [sub-profile-string <sub-profile-string>] [sla-
profile-string <sla-profile-string>] [inter-dest-id <intermediate-destination-id>]
[ancp-string <ancp-string>] [app-profile-string <app-profile-string>] [circuit-id
<circuit-id>] [remote-id <remote-id>]

tools perform subscriber-mgmt eval-ipoe-session [svc-id <service-id>] [sap <sap-
id>]
[mac <mac-address>] [circuit-id <circuit-id>] [remote-id <remote-id>] [subscriber
<sub-ident-string>]
```

## 9.17.5 IPoE Session Termination

When the last subscriber host associated with an IPoE session is deleted from the system, then the IPoE session is also deleted.

An IPoE session and all associated subscriber hosts can be deleted via

- CLI clear command: **clear service id <service-id> ipoe session**
- An **ipoe-session no shutdown** CLI command on a group-interface
- A **no ipoe-session** CLI command on a group-interface. This command resets to the default behavior, which is IPoE sessions disabled.

- Session timeout, configured in the IPoE session policy or obtained from AAA
- Idle timeout
- RADIUS Disconnect Message
- Diameter Gx session termination
- Credit Control: Radius or Diameter Gy

## 9.17.6 Limiting the Number of IPoE sessions

The number of IPoE sessions per SAP is limited with the **sap-session-limit** CLI command configured in the **group interface ipoe-session** context.

The number of IPoE sessions per group interface or retail subscriber interface is limited with the **session-limit** CLI command configured in the group interface ipoe-session or retail subscriber interface ipoe-session context.

Hosts associated with IPoE sessions are subject to the SLA Profile Instance limits configured in the **sla profile >config>subscr-mgmt>sla-prof>host-limits>** CLI context.

## 9.17.7 SAP Session Index

The system will keep track of the number of IPoE sessions active on a given SAP and assign a per SAP session index to each such that always the lowest free index is assigned to the next active IPoE session. When RADIUS authentication is used, the SAP session index can be sent to, and received from, the RADIUS server using the [26-6527-180] Alc-SAP-Session-Index attribute.

It should only be used in a subscriber per VLAN model as the session index is per SAP.

The intended use of the SAP session index is to provide the ability for IPoE sessions in a bridged RG environment to have their own set of queues (for QoS and accounting purposes) when using the same SLA profile name received from a RADIUS server. See Subscriber per PPPoE Session Index for details.

---

## 9.17.8 Resiliency

For non-redundant BNG deployments, the IPoE session state is stored in the subscriber-mgmt persistency file for recovery from Compact Flash after a node maintenance operation or failure. This is configured at the system persistence CLI context.

For multi chassis redundancy scenarios, the IPoE session state is synchronized via the “sub-mgmt ipoe” Multi Chassis Synchronization (MCS) application.

## 9.17.9 Notes

- Static hosts can be configured on a group-interface with IPoE sessions enabled. A static host will not be associated with an IPoE session.
- Up to sixteen Framed-Routes and sixteen Framed-IPv6-Routes can be associated with an IPoE session.
- A fall back action (accept or local user database lookup) when no Radius servers are available for Radius authentication can be specified for IPoE sessions.
- Lawful Intercept sources initiated from Radius always include all IP stacks from the IPoE session regardless the targeted host in the CoA message.
- ARP hosts are not supported in an IPoE session and cannot be instantiated on a group-interface with IPoE sessions enabled.
- The creation of an IPv4 host using the Alc-Create-Host attribute in a Radius CoA message is not supported on a group-interface with IPoE session enabled.
- A local user database host identification based on option60 is ignored when authenticating an IPoE session.
- Radius authentication of an IPoE session fails when the user-name-format is configured to dhcp-client-vendor-options, mac-giaddr or ppp-user-name
- The alc.dtc.setESM() API in the DHCP Transaction Cache (DTC) Python module cannot be used in combination with IPoE sessions.
- The DHCP Python module (alc.dhcp) used to derive subscriber host attributes from a DHCPv4 ACK message is not supported in combination with IPoE sessions.
- A Radius CoA message containing an Alc-Force-Nak or Alc-Force-Renew attribute is not supported for IPoE sessions
- Subscriber Host Connectivity Verification (SHCV) will continue to work on a per-stack basis. In other words, in a dual stack scenario with SHCV action remove enabled for both stacks, a failure in IPv4 connectivity will not clean up the session unless the IPv4 subscriber host was the last associated host.

## 9.17.10 Configuration Steps

To create an IPoE session policy:

```
config
 subscr-mgmt
 ipoe-session-policy "ipoe-policy-1" create
 description "Default IPoE session policy"
 session-key sap mac # default
 no session-timeout # default
 exit
```

Enable IPoE sessions on the capture SAP and/or group interface.

If IPoE sessions is enabled on a capture-sap, then it must also be enabled on the target group-interface. If an IPoE session local user database lookup is configured at the capture-sap, then the same local user database lookup must be configured at the target group-interface.

```
config
 service

 vpls 10 customer 1 create
 ---snip---
 sap 1/1/4:*. * capture-sap create
 ---snip---
 ipoe-session
 description "IPoE sessions - capture-sap"
 ipoe-session-policy "ipoe-policy-1"
 user-db "ludb-1"
 no shutdown
 exit

 ies 1000 customer 1 create
 subscriber-interface "sub-int-1" create
 ---snip---
 group-interface "group-int-1-1" create
 ---snip---
 ipoe-session
 description "IPoE sessions - IES group-interface"
 force-auth cid-change rid-change # default
 ipoe-session-policy "ipoe-policy-1"
 min-auth-interval infinite # default
 sap-session-limit 1 # default
 session-limit 1000
 user-db "ludb-1"
 no shutdown
 exit
```

To display the IPoE session state, use following command:

```
show service id <service-id> ipoe session [detail]
```

## 9.17.11 IPoE Session Migration

This section is only applicable when enabling IPoE sessions on a group interface with active subscriber hosts. When there are no active subscriber hosts on a group interface, there is no need for a migration. Use one of the following CLI commands to determine if there are active hosts on a group interface:

- Check the number of subscriber hosts on a group interface:  
# show service id <service-id> subscriber-hosts detail | match <group-int-name> | count  
DHCPv6 IA-PDs modeled as a managed route are not counted with this command.
- Check the number of IP stacks (client types) attached on a group interface.  
# tools dump router <router-instance> ipoe-session migration interface <group-int-name>  
The number of active IP stacks (client types) on the group interface are listed per type whether or not they are associated with an IPoE session.  
DHCPv6 IA-PDs modeled as a managed route are also counted in the DHCPv6 type counter.
- Check the number of DHCPv4 leases, DHCPv6 leases, and SLAAC hosts on the group interface that are not attached to a session:  
# show service id <service-id> dhcp4 lease-state interface <group-int-name> session none  
# show service id <service-id> dhcp6 lease-state interface <group-int-name> session none  
# show service id <service-id> slaac host interface <group-int-name> session none  
DHCPv6 IA-PDs modeled as a managed route are also counted in the DHCPv6 lease state counter.

By default, IPoE sessions are disabled on a group interface (**ipoe-session shutdown**). Enabling IPoE sessions on a group interface with active subscriber hosts starts a migration process and should be planned carefully to allow a seamless migration.

A migration is required due to the nature of IPoE sessions: a single authentication is performed for all hosts (IP stacks) of a dual-stack end device. All hosts (IP stacks) in an IPoE session share the same MAC address, SAP, and optionally Circuit-ID / Interface-ID or Remote-ID which are configured as the **session-key** in the **ipoe-session-policy**. To determine if hosts (IP stacks) belong to a single session, a new trigger packet is required to obtain the session key.

To guarantee a correct IPoE session configuration and a correct authentication database, the migration is performed when the host state is renewed and a new trigger packet is received:

- DHCPv4 renew or rebind for DHCPv4 hosts
- DHCPv6 renew or rebind for DHCPv6 hosts (IA-NA and IA-PD)
- DHCPv4 renew for IPoE linked SLAAC hosts
- Router Solicit for RS triggered SLAAC hosts

The duration of a migration is therefore dependent on the lease times for DHCPv4 and DHCPv6 hosts and for IPoE linked SLAAC hosts. If possible, the lease times could temporarily be reduced to a couple of hours to facilitate the migration process.

The actual migration is started by the arrival of a new trigger packet of an IP stack (host) that is not associated with an IPoE session. The IPoE session key is composed of the data in the trigger packet (MAC address and SAP, by default). If an IPoE session exists for the obtained IPoE session key, the corresponding session data is used for authentication. If no IPoE session exists for the obtained IPoE session key, authentication is performed, and based on the result, a new IPoE session is created. The old host state is deleted from the system and a trap is sent to indicate that this host is being migrated. A new host (IP stack) is created and associated with the IPoE session. When RADIUS accounting is enabled, this may result in an accounting start and stop depending on the accounting mode. For host accounting, an accounting stop is followed immediately by an accounting start. For queue instance accounting, an accounting stop is generated when the last host associated with the queue instance is migrated. An accounting start is generated when the first host is associated with the IPoE session.

The following notes must be taken into account for the migration procedure:

- For multi-chassis redundant nodes, IPoE sessions should be enabled first on the standby node and immediately thereafter on the active node.
- A renew as part of a DHCPv4 lease split operation will not trigger a migration to the IPoE session. The migration starts only when the renew is forwarded to the DHCP server.
- For DHCPv4 RADIUS proxy scenarios, it is recommended that the lease time be specified with the [26-6527-174] Alc-Lease-Time RADIUS attribute instead of the [27] Session-Timeout attribute. After migration, the [27] Session-Timeout attribute is interpreted as the number of seconds before the session is terminated.
- DHCPv6 IA-PD modeled as a managed route may migrate separately from the IPv6 SLAAC host it is associated with for its next-hop. This could result in a temporary service impact until both the managed route and next-hop host are migrated.

- The migration of idle Router Solicit SLAAC hosts can be facilitated by specifying an inactivity timer.
- When the subscriber ID is auto-generated (**auto-sub-id**), then a new **sub-id** will be generated after migration. This may result in a temporary increase in used resources such as queues until all hosts from a subscriber are migrated.

Example high-level migration steps.

### Important Notes

- It is recommended that a migration plan be built for the target network and validate the plan in advance in a lab environment.
- It is recommended that the migration be performed per group interface or capture SAP with all possible target group interfaces and that the next migration only be started when the previous one is successfully completed.
- When managed SAPs (MSAPs) are used, enabling an IPoE session on a group interface while not enabling IPoE sessions on the corresponding capture SAP, or enabling an IPoE session on a capture SAP while not enabling IPoE sessions on the target group interface, will result in session setup failures for sessions where no MSAPs exist.

1. Using the CLI commands described at the beginning of this section, check if an IPoE session migration is applicable. A migration is not required when there are no active subscriber hosts on the target group interfaces.
2. Check if all preconditions are met:
  - a. There are no conflicting requirements with IPoE sessions such as ARP host support on the same group interface or local user database authentication based on option 60. Check the Notes section above for a list of possible conflicts.
  - b. IPoE session configuration is complete on the group interfaces and corresponding **capture-sap: ipoe-session-policy** (session-key) and on the optional local user database. On the group interfaces, the IPoE session limits should be configured as needed using the **session-limit** and **sap-session-limit** commands.
  - c. Authentication servers are up to date to provide all required authentication data for a single dual-stack end device based on single authentication (for example, return both IP address and IPv6 prefix in a proxy scenario).
  - d. Accounting servers are ready to deal with accounting stop/start when hosts migrate to an IPoE session.

3. Take a snapshot of the active hosts before the migration. Use the commands as described above. The following command provides a summary view:  
# tools dump router <router-instance> ipoe-session migration interface <group-int-name>
4. Start the migration by enabling an IPoE session on the group interface and for MSAPs, by enabling an IPoE session on the capture SAP.
5. Monitor the progress during migration. Look at the events (for example, by using the **show log log-id 99** command) and check the number of hosts migrated with the CLI command:  
# tools dump router <router-instance> ipoe-session migration interface <group-int-name>

The following event is generated when a host is deleted due to migration:

4 2015/06/

29 19:37:57.47 UTC WARNING: SVCMGR #2559 Base IPoE session "IPoE session migration

deleted host 2001:db8:2:101::1 on SAP 1/1/4:1201.2 in service 1000"

2 2015/06/29 19:37:29.41 UTC WARNING: SVCMGR #2559 Base IPoE session "IPoE session

migration deleted host 10.1.1.101 on SAP 1/1/4:1201.2 in service 1000"

DHCP lease states and SLAAC host states associated with IPoE sessions can be found with:

# show service id <service-id> dhcp4 lease-state interface <group-int-name> session

ipoe

# show service id <service-id> dhcp6 lease-state interface <group-int-name> session ipoe

# show service id <service-id> slaac host interface <group-int-name> session ipoe

The migration is finished when all hosts are associated with an IPoE session.

The counters in the column "Non IPoE session" should be all zero. For example:

# tools dump router ipoe-session migration interface group-int-1-1

=====

=====

| Type session | Total | IPoE session | Non IPoE |
|--------------|-------|--------------|----------|
|--------------|-------|--------------|----------|

=====

=====

Group-interface: group-int-1-1 (IPoE session enabled)

|        |       |       |   |
|--------|-------|-------|---|
| DHCPv4 | 16384 | 16384 | 0 |
| DHCPv6 | 16384 | 16384 | 0 |
| SLAAC  | 4096  | 4096  | 0 |

```

IPoE sessions 20480
=====
=====
```

6. Perform post migration steps. For example, verify that the number of users prior to and after the migration are in the same order of magnitude (users may connect and disconnect during the migration). Enable session accounting if required.

### 9.17.11.1 Additional Notes for IPoE Session Migration of IPv4 Hosts as a Control Channel for Dynamic Data Services

During the migration of an IPv4 host as a control channel for Dynamic Data Services to an IPoE session as a control channel, the associated dynamic data services will be deleted and recreated based on the IPoE session authentication data.

When IPoE sessions are enabled on the group interface, at the next DHCPv4 renew or rebind:

- the IPv4 host (control channel) is deleted
- the associated dynamic data services are deleted
- the IPv4 host is added in the IPoE session
- new dynamic data services are created based on IPoE session authentication data

## 9.18 Data-triggered Subscriber Management

This feature allows the creation of ESM subscribers and hosts based on the receipt of upstream data packets.

Data-triggered host creation does not rely on protocol triggers (DHCP, PPPoE) or management triggers (static hosts) to create each host, and is especially useful in the following cases:

- BNG manages subscribers under Layer 3 nodes (BRAS, CMTS, GGSN/PGW, etc.) and is not on the DHCP message path.
- BNG needs to manage large numbers of static hosts and bulk provisioning is required.

BNG authenticates, creates, and deletes subscriber hosts as follows:

- Step 1.** The subscriber SAP, including MSAP, receives a user packet that does not match existing anti-spoof table entries.
- Step 2.** BNG instantiates an IPoE session if there is no existing session with the same session key, and performs authentication using LUDB and RADIUS.

**Note:** Data-triggered ESM is supported only with IPoE sessions.

- Step 3.** A subscriber host is created with the ESM strings provided during authentication.
- Step 4.** The subscriber host is deleted when **session-timeout** or **idle-timeout** expires, CoA triggers a disconnect, SHCV check failure, or management (CLI, SNMP, etc) triggers a host deletion.

**Note:** There are no automatic triggers to delete a host if **session-timeout** or **idle-timeout** and SHCV are not configured.

## 9.18.1 Provisioning Data-triggered ESM

Data-triggered ESM can be enabled on a group interface. The following displays a sample configuration of data-triggered ESM:

```
subscriber-interface "SI1" create
 group-interface "GI1" create
 arp-populate
 ipoe-session
 ipoe-session-policy "IS1"
 exit
 data-trigger
 no shutdown
 exit
```

An IPoE session and ARP population are mandatory when configuring data-triggered ESM.

The following packets can start data-trigger processing:

- IPv4 data packet
- IPv6 data packet

- ARP

To terminate IPv6 hosts that send neighbor RS/NS before sending data packets, **auto-reply** must be configured.

```
subscriber-interface "SI1" create
 group-interface "GI1" create
 ipv6
 auto-reply
 neighbor-solicitation
 exit
```

For MSAP, the “data” trigger packet type can accept data triggers.

```
sap 1/1/2:200.* capture-sap create
 trigger-packet data
```

## 9.18.2 Authentication and Host Creation

Authentication of a data trigger can use LUDB configured in an IPoE session statement under a group interface.

To identify the source IPv4/IPv6 address of data-trigger packets, the IP prefix in the local user database can be configured with **host-identification**.

```
local-user-db "LUDB_DT" create
 ipoe
 match-list ip
 host "10.0.0.8" create
 host-identification
 ip-prefix 10.0.0.8/29
 exit
 host "2001:1:b::1" create
 shutdown
 host-identification
 ip-prefix 2001:a:b::1/128
```

**Note:** Only one IP prefix can be configured for each host. A dual-stack host requires two local user database host entries if the IP prefix needs to be used for host identification.

For RADIUS authentication, the circuit ID includes the source IPv4/IPv6 address of the data-trigger packet.

```
authentication-policy "AUTH1" create
 user-name-format circuit-id
 include-radius-attribute
 circuit-id
```

exit

If IPoE session policy uses circuit ID to identify each session, a new IPoE session is created for each source IPv4/IPv6 address. However, RADIUS can return the circuit ID to merge multiple IPoE sessions with the same SAP, MAC, and circuit ID into a single session.

A host is created using the IPv4/IPv6 source address of the data trigger (a /32 address for IPv4 or a /128 address for IPv6), but IPv6 data-triggered hosts can be created as an IPv6 prefix by configuring **ipv6-delegated-address** in the local user database host entry.

RADIUS can return the following AVPs to model the address/prefix of the data-triggered host:

- Framed-IP-Address: /32 IPv4 address of the host
- Framed-Route: managed IPv4 route with the host as next hop
- Alc-IPv6-Address: /128 IPv6 address of the host
- Delegated-IPv6-Prefix: IPv6 prefix of the host
- Framed-IPv6-Route: managed IPv6 route with the host as next next hop

Information about multiple hosts can be returned in a single Access-Accept message when the **nh-mac anti-spoof** command is configured. This is mandatory when provisioning dual-stack hosts with the same SAP and MAC addresses with **nh-mac anti-spoof** configured, but is mutually exclusive with the CID key in the IPoE session policy.

### 9.18.3 DoS Protection

To authenticate data triggers, only the first packet is used for further processing. Subsequent packets from the same source are discarded until ESM host creation.

Data trigger packets are classified as “all-unspecified” protocol by Distributed CPU protection (DCP).

### 9.18.4 DHCP Promotion

DHCP promotion allows data-triggered subscriber hosts to become DHCP hosts.

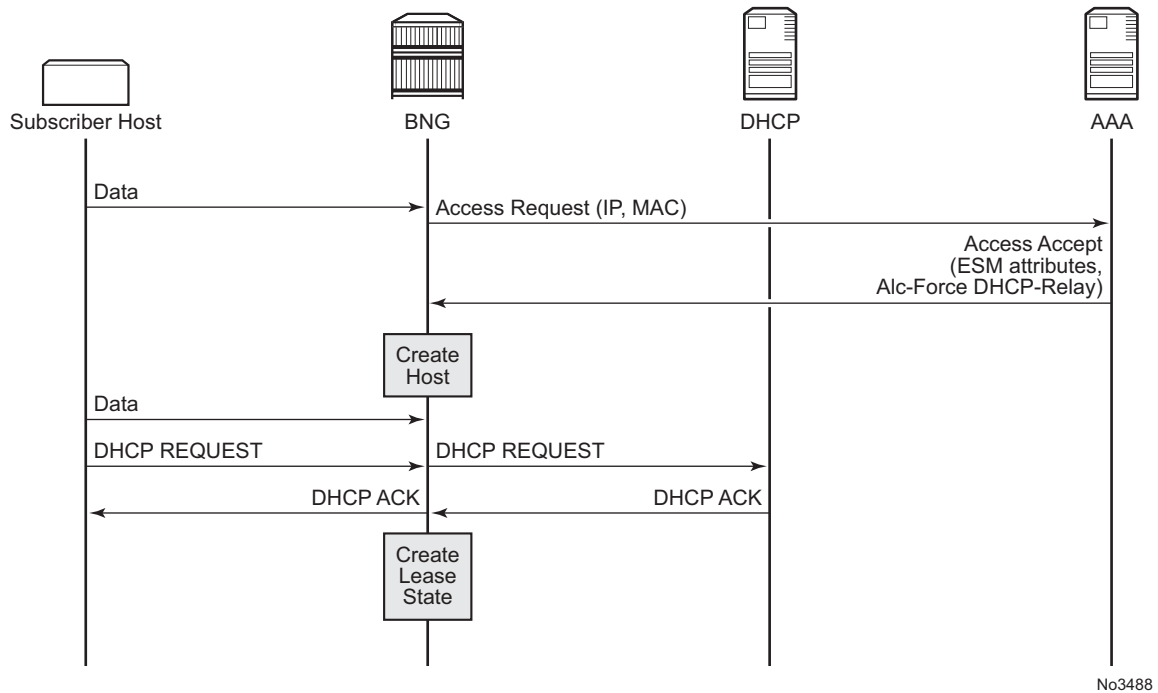

After a data-triggered host is created, DHCP packets sent by the client will start the DHCP promotion process as follows:

1. A DHCP Request/Renew/Rebind message comes from the data-triggered host.
2. Authentication using LUDB and RADIUS is performed. A RADIUS Access-Request message is sent if the authentication policy has re-authentication enabled. DHCP processing is done without authentication if re-authentication is not configured.
3. An Access-Accept message that contains ESM attributes is sent back from the AAA server. If an Access-Reject message is received, the data-triggered host is deleted.
4. A DHCP packet is relayed to the DHCP server.
5. A DHCP server replies with a DHCP Ack/Relay-Reply or Nak message.
6. When an Ack/Relay-Reply message is received, a lease state is created and the data-triggered host is promoted to the DHCP host.
7. If the DHCP server replies with Nak or with IP address information different from the existing data-triggered host, DHCP promotion will fail and the data-triggered host will be deleted.
8. With DHCP proxy, if the LUDB or AAA server returns IP information different from the data-triggered host, then DHCP promotion will fail and the data-triggered host will be deleted.
9. An interim accounting message is generated based on the configuration of the **radius-accounting-policy** command, as follows:
  1. **queue-instance-accounting**: interim-update with Alc-Acct-Triggered-Reason = Promotion of a Data-triggered host.
  2. **session-accounting**: interim-update with Alc-Acct-Triggered-Reason = Promotion of a Data-triggered host, if host-update is configured.
  3. **host-accounting**: interim-update with Alc-Acct-Triggered-Reason = Promotion of a Data-triggered host

Data-triggered hosts can be promoted to DHCP proxy hosts by default. To promote data-triggered hosts using DHCP relay to an internal or external DHCP server, the Alc-Force-DHCP-Relay VSA will be included in Access-Accept messages to authenticate data-triggered hosts.

**Note:** DHCP relay promotion is only supported when using RADIUS. LUDB and NASreq is not supported.

**Figure 145 DHCP Promotion with DHCP Relay**

### 9.18.5 Data-Triggered SLAAC Hosts

A SLAAC host can be created instead of a data-triggered host on data-triggered authentication when the Framed-IPv6-Prefix is returned from the LUDB or AAA server and the IPv6 prefix in the AVP value matches the source address of the data-trigger.

Local address assignment (LAA) is not supported for data-triggered SLAAC hosts. Data-triggered subscriber management (**config>service>vprn>sub-if>grp-if>data-trigger>no shutdown**) and LAA commands (**config>service>vprn>sub-if>grp-if>lcl-addr-assign>ipv6>ipoe-wan | ipoe-slaac**) are mutually exclusive.

## 9.18.6 Stateful Multi-Chassis Redundancy (MCS)

Data-triggered subscriber hosts can be protected with stateful multi-chassis redundancy. Subscriber management MCS applications, under **config>redundancy>multi-chassis>peer>sync>sub-mgmt** also include data-triggered subscriber host information.

## 9.18.7 Stateless Multi-Chassis Redundancy

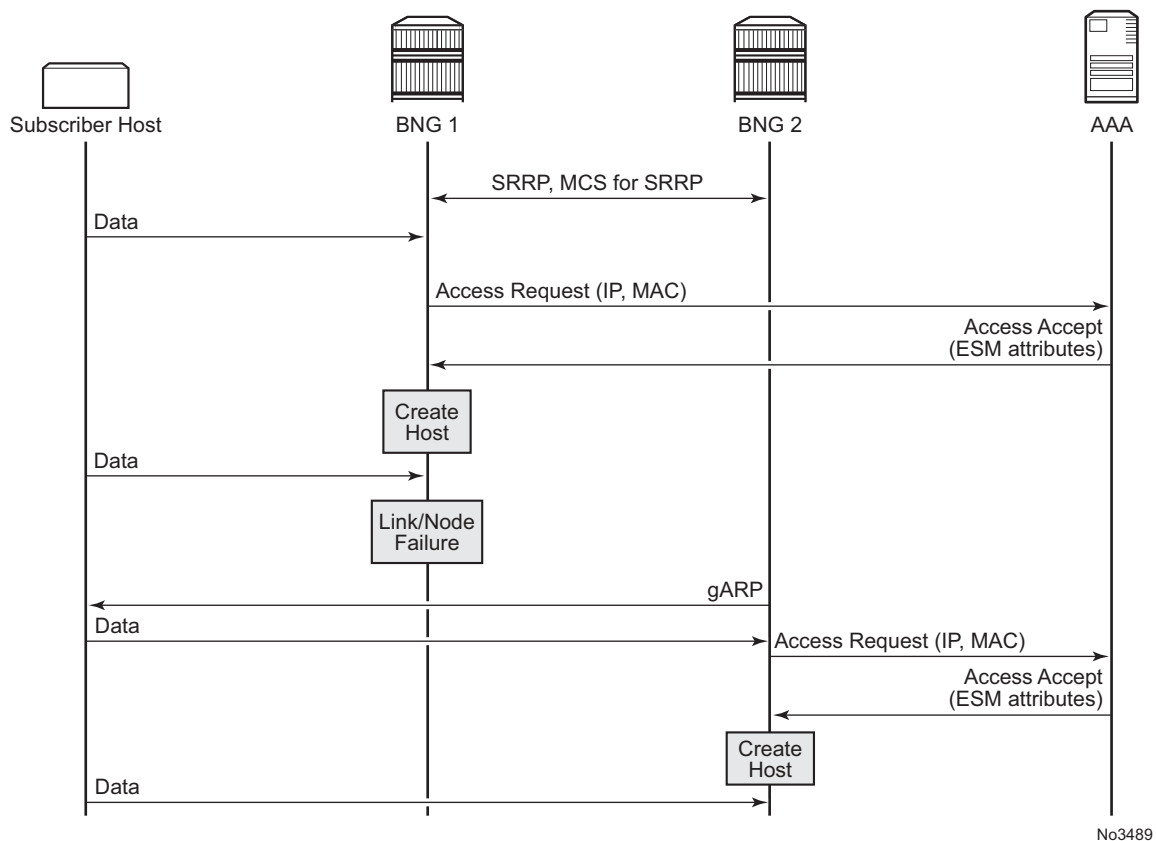

Stateless redundancy uses SRRP in the same form as the current implementation for master/standby selection and peer liveness detection, but does not need subscriber state synchronization using MCS that requires CPM/IOM resources to be on standby node.

Stateless redundancy has the following characteristics:

- IPoE sessions and their hosts (DHCP, DHCP6, SLAAC, and DT) are not synchronized via the subscriber management IPoE MCS client.
- SRRP is synchronized over MCS.
- BNG in the SRRP master state only processes the data-trigger, and authenticates and creates a subscriber host state.
- BNG in the SRRP state other than master, discards all upstream packets.
- Shunt and redundant interfaces are not supported.
- After an SRRP switchover, a new master BNG starts processing subscriber traffic. The old master BNG deletes all IPoE sessions and IPoE subscriber hosts on an SRRP switchover. Accounting stops will be sent to indicate SRRP mastership changed to the backup BNG node. Accounting messages are different based on the **radius-accounting-policy** configuration.
  1. **queue-instance-accounting**: accounting-stop with Alc-Error-Code = Node has switched to stateless backup
  2. **session-accounting**: interim-update with Alc-Acct-Triggered-Reason = Node has switched to stateless backup, upon each stack deletion if host-update is configured, and accounting-stop with Alc-Error-Code = Node has switched to stateless backup
  3. **accounting**: accounting-stop with Alc-Error-Code = Node has switched to stateless backup, upon each host deletion
- The DHCP local server state can be synchronized for DHCP promotion.

- DHCP promotion for BRG requires lease state synchronization between redundant BNGs, which disables protocol-triggered IPoE ESM without an IPoE session. This requires the **config>service>ies | vprn>sub-if>grp-if>ipoe-session>stateless-redundancy** command to be configured.
  - host-PPPoE (PTA and LAC) processing can be tied with an SRRP instance for stateless redundancy. Only the master BNG processes PPPoE/PPP control plane data. A non-master BNG does not send LCP echo messages. After switchover, subscriber hosts will retry to connect after echo timeout.
- Supports both static SAP and MSAP.

**Figure 146** Figure: Stateless Multi-Chassis Redundancy

No3489

### 9.18.7.1 MSAP Support

Stateless redundancy does not have information on MSAP because MCS is not used for synchronizing subscriber host information.

Static SAPs need to be configured to rewrite FDBs on Layer 2 switches via G-ARP in access/aggregation networks.

to rewrite FDBs via G-ARP

```
group-interface <ip-int-name>
sap <sap-id> create
no shutdown
```

This requires the aggregation network to re-learn MAC for multiple C-VLANs using a single G-ARP from a specific C-VLAN.

Two typical scenarios are supported:

- MSAP has qinq encap, and aggregation switches have per-SVLAN FDB
- MSAP has dot1q encap, and aggregation switches have per-SVLAN FDB (Aggregation switches push SVID)

## 9.19 RADIUS Subscriber Services

RADIUS subscriber services enable the activation and deactivation of subscriber functions via RADIUS Access-Accept or CoA messages. Each subscriber service can have its own RADIUS accounting session.

The subscriber service functionality is built using the flexible RADIUS Python script interface to populate the subscriber service data structure using a parameter list received in subscriber service-specific RADIUS Vendor Specific Attributes (VSAs). The format and content of the VSA parameter list is defined by the operator. An accounting start/stop is sent when the subscriber service is activated/deactivated. Optionally, interim updates can be sent in intervals that can be specified per subscriber service instance. Accounting interim updates and stop messages contain the subscriber service-related statistics (time or volume and time).

Subscriber services can be activated on a single-stack or dual-stack PPPoE or IPoE session or on a single-stack IPv4 host.

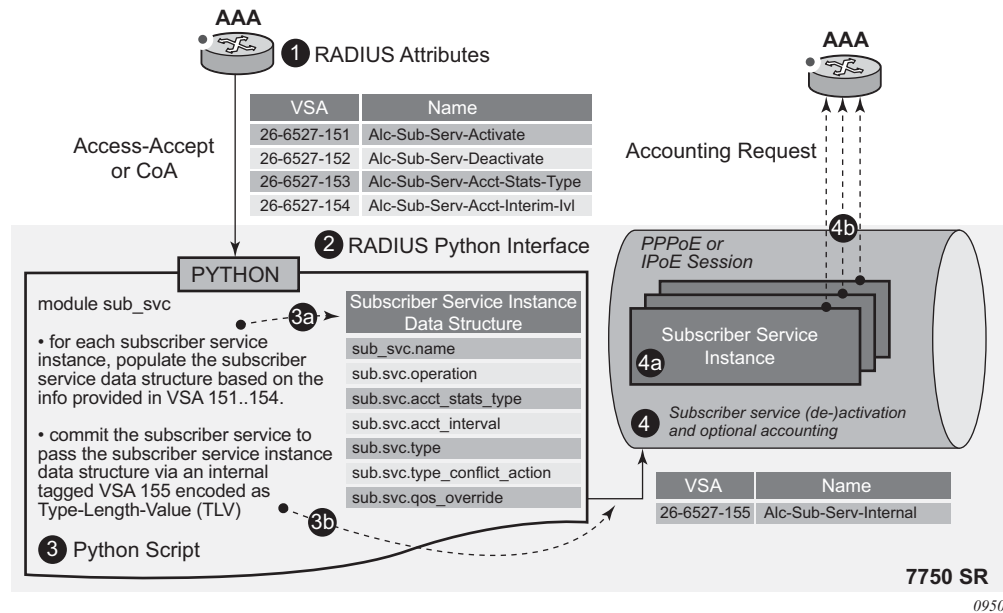

Subscriber service functionality can be built with:

- QoS overrides: changing queue or policer parameters (PIR/CIR rates and CBS/MBS burst sizes), adapting rates of a parent scheduler, root arbiter, or subscriber aggregate rate
- PCC rules: applying QoS or filter actions to a set of IP flows

### 9.19.1 Subscriber Service Building Blocks

Figure 147 shows the building blocks required to activate or deactivate a subscriber service.

**Figure 147**    **Subscriber Services Building Blocks**

Each of the building blocks is described in the following sections.

### 9.19.1.1 RADIUS Access-Accept or CoA Message with Subscriber Service Activate or Deactivate VSAs

A subscriber service instance is activated from the RADIUS server via an Access-Accept or CoA message for a PPPoE or IPE session. Deactivation of a subscriber service instance can be achieved via a RADIUS CoA message or is implicit when the associated subscriber session terminates.

To activate a subscriber service, the Alc-Sub-Serv-Activate (VSA) is used, and to deactivate a subscriber service, the Alc-Sub-Serv-Deactivate VSA is used. The formats of the Alc-Sub-Serv-Activate and Alc-Sub-Serv-Deactivate VSAs can be freely defined by the operator as long as they match with the Python script that is used to commit the subscriber service instance activation or deactivation.

For example, to change the upstream and downstream bandwidth of an IPoE session, the following format can be defined:

```
rate-limit;<upstream_bw_in_kbps>;<downstream_bw_in_kbps>
```

To activate a subscriber service with an upstream bandwidth of 5 Mb/s and a downstream rate of 50 Mb/s, the following VSA can then be included in a RADIUS Access-Accept or CoA message:

```
Alc-Sub-Serv-Activate = "rate-limit;5120;30720"
```

To deactivate the same subscriber service and revert back to the initial bandwidth, the following VSA can be included in a RADIUS CoA message:

```
Alc-Sub-Serv-Deactivate = "rate-limit;5120;30720"
```

To deactivate a subscriber service instance, its unique name must be used. In the example above, the name equals "rate-limit;5120;30720".

To start an accounting session when the subscriber service instance is activated, the following attributes can be included in the Access-Accept or CoA message:

```
Alc-Sub-Serv-Acct-Stats-Type = volume-time | time
Alc-Sub-Serv-Acct-Interim-Ivl = <update-interval>
```

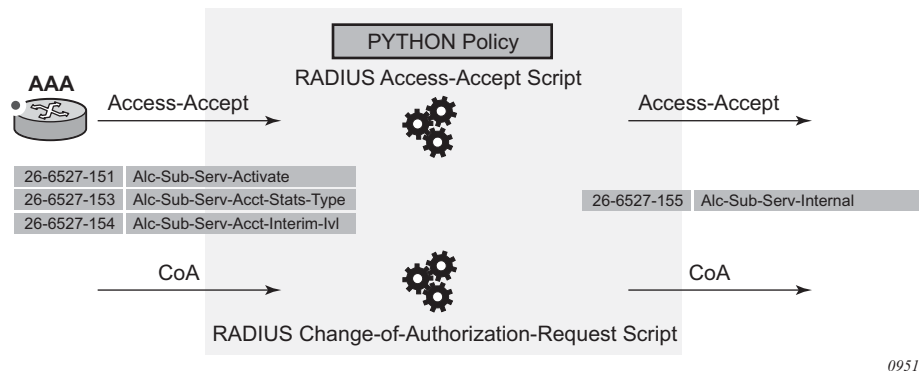

For example, the Alc-Sub-Serv-Acct-Stats-Type attribute value is set to "volume-time" to include both the session time for time-based billing and standard counters for volume statistics collection. The Alc-Sub-Serv-Acct-Interim-Ivl attribute sets the interval for interim updates of the subscriber service instance accounting.

See the [Subscriber Services RADIUS VSAs](#) section for details on RADIUS attributes.

See the [Subscriber Service RADIUS Accounting](#) section for details on subscriber service instance accounting.

### 9.19.1.2 RADIUS Python Interface

The SR OS RADIUS Python interface is used to interpret the parameters specified in the subscriber service-specific VSAs and to generate an internal proprietary format VSA representing the subscriber service instance to activate or deactivate, as shown in [Figure 148](#).

**Figure 148 RADIUS Python Interface**

The SR OS only requires the Alc-Sub-Serv-Internal VSA [26-6527-155] to activate or deactivate the subscriber service. Subscriber service-specific VSAs [26-6527-151..154] are available to be used in the subscriber service Python script but are ignored in the SR OS.

See the [Python Script](#) section for details on the subscriber services Python script functions and operation.

A Python script must be configured for RADIUS Access-Accept and CoA messages; for example:

```
config
 python
 python-script "subsvc-1" create
 primary-url "ftp://user:pwd@10.1.1.1/./py/subsvc-1.py"
 no shutdown
 exit
 python-policy "py-policy-subsvc-1" create
 radius access-accept direction ingress script "subsvc-1"
 radius change-of-authorization-request direction ingress script "subsvc-1"
 exit
 exit
exit
```

The Python policy must then be applied to the **radius-server-policy** to pass the Access-Accept messages to the Python script and to the RADIUS server to pass the CoA messages to the Python script; for example:

```
configure
 router
 radius-server
 server "server-1" address 10.1.1.2 secret <secret> create
 accept-coa
 python-policy "py-policy-subsvc-1"
 exit
 exit
exit
```

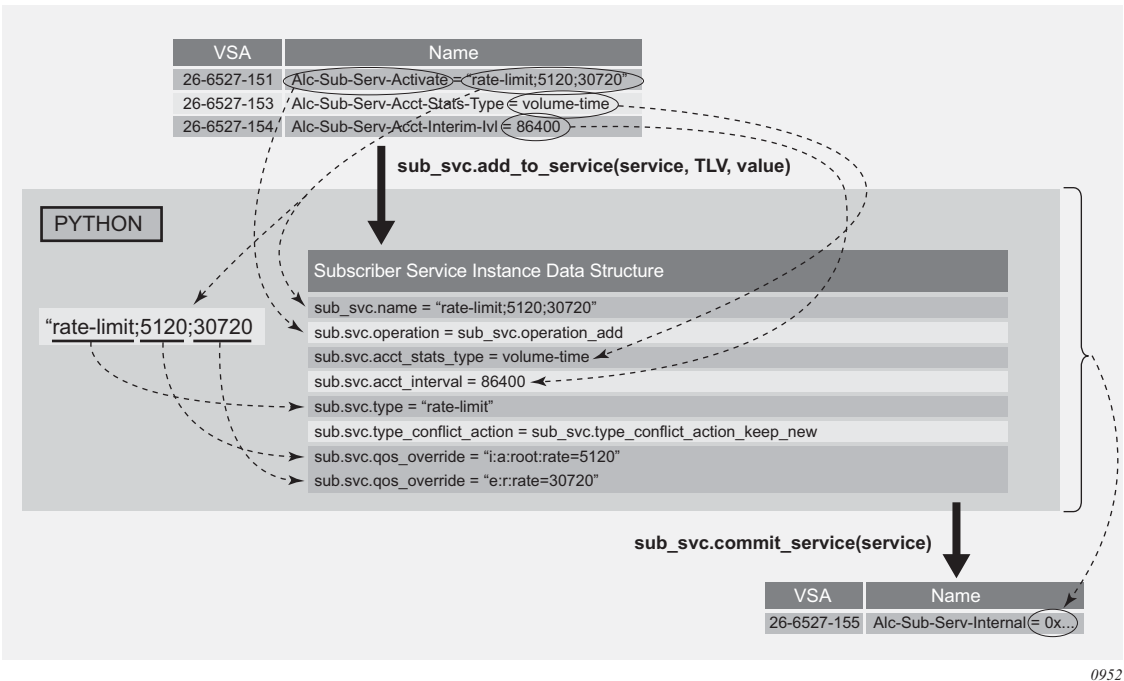

```
aaa
 radius-server-policy "aaa-server-policy-1" create
 python-policy "py-policy-subsvc-1"
 servers
 access-algorithm round-robin
 router "Base"
 server 1 name "server-1"
 exit
exit
exit
```

### 9.19.1.3 Python Script

The RADIUS Access-Accept and CoA messages are passed to the configured RADIUS Python scripts. As shown in [Figure 149](#), the function of the subscriber service Python script is to interpret the subscriber service-specific VSAs that contain the subscriber service instance parameters and to generate a new Alc-Sub-Serv-Internal VSA containing the information required to activate the actual subscriber service on the PPPoE or IPoE session.

This section covers the basics to understand the functionality of a subscriber service Python script. See the [Subscriber Services Python API](#) section for a detailed description of the alc.sub\_svc Python module containing functions and data structures used to define and activate a subscriber service instance.

**Figure 149** Subscriber Service Python Script Operation

The alc.sub\_svc Python module contains the required functions and data structure to commit a subscriber service, including:

- TLVs to build a data structure describing the subscriber service functionality, such as QoS overrides or PCC rules
- functions to populate the data structure such as `sub_svc.add_to_service()`, `sub_svc.pccrule.add_to_pccrule()`, and `sub_svc.flow.add_to_flow()`
- a function to commit the subscriber service and create the internal VSA from the data structure: `sub_svc.commit_service()`

### 9.19.1.3.1 Python Script Example

In this section an example of a Python script is explained that enables the activation or deactivation of a subscriber service.

In the example, it is assumed that only a single subscriber service is activated and/or deactivated per RADIUS message (no tagged VSAs are used) and that only a single Alc-Sub-Serv-Activate or Alc-Sub-Serv-Deactivate VSA is present (no concatenation of VSAs is required).

To change the upstream root arbiter rate and downstream aggregate rate bandwidth of an IPoE session, send the following parameters in the subscriber service activate VSA:

```
rate-limit;<upstream_bw_in_kbps>;<downstream_bw_in_kbps>
```

During the bandwidth change, the traffic should be accounted for in a separate accounting session.

To import the required modules in the Python script:

```
Python - imports
import struct
from alc import radius
from alc import sub_svc
```

The `alc.radius` module provides the API access to the RADIUS VSAs in Access-Accept and CoA messages.

The `alc.sub_svc` module allows the API to activate and deactivate subscriber services.

The `struct` module is a Python module used in the example to convert data obtained from the RADIUS API as a string into Python integer values.

The following constants are used in the script:

```
Python - constants
VSA vendor ID
ALC = 6527
ALC Radius VSA
SUB_SERVICE_ACTIVATE = 151
SUB_SERVICE_DEACTIVATE = 152
SUB_SERVICE_ACCT_STATS_TYPE = 153
SUB_SERVICE_ACCT_INTERIM_IVL = 154
```

The main flow in a subscriber service Python script is to first process the subscriber service deactivations, followed by the subscriber service activations. Optionally, the subscriber service-specific VSAs can be removed from the RADIUS message as they are not required for further processing in the SR OS:

```
Python - main()
deactivate_services()
activate_services()
radius.attributes.clearVSA(ALC, SUB_SERVICE_ACTIVATE)
radius.attributes.clearVSA(ALC, SUB_SERVICE_DEACTIVATE)
radius.attributes.clearVSA(ALC, SUB_SERVICE_ACCT_STATS_TYPE)
radius.attributes.clearVSA(ALC, SUB_SERVICE_ACCT_INTERIM_IVL)
```

The function to deactivate a subscriber service executes the following steps:

- checks if an Alc-Sub-Serv-Deactivate VSA [26-6527-152] is present
- if present:
  - builds the subscriber service data structure. For a subscriber service deactivation, only the subscriber service instance name is required.
  - commits the subscriber service deactivation

```
Python - deactivate_services()
def deactivate_services():
 value = radius.attributes.getVSA(ALC, SUB_SERVICE_DEACTIVATE)
 if value != '':
 service = []
 sub_svc.add_to_service(service, sub_svc.name, value);
 sub_svc.add_to_service(service, sub_svc.operation, sub_svc.operation_del);
 sub_svc.commit_service(service)
```

The function to activate a subscriber service executes the following steps:

- checks if an Alc-Sub-Serv-Activate VSA [26-6527-151] is present
- if present:
  - separates the parameters in the attribute value with a semicolon as the delimiter. The parameters are the subscriber service type, the upstream bandwidth in kb/s, and the downstream bandwidth in kb/s.
  - If the subscriber service type is rate-limit, builds the subscriber service data structure:
    - specifies that the service will be added (activate)
    - adds the complete attribute value as the subscriber service instance name. This name should also be used to deactivate the subscriber service.
    - sets the subscriber service type and conflict action. With the conflict action set to “keep new”, if a new subscriber service of the same type is activated, the old one is deactivated first.
    - configures the upstream and downstream bandwidth with a QoS override on the ingress root arbiter and egress aggregate rate
  - If the subscriber service type is something else (an unknown service type), a warning is printed for debugging purposes. No action is performed in this case.
  - If an Alc-Sub-Serv-Acct-Stats-Type VSA [26-6527-153] is present, adds the corresponding stats-type to the subscriber service data structure. The function also checks whether a Alc-Sub-Acct-Serv-Interim-Int VSA [26-6527-154] is present and adds the interval to the subscriber service data structure.

Both the stats-type and interim interval must be specified as integers in the subscriber service data structure. As the RADIUS API returns an octet string, a conversion is required. The struct.unpack() function is used for this purpose.

– commits the subscriber service activation

```
Python - activate_services()
def activate_services():
 # Subscriber Service Activate VSA
 value = radius.attributes.getVSA(ALC, SUB_SERVICE_ACTIVATE)
 if value != '':
 values = value.split(';')
 if values[0] == "rate-limit":
 service = []
 sub_svc.add_to_service(service, sub_svc.operation, sub_svc.operation_add);
 sub_svc.add_to_service(service, sub_svc.name, value);
 sub_svc.add_to_service(service, sub_svc.type, 'rate-limit')
 sub_svc.add_to_service(service, sub_svc.type_conflict_action, sub_svc.type_conflict_action_keep_new)
 sub_svc.add_to_service(service, sub_svc.qos_override, 'i:a:root:rate=' + values[1])
 sub_svc.add_to_service(service, sub_svc.qos_override, 'e:r:rate=' + values[2])
 else:
 print "WARNING - Unknown service type :", values[0]
 return
 # Subscriber Service Accounting VSA
 stats_type = radius.attributes.getVSA(ALC, SUB_SERVICE_ACCT_STATS_TYPE)
 if stats_type != '':
 sub_svc.add_to_service(service, sub_svc.acct_stats_type, struct.unpack("!I", stats_type)[0]);
 interval = radius.attributes.getVSA(ALC, SUB_SERVICE_ACCT_INTERIM_IVL)
 if interval != '':
 sub_svc.add_to_service(service, sub_svc.acct_interval, struct.unpack("!I", interval)[0]);
 # Activate the Subscriber Service
 sub_svc.commit_service(service)
```

The result of the sub\_svc.commit\_service() function is an Alc-Sub-Serv-Internal VSA [26-6527-155] that contains the required data for the SR OS to activate the corresponding subscriber services.

#### 9.19.1.4 Subscriber Service Instance Activation or Deactivation with Optional RADIUS Accounting

When the SR OS receives an Alc-Sub-Serv-Internal VSA [26-6527-155] in an Access-Accept or CoA message as a result of the Python script sub\_svc.commit\_service() function, the corresponding subscriber services are activated and/or deactivated. Optionally, an accounting session can be started for each subscriber service instance.

The following is an example of the **show service sub-services** command.

```
show service sub-services
=====
Subscriber service table
=====
Username : cpe2@domain1.com
Subscriber : cpe2@domain1.com Type : PPP
SAP : 1/1/4:1201.5 Service : 1000

=====
```

The following rules apply for a subscriber service instance.

- A subscriber service instance can be activated on a:
  - single-stack or dual-stack PPPoE session
  - single-stack or dual-stack IPoE session
  - single-stack IPoEv4 host
- A subscriber service instance is uniquely identified by its name. To deactivate a subscriber service instance, the subscriber service name must be referenced.
- A subscriber service cannot be modified. To update a subscriber service instance, the old subscriber service must be deactivated and a new one activated.
- Multiple subscriber services can be activated or deactivated in a single Access-Accept or CoA message. Tagged subscriber service-specific VSAs are available for this purpose.
- A single subscriber service instance can have multiple actions, such as multiple QoS overrides and/or multiple PCC rules.

- The conflict action determines the behavior when multiple subscriber services of the same type are activated for the same PPPoE or IPoE session:
  - Conflict action = none  
Multiple instances of the same type can be activated.
  - Conflict action = keep new  
Only a single subscriber service instance of the same type is allowed.  
When a new subscriber service instance of the same type is activated on a single PPPoE or IPoE session, the old instance is deactivated and the new subscriber service instance is activated.
  - Conflict action = keep old  
Only a single subscriber service instance of the same type is allowed.  
When a subscriber service instance of the same type is activated on a single PPPoE or IPoE session, the new subscriber service instance is rejected.
- Multi-Chassis Synchronization (MCS) is not supported for subscriber services.

## 9.19.2 Subscriber Services RADIUS VSAs

Subscriber services VSAs 26-6527-151..154 are used as inputs for the subscriber service Python script and are ignored by the SR OS.

The subscriber service VSAs can be tagged to allow activation and deactivation of multiple subscriber service instances with a single RADIUS Access-Accept or CoA message.

[Table 70](#) lists the subscriber services RADIUS VSAs. See the RADIUS Attributes Reference Guide for a complete description of the subscriber services VSAs.

**Table 70** Subscriber Services RADIUS VSAs

| Attribute ID | Attribute Name                    | Description                                                                                                                                                                                                                                                            |
|--------------|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 26-6527-151  | Alc-Sub-Serv-Activate<br>(string) | Activate a subscriber service. The attribute contains parameters as input for the subscriber service Python script to define and activate a subscriber service.<br>Multiple VSAs can be included per message if the parameter list does not fit in a single attribute. |

**Table 70**      **Subscriber Services RADIUS VSAs (Continued)**

| Attribute ID | Attribute Name                             | Description                                                                                                                                                                                                                                                     |
|--------------|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 26-6527-152  | Alc-Sub-Serv-Deactivate<br>(string)        | Deactivate a subscriber service. The attribute contains parameters as input for the subscriber service Python script to deactivate a subscriber service.<br>Multiple VSAs can be included per message if the parameter list does not fit in a single attribute. |
| 26-6527-153  | Alc-Sub-Serv-Acct-Stats-Type<br>(integer)  | Enable or disable subscriber service accounting and specify the statistics type: volume and time or time only.<br>Values: 1=off, 2=volume-time and 3=time                                                                                                       |
| 26-6527-154  | Alc-Sub-Serv-Acct-Interim-Int<br>(integer) | The interim accounting interval in seconds at which Acct-Interim-Update messages should be generated for subscriber service accounting. A value of 0 (zero) corresponds to no interim update messages. The maximum value is 300 seconds (values 1 to 300).      |
| 26-6527-155  | Alc-Sub-Serv-Internal                      | For internal use only. Its value is the result of the subscriber service commit function in Python. (sub_svc.commit_service).                                                                                                                                   |

### 9.19.3 Subscriber Service RADIUS Accounting

The configuration for subscriber service instance accounting sessions is obtained from the RADIUS accounting policies configured in the subscriber profile of the parent subscriber:

- The accounting destinations: RADIUS server configuration  
Subscriber service instance accounting is sent to multiple destinations when multiple RADIUS accounting policies are configured (for example, **config>subscr-mgmt>sub-prof# radius-accounting policy acct-policy-1 acct-policy-2**)
- The accounting attributes (**include-radius-attribute**) with some exceptions.  
Standard accounting attributes are always used for volume accounting, regardless of the configuration in the RADIUS accounting policy.

An untagged [26-6527-151] Alc-Sub-Serv-Activate attribute is included in all subscriber service instance accounting messages. Its value is the subscriber service instance name (alc.sub\_svc.name).

- Accounting interim updates for subscriber service instance accounting are controlled independently from the parent subscriber accounting session:
  - Enabling accounting interim updates for a subscriber service instance is achieved by setting the sub\_svc.acct\_interval TLV in the subscriber services Python script to a value greater than 0:  
`sub_svc.add_to_service(service, sub_svc.acct_interval, 3600)`
  - Disabling accounting interim updates for a subscriber service instance is achieved by setting the sub\_svc.acct\_interval TLV in the subscriber services Python script to 0:  
`sub_svc.add_to_service(service, sub_svc.acct_interval, 0)`

If the parent subscriber has no RADIUS accounting policy configured, subscriber service instance accounting cannot be enabled.

If the parent subscriber has a RADIUS accounting policy configured, subscriber service instance accounting can be disabled by setting the sub\_svc.acct\_stats\_type TLV in the subscriber service Python script to 1 (Off):

```
sub_svc.add_to_service(service, sub_svc.acct_stats_type, 1)
```

Each subscriber service instance has a unique accounting session ID included as [44] Acct-Session-Id. The [50] Acct-Multi-Session-Id contains the accounting session ID of the parent PPPoE or IPoE session as shown in [Table 71](#):

**Table 71**      **Subscriber Service Accounting Multi-Session ID**

| Subscriber Service Parent | [50] Acct-Multi-Session-Id                                                                                            |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------|
| PPPoE session             | Session Acct-Session-Id of the PPPoE session:<br><code>show service id &lt;service-id&gt; pppoe session detail</code> |
| IPoE session              | Session Acct-Session-Id of the IPoE session:<br><code>show service id &lt;service-id&gt; ipoe session detail</code>   |
| IPoEv4 host               | Host Acct-Session-Id of the IPoEv4 host:<br><code>show service id &lt;service-id&gt; subscriber-hosts detail</code>   |

The content of the volume counters when the subscriber service accounting statistics type equals **volume-time** is determined by the subscriber service action. For details, see the subscriber service sections that follow.

### 9.19.4 Accounting-Only Subscriber Service

An accounting-only subscriber service has no specific action such as **qos-override** or **pccrule** defined and has subscriber service instance accounting enabled.

An example of when an accounting-only subscriber service would be used is if additional accounting data is needed for a specific time period in the lifetime of a PPPoE or IPoE session.

The `sub_svc.acct_stats_type` TLV in the subscriber services Python script must be set to a value different from 1 (Off) to enable subscriber service instance accounting. For example:

```
Python example - Accounting only subscriber service
service = []
sub_svc.add_to_service(service, sub_svc.operation, sub_svc.operation_add)
sub_svc.add_to_service(service, sub_svc.name, 'subsvc-acct-1')
sub_svc.add_to_service(service, sub_svc.type, 'acct-only')
sub_svc.add_to_service(service, sub_svc.type_conflict_action, sub_svc.type_conflict_
action_none)
sub_svc.add_to_service(service, sub_svc.acct_stats_type, 2)
sub_svc.add_to_service(service, sub_svc.acct_interval, 3600)
sub_svc.commit_service(service)
```

The volume counters for subscriber service statistics type **volume-time** contain the aggregate forwarded octets and packets of the parent PPPoE or IPoE session **sla-profile** instance since the start of the subscriber service.

### 9.19.5 QoS Override-based Subscriber Service

A subscriber service instance with a **qos-override** action overrides queue/policer parameters (CIR, PIR, CBS, MBS) configured at the **sla-profile** level and hierarchical QoS parameters (aggregate rate, scheduler rate, or root arbiter rate) configured at the sub-profile level.

An example of when a QoS override-based subscriber service would be used is to temporarily offer higher bandwidth and charge for the volume consumed during this period. [Figure 150](#) shows the volume statistics that are reported for the PPPoE or IPoE session accounting and for each of the subscriber service instances accounting sessions that were activated and deactivated.

**Figure 150 Sample Use Case: QoS Override-based Subscriber Services**

- At t0, a subscriber connects and starts consuming bandwidth at the subscriber base egress rate of 1 Mb/s. An accounting session is started for the subscriber.
- At t1, a QoS override-based subscriber service instance is activated that boosts the download bandwidth to 2 Mb/s. A 2 Mb/s QoS override-based subscriber service instance accounting session is started.
- At t2, the 2 Mb/s QoS override-based subscriber service instance is deactivated and replaced with a new one that increases the download bandwidth to 4 Mb/s. The 2 Mb/s QoS override-based subscriber service accounting session is terminated, reporting the volume consumed during t1 to t2. A new 4 Mb/s QoS override-based subscriber service accounting session is started.
- At t3, the 4 Mb/s QoS override-based subscriber service instance is deactivated. The download bandwidth is reduced to the 1 Mb/s base rate again. The 4 Mb/s QoS override-based subscriber service accounting session is terminated, reporting the volume consumed during t2 to t3.
- At t4, the subscriber disconnects. The accounting session for the subscriber is terminated, reporting the volume consumed during t0 to t4.

The sub\_svc.qos\_override TLV in the subscriber services Python script adds a **qos-override** action. For example:

```
Python example - QoS override subscriber service
service = []
sub_svc.add_to_service(service, sub_svc.operation, sub_svc.operation_add)
sub_svc.add_to_service(service, sub_svc.name, 'subsvc-qos-override-1')
sub_svc.add_to_service(service, sub_svc.type, 'qos-override')
sub_svc.add_to_service(service, sub_svc.type_conflict_action, sub_svc.type_conflict_
action_keep_new)
sub_svc.add_to_service(service, sub_svc.qos_override, 'e:q:1:pir=20000,cir=0')
sub_svc.add_to_service(service, sub_svc.qos_override, 'e:q:2:pir=5000,cir=5000')
sub_svc.add_to_service(service, sub_svc.qos_override, 'i:p:1:pir=1000,cir=0')
sub_svc.add_to_service(service, sub_svc.qos_override, 'e:r:rate=20000')
```

```
sub_svc.commit_service(service)
```

Actual values are used to populate the subscriber service data structure in this example; typically, these values are sent as parameters in subscriber service-specific VSAs.

Although a QoS override-based subscriber service instance is activated for a PPPoE or IPoE session, the overrides are applied at the SLA profile instance and/or subscriber level.

QoS override-based subscriber services have precedence over dynamic QoS overrides (RADIUS Alc-Subscriber-QoS-Override VSA or Gx Charging-Rule-Definition with QoS-Information) on the PPPoE or IPoE session.

- When a dynamic QoS override such as via the Alc-Subscriber-QoS-Override VSA is active on the parent PPPoE or IPoE session and a QoS override-based subscriber service is activated, the action from the QoS override-based subscriber service is installed. When the QoS override-based subscriber service is later deactivated, the original dynamic QoS override is restored.
- When a dynamic QoS override such as via the Alc-Subscriber-QoS-Override VSA is received for a parent PPPoE or IPoE session with an active QoS override-based subscriber service, the QoS override-based subscriber service remains installed. If the QoS override-based subscriber service is later deactivated, the previously received dynamic QoS override is installed.
- When both a QoS override-based subscriber service activation and a dynamic QoS override such as via the Alc-Subscriber-QoS-Override VSA is received in a single message for the parent PPPoE or IPoE session, the QoS override-based subscriber service action is installed and the dynamic QoS override is stored for later reference. When the QoS subscriber service is later deactivated, the previously received dynamic QoS override is installed.

The installed QoS override actions can be verified in the output of the **show service active-subscribers detail** CLI command.

The volume counters for subscriber service statistics type **volume-time** contain the aggregate forwarded octets and packets of the parent PPPoE or IPoE session **sla-profile** instance since the start of the subscriber service.

QoS override-based subscriber services are stored in the subscriber-mgmt persistency file.

## 9.19.6 PCC Rule-based Subscriber Services

Policy and Charging Control (PCC) rules are defined in the 3GPP PCC architecture and used in the Diameter Gx application as a collection of parameters that enable IP traffic flows to be identified, QoS parameters and filtering actions to be applied to these flows, and charging to be performed on them. The use of PCC rules in policy management via the Diameter Gx interface is described in the [PCC Rules](#) section in the [Policy Management via Gx Interface](#) chapter.

The same PCC rule construct is used in RADIUS subscriber services to enable IP flow-based actions and accounting.

- Identify IP flows based on 5-tuple (protocol, source and destination IP address, source and destination port) and/or DSCP value.
- Apply QoS actions to these flows, such as rate limiting or change of forwarding class.
- Apply filter actions to these flows, such as forward, drop, HTTP redirect, redirect to a next hop or routing instance.
- Enable RADIUS accounting to report the forwarded octets and packets of the IP flows.

IP flow-based accounting is one use for a subscriber service using PCC rules. Activated via a self-service portal or as part of an Internet subscription package, applications identified by a 5-tuple receive specific treatment, such as bandwidth increase, expedited forwarding, or zero rating. Volume and time statistics for the application data are available in the subscriber service RADIUS accounting session. This is shown in [Figure 151](#).

**Figure 151 Example: PCC Rule-based Subscriber Service**

0954

1. The user subscribes to a service via a web portal.
2. The policy control is informed of the new subscription.
3. The policy control instructs the BNG via RADIUS to activate a subscriber service with PCC rules.
4. The subscriber service is instantiated on the BNG. A dynamic policer is spawned to optionally rate-limit and/or count the application traffic.
5. The subscriber service instance accounting session reports the volume of traffic forwarded as part of this service.

### 9.19.6.1 PCC Rule Actions

A PCC rule is a unidirectional set of IP flows sharing a same set of actions. IPv4 and IPv6 flows can be combined within the same PCC rule.

A PCC rule name must be unique for each rule applied on a single PPPoE or IPoE session. For optimal PCC rule sharing, it is recommended that the same PCC rule name be used when its content is the same (that is, the same set of flows and same set of actions).

An IP flow is identified by a combination of:

- 5-tuple (IPv4 or IPv6): src-ip, src-port, dst-ip, dst-port, protocol/next-header
- DSCP value

The CLI equivalent is:

```
match protocol | next-header <protocol>
 src-ip <ip-address>
 dst-ip <ip-address>
 src-port eq <port> | range <start-port> <end-port>
 dst-port eq <port> | range <start-port> <end-port>
 dscp <dscp>
exit
```

Supported actions include: forward, drop, redirect to ip next hop, redirect to a routing instance, HTTP redirect, forwarding class change, rate-limit, and account.

With a specified set of actions, PCC rules are instantiated in the SR OS via IP criteria or IPv6 criteria entries in SAP ingress or SAP egress QoS policies and/or in IP or IPv6 filter entries. A PCC rule precedence value determines the relative order of different PCC rules when inserted in the QoS or filter policy: a rule with a lower precedence value will be applied before a rule with a higher precedence value. Rules with the same precedence can be automatically optimized; the relative order in which they are applied is determined by the system for optimal sharing. Rules with no precedence are applied at the end and are also automatically optimized.

[Table 72](#) and [Table 73](#) provide an overview of the PCC rule actions and where they apply.

**Table 72** Subscriber Service PCC Rule Actions Resulting in QoS Policy Changes

| Action                       | Direction      | Description                                                                                                                                                                                                                             |

0962

**Notes:**

1. The Flow Status can only be set via Gx.  
For RADIUS subscriber service-based PCC rules, the Flow Status is fixed to Enabled.
2. The filter action forward is ignored (not installed) when combined with the following filter actions: redirect next-hop, redirect router, or http-redirect.
3. The QoS action forward is ignored (not installed) when combined with the following QoS actions: rate-limit, FC change, account/Usage Monitoring (UM).
4. When the QoS action rate-limit and QoS action account or Usage Monitoring (UM) are combined, only a single dynamic policer is installed, which is used for both rate-limiting and obtaining forward statistics for accounting or usage monitoring.

### 9.19.6.2 PCC Rule Instantiation

A PCC rule can result in one or more IPv4/IPv6 filter and/or QoS policy IPv4/IPv6 criteria entries. This is transparent to the operator.

- A PCC rule is split into IPv4 filter entries, IPv6 filter entries, SAP ingress QoS IP or IPv6 criteria, and SAP egress QoS IP or IPv6 criteria. See [Figure 208](#).
- Each entry is inserted into the corresponding policy at a reserved range for dynamic PCC rule inserts. See [Figure 209](#). Within the reserved range, the (optional) precedence value for the rule is taken into account for the relative order of different PCC rules.
- The QoS rate-limit and account actions will spawn a dynamic policer from a reserved range in the QoS policy. A template configuration provides dynamic policer parameters such as hierarchical policing parent, burst sizes (MBS, CBS), statistics mode and packet byte offset. A maximum of one dynamic policer is instantiated per PCC rule. There is a maximum of 63 dynamic policers per direction and per SLA profile instance. The output queue for PCC rule traffic mapped in the dynamic policer is determined by a mechanism called forwarding class inheritance: the output queue is the same queue that would be used if a packet with the same forwarding class as the PCC rule packet was classified using the applied QoS policy. The resulting output queue can be a local subscriber queue (when the FC is mapped to a queue or when the FC is mapped to a policer at egress and the policer is mapped to a local queue), a shared queue (when the FC is mapped to a policer at ingress) or a queue-group queue (when the FC is mapped to a policer at egress).
- Optimal policy and rule sharing is achieved via QoS and filter policy cloning and internal PCC rule optimizations. The mechanisms are the same as for Gx-initiated PCC rules as described in the [Generic Policy Sharing and Rule Sharing](#) and [Gx Rule Ordering](#) sections of the [Diameter and Diameter Applications](#) chapter.

PCC rule sharing can only happen when the content is the same: identical name, direction, precedence value, set of flows, and set of actions. PCC rules with the same content will have the same PCC rule ID.

Filter and QoS policy clones that result from PCC rule instantiation can be recognized by a filter ID or QoS policy ID in the format 1 to 65535:P1 to 4096; for example, filter ip 10:p3

- PCC rules can be inactive if the corresponding host type is not present. For example, a PCC rule-based subscriber service with an IPv6 filter action can be activated on an IPE session while there is no IPv6 host instantiated on the session. When the IPv6 host is later created, the PCC rule is activated.

The following initial configuration is required prior to activating PCC rule-based subscriber services.

- To install PCC rule QoS actions, a non-default ingress and egress QoS policy with a **sub-insert-shared-pccrule** range configured must be associated with the IPoE or PPPoE session (the default QoS policy cannot be modified). If a rate-limit or account action is needed, a dynamic policer range must also be configured. Additional dynamic policer parameters are optional.

```
configure qos
 sap-ingress <policy-id> create
 sub-insert-shared-pccrule start-entry <entry-id> count <count>
 dynamic-policer
 range start-entry <policer-id> count <count>
 packet-byte-offset {add <add-bytes> | subtract <sub-bytes>}
 mbs <size> [bytes|kilobytes]
 cbs <size> [bytes|kilobytes]
 parent <arbiter-name> [weight <weight-level>] [level <level>]
 stat-mode <stat-mode>
 exit
 exit
```

- To install PCC rule filter actions, an IPv4 and/or IPv6 filter with **sub-insert-shared-pccrule** range configured must be associated with the IPoE or PPPoE session.

Although a PCC rule-based subscriber service is activated on a PPPoE or IPoE session, the actions are applied at the SLA profile instance and/or subscriber host level.

- PCC rule QoS actions result in QoS policy clones that are applied at the SLA profile instance level. Traffic from all subscriber hosts and sessions sharing the SLA profile instance will be subject to the specified actions.
- PCC rule filter actions result in IPv4 or IPv6 filter clones that are applied at the subscriber host level. Only traffic from the subscriber host of the same type (IPv4 or IPv6) that belongs to the PPPoE or IPoE session will be subject to the specified actions.

A PCC rule with flow match criteria that are not explicitly IPv4 or IPv6 results in both IPv4 and IPv6 match criteria being installed; for example, destination address = any.

Filter actions are executed before QoS actions. If an IP flow is rate-limited, it should pass the IPv4 or IPv6 filter first. Adding a QoS action rate limit to a PCC rule will not automatically insert a corresponding forward entry in an IP filter. When needed, this must be done explicitly by the operator with a filter forward action. For example, an IP filter with the default action drop and a number of explicit forward entries is applied to an IPoE session. A new IP flow must be rate-limited and accounted for. The PCC rule should include match criteria for the IP flow and a QoS action rate limit, QoS action account, and filter action forward. Without the filter action forward, the IP flow would be dropped by the default action in the filter policy.

```
config>filter
 ip-filter <filter-id> create
 sub-insert-shared-pccrule start-entry <entry-id> count <count>
 exit
 ipv6-filter <filter-id> create
 sub-insert-shared-pccrule start-entry <entry-id> count <count>
 exit
```

### 9.19.6.3 PCC Rules in a Subscriber Service

The example below shows a pseudo-language representation of PCC rules in a subscriber service.

- A subscriber service can contain multiple PCC rules. Because a PCC rule is unidirectional, including an ingress and an egress PCC rule enables subscriber service accounting of bidirectional flows.
- A PCC rule can contain multiple flows. Flows in a PCC rule can be a mix of IPv4 and IPv6 flows.

```
subscriber-service {
 name = <subsvc name>
 operation = add | delete
 acct-stats-type = off | volume-time | time
 acct-interval = <value>
 type = <string>
 type-conflict-action = keep-old | keep-new | none
 pcc-rule {
 name = <name>
 direction = ingress | egress
 flow = <5-tuple> | <dscp>
 flow = <5-tuple> | <dscp>
 ...
 flow = <5-tuple> | <dscp>
 action = <action>
 action = <action>
 ...
 action = <action>
 precedence = <value>
 }
 ...
 pcc-rule {
 name = <name>
 direction = ingress | egress
 flow = <5-tuple> | <dscp>
 flow = <5-tuple> | <dscp>
 ...
 flow = <5-tuple> | <dscp>
 action = <action>
 action = <action>
 ...
 action = <action>
 precedence = <value>
 }
}
```

The `sub_svc.pccrule` TLV in the subscriber services Python script adds a PCC rule to the subscriber service, as shown in the output example below:

Actual values are used to populate the subscriber service data structure in this example; typically, these values are sent as parameters in subscriber service-specific VSAs.

```
Python example - PCC rules subscriber service
service = []
sub_svc.add_to_service(service, sub_svc.operation, sub_svc.operation_add)
sub_svc.add_to_service(service, sub_svc.name, 'subsvc-pccrule-1')
sub_svc.add_to_service(service, sub_svc.type, 'pccrule')
sub_svc.add_to_service(service, sub_svc.type_conflict_action, sub_svc.type_conflict_
action_none)
flow_i = []
sub_svc.flow.add_to_flow(flow_i, sub_svc.flow.dst_ip, '10.1.1.0/24')
rule_i = []
sub_svc.pccrule.add_to_pccrule(rule_i, sub_svc.pccrule.name, 'pcc-rule-1-i')
sub_svc.pccrule.add_to_pccrule(rule_i, sub_svc.pccrule.precedence, 10)
sub_svc.pccrule.add_to_pccrule(rule_i, sub_svc.pccrule.direction, sub_svc.pccrule.di
rection_ingress)
sub_svc.pccrule.add_to_pccrule(rule_i, sub_svc.pccrule.flow, flow_i)
sub_svc.pccrule.add_to_pccrule(rule_i, sub_svc.pccrule.qos_action_rate_limit_pir, 10
00)
sub_svc.pccrule.add_to_pccrule(rule_i, sub_svc.pccrule.qos_action_account, True)
flow_e = []
sub_svc.flow.add_to_flow(flow_e, sub_svc.flow.src_ip, '10.1.1.0/24')
rule_e = []
sub_svc.pccrule.add_to_pccrule(rule_e, sub_svc.pccrule.name, 'pcc-rule-1-e')
sub_svc.pccrule.add_to_pccrule(rule_e, sub_svc.pccrule.precedence, 10)
sub_svc.pccrule.add_to_pccrule(rule_e, sub_svc.pccrule.direction, sub_svc.pccrule.di
rection_egress)
sub_svc.pccrule.add_to_pccrule(rule_e, sub_svc.pccrule.flow, flow_e)
sub_svc.pccrule.add_to_pccrule(rule_e, sub_svc.pccrule.qos_action_rate_limit_pir, 50
00)
sub_svc.pccrule.add_to_pccrule(rule_i, sub_svc.pccrule.qos_action_account, True)
sub_svc.add_to_service(service, sub_svc.pccrule, rule_i)
sub_svc.add_to_service(service, sub_svc.pccrule, rule_e)
sub_svc.add_to_service(service, sub_svc.acct_stats_type, 2)
sub_svc.add_to_service(service, sub_svc.acct_interval, 3600)
sub_svc.commit_service(service)
```

In the above subscriber service example, two PCC rules are installed, each with one flow:

- `pcc-rule-1-i`: ingress traffic to destination 10.1.1.0/24 is rate-limited to 1 Mb/s
- `pcc-rule-1-e`: egress traffic from 10.1.1.0/24 is rate-limited to 5 Mb/s

Subscriber service instance volume-time accounting is enabled. The volume counters include the forwarded octets and packets of the dynamic policers installed for the above rules and count the traffic matching the flows.

The counters reported in PCC rule-based subscriber services RADIUS accounting are determined by the PCC rule QoS account action.

- If at least one PCC rule in the subscriber service has the QoS account action enabled (`pccrule.qos_action_account = True`), then the volume counters contain the sum of the dynamic policer forwarded octets and packets statistics of all the PCC rules in the subscriber service with `pccrule.qos_action_account = True`.
- If all PCC rules in the subscriber service have the QoS account action disabled (`pccrule.qos_action_account = False`), then the volume counters contain the aggregated forwarded octets and packets of the parent PPPoE or IPoE session SLA profile instance since the start of the subscriber service.

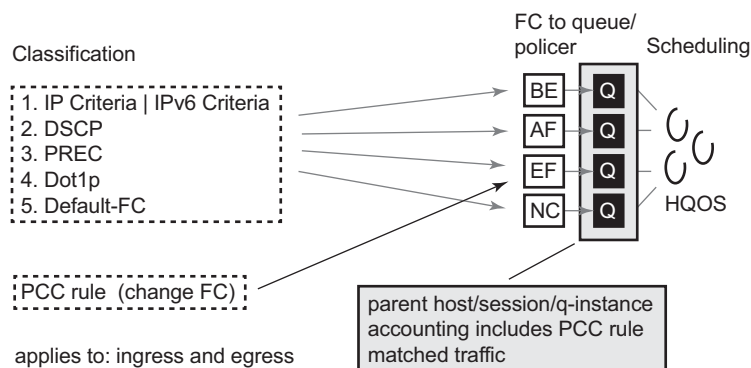

PCC rule-based subscriber services are not stored in the subscriber-mgmt persistency file.

#### 9.19.6.4 Interaction of the PPPoE or IPoE Session QoS Model and PCC Rule-based Subscriber Services

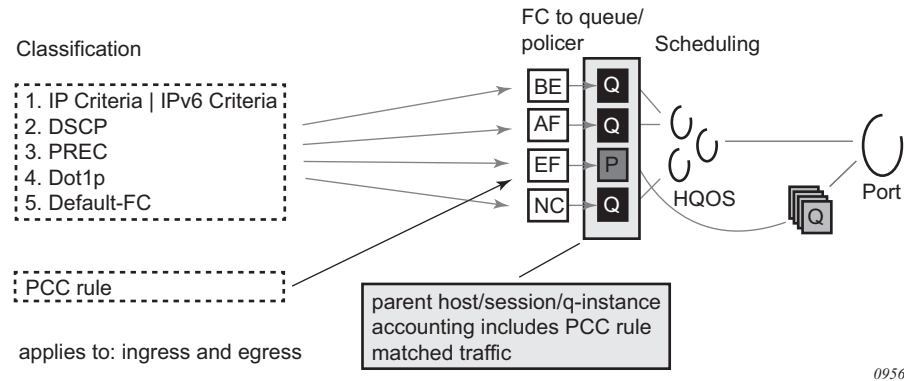

PCC rule-based subscriber services with QoS actions interact with the classification and QoS forwarding mechanisms. This section describes how this affects the parent RADIUS accounting volume counters.

For subscriber service PCC rule QoS actions that do not result in the instantiation of a dynamic policer (such as a change of forwarding class or forward), the PCC rule matched traffic is included in the parent accounting session volume counters. This is shown in [Figure 154](#), where the forwarding class is mapped to a subscriber queue, and in [Figure 155](#) where the forwarding class is mapped to a subscriber policer.

**Figure 154 PCC Rule-based Subscriber Service—QoS Interaction: No Dynamic Policer, FC → Queue**

**Figure 155 PCC Rule-based Subscriber Service—QoS Interaction: No Dynamic Policer, FC → Policer → Queue-group**

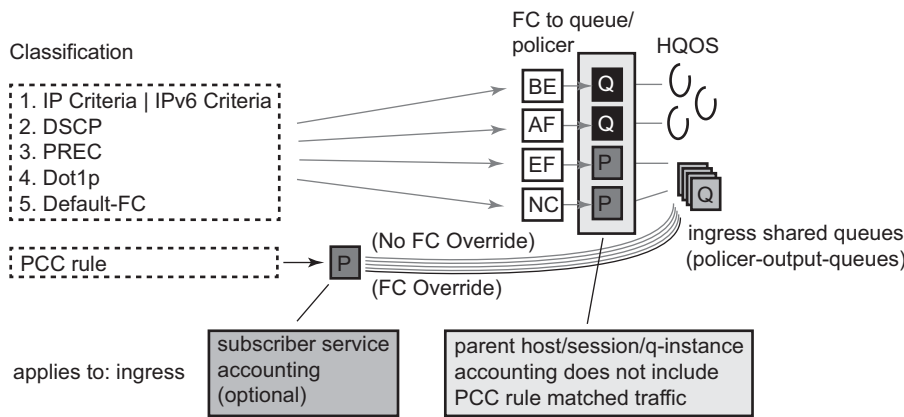

0956

For subscriber service PCC rule QoS actions that result in the instantiation of a dynamic policer (such as rate-limit or account), the dynamic policer counters are not included in the aggregate counters nor are they reported as separate detailed policer statistics. Instead, the traffic matching the PCC rules is counted in the output queues that correspond to the forwarding class of the packets.

- On ingress, the dynamic policer PCC rule traffic is never included in the parent host, session, or queue instance accounting session counters. Ingress policed traffic always uses the ingress shared policer output queues, as shown in [Figure 156](#).

**Figure 156 PCC Rule-based Subscriber Service—QoS Interaction: Dynamic Policer → Ingress Shared Policer Output Queues**

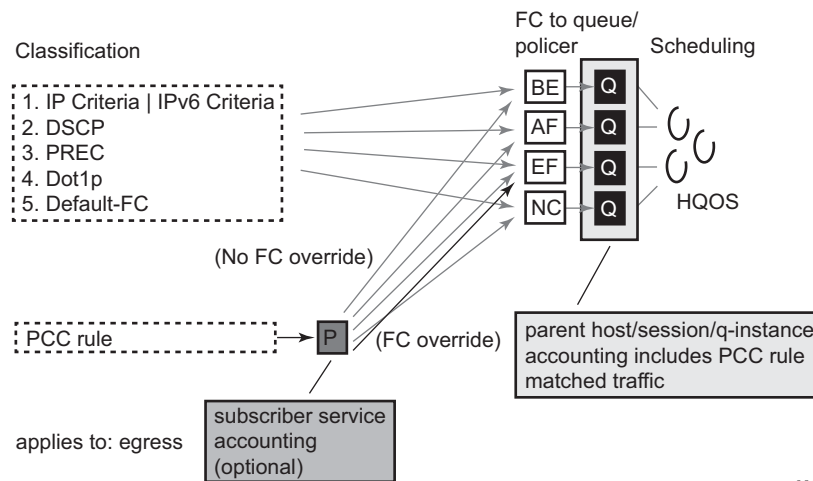

0957

- To include the egress dynamic policer PCC rule traffic in the parent host, session, or queue instance accounting session counters, the dynamic policer must use a local subscriber output queue, as shown in [Figure 157](#).

**Figure 157 PCC Rule-based Subscriber Service—QoS Interaction: Dynamic Policer, FC → Queue (Egress)**

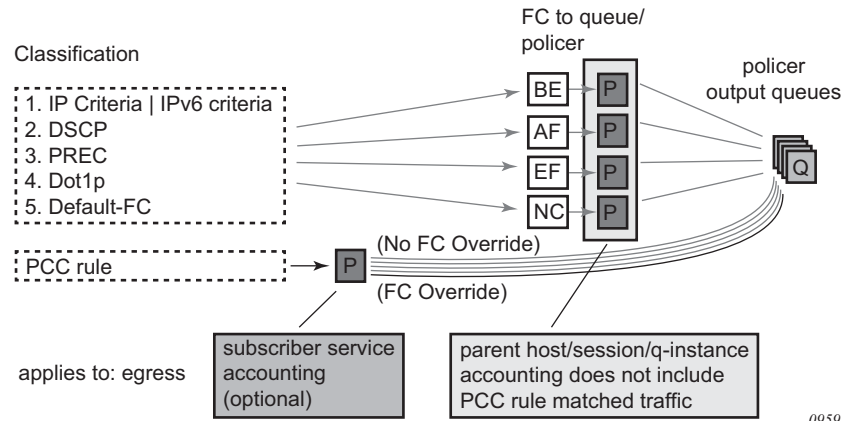

0958

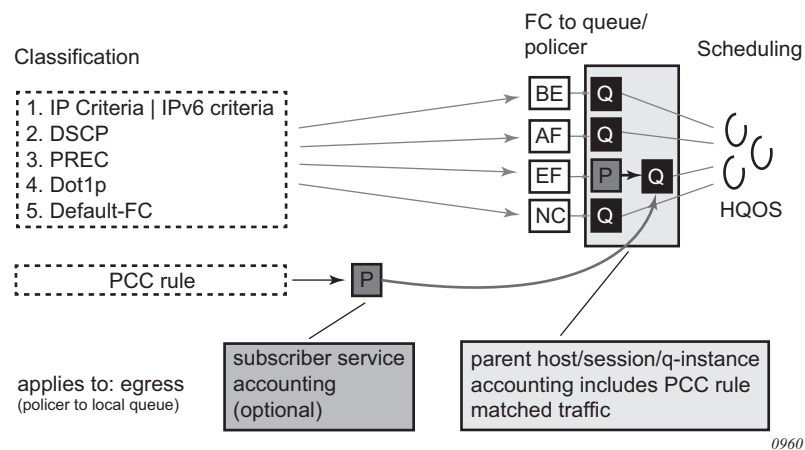

- To exclude the egress dynamic policer PCC rule traffic from the parent host, session, or queue instance accounting session counters, the dynamic policer must use a queue-group output queue, as shown in [Figure 158](#). The dynamic policer traffic inherits the policer-to-output queue mapping from the static policer that corresponds to the forwarding class of the packet. The following SAP egress configuration example uses the default policer output queue-group:

```
config>qos
 sap-egress 10 create
 sub-insert-shared-pccrule start-entry 200 count 10
 dynamic-policer
 range start-entry 10 count 10
 exit
 policer 1 create
 exit
 fc be create
 policer 1
 exit
exit
```

If a packet is classified as FC = Best Effort (BE) and matches a PCC rule with rate-limit action only (no FC change), the traffic will hit the PCC rule dynamic policer and then the queue-group queue associated with policer 1 (the static policer for FC = BE).

**Figure 158 PCC Rule-based Subscriber Service—QoS Interaction: Dynamic Policer, FC → Policer → Policer Output Queues (Egress)**

- A special case occurs when, at egress, the forwarding class maps to a static policer and then to a local subscriber queue. Traffic for that forwarding class hitting a dynamic policer will use the local subscriber queue as the output queue. In this case, the dynamic policer PCC rule traffic is included in the parent host, sessions or queue instance accounting session counters. This is shown in [Figure 159](#).

**Figure 159 PCC Rule-based Subscriber Service—QoS Interaction: Dynamic Policer, FC → Policer → Local Queue (Egress)**

9.19.6.5 PCC Rules on HSMDAv2

This section describes the differences in PCC rule-based subscriber services when applied to subscriber sessions terminating on an HSMDAv2 card, further referred to as HSMDBA.

The activation of PCC rule-based subscriber services is explained in the previous sections.

The filter policy cloning resulting from the instantiation of PCC rule filter actions is the same on the HSMDBA:

- IP or IPv6 filter policies applied at the sla-profile ingress or egress contexts can be cloned when PCC rules with filter actions are instantiated on HSMDBA subscriber sessions.

The QoS policy cloning resulting from the instantiation of PCC rule QoS actions is different on HSMDBAs because of the specific egress QoS architecture:

- **ingress** — The QoS policy applied at the sub-profile contains the active configuration and can be cloned when ingress PCC rules with QoS actions are instantiated on HSMDBA subscriber sessions. When a PCC rule clone exists, the QoS policy applied at the sub-profile ingress cannot be changed.
- **egress:** The QoS policy applied at the sla-profile contains the active configuration except for the HSMDBA queues. This QoS policy can be cloned when egress PCC rules with QoS actions are instantiated on HSMDBA subscriber sessions. When a PCC rule clone exists, the QoS policy associated at the sla-profile egress cannot be changed.

The following table summarizes the configuration of HSMDBA QoS and filter policies:

Table 74 HSMDA QoS and Filter Policy Configurations

| SLA Profile |                                                                                                                                                                                                                                   |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| <b>Sub Profile</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Ingress            | CLI context:<br><b>config&gt;subscr-mgmt&gt;sub-prof&gt;hsm da&gt;ingress-qos</b> <ul style="list-style-type: none"> <li>• qos &lt;policy-id&gt;               <ul style="list-style-type: none"> <li>– IOM queue and policer configuration</li> <li>– classification: dot1p, precedence, DSCP, default-fc, default-priority</li> <li>– Forwarding class to queue/policer mapping</li> <li>– ip-criteria and ipv6-criteria, including action policer &lt;id&gt;</li> <li>– dynamic policer configuration</li> <li>– sub-insert-shared-pccrule</li> </ul> </li> </ul>                                                                                                                                                                                                  |
| Egress             | CLI context:<br><b>config&gt;subscr-mgmt&gt;sub-prof&gt;hsm da&gt;egress-qos</b> <ul style="list-style-type: none"> <li>• qos &lt;policy-id&gt;               <ul style="list-style-type: none"> <li>– No active policer configuration allowed:                   <ul style="list-style-type: none"> <li>• Forwarding Class to policer mapping</li> <li>• ip-criteria and ipv6-criteria action policer &lt;id&gt;</li> </ul> </li> </ul> </li> <li>• HSM DA queue configuration</li> <li>• Other configurations are ignored</li> </ul>                                                                                                                                                                                                                                |

The following restrictions apply for PCC rule based subscriber services on HSMDA subscriber sessions:

- An egress rate limit (PIR/CIR) action is not supported. Egress dynamic policers on HSMDA are always installed with PIR=max and CIR=0. The CBS value for dynamic policers is ignored and it is recommended to keep the default MBS value.
- There is no support for hierarchical policing on egress dynamic policers. The subscriber host or session setup fails when a sub-profile is assigned containing an egress policer-control-policy configuration.
- Only a single SLA Profile Instance (SPI) can be active for a subscriber when a PCC-rule subscriber service containing egress QoS actions is active or activated:
  - The activation of a PCC rule-based subscriber service containing egress QoS actions fails when more than one SPI is active for the subscriber.
  - A new subscriber host or session setup fails when a new SPI is required while a PCC rule based subscriber service containing egress QoS actions is active.
  - A PCC rule based subscriber service containing egress QoS actions must be removed before the SLA profile of a subscriber can be changed.

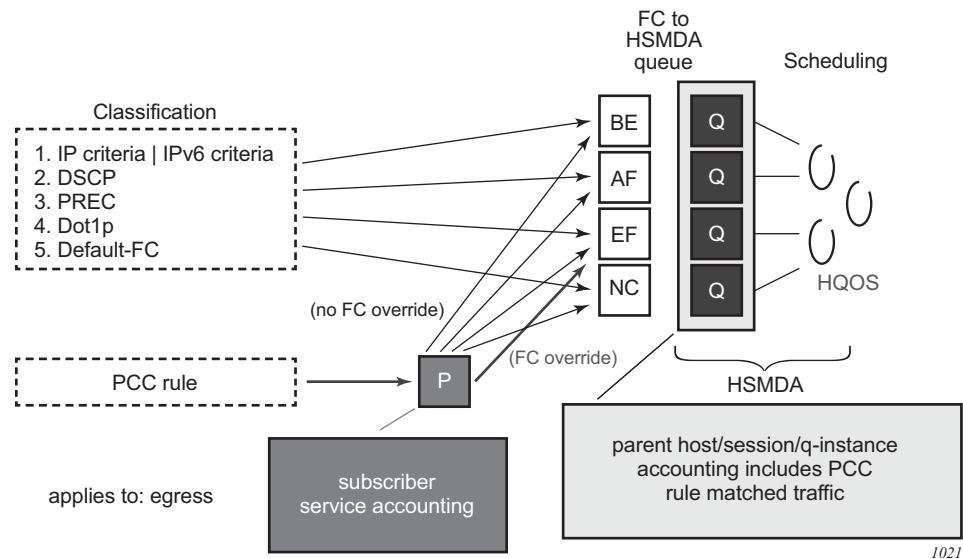

#### **9.19.6.5.1 Interaction between PCC Rule-Based Subscriber Services and RADIUS Queue-Instance, Host or Session Accounting Volume Counters**

PCC rule based subscriber services with QoS actions interact with the classification and QoS forwarding mechanisms. This section describes how this affects the parent RADIUS accounting volume counters.

For subscriber service PCC rule QoS actions that result in the instantiation of a dynamic policer (such as rate-limit or account), the dynamic policer counters are not included in the aggregate counters nor are they reported as separate detailed policer stats. Instead the traffic matching the PCC rules is counted in the output queues that correspond with the Forwarding Class of the packets:

- On ingress, the dynamic policer PCC rule traffic is never included in the parent host, session or queue-instance accounting session counters. Ingress policed traffic always uses the ingress shared policer output queues. This is the same as for non-HSMDA scenarios. See [Figure 156](#).
- On egress, the dynamic policer PCC rule traffic is always included in the parent host, session or queue-instance accounting session counters. Egress policed traffic always uses the egress HSMDA queues as shown in [Figure 160](#).

**Figure 160 PCC Rule-Based Subscriber Service – HSMDA Egress Accounting**

### 9.19.6.6 PCC Rule-based Subscriber Service Activation Failures

PCC rule-based subscriber service activation failures can be categorized as failures detected in the subscriber services Python script as runtime errors (see [Table 75](#)) and failures detected in the Enhanced Subscriber Management (ESM) processing (see [Table 76](#)).

**Table 75 PCC Rule-based Subscriber Service: Python Runtime Errors**

| Python Runtime Errors                                                                  |
|----------------------------------------------------------------------------------------|
| Pcc rule name type must be a string                                                    |
| Pcc rule name value too long                                                           |
| Pcc rule qos action account value must be True(1) or False(0)                          |
| Pcc rule filter action redirect to nexthop_v4/v6 type must be a string                 |
| Pcc rule filter action redirect to nexthop_v4/v6 value must be a valid IPv4/v6 address |
| Pcc rule filter action http redirect value is not a valid URL                          |
| Pcc rule filter action http redirect type must be a string                             |
| Pcc rule filter action http redirect value too long (> 255)                            |

**Table 75 PCC Rule-based Subscriber Service: Python Runtime Errors**

| Python Runtime Errors                                                                             |
|---------------------------------------------------------------------------------------------------|
| Pcc rule qos action fwd class change value is invalid                                             |
| Pcc rule qos action rate limit type must be an int                                                |
| Pcc rule precedence type must be an int                                                           |
| Pcc rule flow dscp match type must be a string                                                    |
| Pcc rule flow dscp match value is invalid                                                         |
| Pcc rule flow src/dst_ip match type must be a string: <ipv4-address> <ipv6-address> any           |
| Pcc rule flow src/dst_ip match value is not a valid IP address: <ipv4-address> <ipv6-address> any |
| Pcc rule flow port match type must be a string: <port>[-<port>] with port [0..65535]              |
| Pcc rule flow protocol match type must be an int                                                  |
| Pcc rule flow protocol match value must be less than 255                                          |
| Pcc rule must have a name                                                                         |

**Table 76 PCC Rule-based Subscriber Service: ESM failures**

| ESM —RADIUS Decoding Failures                                                                                                                         |
|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| The PCC rule precedence must be in the range 0 to 65535.                                                                                              |
| The PCC rule name has a maximum of 100 displayable characters.                                                                                        |
| The PCC rule redirect URL has a maximum of 255 displayable characters.                                                                                |
| All flows in a PCC rule must have the same direction (ingress or egress).                                                                             |
| A PCC rule has a maximum of 128 flows.                                                                                                                |
| A PCC rule name can occur only once in a RADIUS message.                                                                                              |
| A flow in a PCC rule cannot have a mix of IPv4 and IPv6 addresses (for example <b>src-ip</b> and <b>dst-ip</b> ).                                     |
| ESM—Processing Failures                                                                                                                               |
| If a PCC rule contains a direction-specific action (such as a redirect), it must contain at least one flow in that direction.                         |
| If a PCC rule contains only IPv4 actions (such as a redirect to an IPv4 next hop), it must contain at least one IPv4 flow. This also applies to IPv6. |
| The combinations of PCC rule actions must be supported (see <a href="#">Figure 152</a> and <a href="#">Figure 153</a> ).                              |

**Table 76 PCC Rule-based Subscriber Service: ESM failures (Continued)**

|                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------|
| There must be at least one flow and at least one action per PCC rule.                                           |
| There is a maximum of 64 PCC rules per host or session.                                                         |
| There are not enough filter or QoS resources to create policy clones or apply them to the host or session.      |
| The filter or QoS policy clone cannot be created (for example, the redirect service does not exist).            |
| Simultaneous provisioning of PCC rules from Gx and RADIUS is operationally blocked per subscriber session/host. |

## 9.19.7 Combined Subscriber Services

A subscriber service instance can be built with a combination of QoS override actions and PCC rules. In this case, the reported volume counters for subscriber service statistics type volume-time are determined by the PCC rule account action, as shown in [Table 77](#).

**Table 77 Subscriber Service Accounting—Reported Volume Counters**

| QoS Override | PCC Rule                                                                 | Reported Volume Counters                                                             |
|--------------|--------------------------------------------------------------------------|--------------------------------------------------------------------------------------|
| No           | No                                                                       | Aggregated SLA profile queue and policer statistics                                  |
| Yes          | No                                                                       | Aggregated SLA profile queue and policer statistics                                  |
| No           | Yes,<br>“pccrule.qos_action_account = False”<br>for all PCC rules        | Aggregated SLA profile queue and policer statistics                                  |
| No           | Yes,<br>“pccrule.qos_action_account = True”<br>for at least one PCC rule | Dynamic policer statistics for PCC rules with<br>“pccrule.qos_action_account = True” |
| Yes          | Yes,<br>“pccrule.qos_action_account = False”<br>for all PCC rules        | Aggregated SLA profile queue and policer statistics                                  |
| Yes          | Yes,<br>“pccrule.qos_action_account = True”<br>for at least one PCC rule | Dynamic policer statistics for PCC rules with<br>“pccrule.qos_action_account = True” |

## 9.19.8 Subscriber Services Python API

The SR OS alc.sub\_svc Python module offers functions and data structures to describe, activate, and deactivate a subscriber service.

### 9.19.8.1 Common Subscriber Services Python API

[Table 78](#) lists the subscriber service functions in the alc.sub\_svc module.

**Table 78** Subscriber Service Functions in the alc.sub\_svc Module

| sub_svc Functions                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sub_svc.add_to_service (svc, sub_svc TLV, value) | appends a TLV to the service list. The service list describes the subscriber service and should be passed to the sub_svc.commit_service() to activate or deactivate the subscriber service.<br>Parameters:<br>svc (type = list): service list that describes the subscriber service. sub_svc TLVs are appended to this list with the sub_svc.add_to_service() function.<br>sub_svc TLV (type int): TLV that will be appended to the service list<br>value (type as defined for the sub_svc TLV): the value of the sub_svc TLV that will be appended to the service list |
| sub_svc.commit_service (svc)                     | creates the required internal VSAs based on the TLVs provided in the svc list.<br>Parameters:<br>svc (type = list): service list that describes the subscriber service. sub_svc TLVs are appended to this list with the sub_svc.add_to_service() function. The service list should be passed to sub_svc.commit_service() to activate or deactivate the subscriber service.                                                                                                                                                                                              |

[Table 79](#) lists the subscriber service TLVs in the alc.sub\_svc module.

**Table 79**      **Subscriber Service TLVs in the alc.sub\_svc Module**

| sub_svc TLV              | Activate/<br>Deactivate | TLV Details |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

### 9.19.8.2 Subscriber Service QoS Override Python API

Table 80 lists the QoS override TLVs in the alc.sub\_svc module.

**Table 80** QoS Override TLVs in the alc.sub\_svc Module

| sub_svc TLV              | Activate/<br>Deactivate | TLV Details |                                                                                                                                 |
|--------------------------|-------------------------|-------------|---------------------------------------------------------------------------------------------------------------------------------|
| qos_override<br>(string) | O/n.a.                  | Purpose     | Adds a QoS override to the subscriber service. Multiple qos_override TLVs can be added in a single subscriber service instance. |
|                          |                         | Value       | As defined for the RADIUS Alc-Subscriber-QoS-Override VSA [26-6527-126].<br>See details below.                                  |
|                          |                         | Default     | Not included                                                                                                                    |

Note:

- M=Mandatory, O=Optional, n.a.=ignored

QoS override TLV value format:

**<direction>:<QoS object>:[<id or name>:][<parameter>=value,...]**

where:

<direction> = i or I for ingress

<direction> = e or E for egress

<QoS object> = q or Q for queue overrides

<QoS object> = p or P for policer overrides

<QoS object> = r or R for egress aggregate-rate overrides

<QoS object> = a or A for root arbiter overrides

<QoS object> = s or S for scheduler overrides

<id or name> = identifies the QoS object; for example, queue-id

<parameter>=value,... = a comma-separated list of parameters to override with the corresponding value

[ileE]:[qQ]:<queue-id>:(pir=|cir=|mbs=|cbs=|wrr\_weight=)

[ileE]:[pP]:<policer-id>:(pir=|cir=|mbs=|cbs=)

[eE]:[rR]:rate=

[ileE]:[aA]:root:rate=

[ileE]:[sS]:<scheduler-name>:(rate=|cir=)

pir, cir and rate values must be specified in kilobits per second (kb/s)

mbs and cbs values must be specified in bytes

wrr\_weight can be specified for egress queues [1..4] for hsmcsv2 only

9.19.8.3    **Subscriber Service PCC Rules Python API**

Table 82 lists the PCC rule PLVs in the alc.sub\_svc module.

Table 81      PCC Rule TLVs in the alc.sub\_svc Module

| sub_svc TLV       | Activate/<br>Deactivate | TLV Details |                                                                                                                                                                                                                           |
|-------------------|-------------------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pccrule<br>(list) | O/n.a.                  | Purpose     | Adds a PCC rule to the subscriber service. Multiple PCC rule TLVs can be added in a single subscriber service instance.                                                                                                   |
|                   |                         | Value       | A PCC rule list describing the PCC rule with PCC rule TLVs such as name, precedence, direction, flows, and actions<br>PCC rule TLVs are appended to the PCC rule list with the sub_svc.pccrule.add_to_pccrule() function. |
|                   |                         | Default     | Not included                                                                                                                                                                                                              |

Note:

- M=Mandatory, O=Optional, n.a.=ignored

Table 82 lists the alc.sub\_svc.pccrule function.

**Table 82**      **alc.sub\_svc.pccrule Function**

| alc.sub_svc.pccrule Function                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| sub_svc.pccrule.add_to_pccrule (pccrule, pccrule TLV, value) | <p>Appends a PCC rule TLV such as name, precedence, flow, or action to the PCC rule list. The PCC rule list describes the PCC rule and can be added to a subscriber service with the sub_svc.add_to_service() function.</p> <p>Parameters:</p> <p>pccrule (type = list): PCC rule list that describes the PCC rule. PCC rule TLVs are appended to this list with the sub_svc.pccrule.add_to_pccrule() function.</p> <p>pccrule TLV (type int): PCC rule TLV that will be appended to the PCC rule list</p> <p>value (type as defined for the PCC rule TLV): the value of the PCC rule TLV that will be appended to the PCC rule list</p> |

Table 83 lists the PCC rules TLVs in the alc.sub\_svc.pccrule module.

**Table 83**      **PCC Rule TLVs in the alc.sub\_svc.pccrule Module**

| PCC Rule TLV                    | M O | TLV Details |                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------------|-----|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pccrule.name<br>(String)        | M   | Purpose     | <p>Specifies the name of the PCC rule</p> <p>A PCC rule with the same name and same or different content can only be applied once on a single parent PPPoE or IPoE session.</p> <p>A PCC rule with the same name and same or different content can be applied on different parent PPPoE or IPoE sessions. Rules with the same name but different content will get a different PCC rule identifier (rule id).</p>                |
|                                 |     | Value       | Free format string (maximum length = 100 bytes)                                                                                                                                                                                                                                                                                                                                                                                 |
|                                 |     | Default     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                             |
| pccrule.precedence<br>(Integer) | O   | Purpose     | <p>Specifies the precedence value for the PCC rule. The precedence defines a relative order of the different PCC rules: a rule with a lower precedence value will be applied before a rule with a higher precedence value.</p> <p>Rules with the same precedence and rules without precedence can be automatically optimized; the relative order in which they are applied is determined by the system for optimal sharing.</p> |
|                                 |     | Value       | 0 to 65535                                                                                                                                                                                                                                                                                                                                                                                                                      |

## 9.19.9 Operational Commands

### 9.19.9.1 Show Commands

To display the active subscriber services in the system, use the **show service sub-services** CLI command. The **sub-service-name** filter is a longest match.

```
show service sub-services [id <service-id>] [sap <sap-id>] [ip <ip-prefix/prefix-length>] [mac <ieee-address>] [pppoe-session-id <pppoe-session-id>] [sub-service-name <sub-service-name>] [sub-service-type <sub-service-type>] [summary|associations]
```

Sample output:

```
show service sub-services
=====
Subscriber service table
=====
Username : cpe2@domain1.com
Subscriber : cpe2@domain1.com Type : PPP
SAP : 1/1/4:1201.5 Service : 1000
MAC Address : 00:51:00:00:01:01 PPPoE-SID: 114

 ingress arbiter "root" rate 5120
QoS-override
 egress aggregate rate limit 30720

number of subscriber services found: 1
=====
```

To display the active PCC rules in the system, use the **show service active-subscribers pcc-rule** CLI command. A PCC rule can be inactive when, for example, a PCC rule with filter actions on IPv6 flows is activated on an IPv4single-stack PPPoE or IPoE session.

```
show service active-subscribers pcc-rule [subscriber <sub-ident-string>] [detail]
```

## Sample output:

```
show service active-subscribers pcc-rule subscriber "ipoe-bridged-001" detail
=====

=====

=====

```

Use the following alternative command to check the PCC rules in the system:

```

show subscriber-mgmt pcc-rule
- pcc-rule
- pcc-rule monitoring-key <key> detail
- pcc-rule rule-id <id> detail
- pcc-rule rule-name <rule-name>
- pcc-rule rule-name <rule-name> detail
- pcc-rule summary
- pcc-rule monitoring-key <key>
<rule-name> : [100 chars max]
<key> : [80 chars max]
<id> : [1..1023]
<detail> : keyword

```

The statistics of dynamic policers can be displayed with:

```

show service active-subscribers subscriber "ipoe-bridged-001" detail
--- snip ---

SLA Profile Instance per Policer statistics

Packets Octets
--- snip ---
Ingress Policer 10 (Stats mode: minimal)
used by pcc-rule rule-1
Off. All : 0 0
Dro. All : 0 0
For. All : 0 0
--- snip ---

```

The details of the cloned QoS and filter policies as a result of PCC rule activation can be displayed with the following show commands:

```
show qos sap-ingress 10:P1
show qos sap-egress 10:P1
show filter ip 10:P1
show filter ipv6 "10:P1"
```

### 9.19.9.2 Debug Commands

There are no specific RADIUS subscriber services debug commands. The debugging is part of the RADIUS and Python debug output; for example:

```
debug
 router "Base"
 radius
 packet-type authentication accounting coa
 detail-level high
 exit
 exit
 python
 python-script "subsvc-1"
 script-all-info
 exit
 exit
exit
```

### 9.19.9.3 Resource Monitoring

For information on resource monitoring, see the [PCC Rules and Capacity Planning](#) and [PCC Rule Scaling Example](#) sections in the [Diameter and Diameter Applications](#) chapter.

The following CLI command provides an overview of the resource usage per line card, such as the number of ACL and ACL QoS entries, Filters, QoS policies, dynamic policers, and QoS overrides:

```
tools dump resource-usage card [<slot-number>] all
```

These resource counters are available in SNMP and can be used in RMON to trigger threshold crossing alarms; for example:

```
configure system
 thresholds
 rmon
 alarm 1 variable-
oid tFPResIngIPv6AclEntryAlloc.1.1.1 interval 10 rising-event 1 rising-
threshold 25000 falling-event 2 falling-threshold 24000
 event 1 description "Ingress IPv6 ACL Entries too high"
 event 2 description "Ingress IPv6 ACL Entries - below limit"
 exit
```

The summary output of the **show subscriber-mgmt pcc-rule** command lists the number of active PCC rules and the number of active combinations:

```
show subscriber-mgmt pcc-rule summary
=====
PCC Rules Summary
=====
Total Nbr PCC Rules : 2 / 1024
Nbr Active PCC Rules : 2 / 1024
Nbr Active Combinations
 IPv4 Filter : 0 / 4095
 IPv6 Filter : 0 / 4095
 Egress Qos : 1 / 4095
 Ingress Qos : 1 / 4095
=====
```

## 9.20 Residential Gateway Replacement

Residential gateway (RG) replacements are performed for a variety of reasons such as upgrading hardware, replacing broken equipment, or relocating to a new home. However, the BNG's anti-spoof filter and host-limit features can sometime prevent immediate RG replacement. In some cases, a subscriber must wait for an old DHCP lease to expire before a new RG is allowed to connect to the BNG. For example, some service providers assign an IP address and/or prefix based on physical line, SAP-id, circuit-id, or interface-id. Therefore, a home is always assigned the same IP address and/or prefix. On the BNG, an anti-spoof mechanism prevents different MAC addresses from using the same IP address. As a result, the new RG fails the anti-spoof filter and is denied an IP address and/or prefix. The subscriber in this case must wait for the DHCP lease of the RG to time out in order for the anti-spoof filter to remove its entry.

Two features, **lease-override** and **shcv-policy**, may help improve the RG replacement process. These features focus on minimizing service interruption and enhancing the end subscriber experience. RGs, in general, have no mechanisms to inform the BNG or the DHCP server that they have been disconnected from the network. Even if the BNG has periodic SHCV enabled, the detection might take some time. Often, when a subscriber plugs in a new RG, the BNG still has the old RG registered as a host. This has two consequences. First, if the new RG is assigned the same IP address as the old RG, then an IP-conflict occurs and fails the anti-spoof filter. Second, if the SAP has a host limit or a session limit provisioned, then exceeding the limit will prevent the new RG from receiving an IP address and/or prefix.

Starting in Release 13.0R4, if an IP conflict occurs on the same SAP, then by default the new RG (MAC) will immediately override the DHCP lease of the old device. This is known as **lease-override**. This is applicable to DHCP relay and proxy for both IPv4 and IPv6 hosts. Prior to 13R4, lease-override only occurred for DHCPv4 relay. The **lease-override** is performed only when an IP-conflict occurs within the same SAP.

The other option is to use trigger SHCV to check the connectivity status of the old RG before removing it and its lease. This is known as the ip-conflict-triggered SHCV under the SHCV-policy. The SHCV is sent only when the BNG detects an IP address conflict on DHCP discovery. If the host does not respond within the configured timeout, both the host and lease are removed from the BNG. The new RG is required to perform a subsequent DHCP discovery or request in order to install a host. SHCV can help prevent malicious RGs from spoofing another RG IP address. Trigger SHCV for IP-conflict is available for DHCPv4/v6 relay and proxy, as well as ARP hosts. The following table specifies when the SHCV is sent for IP-conflict.

**Table 86 IP-Conflict SHCV Triggering Points**

| Configuration on group interface | Triggered on       |
|----------------------------------|--------------------|
| DHCPv4 proxy                     | DHCP Discovery     |
| DHCPv4 relay                     | DHCP Request       |
| DHCPv6 proxy                     | DHCP Advertisement |
| DHCPv6 relay                     | DHCP Advertisement |
| ARP-host                         | Host's initial ARP |

It is also possible that new RGs are denied of service because of a host limit set against the subscriber. There are various host limit features on the BNG: sla-profile host-limit, ipoe session-limit, and ipoe sap-session limit. For example, setting a host limit of "1" can ensure that each home will only take one IP address. As mentioned before, RGs do not inform the BNG of a disconnect. If SHCV is enabled, it might take some time before the BNG is informed of the disconnect. Therefore, when a new RG connects to the BNG, the BNG will perform a host limit check (if configured) against the subscriber. If the old host is still has an entry on the BNG and there is a host-limit of "1", the new RG is denied an IP address and/or prefix assignment because it has exceeded the host limit. A trigger SHCV, "host-limit-exceeded" inside the shcv-policy can be configured against a group-interface. his SHCV is triggered when an over limit is detected. If the existing host registered on the BNG does not respond within the configured timeout both the host and its lease are removed from the BNG. The SHCV can only remove hosts from the BNG, the new RG is still required to perform a subsequent DHCP discoveries or requests to obtain an IP address.

By providing lease-override and various SHCV triggers in the SHCV policy, service providers have a variety of options to allow subscribers to perform quick and seamless RG replacements.

It is possible to use host-connectivity check without the shcv-policy. The main function of host-connectivity check would be for periodic check. The trigger functions are performed through the SHCV-policy.

## 9.21 ESM Troubleshooting Show Command

Network operators are sometimes unable to turn on debug to troubleshoot customers issues on a live production network. Turning on debug might affect the BNG performance, and some support technicians may not have access to debug and configuration commands.

The **show subscriber-mgmt errors** command is a show command that captures detailed ESM errors. This command helps diagnose problems immediately without the need to turn on the debug function. Only DHCPv4 and PPPv4 supports this command; some support details are provided below. This command will not compromise the BNG performance and does not require debug or configuration commands.

- DHCPv4 support:
  - dropped protocol messages (host setup/renew)
  - protocol timeouts
- PPPv4 support (including PPPoE, PPPoA, and PPPoEoA):
  - dropped protocol messages
  - traps

IPv6 host setup errors may be captured in error logs.

All subscriber problems are first stored in a main circular buffer. The main circular buffer is then fed into smaller circular buffers, organized by MAC addresses. When the buffer is full, the first circular buffer will purge the oldest message to make room for the newest message. The smaller circular buffers (one per MAC address) store a limited number of messages per MAC. Again, the smaller buffer will delete the oldest to make room for the newest. The circular buffer, per MAC, prevents one device from holding all the error messages in the buffer. The main circular buffer can hold 5,000 errors in total, while the smaller buffer can hold 10 log entries per MAC. The circular buffer supports CPM3 and higher.

The **show** command allows sorting by MAC, subscriber SAP, SDP, and unknown-origin (unknown SAP or SDP). The **show** command allows the input of a specific MAC, SAP, or SDP to directly search for particular subscriber issues or problems.

The circular buffer will only log drop reasons for DHCPv4 and PPPoEv4. Non-error reasons are never logged; for example, a drop due to being in SRRP standby is not logged. The circular buffer has a timestamp associated with each error and the errors are listed beginning with the most recent. Error logs are lost on a HA switchover, and persistency is not supported. There is no throttling mechanism for the same errors; it is possible to fill the circular buffer with the same error message from different MAC addresses.

## 9.22 Hybrid Access

In a hybrid access deployment, a home's residential gateway (RG) is connected to the network via both a wired and a wireless link. Traffic can be split over these links via various mechanisms such as per-flow hashing, flow policies, or MP-TCP. Both access connections must be terminated in a common endpoint called the Hybrid Access Gateway (HAG). This gateway provides Internet connectivity to the home.

SR OS TPSDA supports hybrid access deployments where a P-GW acts as a HAG. In this model, both the fixed access and wireless access links share the same Layer 3 IP/IPv6 address. The RG/HAG determines which Layer 2 connection should be used. To support this model, SR OS IPoE session and PPPoE session functionality is extended to connect to a GTP uplink. When this uplink is active, all unicast traffic is forwarded via a GTP tunnel between the BNG and P-GW. This way, the P-GW acts as the Layer 3 gateway and the BNG does not attract subscriber traffic via regular routing. Multicast traffic is not supported and should be handled out of band.

Figure 161 shows a sample Hybrid Access deployment.

**Figure 161** Sample Hybrid Access Deployment

For more details on GTP uplinks, see the GTP section in this guide.

## 9.23 Configuring Enhanced Subscriber Management with CLI

This section provides information to configure subscriber management features using the command line interface. It is assumed that the reader is familiar with VPLS and IES services.

Topics in this section include:

- [Configuring RADIUS Authentication of DHCP Sessions](#)
- [Configuring Enhanced Subscriber Management](#)
  - [Basic Configurations](#)
  - [Configuring Enhanced Subscriber Management Entities](#)
    - [Configuring a Subscriber Identification Policy](#)
    - [Configuring a Subscriber Profile](#)
    - [Configuring an SLA Profile](#)
    - [Configuring Explicit Mapping Entries](#)
  - [Applying the Profiles and Policies](#)
  - [Configuring Dual Homing](#)
- [Python Script Support for ESM](#)
- [Sample Python Scripts](#)

### 9.23.1 Configuring RADIUS Authentication of DHCP Sessions

When RADIUS authentication for subscriber sessions is enabled, DHCP messages from subscribers are temporarily held by the BSA, while the user's credentials are checked on a RADIUS server.

Configuring RADIUS authentication for subscriber sessions is done in two steps:

- First define an authentication-policy in the **config>subscriber-mgmt>authentication-policy** context.
- Then apply the policy to one or more SAPs in the **config>service>vpls>sap>authentication-policy** *auth-plcy-name* context (for a VPLS service).

Or apply the policy to one or more interfaces

**config>service>ies>if>authentication-policy** *auth-plcy-name* context (for an IES service):

The following example displays a partial BSA configuration with RADIUS authentication:

```
A:ALA-1>config>service# info

subscriber-management
 authentication-policy BSA_RADIUS create
 description "RADIUS policy for DHCP users Authentication"
 password "mysecretpassword"
 radius-authentication-server
 server 1 address 10.100.1.1 secret "radiuskey"
 retry 3
 timeout 10
 exit
 re-authentication
 user-name-format circuit-id
 exit
exit
...
vpls 800 customer 6001
 description "VPLS with RADIUS authentication"
 sap 2/1/4:100 split-horizon-group DSL-group create
 authentication-policy BSA_RADIUS
 exit
 sap 3/1/4:200 split-horizon-group DSL-group create
 authentication-policy BSA_RADIUS
 exit
 no shutdown
exit
...

A:ALA-1>config>service#
```

## 9.23.2 TCP MSS adjustment for ESM Hosts

TCP MSS adjustment is supported to prevent fragmentation of TCP packets from/to ESM hosts. See the TCP MSS Adjustment for ESM Hosts section of the Multiservice Integrated Service Adapter Guide.

## 9.23.3 Configuring Enhanced Subscriber Management

### 9.23.3.1 Basic Configurations

Configuring and applying the Enhanced Subscriber Management profiles and policies are optional. There are no default Profiles or policies.

The basic Enhanced Subscriber Management profiles and policies must conform to the following:

- Unique profile or policy names (IDs)
- Profiles and/or policies must be associated with a VPLS or IES service to facilitate Enhanced Subscriber Management.
- QoS and IP filter entries configured in Enhanced Subscriber Management profiles and policies override the defaults and/or modified parameters or the default policies.
- The Enhanced Subscriber Management profiles and policies must be configured within the context of VPLS or IES.

### 9.23.3.2 Subscriber Interface Configuration

The following output displays a basic subscriber interface configuration.

```
*A:ALA-48>config>service>ies>sub-if# info

description "Routed CO - Antwerp 2018"
address 192.168.2.254/24
address 192.168.3.254/24
address 192.168.4.254/24
address 192.168.5.254/24
address 192.168.6.254/24
group-interface "DSLAM_01" create
 description "Routed CO - vlan / subscriber"
 sap 1/1/2:1001 create
 static-host ip 192.168.2.2 create
```

```

 exit
 sap 1/1/2:1002 create
 static-host ip 192.168.2.2 create
 exit
 sap 1/1/2:1004 create
 static-host ip 192.168.2.4 create
 exit
 sap 1/1/2:1100 create
 static-host ip 192.168.2.100 create
 exit
 exit
exit

*A:ALA-48>config>service>ies>sub-if#

```

### 9.23.3.3 Configuring Enhanced Subscriber Management Entities

- [Configuring a Subscriber Identification Policy](#)
- [Configuring a Subscriber Profile](#)
- [Configuring a Subscriber Identification Policy](#)
- [Configuring Explicit Mapping Entries](#)
- [Applying the Profiles and Policies](#)

#### 9.23.3.3.1 Configuring a Subscriber Identification Policy

The following displays an example of a subscriber identification policy configuration:

```

A:ALA-48>config>subscr-mgmt# info

...
 sub-ident-policy "Globocom" create
 description "Subscriber Identification Policy Id Globocom"
 sub-profile-map
 entry key "1/1/2" sub-profile "ADSL Business"
 exit
 sla-profile-map
 entry key "1/1/2" sla-profile "BE-Video"
 exit
 primary
 script-url "primaryscript.py"
 no shutdown
 exit
 secondary
 script-url "secondaryscript.py"
 exit
 tertiary
 script-url "tertiaryscript.py"
 no shutdown

```

```
exit
exit
...

A:ALA-48>config>subscr-mgmt#
```

### 9.23.3.3.2 Configuring a Subscriber Profile

Enhanced Subscriber Management subscriber profile configurations specify existing QoS scheduler profiles. In the following example, “BE-Video-max100M” is specified in the sub-profile “ADSL Business” for the ingress-scheduler-policy. “Upload” is specified in the sub-profile egress-scheduler-policy.

```
#-----
echo "QoS Policy Configuration"
#-----
qos
 scheduler-policy "BE-Video-max100M" create
 description "Scheduler Policy Id BE-Video-max100M"
 tier 1
 scheduler "tier1" create
 description "Scheduler Policy Id BE-Video-max100M Tier 1 tier1"
 exit
 exit
 exit
 scheduler-policy "Upload" create
 description "Scheduler Policy Id Upload"
 tier 3
 scheduler "tier3" create
 description "Scheduler Policy Id Upload Tier 3 tier3"
 exit
 exit
 exit
 sap-ingress 2 create
 description "Description for Sap-Ingress Policy id # 2"
 queue 1 create
 parent "tier1"
 exit
 queue 11 multipoint create
 parent "tier1"
 exit
 exit
 sap-egress 3 create
 description "Description for Sap-Egress Policy id # 3"
 queue 1 create
 parent "tier3"
 exit
 exit
exit
#-----
```

The following displays an example of a subscriber identification policy configuration:

```
A:ALA-48>config>subscr-mgmt# info

...
 sub-profile "ADSL Business" create
 description "Subscriber Profile Id ADSL Business"
 ingress-scheduler-policy "BE-Video-max100M"
 scheduler "tier1" rate 99
 exit
 egress-scheduler-policy "Upload"
 scheduler "tier3" rate 1 cir 1
 exit
 sla-profile-map
 entry key "1/1/3" sla-profile "BE-Video"
 exit
 exit

A:ALA-48>config>subscr-mgmt#
```

### 9.23.3.3.3 Configuring an SLA Profile

The following displays an example of a SLA Profile configuration:

```
A:ALA-48>config>subscr-mgmt# info

 subscriber-mgmt
 sla-profile "BE-Video" create
 description "SLA Profile Id BE-Video"
 ingress
 qos 2
 queue 1
 exit
 exit
 exit
 egress
 qos 3
 queue 1
 exit
 exit
 exit
 exit

A:ALA-48>config>subscr-mgmt#
```

### 9.23.3.3.4 Configuring Explicit Mapping Entries

The following displays an example of a explicit subscriber mapping:

```
A:ALA-7>config>subscr-mgmt# info

A:ALA-48>config>subscr-mgmt# info

...
```

```
 explicit-subscriber-map
 entry key "1/1/1:1111" sub-profile "ADSL GO" alias "Sub-Ident-1/1/1:
1111" sla-profile "BE-Video"
 exit
...

A:A:ALA-48>config>subscr-mgmt#
```

### 9.23.3.4 Routed CO with Basic Subscriber Management Features

The following displays the output of an IES service configured with and without enhanced subscriber management and only applies to the 7750 SR.

```
A:term17>config>service>ies# inf

 subscriber-interface "s2" create
 address 11.20.1.1/16
 dhcp
 gi-address 11.20.1.1

 dhcp
 server 12.1.1.1
 trusted
 lease-populate 8000
```

```
no shutdown
exit
sap 4/1/1:24.4094 create
exit
exit
exit
no shutdown

A:term17>config>service>ies#
```

### 9.23.3.5 Applying the Profiles and Policies

**Note:** Subscriber interfaces operate only with basic (or enhanced) subscriber management. At the very least, a host, either statically configured or dynamically learned by DHCP must be present in order for the interface to be useful. This note applies to the 7750 SR only.

Apply the Enhanced Subscriber Management profiles and policies to the following entities:

- [SLA Profile](#)
- [Subscriber Identification Policy](#)
- [Subscriber Profile](#)

#### 9.23.3.5.1 SLA Profile

The following syntax applies to the 7450 ESS:

**CLI Syntax:**

```
configure>service>ies service-id
interface ip-int-name
 sap sap-id
 host {[ip ip-address] [mac ieee-address]
 [subscriber sub-ident-string] [sub-profile
 sub-profile-name] [sla-profile sla-profile-
 name]}
```

The following syntax applies to the 7750 SR:

**CLI Syntax:**

```
configure>service>ies service-id
interface ip-int-name
 sap sap-id
```

```

host {[ip ip-address] [mac ieee-address]
 [subscriber sub-ident-string] [sub-profile
 sub-profile-name] [sla-profile sla-profile-
 name]
sub-sla-mgmt
 def-sla-profile default-sla-profile-name
 single-sub-parameters
 non-sub-traffic sub-profile sub-
 profile-name sla-profile sla-
 profile-name [subscriber sub-
 ident-string]
subscriber-interface ip-int-name
group-interface ip-int-name
sap sap-id
 host ip ip-address [mac ieee-address]
 [subscriber sub-ident-string]
 [sub-profile sub-profile-name]
 [sla-profile sla-profile-name]
sub-sla-mgmt
 def-sla-profile default-sla-
 profile-name
 single-sub-parameters
 non-sub-traffic sub-
 profile sub-profile-name
 sla-profile sla-profile-
 name [subscriber sub-
 ident-string]

```

The following syntax applies to the 7450 ESS and 7750 SR:

**CLI Syntax:**

```

configure>service>vpls service-id
sap sap-id
 host {[ip ip-address] [mac ieee-address]}
 [subscriber sub-ident-string] [sub-profile sub-
 profile-name] [sla-profile sla-profile-name]
sub-sla-mgmt
 def-sla-profile default-sla-profile-name
 single-sub-parameters
 non-sub-traffic sub-profile sub-profile-
 name sla-profile sla-profile-name
 [subscriber sub-ident-string]

```

The following syntax applies to the 7750 SR:

**CLI Syntax:**

```

configure>service>vprn service-id
interface ip-int-name
sap sap-id

```

---

```
host {[ip ip-address] [mac ieee-address]}
 [subscriber sub-ident-string] [sub-profile
 sub-profile-name] [sla-profile sla-profile-
 name]
```

The following syntax applies to the 7450 ESS and 7750 SR:

**CLI Syntax:**

```
configure>subscriber-mgmt
explicit-subscriber-map
 entry key sub-ident-string [sub-profile sub-
 profile-name] [alias sub-alias-string] [sla-
 profile sla-profile-name]
sub-ident-policy sub-ident-policy-name
sla-profile-map
 entry key sla-profile-string sla-profile sla-
 profile-name
sub-profile sla-profile-map
 sla-profile-map
 entry key sla-profile-string sla-profile sla-
 profile
```

## 9.23.4 Configuring Dual Homing

The following displays an example of a dual homing configuration a. The configuration shows dual homing with a peer node with a system address of 1.1.1.23. The DHCP server returns a default route with a 11.21.1.3 next hop. This example only applies to the 7750 SR.

```
A:ALA-48#
#-----
echo "Redundancy Configuration"
#-----
 redundancy
 multi-chassis
 peer 1.1.1.23 create
 sync
 srrp

 dhcp
 gi-address 11.21.1.1
 exit
 group-interface "g40-1" create
 dhcp
 server 12.1.1.1
 lease-populate 8000
 no shutdown
 exit
 redundant-interface r40-1
 remote-proxy-arp
 sap lag-100:1 create
```

```
 sub-sla-mgmt
 def-sub-profile "subProf"
 def-sla-profile "slaProf"
 sub-ident-policy "subIdentPolicy"
 multi-sub-sap
 no shutdown
 exit
 exit
 sap lag-100:4094 create
 exit
 srrp 1 create
 message-path lag-100:4094
 no shutdown
 exit
 exit
 exit
 no shutdown
 exit
exit
...

A:ALA-48#
```

### 9.23.4.1 SHCV Policies

Under the group-interface, the **host-connectivity-verify** configuration was used as a reference timer for some event triggered SHCV while other used hardcoded values. The SHCV-policy and separated out every type of SHCV and allowed each type to have their individual configurable timer values. Furthermore, individual SHCV trigger types can be shut down. The SHCV policy can be applied to one or more group interfaces and can be configured differently for IPv4 vs. IPv6 hosts.

There are various types of triggered SHCV:

- **ip-conflict**: Sent when a SAP detects that there is a IP address or prefix conflict on the SAP.
- **host-limit-exceeded**: Sent when a subscriber has exceeded a configured host-limit. Host-limits are set on sla-profile host-limit, ipoe-session sap-session-limit, and ipoe-session session-limit.
- **inactivity**: Category-map configured under sla-profile can trigger an SHCV once the subscriber host has become idle.
- **mobility**: Intended for mobility applications such as WiFi. When a subscriber moves between SAPs and requests for the same IP address, a triggered SHCV is sent to verify if the old host is still connected before removing the old host entry.
- **mac-learning**: For IP-only static-host MAC learning. The trigger SHCV is sent to learn the subscriber MAC when a **no shutdown** command is executed on the CLI for the static host.

Note that some SHCVs are triggered based on a host's DHCP messages. These DHCP messages are not buffered. The SHCV is used only to perform a verification check on an old host to verify if the host is still connected to the BNG. Therefore, the BNG still requires the new hosts to retransmit their DHCP messages once the SHCV removes the disconnected host.

### 9.23.4.2 SHCV Policy

Under the group-interface, the **host-connectivity-verify** configuration was used as a reference timer for some event triggered SHCV while other used hardcoded values. The SHCV-policy and separated out every type of SHCV and allowed each type to have their individual configurable timer values. Furthermore, individual SHCV trigger types can be shut down. The SHCV policy can be applied to one or more group interfaces and can be configured differently for IPv4 vs. IPv6 hosts.

There are various types of triggered SHCV:

- **ip-conflict**: Sent when a SAP detects that there is a IP address or prefix conflict on the SAP.
- **host-limit-exceeded**: Sent when a subscriber has exceeded a configured host-limit. Host-limits are set on **sla-profile** *host-limit*, **ipoe-session** *sap-session-limit*, and **ipoe-session** *session-limit*.
- **inactivity**: Category-map configured under sla-profile can trigger an SHCV once the subscriber host has become idle.
- **mobility**: Intended for mobility applications such as WiFi. When a subscriber moves between SAPs and requests for the same IP address, a triggered SHCV is sent to verify if the old host is still connected before removing the old host entry.
- **mac-learning**: For IP-only static-host MAC learning. The trigger SHCV is sent to learn the subscriber MAC when a **no shutdown** command is executed on the CLI for the static host.

Note that some SHCVs are triggered based on a host's DHCP messages. These DHCP messages are not buffered. The SHCV is used only to perform a verification check on an old host to verify if the host is still connected to the BNG. Therefore, the BNG still requires the new hosts to retransmit their DHCP messages once the SHCV removes the disconnected host.

### 9.23.4.3 Subscriber Identification Policy

The following syntax applies to the 7450 ESS:

**CLI Syntax:**

```
configure>service>ies service-id
interface ip-int-name
 sap sap-id
 host {[ip ip-address] [mac ieee-address]
 [subscriber sub-ident-string] [sub-profile
 sub-profile-name] [sla-profile sla-profile-
 name]}
```

The following syntax applies to the 7750 SR:

**CLI Syntax:**

```
configure>service>ies service-id
interface ip-int-name
 sap sap-id
 host {[ip ip-address] [mac ieee-address]
 [subscriber sub-ident-string] [sub-profile
 sub-profile-name] [sla-profile sla-profile-
 name]}
 sub-sla-mgmt
 single-sub-parameters
 non-sub-traffic sub-profile sub-
 profile-name sla-profile sla-
 profile-name [subscriber sub-
 ident-string]
 sub-ident-policy sub-ident-policy-name
```

### 9.23.4.4 Subscriber Profile

The following syntax applies to the 7450 ESS:

**CLI Syntax:**

```
configure>service>ies service-id
interface ip-int-name
 sap sap-id
 host {[ip ip-address] [mac ieee-address]
 [subscriber sub-ident-string] [sub-profile
 sub-profile-name] [sla-profile sla-profile-
 name]}
```

The following syntax applies to the 7750 SR:

**CLI Syntax:**

```
configure>service>ies service-id
interface ip-int-name
```

```

sap sap-id
 host {[ip ip-address] [mac ieee-address]
 [subscriber sub-ident-string] [sub-profile
 sub-profile-name] [sla-profile sla-profile-
 name]}
 sub-sla-mgmt
 def-sub-profile default-subscriber-
 profile-name
 single-sub-parameters
 non-sub-traffic sub-profile sub-
 profile-name sla-profile sla-
 profile-name [subscriber sub-
 ident-string]

```

The following syntax applies to the 7450 ESS and 7750 SR:

**CLI Syntax:**

```

configure>service>vpls service-id
sap sap-id
 host {[ip ip-address] [mac ieee-address]}
 [subscriber sub-ident-string] [sub-profile sub-
 profile-name] [sla-profile sla-profile-name]
 sub-sla-mgmt
 def-sub-profile default-sub-profile-name
 single-sub-parameters
 non-sub-traffic sub-profile sub-profile-
 name sla-profile sla-profile-name
 [subscriber sub-ident-string]

```

The following syntax applies to the 7450 ESS and 7750 SR:

**CLI Syntax:**

```

configure>subscriber-mgmt
sub-profile subscriber-profile-name
explicit-subscriber-map
 entry key sub-ident-string [sub-profile sub-
 profile-name] [alias sub-alias-string] [sla-
 profile sla-profile-name]
sub-ident-policy sub-ident-policy-name
sub-profile-map
 entry key sub-profile-string sub-profile sub-
 profile-name

```

## 9.24 Subscriber Management Command Reference

### 9.24.1 Command Hierarchies

- [ANCP Commands](#)
  - [GSMP Configuration Commands](#)
- [BGP Peering Policy Commands](#)
- [RADIUS Route Download Commands](#)
- [RADIUS Accounting Policy Commands](#)
- [RADIUS Route Download Commands](#)
- [Authentication Policy Commands](#)
- [Category Map and Credit Control Policy Commands](#)
- [Diameter Policy Commands](#)
- [Filter Commands](#)
- [Explicit Subscriber Mapping Commands](#)
- [IGMP Policy Commands](#)
- [Host Lockout Commands](#)
- [Host Tracking Policy Commands](#)
- [PIM Policy Commands](#)
- [Managed SAP Policy Commands](#)
- [Multi-Chassis Redundancy Commands](#)
- [SLA Profile Commands](#)
- [Subscriber Identification Policy Commands](#)
  - [Auto-Generated Subscriber Identification Key Commands](#)
  - [Auto-Generated Subscriber Identification Key Service Commands](#)
- [Subscriber MCAC Policy Commands](#)
- [Subscriber Profile Commands](#)
- [SHCV Policy Commands](#)
- [Subscriber Management Service Commands](#)
  - [VPLS Subscriber Management Configuration Commands](#)
  - [VPRN Subscriber Interface Configuration Commands](#)
  - [IES Subscriber Management Configuration Commands](#)

- [RIP Commands](#)
- [VPort Commands](#)
- [Redundant Interface Commands](#)
- [Wireless Portal Protocol \(WPP\) Commands](#)
- [Multicast Listener Discovery \(MLD\) Commands](#)
- [Show Commands](#)
- [Monitor Commands](#)
- [Clear Commands](#)
- [Debug Commands](#)
- [Tools Commands](#)

**Note:** Enhanced Subscriber Management is supported on the redundant chassis model only.

### 9.24.1.1 ANCP Commands

```

config
 — subscriber-mgmt
 — ancp
 — ancp-policy name
 — egress
 — rate-adjustment adjusted-percent
 — no rate-adjustment
 — rate-modify agg-rate-limit
 — rate-modify scheduler scheduler-name
 — no rate-modify
 — rate-monitor kilobit-per-second [alarm]
 — no rate-monitor
 — rate-reduction kilobit-per-second
 — no rate-reduction
 — ingress
 — rate-adjustment adjusted-percent
 — rate-modify scheduler scheduler-name
 — rate-monitor kilobit-per-second [alarm] [log]
 — rate-reduction kilobit-per-second
 — [no] port-down
 — [no] disable-shcv [alarm] [hold-time seconds]
 — ancp-static-map
 — entry key ancp-string customer customer-id multi-service-site
 customer-site-name ancp-policy policy-name
 — entry key ancp-string sap sap-id ancp-policy policy-name
 — no entry key ancp-string customer customer-id multi-service-site
 customer-site-name
 — no entry key ancp-string sap sap-id

```

## 9.24.1.2 GSMP Configuration Commands

**Note:** The commands listed in this section apply only to the 7750 SR.

```

config
 — service
 — vpls service-id [customer customer-id] [create] [vpn vpn-id] [m-vpls] [b-vpls | i-vpls]
 — no vpls service-id
 — [no] vprn service-id [customer customer-id] [vpn vpn-id] [m-vpls]
 — gsmc
 — [no] group name
 — ancp
 — [no] dynamic-topology-discover
 — [no] oam
 — description description-string
 — no description
 — hold-multiplier multiplier
 — no hold-multiplier
 — [no] idle-filter
 — keepalive seconds
 — no keepalive
 — [no] neighbor ip-address
 — description description-string
 — no description
 — local-address ip-address
 — no local-address
 — priority-marking dscp dscp-name
 — priority-marking prec ip-prec-value
 — no priority-marking
 — [no] shutdown
 — [no] persistency-database
 — [no] shutdown
 — [no] shutdown

```

### 9.24.1.3 Authentication Policy Commands

```

config
 — subscriber-mgmt
 — aaa
 — isa-radius-policy name [create]
 — no isa-radius-policy name
 — radius-coa-port {1647 | 1700 | 1812 | 3799}
 — no radius-coa-port
 — [no] authentication-policy name
 — [no] accept-authorization-change
 — accept-script-policy policy-name
 — no accept-script-policy
 — description description-string
 — no description
 — fallback-action accept [force-probing]
 — fallback-action user-db user-db-local-user-name [force-probing]
 — no fallback-action
 — [no] include-radius-attribute
 — [no] access-loop-options
 — [no] acct-session-id
 — [no] called-station-id
 — calling-station-id
 — calling-station-id {mac | remote-id | sap-id | sap-string}
 — no calling-station-id
 — [no] circuit-id
 — [no] dhcp-options
 — [no] dhcp6-options
 — [no] dhcp-vendor-class-id
 — [no] mac-address
 — [no] nas-identifier
 — nas-port-id [prefix-string string] [suffix suffix-option]
 — nas-port-type
 — nas-port-type [value]
 — no nas-port-type
 — [no] pppoe-service-name
 — [no] remote-id
 — [no] sap-session-index
 — [no] tunnel-server-attrs
 — [no] wifi-num-attached-ues
 — [no] wifi-ssid-vlan
 — password password
 — no password
 — ppp-user-name append domain-name
 — ppp-user-name default-domain domain-name
 — ppp-user-name replace domain-name
 — ppp-user-name strip
 — no ppp-user-name
 — pppoe-access-method {none | padi | pap-chap}
 — no pppoe-access-method
 — radius-authentication-server
 — access-algorithm {direct | round-robin}
 — no access-algorithm

```

- 
- [no] **access-loop-options**
  - **fallback-action** **accept**
  - **fallback-action** **user-db** *local-user-db-name*
  - **no fallback-action**
  - **hold-down-time** *seconds*
  - **no hold-down-time**
  - **retry** *count*
  - **no retry**
  - **router** *router-instance*
  - **router** *service-name*
  - **no router**
  - **server** *server-index* **address** *ip-address* **secret** *key* [**hash** | **hash2**]  
    [**port** *port*] [*coa-only*]
  - **no server** *server-index*
  - **source-address** *ip-address*
  - **no source-address**
  - **timeout** *seconds*
  - **no timeout**
  - **radius-server-policy** *radius-server-policy-name*
  - [no] **radius-server-policy**
    - **server** *server-index* **address** *ip-address* **secret** *key* [**hash** | **hash2**]  
    [**port** *port-num*] [*coa-only*] [**pending-requests-limit** *limit*]  
    — **hold-down-time**
  - [no] **re-authentication**
  - **request-script-policy** *policy-name*
  - **no request-script-policy**
  - **send-acct-stop-on-fail** {[**on-request-failure**] [**on-reject**] [**on-accept-failure**]}
  - **no send-acct-stop-on-fail**
  - **user-name-format** *format* [**mac-format** *mac-format*]
  - **user-name-format** *format* **append** [*domain-name*] [**mac-format** *mac-format*]
  - **user-name-format** *format* **append** **domain-name**
  - **user-name-format** *format* **default-domain** *domain-name* [**mac-format** *mac-format*]
  - **user-name-format** *format* **replace** *domain-name* [**mac-format** *mac-format*]
  - **user-name-format** *format* **strip** [**mac-format** *mac-format*]
  - **no user-name-format**

### 9.24.1.4 RADIUS Accounting Policy Commands

```

config
 — subscriber-mgmt
 — [no] radius-accounting-policy name
 — [no] custom-record
 — [no] override-counter override-counter-id
 — e-counters [all]
 — no e-counters
 — [no] in-profile-octets-discarded-count
 — [no] in-profile-octets-forwarded-count
 — [no] in-profile-packets-discarded-count
 — [no] in-profile-packets-forwarded-count
 — [no] out-profile-octets-discarded-count
 — [no] out-profile-octets-forwarded-count

### 9.24.1.11 Explicit Subscriber Mapping Commands

```

config
— subscriber-mgmt
— explicit-sub-map
— entry key sub-ident-string [sub-profile sub-profile-name] [alias sub-
alias-string] [sla-profile sla-profile-name]
— no entry key sub-ident-string

```

### 9.24.1.12 IGMP Policy Commands

**Note:** The commands listed in this section apply only to the 7750 SR.

```

config
— subscriber-mgmt
— igmp-policy policy-name [create]
— description description-string
— no description
— [no] disable-router-alert-check
— egress-rate-modify [egress-rate-limit | scheduler scheduler-name]
— [no] fast-leave
— import policy-name
— no import
— max-num-groups max-num-groups
— no max-num-groups
— max-num-sources max-num-sources
— no max-num-sources
— max-num-grp-sources [max-num-grp-sources]
— no max-num-grp-sources
— [no] mcast-reporting
— mcast-reporting-dest dest-name
— no mcast-reporting-dest
— opt-reporting-fields [host-mac] [pppoe-session-id] [svc-id] [sap-id]
— no opt-reporting-fields
— [no] shutdown
— per-host-replication [uni-mac|mcast-mac]
— no per-host-replication
— query-interval seconds
— no query-interval
— query-last-member-interval seconds
— no query-last-member-interval
— query-response-interval seconds
— no query-response-interval
— redirection-policy policy-name
— no redirection-policy
— static

```

- [no] **group** *ip-address*
- **version** *version*
- **no version**
- **sub-mcac-policy** *policy-name*
- **sub-profile**
  - **sub-mcac-policy** *policy-name*

### 9.24.1.13 Host Lockout Commands

**Note:** The commands listed in this section apply only to the 7750 SR.

```

config
— subscriber-mgmt
 — host-lockout-policy policy-name [create]
 — no host-lockout-policy policy-name
 — description description-string
 — no description
 — host-key {mac}
 — no host-key
 — lockout-reset-time seconds
 — no lockout-reset-time
 — lockout-time [min seconds] [max seconds]
 — no lockout-time
 — max-lockout-hosts hosts
 — no max-lockout-hosts

config
— service
 — vpn service-id [customer customer-id]
 — no vpn service-id

### 9.24.1.17 Subscriber Identification Policy Commands

```
config
— subscriber-mgmt
— [no] sub-ident-policy sub-ident-policy-name
— app-profile-map
— entry key app-profile-string app-profile app-profile-name
— no entry key app-profile-string
— [no] use-direct-map-as-default
— description description-string
— no description
— primary
— script-url dhcp-primary-script-url
— no script-url
— [no] shutdown
— secondary
— script-url dhcp-secondary-script-url
— no script-url
— [no] shutdown
— sla-profile-map
— entry key sla-profile-string sla-profile sla-profile-name
— no entry key sla-profile-string
— [no] use-direct-map-as-default
— sub-profile-map
— entry key sub-profile-string sub-profile sub-profile-name
— no entry key sub-profile-string
— [no] use-direct-map-as-default
— tertiary
— script-url dhcp-tertiary-script-url
— no script-url
— [no] shutdown
```

## 9.24.1.18 Auto-Generated Subscriber Identification Key Commands

**Note:** These commands are supported on the 7450 ESS in mixed mode.

```
config
 — subscriber-mgmt
 — auto-sub-id-key
 — ipoe-sub-id-key sub-id-key [sub-id-key...(up to 4 max)]
 — no ipoe-sub-id-key
 — ppp-sub-id-key sub-id-key [sub-id-key...(up to 5 max)]
 — no ppp-sub-id-key
```

## 9.24.1.19 Auto-Generated Subscriber Identification Key Service Commands

**Note:** Refer to the Layer 2 Services and EVPN Guide: VLL, VPLS, PBB, and EVPN and Layer 3 Services Guide: Internet Enhanced Services and Virtual Private Routed Network Services for further services commands.

```
config
 — service
 — vprn
 — subscriber-interface ip-int-name
 — group-interface ip-int-name
 — sap sap-id
 — sub-sla-mgmt
 — def-sub-id use-auto-id
 — def-sub-id use-sap-id
 — def-sub-id string sub-id
 — no def-sub-id
 — vpls
 — sap sap-id
 — sub-sla-mgmt
 — def-sub-id use-auto-id
 — def-sub-id use-sap-id
 — def-sub-id string sub-id
 — no def-sub-id
 — ies
 — subscriber-interface ip-int-name
 — group-interface ip-int-name
 — sap sap-id
 — sub-sla-mgmt
 — def-sub-id use-auto-id
```

- 
- **def-sub-id** **use-sap-id**
  - **def-sub-id** **string** *sub-id*
  - **no def-sub-id**
  - **subscriber-management**
    - **msap-policy** *msap-policy-name*
    - **sub-sla-mgmt**
      - **def-sub-id** **use-auto-id**
      - **def-sub-id** **use-sap-id**
      - **def-sub-id** **string** *sub-id*
      - **no def-sub-id**

### 9.24.1.20 Subscriber MCAC Policy Commands

- ```
config
— subscriber-mgmt
  — sub-mcac-policy sub-mcac-policy-name [create]
  — no sub-mcac-policy sub-mcac-policy-name
    — description description-string
    — no description
    — [no] shutdown
    — unconstrained-bw mandatory-bw mandatory-bw
    — no unconstrained-bw
```

9.24.1.21 Subscriber Profile Commands

For information about configuring accounting policies, refer to the **SR OS 7450 ESS and 7750 SR System Management Guide**.

```

config
— subscriber-mgmt
— [no] sub-profile subscriber-profile-name
— accounting-policy acct-policy-id
— no accounting-policy
— ancp
— ancp-policy name
— no ancp-policy
— egress
— rate-adjustment
— rate-adjustment adjusted-percent
— no rate-adjustment
— rate-modify scheduler scheduler-name
— no rate-modify
— rate-monitor kilobit-per-second [alarm]

### 9.24.1.25.8 Service Subscriber Interface, Group Interface IPoE Command

#### VRPN Group Interface Commands

- ```
config
— service
  — vpn service-id [customer customer-id]
  — no vpn service-id
  — ies service-id [customer customer-id]
  — no ies service-id
    — subscriber-interface ip-int-name [fwd-service service-id fwd-subscriber-  

interface ip-int-name] [create]
    — no subscriber-interface ip-int-name
      — group-interface ip-int-name [create]
      — group-interface ip-int-name [create] lns
      — group-interface ip-int-name [create] wlangw
      — no group-interface ip-int-name
        — [no] ipoe-session
          — description description-string
          — no description
          — force-auth [cid-change] [rid-change]
          — force-auth disabled
```

- **no force-auth**
- **ipoe-session-policy** *policy-name*
- **no ipoe-session-policy**
- **min-auth-interval** [**days** *days*] [**hrs** *hours*] [**min** *minutes*] [**sec** *seconds*]
- **min-auth-interval** **infinite**
- **no min-auth-interval**
- **sap-session-limit** *sap-session-limit*
- **no sap-session-limit**
- **session-limit** *session-limit*
- **no session-limit**
- **[no] shutdown**
- **user-db** *local-user-db-name*
- **no user-db**

9.24.1.25.9 RIP Commands

configure

- **subscriber-mgmt**
 - **rip-policy** *policy policy-name* [**create**]
 - **no rip-policy** *policy-name*
 - **authentication-key** *authentication-key* | *hash-key* [**hash** | **hash2**]
 - **no authentication-key**
 - **authentication-type** {**none** | **password** | **message-digest** | **message-digest-20**}
 - **no authentication-type**
 - **description** *description-string*
 - **no description**
 - **local-user-db** *local-user-db-name* [**create**]
 - **no local-user-db** *local-user-db-name*
 - **ppp**
 - **host** *host-name* [**create**]
 - **no host** *host-name*
 - **rip-policy** *policy-name*
 - **no rip-policy**
 - **ipoe**
 - **host** *host-name* [**create**]
 - **no host** *host-name*
 - **rip-policy** *policy-name*
 - **no rip-policy**

configure

- **service**
 - **ies|vprn**
 - **[no] subscriber-interface** *ip-int-name*
 - **[no] group-interface** *ip-int-name*
 - **[no] sap** *sap-id*
 - **static-host** **ip** *ip/did-address* [**mac** *ieee-address*] [**create**]
 - **static-host** **mac** *ieee-address* [**create**]
 - **no static-host** [**ip** *ip-address*] **mac** *ieee-address*

```

— no static-host all [force]
— no static-host ip ip-address
  — rip-policy policy-name
  — no rip-policy
— vprn
  — [no] rip
    — [no] group name
    — [no] neighbor ip-int-name

configure
— router
  — [no] rip
    — [no] group name
    — [no] neighbor ip-int-name

```

9.24.1.25.10 VPort Commands

Refer to the SR OS Interfaces Guide for further information on card, Media Dependent Adapter (MDA), MCM (MDA Carrier Module), CMA (Compact Media Adapter) and port provisioning.

```

config
— port port-id
  — ethernet
    — access
      — egress
        — vport vport-name [create]
        — no vport vport-name
          — agg-rate
            — rate {max | rate}
          — agg-rate-limit limit
          — no agg-rate-limit
          — description description-string
          — no description
          — [no] egress-rate-modify
          — host-match dest string [create]
          — no host-match dest string
          — port-scheduler-policy port-scheduling-policy-name
          — no port-scheduler-policy
          — scheduler-policy scheduler-policy-name
          — no scheduler-policy

```

9.24.1.25.11 Redundant Interface Commands

Note: The commands listed in this section apply only to the 7750 SR.

```

config
  — service
    — ies
      — [no] redundant-interface ip-int-name
        — address {ip-address/mask | ip-address netmask} [remote-ip ip-address]
        — no address
        — [no] description description-string
        — [no] shutdown
        — [no] spoke-sdp sdp-id:vc-id
          — egress
            — filter [ip ip-filter-id]
            — vc-label ingress-vc-label
            — no vc-label [ingress-vc-label]
          — ingress
            — filter [ip ip-filter-id]
            — no filter
            — vc-label ingress-vc-label
            — no vc-label [ingress-vc-label]
          — [no] shutdown

```

```

config
  — service
    — vprn
      — [no] redundant-interface ip-int-name
        — address {ip-address/mask | ip-address netmask} [remote-ip ip-address]
        — no address
        — [no] description description-string
        — [no] shutdown
        — [no] spoke-sdp sdp-id:vc-id
          — egress
            — filter [ip ip-filter-id]

9.24.2.1.1 Generic Commands

description

Syntax	description <i>description-string</i> no description
Context	config>subscr-mgmt>authentication-policy config>subscr-mgmt>host-tracking config>subscr-mgmt>pim-policy config>subscr-mgmt>sla-profile config>subscr-mgmt>sla-profile>egress>ip-filter>entry config>subscr-mgmt>sla-profile>ingress>ip-filter>entry config>subscr-mgmt>sub-ident-pol config>subscr-mgmt>sub-profile config>subscr-mgmt>mld-policy config>service>vpls>gsmp>group config>log>accounting-policy config>service>vprn>redundant-interface config>service>ies>redundant-interface config>service>ies>subscriber-interface config>service>ies>sub-if>grp-if config>service>ies>sub-if>grp-if>dhcp config>service>ies>sub-if>grp-if>srrp config>service>vprn>subscriber-interface config>service>vprn>sub-if>dhcp config>service>vprn>sub-if>grp-if config>service>vprn>sub-if>grp-if>sap config>service>vprn>sub-if>grp-if>srrp config>service>vprn>sub-if>grp-if>dhcp config>service>vprn>gsmp>group config>service>vprn>gsmp>group>neighbor config>service>vprn>sub-if>grp-if>ipoe-session config>redundancy>multi-chassis>peer config>subscr-mgmt>cat-map config>subscr-mgmt>ipoe-session-policy config>service>vpls>sap> ipoe-session config>subscr-mgmt>diam-appl-plcy config>sub-mgmt>credit-control-policy config>sub-mgmt>host-lockout>policy config>subscr-mgmt>sub-mcac-policy config>aaa>route-downloader config>aaa>diam-peer-plcy config>port>ethernet>access>egress config>subscr-mgmt>cat-map>category config>subscr-mgmt>cat-map>category>exh-lvl>egr-ip config>subscr-mgmt>cat-map>category>exh-lvl>egr-ipv6 config>filter>ip-filter

	<code>config>filter>ipv6-filter</code>
Description	<p>This command creates a text description stored in the configuration file for a configuration context.</p> <p>The description command associates a text string with a configuration context to help identify the context in the configuration file.</p> <p>The no form of this command removes any description string from the context.</p>
Default	No description is associated with the configuration context.
Parameters	<i>description-string</i> — A text string describing the entity. Allowed values are any string up to 80 characters long composed of printable, 7-bit ASCII characters excluding double quotes. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

shutdown

Syntax	<code>[no] shutdown</code>
Context	<code>config>subscr-mgmt>sub-ident-pol>primary</code> <code>config>subscr-mgmt>sub-ident-pol>secondary</code> <code>config>subscr-mgmt>sub-ident-pol>tertiary</code> <code>config>service>vpls>sap>sub-sla-mgmt</code> <code>config>service>vpls>gsmp</code> <code>config>service>vpls>gsmp>group</code> <code>config>service>vpls>gsmp>group>neighbor</code> <code>config>service>vprn>redundant-interface</code> <code>config>service>vprn>red-if>spoke-sdp</code> <code>config>service>vprn>subscriber-interface</code> <code>config>service>vprn>sub-if>grp-if</code> <code>config>service>vprn>sub-if>grp-if>dhcp</code> <code>config>service>vprn>sub-if>grp-if>srrp</code> <code>config>service>ies>subscriber-interface</code> <code>config>service>ies>sub-if>grp-if>dhcp</code> <code>config>service>ies>sub-if>grp-if>srrp</code> <code>config>service>ies>redundant-interface</code> <code>config>service>ies>sub-if>grp-if>arp-host</code> <code>config>service>vprn>gsmp>group>neighbor</code> <code>config>service>ies>sub-if>grp-if>wpp</code> <code>config>service>vprn>sub-if>grp-if>wpp</code> <code>config>service>vprn>sub-if>grp-if>wpp>portals</code> <code>config>redundancy>multi-chassis>peer</code> <code>config>redundancy>multi-chassis>peer>mc-lag</code> <code>config>redundancy>multi-chassis>peer>sync</code> <code>config>service>ies>sub-if>dhcp</code> <code>config>subscr-mgmt>sub-mcac-policy</code> <code>config>aaa>route-downloader</code>

```
config>aaa>diam-peer-plcy>peer
config>aaa>diam-peer-plcy>proxy
config>service>vpn>sub-if>grp-if>data-trigger
config>service>ies>sub-if>grp-if>data-trigger
```

Description The **shutdown** command administratively disables the entity. When disabled, an entity does not change, reset, or remove any configuration settings or statistics. Many entities must be explicitly enabled using the **no shutdown** command.

The **shutdown** command administratively disables an entity. The operational state of the entity is disabled as well as the operational state of any entities contained within. Many objects must be shut down before they can be deleted.

Unlike other commands and parameters where the default state is not indicated in the configuration file, **shutdown** and **no shutdown** are always indicated in system generated configuration files.

Shutting down a subscriber interface on a 7750 SR will operationally shut down all child group interfaces and SAPs. Shutting down a group interface on a 7750 SR will operationally shut down all SAPs that are part of that group-interface.

The **no** form of the command puts an entity into the administratively enabled state.

Default no shutdown

subscriber-mgmt

Syntax subscriber-mgmt

Context config

Description This command enables the context to configure subscriber management entities. A subscriber is uniquely identified by a subscriber identification string. Each subscriber can have several DHCP sessions active at any time. Each session is referred to as a subscriber host and is identified by its IP address and MAC address.

All subscriber hosts belonging to the same subscriber are subject to the same hierarchical QoS (HQoS) processing. The HQoS processing is defined in the [sub-profile](#) (the subscriber profile). A sub-profile refers to an existing scheduler policy (configured in **the configure>qos>scheduler-policy** context) and offers the possibility to overrule the rate of individual schedulers within this policy.

Because all subscriber hosts use the same scheduler policy instance, they must all reside on the same complex.

9.24.2.1.2 ANCP and GSMP Commands

ancp

Syntax	ancp
Context	config>subscr-mgmt config>subscr-mgmt>sub-prof
Description	This command enables the context to configure Access Node Control Protocol (ANCP) parameters.

ancp-policy

Syntax	ancp-policy <i>name</i>
Context	config>subscr-mgmt>ancp
Description	<p>This command creates an Access Node Control Protocol (ANCP) policy. The policy is associated with either the ANCP string (static case) or subscriber-profile (dynamic case) and defines the behavior of the hosts belonging to these profiles.</p> <p>ANCP polices control rates and subscribers based on port-up/port-down messages from the access node. When configured, the 7450 ESS or 7750 SR should stop SHCV to a host that is part of a port defined to be down (by port-down message). When the node receives a port-up message for a port that was in port-down, state the node will initiate the SHCV process immediately to verify connectivity.</p> <p>When ANCP is used with Enhanced Subscriber Management, the ANCP string last associated with the subscriber will be used. All hosts of a subscriber will be updated with the new ANCP string.</p>
Default	No policies are defined.
Parameters	<i>name</i> — Configures the ANCP policy name.

ancp-policy

Syntax	ancp-policy <i>name</i>
Context	config>subscr-mgmt>sub-prof>ancp
Description	This command specifies an existing Access Node Control Protocol (ANCP) policy to associate with the subscriber profile. The policy is associated with either the ANCP string (static case) or subscriber-profile (dynamic case) and defines the behavior of the hosts belonging to these profiles.

Default	No policies are defined.
Parameters	<i>name</i> — Specifies an existing ANCP policy name.

ingress

Syntax	ingress
Context	config>subscr-mgmt>sla-prof>ingress config>subscr-mgmt>ancp>ancp-policy
Description	This command configures ingress ANCP policy parameters.

rate-adjustment

Syntax	rate-adjustment <i>adjusted-percent</i> no rate-adjustment
Context	config>subscr-mgmt>ancp>ancp-policy>ingress config>subscr-mgmt>ancp>ancp-policy>egress
Description	<p>This command configures a rate adjustment for the scheduler. The rate-adjustment command should be used when the rate returned by the DSLAM is calculated with different encapsulation than the 7450 ESS or 7750 SR. The node will adjust the rate by the percent specified as:</p> $\text{DSLAM_RATE} * \text{adjust-rate} / 100 \text{ — rate-reduction.}$ <p>The no form of the command returns the default value.</p>
Default	none
Parameters	<i>adjusted-percent</i> — Specifies a rate adjustment for the scheduler.
Values	1 to 200
Default	100

rate-reduction

Syntax	rate-reduction <i>kilobit-per-second</i> no rate-reduction
Context	config>subscr-mgmt>ancp>ancp-policy>ingress config>subscr-mgmt>ancp>ancp-policy>egress

Description	<p>This command defines a constant rate reduction to the rate specified by the DSLAM. The rate-reduction command should be used if the node should adjust the rate to a value that is offset (for example by a fixed multicast dedicated bandwidth) compared to the total available on the DSLAM.</p> <p>When set, the rate will be:</p> $\text{DSLAM_RATE} * \text{adjust-rate} / 100 - \text{rate-reduction}$
Default	none

rate-monitor

Syntax	rate-monitor <i>kilobit-per-second</i> [alarm] no rate-monitor
Context	config>subscr-mgmt>ancp>ancp-policy>ingress config>subscr-mgmt>ancp>ancp-policy>egress
Description	This command configures the rate monitor level.
Default	none
Parameters	<p><i>kilobit-per-second</i> — Specifies the rate, in kilobits, below which the system will generate an event.</p> <p>alarm — When the monitored rate is below the configured value the system generates an alarm (trap) to the management system. The trap includes the rate as well as the ANCP policy name and the ANCP string.</p>

rate-modify

Syntax	rate-modify scheduler <i>scheduler-name</i> no rate-modify
Context	config>subscr-mgmt>ancp>ancp-policy>ingress
Description	This command configures ingress rate modify scheduler parameters.
Default	none
Parameters	scheduler <i>scheduler-name</i> — Specifies a scheduler name.

egress

Syntax	egress
Context	config>subscr-mgmt>ancp>ancp-policy

Description This command configures egress ANCP policy parameters.

rate-modify

Syntax **rate-modify scheduler** *scheduler-name*
rate-modify agg-rate-limit
no rate-modify

Context config>subscr-mgmt>ancp>ancp-policy>egress

Description This command configures egress rate modify scheduler parameters.

Default none

Parameters **agg-rate-limit** — specifies that the maximum total rate for all subscriber egress queues for each subscriber associated with the policy.
scheduler *scheduler-name* — Specify a scheduler name.

port-down

Syntax **[no] port-down**

Context config>subscr-mgmt>ancp>ancp-policy

Description This command specifies the number of GSMP portdown messages received in this ANCP session.

disable-shcv

Syntax **[no] disable-shcv [alarm] [hold-time seconds]**

Context config>subscr-mgmt>ancp>ancp-policy>port-down

Description When this command is configured, the node will suspend SHCV for the hosts defined with this ANCP policy until the access node sends a port-up message. When the hold-time parameter is used, the node will suspend SHCV for the period of time defined. If the hold-time parameter is not defined the node will suspend SHCV until a port-up message is received.

If the optional alarm flag is used the node should send a SHCV alarm before suspending.

Default no disable-shcv

ancp-static-map

Syntax **ancp-static-map**

Context	config>subscr-mgmt>ancp
Description	This command enables the context to configure a static ANCP name map.
Default	ancp-static-map

entry

Syntax	entry key <i>ancp-string</i> customer <i>customer-id</i> multi-service-site <i>customer-site-name</i> ancp-policy <i>policy-name</i> entry key <i>ancp-string</i> sap <i>sap-id</i> ancp-policy <i>policy-name</i> no entry key <i>ancp-string</i> customer <i>customer-id</i> multi-service-site <i>customer-site-name</i> no entry key <i>ancp-string</i> sap <i>sap-id</i>
Context	config>subscr-mgmt>ancp>static-map
Description	<p>This command configures an ANCP name. When ANCP is configured to provide rate adaptation without the use of enhanced subscriber management, this command will define how to map an ANCP key (usually the circuit-id of the DSLAM port) to either a SAP and a scheduler name (when a Multi-Service Site (MSS) is not used) or a customer, site and scheduler name when MSS is used.</p> <p>Different ANCP names may be used with the same SAPs or customer ID/MSS combinations to allow schedulers within the policy to be mapped to the ANCP names. An ANCP string and SAP combination may reference only one ancp-policy. An ANCP string and customer and site-name combination may reference a single ancp-policy.</p>
Default	none
Parameters	<p>key <i>ancp-string</i> — Specify the ASCII representation of the DSLAM circuit-id name.</p> <p>customer <i>customer-id</i> — Specify the associated existing customer name.</p> <p>multi-service-site <i>customer-site-name</i> — Specify the associated customer's configured MSS name.</p> <p>ancp-policy <i>policy-name</i> — Specify an existing ANCP policy name.</p> <p>sap <i>sap-id</i> — Specifies the physical port identifier portion of the SAP definition.</p>

VPRN GSMP Configuration Commands

Note: The commands in this section apply only to the 7750 SR.

gsmp

Syntax	gsmp
Context	config>service>vpls config>service>vprn
Description	This command enables the context to configure GSMP connections maintained in this service.
Default	not enabled

group

Syntax	[no] group <i>name</i>
Context	config>service>vpls>gsmp config>service>vprn>gsmp
Description	This command specifies a GSMP name. A GSMP group name is unique only within the scope of the service in which it is defined.

ancp

Syntax	ancp
Context	config>service>vpls>gsmp>group config>service>vprn>gsmp>group
Description	This command configures ANCP parameters for this GSMP group.

dynamic-topology-discover

Syntax	[no] dynamic-topology-discover
Context	config>service>vpls>gsmp>group>ancp config>service>vprn>gsmp>group>ancp
Description	This command enables the ANCP dynamic topology discovery capability.

The **no** form of this command disables the feature.

oam

Syntax	[no] oam
Context	config>service>vpls>gsmp>group>ancp config>service>vprn>gsmp>group>ancp
Description	This command specifies whether or not the GSMP ANCP OAM capability should be negotiated at startup of the GSMP connection.

The **no** form of this command disables the feature.

hold-multiplier

Syntax	hold-multiplier <i>multiplier</i> no hold-multiplier
Context	config>service>vpls>gsmp config>service>vprn>gsmp
Description	This command configures the hold-multiplier for the GSMP connections in this group.
Parameters	<i>multiplier</i> — Specifies the GSMP hold multiplier value.
Values	1 to 100

idle-filter

Syntax	[no] idle-filter
Context	config>service>vpls>gsmp>group config>service>vprn>gsmp>group
Description	This command when applied will filter out new incoming ANCP messages while subscriber “DSL-line-state” is IDLE. The command takes effect at the time that it is applied. Existing subscriber already in IDLE state are not purged from the database.
Default	no idle-filter

keepalive

Syntax	keepalive <i>seconds</i> no keepalive
---------------	--

Context	config>service>vpls>gsmp>group config>service>vprn>gsmp>group
Description	This command configures keepalive values for the GSMP connections in this group.
Parameters	<i>seconds</i> — Specifies the GSMP keepalive timer value in seconds. Values 1 to 25

neighbor

Syntax	neighbor <i>ip-address</i> [<i>create</i>] no neighbor <i>ip-address</i>
Context	config>service>vpls>gsmp>group config>service>vprn>gsmp>group
Description	This command configures a GSMP ANCP neighbor.
Parameters	<i>ip-address</i> — Specifies the IP address of the GSMP ANCP neighbor.

local-address

Syntax	local-address <i>ip-address</i> no local-address
Context	config>service>vpls>gsmp>group>neighbor config>service>vprn>gsmp>group>neighbor
Description	This command configures the source ip-address used in the connection towards the neighbor. The local address is optional. If specified the node will accept connections only for that address in the service running ANCP. The address may be created after the reference but connections will not be accepted until it is created. If the local address is not used, the system accepts connections on any interface within the routing context.
Parameters	<i>ip-address</i> — Specifies the source IP address to be used in the connection toward the neighbor.

priority-marking

Syntax	priority-marking dscp <i>dscp-name</i> priority-marking prec <i>ip-prec-value</i> no priority-marking
Context	config>service>vpls>gsmp>group>neighbor config>service>vprn>gsmp>group>neighbor
Description	This command configures the type of priority marking to be used.

Parameters	dscp <i>dscp-name</i> — Specifies the DSCP code-point to be used.
Values	be, cp1, cp2, cp3, cp4, cp5, cp6, cp7, cs1, cp9, af11, cp11, af12, cp13, af13, cp15, cs2, cp17, af21, cp19, af22, cp21, af23, cp23, cs3, cp25, af31, cp27, af32, cp29, af33, cp31, cs4, cp33, af41, cp35, af42, cp37, af43, cp39, cs5, cp41, cp42, cp43, cp44, cp45, ef, cp47, nc1, cp49, cp50, cp51, cp52, cp53, cp54, cp55, nc2, cp57, cp58, cp59, cp60, cp61, cp62, cp63
	prec <i>ip-prec-value</i> — Specifies the precedence value to be used.
Values	0 to 7

persistency-database

Syntax	[no] persistency-database
Context	config>service>vpls>gsmp>group config>service>vprn>gsmp>group
Description	This command enables the system to store DSL line information in memory. If the GSMP connection terminates, the DSL line information will remain in memory and accessible for RADIUS authentication and accounting.
Default	no persistency-database

BGP Peering Policy Commands

Note: The commands described in this section apply only to the 7750 SR.

bgp-peering-policy

Syntax	bgp-peering-policy <i>policy-name</i> [create] no bgp-peering-policy <i>policy-name</i>
Context	config>subscr-mgmt
Description	This command configures the name of the BGP peering policy.
Parameters	<i>policy-name</i> — Specifies the BGP peer policy name up to 32 characters in length.

advertise-inactive

Syntax	[no] advertise-inactive
Context	config>subscr-mgmt>bgp-prng-plcy
Description	<p>This command enables or disables the advertising of inactive BGP routes to other BGP peers.</p> <p>By default, BGP only advertises BGP routes to other BGP peers if a given BGP route is chosen by the route table manager as the most preferred route within the system and is active in the forwarding plane. This command allows system administrators to advertise a BGP route even though it is not the most preferred route within the system for a given destination.</p>
Default	no advertise-inactive

aggregator-id-zero

Syntax	[no] aggregator-id-zero
Context	config>subscr-mgmt>bgp-prng-plcy
Description	<p>This command is used to set the router ID in the BGP aggregator path attribute to zero when BGP aggregates routes. This prevents different routers within an AS from creating aggregate routes that contain different AS paths.</p> <p>When BGP is aggregating routes, it adds the aggregator path attribute to the BGP update messages. By default, BGP adds the AS number and router ID to the aggregator path attribute.</p> <p>When this command is enabled, BGP adds the router ID to the aggregator path attribute. The no form of the command used at the global level reverts to default where BGP adds the AS number and router ID to the aggregator path attribute.</p>
Default	no aggregator-id-zero to BGP adds the AS number and router ID to the aggregator path attribute.

as-override

Syntax	[no] as-override
Context	config>subscr-mgmt>bgp-prng-plcy
Description	<p>This command replaces all instances of the peer's AS number with the local AS number in a BGP route's AS_PATH.</p> <p>This command breaks BGP's loop detection mechanism. It should be used carefully.</p>
Default	as-override is not enabled by default.

auth-keychain

Syntax	auth-keychain <i>name</i> no auth-keychain
Context	config>subscr-mgmt>bgp-prng-plcy
Description	This command configures the BGP authentication key for all peers. The keychain allows the rollover of authentication keys during the lifetime of a session.
Default	no auth-keychain
Parameters	<i>name</i> — Specifies the name of an existing keychain, up to 32 characters, to use for the specified TCP session or sessions.

authentication-key

Syntax	authentication-key [<i>authentication-key</i> <i>hash-key</i>] [hash hash2] no authentication-key
Context	config>subscr-mgmt>bgp-prng-plcy
Description	This command configures the BGP authentication key. Authentication is performed between neighboring routers before setting up the BGP session by verifying the password. Authentication is performed using the MD-5 message-based digest. The authentication key can be any combination of letters or numbers from 1 to 16. The no form of the command removes the authentication password from the configuration and effectively disables authentication.
Default	Authentication is disabled and the authentication password is empty.
Parameters	<i>authentication-key</i> — The authentication key. The key can be any combination of ASCII characters up to 255 characters in length (unencrypted). If spaces are used in the string, enclose the entire string in quotation marks (" "). <i>hash-key</i> — The hash key. The key can be any combination of ASCII characters up to 342 characters in length (encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" "). This is useful when a user must configure the parameter, but, for security purposes, the actual unencrypted key value is not provided. hash — Specifies the key is entered in an encrypted form. If the hash or hash2 parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the hash or hash2 parameter specified

hash2 — Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

cluster

Syntax	cluster <i>cluster-id</i> no cluster
Context	config>subscr-mgmt>bgp-prng-plcy
Description	<p>This command configures the cluster ID for a route reflector server.</p> <p>Route reflectors are used to reduce the number of IBGP sessions required within an AS. Normally, all BGP speakers within an AS must have a BGP peering with every other BGP speaker in an AS. A route reflector and its clients form a cluster. Peers that are not part of the cluster are considered to be non-clients.</p> <p>When a route reflector receives a route, first it must select the best path from all the paths received. If the route was received from a non-client peer, then the route reflector sends the route to all clients in the cluster. If the route came from a client peer, the route reflector sends the route to all non-client peers and to all client peers except the originator.</p> <p>For redundancy, a cluster can have multiple route reflectors.</p> <p>Confederations can also be used to remove the full IBGP mesh requirement within an AS.</p> <p>The no form of the command deletes the cluster ID and effectively disables the Route Reflection for the given group.</p>
Default	no cluster — No cluster ID is defined.
Parameters	<i>cluster-id</i> — The route reflector cluster ID is expressed in dot decimal notation.
Values	Any 32 bit number in dot decimal notation. (0.0.0.1 to 255.255.255.255)

connect-retry

Syntax	connect-retry <i>seconds</i> no connect-retry
Context	config>subscr-mgmt>bgp-prng-plcy
Description	<p>This command configures the BGP connect retry timer value in seconds.</p> <p>When this timer expires, BGP tries to reconnect to the configured peer.</p>

The **no** form of the command used at the global level reverts to the default value.

Default 120 seconds

Parameters *seconds* — The BGP Connect Retry timer value in seconds, expressed as a decimal integer.

Values 1 to 65535

damping

Syntax **[no] damping**

Context config>subscr-mgmt>bgp-prng-plcy

Description This command enables BGP route damping for learned routes which are defined within the route policy. Use damping to reduce the number of update messages sent between BGP peers and reduce the load on peers without affecting the route convergence time for stable routes. Damping parameters are set via route policy definition.

The **no** form of the command used at the global level disables route damping.

When damping is enabled and the route policy does not specify a damping profile, the default damping profile is used. This profile is always present and consists of the following parameters:

Half-life:	15 minutes
Max-suppress:	60 minutes
Suppress-threshold:	3000
Reuse-threshold	750

Default no damping — Learned route damping is disabled.

disable-4byte-asn

Syntax **[no] disable-4byte-asn**

Context config>subscr-mgmt>bgp-prng-plcy

Description This command disables the use of 4-byte ASNs. It can be configured at all 3 level of the hierarchy so it can be specified down to the per peer basis.

If this command is enabled 4-byte ASN support should not be negotiated with the associated remote peer(s).

The **no** form of the command resets the behavior to the default which is to enable the use of 4-byte ASN.

disable-client-reflect

Syntax	[no] disable-client-reflect
Context	config>subscr-mgmt>bgp-prng-plcy
Description	<p>This command disables the reflection of routes by the route reflector to the group or neighbor. This only disables the reflection of routes from other client peers. Routes learned from non-client peers are still reflected to all clients.</p> <p>The no form re-enables client reflection of routes.</p>
Default	no disable-client-reflect — Client routes are reflected to all client peers.

disable-communities

Syntax	disable-communities [standard] [extended] no disable-communities
Context	config>subscr-mgmt>bgp-prng-plcy
Description	This command configures BGP to disable sending communities.
Parameters	<p>standard — Specifies standard communities that existed before VPRNs or 2547.</p> <p>extended — Specifies BGP communities used were expanded after the concept of 2547 was introduced, to include handling the VRF target.</p>

disable-fast-external-failover

Syntax	[no] disable-fast-external-failover
Context	config>subscr-mgmt>bgp-prng-plcy
Description	This command configures BGP fast external failover.

export

Syntax	export <i>policy</i> [<i>policy</i>...] no export
Context	config>subscr-mgmt>bgp-prng-plcy
Description	This command specifies the export policies to be used to control routes advertised to BGP neighbors.

When multiple policy names are specified, the policies are evaluated in the order they are specified. A maximum of five (5) policy names can be configured. The first policy that matches is applied.

Note: If a non-existent route policy is applied to a VPRN instance, the CLI generates a warning message. This message is only generated at an interactive CLI session and the route policy association is made. No warning message is generated when a non-existent route policy is applied to a VPRN instance in a configuration file or when SNMP is used.

The **no** form of this command removes all route policy names from the export list.

Default no export — BGP advertises routes from other BGP routes but does not advertise any routes from other protocols unless directed by an export policy.

Parameters *policy* — A route policy statement name.

hold-time

Syntax **hold-time** *seconds*
no hold-time

Context config>subscr-mgmt>bgp-prng-plcy

Description This command configures the BGP hold time, expressed in seconds.

The BGP hold time specifies the maximum time BGP waits between successive messages (either keepalive or update) from its peer, before closing the connection.

Even though the router OS implementation allows setting the keepalive time separately, the configured keepalive timer is overridden by the hold-time value under the following circumstances:

If the specified hold-time is less than the configured keepalive time, then the operational keepalive time is set to a third of the hold-time; the configured keepalive time is not changed.

If the hold-time is set to zero, then the operational value of the keepalive time is set to zero; the configured keepalive time is not changed. This means that the connection with the peer is up permanently and no keepalive packets are sent to the peer.

The **no** form of the command used at the global level reverts to the default value.

Default 90 seconds

Parameters *seconds* — The hold-time, in seconds, expressed as a decimal integer. A value of 0 indicates the connection to the peer is up permanently.

Values 0, 3 to 65535

import

Syntax	import <i>policy</i> [<i>policy</i> ...] no import
Context	config>subscr-mgmt>bgp-prng-plcy
Description	<p>This command specifies the import policies to be used to control routes advertised to BGP neighbors. Route policies are configured in the config>router>policy-options context. When multiple policy names are specified, the policies are evaluated in the order they are specified. A maximum of five (5) policy names can be specified. The first policy that matches is applied.</p> <p>The no form of this command removes all route policy names from the import list.</p>
Default	no import — BGP accepts all routes from configured BGP neighbors. Import policies can be used to limit or modify the routes accepted and their corresponding parameters and metrics.
Parameters	<i>policy</i> — A route policy statement name.

keepalive

Syntax	keepalive <i>seconds</i> no keepalive
Context	config>subscr-mgmt>bgp-prng-plcy
Description	<p>This command configures the BGP keepalive timer. A keepalive message is sent every time this timer expires.</p> <p>The keepalive value is generally one-third of the hold-time interval. Even though the OS implementation allows the keepalive value and the hold-time interval to be independently set, under the following circumstances, the configured keepalive value is overridden by the hold-time value:</p> <p>If the specified keepalive value is greater than the configured hold-time, then the specified value is ignored, and the keepalive is set to one third of the current hold-time value.</p> <p>If the specified hold-time interval is less than the configured keepalive value, then the keepalive value is reset to one third of the specified hold-time interval.</p> <p>If the hold-time interval is set to zero, then the configured value of the keepalive value is ignored. This means that the connection with the peer is up permanently and no keepalive packets are sent to the peer.</p> <p>The no form of the command used at the global level reverts to the default value.</p>
Default	30 seconds

Parameters	<i>seconds</i> — The keepalive timer in seconds, expressed as a decimal integer.
Values	0 to 21845

local-address

Syntax	local-address <i>ip-address</i> no local-address
Context	config>subscr-mgmt>bgp-prng-plcy
Description	<p>Configures the local IP address used by the group or neighbor when communicating with BGP peers.</p> <p>Outgoing connections use the local-address as the source of the TCP connection when initiating connections with a peer.</p> <p>When a local address is not specified, the 7750 SR OS uses the system IP address when communicating with IBGP peers and uses the interface address for directly connected EBGP peers. This command is used at the neighbor level to revert to the value defined under the group level.</p> <p>The no form of the command removes the configured local-address for BGP.</p> <p>The no form of the command used at the group level reverts to the value defined at the global level.</p> <p>The no form of the command used at the neighbor level reverts to the value defined at the group level.</p>
Default	no local-address
	<p>For IPv4, the local address is expressed in dotted decimal notation. Allowed values are a valid routable IP address on the router, either an interface or system IP address.</p> <p>For IPv6, the local address is expressed in semi-colon hexadecimal notation. Allowed values is an interface or a system IP address.</p>

local-as

Syntax	local-as <i>as-number</i> [private] no local-as
Context	config>subscr-mgmt>bgp-prng-plcy
Description	This command configures a BGP virtual autonomous system (AS) number.

In addition to the AS number configured for BGP in the `config>router>autonomous-system` context, a virtual (local) AS number is configured. The virtual AS number is added to the `as-path` message before the router's AS number makes the virtual AS the second AS in the `as-path`.

This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in `peer-group`) or neighbor level (only applies to specified peer). Thus, by specifying this at each neighbor level, it is possible to have a separate `as-number` per EBGP session.

When a command is entered multiple times for the same AS, the last command entered is used in the configuration. The **private** attribute can be added or removed dynamically by reissuing the command.

Changing the local AS at the global level in an active BGP instance causes the BGP instance to restart with the new local AS number. Changing the local AS at the global level in an active BGP instance causes BGP to re-establish the peer relationships with all peers in the group with the new local AS number. Changing the local AS at the neighbor level in an active BGP instance causes BGP to re-establish the peer relationship with the new local AS number.

This is an optional command and can be used in the following circumstance:

Provider router P is moved from AS1 to AS2. The customer router that is connected to P, however, is configured to belong to AS1. To avoid reconfiguring the customer router, the **local-as** value on router P can be set to AS1. Thus, router P adds AS1 to the `as-path` message for routes it advertises to the customer router.

The **no** form of the command used at the global level will remove any virtual AS number configured.
The **no** form of the command used at the group level reverts to the value defined at the global level.

The **no** form of the command used at the neighbor level reverts to the value defined at the group level.

Default	no local-as
Parameters	<i>as-number</i> — The virtual autonomous system number, expressed as a decimal integer. Values 1 to 65535 private — Specifies the local-as is hidden in paths learned from the peering.

local-preference

Syntax	local-preference <i>local-preference</i> no local-preference
Context	config>subscr-mgmt>bgp-prng-plcy

Description	<p>This command enables setting the BGP local-preference attribute in incoming routes if not specified and configures the default value for the attribute. This value is used if the BGP route arrives from a BGP peer without the local-preference integer set.</p> <p>The specified value can be overridden by any value set via a route policy.</p> <p>The no form of the command at the global level specifies that incoming routes with local-preference set are not overridden and routes arriving without local-preference set are interpreted as if the route had local-preference value of 100.</p>
Default	<p>no local-preference</p> <p>Does not override the local-preference value set in arriving routes and analyze routes without local preference with value of 100.</p>
Parameters	<p><i>local-preference</i> — The local preference value to be used as the override value, expressed as a decimal integer.</p> <p>Values 0 to 4294967295</p>

loop-detect

Syntax	<p>loop-detect {drop-peer discard-route ignore-loop off} no loop-detect</p>
Context	<p>config>subscr-mgmt>bgp-prng-plcy</p>
Description	<p>This command configures how the BGP peer session handles loop detection in the AS path.</p> <div><p>Note: Dynamic configuration changes of loop-detect are not recognized.</p></div> <p>The no form of the command used at the global level reverts to default, which is loop-detect ignore-loop.</p>
Default	<p>loop-detect ignore-loop</p>
Parameters	<p>drop-peer — Sends a notification to the remote peer and drops the session.</p> <p>discard-route — Discards routes received with loops in the AS path.</p> <p>ignore-loop — Ignores routes with loops in the AS path but maintains peering.</p> <p>off — Disables loop detection.</p>

med-out

Syntax	med-out { number igp-cost } no med-out
Context	config>subscr-mgmt>bgp-prng-plcy
Description	<p>This command enables advertising the Multi-Exit Discriminator (MED) and assigns the value used for the path attribute for the MED advertised to BGP peers if the MED is not already set.</p> <p>The specified value can be overridden by any value set via a route policy.</p> <p>The no form of the command used at the global level reverts to default where the MED is not advertised.</p> <p>no med-out</p>
Parameters	<p><i>number</i> — The MED path attribute value, expressed as a decimal integer.</p> <p>Values 0 to 4294967295</p> <p>igp-cost — The MED is set to the IGP cost of the given IP prefix.</p>

min-as-origination

Syntax	min-as-origination <i>seconds</i> no min-as-origination
Context	config>subscr-mgmt>bgp-prng-plcy
Description	<p>This command configures the minimum interval, in seconds, at which a path attribute, originated by the local router, can be advertised to a peer.</p> <p>The no form of the command used at the global level reverts to default.</p>
Default	15 seconds
Parameters	<p><i>seconds</i> — The minimum path attribute advertising interval in seconds, expressed as a decimal integer.</p> <p>Values 2 to 255</p>

min-route-advertisement

Syntax	min-route-advertisement <i>seconds</i> no min-route-advertisement
Context	config>subscr-mgmt>bgp-prng-plcy

Description	<p>This command configures the minimum interval, in seconds, at which a prefix can be advertised to a peer.</p> <p>The no form of the command reverts to default values.</p>
Default	30 seconds
Parameters	<p><i>seconds</i> — The minimum route advertising interval, in seconds, expressed as a decimal integer.</p> <p>Values 1 to 255</p>

multihop

Syntax	multihop <i>ttl-value</i> no multihop
Context	config>subscr-mgmt>bgp-prng-plcy
Description	<p>This command configures the time to live (TTL) value entered in the IP header of packets sent to an EBGp peer multiple hops away.</p> <p>This parameter is meaningful only when configuring EBGp peers. It is ignored if set for an IBGP peer.</p> <p>The no form of the command is used to convey to the BGP instance that the EBGp peers are directly connected.</p> <p>The no form of the command reverts to default values.</p>
Default	<p>1 — EBGp peers are directly connected.</p> <p>64 — IBGP</p>
Parameters	<p><i>ttl-value</i> — The TTL value, expressed as a decimal integer.</p> <p>Values 1 to 255</p>

next-hop-self

Syntax	[no] next-hop-self
Context	config>subscr-mgmt>bgp-prng-plcy
Description	<p>This command configures the neighbor to always set the NEXTHOP path attribute to its own physical interface when advertising to a peer.</p> <p>The no form of the command disables the command.</p>
Default	no next-hop-self

passive

Syntax	[no] passive
Context	config>subscr-mgmt>bgp-prng-plcy
Description	This command enables the passive mode for the BGP neighbors. The no form of the command disables the passive mode.
Default	no passive

peer-as

Syntax	peer-as <i>as-number</i> no peer-as
Context	config>subscr-mgmt>bgp-prng-plcy
Description	This command configures the autonomous system number for the remote peer. The peer AS number must be configured for each configured peer. The no form of the command removes the <i>as-number</i> from the configuration.
Default	No AS numbers are defined.
Parameters	<i>as-number</i> — Specifies the AS number for the remote peer. Values 1 to 4294967295

preference

Syntax	[no] preference <i>preference</i>
Context	config>subscr-mgmt>bgp-prng-plcy
Description	This command configures the route preference for routes learned from the configured peer(s). The lower the preference the higher the chance of the route being the active route. The OS assigns BGP routes highest default preference compared to routes that are direct, static or learned via MPLS or OSPF. The no form of the command used at the global level reverts to default value.
Default	170
Parameters	<i>preference</i> — The route preference, expressed as a decimal integer. Values 1 to 255

prefix-limit

Syntax	prefix-limit <i>limit</i> [log-only] [threshold <i>percent</i>] no prefix-limit
Context	config>subscr-mgmt>bgp-prng-plcy
Description	<p>This command configures the maximum number of routes BGP can learn from a peer.</p> <p>When the number of routes reaches 90% of this limit, an SNMP trap is sent. When the limit is exceeded, the BGP peering is dropped and disabled.</p> <p>The no form of the command removes the prefix-limit.</p>
Default	no prefix-limit
Parameters	<p><i>log-only</i> — Enables the warning message to be sent at the specified threshold percentage, and also when the limit is exceeded. However, the BGP peering is not dropped.</p> <p><i>percent</i> — The threshold value (as a percentage) that triggers a warning message to be sent.</p> <p><i>limit</i> — The number of routes that can be learned from a peer, expressed as a decimal integer.</p> <p>Values 1 to 4294967295</p>

remove-private

Syntax	[no] remove-private
Context	config>subscr-mgmt>bgp-prng-plcy
Description	<p>This command allows private AS numbers to be removed from the AS path before advertising them to BGP peers.</p> <p>The OS software recognizes the set of AS numbers that are defined by IANA as private. These are AS numbers in the range 64512 through 65535, inclusive.</p> <p>The no form of the command used at the global level reverts to default value.</p>
Default	no remove-private
	Private AS numbers will be included in the AS path attribute.

type

Syntax	[no] type {internal external}
---------------	--

Context	config>subscr-mgmt>bgp-prng-plcy
Description	<p>This command designates the BGP peer as type internal or external.</p> <p>The type of internal indicates the peer is an IBGP peer while the type of external indicates that the peer is an EBGP peer.</p> <p>By default, the OS derives the type of neighbor based on the local AS specified. If the local AS specified is the same as the AS of the router, the peer is considered internal. If the local AS is different, then the peer is considered external.</p> <p>The no form of the command used at the group level reverts to the default value.</p>
Default	<p>no type</p> <p>Type of neighbor is derived on the local AS specified.</p>
Parameters	<p>internal — Configures the peer as internal.</p> <p>external — Configures the peer as external.</p>

ttl-security

Syntax	ttl-security <i>min-ttl-value</i> no ttl-security
Context	config>subscr-mgmt>bgp-prng-plcy
Description	Configure TTL security parameters for incoming packets.
Parameters	<i>min-ttl-value</i> — Specify the minimum TTL value for an incoming BGP packet. Values 1 to 255

9.24.2.1.3 RADIUS Policy Commands

isa-radius-policy

Syntax	isa-radius-policy <i>name</i> [create] no isa-radius-policy <i>name</i>
Context	config>aaa
Description	This command enables the context to configure an ISA RADIUS policy.
Default	none
Parameters	<i>name</i> — Specifies the identifier of this ISA RADIUS policy up to 32 characters in length.

radius-coa-port

Syntax	radius-coa-port { <i>port-number</i> } no radius-coa-port
Context	config>aaa
Description	<p>This command configures the system-wide UDP port number that RADIUS is listening on for CoA and Disconnect messages</p> <p>The no form of the command resets the default UDP port to 3799.</p>
Default	3799
Parameters	<p><i>port-number</i> — Specifies the udp port number for RADIUS CoA and Disconnect Messages.</p> <p>Values 1647, 1700, 1812, 3799</p>

authentication-policy

Syntax	authentication-policy <i>name</i> [create] no authentication-policy
Context	config>subscr-mgmt
Description	<p>This command creates the context to configure RADIUS server parameters for session authentication. The policies can be applied to an IES or VPRN interface, or a VPLS SAP.</p> <p>The no form of the command removes the RADIUS server configuration for session authentication.</p> <p>RADIUS servers can be configured for three different applications:</p> <ol style="list-style-type: none">1. For authentication of dynamic Triple Play subscriber sessions, under config>subscr-mgmt>authentication-plcy2. For 802.1x port authentication, under config>system>security>dot1x>radius-plcy3. For CLI login users, under config>system>radius
Default	none
Parameters	<p><i>name</i> — The name of the profile. The string is case sensitive and limited to 32 ASCII 7-bit printable characters with no spaces.</p>

pim-policy

Syntax	pim-policy <i>policy-name</i> no pim-policy <i>policy-name</i>
---------------	---

Context	config>subscr-mgmt>sub-prof
Description	This command adds an existing PIM policy to this subscriber profile. The no form of the command removes the specified PIM policy from this subscriber profile.
Default	No PIM policy is added to a subscriber profile by default.
Parameters	<i>policy-name</i> — The name of the PIM policy. The string is case sensitive and limited to 32 ASCII 7-bit printable characters with no spaces.

radius-accounting-policy

Syntax	radius-accounting-policy <i>name</i> no radius-accounting-policy
Context	config>subscr-mgmt config>subscr-mgmt>sub-prof>rad-acct-policy
Description	This command specifies a subscriber RADIUS based accounting policy.
Parameters	<i>name</i> — The name of the policy. The string is case sensitive and limited to 32 ASCII 7-bit printable characters with no spaces.

accept-authorization-change

Syntax	[no] accept-authorization-change
Context	config>subscr-mgmt>auth-policy
Description	This command specifies whether or not the system should handle the CoA messages initiated by the RADIUS server, and provide for mid-session interval changes of policies applicable to subscriber hosts.
Default	no accept-authorization-change

accept-script-policy

Syntax	accept-script-policy <i>policy-name</i> no accept-script-policy
Context	config>subscr-mgmt>auth-policy
Description	This command configures a RADIUS script policy used to change the RADIUS attributes of the incoming Access-Accept messages.
Parameters	<i>policy-name</i> — Configures a Python script policy to modify Access-Accept messages.

access-loop-options

Syntax	[no] access-loop-options
Context	config>subscr-mgmt>auth-plcy>include-radius-attribute config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	<p>This command enables inclusion of access loop information: Broadband Forum (BBF) access loop characteristics, DSL line state and DSL type. The BBF access loop characteristics are returned as BBF specific RADIUS attributes where DSL line state and DSL type are returned as Nokia-specific RADIUS VSA's.</p> <p>Information obtained via the ANCP protocol has precedence over information received in PPPoE Vendor Specific BBF tags or DHCP Vendor Specific BBF Options.</p> <p>If ANCP is utilized and interim accounting update is enabled, any Port Up event from GSMP will initiate in an interim update. Port Up messages can include information such as an update on the current subscriber actual-upstream-speed. The next interim accounting message will be from "port up" triggering point.</p>
Default	no access-loop-options

host-accounting

Syntax	[no] host-accounting [interim-update]
Context	config>subscr-mgmt>acct-plcy
Description	<p>This command enables per host accounting mode. In host accounting mode, the acct-session-id is generated per host. This acct-session-id is uniformly included in all accounting messages (START/INTERIM-UPDTATE/STOP) and it can be included in RADIUS Access-Request message.</p> <p>Accounting counters are based on the queue counters and as such are aggregated for all host sharing the queues within an sla-profile instance (non HSMDA) or a subscriber (HSMDA). CoA and LI is supported based on the acct-session-id of the host.</p>
Default	no host-accounting
Parameters	interim-update — Without this keyword only START and STOP accounting messages are generated when the host is established/terminated. This is equivalent to a time-based accounting where only the duration of the session is required.

include-radius-attribute

Syntax	[no] include-radius-attribute
Context	config>subscr-mgmt>auth-plcy

config>subscr-mgmt>acct-plcy

Description This command enables the context to specify the RADIUS parameters that the system should include into RADIUS authentication-request messages.

acct-authentic

Syntax [no] acct-authentic

Context config>subscr-mgmt>auth-policy>include-radius-attribute
config>subscr-mgmt>acct-plcy>include-radius-attribute

Description This command enables the generation of the acct-authentic RADIUS attribute and only applies to the 7750 SR.

acct-delay-time

Syntax [no] acct-delay-time

Context config>subscr-mgmt>auth-policy>include-radius-attribute
config>subscr-mgmt>acct-plcy>include-radius-attribute

Description This command enables the generation of the acct-delay-time RADIUS attribute and only applies to the 7750 SR.

alc-error-code

Syntax [no] alc-error-code

Context config>subscr-mgmt>acct-plcy>include-radius-attribute

Description This command enables RADIUS accounting messages to include an error number and error code when the subscriber host session terminates. To obtain a complete list of error numbers and their corresponding codes, use the **tools>dump>aaa>radius-acct-terminate-cause** command.

all-authorized-session-addresses

Syntax [no] all-authorized-session-addresses

Context config>subscr-mgmt>acct-plcy>include-radius-attribute

Description Applicable for session-accounting mode only.

With this flag enabled, all IP address attributes explicitly enabled to be included are the following:

- delegated-ipv6-prefix
- framed-ip-address
- framed-ip-netmask
- framed-ipv6-prefix
- ipv6-address

These are included if the corresponding addresses or prefixes are authorized (via access-accept or ludb) and independent if they are used or not.

Default no all-authorized-session-addresses

called-station-id

Syntax [no] called-station-id

Context config>subscr-mgmt>auth-policy>include-radius-attribute
config>subscr-mgmt>acct-plcy>include-radius-attribute

Description This command includes called station id attributes and only applies to the 7750 SR.

The **no** form of the command excludes called station id attributes.

calling-station-id

Syntax calling-station-id
calling-station-id {mac | remote-id | sap-id | sap-string}
no calling-station-id

Context config>service>ies>if>sap
config>service>ies>sub-if>grp-if>sap
config>service>vpls>sap
config>service>vprn>if>sap
config>service>vprn>sub-if>grp-if>sap
config>subscr-mgmt>auth-plcy>include-radius-attribute
config>subscr-mgmt>acct-plcy>include>include-radius-attribute

Description This command enables the inclusion of the calling-station-id attribute in RADIUS authentication requests and RADIUS accounting messages. The value inserted is set at the SAP level. If no **calling-station-id** value is set at the SAP level, the **calling-station-id** attribute will not be sent.

Default no calling-station-id

Parameters **mac** — Specifies that the mac-address will be sent.
remote-id — Specifies that the remote-id will be sent.
sap-id — Specifies that the sap-id will be sent.

sap-string — Specifies that the value is the inserted value set at the SAP level. If no **calling-station-id** value is set at the SAP level, the **calling-station-id** attribute will not be sent.

access-loop-options

Syntax	[no] access-loop-options
Context	config>subscr-mgmt>auth-plcy>include-radius-attribute config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	<p>This command enables inclusion of access loop information: Broadband Forum (BBF) access loop characteristics, DSL line state and DSL type. The BBF access loop characteristics are returned as BBF specific RADIUS attributes where DSL line state and DSL type are returned as Nokia-specific RADIUS VSA's.</p> <p>Information obtained via the ANCP protocol has precedence over information received in PPPoE Vendor Specific BBF tags or DHCP Vendor Specific BBF Options.</p>

acct-session-id

Syntax	[no] acct-session-id
Context	config>subscr-mgmt>auth-plcy>include-radius-attribute
Description	<p>The acct-session-id attribute for each subscriber host will be generated at the very beginning of the session initiation. This command will enable or disable sending this attribute to the RADIUS server in the Access-Request messages regardless of whether the accounting is enabled or not. The acct-session-id attribute can be used to address the subscriber hosts from the RADIUS server in the CoA Request.</p> <p>The acct-session-id attribute will be unique per subscriber host network wide. It is a 22bytes long field comprised of the system MAC address along with the creation time and a sequence number in a hex format.</p>
Default	Disabled

circuit-id

Syntax	[no] circuit-id
Context	config>subscr-mgmt>auth-policy>include-radius-attribute config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command enables the generation of the agent-circuit-id for RADIUS.

delegated-ipv6-prefix

Syntax	[no] delegated-ipv6
Context	config>subscr-mgmt>auth-policy>include-radius-attribute config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command enables the generation of the delegated-ipv6-prefix RADIUS attribute and only applies to the 7750 SR.

detailed-acct-attributes

Syntax	[no] detailed-acct-attributes
Context	config>subscr-mgmt>auth-plcy>include-radius-attribute
Description	<p>This command enables detailed reporting of per queue and per policer octet and packet counters using RADIUS VSAs. Enabled by default. It can be enabled simultaneously with aggregate counters (std-acct-attributes).</p> <p>The no form of the command excludes the detailed counter VSAs from the RADIUS accounting messages.</p>
Default	detailed-acct-attributes

dhcp-options

Syntax	[no] dhcp-options
Context	config>subscr-mgmt>auth-plcy>include-radius-attribute
Description	This command enables insertion of RADIUS VSA containing all dhcp-options from dhcp-discover (or dhcp-request) message. The VSA contains all dhcp-options in a form of the string. If required (the total length of all dhcp-options exceeds 255B), multiple VSAs are included.
Default	no dhcp-options

dhcp6-options

Syntax	[no] dhcp6-options
Context	config>subscr-mgmt>auth-policy>include
Description	This command will copy DHCPv6 options from received DHCPv6 messages on ingress access and pass them to the RADIUS server in Accept-Request. The messages will be carried in the ALU VSA Alc-ToServer-Dhcp6-Options.

Default no dhcp6-options

dhcp-vendor-class-id

Syntax [no] dhcp-vendor-class-id

Context config>subscr-mgmt>auth-plcy>include-radius-attribute

Description This command includes the “[26-6527-36] Alc-DHCP-Vendor-Class-Id” attribute in RADIUS accounting messages. The content of the DHCP Vendor-Class-Identifier option (60) is mapped in this attribute.

Default no dhcp-vendor-class-id

framed-interface-id

Syntax [no] framed-interface-id

Context config>subscr-mgmt>auth-policy>include-radius-attribute
config>subscr-mgmt>acct-plcy>include-radius-attribute

Description This command enables the generation of the framed-interface-id RADIUS attribute and only applies to the 7750 SR.

framed-ip-addr

Syntax [no] framed-ip-addr

Context config>subscr-mgmt>acct-plcy>include-radius-attribute

Description This command enables the inclusion of the framed-ip-addr attribute.

framed-ip-netmask

Syntax [no] framed-ip-netmask

Context config>subscr-mgmt>acct-plcy>include-radius-attribute

Description This command enables the inclusion of the framed-ip-netmask attribute.

framed-ipv6-prefix

Syntax [no] framed-ipv6-prefix

Context	config>subscr-mgmt>auth-policy>include-radius-attribute config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command enables the generation of the framed-ipv6-prefix RADIUS attribute and only applies to the 7750 SR.

framed-ipv6-route

Syntax	[no] framed-ipv6-route
Context	config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	When enabled, all valid [99] Framed-IPv6-Route attributes as received in the RADIUS authentication phase and associated with an instantiated IPv6 wan host will be included in the RADIUS accounting request messages. The state of the Framed-IPv6-Route (installed, shadowed, hostInactive, etc.) is not taken into account for reporting in the accounting request messages.
Default	no framed-ipv6-route

framed-route

Syntax	[no] framed-route
Context	config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	When enabled, all valid [22] Framed-Route attributes as received in the RADIUS authentication phase and associated with an instantiated IPv4 host will be included in the RADIUS accounting request messages. The state of the Framed-Route (installed, shadowed, hostInactive, etc.) is not taken into account for reporting in the accounting request messages.
Default	no framed-route

ipv6-address

Syntax	[no] framed-ipv6-address
Context	config>subscr-mgmt>auth-policy>include-radius-attribute config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command enables the generation of the ipv6-address RADIUS attribute.

mac-address

Syntax	[no] mac-address
Context	config>subscr-mgmt>auth-policy>include-radius-attribute config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command enables the generation of the client MAC address RADIUS attribute.

nas-identifier

Syntax	[no] nas-identifier
Context	config>subscr-mgmt>auth-policy>include-radius-attribute config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command enables the generation of the nas-identifier RADIUS attribute.

nas-port

Syntax	[no] nas-port <i>bit-specification binary-spec</i>
Context	config>subscr-mgmt>auth-policy>include-radius-attribute config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	<p>This command enables the generation of the nas-port RADIUS attribute. You enter decimal representation of a 32-bit string that indicates your port information. This 32-bit string can be compiled based on different information from the port (data types). By using syntax number-of-bits data-type you indicate how many bits from the 32 bits are used for the specific data type. These data types can be combined up to 32 bits in total. In between the different data types 0's and/or 1's as bits can be added.</p> <p>The no form of this command disables your nas-port configuration.</p>
Parameters	<i>bit-specification binary-spec</i> — Specifies the NAS-Port attribute

Values		
binary-spec		<bit-specification> <binary-spec>
bit-specification		0 1 <bit-origin>
bit-origin		*<number-of-bits><origin>
number-of-bits		1 to 32
origin		o i s m p
		outer VLAN ID
	i	inner VLAN ID
	s	slot number
	m	MDA number

p port number or lag-id

Output

Sample

```
*12o*12i00*2s*2m*2p => 0000 0000 0000 iiii iiii iiii 00ss mmpp
If outer vlan = 0 & inner vlan = 1 & slot = 3 & mda = 1 & port = 1
=> 0000 0000 0000 0000 0000 0001 0011 0101 => nas-port = 309
```

nas-port-id

Syntax	[no] nas-port-id [prefix-string <i>string</i>] [suffix <i>suffix-option</i>]
Context	config>subscr-mgmt>auth-policy>include-radius-attribute config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command enables the generation of the nas-port-id RADIUS attribute. Optionally, the value of this attribute (the SAP-id) can be prefixed by a fixed string and suffixed by the circuit-id or the remote-id of the client connection. If a suffix is configured, but no corresponding data is available, the suffix used will be 0/0/0/0/0/0.
Parameters	prefix-string <i>string</i> — Specifies that a user configurable string will be added to the RADIUS NAS port attribute, up to 8 characters in length. suffix <i>suffix-option</i> — Specifies the suffix type to be added to the RADIUS NAS port attribute.
Values	circuit-id, remote-id

nas-port-type

Syntax	nas-port-type nas-port-type [value] no nas-port-type
Context	config>subscr-mgmt>auth-plcy>include-radius-attribute config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command enables the generation of the nas-port-type RADIUS attribute. If set to nas-port-type , the following will be sent: values: 32 (null-encap), 33 (dot1q), 34 (qinq), 15 (DHCP hosts). The nas-port-type can also be set as a specified value, with an integer from 0 to 255. The no form of the command reverts to the default.
Default	no nas-port-type

Parameters	<i>value</i> — Specifies an enumerated integer that specifies the value that will be put in the RADIUS nas-port-type attribute.
Values	0 to 255

nat-port-range

Syntax	[no] nat-port-range
Context	config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command enables the generation of the of nat-port-range attribute and only applies to the 7750 SR.
Default	no nat-port-range

pppoe-service-name

Syntax	[no] pppoe-service-name
Context	config>subscr-mgmt>auth-policy>include-radius-attribute config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command enables the generation of the pppoe-service-name RADIUS attribute.

remote-id

Syntax	[no] remote-id
Context	config>subscr-mgmt>auth-policy>include-radius-attribute config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command enables the generation of the agent-remote-id for RADIUS.

sap-session-index

Syntax	[no] sap-session-index
Context	config>subscr-mgmt>acct-plcy>include-radius-attribute config>subscr-mgmt>auth-plcy>include-radius-attribute
Description	This command enables the generation of the per-SAP unique session index. The no form of the command excludes sap-session-index attributes.

tunnel-server-attrs

Syntax	[no] tunnel-server-attrs
Context	config>subscr-mgmt>auth-plcy>include-radius-attribute
Description	This command includes tunnel-server attribute.

wifi-num-attached-ues

Syntax	[no] wifi-num-attached-ues
Context	config>subscr-mgmt>acct-plcy>include config>subscr-mgmt>auth-plcy>include config>aaa>isa-radius-plcy>auth-include-attributes config>aaa>isa-radius-plcy>acct-include-attributes
Description	When enabled, this command indicates the number of UEs connected to the tunnel to which the radius message applies to. For session/host accounting this is the tunnel of the associated UE. For queue-instance accounting this attribute will not be included. The no form of the command removes the attribute from inclusion.

wifi-ssid-vlan

Syntax	[no] wifi-ssid-vlan
Context	config>subscr-mgmt>acct-plcy>include config>subscr-mgmt>auth-plcy>include config>aaa>isa-radius-plcy>auth-include-attributes config>aaa>isa-radius-plcy>acct-include-attributes
Description	This command enables including the per-SSID VLAN ID in a Alc-Wlan-SSID-VLAN.

sla-profile

Syntax	[no] sla-profile
Context	config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command specifies that SLA profile attributes should be included into RADIUS accounting messages.

std-acct-attributes

Syntax	[no] std-acct-attributes
Context	config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command enables reporting of aggregated forwarded IPv4 and IPv6 octet, packet and gigaword counters using standard Radius attributes. Disabled by default. It can be enabled simultaneously with detailed per queue/policer counters (detailed-acct-attributes).
Default	no std-acct-attributes

sub-profile

Syntax	[no] sub-profile
Context	config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command specifies that subscriber profile attributes should be included into RADIUS accounting messages.

subscriber-id

Syntax	[no] subscriber-id
Context	config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command specifies that subscriber ID attributes should be included into RADIUS accounting messages.

tunnel-server

Syntax	[no] tunnel-server
Context	config>subscr-mgmt>auth-policy>include-radius-attribute config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command enables the generation of the tunnel-server RADIUS attribute and only applies to the 7750 SR.

user-name

Syntax	[no] user-name
Context	config>subscr-mgmt>acct-plcy>include-radius-attribute

Description	This command enables the inclusion of the user-name attribute. The no form of the command disables the inclusion of the user-name attribute.
Default	no user-name

v6-aggregate-stats

Syntax	[no] v6-aggregate-stats
Context	config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command enables reporting of IPv6 aggregated forwarded octet and packet counters using RADIUS VSAs. Disabled by default. It requires stat-mode v4-v6 for policers and queues for which the IPv6 aggregate forwarded packets should be counted.
Default	no v6-aggregate-stats

wifi-rssi

Syntax	[no] wifi-rssi
Context	config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command enables the inclusion of the 802.11 Received Signal Strength Indication attribute.

password

Syntax	password <i>password</i> [hash hash2] no password
Context	config>subscr-mgmt>auth-policy
Description	This command sets a password that is sent with user-name in every RADIUS authentication request sent to the RADIUS server upon receipt of DHCP discover or request messages. If no password is configured, no password AVP will be sent. The no form of the command reverts to the default value.
Default	none
Parameters	<i>password</i> — A text string containing the password. Allowed values are any string up to 64 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

hash — Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified

hash2 — Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

password

Syntax	password <i>password</i> [hash hash2] no password
Context	config>subscr-mgmt>diam-appl-plcy>nasreq
Description	<p>This command sets a password that is sent with user-name in every RADIUS authentication request sent to the RADIUS server upon receipt of DHCP discover or request messages. If no password is provided, an empty password will be sent.</p> <p>The no form of the command reverts to the default value.</p>
Default	no password
Parameters	<p><i>password</i> — A text string containing the password. Allowed values are any string up to 64 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.</p> <p>hash — Specifies the key is entered in an encrypted form. If the hash or hash2 parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the hash or hash2 parameter specified</p> <p>hash2 — Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the hash2 encrypted variable cannot be copied and pasted. If the hash or hash2 parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the hash or hash2 parameter specified.</p>

ppp-user-name

Syntax	ppp-user-name append <i>domain-name</i> ppp-user-name default-domain <i>domain-name</i> ppp-user-name replace <i>domain-name</i> ppp-user-name strip no ppp-user-name
---------------	--

Context	config>subscr-mgmt>auth-plcy
Description	<p>This command configures the password that is sent with the User-Name in Diameter NASREQ AA-Requests for IPoE hosts.</p> <p>When no password is configured, an empty password will be sent.</p>
Default	no ppp-user-name
Parameters	<p>append <i>domain-name</i> — A string specified by tmnxSubAuthPlcyPppDomain, preceded with a '@', is appended to the PAP/CHAP user name.</p> <p>default-domain <i>domain-name</i> — The same action is performed as with appendDomain, but only if the PAP/CHAP user name does not already contain a domain name.</p> <p>replace <i>domain-name</i> — All characters after a '@' delimiter are replaced with the string specified by tmnxSubAuthPlcyPppDomain.</p> <p>strip — Any '@' character and all subsequent characters are removed from the PAP/CHAP user name.</p>

pppoe-access-method

Syntax	pppoe-access-method {none padi pap-chap} no pppoe-access-method
Context	config>subscr-mgmt>auth-plcy
Description	This command indicates the authentication method used towards the RADIUS server in case the policy is used for PPPoE.
Parameters	<p>none — Indicates that the client will be authenticated by the local user database defined under the group interface and not through RADIUS.</p> <p>padi — Indicates that the client will be authenticated by RADIUS as soon as the PADI packet comes in (there is no PPP authentication done in the session in this case).</p> <p>pap-chap — Indicates that the RADIUS authentication of the client will be delayed until the authentication protocol phase in the PPP session (PAP or CHAP) and authentication will be performed with the user name and PAP password / CHAP response supplied by the client.</p>

queue-instance-accounting

Syntax	queue-instance-accounting [interim-update] no queue-instance-accounting
Context	config>subscr-mgmt>acct-plcy

Description	<p>This command enables per queue-instance-accounting. A stream of accounting messages (START/INTERIM-UPDATE/STOP) is generated per queuing instance. A queuing instance is equivalent to an sla-profile instance on non HSMDA based hardware and to subscriber on HSMDA based hardware. Accounting session id is generated per queuing instance and this accounting session id CANNOT be included in RADIUS Access-Request message. Queue instance counters represent volume based aggregation for all hosts sharing the queuing instance.</p> <p>CoA and LI is supported based on the acct-session-id of the queuing instance.</p>
Default	interim-update
Parameters	interim-update — specifies whether accounting messages are sent for the queue-instance. The queue-instance is the subscriber on High Scale MDA (HSMDA), or the SLA profile instance otherwise.

radius-authentication-server

Syntax	radius-authentication-server
Context	config>subscr-mgmt>acct-plcy
Description	This command creates the context for defining RADIUS authentication server attributes under a given session authentication policy.

access-algorithm

Syntax	access-algorithm {direct round-robin} no access-algorithm
Context	config>subscr-mgmt>auth-plcy-srvr config>subscr-mgmt>acct-plcy>server
Description	This command configures the algorithm used to access the list of configured RADIUS servers.
Parameters	direct — Specifies that the first server will be used as primary server for all requests, the second as secondary and so on. round-robin — Specifies that the first server will be used as primary server for the first request, the second server as primary for the second request, and so on. If the router gets to the end of the list, it starts again with the first server.

fallback-action

Syntax	fallback-action accept [force-probing] fallback-action user-db <i>local-user-db-name</i> [force-probing]
---------------	---

no fallback-action

Context	config>subscr-mgmt>auth-plcy
Description	<p>This command configures the action when no RADIUS server is available; servers are either out of service or are in a probing state.</p> <p>The no form of the command removes the action from the configuration.</p>
Default	no fallback-action
Parameters	<p>accept — specifies that all authentication requests are automatically accepted</p> <p><i>local-user-db-name</i> — specifies that the LUDB is used to authenticate to the server</p> <p>force-probing — specifies that a subscriber or a test user auth-request, depending which arrives first, is used to probe a RADIUS server before continuing with accept or user-db. This forces an out-of-service server to transition to a probing state.</p>

hold-down-time

Syntax	hold-down-time <i>seconds</i> no hold-down-time
Context	config>subscr-mgmt>auth-plcy>radius-auth-server
Description	<p>This command determines the interval during which no new communication attempts will be made to a RADIUS server that is marked down to prevent immediately overloading the server when it is starting up. The only exception is when all servers in the authentication policy are marked down; in that case they will all be used again to prevent failures on new client connections.</p>
Default	30
Parameters	<p><i>seconds</i> — Specifies the hold time before re-using a RADIUS server that was down.</p> <p>Values 30 to 900</p>

router

Syntax	router <i>router-instance</i> router <i>service-name</i> no router
Context	config>subscr-mgmt>auth-plcy-srvr config>subscr-mgmt>acct-plcy>server
Description	<p>This command specifies the virtual router instance applicable for the set of configured RADIUS servers. This value cannot be changed once a RADIUS server is configured for this policy. When the value is zero, both base and management router instances are matched.</p>

Parameters *router-instance* — Specifies the virtual router instance.

Values

router-name: Base, management
service-id: 1 to 2147483647
service-name: Specifies the service name up to 64 characters in
length

retry

Syntax **retry** *count*
no retry

Context config>subscr-mgmt>auth-plcy-srvr
config>subscr-mgmt>acct-plcy>server

Description This command configures the number of times the router attempts to contact the RADIUS server for authentication, if not successful the first time.

The **no** form of the command reverts to the default value.

Default 3

Parameters *count* — The retry count.

Values 1 to 10

radius-server-policy

Syntax **radius-server-policy** *radius-server-policy-name*
no radius-server-policy

Context config>subscr-mgmt>auth-plcy
config>subscr-mgmt>acct-plcy

Description This command references an existing radius-server-policy (available under the config>aaa context) for use in subscriber management authentication and accounting.

When configured in an authentication-policy, following CLI commands are ignored in the policy to avoid conflicts:

- all commands in the radius-authentication-server context
- accept-authorization-change
- coa-script-policy
- accept-script-policy
- request-script-policy

When configured in a radius-accounting-policy, following CLI commands are ignored in the policy to avoid conflicts:

- all commands in the radius-accounting-server context
- acct-request-script-policy

The **no** form of the command removes the radius-server-policy reference from the configuration

Default	no radius-server-policy
Parameters	<i>radius-server-policy-name</i> — Specifies the RADIUS server policy.

server

Syntax	server <i>server-index</i> address <i>ip-address</i> secret <i>key</i> [hash hash2] [port <i>port-num</i>] [coa-only] [pending-requests-limit <i>limit</i>] no server <i>index</i>
Context	config>subscr-mgmt>auth-policy>radius-auth-server config>subscr-mgmt>acct-plcy>server
Description	<p>This command adds a RADIUS server and configures the RADIUS server IP address, index, and key values.</p> <p>Up to sixteen RADIUS servers can be configured at any one time in a RADIUS authentication policy. Only five can be used for authentication, all other servers should be configured as coa-only servers. In a RADIUS accounting policy, up to five RADIUS servers can be configured. RADIUS servers are accessed in order from lowest to highest index for authentication or accounting requests until a response from a server is received. A higher indexed server is only queried if no response is received from a lower indexed server (which implies that the server is not available). If a response from a server is received, no other RADIUS servers are queried.</p> <p>The no form of the command removes the server from the configuration.</p>
Default	No RADIUS servers are configured.
Parameters	<p><i>server-index</i> — The index for the RADIUS server. The index determines the sequence in which the servers are queried for authentication requests. Servers are queried in order from lowest to highest index.</p> <p>Values 1 to 16 (a maximum of 5 authentication servers)</p> <p>address <i>ip-address</i> — The IP address of the RADIUS server. Two RADIUS servers cannot have the same IP address. An error message is generated if the server address is a duplicate.</p>

secret key — The secret key to access the RADIUS server. This secret key must match the password on the RADIUS server.

Values secret-key: Up to 20 characters in length.
hash-key: Up to 33 characters in length.
hash2-ke: Up to 55 characters in length.

hash — Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified

hash2 — Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

port *port-num* — Specifies the UDP port number on which to contact the RADIUS server for authentication.

Values 1 to 65535

coa-only — Specifies Change-of-Authorization Messages only. Servers that are marked with the coa-only flag will not be used for authentication, but they will be able to accept RADIUS CoA messages, independent of the accept-authorization-change setting in the authentication policy.

For authentication purposes, the maximum number of servers is 5. All other servers may only be used as coa-only servers.

pending-requests-limit *limit* — Specifies the maximum number of outstanding RADIUS authentication requests for this authentication server.

Values 1 to 4096

Default The default value when not configured is 4096.

hold-down-time

Syntax	[no] hold-down-time [sec seconds] [min minutes] [hrs hours] [days days]
Context	config>aaa>radius-srv-plcy>servers
Description	This command determines the interval during which no new communication attempts will be made to a RADIUS server that is marked down to prevent immediately overloading the server when it is starting up. The only exception is when all servers in the authentication policy are marked down; in that case, they will all be used again to prevent failures on new client connections.
Default	30s

Parameters	<p><i>days</i> — Specifies the hold time in days before re-using a RADIUS server that was down.</p> <p>Values 1 to 1</p> <p><i>hours</i> — Specifies the hold time in hours before re-using a RADIUS server that was down.</p> <p>Values 1 to 23</p> <p><i>minutes</i> — Specifies the hold time in minutes before re-using a RADIUS server that was down.</p> <p>Values 1 to 59</p> <p><i>seconds</i> — Specifies the hold time in seconds before re-using a RADIUS server that was down.</p> <p>Values 1 to 59</p>
-------------------	--

down-timeout

Syntax	[no] down-timeout
Context	config>aaa>radius-srv-plcy>servers>health-check
Description	<p>This command determines the interval to wait for a RADIUS reply message from the RADIUS server before a RADIUS server is declared “out-of-service”. By default, the value of the “down-timeout” is the number of retries multiplied by the timeout interval. Each host will use the configured timeout and retry value under the AAA RADIUS server policy.</p> <p>timeout refers to the waiting period before the next retry attempt</p> <p>retry refers the number of times the host will attempt to contact the RADIUS server.</p> <p>If a RADIUS server is declared “out-of-service”, the host pending retry attempts will move on to the next RADIUS server.</p>
Default	By default the down-timeout interval is timeout multiply by retry attempts.
Parameters	<p><i>minutes</i> — Specifies the timer to wait in minutes before declaring the RADIUS server that is down.</p> <p>Values 0 to 59</p> <p><i>seconds</i> — Specifies the timer to wait in seconds before declaring the RADIUS server that is down.</p> <p>Values 1 to 5</p>

source-address

Syntax	source-address <i>ip-address</i>
---------------	---

no source-address

Context	config>subscr-mgmt>auth-plcy-srvr config>subscr-mgmt>acct-plcy>server
Description	This command configures the source address of the RADIUS packet. The system IP address must be configured in order for the RADIUS client to work. See Configuring a System Interface in the Router Configuration Guide.

Note: The system IP address must only be configured if the source-address is not specified. When the **no source-address** command is executed, the source address is determined at the moment the request is sent. This address is also used in the nas-ip-address attribute: over there it is set to the system IP address if **no source-address** was given.

The **no** form of the command reverts to the default value.

Default	System IP address
Parameters	<i>ip-address</i> — The IP prefix for the IP match criterion in dotted decimal notation. Values 0.0.0.0 - 255.255.255.255

timeout

Syntax	timeout <i>seconds</i> no timeout
Context	config>subscr-mgmt>auth-plcy-srvr config>subscr-mgmt>acct-plcy>server
Description	This command configures the number of seconds the router waits for a response from a RADIUS server. The no form of the command reverts to the default value.
Default	3 seconds
Parameters	<i>seconds</i> — The number of seconds the router waits for a response from a RADIUS server, expressed as a decimal integer. Values 1 to 90

session-accounting

Syntax	session-accounting [<i>interim-update</i>] [<i>host-update</i>] no session-accounting
---------------	--

Context	config>subscr-mgmt>acct-plcy
Description	<p>This command enables per session accounting mode. In per session accounting mode, the acct-session-id is generated per session. This acct-session-id is uniformly included in all accounting messages (START/INTERIM-UPDTATE/STOP) and it can be included in RADIUS Access-Request message.</p> <p>This accounting mode of operation can be used only in PPPoE environment with dual-stack host in which case both hosts (IPv4 and IPv6) are considered part of the same session. In addition to regular interim-updates, <i>triggered</i> interim-updates are sent by a host joining or leaving the session.</p> <p>When an IPv4/v6 address is allocated, or released from a dual-stack host, a triggered interim-update message is immediately sent. This triggered interim-update message reflects the change in the IP address. The triggered interim-update has no effect on the interval at which the regular interim updates are scheduled.</p> <p>Accounting counters are based on the queue counters and as such are aggregated for all host sharing the queues within an sla-profile instance (non HSMDA) or a subscriber (HSMDA).</p> <p>CoA and LI is supported based on the acct-session-id of the session.</p>
Default	no session-accounting
Parameters	<p>interim-update — Without this keyword only START and STOP accounting messages are generated when the session is established/terminated. This is equivalent to a time-based accounting where only the duration of the session is required.</p> <p>host-update — This keyword indicates that host updates messages are sent. INTERIM-UPDATE messages can be generated (volume based accounting) by selecting this keyword.</p>

session-id-format

Syntax	session-id-format {description number} no session-id-format
Context	config>subscr-mgmt>acct-plcy
Description	This command specifies the format for the acct-session-id attribute used in RADIUS accounting requests.
Parameters	<p>description — Specifies to use a string containing following information <subscriber>@<sap-id>@<SLA-profile>_<creation-time>.</p> <p>number — Specifies to use a unique number generated by the OS to identify a given session.</p>

update-interval

Syntax	update-interval <i>minutes</i> no update-interval
Context	config>subscr-mgmt>acct-plcy
Description	<p>This command specifies the interval at which accounting data of subscriber hosts will be updated in a RADIUS Accounting Interim-Update message. Requires interim-update to be enabled when specifying the accounting mode in the radius accounting policy.</p> <p>A RADIUS specified interim interval (attribute [85] Acct-Interim-Interval) overrides the CLI configured value.</p>
Parameters	<i>minutes</i> — Specifies the interval, in minutes, at which accounting data of subscriber hosts will be updated.
	Values 5 to 259200

update-interval-jitter

Syntax	update-interval-jitter absolute <i>seconds</i> no update-interval-jitter
Context	config>subscr-mgmt>acct-plcy
Description	<p>This command specifies the absolute maximum random delay introduced on the update interval between two accounting interim update messages. The effective maximum random delay value is the minimum of the configured absolute jitter value and 10% of the configured update-interval.</p> <p>A value of zero will send the accounting interim update message without introducing an additional random delay.</p> <p>The no form of the command sets the default to 10% of the configured update-interval.</p>
Default	<p>no update-interval-jitter</p> <p>This corresponds with 10% of the configured update-interval</p>
Parameters	absolute <i>seconds</i> — specifies the absolute maximum jitter value in seconds.
	Values 0 to 36000

re-authentication

Syntax	[no] re-authentication
Context	config>subscr-mgmt>auth-policy

Description	This command enables authentication process at every DHCP address lease renewal s only if RADIUS did not reply any special attributes (for example, authentication only, no authorization). The no form of the command reverts to the default value.
Default	disabled

request-script-policy

Syntax	request-script-policy <i>policy-name</i> no request-script-policy
Context	config>subscr-mgmt>auth-policy
Description	This command specifies the RADIUS script policy used to change the RADIUS attributes of the outgoing Access-Request messages.
Default	none
Parameters	<i>policy-name</i> — Configures a Python script policy to modify Access-Request messages.

send-acct-stop-on-fail

Syntax	send-acct-stop-on-fail {[on-request-failure] [on-reject] [on-accept-failure]} no send-acct-stop-on-fail
Context	config>subscr-mgmt>auth-policy
Description	<p>This command activates the reporting of RADIUS authentication failures of a PPPoE session to a RADIUS accounting server with an Accounting Stop message.</p> <p>Three failure categories can be enabled separately:</p> <ul style="list-style-type: none">• on-request-failure: All failure conditions between the sending of an Access-Request and the reception of an Access-Accept or Access-Reject.• on-reject: When an Access-Reject is received• on-accept-failure: All failure conditions that appear after receiving an Access-Accept and before successful instantiation of the host or session. <p>The RADIUS accounting policy to be used for sending the Accounting Stop messages must be obtained prior to RADIUS authentication via local user database pre-authentication.</p>
Default	no send-acct-stop-on-fail

user-name-format

Syntax	user-name-format <i>format</i> [mac-format <i>mac-format</i>] user-name-format <i>format</i> append [<i>domain-name</i>] [mac-format <i>mac-format</i>] user-name-format <i>format</i> append <i>domain-name</i> user-name-format <i>format</i> default-domain <i>domain-name</i> [mac-format <i>mac-format</i>] user-name-format <i>format</i> replace <i>domain-name</i> [mac-format <i>mac-format</i>] user-name-format <i>format</i> strip [mac-format <i>mac-format</i>] no user-name-format
Context	config>subscr-mgmt>auth-policy
Description	<p>This command defines the format of the “user-name” field in the session authentication request sent to the RADIUS server.</p> <p>The no form of the command switches to the default format, mac.</p>
Default	By default, the MAC source address of the DHCP DISCOVER message is used in the user-name field.
Parameters	<p><i>format</i> — Specifies the user name format in RADIUS message.</p> <p>Values <i>ascii-converted-circuit-id</i>, <i>ascii-converted-tuple</i>, <i>circuit-id</i>, <i>dhcp-client-vendor-opts</i>, <i>mac</i>, <i>mac-giaddr</i>, <i>tuple</i></p> <p>ascii-converted-circuit-id — Identical to <i>circuit-id</i>, but the user name will be sent to the RADIUS server as a string of hex digits, for use if there is binary data in the <i>circuit-id</i>.</p> <p>ascii-converted-tuple — Identical to <i>tuple</i>, but the <i>circuit-id</i> part of the user name will be sent to the RADIUS server as a string of hex digits, for use if there is binary data in the <i>circuit-id</i>.</p> <p>circuit-id — If the system serves as a DHCP relay server which inserts option 82 info, the user name will be formatted as defined under DHCP information option. If the system is not a DHCP relay server, the <i>circuit-id</i> will be taken from option 82 in the received DHCP message. If no <i>circuit-id</i> can be found, the DHCP-msg is rejected.</p> <p>dhcp-client-vendor-opts — Creates a concatenation of the DHCP client-identifier option (option 61), a “@” delimiter and the DHCP vendor-class identifier option {option 60}. The two option strings are parsed for any characters which are non-printing are considered invalid and must be converted to underscore “_” characters. In addition, any space character (hex 20) and @ character (hex 40) are also converted to underscore. The character set considered valid is ASCII hex 21 through hex 3F, and hex 41 through hex 7E. Any character outside this set will be converted into an underscore (hex 5F) character.</p> <p>mac — The MAC source address of the DHCP DISCOVER message is used in the user-name field. The format of the MAC address string used as the user name in the RADIUS authentication requests uses lowercase hex digits, and “:” as the inter-digit separator, for example, 00:11:22:aa:bb:cc is valid but 00-11-22-AA-BB-CC will return an error. The RADIUS server must be configured accordingly, otherwise the authentication request will fail.</p>

mac-giaddr — Specifies that MAC giaddr indicates the format used to identify the user towards the RADIUS server.

tuple — The concatenation of MAC source address and circuit-ID are used in the user-name field.

mac-format — Specifies how a MAC address is represented when contacting a RADIUS server. This is only used while the value of is equal to the DHCP client vendor options and if the MAC address is used by default of the DHCP client vendor options.

Examples: ab: 00:0c:f1:99:85:b8 7xxx style
 XY- 00-0C-F1-99-85-B8 IEEE canonical style
 mmmm. 0002.03aa.abff Cisco style

append — Specifies the data type which is an enumerated integer that indicates what needs to be appended to the user-name sent to the RADIUS server.

Values 1 — nothing
 2 — domain name

domain — In some instances it is desired to add a domain only to usernames which have omitted the domain (@domain). In these instances a default-domain can be appended to usernames which lack a @domain

append — Adds a “@” delimiter and the specified string after the PAP/CHAP username. No allowance is made for the presence of an existing domain or @ delimited.

replace — Replaces the character-string after the “@” delimiter with the string specified.

strip — Removes all characters after and including the “@” delimiter.

Example:

```
Command: append
String:       domainA-1.com
PAP/CHAP User:     someuser
Resulting User:    someuser@domainA-1.com
```

```
Command: append
String:       domainA-1.com
PAP/CHAP User:    someuser@existing-domain.net
Resulting User:    someuser@existing-domain.net@domainA-1.com
```

```
Command: strip
String:
PAP/CHAP User:     someuser@existing-domain.net
Resulting User:    someuser
```

```
Command: replace
String:       domainA-1.com
PAP/CHAP User:    someuser@existing-domain.net
Resulting User:    someuser@domainA-1.com
```

```
Command: default-domain
String:       domainA-1.com
PAP/CHAP User:    someuser@existing-domain.net
Resulting User:    someuser@existing-domain.net
```

```
Command: default-domain
String: domainA-1.com
PAP/CHAP User:      someuser
Resulting User:      someuser@domainA-1.com
```

user-name-format

Syntax	user-name-format <i>format</i> no user-name-format
Context	config>subscr-mgmt>diam-appl-plcy>nasreq
Description	This command defines the format of the User-Name AVP value in Diameter NASREQ AA-Requests for IPoE hosts.
Parameters	<i>format</i> — Specifies the format of the User-Name AVP value. Values mac — The MAC source address of the DHCP DISCOVER message is used in the user-name field. The format of the MAC address string is defined with the mac-format CLI command. circuit-id — If the system serves as a DHCP relay server which inserts option 82 info, the user name will be formatted as defined under DHCP information option. If the system is not a DHCP relay server, the circuit-id will be taken from option 82 in the received DHCP message. If no circuit-id can be found, the DHCP-msg is rejected. tuple — A concatenation of MAC source address and circuit-ID. ascii-converted-circuit-id — Identical to circuit-id, but the user name is a string of hex digits, for use if there is binary data in the circuit-id. ascii-converted-tuple — Identical to tuple, but the circuit-id part of the user name is a string of hex digits, for use if there is binary data in the circuit-id. dhcp-client-vendor-opts — A concatenation of the DHCP client-identifier option (option 61), “@” as delimiter and the DHCP vendor-class identifier option (option 60). Spaces (hex 20), @ character (hex 40) and non printable characters (all character outside range hex 21 through hex 7E) are converted to underscore “_” (hex 5F). mac-giaddr — A concatenation of MAC source address and DHCP gi address. nas-port-id — The value of the nas-port-id with format defined in the include-avp section.

user-name-operation

Syntax	user-name-operation operation [domain <i>domain-name</i>] no user-name-operation
Context	config>subscr-mgmt>diam-appl-plcy>nasreq
Description	<p>This command enables domain name manipulation of the user name, such as append, strip, replace or add as default.</p> <p>For IPoE, this command only applies when user-name-format is configured to dhcp-client-vendor-opts.</p>
Default	no user-name-operation
Parameters	<p>operation — Specifies the user name manipulations with respect to domain name values.</p> <p>Values</p> <ul style="list-style-type: none"> append-domain – appends an “@” delimiter with the specified domain-name at the end of the user-name, independent if a domain name was already present. strip-domain – removes all characters after and including the “@” delimiter. default-domain – adds an “@” delimiter and the specified domain name to user-names that have no domain name present. replace-domain – replaces the characters after the “@” delimiter with the specified domain-name. <p><i>domain domain-name</i> — Specifies the domain name string to be used in the specified operation. Maximum 128 characters.</p>

RADIUS Accounting Policy Custom Record Commands

custom-record

Syntax	[no] custom-record
Context	config>subscr-mgmt>acct-plcy
Description	<p>This command enables the context to configure the layout and setting for a custom accounting record associated with this accounting policy.</p> <p>The no form of the command reverts the configured values to the defaults.</p>

delay-start-time

Syntax	[no] delay-start-time
Context	config>subscr-mgmt>acct-plcy
Description	It is recommended to only use this command when session-accounting is used. By default, a dual stack subscriber generates a RADIUS accounting interim message for each new host update (IPv4, IPv6 WAN, and IPv6 PD). This command delays the trigger of a RADIUS accounting start message and allows all hosts to connect first. When the delay timer expires, a single RADIUS accounting start message containing all the host currently connected to the BNG is sent to the server. Subsequent host connections will trigger interim-updates if host-update is enabled on session-accounting. For all other accounting modes, this command will delay the trigger of an accounting start when a host connects.
Default	no delay-start-time

override-counter

Syntax	[no] override-counter <i>override-counter-id</i>
Context	config>log>acct-policy>cr
Description	This command enables the context to configure Application Assurance override counter parameters. The no form of the command removes the ID from the configuration.
Parameters	<i>override-counter-id</i> — Specifies the override counter ID. Values 1 to 8

e-counters

Syntax	e-counters [all] no e-counters
Context	config>log>acct-policy>cr>override-cntr config>log>acct-policy>cr>queue config>log>acct-policy>cr>ref-override-cntr config>log>acct-policy>cr>ref-queue
Description	This command configures egress counter parameters for this custom record. The no form of the command
Parameters	all — Includes all counters.

i-counters

Syntax	i-counters [all] no i-counters
Context	config>log>acct-policy>cr>override-cntr config>log>acct-policy>cr>ref-override-cntr config>log>acct-policy>cr>ref-queue
Description	This command configures ingress counter parameters for this custom record. The no form of the command
Parameters	all — Includes all counters.

queue

Syntax	[no] queue <i>queue-id</i>
Context	config>log>acct-policy>cr
Description	This command specifies the queue-id for which counters will be collected in this custom record. The counters that will be collected are defined in egress and ingress counters. The no form of the command reverts to the default value
Parameters	<i>queue-id</i> — Specifies the queue-id for which counters will be collected in this custom record.

in-profile-octets-discarded-count

Syntax	[no] in-profile-octets-discarded-count
Context	config>log>acct-policy>cr>oc>e-count config>log>acct-policy>cr>roc>e-count config>log>acct-policy>cr>queue>e-count config>log>acct-policy>cr>ref-queue>e-count
Description	This command includes the in-profile octets discarded count. For queues with stat-mode v4-v6 , this command includes the IPv4 octets discarded count instead. The no form of the command excludes the in-profile octets discarded count.

in-profile-octets-forwarded-count

Syntax	[no] in-profile-octets-forwarded-count
Context	config>log>acct-policy>cr>oc>e-count config>log>acct-policy>cr>roc>e-count config>log>acct-policy>cr>queue>e-count config>log>acct-policy>cr>ref-queue>e-count
Description	This command includes the in-profile octets forwarded count. For queues with stat-mode v4-v6 , this command includes the IPv4 octets forwarded count instead. The no form of the command excludes the in-profile octets forwarded count.

in-profile-packets-discarded-count

Syntax	[no] in-profile-packets-discarded-count
Context	config>log>acct-policy>cr>oc>e-count config>log>acct-policy>cr>roc>e-count config>log>acct-policy>cr>queue>e-count config>log>acct-policy>cr>ref-queue>e-count
Description	This command includes the in-profile packets discarded count. For queues with stat-mode v4-v6 , this command includes the IPv4 packets discarded count instead. The no form of the command excludes the in-profile packets discarded count.

in-profile-packets-forwarded-count

Syntax	[no] in-profile-packets-forwarded-count
Context	config>log>acct-policy>cr>oc>e-count config>log>acct-policy>cr>roc>e-count config>log>acct-policy>cr>queue>e-count config>log>acct-policy>cr>ref-queue>e-count
Description	This command includes the in-profile packets forwarded count. For queues with stat-mode v4-v6 , this command includes the IPv4 packets forwarded count instead. The no form of the command excludes the in-profile packets forwarded count.

out-profile-octets-discarded-count

Syntax	[no] out-profile-octets-discarded-count
Context	config>log>acct-policy>cr>oc>e-count config>log>acct-policy>cr>roc>e-count config>log>acct-policy>cr>queue>e-count config>log>acct-policy>cr>ref-queue>e-count
Description	<p>This command includes the out of profile packets discarded count.</p> <p>For queues with stat-mode v4-v6, this command includes the IPv6 octets discarded count instead.</p> <p>The no form of the command excludes the out of profile packets discarded count.</p>

out-profile-octets-forwarded-count

Syntax	[no] out-profile-octets-forwarded-count
Context	config>log>acct-policy>cr>oc>e-count config>log>acct-policy>cr>roc>e-count config>log>acct-policy>cr>queue>e-count config>log>acct-policy>cr>ref-queue>e-count
Description	<p>This command includes the out of profile octets forwarded count.</p> <p>For queues with stat-mode v4-v6, this command includes the IPv6 octets forwarded count instead.</p> <p>The no form of the command excludes the out of profile octets forwarded count.</p>

out-profile-packets-discarded-count

Syntax	[no] out-profile-packets-discarded-count
Context	config>log>acct-policy>cr>oc>e-count config>log>acct-policy>cr>roc>e-count config>log>acct-policy>cr>queue>e-count config>log>acct-policy>cr>ref-queue>e-count
Description	<p>This command includes the out of profile packets discarded count.</p> <p>For queues with stat-mode v4-v6, this command includes the IPv6 packets discarded count instead.</p> <p>The no form of the command excludes the out of profile packets discarded count.</p>

out-profile-packets-forwarded-count

Syntax	[no] out-profile-packets-forwarded-count
Context	<pre>config>log>acct-policy>cr>oc>e-count config>log>acct-policy>cr>roc>e-count config>log>acct-policy>cr>queue>e-count config>log>acct-policy>cr>ref-queue>e-count</pre>
Description	<p>This command includes the out of profile packets forwarded count.</p> <p>For queues with stat-mode v4-v6, this command includes the IPv6 packets forwarded count instead.</p> <p>The no form of the command excludes the out of profile packets forwarded count.</p>

all-octets-offered-count

Syntax	[no] all-octets-offered-count
Context	<pre>config>log>acct-policy>cr>oc>i-count config>log>acct-policy>cr>roc>i-count config>log>acct-policy>cr>queue>i-count config>log>acct-policy>cr>ref-queue>i-count</pre>
Description	<p>This command includes all octets offered in the count.</p> <p>The no form of the command excludes the octets offered in the count.</p>
Default	no all-octets-offered-count

all-packets-offered-count

Syntax	[no] all-packets-offered-count
Context	<pre>config>log>acct-policy>cr>oc>i-count config>log>acct-policy>cr>roc>i-count config>log>acct-policy>cr>queue>i-count config>log>acct-policy>cr>ref-queue>i-count</pre>
Description	<p>This command includes all packets offered in the count.</p> <p>The no form of the command excludes the packets offered in the count.</p>
Default	no all-packets-offered-count

high-octets-discarded-count

Syntax	[no] high-octets-discarded-count
Context	config>log>acct-policy>cr>oc>i-count config>log>acct-policy>cr>roc>i-count config>log>acct-policy>cr>queue>i-count config>log>acct-policy>cr>ref-queue>i-count
Description	<p>This command includes the high octets discarded count.</p> <p>For queues with stat-mode v4-v6, this command includes the IPv4 octets discarded count instead.</p> <p>The no form of the command excludes the high octets discarded count.</p>
Default	no high-octets-discarded-count

high-octets-offered-count

Syntax	[no] high-octets-offered-count
Context	config>log>acct-policy>cr>oc>i-count config>log>acct-policy>cr>roc>i-count config>log>acct-policy>cr>queue>i-count config>log>acct-policy>cr>ref-queue>i-count
Description	<p>This command includes the high octets offered count.</p> <p>The no form of the command excludes the high octets offered count.</p>

high-packets-discarded-count

Syntax	[no] high-packets-discarded-count
Context	config>log>acct-policy>cr>oc>i-count config>log>acct-policy>cr>roc>i-count config>log>acct-policy>cr>queue>i-count config>log>acct-policy>cr>ref-queue>i-count
Description	<p>This command includes the high packets discarded count.</p> <p>For queues with stat-mode v4-v6, this command includes the IPv4 packets discarded count instead.</p> <p>The no form of the command excludes the high packets discarded count.</p>
Default	no high-packets-discarded-count

high-packets-offered-count

Syntax	[no] high-packets-offered-count
Context	config>log>acct-policy>cr>oc>i-count config>log>acct-policy>cr>roc>i-count config>log>acct-policy>cr>queue>i-count config>log>acct-policy>cr>ref-queue>i-count
Description	This command includes the high packets offered count. The no form of the command excludes the high packets offered count.
Default	no high-packets-offered -count

in-profile-octets-forwarded-count

Syntax	[no] in-profile-octets-forwarded-count
Context	config>log>acct-policy>cr>oc>i-count config>log>acct-policy>cr>roc>i-count config>log>acct-policy>cr>queue>i-count config>log>acct-policy>cr>ref-queue>i-count
Description	This command includes the in profile octets forwarded count. For queues with stat-mode v4-v6 , this command includes the IPv4 octets forwarded count instead. The no form of the command excludes the in profile octets forwarded count.
Default	no in-profile-octets-forwarded-count

in-profile-packets-forwarded-count

Syntax	[no] in-profile-packets-forwarded-count
Context	config>log>acct-policy>cr>oc>i-count config>log>acct-policy>cr>roc>i-count config>log>acct-policy>cr>queue>i-count config>log>acct-policy>cr>ref-queue>i-count
Description	This command includes the in profile packets forwarded count. For queues with stat-mode v4-v6 , this command includes IPv4 packets forwarded count instead. The no form of the command excludes the in profile packets forwarded count.

Default no in-profile-packets-forwarded-count

low-octets-discarded-count

Syntax [no] low-octets-discarded-count

Context config>log>acct-policy>cr>oc>i-count
config>log>acct-policy>cr>roc>i-count
config>log>acct-policy>cr>queue>i-count
config>log>acct-policy>cr>ref-queue>i-count

Description This command includes the low octets discarded count.

For queues with **stat-mode v4-v6**, this command includes the IPv6 octets discarded count instead.

The **no** form of the command excludes the low octets discarded count.

Default no low-octets-discarded-count

low-packets-discarded-count

Syntax [no] low-packets-discarded-count

Context config>log>acct-policy>cr>oc>i-count
config>log>acct-policy>cr>roc>i-count
config>log>acct-policy>cr>queue>i-count
config>log>acct-policy>cr>ref-queue>i-count

Description This command includes the low packets discarded count.

For queues with **stat-mode v4-v6**, this command includes the IPv6 packets discarded count instead.

The **no** form of the command excludes the low packets discarded count.

Default no low-packets-discarded-count

low-octets-offered-count

Syntax [no] low-octets-offered-count

Context config>log>acct-policy>cr>oc>i-count
config>log>acct-policy>cr>roc>i-count
config>log>acct-policy>cr>queue>i-count
config>log>acct-policy>cr>ref-queue>i-count

Description This command includes the low octets discarded count.
The **no** form of the command excludes the low octets discarded count.

low-packets-offered-count

Syntax [no] low-packets-offered-count

Context config>log>acct-policy>cr>oc>i-count
config>log>acct-policy>cr>roc>i-count
config>log>acct-policy>cr>queue>i-count
config>log>acct-policy>cr>ref-queue>i-count

Description This command includes the low packets discarded count.
The **no** form of the command excludes the low packets discarded count.

out-profile-octets-forwarded-count

Syntax [no] out-profile-octets-forwarded-count

Context config>log>acct-policy>cr>oc>i-count
config>log>acct-policy>cr>roc>i-count
config>log>acct-policy>cr>queue>i-count
config>log>acct-policy>cr>ref-queue>i-count

Description This command includes the out of profile octets forwarded count.
For queues with **stat-mode v4-v6**, this command includes the IPv6 octets forwarded count instead.
The **no** form of the command excludes the out of profile octets forwarded count.

Default no out-profile-octets-forwarded-count

out-profile-packets-forwarded-count

Syntax [no] out-profile-packets-forwarded-count

Context config>log>acct-policy>cr>oc>i-count
config>log>acct-policy>cr>roc>i-count
config>log>acct-policy>cr>queue>i-count
config>log>acct-policy>cr>ref-queue>i-count

Description This command includes the out of profile packets forwarded count.

For queues with **stat-mode v4-v6**, this command includes the IPv6 packets forwarded count instead.

The **no** form of the command excludes the out of profile packets forwarded count.

Default no out-profile-packets-forwarded-count

uncoloured-octets-offered-count

Syntax [no] uncoloured-packets-offered-count

Context config>log>acct-policy>cr>queue>i-count
config>log>acct-policy>cr>ref-queue>i-count

Description This command includes the uncoloured octets offered in the count.

The **no** form of the command excludes the uncoloured octets offered in the count.

uncoloured-packets-offered-count

Syntax [no] uncoloured-packets-offered-count

Context config>log>acct-policy>cr>queue>i-count
config>log>acct-policy>cr>ref-queue>i-count

Description This command includes the uncoloured packets offered count.

The **no** form of the command excludes the uncoloured packets offered count.

ref-aa-specific-counter

Syntax [no] ref-aa-specific-counter any

Context config>log>acct-policy>cr

Description This command

The **no** form of the command

ref-override-counter

Syntax ref-override-counter *ref-override-counter-id*
ref-override-counter all
no ref-override-counter

Context config>log>acct-policy>cr

Description This command configures a reference override counter.
The **no** form of the command reverts to the default value.

Default no ref-override-counter

ref-queue

Syntax **ref-queue** *queue-id*
ref-queue all
no ref-queue

Context config>log>acct-policy>cr

Description This command configures a reference queue.
The **no** form of the command reverts to the default value.

Default no ref-queue

significant-change

Syntax **significant-change** *delta*
no significant-change

Context config>log>acct-policy>cr

Description This command configures the significant change required to generate the record.

Parameters *delta* — Specifies the delta change (significant change) that is required for the custom record to be written to the xml file.

Values 0 to 4294967295

9.24.2.1.4 RADIUS Route Download Commands

route-downloader

Syntax **route-downloader** *name* [create]
no route-downloader *name*

Context config>aaa

Description	<p>This command creates or enters the configuration of a route-downloader instance. The route-downloader is a process that uses radius access-request messages to a particular server. The server returns either an access-accept or access-deny message. Access-accept messages also contain the prefixes (in the form of static blackhole routes in various formats)</p> <p>The no form of the command removes the name from the configuration. The object must be shutdown prior to deletion. No prefix is needed to delete an existing route-download object.</p>
Default	None. Only a single route-downloader object can be created.
Parameters	<p><i>name</i> — Specifies the name of this RADIUS route downloader.</p> <p>create — This keyword is mandatory while creating an instance of the route-download object.</p>

base-user-name

Syntax	base-user-name <i>user-name</i> no base-user-name
Context	config>aaa>route-downloader
Description	<p>This command sets the prefix for the user name that shall be used as access requests. The actual name used will be a concatenation of this string, the "-" (dash) character and a monotonically increasing integer.</p> <p>The no form of the command removes the user-name from the configuration.</p>
Default	The system's configured name (system-name).
Parameters	<i>user-name</i> — Specifies the prefix of the username that is used in the RADIUS access requests. The username used in the RADIUS access requests is a concatenation of this string, the dash character and an increasing integer.

default-metric

Syntax	default-metric <i>metric</i> no default-metric
Context	config>aaa>route-downloader
Description	<p>This command sets the default metric that routes imported by the RTM will acquire.</p> <p>The no form of the command removes the metric</p>
Default	2
Parameters	<i>metric</i> — Specifies the default metric of the routes imported.
Values	0 to 254

default-tag

Syntax	default-tag <i>tag</i> no default-tag
Context	config>aaa>route-downloader
Description	This command sets the default tag that routes processed by the AAA route downloader will take.

Note: Any route received with a specific tag retains the specific tag. The tag value is passed to the Route Table Manager and is available as match condition on the export statement of other routing protocols.

The **no** form of the command reverts to the default.

Default	0
Parameters	<i>tag</i> — Specifies the default tag of the routes imported.
Values	0 to 4294967295

download-interval

Syntax	download-interval <i>minutes</i> no download-interval
Context	config>aaa>route-downloader
Description	This command sets the time interval, in minutes, that the system waits for between two consecutive runs of the route-download process. The time is counted from the start-time of the run, thus, if an route-download process is still ongoing by the time the timer expires, the process will restart from count=1. The no form of the command reverts to the default value.
Default	720
Parameters	<i>minutes</i> — Specifies the time interval, in minutes, between the start of the last route downloader run and the start of the next route downloader run.
Values	1 to 1440

max-routes

Syntax	max-routes <i>routes</i> no max-routes
---------------	---

Context	config>aaa>route-downloader
Description	<p>This command determines the upper limits for total number of routes to be received and accepted by the system. The total number is inclusive of both IPv4 and IPv6 addresses and no differentiation is needed across protocols. It includes the sum of both. Once this limit is reached, the download process stops sending new access-requests until the next download-interval expires.</p> <p>The no form of the command reverts to the default value.</p>
Default	200000
Parameters	<i>routes</i> — Specifies the maximum number of the routes imported.
Values	1 to 200000

password

Syntax	password <i>password</i> [hash hash2] no password
Context	config>aaa>route-downloader
Description	<p>This command specifies the password that is used in the RADIUS access requests. It shall be specified as a string of up to 32 characters in length.</p> <p>The no form of the command resets the password to its default of ALU and will be stored using hash/hash2 encryption.</p>
Default	ALU
Parameters	<p><i>password</i> — Specifies a password string up to 32 characters in length.</p> <p>hash — Specifies the key is entered in an encrypted form. If the hash or hash2 parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the hash or hash2 parameter specified</p> <p>hash2 — Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the hash2 encrypted variable cannot be copied and pasted. If the hash or hash2 parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the hash or hash2 parameter specified.</p>

radius-server-policy

Syntax	radius-server-policy <i>policy-name</i> no radius-server-policy
Context	config>aaa>route-downloader

Description	This command references an existing radius-server-policy (available under the config>aaa context). The server (or servers) referenced by the policy will be used as the targets for the access-request message. The no form of the command removes the policy name from the route-downloader configuration.
Default	none
Parameters	<i>policy-name</i> — Specifies the RADIUS server policy.

retry-interval

Syntax	retry-interval min <i>minimum</i> max <i>maximum</i> no retry-interval
Context	config>aaa>route-downloader
Description	This command sets the duration, in minutes, of the retry interval. The retry interval is the interval meant for the system to retry sending an Access Request message after the previous one was un-answered (not with an access reject but rather just a RADIUS failure or ICMP port unreachable). This timer is actually an exponential backoff timer that starts at min and is capped at max minutes. The no form of the command reverts to the default values.
Default	retry-interval min 10 max 20
Parameters	min <i>minimum</i> — Specifies the duration, in minutes, of the retry interval. This duration grows exponentially after each sequential failure. Values 1 to 1440 Default 10 max <i>maximum</i> — Specifies the maximum duration, in minutes, of the retry interval. Values 1 to 1440 Default 20

Category Map Commands

category-map

Syntax	category-map <i>category-map-name</i> [create] no category-map <i>category-map-name</i>
---------------	---

Context	config>subscr-mgmt config>subscr-mgmt>sla-prof
Description	This command specifies the category map name.
Default	none
Parameters	<i>category-map-name</i> — Specifies the category map name up to 32 characters in length. create — Mandatory keyword when creating a new category map.

credit-control-policy

Syntax	credit-control-policy <i>policy-name</i> [create] credit-control-policy diameter <i>policy-name</i> no credit-control-policy <i>policy-name</i>
Context	config>subscr-mgmt
Description	This command creates, configures or deletes a credit control policy.
Parameters	<i>policy-name</i> — Specifies the policy name, 32 characters max.

credit-control-server

Syntax	credit-control-server <i>radius</i> credit-control-server diameter <i>policy-name</i> no credit-control-server
Context	config>subscr-mgmt>credit-control-policy
Description	This command configures the credit control server to use. In case of RADIUS, the servers defined in the authentication policy are used. For Diameter, the peers defined in the specified Diameter policy are used.
Default	no credit-control-server
Parameters	<i>radius</i> — Use the RADIUS authentication servers defined in the RADIUS authentication policy in the group-interface to report credit usage and obtain new credit. diameter <i>policy-name</i> — Use the diameter peers specified in the diameter policy <i>policy-name</i> to report credit usage and obtain new credit.

default-category-map

Syntax	default-category-map <i>category-map-name</i> no default-category-map
---------------	--

Context	config>subscr-mgmt>credit-control-policy
Description	This command configures the default category map.
Parameters	<i>category-map-name</i> — Specifies the category map name, 32 chars max.

error-handling-action

Syntax	error-handling-action {continue block} no error-handling-action
Context	config>subscr-mgmt>credit-control-policy
Description	This command configures the error handling action for the policy.

out-of-credit-action

Syntax	out-of-credit-action action {continue disconnect-host block-category change-service-level} no out-of-credit-action
Context	config>subscr-mgmt>credit-control-policy
Description	This command configures the action to be performed when out of credit is reached.
Parameters	<i>action</i> — Specifies the action to be taken when out of credit is reached. Values continue disconnect-host block-category change-service-level

activity-threshold

Syntax	activity-threshold kilobits-per-second no activity-threshold
Context	config>subscr-mgmt>cat-map
Description	This command configures the threshold that is applied to determine whether or not there is activity. This is only valid for credit-type = time (not volume).
Default	0
Parameters	<i>kilobits-per-second</i> — Specifies the activity threshold value in kilobits per second. Values 1 to 100000000

category

Syntax	category <i>category-name</i> [create] no category <i>category-name</i>
Context	config>subscr-mgmt>cat-map
Description	<p>This command creates a category for use in RADIUS credit control, Diameter credit control (Gy), Diameter Gx Usage Monitoring, or Idle-Timeout.</p> <p>Up to sixteen categories can be configured per category map. The internal category for Gx session level Usage Monitoring is included in this limit. The instantiation of the internal category is controlled with the gx-session-level-usage CLI command.</p>
Default	n/a
Parameters	<i>category-name</i> — specifies the category name up to 32 characters in length create — specifies the mandatory keyword when creating a new category

category-map

Syntax	category-map <i>category-map-name</i> no category-map
Context	config>subscr-mgmt>sla-prof
Description	This command references the category-map to be used for the idle-timeout monitoring of subscriber hosts associated with this sla-profile. The category-map must already exist in the config>subscr-mgmt context.
Parameters	<i>category-map-name</i> — Specifies the name of the category map (up to 32 characters in length) where the activity-threshold and the category is defined for idle-timeout monitoring of subscriber hosts.

category

Syntax	category <i>category-name</i> [create] no category <i>category-name</i>
Context	config>subscr-mgmt>sla-prof>cat-map
Description	This command defines the category in the category-map to be used for the idle-timeout monitoring of subscriber hosts.
Parameters	<i>category-name</i> — Specifies the name (up to 32 characters in length) of the category where the queues and policers are defined for idle-timeout monitoring of subscriber hosts.

create — Mandatory keyword when creating a new category

idle-timeout

Syntax	idle-timeout <i>timeout</i> no idle-timeout
Context	config>subscr-mgmt>sla-prof>cat-map>category
Description	This command defines the idle-timeout value.
Default	no idle-timeout – corresponds with an infinite idle-timeout
Parameters	<i>timeout</i> — Specifies the idle-timeout in seconds. Values 60 to 15552000

idle-timeout-action

Syntax	idle-timeout-action { shcv-check terminate } no idle-timeout-action
Context	config>subscr-mgmt>sla-prof>cat-map>category
Description	This command defines the action to be executed when the idle-timeout is reached. The action is performed for all hosts associated with the sla-profile instance.
Default	terminate
Parameters	shcv-check — performs a subscriber host connectivity verification check (IPoE hosts only).

Note: Host connectivity verification must be enabled on the group-interface where the host is connected.

If the check is successful, the hosts are not disconnected and the idle-timeout timer is reset.

If the check fails, the hosts are deleted, similar as for “idle-timeout-action=terminate”.

terminate — Deletes the subscriber host from the system: for PPP hosts, a terminate request is send; for IPoE hosts a DHCP release is send to the DHCP server.

credit-type-override

Syntax	credit-type-override { volume time }
---------------	---

no credit-type-override

Context	config>subscr-mgmt>cat-map>category
Description	This command overrides the credit-type configured in the config>subscr-mgmt>cat-map context for the given category.
Default	no credit-type-override
Parameters	<p>volume — If different than the value specified in the credit-type command, the value overrides the credit-type.</p> <p>time — If different than the value specified in the credit-type command, the value overrides the credit-type.</p>

default-credit

Syntax	default-credit volume <i>credits bytes kilobytes megabytes gigabytes</i> default-credit time <i>seconds</i> no default-credit
Context	config>subscr-mgmt>cat-map>category
Description	<p>This command configures the default credit values for RADIUS credit control and Diameter Gy application credit control.</p> <p>For RADIUS credit control, this command configures the default time or volume credit for this category. The default credit is used during initial setup when no quota is received from the RADIUS server. Refer to the Minimum Credit Control Quota Values for more information.</p> <p>For Diameter Gy credit control, this command specifies the interim credit assigned to this category (rating group) when Extended Failure Handling (EFH) is enabled. This command is ignored when EFH is disabled.</p>
Default	no default-credit
Parameters	<p>volume <i>credits bytes kilobytes megabytes gigabytes</i> — specifies the default value for the volume credit and the unit in which the default value is expressed</p> <p>Values 1 to 4294967295 (minimum 1 byte)</p> <p>time <i>seconds</i> — specifies the default value for the time credit, in seconds</p> <p>Values 1 to 4294967295 (minimum 1 second)</p>

exhausted-credit-service-level

Syntax	[no] exhausted-credit-service-level
Context	config>subscr-mgmt>cat-map>category

Description	This command enables the context to configure the exhausted credit service level
Default	exhausted-credit-service-level

egress-ip-filter-entries

Syntax	[no] egress-ip-filter-entries
Context	config>subscr-mgmt>cat-map>category>exh-lvl
Description	This command configures the egress IP filter entries.

egress-ipv6-filter-entries

Syntax	[no] egress-ipv6-filter-entries
Context	config>subscr-mgmt>cat-map>category>exh-lvl
Description	This command configures the egress IPv6 filter entries.

ingress-ip-filter-entries

Syntax	[no] ingress-ip-filter-entries
Context	config>subscr-mgmt>cat-map>category>exh-lvl
Description	This command configures the ingress IP filter entries.

ingress-ipv6-filter-entries

Syntax	[no] ingress-ipv6-filter-entries
Context	config>subscr-mgmt>cat-map>category>exh-lvl
Description	This command configures the ingress IPv6 filter entries.

pir

Syntax	[no] pir
Context	config>subscr-mgmt>cat-map>category>exh-lvl
Description	This command configures the PIR.

entry

Syntax	entry <i>entry-id</i> [create]
Context	config>subscr-mgmt>cat-map>category>exh-lvl>ingr-ip config>subscr-mgmt>cat-map>category>exh-lvl>ingr-ipv6 config>subscr-mgmt>cat-map>category>exh-lvl>egr-ip config>subscr-mgmt>cat-map>category>exh-lvl>egr-ipv6
Description	This command configures the IP filter entry.
Parameters	<i>entry-id</i> — Specifies the entry ID. Values 1 to 65535

action

Syntax	action drop action forward action http-redirect <i>url</i> no action
Context	config>subscr-mgmt>cat-map>category>exh-lvl>ingr-ip>entry config>subscr-mgmt>cat-map>category>exh-lvl>ingr-ipv6>entry config>subscr-mgmt>cat-map>category>exh-lvl>egr-ip>entry config>subscr-mgmt>cat-map>category>exh-lvl>egr-ipv6>entry
Description	This command configures the action for the filter entry.
Parameters	drop — Specifies to drop the IP filter entry. forward — Specifies to forward the IP filter entry. http-redirect <i>url</i> — Specifies the HTTP web address that will be sent to the user's browser.

Note: Http-redirect is not supported on 7450 ESS-1 models.

The following displays information that can optionally be added as variables in the portal URL (http-redirect url):

- \$IP – Customer's IP address
- \$MAC – Customer's MAC address
- \$URL – Original requested URL
- \$SAP – Customer's SAP
- \$SUB – Customer's subscriber identification string

- \$CID – string that represents the circuit-id or interface-id of the subscriber host (hexadecimal format)
- \$RID – string that represents the remote-id of the subscriber host (hexadecimal format)

Values 255 characters maximum

match

Syntax	match [<i>next-header next-header</i>] no match
Context	config>subscr-mgmt>cat-map>category>exh-lvl>ingr-ip>entry config>subscr-mgmt>cat-map>category>exh-lvl>ingr-ipv6>entry config>subscr-mgmt>cat-map>category>exh-lvl>egr-ip>entry config>subscr-mgmt>cat-map>category>exh-lvl>egr-ipv6>entry
Description	This command configures the match criteria for this IP filter entry.
Parameters	<i>protocol-id</i> — Specifies the protocol number accepted in DHB.
Values	0 to 255

dscp

Syntax	dscp <i>dscp-name</i> no dscp
Context	config>subscr-mgmt>cat-map>category>exh-lvl>ingr-ip>entry>match config>subscr-mgmt>cat-map>category>exh-lvl>ingr-ipv6>entry>match config>subscr-mgmt>cat-map>category>exh-lvl>egr-ip>entry>match config>subscr-mgmt>cat-map>category>exh-lvl>egr-ipv6>entry>match
Description	This command configures DSCP match conditions.
Parameters	<i>dscp-name</i> — Specifies the DSCP name.
Values	32 chars max

dst-ip

Syntax	dst-ip { <i>ip-address/mask</i> <i>ip-address netmask</i> } no dst-ip
Context	config>subscr-mgmt>cat-map>category>exh-lvl>ingr-ip>entry>match config>subscr-mgmt>cat-map>category>exh-lvl>ingr-ipv6>entry>match
Description	This command configures the destination IP match condition.

Parameters	<i>ip-address/mask</i> — Specifies the IPv4 address and mask.	
Values	<i>ip-address</i>	a.b.c.d
	<i>mask</i>	0 to 32
	<i>ipv6-address/prefix-length</i> — Specifies the IPv6 address and length (applies only to the 7750 SR).	
Values	<i>ipv6-address</i>	x::x::x::x::x::x (where x is [0 to FFFFH]) :x::x::x::x::d.d.d.d (where d is [0 to 255]D)
	<i>prefix-length</i> — Specifies the prefix length (applies only to the 7750 SR).	
Values	1 to 128	
	<i>netmask</i> — Specifies the mask, expressed as a dotted quad.	
Values	a.b.c.d	

dst-port

Syntax	dst-port {lt gt eq} <i>dst-port-number</i> dst-port range <i>start end</i> no dst-port
Context	config>subscr-mgmt>cat-map>category>exh-lvl>ingr-ip>entry>match config>subscr-mgmt>cat-map>category>exh-lvl>ingr-ipv6>entry>match config>subscr-mgmt>cat-map>category>exh-lvl>egr-ip>entry>match config>subscr-mgmt>cat-map>category>exh-lvl>egr-ipv6>entry>match
Description	This command configures the destination port match condition.
Parameters	<i>lt gt eq</i> — Specifies the operator. <i>dst-port-number</i> — Specifies the destination port number as a decimal hex or binary.
Values	0 to 65535

fragment

Syntax	fragment {true false}
Context	config>subscr-mgmt>cat-map>category>exh-lvl>ingr-ip>entry>match config>subscr-mgmt>cat-map>category>exh-lvl>egr-ip>entry>match
Description	This command configures the fragmentation match condition.

Parameters **true|false** — Sets/resets fragmentation check.

icmp-code

Syntax **icmp-code** *icmp-code*
 no icmp-code

Context config>subscr-mgmt>cat-map>category>exh-lvl>ingr-ip>entry>match
 config>subscr-mgmt>cat-map>category>exh-lvl>ingr-ipv6>entry>match
 config>subscr-mgmt>cat-map>category>exh-lvl>egr-ip>entry>match
 config>subscr-mgmt>cat-map>category>exh-lvl>egr-ipv6>entry>match

Description This command configures the ICMP code match condition.

Parameters *icmp-code* — Specifies the ICMP code numbers accepted in DHB.

Values 0 to 255

icmp-type

Syntax **icmp-type** *icmp-type*
 no icmp-type

Context config>subscr-mgmt>cat-map>category>exh-lvl>ingr-ip>entry>match
 config>subscr-mgmt>cat-map>category>exh-lvl>ingr-ipv6>entry>match
 config>subscr-mgmt>cat-map>category>exh-lvl>egr-ip>entry>match
 config>subscr-mgmt>cat-map>category>exh-lvl>egr-ipv6>entry>match

Description This command configures the ICMP type match condition.

Parameters *icmp-type* — Specifies the ICMP type numbers accepted in DHB.

Values 0 to 255

ip-option

Syntax **ip-option** *ip-option-value* [*ip-option-mask*]
 no ip-option

Context config>subscr-mgmt>cat-map>category>exh-lvl>ingr-ip>entry>match
 config>subscr-mgmt>cat-map>category>exh-lvl>egr-ip>entry>match

Description This command configures the IP option match condition.

Parameters *ip-option-value* — Specifies the IP option value as a decimal hex or binary.

Values 0 to 255

ip-option-mask — Specifies the IP option mask as a decimal hex or binary.

Values 0 to 255

multiple-option

Syntax	multiple-option {true false}
Context	config>subscr-mgmt>cat-map>category>exh-lvl>ingr-ip>entry>match config>subscr-mgmt>cat-map>category>exh-lvl>egr-ip>entry>match
Description	This command configures the multiple-option match condition.
Parameters	true false — Sets or resets the multiple option check.

option-present

Syntax	option-present {true false}
Context	config>subscr-mgmt>cat-map>category>exh-lvl>ingr-ip>entry>match config>subscr-mgmt>cat-map>category>exh-lvl>egr-ip>entry>match
Description	This command configures the option-present match condition.
Parameters	true false — Sets or resets the option present check.

src-ip

Syntax	src-ip {ip-address/mask ip-address netmask} no src-ip
Context	config>subscr-mgmt>cat-map>category>exh-lvl>egr-ip>entry>match config>subscr-mgmt>cat-map>category>exh-lvl>egr-ipv6>entry>match
Description	This command configures the source IP match condition.
Parameters	<i>ip-address/mask</i> — Specifies the IPv4 address and mask. Values ip-address a.b.c.d mask 0 to 32 <i>netmask</i> — Specifies the mask, expressed as a dotted quad. Values a.b.c.d <i>ipv6-address/prefix-length</i> — Specifies the IPv6 address and length (applies only to the 7750 SR). Values ipv6-address x:x:x:x:x:x:x (where x is [0 to FFFFH])

x:x:x:x:x:d.d.d.d (where d is [0 to 255]D)

prefix-length — Specifies the prefix length (applies only to the 7750 SR).

Values 1 to 128

src-port

Syntax **src-port** {**lt** | **gt** | **eq**} *src-port-number*
src-port range *start end*
no src-port

Context config>subscr-mgmt>cat-map>category>exh-lvl>ingr-ip>entry>match
config>subscr-mgmt>cat-map>category>exh-lvl>ingr-ipv6>entry>match
config>subscr-mgmt>cat-map>category>exh-lvl>egr-ip>entry>match
config>subscr-mgmt>cat-map>category>exh-lvl>egr-ipv6>entry>match

Description This command configures the source port match condition.

Parameters **lt|gt|eq** — Specifies the operators.

src-port-number — Specifies the source port number as a decimal hex or binary.

Values 0 to 65535

dst-port-number — Specifies the destination port number as a decimal hex or binary.

Values 0 to 65535

tcp-ack

Syntax **tcp-ack** {**true** | **false**}
no tcp-ack

Context config>subscr-mgmt>cat-map>category>exh-lvl>ingr-ip>entry>match
config>subscr-mgmt>cat-map>category>exh-lvl>ingr-ipv6>entry>match
config>subscr-mgmt>cat-map>category>exh-lvl>egr-ip>entry>match
config>subscr-mgmt>cat-map>category>exh-lvl>egr-ipv6>entry>match

Description This command configures the TCP ACK match condition. The **no tcp-ack** command disables the checking on the presence or absence of the tcp-ack flag.

Parameters **true | false** — True | false indicates that the entry will match on the presence resp. absence of the tcp-ack flag in the received packet. .

tcp-syn

Syntax	tcp-syn {true false} no tcp-syn
Context	config>subscr-mgmt>cat-map>category>exh-lvl>ingr-ip>entry>match config>subscr-mgmt>cat-map>category>exh-lvl>ingr-ipv6>entry>match config>subscr-mgmt>cat-map>category>exh-lvl>egr-ip>entry>match config>subscr-mgmt>cat-map>category>exh-lvl>egr-ipv6>entry>match
Description	This command configures the TCP SYN match condition. The no tcp-syn command disables the checking on the presence or absence of the tcp-syn flag.
Parameters	true false — True false indicates that the entry will match on the presence resp. absence of the tcp-syn flag in the received packet.

pir

Syntax	pir <i>pir-rate</i> pir max no pir
Context	config>subscr-mgmt>cat-map>category>svc-lvl
Description	This command configures the PIR which will be enforced for all queues pertaining to this category.
Default	no pir
Parameters	<i>pir-rate</i> — Specifies the amount of bandwidth in kilobits per second (thousand bits per second). Values 1 to 40000000 max — Specifies to use the maximum amount of bandwidth.

out-of-credit-action-override

Syntax	out-of-credit-action-override {continue block-category change-service-level} no out-of-credit-action-override
Context	config>subscr-mgmt>cat-map>category
Description	This command specifies the action to be taken if the credit is exhausted.
Default	no out-of-credit-action-override
Parameters	continue — Specifies to continue when running out of credit. block-category — Specifies to block the category when running out of credit.

change-service-level — Specifies to change the service level when running out of credit.

policer

Syntax	policer <i>policer-id</i> { ingress-only egress-only ingress-egress } no policer <i>policer-id</i>
Context	config>subscr-mgmt>cat-map>category
Description	This command configures a policer in this category.
Parameters	<i>policer-id</i> — Specifies a policer identifier. The parameter <i>policer-id</i> references a <i>policer-id</i> that must be previously created within the SAP QoS policy.
Values	1 to 63
	ingress-only — Specifies that ingress policers are defined in this category.
	egress-only — Specifies that egress policers are defined in this category.
	ingress-egress — Specifies that ingress and egress policers are defined in this category.

queue

Syntax	queue <i>queue-id</i> { ingress-only egress-only ingress-egress } no queue <i>queue-id</i>
Context	config>subscr-mgmt>cat-map>category
Description	This command configures a queue in this category.
Default	none
Parameters	<i>queue-id</i> — Specifies the queue ID for this instances. Each queue nominated in the category map is monitored for activity (over a period of approximately 60 seconds), should the activity fall below the threshold value then a timer is started. Whenever this timer exceeds the configured timeout under the idle-timeout the action (currently disconnect) is executed for that subscriber and all hosts under that given SLA-profile-instance.
Values	1 to 32
	ingress-only — Specifies that ingress queues are defined in this category.
	egress-only — Specifies that egress queues are defined in this category.
	ingress-egress — Specifies that ingress and egress queues are defined in this category.

rating-group

Syntax	rating-group <i>rating-group-id</i> no rating-group
Context	config>subscr-mgmt>cat-map>category
Description	This command configures the rating group applicable for this category.
Default	no rating group
Parameters	<i>rating-group-id</i> — Specifies the rating group applicable for this category.

credit-exhaust-threshold

Syntax	credit-exhaust-threshold <i>threshold-percentage</i> no credit-exhaust-threshold
Context	config>subscr-mgmt>cat-map
Description	This command specifies the credit exhaust threshold taken into account to take action. The no form of the command reverts the configured value to the default.
Default	100
Parameters	<i>threshold-percentage</i> — Specifies the percent to use for the credit exhaust threshold. Values 50 to 100

credit-type

Syntax	credit-type { volume time } no credit-type
Context	config>subscr-mgmt>cat-map
Description	This command specifies whether volume or time based accounting is performed.
Default	volume
Parameters	volume — specifies volume-based accounting time — specifies time-based accounting

gx-session-level-usage

Syntax	gx-session-level-usage
---------------	-------------------------------

no gx-session-level-usage

Context	config>subscr-mgmt>cat-map
Description	<p>This command controls the instantiation of an internal category required for Diameter Gx session level Usage Monitoring (per IP-CAN session).</p> <p>When configured, Gx session level Usage Monitoring can be enabled for sessions associated with this category map.</p> <p>The internal category for Gx session level Usage Monitoring is counted against the maximum of sixteen categories that can be configured.</p> <p>When not configured (default), then no internal category is instantiated and Gx session level Usage Monitoring cannot be enabled for sessions associated with this category map.</p>
Default	no gx-session-level-usage

Diameter Commands

diameter-peer-policy

Syntax	diameter-peer-policy <i>peer-policy-name</i> [role {client proxy}] [create] no diameter-peer-policy
Context	config>aaa
Description	This command creates a base diameter policy with up to 5 peers. There is a (TCP) connection created to each peer while only two peers can be active (used by applications) simultaneously. Various diameter applications can reference this policy.
Default	none
Parameters	<p><i>peer-policy-name</i> — Specifies the name of the policy that is created.</p> <p>role client — Diameter is configured as client. The client initiate peering connections towards the server or Diameter proxy. Various applications such as Gx, Gy or NASREQ are layered directly on top of the Diameter client.</p> <p>role proxy — Diameter is configured as proxy. Diameter proxy is used to provide multi-chassis redundancy and it can assumes active or standby state. The proxy relays messages between the Diameter client on one side and the server on the other side.</p> <p>create — Keyword used to create the diameter-peer-policy. The create keyword requirement can be enabled/disabled in the environment>create context.</p>

diameter-application-policy

Syntax	diameter-application-policy <i>application-policy-name</i> [create] no diameter-application-policy <i>application-policy-name</i>
Context	config>subscr-mgmt
Description	This command creates diameter application policy.
Default	none
Parameters	<i>application-policy-name</i> — Specifies the name of the diameter policy up to 32 characters in length. create — Keyword used to create the diameter-application-policy . The create keyword requirement can be enabled/disabled in the environment>create context.

diameter-peer-policy

Syntax	diameter-peer-policy <i>referenced-policy-name</i> no diameter-peer-policy
Context	config>subscr-mgmt>diam-app-plcy
Description	This command is used by an application (DCCA, Gx, policy-management application, etc.) to reference a base diameter peer policy that the application will use.
Default	none
Parameters	<i>referenced-policy-name</i> — Specifies the name of the referenced policy.

applications

Syntax	applications {[gx] [gy] [nasreq]} no application
Context	config>aaa>diam-peer-plcy
Description	This command specifies which applications are advertised in the Capability Exchange Request (CER) messages sent on the peers. Applications that can be configured on a Diameter peer policy: <ul style="list-style-type: none">• client and proxy role:<ul style="list-style-type: none">– gx– nasreq– gx nasreq• client role only:

– gy

Note: Gx and nasreq applications can be enabled simultaneously on a single diameter peer.

Default	none
Parameters	gx — Gx application support will be advertised in CER. gy — Gy (DCCA) application support will be advertised in CER. nasreq — NASREQ application support will be advertised in CER.

application

Syntax	application {gx gy nasreq} no application
Context	config>subscr-mgmt>diam-appl-plcy
Description	This command specifies the Diameter application for which this policy contains the configuration details, such as AVPs to include and their format. Applications are mutually exclusive.
Default	none
Parameters	gx — This policy contains Gx application configuration options. gy — This policy contains Gy application configuration options. nasreq — This policy contains NASREQ application configuration options.

connection-timer

Syntax	[no] connection-timer <i>connection-time</i>
Context	config>aaa>diam-peer-plcy config>aaa>diam-peer-plcy>peer
Description	This command defines the frequency of attempts to open a TCP connection to each peer that is configured in the diameter-peer-policy. Once a TCP connection fails to be established (transaction-timer expires at sending TCP SYN) or an existing TCP connection fails, the next attempt to open the connection will be tried upon the expiry of the connection-timer. There is no limit on the number of attempts.
Default	30 seconds at diameter-base level

The default value at peer is taken from diameter-base.

Parameters *connection-time* — Specifies the amount of time, in seconds.
Values 1 to 1000

ipv6-source-address

Syntax **ipv6-source-address** *ipv6-address*
 no ipv6-source-address

Context config>aaa>diam-peer-plcy

Description This command configures the IPv6 source address for all diameter messages sent to IPv6-reachable peers.

When no IPv6 source address is specified, then the source address is determined by:

- router = “management”; use the active management port IP address as configured in the Boot Options File (BOF): **bof address** *ipv6-prefix/ipv6-prefix-length*
- router = “Base” or VPRN service ID; use the system interface IP address: configure router interface “system” **ipv6 address** *ipv6-address/prefix-length*

Default no ipv6-source-address

Parameters *ipv6-address* — Specifies the source IPv6 address to use for outgoing diameter messages to an IPv6-reachable peer.

Values

ipv6-address: x:x:x:x:x:x:x (eight 16-bit pieces)
 x:x:x:x:x:x:d.d.d.d
 x - [0 to FFFF]H
 d - [0 to 255]D

origin-host

Syntax **origin-host** *origin-host-string*
 no origin-host

Context config>aaa>diam-peer-plcy

Description This command configures the origin-realm AVP that will be sent in CER messages and all application based messages. Together with the Origin-Host AVP, these two AVPs form a Diameter Identity.

Parameters *origin-host-string* — Specifies the Origin-Host AVP (Attribute Value Pair) used by this policy up to 80 characters in length.

origin-realm

Syntax	origin-realm <i>origin-realm-string</i> no origin-realm
Context	config>aaa>diam-peer-plcy config>aaa>diam-peer-plcy>peer
Description	This command configures the <i>origin-realm</i> AVP that will be sent in CER messages and all application based messages. Together with the Origin-Host AVP, these two AVPs form a Diameter Identity.
Parameters	<i>origin-realm-string</i> — Specifies the origin-realm AVP (Attribute Value Pair) used by this policy. up to 80 characters in length.

peer

Syntax	peer <i>name</i> [create] no peer name
Context	config>aaa>diam-peer-plcy
Description	This command enables the context to configure diameter peer parameters. Up to five diameter peers can be defined inside of a diameter peer policy.
Default	none
Parameters	<i>name</i> — Specifies the peer name, up to a maximum of 32 characters.

address

Syntax	address <i>ip-address</i> no address
Context	config>aaa>diam-peer-plcy>peer
Description	This command configures the IPv4 or IPv6 address of the diameter peer.
Parameters	<i>ip-address</i> — Specifies the IPv4 or IPv6 address of the diameter peer.

Values

ipv4-address: a.b.c.d
ipv6-address: x:x:x:x:x:x:x (eight 16-bit pieces)
 x:x:x:x:x:d.d.d.d
 x - [0 to FFFF]H

d - [0 to 255]D

destination-host

Syntax	destination-host <i>destination-host-string</i> no destination-host
Context	config>>aaa>diam-peer-plcy>peer
Description	This command configures the destination-host AVP that will be sent in CCR-i/u and RAA messages. If the destination-host is not explicitly set via configuration, it will be learned from CCA or RAR messages. In other words, the origin-host received in the CCA or RAR message will be used to populate or replace the destination-host for the DCAA or GX session in the router.
Parameters	<i>destination-host-string</i> — Specifies the destination host name up 80 characters in length.

preference

Syntax	preference <i>preference</i> no preference
Context	config>aaa>diam-peer-plcy>peer
Description	<p>This command configured preference per peer. Only the two peers with the highest preference in the peer table are considered for use (primary and secondary). Other peers can be the Open state and they just run keepalives (watchdog-request/answer messages). Once the primary peer fails, the secondary peer will be used as long as the last transaction on it has succeeded (stickiness). Another peer in the Open state will become secondary. Load balancing between peers is not supported.</p> <p>The no form of the command reverts to the default value.</p>
Default	50
Parameters	<i>preference</i> — Specifies the preference of this DIAMETER policy peer.
Values	1 to 100

transaction-timer

Syntax	transaction-timer <i>seconds</i> no transaction-timer
Context	config>aaa>diam-peer-plcy config>aaa>diam-peer-plcy>peer

Description	<p>This command defines the time-out value for the Base Diameter messages (DWR, CER, DPR). Once the transaction-timer expires, an appropriate action will be taken for each message type.</p> <p>This timer is used in the following cases:</p> <ul style="list-style-type: none"> • Opening the TCP connection (and completing the 3-way handshake) - if the TCP ACK is not received within the time specified by the transaction-timer, the TCP connection is closed and the connection-timer is started waiting for the new connection to be initiated. • Capability Exchange – if the response to the CER message (CEA) is not received within the time specified by the transaction-timer, the peer connection is closed and the connection-timer is started waiting for the new connection to be initiated. • Peer disconnect Request- if the response to the DPR message is not received (DPA) within the time specified by the transaction-timer, the peer connection is closed. • DWR Timeout - if the response to the DWR message is not received (DWA) within the time specified by the transaction-timer, the peer connection is NOT closed. Instead the peer will transition into a peer suspended mode and at the same time the watchdog timer is restarted.
Default	none
Parameters	<p><i>seconds</i> — Specifies the policy peer transaction timer value in seconds.</p> <p>Values 1 to 1000</p>

transport

Syntax	<p>transport tcp port <i>port</i></p> <p>no transport</p>
Context	config>aaa>diam-peer-plcy>peer
Description	This command defines source tcp port of the connection channel. Only TCP transport is currently supported
Default	3868
Parameters	<p><i>port port</i> — Specifies the transport protocol port number used towards this policy peer.</p> <p>Values 1 to 65535</p>

destination-realm

Syntax	<p>destination-realm <i>destination-realm-string</i></p> <p>no destination-realm</p>
Context	config>aaa>diam-peer-plcy>peer

Description	This command configures the destination-realm AVP that will be sent in CCR-i/u and RAA messages. The Destination-Realm cannot be learned dynamically from the CCA or RAR messages and therefore it should be explicitly configured in the router. Once configured, it cannot be changed while peers are open.
Parameters	<i>destination-realm-string</i> — Specifies the destination realm name, maximum 80 displayable characters.

watchdog-timer

Syntax	watchdog-timer <i>seconds</i> no watchdog-timer
Context	config>aaa>diam-peer-plcy config>aaa>diam-peer-plcy>peer
Description	<p>This command configures the interval between consecutive watchdog messages. On the first timeout of the DWR, the node will resend the DWR message. The peer is still operation during this time.</p> <p>On the second timeout, the peer will transition into a suspended mode and the peer-failover procedure will be initiated (if the peer-failover is enabled via configuration). In this state the peer is not used for new transactions. At the same time, the cooldown procedure is started which means that it would take 3 successful DWR/DWA message exchanges to re-instate the peer in a fully operation state.</p> <p>On the third timeout, the peer is removed and its connection is closed.</p> <p>This behavior is described in RFC 3539, §3.4.1)</p>
Default	30
Parameters	<i>seconds</i> — specifies the device watchdog timer in seconds used by this policy peer. Values 1 to 1000

proxy

Syntax	proxy
Context	config>aaa>diam-peer-plcy
Description	This command enables the context to configure the diameter peer policy proxy.

mcs-peer

Syntax	mcs-peer <i>ip-address</i> sync-tag <i>name</i>
---------------	---

no mcs-peer

Context	config>aaa>diam-peer-plcy>proxy
Description	<p>This command configures multi-chassis synchronization (MCS) peer (redundant node). The sync-tag identifies Diameter proxies that will participate in synchronization.</p> <p>The no form of the command reverts to the default.</p>
Default	no mcs-peer
Parameters	<p><i>ip-address</i> — Specifies the IPv4 or IPv6 address of the MCS peer</p> <p><i>name</i> — Specifies the sync tag name up to 32 characters in length. The name must match on both nodes for the pair of redundant diameter proxies.</p>

router

Syntax	router <i>router-instance</i> address <i>ip-address</i> no router
Context	config>>aaa>diam-peer-plcy>proxy
Description	This command configures the IPv4 or IPv6 address and routing context on which the diameter proxy is listening for the client connections.
Default	no router
Parameters	<p><i>router-instance</i> — Specifies the routing context in which diameter proxy is configured.</p> <p><i>ip-address</i> — Specifies the IPv4 or IPv6 address to which the diameter proxy is listening.</p>

Values

ipv4-address: a.b.c.d
ipv6-address: x:x:x:x:x:x:x (eight 16-bit pieces)
x:x:x:x:x:d.d.d.d
x - [0 to FFFF]H
d - [0 to 255]D

python-policy

Syntax	python-policy [32 chars max] no python-policy
Context	config>aaa>diam-peer-plcy
Description	This command specified the python-policy for Diameter messages received or transmitted on the Diameter peers defined in the diameter-peer-policy.

Default	none
Parameters	<i>name</i> — Specifies the name of the Python policy, up to 32 characters long.

router

Syntax	router <i>router-instance</i> router service <i>service-name</i> no router
Context	config>aaa>diam-peer-plcy
Description	This command references the routing instance from which diameter peering is instantiated.
Parameters	<i>router-instance</i> — Specify one of the following parameters for the router instance: <i>router-name</i> — Specifies a router name up to 32 characters to be used in the match criteria. Values Base, management Default Base <i>service-id</i> — Specifies an existing service ID to be used in the match criteria. Values 1 to 2147483647 <i>service-name service-name</i> — Specifies an existing service name up to 64 characters in length.

source-address

Syntax	source-address <i>ip-address</i> no source-address
Context	config>aaa>diam-peer-plcy
Description	This command configures the IPv4 source-address that the node will use for peering connections.
Parameters	<i>ip-address</i> — The IP prefix for the IP match criterion in dotted decimal notation. Values 0.0.0.0 to 255.255.255.255

vendor-support

Syntax	vendor-support [three-gpp vodafone] no vendor-support
Context	config>subscr-mgmt>diam-appl-plcy>gy

```
config>aaa>diam-peer-plcy
```

Description In a diameter peer policy, this command specifies the vendor support announced in the capability exchange. In a Gy diameter application policy, this command specifies the vendor specific attributes for the user sessions.

The **no** form of the command reverts to the default value.

Default three-gpp

Parameters **three-gpp** — Specifies the 3GPP diameter policy vendor type.
vodafone — Specifies the vodafone diameter policy vendor type.

extended-failure-handling

Syntax **extended-failure-handling**

Context config>subscr-mgmt>diam-appl-plcy>gy

Description This command enables the context to configure Extended Failure Handling (EFH), a mechanism to establish a new Diameter Gy session with the Online Charging Server (OCS) after Credit Control Failure Handling (CCFH) CONTINUE is triggered.

interim-credit

Syntax **interim-credit**

Context config>subscr-mgmt>diam-appl-plcy>gy>efh

Description This command enables the context to configure interim credit parameters for Extended Failure Handling (EFH).

max-attempts

Syntax **max-attempts** *count*
max-attempts *infinite*
no max-attempts

Context config>subscr-mgmt>diam-appl-plcy>gy>efh>interim-c

Description This command configures the maximum number of attempts made to establish a new Diameter Gy session with the Online Charging Server (OCS) when Extended Failure Handling (EFH) is active.

A new attempt is made when the volume or time interim credit of a rating group is consumed or when the validity time expires for a rating group.

When the maximum number of attempts is reached, the user session associated with the Diameter session is terminated (the corresponding subscriber hosts are deleted from the system).

The **no** version of this command resets the value to the default value.

Default max-attempts 10

Parameters *count* — specifies the maximum number attempts that will be made to establish a Diameter Gy session with the OCS when EFH is active

Values 1 to 4294967295

infinite — specifies that an unlimited number of attempts will be made to establish a Diameter Gy session with the OCS when EFH is active

reporting

Syntax reporting
no reporting

Context config>subscr-mgmt>diam-appl-plcy>gy>efh>interim-c

Description This command enables reporting of the used interim credit for each rating group when a new Diameter Gy session is successfully established with the Online Charging Server (OCS).

When enabled, the used interim credit report includes:

- the unreported used credit assigned via the initial Diameter Gy session when Extended Failure Handling (EFH) became active
- the used interim credits during EFH
- the used credits assigned via the new established Diameter Gy session

The **no** version of this command disables interim credit reporting. Only credit assigned via the new established Diameter Gy session is reported.

Default no reporting

validity-time

Syntax validity-time *seconds*
no validity-time

Context config>subscr-mgmt>diam-appl-plcy>gy>efh>interim-c

Description This command configures the validity time for the interim credit allocated to rating groups of a Diameter Gy session when Extended Failure Handling (EFH) is active. When either the allocated interim credit is consumed or the validity time expires, a new attempt is made to establish a Diameter Gy session with the Online Charging Server (OCS).

The validity time applies to all interim credit allocated via the **configure subscriber-mgmt diameter-application-policy** *application-policy-name* **gy extended-failure-handling interim-credit volume** and **configure subscriber-mgmt category-map** *category-map-name* **category** *category-name* **default-credit** CLI commands.

A validity time value of 0 (zero) disables the validity time for the assigned interim credit.

The **no** version of this command resets the value to the default value.

Default	validity-time 1800
Parameters	<i>seconds</i> — specifies the validity time in seconds applicable to the interim credit
Values	0 to 4294967295

volume

Syntax	volume <i>credits</i> { bytes kilobytes megabytes gigabytes } no volume
Context	config>subscr-mgmt>diam-appl-plcy>gy>efh>interim-c
Description	This command configures the default volume interim credit that is allocated to all rating groups of a Diameter Gy session when Extended Failure Handling (EFH) is active and for which no default credit is configured at the category map category level. The no version of this command resets the value to the default value.
Default	volume 500 megabytes
Parameters	<i>credits</i> — specifies the amount of volume credit that is allocated by default to all rating groups of a Diameter Gy session when EFH is active Values 1 to 4294967295 bytes kilobytes megabytes gigabytes — specifies whether credits are in bytes, kilobytes, megabytes, or gigabytes

new-session-id

Syntax	[no] new-session-id
Context	config>subscr-mgmt>diam-appl-plcy>gy>efh
Description	This command determines the Diameter session ID when Extended Failure Handling (EFH) is active and an attempt is made to establish a new Diameter Gy session with the Online Charging Server (OCS). An attempt to establish a new Diameter Gy session is made when the allocated interim credit is used or the validity time expires for a rating group of a Diameter Gy session. The first attempt always uses a new Diameter session ID. This command controls the behavior for each subsequent attempt. The behavior is as follows:

- no new-session-id (default) — The same Diameter session ID is used for each subsequent attempt.
- new-session-id — A new Diameter session ID is used for each attempt.

Default no new-session-id

shutdown

Syntax [no] shutdown

Context config>subscr-mgmt>diam-appl-plcy>gy>efh

Description This command enables or disables Extended Failure Handling (EFH) for Diameter Gy sessions established using this Diameter application policy.

no shutdown — enables EFH for Diameter Gy sessions established using this Diameter application policy

shutdown — disables EFH for Diameter Gy sessions established using this Diameter application policy

Default shutdown

include-avp

Syntax [no] include-avp

Context config>subscr-mgmt>diam-appl-plcy>gy
config>subscr-mgmt>diam-appl-plcy>gx
config>subscr-mgmt>diam-appl-plcy>nasreq

Description This command enables the context to configure AVPs and their format to be included in Diameter Gx, Gy or NASREQ application messages.

an-gw-address

Syntax [no] an-gw-address

Context config>subscr-mgmt>diam-appl-plcy>gx>include-avp

Description This command configures the IPv4 address of the node.

called-station-id

Syntax [no] called-station-id

Context	config>subscr-mgmt>diam-appl-plcy>gx>include-avp config>subscr-mgmt>diam-appl-plcy>nasreq>include-avp
Description	This command configures the MAC address of AP in WiFi.
Default	no called-station-id

calling-station-id

Syntax	calling-station-id [type {llid mac remote-id sap-id sap-string}] no calling-station-id
Context	config>subscr-mgmt>diam-appl-plcy>gx>include-avp config>subscr-mgmt>diam-appl-plcy>nasreq>include-avp
Description	This command includes the calling-station-id AVP in the specified format.
Default	no calling-station-id
Parameters	type — Specifies the format of the Calling-Station-ID AVP. Values llid — The LLID (logical link identifier) is the mapping from a physical to logical identification of a subscriber line and supplied by a RADIUS llid-server. mac — Specifies that the mac-address will be sent. remote-id — Specifies that the remote-id will be sent. sap-id — Specifies that the sap-id will be sent. sap-string — Specifies that the value is the inserted value set at the SAP level. If no calling-station-id value is set at the SAP level, the calling-station-id attribute will not be sent.

circuit-id

Syntax	[no] circuit-id
Context	config>subscr-mgmt>diam-appl-plcy>nasreq>include-avp
Description	This command includes the Agent-Circuit-Id AVP.

ip-can-type

Syntax	[no] ip-can-type
Context	config>subscr-mgmt>diam-appl-plcy>gx>include-avp

Description This command includes the ip-can-type.

logical-access-id

Syntax [no] **logical-access-id**

Context config>subscr-mgmt>diam-appl-plcy>gx>include-avp

Description This command includes the logical-access-id.

nas-port

Syntax **nas-port** *binary-spec*
no nas-port

Context config>subscr-mgmt>diam-appl-plcy>gx>include-avp
config>subscr-mgmt>diam-appl-plcy>nasreq>include-avp

Description This command specifies the format of the 32 bit string used as value for the Nas-Port AVP.

Default no nas-port

Parameters *binary-spec* — Specifies the NAS-Port AVP format.

Values

binary-spec	<bit-specification> <binary-spec>
bit-specification	0 1 <bit-origin>
bit-origin	*<number-of-bits><origin>
number-of-bits	1 to 32
origin	s m p o i v c
s	- slot number
m	- MDA number
p	- port number or lag-id
o	- outer VLAN ID
i	- inner VLAN ID
v	- ATM VPI
c	- ATM VCI

nas-port-id

Syntax **nas-port-id** [**prefix-type** {none | user-string}] [**prefix-string** *prefix-string*] [**suffix-type** {circuit-id | none | remote-id | user-string}] [**suffix-string** *suffix-string*]
no nas-port-id

Context	config>subscr-mgmt>diam-appl-plcy>gx>include-avp config>subscr-mgmt>diam-appl-plcy>nasreq>include-avp
Description	This command includes the Nas-Port-Id AVP.
Default	no nas-port-id
Parameters	<p>prefix-type — Specifies what type of prefix will be added to the NAS-Port-Id attribute if included in Nas-Port-Id AVP messages.</p> <p>Values</p> <ul style="list-style-type: none">none — No prefix is added.user-string — Specifies the user configurable string to be added as prefix to the NAS-Port-Id attribute if included in DIAMETER Gx messages. <p><i>prefix-string</i> — Specifies the user configurable string up to 8 characters in length, to be added as a prefix.</p> <p>suffix-type — specifies the suffix to be added to the NAS-Port attribute NAS-Port AVP.</p> <p>Values</p> <ul style="list-style-type: none">one — No suffix is added.circuit-id — the circuit-id is added as suffix-string.remote-id — the remote-id is added as suffix-string.user-string — a user configurable suffix-string is added. <p><i>suffix-string</i> — Specifies the string up to 64 characters in length to be added as suffix.</p>

nas-port-type

Syntax	nas-port-type nas-port-type [type] no nas-port-type
Context	config>subscr-mgmt>diam-appl-plcy>gx>include-avp config>subscr-mgmt>diam-appl-plcy>nasreq>include-avp
Description	This command includes the Nas-Port-Type AVP.
Default	no nas-port-type
Parameters	<p>none — Values as defined in RFC 2865, Remote Authentication Dial In User Service (RADIUS), and RFC 4603, Additional Values for the NAS-Port-Type Attribute.</p> <p><i>type</i> — Specifies the integer value for the Nas-Port-Type AVP.</p> <p>Values 0 to 255</p>

remote-id

Syntax	[no] remote-id
---------------	----------------

Context config>subscr-mgmt>diam-appl-plcy>gx>include-avp
config>subscr-mgmt>diam-appl-plcy>nasreq>include-avp

Description This command enables the generation of the agent-remote-id for RADIUS.

physical-access-id

Syntax [no] physical-access-id

Context config>subscr-mgmt>diam-appl-plcy>gx>include-avp

Description This command includes the physical access ID.

rat-type

Syntax [no] rat-type

Context config>subscr-mgmt>diam-appl-plcy>gx>include-avp

Description This command includes the RAT type.

supported-features

Syntax [no] supported-features

Context config>subscr-mgmt>diam-appl-plcy>gx>include-avp

Description This command includes the supported-features.

user-equipment-info

Syntax user-equipment-info [type *ue-info-type*]
no user-equipment-info

Context config>subscr-mgmt>diam-appl-plcy>gx>include-avp

Description This command includes the user-equipment-info.

mac-format

Syntax mac-format *mac-format*
no mac-format

Context config>subscr-mgmt>diam-appl-plcy>gx

	config>subscr-mgmt>diam-appl-plcy>nasreq
Description	This command configures the format of the MAC address when reported in Gx or NASREQ application message AVPs such as Calling-Station-Id or User-Name.
Default	mac-format "aa:"
Parameters	<i>mac-format</i> — Specifies the MAC address format.
Values	like aa: for 00:0c:f1:99:85:b8 or XY- for 00-0C-F1-99-85-B8 or mmmm. for 0002.03aa.abff or xx for 000cf19985b8

report-ip-address-event

Syntax	[no] report-ip-address-event
Context	config>subscr-mgmt>diam-appl-plcy>gx
Description	This command enables triggered CCR-u messages based on IP address allocation/de-allocation for the subscriber-host.

In case that the requests for both IP address families (IPv4 and IPv6) arrive at approximately the same time, a single CCR-i will be sent containing the IP addresses from both address families - IPv4 and IPv6 (NA, PD or SLAAC). Otherwise, in case that the requests for IP addresses are not nearly simultaneous, the CCR-i will contain only the IP address that was allocated first (the one that triggered the session creation). The request for the second IP address family will, depending on configuration, trigger an additional CCR-u that will carry the IP address allocation update to the PCRF along with the UE_IP_ADDRESS_ALLOCATE (18) event. Apart from that, the CCR-u content should mirror the content of the CCR-i with exception of already allocated IP address(es).

In case that this command is disabled, IP address triggered CCR-u messages will not be sent.

Default	report-ip-addr-event (enabled)
----------------	--------------------------------

3gpp-ggsn-address

Syntax	3gpp-ggsn-address no 3gpp-ggsn-address
Context	config>subscr-mgmt>diam-appl-plcy>gy>include-avp
Description	This command includes the [10415-7] 3GPP-GGSN-Address AVP in the diameter gy messages. It's value is set to the source IPv4 address that is used for outgoing diameter messages.

Default 3gpp-ggsn-address

3gpp-ggsn-ipv6-address

Syntax **3gpp-ggsn-ipv6-address**
no 3gpp-ggsn-ipv6-address

Context config>subscr-mgmt>diam-appl-plcy>gy>include-avp

Description This command includes the [10415-16] 3GPP-GGSN-IPv6-Address AVP in the diameter gy messages. It's value is set to the source IPv6 address that is used for outgoing diameter messages.

Default no 3gpp-ggsn-ipv6-address

3gpp-imsi

Syntax **3gpp-imsi {circuit-id|imsi|subscriber-id}**
no 3gpp-imsi

Context config>subscr-mgmt>diam-appl-plcy>gy>include-avp

Description This command specifies the origin of the information to send in the DCCA IMSI AVP.
The **no** form of the command reverts to the default value.

Default subscriber-id

Parameters **circuit-id** — Specifies the circuit-id as DCCA IMSI AVP value.
subscriber-id — Specifies the subscriber-id as DCCA IMSI AVP value.
imsi — Specifies the imsi as DCCA IMSI AVP value.

called-station-id

Syntax **called-station-id [64 chars max]**
no called-station-id

Context config>subscr-mgmt>diam-appl-plcy>gy>include-avp

Description This command configures the value of the called station ID AVP.

Default no called-station-id

Parameters **64 chars max** — Specifies the called station ID up to 64 characters in length.

radius-user-name

Syntax	[no] radius-user-name
Context	config>subscr-mgmt>diam-appl-plcy>gy>include-avp
Description	This command includes the RADIUS user name AVP in the Diameter gy messages.
Default	no radius-user-name

service-context-id

Syntax	service-context-id <i>name</i> no service-context-id
Context	config>subscr-mgmt>diam-appl-plcy>gy>include-avp
Description	This command configure the value of the service context ID AVP.
Default	no service-context-id
Parameters	<i>name</i> — Specifies the service context ID AVP value up to 32 displayable characters.

transaction-timer

Syntax	[no] transaction-timer <i>transaction-time</i>
Context	config>aaa>diam-peer-plcy config>aaa>diam-peer-plcy>peer
Description	This command defines the time-out value for the Base Diameter messages (DWR, CER, DPR). Once the transaction-timer expires, an appropriate action will be taken for each message type.

This timer is used in the following cases:

- Opening the TCP connection (and completing the 3-way handshake) - if the TCP ACK is not received within the time specified by the transaction-timer, the TCP connection is closed and the connection-timer is started waiting for the new connection to be initiated.
- Capability Exchange — If the response to the CER message (CEA) is not received within the time specified by the transaction-timer, the peer connection is closed and the connection-timer is started waiting for the new connection to be initiated.
- Peer disconnect Request — If the response to the DPR message is not received (DPA) within the time specified by the transaction-timer, the peer connection is closed.
- DWR Timeout — If the response to the DWR message is not received (DWA) within the time specified by the transaction-timer, the peer connection is NOT closed. Instead the peer will transition into a peer suspended mode and at the same time the watchdog timer is restarted.

Default	none
Parameters	<i>transaction</i> — Specifies the DIAMETER peer policy transaction timer in seconds.
Values	1 to 1000
Default	30 seconds at diameter-base level Default value at peer is taken from diameter-base.

gx

Syntax	gx
Context	config>subscr-mgmt>diam-appl-plcy
Description	This command enables the context to configure Gx parameters.

gy

Syntax	gy
Context	config>subscr-mgmt>diam-appl-plcy
Description	This command enables the context to configure Diameter Credit Control Application or Gy-specific options.

nasreq

Syntax	nasreq
Context	config>subscr-mgmt>diam-appl-plcy
Description	This command enables the context to configure NASREQ application-specific attributes.

avp-subscription-id

Syntax	avp-subscription-id origin [type type] no avp-subscription-id
Context	config>subscr-mgmt>diam-appl-plcy>gx config>subscr-mgmt>diam-appl-plcy>gy
Description	This command is used to provide identification information to the PCRF for the end user. Subscription-id is a grouped AVP. In case that parameter designated to be the subscription-id is not available, the subscription-avp will not be sent.

The **no** form of the command reverts to the default value.

Default none

avp-subscription-id subscriber-id type private

Parameters **origin** — Specifies the origin of the information to send in the Subscription-Id-Data AVP.

Values

- circuit-id** — The circuit ID.
- dual-stack-remote-id** — The remote-id for IPv4 and IPv6. The enterprise-id field is stripped off from IPv6 remote-id before it is passed to the PCRF in Gx message.
- imei** — The physical ID of the end device.
- imsi** — The SIM ID.
- mac** — The MAC address of the end device.
- msisdn** — The phone number of the end device.
- nas-port-id** — nas-port-id can be a prefix or suffix with a custom string to make it unique network wide.
- subscriber-id** — The subscriber ID.
- username** — The username identifier can be of type **private** or **nai**. — The username is a ppp-username (PAP/CHAP). In case that ppp-username is not available, the string in the Username attribute returned via RADIUS or NASREQ will be used.

type — Specifies the type of the identifier stored in the Subscription-Id-Data AVP.

Values

- e164** — The identifier is in international E.164 format (e.g., MSISDN).
- imsi** — The identifier is in international IMSI format according to the ITU-T E.212 numbering plan.
- nai** — The identifier is in the form of a Network Access Identifier as defined in RFC 2486.
- private** — The identifier is a private type identifier.

ccrt-replay-interval

Syntax **ccrt-replay-interval** [*interval*]
no ccrt-replay-interval

Context config>subscr-mgmt>diam-appl-plcy>gx

Description This command enables sending CCR-t messages for a given Gx session until a valid response (CCA-t) is received or until a 24h period expires, whichever comes first. The purpose of replaying CCR-t message is to ensure that the Gx session is cleared on the PCRF side in case that the peering session to the PCRF was not available at the time when the initial and the first retransmitted CCR-t was sent.

In case that a valid CCA-t response is not received, the system will continue to replay CCR-t messages at configurable interval for the duration of 24 hours.

The subscriber-host behind the Gx session that is in CCR-t replay mode is terminated at the time when the initial CCR-t is sent. This means that all resources associated with the subscriber (queues, DHCP lease states, PPPoE states, etc) are freed. What is left behind in the node is an orphaned Gx session in a replay mode trying to clear itself on the PCRF side.

Default none

Parameters *interval* — Specifies the interval at which the CCR-t messages are replayed for a given Gx session. The messages will be replayed until a valid CCA-t response is received or until a 24h period expires, whichever comes first.

Values 60 to 86400

out-of-credit-reporting

Syntax **out-of-credit-reporting {final|quota-exhausted}**
no out-of-credit-reporting

Context config>subscr-mgmt>diam-appl-plcy>gy

Description This command changes the reporting reason in an intermediate interrogation when the final granted units have been consumed and a corresponding out-of-credit-action different from "disconnect-host" is started.

The no form of the command reverts to the default value

Default out-of-credit-reporting final

Parameters **final** — Specifies the reporting reason in an intermediate interrogation when the final granted units have been consumed and a corresponding out-of-credit-action different from **disconnect-host** is started.

quota-exhausted — Specifies the reporting reason in an intermediate interrogation when the final granted units have been consumed and a corresponding out-of-credit-action different from **disconnect-host** is started.

on-failure

Syntax **on-failure [failover {enabled|disabled}] [handling {continue | retry-and-terminate | terminate}]**
no on-failure

Context config>subscr-mgmt>diam-appl-plcy

Description Behavior of the application's session in case of a peer failure can be controlled by the Diameter server through two AVPs carried in CCA messages that are defined in RFC4006:

- CC-Session-Failover AVP
 - FAILOVER_NOT_SUPPORTED
 - FAILOVER_SUPPORTED
- Credit-Control-Failure-Handling AVP
 - TERMINATE
 - CONTINUE
 - RETRY_AND_TERMINATE

In case that those AVPs are not provided by the Diameter server, the local configuration provided by this command will take effect. This command defines the following:

- Peer-failover behavior to a secondary peer in case that the primary peer is unresponsive. The primary peer is considered unresponsive in case that the application message sent to it, times out. The failover mechanism defined by this command is only applicable to CCR messages (and not to RAA messages since there is no response expected). The time out of the message is determined by the **tx-timer** command.

The peer-failover action based on the message timeout is defined per session. In other words, a message timeout for one session cannot cause the failover for some other session.

The maximum number of transmissions per session is hardcoded to 2 and the same message is never re-transmitted to the same TCP socket (a TCP socket is defined as a current peering connection defined by the TCP source/destination IP addresses/ports; closing and then reopening a connection to the same peer will result in creation of a new TCP socket). Once the original message for the session times out on the primary peer, the message will be re-transmitted to the secondary peer, provided that the secondary peer is available and the failover is enabled with the corresponding handling mechanism. In case that the secondary peer is unavailable, the original message will not be re-transmitted to the same primary peer again.

Once the reply from a peer is received, the session will be tied to that peer until the next timeout. In other words, the session always sticks to the peer from which it received the last response.

- Handling behavior in case that the response from the peer is not received or the peers are not available at all (all peering connections are closed). This behavior is applicable to CCR-i messages in Gx and CCR-i/u messages in Gy. In case of Gx, if the response to a session initiation message (CCR-i) is not received, the fate of the session will depend on the configuration (the session can be terminated or continue to exist with default parameters).

Default	on-failure failover enabled handling terminate
Parameters	failover enabled — The session is allowed to switch to the secondary peer. failover disabled — The session is NOT allowed to switch to the secondary peer.

handling continue — The sessions will continue to exist if the response to a transmitted CCR message is not received. Whether the transmitted message will be re-transmitted depends on the failover configuration. In case of session initiation procedure in the Gx case (CCR-i timeout), the subscriber host will be instantiated with the default parameters, assuming that they are provided. In the default parameter are not provided, the subscriber host initiation will fail.

handling retry-and-terminate — The message will be re-transmitted in case that the peer-failover is enabled and the secondary peer is available. Once the retransmitted message (CCR-i in Gx; CCR-i/u in Gy) is timed-out, the application session will be terminated.

handling terminate — The session will be terminated if the response to the original message (CCR-I in Gx; CCR-i/u in Gy) is not received. No re-transmissions will be attempted, regardless of whether the failover is enabled or not.

tx-timer

Syntax	tx-timer <i>seconds</i> no tx-timer
Context	config>subscr-mgmt>diam-app-plcy
Description	<p>This command defines the time-out period for the application's CCR-i/u messages that are waiting for a reply from a peer (message is in a pending state). Peer-failover behavior determines the action that will be taken once the message times out. Peer-failover behavior can be dictated by the PCRF or can be locally configured in the router.</p> <p>Per RFC 4006, sec 13, <i>Diameter Credit-Control Application, Credit-Control Application Related Parameters</i>, When real-time credit-control is required, the credit-control client contacts the credit-control server before and while the service is provided to an end user. Due to the real-time nature of the application, the communication delays SHOULD be minimized; e.g., to avoid an overly long service setup time experienced by the end user. The Tx timer is introduced to control the waiting time in the client in the Pending state. When the Tx timer elapses, the credit-control client takes an action to the end user according to the value of the Credit-Control-Failure-Handling AVP or Direct-Debiting-Failure-Handling AVP. The recommended value is 10 seconds.</p>
Default	10
Parameters	<i>seconds</i> — specifies the Tx Timer value (in seconds) for this policy. Values 10 to 1000

diameter-application-policy

Syntax	diameter-application-policy <i>policy-name</i> no diameter-application-policy
---------------	--

Context	config>service>vprn>sub-if>grp-if config>service>ies>sub-if>grp-if config>subscr-mgmt>loc-user-db>ipoe>host config>subscr-mgmt>loc-user-db>ppp>host
Description	This command associates the specified diameter-application-policy with the processing of the host attachment requests.
Default	none
Parameters	<i>policy-name</i> — Specifies the name of the diameter policy up to 32 characters in length.

Filter Commands

filter

Syntax	filter
Context	configure
Description	This command manages the configuration of filters.

copy

Syntax	copy {ip-filter mac-filter ipv6-filter} src-filter-id [src-entry src-entry-id] to dst-filter-id [dst-entry dst-entry-id] [overwrite]
Context	config>filter
Description	This command copies filters and its entries.
Parameters	<i>src-filter-id</i> — Specifies the source filter ID. Values 1 to 65535 <i>src-entry-id</i> — Specifies the source entry ID. Values 1 to 65535 <i>dst-filter-id</i> — Specifies the destination filter ID. Values 1 to 65535 <i>dst-entry-id</i> — Specifies the destination entry ID. Values 1 to 65535 overwrite — Specifies an overwrite.

dhcp6-filter

Syntax	dhcp6-filter <i>filter-id</i> [create] no dhcp6-filter <i>filter-id</i>
Context	config>filter
Description	This command configures the DHCPv6 filter to either bypass ESM host creation or drop DHCPv6 relay-reply messages.
Default	no dhcpv6-filter
Parameters	<i>filter-id</i> — Specifies the filter ID. Values 1 to 65535 create — Keyword used to create the DHCPv6 filter. The create keyword requirement can be enabled/disabled in the environment>create context. This parameter only applies to the 7750 SR.

default-action

Syntax	default-action bypass-host-creation [na] [pd] default-action drop no default-action
Context	config>filter>dhcp6-filter
Description	This command specifies the default action when no entries match.
Parameters	bypass-host-creation — bypass ESM host creation options. Values na — Bypasses the DHCP NA hosts creation. pd — Bypasses the DHCP PD hosts creation. drop — Specifies to drop and not process the DHCP6 message.

entry

Syntax	entry <i>entry-id</i> [create] no entry <i>entry-id</i>
Context	config>filter>dhcp6-filter
Description	This command configures a DHCPv6 filter entry.
Parameters	<i>entry-id</i> — Specifies the entry ID. Values 1 to 65535

create — Keyword used to create the DHCPv6 filter. The **create** keyword requirement can be enabled/disabled in the **environment>create** context. This parameter only applies to the 7750 SR.

action

Syntax	action bypass-host-creation [na] [pd] action drop no action
Context	config>filter>dhcp6-filter>entry
Description	This command configures an action for the DHCP6 filter entry.
Parameters	bypass-host-creation — bypass ESM host creation options. Values na — Bypasses the DHCP NA hosts creation. pd — Bypasses the DHCP PD hosts creation. drop — Specifies to drop and not process the DHCP6 message.

option

Syntax	option <i>dhcp6-option-number</i> { present absent } option <i>dhcp6-option-number</i> match hex <i>hex-string</i> [exact] [invert-match] option <i>dhcp6-option-number</i> match string <i>ascii-string</i> [exact] [invert-match] no option
Context	config>filter>dhcp6-filter>entry
Description	This command configures the DHCPv6 option to match.
Parameters	present absent — Specifies the number of the DHCP6 option to filter on. The present keyword specifies that the DHCP6 option must be present. The absent keyword specifies that the DHCP6 option must be absent. match hex <i>hex-string</i> — Specifies to match the Hex string. match string <i>ascii-string</i> — Specifies to match the ASCII string. exact — Requires an exact match. invert-match — Requires the option not to (partially) match.

ip-filter

Syntax	ip-filter <i>filter-id</i> [create] no ip-filter <i>filter-id</i>
---------------	---

Context	config>filter
Description	This command configures an IP filter.
Parameters	<i>filter-id</i> — Specifies the filter ID.
Values	1 to 65535

ipv6-filter

Syntax	ipv6-filter <i>ipv6-filter-id</i> [create] no ipv6-filter <i>ipv6-filter-id</i>
Context	config>filter
Description	This command configures an IPv6 filter.
Parameters	<i>filter-id</i> — Specifies the filter ID.
Values	1 to 65535

default-action

Syntax	default-action drop forward
Context	config>filter>ip-filter config>filter>ipv6-filter
Description	This command configures default-action for the IP or IPv6 filter.
Parameters	drop forward — This keyword specifies the filter action.

entry

Syntax	entry <i>entry-id</i> [create] no entry <i>entry-id</i>
Context	config>filter>ip-filter config>filter>ipv6-filter
Description	This command configures an IP or IPv6 filter entry.
Parameters	<i>entry-id</i> — Specifies the entry ID.
Values	1 to 65535

action

Syntax	action <i>drop forward</i> no action
Context	config>filter>ip-filter>entry config>filter>ipv6-filter>entry
Description	This command configures actions for the IP or IPv6 filter entry.
Parameters	<i>drop forward</i> — Specifies the filter action.

tcp-mss-adjust

Syntax	tcp-mss-adjust
Context	config>filter>ip-filter>entry>action config>filter>ipv6-filter>entry>action
Description	This command configures the Maximum Segment Size (MSS) adjustment for TCP packets. The no form of the command disables adjusting TCP MSS values.

log

Syntax	log <i>log-id</i> no log
Context	config>filter>ip-filter>entry config>filter>ipv6-filter>entry
Description	This command configures the log for the IP or IPv6 filter entry.
Parameters	<i>log-id</i> — Specifies the log ID. Values 101 to 199

match

Syntax	match [next-header <i>next-header</i>] no match
Context	config>filter>ip-filter>entry config>filter>ipv6-filter>entry
Description	This command configures the match criteria for the IP or IPv6 filter entry.

Parameters	<i>next-header</i> — Specifies the protocol numbers accepted in DHB.
Values	[1 to 42 45 to 49 52 to 29 61 to 255]
Values	none crtp crudp egp eigrp encap ether-ip gre icmp idrp igmp igp ip ipv6 ipv6-icmp ipv6-no-nxt isis iso-ip l2tp ospf-igp pim pnni ptp rdp rsvp stp tcp udp vrrp * udp/tcp wildcard

dscp

Syntax	[no] dscp
Context	config>filter>ip-filter>entry>match config>filter>ipv6-filter>entry>match
Description	This command configures DSCP match condition.

dst-ip

Syntax	[no] dst-ip
Context	config>filter>ip-filter>entry>match config>filter>ipv6-filter>entry>match
Description	This command configures the destination IP or IPv6 address match condition.

dst-port

Syntax	[no] dst-port
Context	config>filter>ip-filter>entry>match config>filter>ipv6-filter>entry>match
Description	This command configures the destination port match condition.

icmp-code

Syntax	[no] icmp-code
Context	config>filter>ip-filter>entry>match config>filter>ipv6-filter>entry>match
Description	This command configures the ICMP code match condition.

icmp-type

Syntax	[no] icmp-type
Context	config>filter>ip-filter>entry>match config>filter>ipv6-filter>entry>match
Description	This command configures the ICMP type match condition.

src-ip

Syntax	[no] src-ip
Context	config>filter>ip-filter>entry>match config>filter>ipv6-filter>entry>match
Description	This command configures the source IP or IPv6 address match condition.

src-port

Syntax	[no] src-port
Context	config>filter>ip-filter>entry>match config>filter>ipv6-filter>entry>match
Description	This command configures the source port match condition.

tcp-ack

Syntax	[no] tcp-ack
Context	config>filter>ip-filter>entry>match config>filter>ipv6-filter>entry>match
Description	This command configures the TCP ACK match condition.

tcp-syn

Syntax	[no] tcp-syn
Context	config>filter>ip-filter>entry>match config>filter>ipv6-filter>entry>match
Description	This command configures the TCP SYN match condition.

group-inserted-entries

Syntax	group-inserted-entries <i>application application location location</i>
Context	config>filter>ip-filter config>filter>ipv6-filter
Description	This command groups auto-inserted entries.
Parameters	<i>application</i> — Specifies the application. Values radius, credit-control <i>location</i> — Specifies the location. Values top bottom

renum

Syntax	renum <i>old-entry-id new-entry-id</i>
Context	config>filter>ip-filter config>filter>ipv6-filter
Description	This command renumbers an IP or IPv6 filter entry.
Parameters	<i>old-entry-id</i> — Specifies the old entry ID to be renumbered. Values 1 to 65535 <i>new-entry-id</i> — Specifies the new entry ID. Values 1 to 65535

scope

Syntax	scope <i>exclusive template</i> no scope
Context	config>filter>ip-filter config>filter>ipv6-filter
Description	This command configures the scope for the IP or IPv6 filter.
Parameters	<i>exclusive template</i> — Specifies the type of policy.

shared-radius-filter-wmark

Syntax	shared-radius-filter-wmark low <i>low-watermark</i> high <i>high-watermark</i>
---------------	---

no shared-radius-filter-wmark

Context	config>filter>ip-filter config>filter>ipv6-filter
Description	This command defines the thresholds that will be used to raise a respective alarm when the number of shared filter copies increases.
Default	no shared-radius-filter-wmark
Parameters	<i>low-watermark</i> — specifies low threshold for the number of shared filter copies Values 0-8000 <i>high-watermark</i> — specifies high threshold for the number of shared filter copies Values 0-8000

sub-insert-radius

Syntax	sub-insert-radius start-entry <i>entry-id</i> count <i>count</i> no sub-insert-radius
Context	config>filter>ip-filter config>filter>ipv6-filter
Description	This command defines the range of filter entries which will be reserved for entries created based on information (match criteria and action) from RADIUS auth-response messages. The no version of the command disables the insertion, which means that information from auth-response messages cannot be stored in the filter, and the corresponding host will not be created in the system.
Default	per default insertion is disabled
Parameters	<i>entry-id</i> — An integer defining the lowest entry of the range. <i>count</i> — An integer defining the number of entries in the range.

sub-insert-credit-control

Syntax	sub-insert-credit-control start-entry <i>entry-id</i> count <i>count</i> no sub-insert-credit-control
Context	config>filter>ip-filter config>filter>ipv6-filter
Description	This command defines the range of filter entries that will be reserved for entries created based on information (match criteria and action) configured under the category-map configuration tree to enforce reduced-service level in case of credit exhaustion.

The **no** version of the command disables the insertion, which means that entries will not be installed even though the credit for the given category and subscriber-host has been exhausted.

Default per default insertion is disabled

Parameters *entry-id* — An integer defining the lowest entry of the range.
count — An integer defining the number of entries in the range.

sub-insert-shared-radius

Syntax **sub-insert-shared-radius start-entry** *entry-id* **count** *count*
no sub-insert-shared-radius

Context config>filter>ip-filter
config>filter>ipv6-filter
config>filter>ip-filter
config>filter>ipv6-filter

Description This command defines the range of filter entries that will be reserved for shared filter entries received in RADIUS messages.

The **no** version of the command disables the insertion resulting in a host setup failure when shared filter attributes are received in a RADIUS authentication response.

Default no sub-insert-shared-radius

Parameters *entry-id* — specifies the lowest entry of the range.

Values 1-65535

count — specifies the number of entries in the range.

Values 1-65535

sub-insert-wmark

Syntax **sub-insert-wmark** [**low** *percentage*] [**high** *percentage*]
no sub-insert-wmark

Context config>filter>ip-filter
config>filter>ipv6-filter

Description This command defines the thresholds that will be used to raise a respective alarm to provide monitoring of the resources for subscriber-specific filter insertion.

The **no** version of the command sets the default values for the respective thresholds.

Default low - 90%

high - 95%

Parameters *percentage* — Defines in percentage the threshold used to raise an alarm.
Values 1-100, integer

9.24.2.1.5 IGMP Policy Commands

Note: The commands described in this section apply only to the 7750 SR.

igmp-policy

Syntax **igmp-policy** *policy-name* [**create**]
no igmp-policy

Context config>sub-mgmt

Description This command configures an IGMP policy.

Parameters *policy-name* — Specifies the policy name.
Values 32 chars max

disable-router-alert-check

Syntax [**no**] **disable-router-alert-check**

Context config>sub-mgmt>igmp-policy

Description This command disables router alert checking for IGMP messages received on this interface. The **no** form of the command enables router alert checking.

egress-rate-modify

Syntax **egress-rate-modify** [**egress-rate-limit** | **scheduler** *scheduler-name*]
no egress-rate-modify

Context config>sub-mgmt>igmp-policy

Description This command is used to apply HQoS Adjustment to a subscriber. HQoS Adjustment is needed when multicast traffic flow for the subscriber is dissociated from subscriber host queues. Multicast redirection is typical such case although it can be applied in direct IPoE subscriber per-sap replication mode.

The channel bandwidth definition policy is defined in the mcac policy under the config>router>mcac>policy hierarchy. The policy is applied under the redirected interface or under the group-interface.

In order for HQoS Adjustment to take effect, sub-mcac-policy must be in a no shutdown mode and applied under the sub-profile even if mcac is not deployed.

Default	HQoS Adjustment is disabled.
Parameters	<p>egress-rate-limit — Subscriber's bandwidth is capped via the aggregate-rate-limit command in the sub-profile or via a Change of Authorization (CoA) request. This bandwidth cap will be dynamically adjusted according to the multicast channel definition and channel association with the host via IGMP.</p> <p>scheduler <i>scheduler-name</i> — Subscriber's bandwidth is capped via the scheduling-policy in the sub-profile or via a Change of Authorization (CoA) request. HQoS Adjustment will modify the rate of the scheduler (scheduler-name) defined in the scheduling-policy or configured via CoA.</p>

import

Syntax	import <i>policy-name</i> no import
Context	config>sub-mgmt>igmp-policy
Description	This command specifies the import policy to filter IGMP packets.
Parameters	<i>policy-name</i> — Specifies the policy name.
Values	32 chars max

max-num-groups

Syntax	max-num-groups <i>b</i> no max-num-groups
Context	config>sub-mgmt>igmp-policy
Description	This command configures the max number of multicast groups.
Parameters	<i>max-num-groups</i> — Specifies the maximum number of multicast groups.
Values	0 to 16000

max-num-sources

Syntax	max-num-sources <i>max-num-sources</i>
---------------	---

no max-num-sources

Context	config>sub-mgmt>igmp-policy
Description	This command configures the maximum number of multicast sources. The no form of the command disables the command.
Default	no max-num-sources
Parameters	<i>max-num-sources</i> — Specifies the maximum number of multicast sources. Values 1 to 1000

max-num-grp-sources

Syntax	max-num-grp-sources [<i>max-num-grp-sources</i>] no max-num-grp-sources
Context	config>sub-mgmt>igmp-policy config>sub-mgmt>msap-policy>igmp-host-tracking
Description	This command configures the maximum number of group sources for which IGMP can have local receiver information based on received IGMP reports on this interface. When this configuration is changed dynamically to a value lower than currently accepted number of group sources, the group sources that are already accepted are not deleted. Only new group sources will not be allowed. When this object has a value of 0, there is no limit to the number of group sources. The no form of the command removes the value from the configuration.
Default	no max-num-grp-sources
Parameters	<i>max-num-grp-sources</i> — Specifies the maximum number of multicast sources allowed to be tracked per group. Values 1 to 32000

mcast-reporting

Syntax	[no] mcast-reporting
Context	config>sub-mgmt>igmp-policy
Description	This command configures mcast reporting.

mcast-reporting-dest

Syntax	mcast-reporting-dest <i>dest-name</i> no mcast-reporting-dest
Context	config>subscriber-mgmt>igmp-policy>mcast-reporting> config>subscriber-mgmt>host-tracking-policy>mcast-reporting>
Description	<p>This command references Multicast Reporting Destination to which IGMP related events are exported.</p> <p>The Multicast Reporting Destination is referenced with the subscriber itself or within the Host-Tracking-Policy.</p>
Default	no mcast-reporting-dest is referenced.
Parameters	<i>dest-name</i> — Name of the Multicast Reporting Destination.

opt-reporting-fields

Syntax	opt-reporting-fields [host-mac] [pppoe-session-id] [svc-id] [sap-id] no opt-reporting-fields
Context	config>subscriber-mgmt>igmp-policy>mcast-reporting> config>subscriber-mgmt>host-tracking-policy>mcast-reporting>
Description	<p>This command will specify optional data relevant to the IGMP event that can be exported. This optional data includes:</p> <ul style="list-style-type: none">• Host MAC address• PPPoE session-ID• Service ID• SAP
Default	Optional data is disabled.
Parameters	<p>host-mac — Specifies the host-mac optional field should be included into the multicast reporting messages.</p> <p>pppoe-session-id — Specifies the pppoe-session-id optional field should be included into the multicast reporting messages.</p> <p>svc-id — Specifies the svc-id optional field should be included into the multicast reporting messages.</p> <p>sap-id — Specifies the sap-id optional field should be included into the multicast reporting messages.</p>
Output	

Sample Output

```
configure
  system
    security
      source-address
        application <app> <ip-int-name | ip-address>

<app>                : cflowd|dns|ftp|ntp|ping|radius|snmptrap|snmp|ssh|
                      syslog|tacplus|telnet|traceroute|mcreporter
<ip-int-name|ip-ad*> : ip-int-name    - 32 chars max
                      ip-address      - a.b.c.d
```

query-interval

Syntax	query-interval <i>seconds</i> no query-interval
Context	config>subscriber-mgmt>igmp-policy
Description	This command specifies the frequency at which the querier router transmits general host-query messages. Host-query messages solicit group membership information and are sent to the all-systems multicast group address, 224.0.0.1. If nothing is configured, by default, the query-interval takes the value defined in the config>router>igmp context or in the config>service>vprn>igmp context. It is highly recommended that all three query intervals be configured together on each IGMP policy.
Parameters	<i>seconds</i> — specifies the frequency, in seconds, at which the router transmits general host-query messages Values 2 to 1024

query-last-member-interval

Syntax	query-last-member-interval <i>seconds</i> no query-last-member-interval
Context	config>subscriber-mgmt>igmp-policy
Description	This command configures the frequency at which the querier router sends group-specific query messages, including the messages sent in response to leave-group messages. The shorter the interval, the faster a loss of the last member of a group can be detected. If nothing is configured, by default, the query-last-member-interval takes the value defined in the config>router>igmp context or the config>service>vprn>igmp context. It is highly recommended that all three query intervals be configured together on each IGMP policy.
Parameters	<i>seconds</i> — specifies the frequency, in seconds, at which query messages are sent Values 1 to 1024

query-response-interval

Syntax	query-response-interval <i>seconds</i> no query-response-interval
Context	config>subscriber-mgmt>igmp-policy
Description	This command configures the query response interval. If nothing is configured, by default, the query-response-interval takes the value defined in the config>router>igmp context or in the config>service>vprn>igmp context. It is highly recommended that all three query intervals be configured together on each IGMP policy.
Parameters	<i>seconds</i> — specifies the length of time that the querier router waits to receive a response to from the host Values 1 to 1023

sub-mcac-policy

Syntax	sub-mcac-policy <i>policy-name</i> no sub-mcac-policy
Context	config>subscr-mgmt
Description	<p>This command will create a policy template with mcac bandwidth limits that will be applied to the subscriber.</p> <p>Per interface mcac bandwidth limits will be set directly under the interface (regular interface or group-interface) and no such policy templates are needed.</p> <p>The need for a separate policy template for subscribers is due to the fact that sub-groups of subscribers under the group-interface can share certain settings that can be configured via templates.</p> <p>To summarize, the mcac bandwidth constraints for subscribers are defined in the sub-mcac-policy while the mcac bandwidth constraints for the interface are configured directly under the igmp>interface>mcac or igmp>grp-if>mcac context without the need for policy templates.</p> <div>Note: The sub-mcac-policy only deals with the mcac bandwidth limits and not the channel bandwidth definitions. Channels bandwidth is defined in a different policy (under the config>router>mcac hierarchy) and that policy is applied on the interface level as follows:</div> <p>In case of HQoS Adjustment, it is mandatory that the sub-mcac-policy be created and applied to the subscriber. The sub-mac-policy does not have to contain any bandwidth constrains, but it has to be in a no shutdown state in order for HQoS Adjustment to work.</p>
Default	No sub-mcac-policy is created.

Parameters *policy-name* — Name of the policy.

sub-mcac-policy

Syntax **sub-mcac-policy** *policy-name*
 no sub-mcac-policy

Context config>subscr-mgmt>sub-profile

Description This command references the policy template in which the mcac bandwidth limits are defined. Mcac for the subscriber is effectively enabled with this command when the sub-profile is applied to the subscriber. The bandwidth of the channels is defined in a different policy (under the config>router>mcac hierarchy) and this policy is applied on the interface level as follows:

 for regular interfaces under the config>service/router>igmp>interface>mcac hierarchy

 In case of HQoS Adjustment, it is mandatory that the sub-mcac-policy be created and applied to the subscriber. The sub-mac-policy does not have to contain any bandwidth constraints, but it has to be in a no shutdown state in order for HQoS Adjustment to work.

Default No policy is referenced.

Parameters *policy-name* — Name of the policy.

version

Syntax **version** *version*
 no version

Context config>sub-mgmt>igmp-policy

Description This command configures the version of IGMP.

Parameters *version* — Specifies the version of IGMP.

Values 1, 2 or 3

fast-leave

Syntax **[no] fast-leave**

Context config>sub-mgmt>igmp-policy

Description This command enables/disables IGMP fast-leave processing.

Default fast-leave

static

Syntax	static
Context	config>sub-mgmt>igmp-policy
Description	This command adds or removes IGMP static group membership.

per-host-replication

Syntax	per-host-replication [uni-mac mcast-mac] no per-host-replication
Context	config>subscr-mgmt>igmp-policy
Description	<p>This command enables per-host-replication in IPoE model. For PPPoX, per-host-replication is the only mode of operation. In the per-host-replication mode, multicast traffic is replicated per each host within the subscriber irrespective of the fact that some hosts may be subscribed to the same multicast stream. As a result, in case that multiple hosts within the subscriber are registered for the same multicast group, the multicast streams of that group will be generated. The destination MAC address of multicast streams will be changed to unicast so that each host receives its own copy of the stream. Multicast traffic in the per-host-replication mode can be classified via the existing QoS CLI structure. As such the multicast traffic will flow through the subscriber queues. HQoS Adjustment is not needed in this case.</p> <p>The alternative behavior for multicast replication in IPoE environment is per-SAP- replication. In this model, only a single copy of the multicast stream is sent per SAP, irrespective of the number of hosts that are subscribed to the same multicast group. This behavior applies to 1:1 connectivity model as well as on 1:N connectivity model (SAP centric behavior as opposed to subscriber centric behavior).</p> <p>In the per-SAP-replication model the destination MAC address is multicast (as opposed to unicast in the per-host-replication model). Multicast traffic is flowing via the SAP queue which is outside of the subscriber context. The consequence is that multicast traffic is not accounted in the subscriber HQoS. In addition, HQoS Adaptation is not supported in the per SAP replication model.</p>
Default	By default there is no per host replication and replication is done per SAP. This mode utilizes the SAP queues. With per-host-replication it will allow the use of the subscriber queues. Per-host-replication uses unicast MAC and multicast IP to deliver multicast content to end hosts. This is useful for multi host per SAP cases. To interoperate with end devices that do not support unicast MAC, there is an option to use per-host-replication with a multicast MAC. The traffic will be the same as replication per SAP but the difference of using the subscriber queues.
Parameters	uni-mac — Specifies that multicast traffic is sent with a unicast MAC and multicast IP. mcast-mac — Specifies that multicast traffic is sent with a multicast MAC and IP.

redirection-policy

Syntax	redirection-policy <i>policy-name</i> no redirection-policy
Context	config>sub-mgmt>igmp-policy
Description	<p>This command will apply multicast redirection action to the subscriber. The redirection action along with the redirected interface (and possibly service id) is defined in the referenced <i>policy-name</i>. IGMP messages will be redirected to an alternate interface if that alternate interface has IGMP enabled. The alternate interface does not have to have any multicast groups registered via IGMP. Currently all IGMP messages are redirected and there is no ability to selectively redirect IGMP messages based on match conditions (multicast-group address, source IP address, etc.). Multicast redirection is supported between VPRN services and also between interfaces within the Global Routing Context. Multicast Redirection is not supported between the VPRN services and the Global Routing Table (GRT).</p> <p>IGMP state is maintained per subscriber host and per redirected interface. Traffic is however forwarded only on the redirected interface.</p>
Default	none
Parameters	<i>policy-name</i> — This is a regular policy defined under the config>router>policy-option>policy-statement context.

group

Syntax	[no] group <i>ip-address</i>
Context	config>sub-mgmt>igmp-policy>static
Description	This command adds or removes a static multicast group.
Parameters	<i>ip-address</i> — Specifies the IP address.
Values	a.b.c.d

Host Lockout Commands

Note: The commands described in this section apply only to the 7750 SR.

host-key

Syntax	host-key { <i>mac</i> }
---------------	--------------------------------

	no host-key
Context	config>subscr-mgmt>host-lockout-plcy
Description	<p>This command specifies the parameters used in host identification for lockout on a given SAP or capture SAP:</p> <p>no host-key – include (MAC address, Circuit-Id, Remote-Id)</p> <p>host-key mac – include MAC address only</p> <p>“host-key mac” should be used in DHCPv4 scenarios where Circuit-Id and Remote-Id are changed with “dhcp option action replace” configuration: a host lockout context is created with the replaced Circuit-Id/Remote-Id; with the default host-key (including Circuit-Id and Remote-Id), lockout does not kick in on the original trigger packet when it is retransmitted by the client.</p> <p>Changing the host-key to mac should be used with care: all hosts with the same MAC address on a given SAP or capture SAP are identified as a single host with respect to host-lockout.</p> <p>The host-key command cannot be changed when the host-lockout-policy is referenced (i.e. configured under a SAP context).</p>
Default	no host-key
Parameters	mac — Specifies to use the MAC address only for host identification for lockout.

host-lockout-policy

Syntax	host-lockout-policy <i>policy-name</i> [create] no host-lockout-policy <i>policy-name</i>
Context	config>subscriber-mgmt
Description	<p>This command creates a host lockout policy. The policy contains set of host lockout configuration parameters. It is applied to SAP or MSAPs (by a MSAP-policy). Any change does not impact existing locked-out hosts, but only new incoming hosts that enter lockout.</p> <p>The no form of the command removes the policy name from the configuration. The policy must not be associated with any entity.</p>
Default	none
Parameters	<p><i>policy-name</i> — Specifies an existing host lockout policy to associate with the SAP.</p> <p>create — Keyword used to create the host lockout policy. The create keyword requirement can be enabled/disabled in the environment>create context.</p>

ies

Syntax	ies <i>service-id</i> customer <i>customer-id</i> [vpn <i>vpn-id</i>] [create]
Context	config>service
Description	<p>This command enables the context to configure or edit an IES service instance. The ies command is used to create or maintain an Internet Enhanced Service (IES). If the <i>service-id</i> does not exist, a context for the service is created. If the <i>service-id</i> exists, the context for editing the service is entered.</p> <p>For further information about the vpls command usage, syntax and description, refer to the Layer 3Services Guide.</p>

vpls

Syntax	vpls <i>service-id</i>
Context	config>service
Description	<p>This command enables the context to configure or edit a Virtual Private LAN Services (VPLS) instance. The vpls command is used to create or maintain a VPLS service. If the <i>service-id</i> does not exist, a context for the service is created. If the <i>service-id</i> exists, the context for editing the service is entered.</p> <p>For further information about the vpls command usage, syntax and description, refer to the Layer 2 Services Guide.</p>

vprn

Syntax	vprn <i>service-id</i> [customer <i>customer-id</i>] [create]
Context	config>service
Description	<p>This command creates or edits a Virtual Private Routed Network (VPRN) service instance. If the <i>service-id</i> does not exist, a context for the service is created. If the <i>service-id</i> exists, the context for editing the service is entered.</p> <p>For further information about the vprn command usage, syntax and description, refer to the Layer 3Services Guide.</p>

interface

Syntax	[no] interface <i>ip-int-name</i>
Context	config>service>ies config>service>vprn

Description	<p>This command creates a logical IP routing interface for an Layer 3 service. Once created, attributes like an IP address and service access point (SAP) can be associated with the IP interface.</p> <p>For further information about the interface command usage, syntax and description, refer to the Layer 3 Services Guide.</p>
Default	none
Parameters	<i>ip-int-name</i> — Specifies the name of the IP interface. Interface names must be unique within the group of defined IP interfaces for config router interface and config service vprn interface commands. An interface name cannot be in the form of an IP address. Interface names can be from 1 to 32 alphanumeric characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

sap

Syntax	[no] sap <i>sap-id</i>
Context	config>service>ies config>service>vprn config>service>ies>if config>service>vprn>if config>service>ies>sub-if config>service>vprn>sub-if
Description	<p>This command creates a Service Access Point (SAP) within a service. A SAP is a combination of port and encapsulation parameters which identifies the service access point on the interface and within the router. Each SAP must be unique.</p> <p>For further information about the sap command usage, syntax and description, refer to the Layer 2 Services Guide and the Layer 3 Services Guide.</p>

cflowd

Syntax	cflowd { acl interface }
Context	config>service>ies>if
Description	<p>This command enables cflowd to collect traffic flow samples through a router for analysis. cflowd is used for network planning and traffic engineering, capacity planning, security, application and user profiling, performance monitoring, usage-based billing, and SLA measurement. When Triple Play Service Delivery Architecture 7750 SR Triple Play Service Delivery Architecture Page 109 cflowd is enabled at the interface level, all packets forwarded by the interface are subjected to analysis according to the cflowd configuration.</p>
Default	no cflowd

- Parameters**
- act** — Specifies to include the cflowd configuration associated with a filter.
 - interface** — Specifies to include the cflowd configuration associated with an interface.

host-lockout-policy

- Syntax** **host-lockout-policy** *policy-name*
no host-lockout-policy
- Context** config>service>ies>if>sap
config>service>ies>sub-if>sap
config>service>vpls>sap
config>service>vprn>if>sap
config>service>vprn>sub-if>sap
- Description** This command selects an existing host lockout policy. The **host-lockout-policy** *policy-name* is created in the **config>subscriber-mgmt** context.
- The **no** form of the command removes the policy name from the SAP configuration.
- Default** none
- Parameters** *policy-name* — Specifies an existing host lockout policy to associate with the SAP.

lockout-time

- Syntax** **lockout-time** [*min seconds*] [*max seconds*]
no lockout-time
- Context** config>subscriber-mgmt>host-lockout-policy
- Description** This command configures the time for which a client stays in the lockout state during which authentication and ESM host creation is suppressed. The range for the min and max lockout times is 1 second to 86400 seconds. The min time defaults to 10 seconds, and max time defaults to 3600 seconds.
- The no form of the command reverts to the default value.
- Parameters** **min** *seconds* — specifies the minimum lockout-time for this host lockout policy.
- Values** 1 to 86400
- Default** 10 seconds
- max** *seconds* — specifies the maximum lockout-time for this host lockout policy.
- Values** 1 to 86400
- Default** 3600 seconds

lockout-reset-time

Syntax	lockout-reset-time <i>seconds</i> no lockout-reset-time
Context	config>subscriber-mgmt>host-lockout-policy
Description	<p>This command configures the time that needs to elapse from the point a client enters lockout to when the client's lockout time can be reset to the configured minimum value. The range is 1 sec</p> <p>The no form of the command reverts to the default value.</p>
Parameters	<i>seconds</i> — Specifies the lockout reset time in seconds.
	Values 1 to 86400
	Default 60 seconds

max-lockout-hosts

Syntax	max-lockout-hosts <i>hosts</i> no max-lockout-hosts
Context	config>subscriber-mgmt>host-lockout-policy
Description	<p>When a client enters lockout, authentication and ESM host creation is suppressed. A lightweight context maintains the lockout state and the timeouts for the client in lockout. This command allows the number of lockout contexts to be configured per SAP. If the number of existing contexts reaches the configured count, incoming hosts that fail authentication or creation are not subject to lockout, and are retired as normal.</p> <p>The no form of the command reverts to the default value.</p>
Parameters	<i>hosts</i> — Specifies the maximum number of lockout hosts.
	Values 1 to 32000
	Default 100

host-tracking-policy

Syntax	host-tracking-policy <i>policy-name</i> [create] no host-tracking-policy <i>policy-name</i>
Context	config>subscr-mgmt config>subscr-mgmt>sub-prof

Description	This command configures a host tracking policy. IGMP host tracking is an option in the subscriber profile that allows the factoring in of a subscriber's (multicast) video traffic by reducing the unicast operational egress aggregate rate or the rate of the scheduler specified in the ANCP policy to account for a subscriber's multicast traffic. If no ANCP policy is defined, the egress aggregate rate configured in the subscriber profile is reduced. If an ANCP policy is defined, the "rate-modify" parameter in the policy specifies whether the egress aggregate rate or the rate of the egress policer specified in the policy is to be reduced to account for the subscriber's multicast traffic.
Default	disabled

egress-rate-modify

Syntax	egress-rate-modify agg-rate-limit egress-rate-modify scheduler <i>scheduler-name</i> no egress-rate-modify
Context	config>subscr-mgmt>trk-plcy
Description	This command specifies the egress-rate modification that is to be applied.
Parameters	agg-rate-limit — Specifies the egress rate limit. scheduler <i>scheduler-name</i> — Specifies the scheduler name to use.

9.24.2.1.6 PIM Policy Commands

pim-policy

Syntax	pim-policy <i>pim-policy-name</i> [create] no pim-policy <i>pim-policy-name</i>
Context	config>subscr-mgmt
Description	This command creates a PIM policy or enables the context to configure a PIM policy. The no form of this command deletes the specified PIM policy.
Default	none
Parameters	<i>pim-policy-name</i> — Specifies the PIM policy name. Values Valid names consist of any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes. create — Keyword used to create the PIM policy. The create keyword requirement can be enabled/disabled in the environment>create context.

9.24.2.1.7 Managed SAP Policy Commands

msap-policy

Syntax	msap-policy <i>msap-policy-name</i> [create] no msap-policy <i>msap-policy-name</i>
Context	config>subscr-mgmt
Description	This command configures a managed SAP policy. Managed SAPs allow the use of policies and a SAP template for the creation of a SAP.
Default	none
Parameters	<i>msap-policy-name</i> — Specifies the managed SAP policy name. Values Valid names consist of any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes. create — Keyword used to create the managed SAP policy. The create keyword requirement can be enabled/disabled in the environment>create context.

cpu-protection

Syntax	cpu-protection
Context	config>sys>security config>service>vprn>sub-if>grp-if>sap
Description	This command enables the context to configure CPU protection policies.

cpu-protection

Syntax	cpu-protection <i>policy-id</i> [mac-monitoring] no cpu-protection
Context	config>subscr-mgmt>msap-policy [mac-monitoring] config>service>ies>sub-if>grp-if>sap [mac-monitoring] config>service>vpls>sap [mac-monitoring] config>service>vprn>sub-if>grp-if>sap [mac-monitoring]
Description	<p>This command assigns an existing CPU protection policy to the SAP or interface.</p> <p>CPU protection policies are configured in the config>sys>security>cpu-protection context.</p> <p>The no form of the command removes the policy ID from the SAP or interface configuration.</p>
Default	none
Parameters	<i>policy-id</i> — Specifies an existing CPU protection policy to assign to the SAP or interface. mac-monitoring — Specifies that the per-source rate limit be applied.

cpu-protection

Syntax	cpu-protection <i>policy-id</i> no cpu-protection
Context	config>router>if config>service>ies>if config>service>vprn>if
Description	<p>This command assigns an existing CPU protection policy to the SAP or interface.</p> <p>CPU protection policies are configured in the config>sys>security>cpu-protection context.</p> <p>The no form of the command removes the policy ID from the SAP or interface configuration.</p>
Default	none

Parameters *policy-id* — Specifies an existing CPU protection policy to assign to the SAP.

default-host

Syntax **default-host** *ip-address/mask* **next-hop** *next-hop-ip*
no default-host

Context config>service>ies>sub-if>grp-if>sap
 config>service>vprn>sub-if>grp-if>sap

Description This command configures the default-host to be used. More than one default-host can be configured per SAP.

 The **no** form of the command removes the values from the configuration.

Parameters *ip-address/mask* — Assigns an IP address/IP subnet format to the interface.
 next-hop *next-hop-ip* — Assigns the next hop IP address.

dist-cpu-protection

Syntax **dist-cpu-protection** *policy-name*
no dist-cpu-protection

Context config>subscriber-management>msap-policy

Description This command assigns a Distributed CPU Protection (DCP) policy to the MSAP policy. The DCP policy will automatically get assigned to any MSAPs created with this policy. A non-existent DCP policy can be assigned to an msap-policy since an msap-policy is effectively a template that gets applied at some point in the future during msap creation. The existence of the DCP policy will be validated at the time that the msap is created, and the msap creation will be blocked (and an appropriate log event created) if the DCP policy does not exist.

Note: For other types of objects (for example, normal non-msap SAPs and network interfaces) the DCP policy must exist before it can be assigned to the SAP.

Default no dist-cpu-protection

ies-vprn-only-sap-parameters

Syntax **ies-vprn-only-sap-parameters**

Context config>subscr-mgmt>msap-policy

Description	This command configures Managed SAP IES and VPRN properties. VPRN services are supported on the 7750 SR only.
--------------------	---

igmp-host-tracking

Syntax	igmp-host-tracking
Context	config>subscr-mgmt>msap-policy
Description	This command enables the context to configure IGMP host tracking parameters.

disable-router-alert-check

Syntax	[no] disable-router-alert-check
Context	config>service>vprn>sub-if>grp-if>sap>igmp-host-tracking
Description	This command enables the IGMP router alert check option. The no form of the command disables the router alert check.

expiry-time

Syntax	expiry-time <i>expiry-time</i> no expiry-time
Context	config>subscr-mgmt>msap-policy>igmp-host-tracking
Description	This command configures the time that the system continues to track inactive hosts. The no form of the command removes the values from the configuration.
Default	no expiry-time
Parameters	<i>expiry-time</i> — Specifies the time, in seconds, that this system continues to track an inactive host. Values 1 to 65535

import

Syntax	import <i>policy-name</i> no import
Context	config>subscr-mgmt>msap-policy>igmp-host-tracking

Description	This command specifies the import routing policy to be used for IGMP packets to be used on this SAP or SDP. Only a single policy can be imported on a single SAP at any time. The no form of the command removes the policy association from the SAP or SDP.
Default	no import (No import policy is specified)
Parameters	<i>policy-name</i> — The routing policy name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters excluding double quotes. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes. Routing policies are configured in the config>router>policy-options context The router policy must be defined before it can be imported.

max-num-group

Syntax	max-num-groups <i>max-num-groups</i> no max-num-groups
Context	config>subscr-mgmt>msap-policy>igmp-host-tracking
Description	This command configures the maximum number of multicast groups allowed to be tracked. The no form of the command removes the values from the configuration.
Default	no max-num-groups
Parameters	<i>max-num-groups</i> — Specifies the maximum number of multicast groups allowed to be tracked. Values 1 to 196607

max-num-sources

Syntax	max-num-sources <i>max-num-sources</i> no max-num-sources
Context	config>subscr-mgmt>msap-policy>igmp-host-tracking
Description	This command configures the maximum number of multicast sources allowed to be tracked per group. The no form of the command removes the value from the configuration.
Parameters	<i>max-num-sources</i> — Specifies the maximum number of multicast sources allowed to be tracked per group. Values 1 to 1000

max-num-grp-sources

Syntax	max-num-grp-sources [<i>max-num-grp-sources</i>] no max-num-grp-sources
Context	config>subscr-mgmt>msap-policy>igmp-host-tracking
Description	<p>This command configures the maximum number of group sources for which IGMP can have local receiver information based on received IGMP reports on this interface. When this configuration is changed dynamically to a value lower than currently accepted number of group sources, the group sources that are already accepted are not deleted. Only new group sources will not be allowed. When this object has a value of 0, there is no limit to the number of group sources.</p> <p>The no form of the command removes the value from the configuration.</p>
Default	no max-num-grp-sources
Parameters	<i>max-num-grp-sources</i> — Specifies the maximum number of multicast sources allowed to be tracked per group. Values 1 to 32000

lag-link-map-profile

Syntax	lag-link-map-profile <i>link-map-profile-id</i> no lag-link-map-profile
Context	config>subscr-mgmt>msap-policy
Description	<p>This command assigns a pre-configured lag link map profile to a SAP/network interface configured on a LAG or a PW port that exists on a LAG. Once assigned/de-assigned, the SAP/network interface egress traffic will be re-hashed over LAG as required by the new configuration.</p> <p>The no form of this command reverts the SAP/network interface to use per-flow, service or link hash as configured for the service/LAG.</p>
Default	no lag-link-map-profile
Parameters	<i>link-map-profile-id</i> — An integer from 1 to 32 that defines a unique lag link map profile on which the LAG the SAP/network interface exist.

sticky

Syntax	[no] sticky
Context	config>subscr-mgmt>msap-policy

Description	This command prevents MSAPs associated with the specified MSAP policy from being deleted unless a manual clear command is issued. If this command is not enabled, an MSAP is deleted when a host creation fails or when a subscriber is no longer associated with the MSAP, for example, when a subscriber ends the session. This feature is useful for an operator who wants to keep historical statistics records on MSAPs. It can also speed up host creation on an MSAP since the MSAP is already created.
Default	no sticky

sub-sla-mgmt

Syntax	[no] sub-sla-mgmt
Context	config>subscr-mgmt>msap-policy config>service>vprn>sub-if>grp-if>sap>sub-sla-mgmt config>service>vpls>sap>sub-sla-mgmt
Description	This command enables the context to configure subscriber management parameters for an MSAP.
Default	no sub-sla-mgmt

def-app-profile

Syntax	def-app-profile <i>app-profile-name</i> no def-app-profile
Context	config>service>ies>sub-if>grp-if>sap>sub-sla-mgmt config>service>ies>sub-if>grp-if>sap-param>sub-sla-mgmt config>service>vprn>sub-if>grp-if>sap>sub-sla-mgmt config>service>vprn>sub-if>grp-if>sap-param>sub-sla-mgmt config>service>vpls>sap>sub-sla-mgmt
Description	This command specifies the application profile to be used by a subscriber host. The no form of the command removes the application profile name from the configuration.
Default	no def-app-profile
Parameters	<i>app-profile-name</i> — Specifies an existing application profile to be mapped to the subscriber profile by default.

def-inter-dest-id

Syntax	def-inter-dest-id { string <i>string</i> use-top-q } no def-inter-dest-id
---------------	--

Context	config>subscr-mgmt>msap-policy>sub-sla-mgmt
Description	<p>This command specifies a default destination string for all subscribers associated with the SAP. The command also accepts the use-top-q flag that automatically derives the string based on the top most delineating Dot1Q tag from the SAP's encapsulation.</p> <p>The no form of the command removes the default subscriber identification string from the configuration.</p>
Default	no def-inter-dest-id
Parameters	<p>use-top-q — Derives the string based on the top most delineating Dot1Q tag from the SAP's encapsulation.</p> <p>string <i>string</i> — Specifies the subscriber identification applicable for a subscriber host.</p>

def-sub-id

Syntax	def-sub-id use-auto-id def-sub-id use-sap-id def-sub-id string <i>sub-id</i> no def-sub-id
Context	config>subscr-mgmt>msap-policy>sub-sla-mgmt config>service>ies>sub-if>grp-if>sap>sub-sla-mgmt config>service>ies>sub-if>grp-if>sap-param>sub-sla-mgmt config>service>vprn>sub-if>grp-if>sap>sub-sla-mgmt config>service>vprn>sub-if>grp-if>sap-param>sub-sla-mgmt config>service>vpls>sap>sub-sla-mgmt
Description	<p>This command specifies the explicit default sub-id for dynamic subscriber hosts (including ARP hosts) in case that the sub-id string is NOT supplied through RADIUS or LUDB.</p> <p>The sub-id is assigned to a new subscriber host in the following order of priority:</p> <ul style="list-style-type: none">• RADIUS• LUDB• Explicit default – the def-sub-id command is used to explicitly set the sub-id name of the host as one of the following:<ul style="list-style-type: none">– The sap-id to which the new host is associated with– Explicit string– Auto-generated string consisting of the concatenated subscriber identification fields defined under the subscr-mgmt>auto-sub-id-key node. The fields are taken in the order in which they are configured and are separated by a ' ' character. The subscriber host identification fields are separately defined for IPoE and PPPoE host types.

- Implicit default – in case that the sub-id string is not returned via RADIUS or LUDB and there is no def-sub-id configured, the sub-id name will be generated as a random 10 character encoded string based on the auto-sub-id-keys. This 10 characters encoded string will be unique per chassis as well as in dual-homed environment. It is generated based on auto-sub-id-keys. If auto-sub-id-keys are not explicitly configured, the default ones are:
 - <mac, sap-id, session-id> for PPP type hosts
 - <mac, sap-id> for IPoE type hosts.

This command does not apply to static subscribers.

Parameters **use-sap-id** — Specifies the sub-id name-id on which the original request for host creation arrived (DHCP Discover, or PADI or ARP Request).

string *sub-id* — Explicitly configured sub-id name.

use-auto-id — The sub-id name is the concatenated string of auto-sub-id-keys separated by a “|” character.

Default no def-sub-id

Implicit default If the sub-id string is not supplied through RADIUS, LUDB, or **def-sub-id** configuration, then a random 10 character encoded sub-id name will be generated. This random sub-id name will be based on the subscriber identification keys defined under the **subscr-mgmt>auto-sub-id-key** node. In case that the auto-sub-id-keys are not defined explicitly, the default ones are:

- <mac, sap-id, session-id> for PPPoE type hosts
- <mac, sap-id> for IPoE type hosts

def-sla-profile

Syntax **def-sla-profile** *default-sla-profile-name*
no def-sla-profile

Context config>subscr-mgmt>msap-policy>sub-sla-mgmt

Description This command specifies a default SLA profile for an MSAP.

An SLA profile is a named group of QoS parameters used to define per service QoS for all subscriber hosts common to the same subscriber within a provider service offering. A single SLA profile may define the QoS parameters for multiple subscriber hosts.

The **no** form of the command removes the default SLA profile from the MSAP configuration.

Default no def-sla-profile

Parameters *default-sla-profile-name* — Specifies a default SLA profile for an MSAP.

def-sub-profile

Syntax	def-sub-profile <i>default-subscriber-profile-name</i>
Context	config>subscr-mgmt>msap-policy>sub-sla-mgmt
Description	<p>This command specifies a default subscriber profile for an MSAP.</p> <p>A subscriber profile defines the aggregate QoS for all hosts within a subscriber context. This is done through the definition of the egress and ingress scheduler policies that govern the aggregate SLA for subscriber using the subscriber profile.</p> <p>The no form of the command removes the default SLA profile from the SAP configuration.</p>
Parameters	<i>default-sub-profile</i> — Specifies a default subscriber profile for this SAP.

multi-sub-sap

Syntax	multi-sub-sap [<i>limit limit</i>] no multi-sub-sap
Context	config>subscr-mgmt>msap-policy>sub-sla-mgmt
Description	<p>This command defines the maximum number of subscribers (dynamic + static) that can be simultaneously active on an MSAP.</p> <p>If the limit is reached, a new host will be denied access and the corresponding DHCP ACK will be dropped.</p> <p>The no form of the command reverts back to the default setting.</p>
Default	1
Parameters	<i>limit</i> — Specifies the maximum allowed.

Note: The operational maximum value may be smaller due to equipped hardware dependencies.

Values 1 to 131071

single-sub-parameters

Syntax	single-sub-parameters
Context	config>subscr-mgmt>msap-policy>sub-sla-mgmt

Description This command enables the context to configure single subscriber MSAP parameters.

non-sub-traffic

Syntax **non-sub-traffic sub-profile** *sub-profile-name* **sla-profile** *sla-profile-name* [**subscriber** *sub-ident-string*] [**app-profile** *app-profile-name*]
no non-sub-traffic

Context config>subscr-mgmt>msap-policy>sub-sla-mgmt>single-sub

Description This command configures traffic profiles for non-IP traffic such as PPPoE. It is used in conjunction with the profiled-traffic-only on single subscriber SAPs and creates a subscriber host which is used to forward non-IP traffic through the single subscriber SAP without the need for SAP queues.

The **no** form of the command removes any configured profile.

Default no non-sub-traffic

Parameters *sub-profile-name* — Identifies the subscriber profile name.
Values 32 characters maximum
sla-profile-name — Identifies the SLA profile name.
Values 32 characters maximum

profiled-traffic-only

Syntax [**no**] **profiled-traffic-only**

Context config>subscr-mgmt>msap-policy>sub-sla-mgmt>single-sub

Description This command specifies whether only profiled traffic is applicable for an MSAP. When enabled, all queues will be deleted.

The **no** form of the command reverts to the default setting.

Default no profiled-traffic-only

sub-ident-policy

Syntax [**no**] **sub-ident-policy** *sub-ident-policy-name*

Context config>subscr-mgmt>msap-policy>sub-sla-mgmt

Description	<p>This command specifies an existing subscriber identification policy. Each subscriber identification policy can have a default subscriber profile defined. The subscriber identification policy default subscriber profile overrides the system default and the subscriber SAP default subscriber profiles. Defining a subscriber identification policy default subscriber profile is optional.</p> <p>Defining a subscriber profile as a subscriber identification policy default subscriber profile will cause all active subscribers currently associated with a subscriber SAP using the policy and associated with a subscriber policy through the system default or subscriber SAP default subscriber profiles to be reassigned to the subscriber policy defined as default on the subscriber identification policy.</p> <p>Attempting to delete a subscriber profile that is currently defined as a default for a subscriber identification policy will fail.</p> <p>When attempting to remove a subscriber identification policy default subscriber profile definition, the system will evaluate each active subscriber on all subscriber SAPs the subscriber identification policy is currently associated with that are using the default definition to determine whether the active subscriber can be either reassigned to a subscriber SAP default or the system default subscriber profile. If all active subscribers cannot be reassigned, the removal attempt will fail.</p>
Parameters	<i>sub-ident-policy-name</i> — Specifies the name of the subscriber identification policy.

vpls-only-sap-parameters

Syntax	vpls-only-sap-parameters
Context	config>subscr-mgmt>msap-policy
Description	This command enables the context to configure MSAP VPLS properties.

arp-host

Syntax	arp-host
Context	config>subscr-mgmt>msap-policy>vpls-only config>service>vpls>sap>arp-host config>service>ies>sub-if>grp-if config>service>vprn>sub-if>grp-if
Description	This command enables the context to configure ARP host parameters.

host-limit

Syntax	host-limit <i>max-num-hosts</i>
---------------	--

no host-limit

Context	config>subscr-mgmt>msap-policy>vpls-only>arp-host config>service>vpls>sap>arp-host config>service>ies>sub-if>grp-if>arp-host config>service>vprn>sub-if>grp-if>arp-host
Description	This command configures the maximum number of ARP hosts.
Parameters	<i>max-num-hosts</i> — Specifies the maximum number of ARP hosts.

Note: The operational maximum value may be smaller due to equipped hardware dependencies.

Values 1 to 131071

min-auth-interval

Syntax	min-auth-interval <i>min-auth-interval</i> no min-auth-interval
Context	config>subscr-mgmt>msap-policy>vpls-only config>service>vpls>sap>arp-host config>service>ies>sub-if>grp-if config>service>vprn>sub-if>grp-if>arp-host
Description	This command configures the minimum authentication interval.
Parameters	<i>min-auth-interval</i> — Specifies the minimum authentication interval.

Values 1 to 6000

sap-host-limit

Syntax	sap-host-limit <i>max-num-hosts-sap</i> no sap-host-limit
Context	config>service>ies>sub-if>grp-if>arp-host config>service>vprn>sub-if>grp-if>arp-host
Description	This command configures the maximum number of ARP hosts per SAP.
Parameters	<i>max-num-hosts-sap</i> — Specifies the maximum number of ARP hosts per SAP allowed on this IES interface.

Note: The operational maximum value may be smaller due to equipped hardware dependencies.

Values 1 to 131071

arp-reply-agent

Syntax	arp-reply-agent [sub-ident] no arp-reply-agent
Context	config>subscr-mgmt>msap-policy>vpls-only
Description	<p>This command enables a special ARP response mechanism in the system for ARP requests destined to static or dynamic hosts associated with the SAP. The system responds to each ARP request using the hosts MAC address as the both the source MAC address in the Ethernet header and the target hardware address in the ARP header.</p> <p>ARP replies and requests received on an MSAP with arp-reply-agent enabled will be evaluated by the system against the anti-spoof filter entries associated with the ingress SAP (if the SAP has anti-spoof filtering enabled). ARPs from unknown hosts on the SAP will be discarded when anti-spoof filtering is enabled.</p> <p>The ARP reply agent only responds if the ARP request enters an interface (SAP, spoke-SDP or mesh-SDP) associated with the VPLS instance of the MSAP.</p> <p>A received ARP request that is not in the ARP reply agent table is flooded to all forwarding interfaces of the VPLS capable of broadcast except the ingress interface while honoring split-horizon constraints.</p> <p>Static hosts can be defined using the host command. Dynamic hosts are enabled on the system by enabling the lease-populate command in the dhcp context. In the event that both a static host and a dynamic host share the same IP and MAC address, the VPLS ARP reply agent will retain the host information until both the static and dynamic information are removed. In the event that both a static and dynamic host share the same IP address, but different MAC addresses, the VPLS ARP reply agent is populated with the static host information.</p> <p>The arp-reply-agent command will fail if an existing static host does not have both MAC and IP addresses specified. Once the ARP reply agent is enabled, creating a static host on the MSAP without both an IP address and MAC address will fail.</p> <p>The ARP-reply-agent may only be enabled on SAPs supporting Ethernet encapsulation.</p> <p>The no form of the command disables ARP-reply-agent functions for static and dynamic hosts on the MSAP.</p>
Default	not enabled

Parameters	<p>sub-ident — Configures the arp-reply-agent to discard ARP requests received on the MSAP that are targeted for a known host on the same MSAP with the same subscriber identification.</p> <p>Hosts are identified by their subscriber information. For DHCP subscriber hosts, the subscriber hosts, the subscriber information is configured using the optional subscriber parameter string.</p> <p>When arp-reply-agent is enabled with sub-ident:</p> <ul style="list-style-type: none">• If the subscriber information for the destination host exactly matches the subscriber information for the originating host and the destination host is known on the same MSAP as the source, the ARP request is silently discarded.• If the subscriber information for the destination host or originating host is unknown or undefined, the source and destination hosts are not considered to be the same subscriber. The ARP request is forwarded outside the MSAP's Split Horizon Group.• When sub-ident is not configured, the arp-reply-agent does not attempt to identify the subscriber information for the destination or originating host and will not discard an ARP request based on subscriber information.
-------------------	---

dhcp

Syntax	dhcp
Context	config>subscr-mgmt>msap-policy>vpls-only
Description	This command enables the context to configure DHCP parameters.

option

Syntax	[no] option
Context	config>subscr-mgmt>msap-policy>vpls-only>dhcp config>service>ies>sub-if>dhcp
Description	<p>This command enables DHCP Option 82 (Relay Agent Information Option) parameters processing and enters the context for configuring Option 82 sub-options.</p> <p>The no form of this command returns the system to the default.</p>
Default	no option

action

Syntax	action {replace drop keep} no action
---------------	---

Context	config>subscr-mgmt>msap-policy>vpls-only>dhcp>option
Description	<p>This command configures the Relay Agent Information Option (Option 82) processing.</p> <p>The no form of this command returns the system to the default value.</p>
Default	The default is to keep the existing information intact.
Parameters	<p>replace — In the upstream direction (from the user), the Option 82 field from the router is inserted in the packet (overwriting any existing Option 82 field). In the downstream direction (towards the user) the Option 82 field is stripped (in accordance with RFC 3046).</p> <p>drop — The DHCP packet is dropped if an Option 82 field is present, and a counter is incremented.</p> <p>keep — The existing information is kept in the packet and the router does not add any additional information. In the downstream direction the Option 82 field is not stripped and is forwarded towards the client.</p>

circuit-id

Syntax	circuit-id [ascii-tuple vlan-ascii-tuple] no circuit-id
Context	config>subscr-mgmt>msap-policy>vpls-only>dhcp>option
Description	<p>When enabled, the router sends an ASCII-encoded tuple in the circuit-id sub-option of the DHCP packet. This ASCII-tuple consists of the access-node-identifier, service-id, and SAP-ID, separated by “ ”.</p> <p>If disabled, the circuit-id sub-option of the DHCP packet will be left empty.</p> <p>The no form of this command returns the system to the default.</p>
Default	circuit-id
Parameters	<p>ascii-tuple — Specifies that the ASCII-encoded concatenated tuple consisting of the access-node-identifier, service-id, and interface-name is used.</p> <p>vlan-ascii-tuple — Specifies that the format will include VLAN-id and dot1p bits in addition to what is included in ascii-tuple already. The format is supported on dot1q and qinq ports only. Thus, when the option 82 bits are stripped, dot1p bits will be copied to the Ethernet header of an outgoing packet.</p>

vendor-specific-option

Syntax	[no] vendor-specific-option
Context	config>subscr-mgmt>msap-policy>vpls-only>dhcp>option

```
config>service>ies>sub-if>dhcp
```

Description This command configures the Nokia vendor-specific sub-option of the DHCP relay packet.

client-mac-address

Syntax [no] client-mac-address

Context config>subscr-mgmt>msap-policy>vpls-only>dhcp>option>vendor
config>service>ies>sub-if>dhcp>option

Description This command enables the sending of the MAC address in the Nokia vendor-specific sub-option of the DHCP relay packet.

The **no** form of the command disables the sending of the MAC address in the Nokia vendor-specific sub-option of the DHCP relay packet.

sap-id

Syntax [no] sap-id

Context config>subscr-mgmt>msap-policy>vpls-only>dhcp>option>vendor
config>service>ies>sub-if>dhcp>option

Description This command enables the sending of the SAP ID in the ANokia vendor-specific sub-option of the DHCP relay packet.

The **no** form of the command disables the sending of the SAP ID in the Nokia vendor-specific sub-option of the DHCP relay packet.

service-id

Syntax [no] service-id

Context config>subscr-mgmt>msap-policy>vpls-only>dhcp>option>vendor
config>service>ies>sub-if>dhcp>option

Description This command enables the sending of the service ID in the Nokia vendor-specific sub-option of the DHCP relay packet.

The **no** form of the command disables the sending of the service ID in the Nokia vendor-specific sub-option of the DHCP relay packet.

string

Syntax	[no] string <i>text</i>
Context	config>subscr-mgmt>msap-policy>vpls-only>dhcp>option>vendor config>service>ies>sub-if>dhcp>option
Description	This command specifies the string in the Nokia vendor-specific sub-option of the DHCP relay packet. The no form of the command returns the default value.
Parameters	<i>text</i> — The string can be any combination of ASCII characters up to 32 characters in length. If spaces are used in the string, enclose the entire string in quotation marks (" ").

system-id

Syntax	[no] system-id
Context	config>subscr-mgmt>msap-policy>vpls-only>dhcp>option>vendor config>service>ies>sub-if>dhcp>option
Description	This command specifies whether the system-id is encoded in the ANokia vendor-specific sub-option of Option 82.

emulated-server

Syntax	emulated-server <i>ip-address</i> no emulated-server
Context	config>subscr-mgmt>msap-policy>vpls-only>dhcp>proxy config>service>ies>sub-if>dhcp
Description	This command configures the IP address which will be used as the DHCP server address in the context of the MSAP. Typically, the configured address should be in the context of the subnet represented by the service. The no form of this command reverts to the default setting. The local proxy server will not become operational without the emulated-server address being specified.
Parameters	<i>ip-address</i> — Specifies the emulated server's IP address. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).

lease-time

Syntax	lease-time [days <i>days</i>] [hrs <i>hours</i>] [min <i>minutes</i>] [sec <i>seconds</i>] [override] no lease-time
Context	config>subscr-mgmt>msap-policy>vpls-only>dhcp>proxy config>service>ies>sub-if>dhcp
Description	<p>This command defines the length of lease-time that will be provided to DHCP clients. By default the local-proxy-server will always make use of the lease-time information provide by either a RADIUS or DHCP server.</p> <p>The no form of this command disables the use of the lease-time command. The local-proxy-server will use the lease-time offered by either a RADIUS or DHCP server.</p>
Default	7 days 0 hours 0 seconds
Parameters	<p>override — Specifies that the local-proxy-server will use the configured lease-time information to provide DHCP clients.</p> <p><i>days</i> — Specifies the number of days that the given IP address is valid.</p> <p>Values 0 to 3650</p> <p><i>hours</i> — Specifies the number of hours that the given IP address is valid.</p> <p>Values 0 to 23</p> <p><i>minutes</i> — Specifies the number of minutes that the given IP address is valid.</p> <p>Values 0 to 59</p> <p><i>seconds</i> — Specifies the number of seconds that the given IP address is valid.</p> <p>Values 0 to 59</p>

egress

Syntax	egress
Context	config>subscr-mgmt>msap-policy>vpls-only
Description	This command configures egress policies for MSAPs.

multicast-group

Syntax	multicast-group <i>group-name</i> no multicast-group
Context	config>subscr-mgmt>msap-policy>vpls-only>egress

Description This command specifies an existing egress multicast group (EMG). An EMG is created as an object used to group VPLS SAPs that are allowed to participate in efficient multicast replication (EMR). EMR is a method to increase the performance of egress multipoint forwarding by sacrificing some destination-based features. Eliminating the requirement to perform unique features for each destination allows the egress forwarding plane to chain together multiple destinations into a batch replication process. In order to perform this batch replication function, similar characteristics are required on each SAP within the EMG.

Only SAPs defined on Ethernet access ports are allowed into an egress-multicast-group.

In order to understand the purpose of an egress-multicast-group, an understanding of the system's use of flooding lists is required. A flooding list is maintained at the egress forwarding plane to define a set of destinations to which a packet must be replicated. Multipoint services make use of flooding lists to enable forwarding a single packet to many destinations. Examples of multipoint services that use flooding lists are VPLS, IGMP snooping and IP multicast routing. Currently, the egress forwarding plane will only use efficient multicast replication for VPLS and IGMP snooping flooding lists.

In VPLS services, a unique flooding list is created for each VPLS context. The flooding list is used when a packet has a broadcast, multicast or unknown destination MAC address. From a system perspective, proper VPLS handling requires that a broadcast, multicast or unknown destined packet be sent to all destinations that are in the forwarding state. The ingress forwarding plane ensures the packet gets to all egress forwarding planes that include a destination in the VPLS context. It is the egress forwarding plane's job to replicate the packet to the subset of the destinations that are reached through its interfaces and each of these destinations are included in the VPLS context's flooding list.

For IGMP snooping, a unique flooding list is created for each IP multicast (s,g) record. This (s,g) record is associated with an ingress VPLS context and may be associated with VPLS destinations in the source VPLS instance or other VPLS instances (in the case of MVR). Again, the ingress forwarding plane ensures that an ingress IP multicast packet matching the (s,g) record gets to all egress forwarding planes that have a VPLS destination associated with the (s,g) record. The egress forwarding plane uses the flooding list owned by the (s,g) record to replicate the packet to all VPLS destinations in the flooding list. The IGMP Snooping function identifies which VPLS destinations should be associated with the (s,g) record.

With normal multicast replication, the egress forwarding plane examines which features are enabled for each destination. This includes ACL filtering, mirroring, encapsulation and queuing. The resources used to perform this per destination multicast processing are very expensive to the egress forwarding plane when high replication bandwidth is required. If destinations with similar egress functions can be grouped together, the egress forwarding plane can process them in a more efficient manner and maximize replication bandwidth.

The egress-multicast-group object is designed to allow the identification of SAPs with similar egress characteristics. When a SAP is successfully provisioned into an egress-multicast-group, the system is ensured that it may be batched together with other SAPs in the same group at the egress forwarding plane for efficient multicast replication. A SAP that does not meet the common requirements is not allowed into the egress-multicast-group.

At the forwarding plane level, a VPLS flooding list is categorized into chainable and non-chainable destinations. Currently, the only chainable destinations are SAPs within an egress-multicast-group. The chainable destinations are further separated by egress-multicast-group association. Chains are then created following the rules below:

- A replication batch chain may only contain SAPs from the same egress-multicast-group
- A replication batch chain length may not exceed the dest-chain-limit of the egress-multicast-group to which the SAPs are members

Further subcategories are created for an IGMP (s,g) flooding list. A Layer 2 (s,g) record is created in a specific VPLS instance (the instance the (s,g) flow ingresses). SAPs within that VPLS context that join the (s,g) record are considered native SAPs within the flooding list. SAPs that join the (s,g) flooding list through the multicast VPLS registration process (MVR) from another VPLS context using the **from-vpls** command are considered alien SAPs. The distinction between native and alien in the list is maintained to allow the forwarding plane to enforce or suspend split-horizon-group (SHG) squelching. When the source of the (s,g) matching packet is in the same SHG as a native SAP, the packet must not be replicated to that SAP. For a SAP in another VPLS context, the source SHG of the packet has no meaning and the forwarding plane must disregard SHG matching between the native source of the packet and the alien destination. Because the SHG squelch decision is done for the whole chain based on the first SAP in the chain, all SAPs in the chain must be all native or all alien SAPs. Chains for IGMP (s,g) flooding lists are created using the following rules:

1. A replication batch chain may only contain SAPs from the same egress-multicast-group.
2. A replication batch chain may only contain all alien or all native SAPs.
3. A replication batch chain length may not exceed the dest-chain-limit of the egress-multicast-group to which the SAPs are members

When a packet associated with a flooding list is received by the egress forwarding plane, it processes the packet by evaluating each destination on the list sequentially in a replication context. If the current entry being processed in the list is a non-chained destination, the forwarding plane processes the packet for that destination and then moves on to process other packets currently in the forwarding plane before returning to process the next destination in the list. If the current entry being processed is a chained destination, the forwarding plane remains in the replication context until it has forwarded to each entry in that chain. Once the replication context finishes with the last entry in the chain, it moves on to process other packets waiting for egress processing before returning to the replication context. Processing continues in this manner until the packet has been forwarded to all destinations in the list.

Batch chain processing of a chain of SAPs improves replication efficiency by bypassing the functions that perform egress mirroring decisions on SAPs within the chain and making a single ACL filtering decision for the whole chain. Each destination in the chain may have a unique egress QoS policy and per destination queuing is still performed for each destination in the chain. Also, while each SAP in the chain must be on access ports with the same encaps-type, if the encaps-type is dot1q, each SAP may have a unique dot1q tag.

One caveat to each SAP having a unique egress QoS policy in the chain is that only the Dot1P marking decisions for the first SAP in the list is enforced. If the first SAP's QoS policy forwarding class action states that the packet should not be remarked, none of the replicated packets in the chain will have the dot1P bits remarked. If the first SAP's QoS policy forwarding class action states that the packet should be remarked with a specific dot1P value, all the replicated packets for the remaining SAPs in the chain will have the same dot1P marking.

While the system supports 32 egress multicast groups, a single group would usually suffice. An instance where multiple groups would be needed is when all the SAPs requiring efficient multicast replication cannot share the same common requirements. In this case, an egress multicast group would be created for each set of common requirements. An egress multicast group may contain SAPs from many different VPLS instances. It should be understood that an egress multicast group is not equivalent to an egress forwarding plane flooding list. An egress multicast group only identifies which SAPs may participate in efficient multicast replication. As stated above, entries in a flooding list are populated due to VPLS destination creation or IGMP snooping events.

The **no** form of the command removes a specific egress multicast group. Deleting an egress multicast group will only succeed when the group has no SAP members. To remove SAP members, use the **no multicast-group group-name** command under each SAP's egress context.

Note: Efficient multicast replication will only be performed on IOMs that support chassis mode b. If an IOM does not support mode b operation, egress-multicast-group membership is ignored on that IOM's egress forwarding planes. The chassis need not be placed into mode b for efficient multicast replication to be performed on the capable IOMs.

Parameters	<i>group-name</i> — Multiple egress multicast groups may be created on the system. Each must have a unique name. The egress-multicast-group-name is an ASCII string up to 16 characters in length and follows all the naming rules as other named policies in the system. The group's name is used throughout the system to uniquely identify the Egress Multicast Group and is used to provision a SAP into the group.
Values	Up to 32 egress multicast groups may be created on the system.
Default	None, each egress multicast group must be explicitly configured.

igmp-snooping

Syntax	igmp-snooping
Context	config>subscr-mgmt>msap-policy>vpls-only
Description	This command enables the Internet Group Management Protocol (IGMP) snooping context.
Default	none

fast-leave

Syntax	[no] fast-leave
Context	config>subscr-mgmt>msap-policy>vpls-only>igmp-snp
Description	<p>This command enables fast leave.</p> <p>When IGMP fast leave processing is enabled, the 7450 ESS or 7750 SR will immediately remove a SAP or SDP from the IP multicast group when it detects an IGMP 'leave' on that SAP or SDP. Fast leave processing allows the switch to remove a SAP or SDP that sends a 'leave' from the forwarding table without first sending out group-specific queries to the SAP or SDP, and thus speeds up the process of changing channels ('zapping').</p> <p>Fast leave should only be enabled when there is a single receiver present on the SAP or SDP.</p> <p>When fast leave is enabled, the configured last-member-query-interval value is ignored.</p>
Default	no fast-leave

import

Syntax	import <i>policy-name</i> no import
Context	config>subscr-mgmt>msap-policy>vpls-only>igmp-snp
Description	<p>This command specifies the import routing policy to be used for IGMP packets to be used on this SAP or SDP. Only a single policy can be imported on a single SAP at any time.</p> <p>The no form of the command removes the policy association from the SAP or SDP.</p>
Default	no import (No import policy is specified)
Parameters	<i>policy-name</i> — The routing policy name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters excluding double quotes. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes. Routing policies are configured in the config>router>policy-options context The router policy must be defined before it can be imported.

last-member-query-interval

Syntax	last-member-query-interval <i>tenths-of-seconds</i> no last-member-query-interval
Context	config>subscr-mgmt>msap-policy>vpls-only>igmp-snp

Description	<p>This command configures the maximum response time used in group-specific queries sent in response to 'leave' messages, and is also the amount of time between 2 consecutive group-specific queries. This value may be tuned to modify the leave latency of the network. A reduced value results in reduced time to detect the loss of the last member of a group.</p> <p>The configured last-member-query-interval is ignored when fast-leave is enabled on the SAP or SDP.</p>
Default	10
Parameters	<i>seconds</i> — Specifies the frequency, in tenths of seconds, at which query messages are sent.
Values	1 to 50

max-num-groups

Syntax	max-num-groups <i>max-num-groups</i> no max-num-groups
Context	config>subscr-mgmt>msap-policy>vpls-only>igmp-snp
Description	This command defines the maximum number of multicast groups that can be joined on an MSAP or SDP. If the router receives an IGMP join message that would exceed the configured number of groups, the request is ignored.
Default	no max-num-groups
Parameters	<i>max-num-groups</i> — Specifies the maximum number of groups that can be joined on an MSAP or SDP.
Values	1 to 1000

mcac

Syntax	mcac
Context	config>subscr-mgmt>msap-policy>vpls-only>igmp-snp>
Description	This command enables the context to configure multicast CAC parameters.
Default	none

if-policy

Syntax	if-policy <i>mcac-if-policy-name</i> no if-policy
---------------	--

Context	config>subscr-mgmt>msap-policy>vpls-only>igmp-snp>mcac
Description	This command assigns an existing MCAC interface policy to this MSAP policy. The no form of the command removes the MCAC interface policy association.
Default	no if-policy
Parameters	<i>mcac-if-policy-name</i> — Specifies an existing MCAC interface policy

mc-constraints

Syntax	mc-constraints
Context	config>subscr-mgmt>msap-policy>vpls-only>igmp-snp>mcac
Description	This command enables the context to configure the level and its associated bandwidth for a bundle or a logical interface.
Default	none

level

Syntax	level <i>level-id</i> bw <i>bandwidth</i> no level <i>level-id</i>
Context	config>subscr-mgmt>msap-policy>vpls-only>igmp-snp>mcac
Description	This command configures levels and their associated bandwidth for multicast CAC policy on an interface.
Parameters	<i>level-id</i> — Specifies has an entry for each multicast CAC policy constraint level configured on a system. Values 1 to 8 <i>bandwidth</i> — Specifies the bandwidth in kilobits per second (kbps) for the level. Values 1 to 2147483647

number-down

Syntax	number-down <i>number-lag-port-down</i> level <i>level-id</i> no number-down <i>number-lag-port-down</i>
Context	config>subscr-mgmt>msap-policy>vpls-only>igmp-snp>mcac
Description	This command configures the number of ports down along with level for multicast CAC policy on an MSAP

Parameters	<i>number-lag-port-down</i> — If the number of ports available in the LAG is reduced by the number of ports configured in this command here then bandwidth allowed for bundle and/or interface will be as per the levels configured in this context.
Values	1 to 64 (for 64-link LAG) 1 to 32 (for other LAGs)
level	<i>level-id</i> — Specifies the amount of bandwidth available within a given bundle for MC traffic for a specified level.

policy

Syntax	policy <i>policy-name</i> no policy
Context	config>subscr-mgmt>msap-policy>vpls-only>igmp-snp>mcac
Description	This command configures the multicast CAC policy name.
Parameters	<i>policy-name</i> — The multicast CAC policy name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

unconstrained-bw

Syntax	unconstrained-bw <i>bandwidth</i> mandatory-bw <i>mandatory-bw</i> no unconstrained-bw
Context	config>subscr-mgmt>msap-policy>vpls-only>igmp-snp>mcac
Description	This command configures the bandwidth for the interface's multicast CAC policy traffic. When disabled (no unconstrained-bw) there will be no checking of bandwidth constraints on the interface level. When enabled and a policy is defined, enforcement is performed. The allocated bandwidth for optional channels should not exceed the unconstrained-bw minus the mandatory-bw and the mandatory channels have to stay below the specified value for the mandatory-bw . After this interface check, the bundle checks are performed.
Parameters	<i>bandwidth</i> — The bandwidth assigned for interface's MCAC policy traffic, in kilo-bits per second (kbps). Values 0 to 2147483647 mandatory-bw <i>mandatory-bw</i> — Specifies the bandwidth pre-reserved for all the mandatory channels on a given interface in kilo-bits per second (kbps). If the <i>bandwidth</i> value is 0, no mandatory channels are allowed. If the value of <i>bandwidth</i> is '-1', then all mandatory and optional channels are allowed.

If the value of *mandatory-bw* is equal to the value of *bandwidth*, then all the unconstrained bandwidth on a given interface is allocated to mandatory channels configured through multicast CAC policy on that interface and no optional groups (channels) are allowed.

The value of *mandatory-bw* should always be less than or equal to that of *bandwidth*. An attempt to set the value of *mandatory-bw* greater than that of *bandwidth*, will result in inconsistent value error.

Values 0 to 2147483647

use-lag-port-weight

Syntax	use-lag-port-weight no use-lag-port-weight
Context	config>subscr-mgmt>msap-policy>vpls-only>igmp-snp>mcac>mc-constraints
Description	This command enables port weight to be used when determining available bandwidth per level when LAG ports go down/come up. The command is required for proper operation on mixed port-speed LAGs and can be used for non-mixed port-speed LAGs as well.
Default	no use-lag-port-weight
	port number is used when determining available BW per level when LAG ports go down/come up

sub-mcac-policy

Syntax	sub-mcac-policy <i>sub-mcac-policy-name</i> [create] no sub-mcac-policy <i>b</i>
Context	config>subscr-mgmt
Description	<p>This command will create a policy template with mcac bandwidth limits that will be applied to the subscriber.</p> <p>Per interface mcac bandwidth limits will be set directly under the interface (regular interface or group-interface) and no such policy templates are needed.</p> <p>The need for a separate policy template for subscribers is due to the fact that groups of subscribers under the same group-interface can share certain settings that can be configured via this template.</p> <p>To summarize, the mcac bandwidth constraints for subscribers are defined in the sub-mcac-policy while the mcac bandwidth constraints for the interface are configured directly under the igmp>interface>mcac or igmp>grp-if>mcac context without the need for policy templates.</p>

Note: The sub-mcac-policy only deals with the mcac bandwidth limits and not the channel bandwidth definitions. Channels bandwidth is defined in a different policy (under the config>router>mcac hierarchy) and that policy is applied on the interface level as follows:

- For group-interface: under the **config>service>vprn>igmp>grp-if>mcac** context
- For regular interface: under the **config>service/router>igmp>interface>mcac** context.

In case of HQoS Adjustment, it is mandatory that the sub-mcac-policy be created and applied to the subscriber. The sub-mac-policy does not have to contain any bandwidth constraints, but it has to be in a no shutdown state in order for HQoS Adjustment to work.

Parameters *policy-name* — Specifies the name of the policy.

mvr

Syntax **mvr**

Context config>subscr-mgmt>msap-policy>vpls-only>igmp-snp

Description This command enables the context to configure Multicast VPLS Registration (MVR) parameters.

from-vpls

Syntax **from-vpls** *service-id*
 no from-vpls

Context config>subscr-mgmt>msap-policy>vpls-only>igmp-snp>mvr

Description This command configures the VPLS from which multicast traffic is copied upon receipt of an IGMP join request.

 IGMP snooping must be enabled on the MVR VPLS.

Default no from-vpls

Parameters *service-id* — Specifies the MVR VPLS from which multicast channels should be copied into an MSAP.

Values

service-id: 1 to 2147483647

svc-name: 64 characters maximum(applies only to the 7750 SR)

query-interval

Syntax	query-interval <i>seconds</i> no query-interval
Context	config>subscr-mgmt>msap-policy>vpls-only>igmp-snp
Description	<p>This command configures the IGMP query interval. If the send-queries command is enabled, this parameter specifies the interval between two consecutive general queries sent by the system on an MSAP or SDP.</p> <p>The configured query-interval must be greater than the configured query-response-interval.</p> <p>If send-queries is not enabled on an MSAP or SDP, the configured query-interval value is ignored.</p>
Default	125
Parameters	<i>seconds</i> — The time interval, in seconds, that the router transmits general host-query messages. Values 2 to 1024

query-response-interval

Syntax	query-response-interval <i>seconds</i>
Context	config>subscr-mgmt>msap-policy>vpls-only>igmp-snp
Description	<p>This command configures the IGMP query response interval. If the send-queries command is enabled, this parameter specifies the maximum response time advertised in IGMPv2/v3 queries.</p> <p>The configured query-response-interval must be smaller than the configured query-interval.</p> <p>If send-queries is not enabled on an MSAP or SDP, the configured query-response-interval value is ignored.</p>
Default	10
Parameters	<i>seconds</i> — Specifies the length of time to wait to receive a response to the host-query message from the host. Values 1 to 1023

robust-count

Syntax	robust-count <i>robust-count</i> no robust-count
---------------	---

Context	config>subscr-mgmt>msap-policy>vpls-only>igmp-snp
Description	<p>This command configures the IGMP robustness variable. If the send-queries command is enabled, this parameter allows tuning for the expected packet loss on a SAP or SDP. The robust-count variable allows tuning for the expected packet loss on a subnet and is comparable to a retry count. If an MSAP or SDP is expected to be “lossy”, this parameter may be increased. IGMP snooping on an MSAP or SDP is robust to (robust-count-1) packet losses.</p> <p>If send-queries is not enabled, this parameter will be ignored.</p>
Default	2
Parameters	<i>robust-count</i> — Specifies the robust count for the SAP or SDP.
Values	2 to 7

send-queries

Syntax	[no] send-queries
Context	config>subscr-mgmt>msap-policy>vpls-only>igmp-snp
Description	<p>This command specifies whether to send IGMP general query messages on the managed SAP. When send-queries is configured, all type of queries generate ourselves are of the configured version. If a report of a version higher than the configured version is received, the report will get dropped and a new wrong version counter will get incremented.</p> <p>If send-queries is not configured, the version command has no effect. The version used on that SAP/SDP will be the version of the querier. This implies that, for example, when there is a v2 querier, a v3 group or group-source specific query is never sent when a host wants to leave a certain group.</p>
Default	no send-queries

version

Syntax	version <i>version</i> no version
Context	config>subscr-mgmt>msap-policy>vpls-only>igmp-snp
Description	<p>This command specifies the version of IGMP which is running on an MSAP. This object can be used to configure a router capable of running either value. For IGMP to function correctly, all routers on a LAN must be configured to run the same version of IGMP on that LAN.</p> <p>When the send-query command is configured, all type of queries generate ourselves are of the configured version. If a report of a version higher than the configured version is received, the report gets dropped and a new “wrong version” counter is incremented.</p>

If the **send-query** command is not configured, the **version** command has no effect. The version used on that SAP or SDP will be the version of the querier. This implies that, for example, when there is a v2 querier, a v3 group or group-source specific query when a host wants to leave a certain group will never be sent.

Parameters *version* — Specify the IGMP version.

Values 1, 2, 3

mac-da-hashing

Syntax **[no] mac-da-hashing**

Context config>subscr-mgmt>msap-policy>vpls-only>igmp-snp

Description This command specifies whether subscriber traffic egressing a LAG SAP has its egress LAG link selected by a function of the MAC destination address instead of the subscriber ID.

This command is only meaningful if subscriber management is enabled and can be configured for a VPLS service.

split-horizon-group

Syntax **split-horizon-group** *group-name*

Context config>subscr-mgmt>msap-policy>vpls-only>igmp-snp

Description This command specifies the name of the split horizon group to which the MSAP belongs.

default-msap-policy

Syntax **default-msap-policy** *policy-name*
no default-msap-policy

Context config>service>vpls>sap

Description This command specifies the default managed SAP policy to use to create MSAPs when the response from the RADIUS server does not specify a managed SAP policy.

The *policy-name* parameter is only valid for a SAP with the keywords **capture-sap** specified in the SAP's configuration. The **capture-sap** keyword in the SAP configuration captures the SAP where triggering packets will be sent to the CPM. Non-triggering packets captured by the capture SAP will be dropped.

The managed SAP policy must already be defined in the **config>subscr-mgmt>msap-policy** context

The **no** form of the command removes the policy-name from the configuration.

Default	no default-msap-policy
Parameters	<i>policy-name</i> — /Specifies an existing default managed SAP policy.

trigger-packet

Syntax	trigger-packet [dhcp] [pppoe] [arp] [dhcp6] [ppp] [rtr-solicit] [data] no trigger-packet
Context	config>service>vpls>sap
Description	This command enables triggering packet to initiate RADIUS authentication that provides a service context. The authentication, together with the service context for this request, creates a managed SAP. The VLAN is the same as the triggering packet. This SAP behaves as a regular SAP but the configuration is not user-editable and not maintained in the configuration file. The managed SAP remains active as long as the session is active.
Default	none
Parameters	<p>dhcp — Specifies whether the receipt of DHCP trigger packets on this VPLS SAP when the keyword capture-sap is specified in the sap command creation string, will result in a RADIUS authentication that will provide a service context and the creation of a SAP with a value of 'managed'.</p> <p>pppoe — Specifies whether the receipt of PPPoE trigger packets on this VPLS SAP when the keyword capture-sap is specified in the sap command creation string, will result in a RADIUS authentication that will provide a service context and the creation of a SAP with a value of 'managed'.</p> <p>arp — Indicates that ARP is the type of trigger packets for this entry.</p> <p>dhcp6 — Indicates that DHCP6 is the type of trigger packets for this entry.</p> <p>ppp — Indicates that PPP is the type of trigger packets for this entry.</p> <p>rtr-solicit — Indicates that router solicit is the type of trigger packets for this entry.</p> <p>data — Indicates that data is the type of trigger packets for this entry.</p>

allow-dot1q-msaps

Syntax	[no] allow-dot1q-msaps
Context	config>service>vpls>sap
Description	<p>This command enables support for single tagged traffic triggering managed SAP creation on a qinq encapsulated capture SAP.</p> <p>With this command enabled, a single tagged trigger packet received on a qinq encapsulated capture SAP (x/y/z:.* or x/y/z:tag.*) can trigger the creation of an x/y/z:tag.0 managed SAP (MSAP).</p>

The **config>system>ethernet>new-qinq-untagged-sap** command should be configured:

- as a prerequisite for an x/y/z:tag.* capture-sap
- where x/y/z:tag1.0 and x/y/z:tag1.tag2 MSAPs for an x/y/z:.* capture-sap should co-exist

Note that enabling `new-qinq-untagged-sap` affects the behavior of existing `<port-id>:tag.0` SAPs.

With the `allow-dot1q-msaps` command disabled (default), a single tagged trigger packet received on a QinQ encapsulated capture SAP (`x/y/z:.*` or `x/y/z.tag.*`) is dropped as “Invalid QTag”.

This command cannot be enabled on:

- a dot1q encapsulated **capture-sap**
- an inverse capture sap (x/y/z:*.tag)

Default no allow-dot1q-msaps

9.24.2.1.8 Multi-Chassis Redundancy Commands

redundancy

Syntax	redundancy
Context	config
Description	This command allows the user to perform redundancy operations.
Parameters	force-switchover — Forces a switchover to the standby CPM card
	Values
	now keyword - switch to standby CPM)

Note: Switching to the standby displays the following message.

WARNING: Configuration and/or Boot options may have changed since the last save.

Are you sure you want to switchover (y/n)?

synchronize — Synchronizes the secondary CPM.

Values *boot-env/config* : keywords

synchronize

Syntax	synchronize {boot-env config}
Context	config>redundancy
Description	<p>This command performs a synchronization of the standby CPM images and/or config files to the active CPM. Either the boot-env or config parameter must be specified.</p> <p>In the config>redundancy context, this command performs an automatically triggered standby CPM synchronization.</p> <p>When the standby CPM takes over operation following a failure or reset of the active CPM, it is important to ensure that the active and standby CPM have identical operational parameters. This includes the saved configuration, CPM and IOM images.</p> <p>The active CPM ensures that the active configuration is maintained on the standby CPM. However, to ensure smooth operation under all circumstances, runtime images and system initialization configurations must also be automatically synchronized between the active and standby CPM.</p> <p>If synchronization fails, alarms and log messages that indicate the type of error that caused the failure of the synchronization operation are generated. When the error condition ceases to exist, the alarm is cleared.</p> <p>Only files stored on the router are synchronized. If a configuration file or image is stored in a location other than on a local compact flash, the file is not synchronized (for example, storing a configuration file on an FTP server).</p>
Default	enabled
Parameters	<p>boot-env — Synchronizes all files required for the boot process (loader, BOF, images, and configuration files.</p> <p>config — Synchronize only the primary, secondary, and tertiary configuration files.</p>
	Default config

multi-chassis

Syntax	multi-chassis
Context	config>redundancy
Description	This command enables the context to configure multi-chassis parameters.

peer

Syntax	peer ip-address [create]
---------------	---------------------------------

	no peer <i>ip-address</i>
Context	config>redundancy>multi-chassis
Description	<p>This command creates a new multi-chassis redundancy peer or enables the context to configure an existing peer.</p> <p>The peer address can be either an IPv4 address or an IPv6 address. If an IPv6 address is used, the following MCS clients are not supported:</p> <ul style="list-style-type: none">• mc-endpoint• l2tp
Default	none
Parameters	<i>ip-address</i> — Specifies an IPv4 or IPv6 unicast address

authentication-key

Syntax	authentication-key [<i>authentication-key</i> <i>hash-key</i>] [hash hash2] no authentication-key
Context	config>redundancy>multi-chassis>peer
Description	This command configures the authentication key used between this node and the multi-chassis peer. The authentication key can be any combination of letters or numbers.
Parameters	<p><i>authentication-key</i> — Specifies the authentication key. Allowed values are any string up to 20 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.</p> <p><i>hash-key</i> — The hash key. The key can be any combination of ASCII characters up to 33 (hash1-key) or 55 (hash2-key) characters in length (encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").</p> <p>hash — Specifies the key is entered in an encrypted form. If the hash or hash2 parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the hash or hash2 parameter specified</p> <p>hash2 — Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the hash2 encrypted variable cannot be copied and pasted. If the hash or hash2 parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the hash or hash2 parameter specified.</p>

mc-ipsec

Syntax	mc-ipsec
Context	config>redundancy>multi-chassis>peer
Description	This command enters the configuration context of multi-chassis IPSec.

discovery-interval

Syntax	discovery-interval <i>interval-1</i> [boot <i>interval-2</i>] no discovery-interval
Context	config>redundancy>multi-chassis>peer>mc-ipsec
Description	This command specifies the time interval of tunnel-group stays in “Discovery” state. Interval-1 is used as discovery-interval when a new tunnel-group is added to multi-chassis redundancy (mp-ipsec); interval-2 is used as discovery-interval at system boot-up. It is optional and when it is not specified, interval-1 will be used.
Default	300
Parameters	<i>interval-1/2</i> — Specifies the interval in seconds. Values 1 to 1800 seconds

keep-alive-interval

Syntax	keep-alive-interval <i>time-interval</i> no keep-alive-interval
Context	config>redundancy>multi-chassis>peer>mc-ipsec
Description	This command specifies the time interval of the mastership election protocol sending the keep-alive packet.
Default	10
Parameters	<i>time-interval</i> — Specifies the time interval in tenths of a second. Values 5 to 500

hold-on-neighbor-failure

Syntax	hold-on-neighbor-failure <i>multiplier</i> no hold-on-neighbor-failure
Context	config>redundancy>multi-chassis>peer>mc-ipsec

Description	This command specifies the number of keep-alive failures before the peer is considered down.
Default	3
Parameters	<i>multiplier</i> — Specifies the multiplier.
Values	2 to 25

bfd-enable

Syntax	bfd-enable service <i>service-id</i> interface <i>interface-name</i> dst-ip <i>ip-address</i> no bfd-enable
Context	config>redundancy>multi-chassis>peer>mc-ipsec
Description	<p>This command enables tracking a central BFD session. If the BFD session goes down, then the system considers the peer down and changes the mc-ipsec status of the configured tunnel-group accordingly.</p> <p>The BFD session uses the specified loopback interface (in the specified service) address as the source address and uses the specified dst-ip as the destination address. Other BFD parameters are configured with the “bfd” command on the specified interface.</p>
Parameters	<p><i>interface-name</i> — Specifies the name of the loopback interface.</p> <p><i>service-id</i> — Specifies the ID of the service.</p> <p><i>dst-id</i> — Specifies the destination address of the BFD packet.</p>

tunnel-group

Syntax	tunnel-group <i>group-id</i> [create] no tunnel-group <i>group-id</i>
Context	config>redundancy>multi-chassis>peer>mc-ipsec
Description	This command enables multi-chassis redundancy for the specified tunnel-group or enters an already configured tunnel-group context. The configured tunnel-group could failover independently.
Parameters	<p><i>group-id</i> — Specifies the tunnel-group ID.</p> <p>Values 1 to 16</p> <p>create — Enables multi-chassis redundancy for the specified tunnel-group.</p>

peer-group

Syntax	peer-group <i>group-id</i> no peer-group
Context	config>redundancy>multi-chassis>peer>mc-ipsec>tunnel-group
Description	This command specifies the corresponding tunnel-group ID on the peer node. The peer tunnel-group ID does not necessarily equal the local tunnel-group ID.
Parameters	<i>group-id</i> — Specifies the tunnel-group ID. Values 1 to 16

priority

Syntax	priority <i>priority</i> no priority
Context	config>redundancy>multi-chassis>peer>mc-ipsec>tunnel-group
Description	This command specifies the local priority of the tunnel-group. This is used to elect the master (higher number is the master). If priorities are the same, then the peer with the more active ISA becomes the master. If the priority and the number of active ISAs are the same, then the peer with the higher IP address is the master.
Parameters	<i>priority</i> — Specifies the priority of the tunnel-group. Values 0 to 255

preempt

Syntax	[no] preempt
Context	config>redundancy>multi-chassis>peer>mc-ipsec>tunnel-group
Description	This command enables the preempt behavior of local node.

mc-lag

Syntax	[no] mc-lag
Context	config>redundancy>multi-chassis>peer>mc-lag
Description	This command enables the context to configure multi-chassis LAG operations and related parameters.

The **no** form of this command administratively disables multi-chassis LAG. MC-LAG can only be issued only when mc-lag is shutdown.

hold-on-neighbor-failure

Syntax	hold-on-neighbor-failure <i>multiplier</i> no hold-on-neighbor-failure
Context	config>redundancy>multi-chassis>peer>mc-lag
Description	This command specifies the interval that the standby node will wait for packets from the active node before assuming a redundant-neighbor node failure. This delay in switch-over operation is required to accommodate different factors influencing node failure detection rate, such as IGP convergence, or HA switch-over times and to prevent the standby node to take action prematurely. The no form of this command sets this parameter to default value.
Default	3
Parameters	<i>multiplier</i> — The time interval that the standby node will wait for packets from the active node before assuming a redundant-neighbor node failure. Values 2 to 25

keep-alive-interval

Syntax	keep-alive-interval <i>interval</i> no keep-alive-interval
Context	config>redundancy>multi-chassis>peer>mc-lag
Description	This command sets the interval at which keep-alive messages are exchanged between two systems participating in MC-LAG. These keep-alive messages are used to determine remote-node failure and the interval is set in deci-seconds. The no form of this command sets the interval to default value
Default	1s (10 hundreds of milliseconds means interval value of 10)
Parameters	<i>interval</i> — The time interval expressed in deci-seconds Values 5 to 500

lag

Syntax	lag <i>lag-id</i> lACP-key <i>admin-key</i> system-id <i>system-id</i> [remote-lag <i>lag-id</i>] system-priority <i>system-priority</i>
---------------	---

no lag *lag-id*

Context config>redundancy>multi-chassis>peer>mc-lag

Description This command defines a LAG which is forming a redundant-pair for MC-LAG with a LAG configured on the given peer. The same LAG group can be defined only in the scope of 1 peer.

The same **lacp-key**, **system-id**, and **system-priority** must be configured on both nodes of the redundant pair in order to MC-LAG to become operational. In order MC-LAG to become operational, all parameters (**lacp-key**, **system-id**, **system-priority**) must be configured the same on both nodes of the same redundant pair.

The partner system (the system connected to all links forming MC-LAG) will consider all ports using the same **lacp-key**, **system-id**, **system-priority** as the part of the same LAG. In order to achieve this in MC operation, both redundant-pair nodes have to be configured with the same values. In case of the mismatch, MC-LAG is kept in oper-down status.

Default none

Parameters *lag-id* — The LAG identifier, expressed as a decimal integer. Specifying the *lag-id* allows the mismatch between lag-id on redundant-pair. If no **lag-id** is specified it is assumed that neighbor system uses the same *lag-id* as a part of the given MC-LAG. If no matching MC-LAG group can be found between neighbor systems, the individual LAGs will operate as usual (no MC-LAG operation is established.).

Values 1 to 800

lacp-key *admin-key* — Specifies a 16 bit key that needs to be configured in the same manner on both sides of the MC-LAG in order for the MC-LAG to come up.

Values 1 to 65535

system-id *system-id* — Specifies a 6 byte value expressed in the same notation as MAC address

Values xx:xx:xx:xx:xx:xx - xx [00 to FF]

remote-lag *lag-id* — Specifies the LAG ID on the remote system.

Values 1 to 200 (applies to the 7450 ESS)
1 to 800 (applies to the 7750 SR)

system-priority *system-priority* — Specifies the system priority to be used in the context of the MC-LAG. The partner system will consider all ports using the same **lacp-key**, **system-id**, and **system-priority** as part of the same LAG.

Values 1 to 65535

source-address

Syntax **source-address** *ip-address*
no source-address

Context	config>redundancy>multi-chassis>peer
Description	This command specifies the source address used to communicate with the multi-chassis peer.
Parameters	<i>ip-address</i> — Specifies the source address used to communicate with the multi-chassis peer.

sync

Syntax	[no] sync
Context	config>redundancy>multi-chassis>peer
Description	This command enables the context to configure synchronization parameters.

igmp

Syntax	[no] igmp
Context	config>redundancy>multi-chassis>peer>sync
Description	This command specifies whether IGMP protocol information should be synchronized with the multi-chassis peer.
Default	no igmp

igmp-snooping

Syntax	[no] igmp-snooping
Context	config>redundancy>multi-chassis>peer>sync
Description	This command specifies whether IGMP snooping information should be synchronized with the multi-chassis peer.
Default	no igmp-snooping

local-dhcp-server

Syntax	[no] local-dhcp-server
Context	config>redundancy>multi-chassis>peer>sync
Description	This command synchronizes DHCP server information.

mc-ring

Syntax	[no] mc-ring
Context	config>redundancy>multi-chassis>peer>sync
Description	This command synchronizes mc-ring information.

mld-snooping

Syntax	[no] mld-snooping
Context	config>redundancy>multi-chassis>peer>sync
Description	This command is not supported. It is not blocked for backwards-compatibility reasons but has no effect on the system if configured.

pim-snooping

Syntax	pim-snooping [saps] no pim-snooping
Context	config>redundancy>multi-chassis>peer>sync
Description	This command specifies whether PIM snooping for IPv4 information should be synchronized with the multi-chassis peer. Entering only pim-snooping (without any parameter) results in the synchronization being applicable only to SAPs.
Default	no pim-snooping
Parameters	<i>saps</i> — Specifies that SAPs are to be synchronized with the multi-chassis peer relating to <i>sync-tags</i> configured on ports. This is the default when no parameters are included.

port

Syntax	port [port-id lag-id] [sync-tag sync-tag] [create] no port [port-id lag-id]
Context	config>redundancy>multi-chassis>peer>sync
Description	This command specifies the port to be synchronized with the multi-chassis peer and a synchronization tag to be used while synchronizing this port with the multi-chassis peer.
Parameters	<i>port-id</i> — Specifies the port to be synchronized with the multi-chassis peer. <i>lag-id</i> — Specifies the LAG ID to be synchronized with the multi-chassis peer.

sync-tag *sync-tag* — Specifies a synchronization tag to be used while synchronizing this port with the multi-chassis peer, up to 32 characters in length.

range

Syntax	range <i>encap-range</i> sync-tag <i>sync-tag</i> no range <i>encap-range</i>	
Context	config>redundancy>multi-chassis>peer>sync>port	
Description	This command configures a range of encapsulation values.	
Parameters	<i>encap-range</i> — Specifies a range of encapsulation values on a port to be synchronized with a multi-chassis peer.	
	Values	
	Dot1Q	<i>start-vlan-end-vlan</i>
	QinQ	<i>Q1.start-vlan-Q1.end-vlan</i>

sync-tag *sync-tag* — specifies a synchronization tag up to 32 characters in length to be used while synchronizing this encapsulation value range with the multi-chassis peer.

srrp

Syntax	[no] srrp
Context	config>redundancy>multi-chassis>peer>sync
Description	This command specifies whether subscriber routed redundancy protocol (SRRP) information should be synchronized with the multi-chassis peer.
Default	no srrp

sub-host-trk

Syntax	[no] sub-host-trk
Context	config>redundancy>multi-chassis>peer>sync
Description	This command synchronizes subscriber host tracking information.

sub-mgmt

Syntax	sub-mgmt [ipoe ppoe]
---------------	-------------------------------

no sub-mgmt

Context	config>redundancy>multi-chassis>peer>sync
Description	<p>This command will enable synchronization of subscriber states between chassis. Synchronization will be enabled per protocol type (IPoE or PPPoE).</p> <p>The keywords (ipoe, pppoe) must match on both nodes. If not, subscriber synchronization will fail.</p> <p>For example if one node is configured with:</p> <pre>config>multi-chassis>peer>sync>sub-mgmt ipoe</pre> <p>but the other node is configured with:</p> <pre>config>multi-chassis>peer>sync>sub-mgmt ipoe pppoe</pre> <p>synchronization will fail even for ipoe application.</p>
Default	no sub-mgmt
Parameters	<p>ipoe — ipoe subscribers will be synchronized</p> <p>pppoe — pppoe subscribers will be synchronized</p>

tunnel-group

Syntax	tunnel-group <i>tunnel-group-id</i> sync-tag <i>tag-name</i> [create] no tunnel-group
Context	config>redundancy>multi-chassis>peer>sync
Description	This command enables multi-chassis synchronization of IPSec states of a specified tunnel-group with its peer. Sync-tag is used to match corresponding tunnel-groups on both peers. IPSec states will be synchronized between tunnel-groups with the same sync-tag.
Parameters	<p><i>tunnel-group-id</i> — Specifies the ID of the tunnel-group</p> <p><i>tag-name</i> — Specifies the name of sync-tag.</p>

ipsec

Syntax	[no] ipsec
Context	config>redundancy>multi-chassis>peer>sync
Description	This command enables multi-chassis synchronization of IPSec states on system level.

mc-ring

Syntax	mc-ring
Context	config>redundancy>multi-chassis>peer
Description	This command enables the context to configure the multi-chassis ring parameters.
Default	mc-ring

ring

Syntax	ring <i>sync-tag</i> [create] no ring sync-tag
Context	config>redundancy>multi-chassis>peer>mcr
Description	This command configures a multi-chassis ring. The no form of the command removes the sync-tag from the configuration.
Default	none

l3-ring

Syntax	l3-ring <i>name</i> [create] no l3-ring name
Context	config>redundancy>multi-chassis>peer>mcr
Description	This command configures a Layer 3 multi-chassis ring.

in-band-control-path

Syntax	in-band-control-path
Context	config>redundancy>multi-chassis>peer>mcr>ring config>redundancy>multi-chassis>peer>mc>l3-ring
Description	This command enables the context to configure control path parameters.
Default	none

debounce

Syntax	[no] debounce
---------------	----------------------

Context config>redundancy>multi-chassis>peer>mcr>ring>in-band-control-path
config>redundancy>multi-chassis>peer>mc>l3-ring>in-band-control-path

Description This command enables the inband control path debouncing. The **no** form of the command disables inband control path debouncing.

dst-ip

Syntax **dst-ip** *ip-address*
no dst-ip

Context config>redundancy>multi-chassis>peer>mcr>ring>in-band-control-path
config>redundancy>multi-chassis>peer>mc>l3-ring>in-band-control-path

Description This command specifies the destination IP address used in the inband control connection.
If the destination IP address is not configured, the ring cannot become operational.

Default none

Parameters *ip-address* — The destination IP address.

interface

Syntax **interface** *ip-int-name*
no interface

Context config>redundancy>multi-chassis>peer>mcr>ring>in-band-control-path
config>redundancy>multi-chassis>peer>mc>l3-ring>in-band-control-path

Description This command specifies the name of the IP interface used for the inband control connection.
If an interface name is not configured, the ring cannot become operational.

Parameters *ip-int-name* — Specifies an interface name up to 32 characters in length.

max-debounce-time

Syntax **max-debounce-time** *max-debounce-time*
no max-debounce-time

Context config>redundancy>multi-chassis>peer>mcr>ring>in-band-control-path
config>redundancy>multi-chassis>peer>mc>l3-ring>in-band-control-path

Description This command configures the inband control path maximum debounce time.

Parameters	<i>max-debounce-time</i> — Specifies the maximum debounce time on the transition of the operational state of the inband control connection.
Values	5 to 200 seconds

service-id

Syntax	service-id <i>service-id</i> no service-id
Context	config>redundancy>multi-chassis>peer>mcr>ring>in-band-control-path config>redundancy>multi-chassis>peer>mc>l3-ring>in-band-control-path
Description	This command configures the service ID of the SAP used for the Ring-Node Connectivity Verification of this ring node.
Parameters	<i>service-id</i> — [Specifies an existing service ID or service name.
Values	service-id: 1 to 214748364 svc-name: A string up to 64 characters in length.

path-b

Syntax	[no] path-b
Context	config>redundancy>multi-chassis>peer>mcr>ring
Description	This command specifies the set of upper-VLAN IDs associated with the SAPs that belong to path B with respect to load-sharing. All other SAPs belong to path A.
Default	If not specified, the default is an empty set.

range

Syntax	[no] range <i>vlan-range</i>
Context	config>redundancy>multi-chassis>peer>mcr>ring>path-b config>redundancy>multi-chassis>peer>mcr>ring>path-excl
Description	This command specifies the set of VLAN IDs associated with the SAPs that are controlled by the remote peer. It is a bitmap that associates bit i with VLAN ID i, with i in [0 to 4094]. Setting the value to the empty string is equivalent to setting it to 512 zeroes.

ring-node

Syntax	[no] ring-node <i>ring-node-name</i>
---------------	---

Context	config>redundancy>mc>peer>mcr>ring
Description	This command specifies the unique name of a multi-chassis ring access node.

path-excl

Syntax	[no] path-excl
Context	config>redundancy>multi-chassis>peer>mcr>ring
Description	This command specifies the set of upper-VLAN IDs associated with the SAPs that are to be excluded from control by the multi-chassis ring.
Default	If not specified, the default is an empty set.

connectivity-verify

Syntax	connectivity-verify
Context	config>redundancy>multi-chassis>peer>mcr>ring config>redundancy>multi-chassis>peer>mc>l3-ring
Description	This command configures the node connectivity check.

interval

Syntax	interval <i>interval</i>
Context	config>redundancy>multi-chassis>peer>mcr>ring>>connectivity-verify config>redundancy>multi-chassis>peer>mc>l3-ring>connectivity-verify
Description	This command specifies the polling interval of the ring-node connectivity verification of this ring node.
Parameters	<i>interval</i> — Specifies the polling interval of the ring-node connectivity verification of this ring node.
Values	1 to 6000

service-id

Syntax	service-id <i>service-id</i> no service-id
Context	config>redundancy>mc>peer>mcr>ring-node>connect-verify config>redundancy>multi-chassis>peer>mc>l3-ring>connectivity-verify

Description	This command specifies the service ID of the SAP used for ring-node connectivity verification of this ring node.
Parameters	<i>service-id</i> — Specifies the service ID or service name.
Values	service-id: 1 to 214748364 svc-name: A string up to 64 characters in length.

src-ip

Syntax	src-ip <i>ip-address</i> no src-ip
Context	config>redundancy>mc>peer>mcr>ring-node>connect-verify config>redundancy>multi-chassis>peer>mc>l3-ring>connectivity-verify
Description	This command specifies the source IP address used in ring-node connectivity verification of this ring node.
Parameters	<i>ip-address</i> — Specifies the source IP address used in ring-node connectivity verification of this ring node.

src-mac

Syntax	src-mac <i>ieee-address</i> no src-mac
Context	config>redundancy>mc>peer>mcr>ring-node>connect-verify config>redundancy>multi-chassis>peer>mc>l3-ring>connectivity-verify
Description	This command specifies the source MAC address used for the Ring-Node Connectivity Verification of this ring node. If all zeros are specified, then the MAC address of the system management processor (CPM) is used.
Parameters	<i>ieee-address</i> — Specifies the 48-bit MAC address for the static ARP in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee, and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.

vlan

Syntax	vlan [<i>vlan-encap</i>]
Context	config>redundancy>mc>peer>mcr>ring-node>connect-verify config>redundancy>mc>peer>mcr>l3ring>node>cv

Description	This command specifies the VLAN tag of the SAP used for ring-node connectivity verification of this ring node. It is only meaningful if the value of is not zero.
Parameters	<i>vlan-encap</i> — Specifies the node cc VLAN.

srrp-instance

Syntax	[no] srrp-instance <i>srrp-id</i>
Context	config>redundancy>multi-chassis>peer>mc>l3-ring
Description	This command configures an SRRP instance for Layer 3 ring.
Parameters	<i>srrp-id</i> — Specifies the SRRP ID of this SRRP instance. Values 1 to 4294967295

9.24.2.1.9 SLA Profile Commands

sla-profile

Syntax	sla-profile <i>sla-profile-name</i>
Context	config>subscr-mgmt
Description	<p>This command configures an SLA profile mapping. Hosts associated with a subscriber are subdivided into Service Level Agreement (SLA) profiles. For each subscriber host an SLA profile can be specified. For a subscriber host, the SLA profile determines:</p> <ul style="list-style-type: none">• The QoS-policies to use<ul style="list-style-type: none">– The classification– The queues– The queue mapping• The IP filters to use <p>The SLA profile also has the attribute host-limit which limits the total number of hosts (belonging to the same subscriber) on a certain SAP that can be using this SLA profile.</p>
Default	none
Parameters	<i>sla-profile-name</i> — Specifies the name of the SLA profile.

egress

Syntax	egress
Context	config>subscr-mgmt>sla-profile
Description	This command configures egress parameters for the SLA profile.

ingress

Syntax	ingress
Context	config>subscr-mgmt>sla-profile
Description	This command configures ingress parameters for the SLA profile.

host-limits

Syntax	[no] no host-limits
Context	config>subscr-mgmt>sla-profile
Description	This command configures the maximum number of hosts per host type for this SLA profile.

ipv4-arp

Syntax	ipv4-arp <i>max-nr-of-hosts</i> no ipv4-arp
Context	config>subscr-mgmt>sla-profile>host-limits
Description	This command configures the maximum number of IPv4 ARP hosts. The no form of the command removes the number of IPv4 ARP hosts from the SLA profile.
Default	no ipv4-arp
Parameters	<i>max-nr-of-hosts</i> — Specifies the maximum number of IPv4 ARP hosts.

Note: The operational maximum value may be smaller due to equipped hardware dependencies.

Values 0 to 131071

ipv4-dhcp

Syntax	ipv4-dhcp <i>max-nr-of-hosts</i> no ipv4-dhcp
Context	config>subscr-mgmt>sla-profile>host-limits
Description	This command limits the number of IPv4 DHCP hosts. The no form of the command removes the number of IPv4 DHCP hosts from the SLA profile.
Default	no ipv4-dhcp
Parameters	<i>max-nr-of-hosts</i> — Specifies the maximum number of IPv4 DHCP hosts.

Note: The operational maximum value may be smaller due to equipped hardware dependencies.

Values 0 to 131071

ipv4-overall

Syntax	ipv4-overall <i>max-nr-of-hosts</i> no ipv4-overall
Context	config>subscr-mgmt>sla-profile>host-limits
Description	This command limits the total number of IPv4 hosts. The no form of the command removes the number of IPv4 hosts from the SLA profile.
Default	no ipv4-overall
Parameters	<i>max-nr-of-hosts</i> — Specifies the maximum number of IPv4 hosts.

Note: The operational maximum value may be smaller due to equipped hardware dependencies.

Values 0 to 32767

ipv4-ppp

Syntax **ipv4-ppp** *max-nr-of-hosts*

no ipv4-ppp

Context	config>subscr-mgmt>sla-profile>host-limits
Description	<p>This command limits the total number of IPv4 PPP hosts.</p> <p>The no form of the command removes the number of IPv4 PPP hosts from the SLA profile.</p>
Default	no ipv4-ppp
Parameters	<i>max-nr-of-hosts</i> — Specifies the maximum number of IPv4 PPP hosts.
Values	0 to 32767

ipv6-overall

Syntax	ipv6-overall <i>max-nr-of-hosts</i> no ipv6-overall
Context	config>subscr-mgmt>sla-profile>host-limits
Description	<p>This command limits the total number of IPv6 hosts.</p> <p>The no form of the command removes the number of IPv6 hosts from the SLA profile.</p>
Default	no ipv6-overall
Parameters	<i>max-nr-of-hosts</i> — Specifies the maximum number of IPv6 hosts.

Note: The operational maximum value may be smaller due to equipped hardware dependencies.

Values 0 to 32767

ipv6-pd-ipoe-dhcp

Syntax	ipv6-pd-ipoe-dhcp <i>max-nr-of-hosts</i> no ipv6-pd-ipoe-dhcp
Context	config>subscr-mgmt>sla-profile>host-limits
Description	<p>This command configures the total number of IPv6 DHCP PD hosts.</p> <p>The no form of the command removes the number of IPv6 DHCP hosts from the SLA profile.</p>
Default	no ipv6-dhcp
Parameters	<i>max-nr-of-hosts</i> — Specifies the total number of IPv6 DHCP PD hosts.

Note: The operational maximum value may be smaller due to equipped hardware dependencies.

Values 0 to 32767

ipv6-pd-overall

Syntax	ipv6-pd-overall max-nr-of-hosts no ipv6-pd-overall
Context	config>subscr-mgmt>sla-profile>host-limits
Description	This command limits the total number of IPv6-PD hosts. The no form of the command removes the number of IPv6-PD hosts from the SLA profile.
Default	no ipv6-pd-overall
Parameters	<i>max-nr-of-hosts</i> — Specifies the maximum number of IPv6-PD hosts overall.

Note: The operational maximum value may be smaller due to equipped hardware dependencies.

Values 0 to 32767

ipv6-pd-ppp-dhcp

Syntax	ipv6-pd-ppp-dhcp max-nr-of-hosts no ipv6-pd-ppp-dhcp
Context	config>subscr-mgmt>sla-profile>host-limits
Description	This command configures the maximum number of IPv6-WAN PPP DHCP hosts. The no form of the command removes the number of IPv6-WAN PPP DHCP hosts from the SLA profile.
Default	no ipv6-pd-ppp-dhcp
Parameters	<i>max-nr-of-hosts</i> — Specifies the maximum number of IPv6-WAN PPP DHCP hosts.

Note: The operational maximum value may be smaller due to equipped hardware dependencies.

Values 0 to 32767

ipv6-wan-ipoe-dhcp

Syntax	ipv6-wan-ipoe-dhcp <i>max-nr-of-hosts</i> no ipv6-wan-ipoe-dhcp
Context	config>subscr-mgmt>sla-profile>host-limits
Description	This command configures the maximum number of IPv6-WAN PPP DHCP hosts. The no form of the command removes the number of IPv6-WAN PPP DHCP hosts from the SLA profile.
Default	no ipv6-wan-ipoe-dhcp
Parameters	<i>max-nr-of-hosts</i> — Specifies the maximum number of IPv6-WAN PPP DHCP hosts.

Note: The operational maximum value may be smaller due to equipped hardware dependencies.

Values 0 to 32767

ipv6-wan-ipoe-slaac

Syntax	ipv6-wan-ipoe-slaac <i>max-nr-of-hosts</i> no ipv6-wan-ipoe-slaac
Context	config>subscr-mgmt>sla-profile>host-limits
Description	This command configures the maximum number of IPv6-WAN IPoE SLAAC hosts. The no form of the command removes the number of IPv6-WAN IPoE SLAAC hosts from the SLA profile.
Default	no ipv6-wan-ipoe-slaac
Parameters	<i>max-nr-of-hosts</i> — Specifies the maximum number of IPv6-WAN IPoE SLAAC hosts.

Note: The operational maximum value may be smaller due to equipped hardware dependencies.

Values 0 to 32767

ipv6-wan-overall

Syntax	ipv6-wan-overall <i>max-nr-of-hosts</i> no ipv6-wan-overall
Context	config>subscr-mgmt>sla-profile>host-limits
Description	This command configures the total number of IPv6 WAN hosts. The no form of the command removes the number of IPV6 WAN hosts from the SLA profile.
Default	no ipv6-wan-overall
Parameters	<i>max-nr-of-hosts</i> — Specifies the maximum number of IPv6 WAN hosts.

Note: The operational maximum value may be smaller due to equipped hardware dependencies.

Values 0 to 32767

ipv6-wan-ppp-dhcp

Syntax	ipv6-wan-ppp-dhcp <i>max-nr-of-hosts</i> no ipv6-wan-ppp-dhcp
Context	config>subscr-mgmt>sla-profile>host-limits
Description	This command configures the total number of IPv6 PPP DHCP WAN hosts. The no form of the command removes the number of IPv6 PPP DHCP WAN hosts from the SLA profile.
Default	no ipv6-wan-ppp-dhcp
Parameters	<i>max-nr-of-hosts</i> — Specifies the maximum number of IPv6 PPP DHCP WAN hosts.

Note: The operational maximum value may be smaller due to equipped hardware dependencies.

Values 0 to 32767

ipv6-wan-ppp-slaac

Syntax	ipv6-wan-ppp-slaac <i>max-nr-of-hosts</i> no ipv6-wan-ppp-slaac
Context	config>subscr-mgmt>sla-profile>host-limits
Description	This command configures the total number of SLAAC hosts. The no form of the command removes the number of SLAAC hosts from the SLA profile.
Default	no ipv6-wan-ppp-slaac
Parameters	<i>max-nr-of-hosts</i> — Specifies the maximum number of SLAAC hosts.

Note: The operational maximum value may be smaller due to equipped hardware dependencies.

Values 0 to 32767

lac-overall

Syntax	lac-overall <i>max-nr-of-hosts</i> no lac-overall
Context	config>subscr-mgmt>sla-profile>host-limits
Description	This command configures the total number of L2TP LAC hosts The no form of the command removes the number of L2TP LAC from the SLA profile.
Default	no lac-overall
Parameters	<i>max-nr-of-hosts</i> — Specifies the maximum number of L2TP LAC hosts.

Note: The operational maximum value may be smaller due to equipped hardware dependencies.

Values 0 to 32767

overall

Syntax	overall <i>max-nr-of-hosts</i> no overall
Context	config>subscr-mgmt>sla-profile>host-limits
Description	This command configures the total number of hosts. The no form of the command reverts to the default.
Default	no overall
Parameters	<i>max-nr-of-hosts</i> — Specifies the maximum number of hosts. Values 0 to 32767

remove-oldest

Syntax	[no] remove-oldest
Context	config>subscr-mgmt>sla-profile>host-limits
Description	This command removes the oldest subscriber host when the host limit is reached. The no form of the command maintains the oldest subscriber host when the host limit is reached.
Default	no remove-oldest

ip-filter

Syntax	[no] ip-filter <i>filter-id</i>
Context	config>subscr-mgmt>sla-profile>egress config>subscr-mgmt>sla-profile>ingress
Description	This command configures an egress or ingress IP filter.
Parameters	<i>filter-id</i> — Specify an existing IP filter policy ID. Values 1 to 65535

SLA Profile QoS Commands

qos

Syntax	qos <i>sap-egress-policy-id</i> [<i>vport-scheduler</i> <i>port-scheduler</i>] [force] no qos
Context	config>subscr-mgmt>sla-prof>egress
Description	This command specifies the egress QoS policy applicable to this SLA profile. The policy must already be defined in the config>qos>sap-egress context.
Default	1
Parameters	<p><i>sap-egress-policy-id</i> — Specifies the egress policy to be applied to the egress SLA profile.</p> <p>Values 1 to 65535</p> <p><i>vport-scheduler</i> <i>port-scheduler</i> — Specifies if a host queue with the port-parent option enabled should be scheduled within the context of a vport port scheduler policy or a the port's port scheduler policy.</p> <p>force — Forces a policy change.</p>

qos

Syntax	qos <i>policy-id</i> [shared-queuing multipoint-shared service-queuing] [force] no qos
Context	config>subscr-mgmt>sla-prof>ingress
Description	This command specifies the ingress QoS policy applicable to this SLA profile. The policy must already be defined in the config>qos>sap-ingress context.
Default	qos 1
Parameters	<p><i>sap-ingress-policy-id</i> — Specifies the policy to be applied to the ingress SLA profile.</p> <p>Values 1 to 65535</p> <p>shared-queuing — This keyword is mutually exclusive with the multipoint-shared and service-queuing keywords to specify the policy used by this SAP. When the value of this object is null it means that the SAP will use individual ingress QoS queues, instead of the shared ones.</p> <p>multipoint-shared — This keyword is mutually exclusive with the shared-queuing and service-queuing keywords. When multipoint-shared is specified, the ingress forwarding plane will conserve hardware queues by performing two tier queuing on ingress unicast and multipoint packets through the SAP. Unicast service queues defined in the SAP ingress QoS policy are created for the SAP on the ingress</p>

forwarding plane without regard for the switch fabric destinations to which the SAP may need to forward (other destinations in the VPLS context). The multipoint queues defined in the SAP ingress QoS policy are not created for the SAP. Instead, all multipoint traffic is mapped to the unicast queues based on forwarding class in the first pass. In the second pass the unicast packets will be mapped to the unicast shared queues while the multipoint traffic will be mapped to the multipoint shared queues.

service-queuing — This keyword is mutually exclusive with the **multipoint-shared** and **shared-queuing** keywords to state that service queueing is needed.

force — Forces a policy change.

queue

Syntax	[no] queue <i>queue-id</i>
Context	config>subscr-mgmt>sla-prof>egress>qos config>subscr-mgmt>sla-prof>ingress>qos
Description	<p>This command configures the context to configure egress or ingress queue parameters. Parameters defined in the config>qos>sap-egress <i>policy-id</i> or the config>qos>sap-ingress <i>policy-id</i> context are overridden by parameters specified in the subscriber management SLA profile context.</p> <p>The classification and the queue mapping are shared by all the hosts on the same complex that use the same QoS policy (specified in the sla-profile SAP egress and SAP ingress policy IDs).</p> <p>The queues are shared by all the hosts (of the same subscriber) on the same SAP that are using the same SLA profile. Queues are instantiated when, on a given SAP, a host of a subscriber is the first to use a certain SLA profile. This instantiation is referred to as an SLA profile instance.</p> <p>The no form of the command removes the <i>queue-id</i> from the SLA profile.</p>
Default	none
Parameters	<p><i>queue-id</i> — Specifies the <i>queue-id</i> for the SAP egress or ingress queue, expressed as a decimal integer. The <i>queue-id</i> uniquely identifies the queue within the profile.</p> <p>Default none</p>

avg-frame-overhead

Syntax	avg-frame-overhead <i>percent</i> no avg-frame-overhead
Context	config>subscr-mgmt>sla-prof>egress>qos>queue

Description This command configures the average frame overhead to define the average percentage that the offered load to a queue will expand during the frame encapsulation process before sending traffic on-the-wire. While the avg-frame-overhead value may be defined on any queue, it is only used by the system for queues that egress a SONET or SDH port or channel. Queues operating on egress Ethernet ports automatically calculate the frame encapsulation overhead based on a 20 byte per packet rule (8 bytes for preamble and 12 bytes for Inter-Frame Gap).

When calculating the frame encapsulation overhead for port scheduling purposes, the system determines the following values:

- **Offered-load** — The offered-load of a queue is calculated by starting with the queue depth in octets, adding the received octets at the queue and subtracting queue discard octets. The result is the number of octets the queue has available to transmit. This is the packet based offered-load.
- **Frame encapsulation overhead** — Using the avg-frame-overhead parameter, the frame encapsulation overhead is simply the queues current offered-load (how much has been received by the queue) multiplied by the avg-frame-overhead. If a queue had an offered load of 10000 octets and the avg-frame-overhead equals 10%, the frame encapsulation overhead would be 10000×0.1 or 1000 octets.

For egress Ethernet queues, the frame encapsulation overhead is calculated by multiplying the number of offered-packets for the queue by 20 bytes. If a queue was offered 50 packets then the frame encapsulation overhead would be 50×20 or 1000 octets.

- **Frame based offered-load** — The frame based offered-load is calculated by adding the offered-load to the frame encapsulation overhead. If the offered-load is 10000 octets and the encapsulation overhead was 1000 octets, the frame based offered-load would equal 11000 octets.
- **Packet to frame factor** — The packet to frame factor is calculated by dividing the frame encapsulation overhead by the queues offered-load (packet based). If the frame encapsulation overhead is 1000 octets and the offered-load is 10000 octets then the packet to frame factor would be $1000 / 10000$ or 0.1. When in use, the avg-frame-overhead will be the same as the packet to frame factor making this calculation unnecessary.
- **Frame based CIR** — The frame based CIR is calculated by multiplying the packet to frame factor with the queues configured CIR and then adding that result to that CIR. If the queue CIR is set at 500 octets and the packet to frame factor equals 0.1, the frame based CIR would be 500×1.1 or 550 octets.
- **Frame based within-cir offered-load** — The frame based within-cir offered-load is the portion of the frame based offered-load considered to be within the frame-based CIR. The frame based within-cir offered-load is the lesser of the frame based offered-load and the frame based CIR. If the frame based offered-load equaled 11000 octets and the frame based CIR equaled 550 octets, the frame based within-cir offered-load would be limited to 550 octets. If the frame based offered-load equaled 450 octets and the frame based CIR equaled 550 octets, the frame based within-cir offered-load would equal 450 octets (or the entire frame based offered-load).

As a special case, when a policer, queue or associated intermediate scheduler is configured with a CIR-weight equal to 0, the system automatically sets the queue's frame based within-cir offered-load to 0, preventing it from receiving bandwidth during the port scheduler's within-cir pass.

- **Frame based PIR** — The frame based PIR is calculated by multiplying the packet to frame factor with the queue's configured PIR and then adding the result to that PIR. If the queue PIR is set to 7500 octets and the packet to frame factor equals 0.1, the frame based PIR would be 7500 x 1.1 or 8250 octets.
- **Frame based within-pir offered-load** — The frame based within-pir offered-load is the portion of the frame based offered-load considered to be within the frame based PIR. The frame based within-pir offered-load is the lesser of the frame based offered-load and the frame based PIR. If the frame based offered-load equaled 11000 octets and the frame based PIR equaled 8250 octets, the frame based within-pir offered-load would be limited to 8250 octets. If the frame based offered-load equaled 7000 octets and the frame based PIR equaled 8250 octets, the frame based within-pir offered load would equal 7000 octets.

Port scheduler operation using frame transformed rates — The port scheduler uses the frame based rates to determine the maximum rates that each queue may receive during the within-cir and above-cir bandwidth allocation passes. During the within-cir pass, a queue may receive up to its frame based within-cir offered-load. The maximum it may receive during the above-cir pass is the difference between the frame based within-pir offered load and the amount of actual bandwidth allocated during the within-cir pass.

SAP and subscriber SLA-profile average frame overhead override — The average frame overhead parameter on a sap-egress may be overridden at an individual egress queue basis. On each SAP and within the sla-profile policy used by subscribers an avg-frame-overhead command may be defined under the queue-override context for each queue. When overridden, the queue instance will use its local value for the average frame overhead instead of the sap-egress defined overhead.

The **no** form of this command restores the average frame overhead parameter for the queue to the default value of 0 percent. When set to 0, the system uses the packet based queue statistics for calculating port scheduler priority bandwidth allocation. If the no avg-frame-overhead command is executed in a queue-override queue id context, the avg-frame-overhead setting for the queue within the sap-egress QoS policy takes effect.

Default 0

Parameters *percent* — This parameter sets the average amount of packet-to-frame encapsulation overhead expected for the queue. This value is not used by the system for egress Ethernet queues.

Values 0 — 100

burst-limit

Syntax burst-limit {default | size [byte | kilobyte]}

no burst-limit

Context	config>subscr-mgmt>sla-prof>egress>qos>queue config>subscr-mgmt>sla-prof>ingress>qos>queue
Description	<p>The queue burst-limit command is used to define an explicit shaping burst size for a queue. The configured size defines the shaping leaky bucket threshold level that indicates the maximum burst over the queue's shaping rate.</p> <p>The burst-limit command is supported under the sap-ingress and sap-egress QoS policy queues. The command is also supported under the ingress and egress queue-group-templates queues.</p> <p>The no form of this command is used to restore the default burst limit to the specified queue. This is equivalent to specifying burst-limit default within the QoS policies or queue group templates. When specified within a queue-override queue context, any current burst limit override for the queue will be removed and the queue's burst limit will be controlled by its defining policy or template.</p>
Parameters	<p><i>default</i> — The default parameter is mutually exclusive to specifying an explicit size value. When burst-limit default is executed, the queue is returned to the system default value.</p> <p><i>size</i> — When a numeric value is specified (size), the system interprets the value as an explicit burst limit size. The value is expressed as an integer and by default is interpreted as the burst limit in Kilobytes. If the value is intended to be interpreted in bytes, the byte qualifier must be added following size.</p> <p>Values 1 to 14,000 (14,000 or 14,000,000 depending on bytes or kilobytes)</p> <p>Default No default for size, use the default keyword to specify default burst limit</p> <p><i>byte</i> — The bytes qualifier is used to specify that the value given for size must be interpreted as the burst limit in bytes. The byte qualifier is optional and mutually exclusive with the kilobytes qualifier.</p> <p><i>kilobyte</i> — The kilobyte qualifier is used to specify that the value given for size must be interpreted as the burst limit in Kilobytes. The kilobyte qualifier is optional and mutually exclusive with the bytes qualifier. If neither bytes nor kilobytes is specified, the default qualifier is kilobytes.</p>

cbs

Syntax	cbs <i>size-in-kbytes</i> no cbs
Context	config>subscr-mgmt>sla-prof>egress>qos>queue config>subscr-mgmt>sla-prof>ingress>qos>queue

Description	<p>This command can be used to override specific attributes of the specified queue's CBS parameters. It is permissible, and possibly desirable, to oversubscribe the total CBS reserved buffers for a given access port egress buffer pool. Oversubscription may be desirable due to the potential large number of service queues and the economy of statistical multiplexing the individual queues' CBS settings into the defined reserved total.</p> <p>When oversubscribing the reserved total, it is possible for a queue depth to be lower than its CBS setting and still not receive a buffer from the buffer pool for an ingress frame. As more queues are using their CBS buffers and the total in use exceeds the defined reserved total, essentially the buffers are being removed from the shared portion of the pool without the shared in use average and total counts being decremented. This can affect the operation of the high and low priority RED slopes on the pool, causing them to miscalculate when to start randomly drop packets.</p> <p>The no form of this command returns the CBS size to the size as configured in the QoS policy.</p>
Default	no cbs
Parameters	<p><i>size-in-kbytes</i> — The size parameter is an integer expression of the number of kilobytes reserved for the queue. If a value of 10KBytes is desired, enter the value 10. A value of 0 specifies that no reserved buffers are required by the queue (a minimal reserved size can still be applied for scheduling purposes).</p> <p>Values 0 to 131072 or default</p>

high-prio-only

Syntax	<p>high-prio-only <i>percent</i> no high-prio-only</p>
Context	<p>config>subscr-mgmt>sla-prof>egress>qos>queue config>subscr-mgmt>sla-prof>ingress>qos>queue</p>
Description	<p>This command configures the value of the percentage of buffer space for the queue, used exclusively by high priority packets. The specified value overrides the default value for the context.</p> <p>The priority of a packet can only be set in the SAP ingress QoS policy and is only applicable on the ingress queues for a SAP. The high-prio-only parameter is used to override the default value derived from the network-queue command.</p> <p>The defined high-prio-only value cannot be greater than the MBS size of the queue. Attempting to change the MBS to a value smaller than the high priority reserve will generate an error and fail execution. Attempting to set the high-prio-only value larger than the current MBS size will also result in an error and fail execution.</p> <p>The no form of this command returns high-prio-only to the size as configured in the QoS policy.</p>

Default	no high-prio-only
Parameters	<i>percent</i> — The <i>percent</i> parameter is the percentage reserved for high priority traffic on the queue. If a value of 10KBytes is desired, enter the value 10. A value of 0 specifies that none of the MBS of the queue will be reserved for high priority traffic. This does not affect RED slope operation for packets attempting to be queued.
Values	0 to 100 default

mbs

Syntax	mbs <i>size-in-kbytes</i> no mbs
Context	config>subscr-mgmt>sla-prof>egress>qos>queue
Description	<p>This command configures the maximum size for the queue.</p> <p>The sum of the MBS for all queues on an egress access port can oversubscribe the total amount of buffering available. When congestion occurs and buffers become scarce, access to buffers is controlled by the RED slope a packet is associated with. A queue that has not exceeded its MBS size is not guaranteed that a buffer will be available when needed or that the packet's RED slope will not force the discard of the packet. Setting proper CBS parameters and controlling CBS oversubscription is one major safeguard to queue starvation (when a queue does not receive its fair share of buffers). Another is properly setting the RED slope parameters for the needs of services on this port or channel.</p> <p>The no form of this command returns the MBS size to the size as configured in the QoS policy.</p>
Default	no mbs
Parameters	<i>size-in-kbytes</i> — The size parameter is an integer expression of the maximum number of kilobytes of buffering allowed for the queue. For a value of 100 kbps, enter the value 100. A value of 0 causes the queue to discard all packets.
Values	0 to 1073741824 or default

mbs

Syntax	mbs <i>size</i> [bytes kilobytes] no mbs
Context	config>subscr-mgmt>sla-prof>ingress>qos>queue config>subscr-mgmt>sub-prof>hsmda>egress-qos>qos>queue
Description	The Maximum Burst Size (MBS) command configures the explicit definition of the maximum amount of buffers allowed for a specific queue.

The MBS value is used by a queue to determine whether it has exhausted all of its buffers while enqueueing packets. Once the queue has exceeded the amount of buffers allowed by MBS, all packets are discarded until packets have been drained from the queue.

The sap-ingress context for mbs provides a mechanism for overriding the default maximum size for the queue.

The sum of the MBS for all queues on an ingress access port can oversubscribe the total amount of buffering available. When congestion occurs and buffers become scarce, access to buffers is controlled by the RED slope a packet is associated with. A queue that has not exceeded its MBS size is not guaranteed that a buffer will be available when needed or that the packet's RED slope will not force the discard of the packet. Setting proper CBS parameters and controlling CBS oversubscription is one major safeguard to queue starvation (when a queue does not receive its fair share of buffers). Another is properly setting the RED slope parameters for the needs of services on this port or channel.

The defined high-prio-only value cannot be greater than the MBS size of the queue. Attempting to change the MBS to a value smaller than the high priority reserve will generate an error and fail execution. Attempting to set the high-prio-only value larger than the current MBS size will also result in an error and fail execution.

The **no** form of this command returns the MBS size to the size as configured in the QoS policy.

Default	no mbs
Parameters	<div> size [bytes kilobytes] — The size parameter is an integer expression of the maximum number of bytes or kilobytes of buffering allowed for the queue. For a value of 100 kbps enter the value 100 and specify the kilobytes parameter. A value of 0 causes the queue to discard all packets. </div> <div> Values 0 to 1073741824 or default </div>

rate

Syntax	<div> rate <i>pir-rate</i> [cir <i>cir-rate</i>] </div> <div>no rate</div>
Context	config>subscr-mgmt>sla-prof>egress>qos>queue
Description	This command defines the administrative Peak Information Rate (PIR) and the administrative Committed Information Rate (CIR) parameters for the queue. The PIR defines the maximum rate that the queue can transmit packets out an egress interface (for SAP egress queues). Defining a PIR does not necessarily guarantee that the queue can transmit at the intended rate. The actual rate sustained by the queue can be limited by oversubscription factors or available egress bandwidth.

The CIR defines the rate at which the system prioritizes the queue over other queues competing for the same bandwidth. In-profile then out-of-profile packets are preferentially queued by the system at egress and at subsequent next hop nodes where the packet can traverse. To be properly handled throughout the network, the packets must be marked accordingly for profiling at each hop.

The CIR can be used by the queue's parent command's *cir-level* and *cir-weight* parameters to define the amount of bandwidth considered to be committed for the child queue during bandwidth allocation by the parent scheduler.

The **rate** command can be executed at anytime, altering the PIR and CIR rates for all queues created through the association of the SAP egress QoS policy with the *queue-id*.

The **no** form of the command returns all queues created with the *queue-id* by association with the QoS policy to the default PIR and CIR parameters (**max**, 0).

Default	no rate
Parameters	<p><i>pir-rate</i> — Defines the administrative PIR rate, in kilobits, for the queue. When the rate command is executed, a valid PIR setting must be explicitly defined. When the rate command has not been executed, the default PIR of max is assumed.</p> <p>Fractional values are not allowed and must be given as a positive integer.</p> <p>The actual PIR rate is dependent on the queues adaptation-rule parameters and the actual hardware where the queue is provisioned.</p> <p>Values 1 to 2000000000, max</p> <p>Default max</p> <p><i>cir-rate</i> — The cir parameter overrides the default administrative CIR used by the queue. When the rate command is executed, a CIR setting is optional. When the rate command has not been executed or the cir parameter is not explicitly specified, the default CIR (0) is assumed.</p> <p>Fractional values are not allowed and must be given as a positive integer.</p> <p>Values 0 to 2000000000, max</p> <p>Default 0</p>

qos-marking-from-sap

Syntax	[no] qos-marking-from-sap
Context	config>subscr-mgmt>sla-profile>egress
Description	This command sets the QoS policy from which the egress QoS marking rules are applied.

Note: If applied to a managed SAP, the default SAP-egress qos-policy (sap-egress 1) cannot be changed.

The **no** form of the command reverts to the egress QoS marking defined in SAP-egress policy defined at sla-profile level.

Default qos-marking-from-sap

report-rate

Syntax	report-rate agg-rate-limit report-rate scheduler <i>scheduler-name</i> report-rate pppoe-actual-rate report-rate rfc5515-actual-rate no report-rate
Context	config>subscr-mgmt>sla-prof>ingress config>subscr-mgmt>sla-prof>egress
Description	This command configures the source for Tx and Rx connect speeds in AVP 38 (Rx Connect Speed) and AVP 24 (Tx Connect Speed) of an L2TP session established on a LAC.
Default	no report-rate – Rates takes from the physical port speed.
Parameters	<p>agg-rate-limit — (egress only) rate taken from:</p> <ol style="list-style-type: none"> 1. The agg-rate RADIUS override (RADIUS VSA “Alc-Subscriber-QoS-Override” in a RADIUS Access-Accept message) if present. 2. The configured agg-rate-limit in the config>subscr-mgmt>sub-prof>egr context. 3. Fall back to the default (no report-rate). <p>scheduler <i>scheduler-name</i> — Specifies the rate taken from the scheduler scheduler-name. If the scheduler scheduler-name is not present in the scheduler-policy configured in the config>subscr-mgmt>sub-prof>egr context, fall back to the default (no report-rate)</p> <p>pppoe-actual-rate — Specifies rates taken from the “DSL Line characteristics” PPPoE tags (Actual Data Rate Upstream/Downstream) if present; otherwise fall back to the default (no report-rate).</p> <p>report-rate rfc5515-actual-rate — Puts the same value as the transmitted Actual-Data-Rate-Upstream AVP in the Rx-Connect-Speed AVP, and the same value as the transmitted Actual-Data-Rate-Downstream AVP in the Tx-Connect-Speed AVP.</p>

scheduler-policy

Syntax	scheduler-policy <i>scheduler-policy-name</i> no scheduler-policy
Context	config>subscr-mgmt>sla-prof>egress

Description This command specifies a scheduler policy to associate to the sla profile. Scheduler policies are configured in the **configure>qos>scheduler>policy** context. Each scheduler policy is divided up into groups of schedulers based on the tier each scheduler is created under. A tier is used to give structure to the schedulers within a policy and define rules for parent scheduler associations. The policy defines the hierarchy and operating parameters for virtual schedulers.

The **no** form of the command removes the scheduler-policy-name from the configuration.

Default no scheduler-policy

Parameters *scheduler-policy-name* — Specify an existing scheduler policy name.

scheduler

Syntax **scheduler** *scheduler-name* **rate** *pir-rate* [**cir** *cir-rate*]
no scheduler *scheduler-name*

Context config>subscr-mgmt>sla-prof>egress>sched

Description This command provides a way to override parameters of the existing scheduler associated with the

egress scheduler policy. A scheduler defines bandwidth controls that limit each child (other schedulers and queues) associated with the scheduler. Scheduler objects are created within the hierarchical tiers of the policy. It is assumed that each scheduler created will have queues or other schedulers defined as child associations. The scheduler can be a child (take bandwidth from a scheduler in a higher tier).

Parameters **scheduler** *scheduler-name* — Specify an existing scheduler policy name.

pir-rate — The pir-rate parameter, in kilobits, overrides the administrative PIR used by the scheduler. When the rate command is executed, a valid PIR setting must be explicitly defined.

Fractional values are not allowed and must be given as a positive integer.

Values 1 to 3200000000, max

Default none

cir-rate — The cir parameter, in kilobits, overrides the administrative CIR used by the scheduler. When the rate command is executed, a CIR setting is optional. The sum keyword specifies that the CIR be used as the summed CIR values of the children schedulers or queues.

Fractional values are not allowed and must be given as a positive integer.

Values 0 to 3200000000, sum, max

Default sum

use-ingress-l2tp-dscp

Syntax	[no] use-ingress-l2tp-dscp
Context	config>subscr-mgmt>sla-prof>egress
Description	<p>This command enables the use of the DSCP marking taken from the L2TP header received on an L2TP Access Concentrator (LAC) for egress classification for the subscriber host using the associated sla-profile.</p> <p>This command is ignored if the ingress packet is not identified as an L2TP packet.</p>
Default	no use-ingress-l2tp-dscp

one-time-http-redirection

Syntax	one-time-http-redirection <i>filter-id</i> one-time-http-redirection
Context	config>subscr-mgmt>sla-prof
Description	<p>This command specify the one-time http redirection filter id. This filter will apply to the host when host is created, and will be replaced by the sla-profile ingress filter (configured in the config>subscr-mgmt>sla-prof>ingress context) after first HTTP request from host has been redirected.</p>

Note: The system does not check if the configured filter include http-redirection entry. If the filter does not include the http-redirection then it will not be replaced in future.

If 7750 SR receives filter insertion via CoA or access-accept when one-time redirection filter is still active then the received filter entries will only be applied to the sla-profile ingress filter. And after 1st http redirection, the original sla-profile ingress filter + received filter will replace the redirection filter.

Default	no
Parameters	<i>filter-id</i> — Specifies the id of filter that is used for HTTP redirection.

rate

Syntax	rate <i>pir-rate</i> [cir <i>cir-rate</i>] no rate
Context	config>subscr-mgmt>sla-prof>ingress>qos>queue

Description	<p>This command defines the administrative Peak Information Rate (PIR) and the administrative Committed Information Rate (CIR) parameters for the queue. The PIR defines the maximum rate that the queue can transmit packets through the switch fabric (for SAP ingress queues). Defining a PIR does not necessarily guarantee that the queue can transmit at the intended rate. The actual rate sustained by the queue can be limited by oversubscription factors or available egress bandwidth.</p> <p>The CIR defines the rate at which the system prioritizes the queue over other queues competing for the same bandwidth. For SAP ingress, the CIR also defines the rate that packets are considered in-profile by the system. In-profile then out-of-profile packets are preferentially queued by the system at egress and at subsequent next hop nodes where the packet can traverse. To be properly handled throughout the network, the packets must be marked accordingly for profiling at each hop.</p> <p>The CIR can be used by the queue's parent command's <i>cir-level</i> and <i>cir-weight</i> parameters to define the amount of bandwidth considered to be committed for the child queue during bandwidth allocation by the parent scheduler.</p> <p>The rate command can be executed at anytime, altering the PIR and CIR rates for all queues created through the association of the SAP ingress or SAP egress QoS policy with the <i>queue-id</i>.</p> <p>The no form of the command returns all queues created with the <i>queue-id</i> by association with the QoS policy to the default PIR and CIR parameters (max, 0).</p>
Default	no rate
Parameters	<p><i>pir-rate</i> — Defines the administrative PIR rate, in kilobits, for the queue. When the rate command is executed, a valid PIR setting must be explicitly defined. When the rate command has not been executed, the default PIR of max is assumed.</p> <p>Fractional values are not allowed and must be given as a positive integer.</p> <p>The actual PIR rate is dependent on the queues adaptation-rule parameters and the actual hardware where the queue is provisioned.</p> <p>Values 1 to 2000000000, max</p> <p>Default max</p> <p><i>cir-rate</i> — Specifies the cir parameter used by the queue. When the rate command is executed, a CIR setting is optional. When the rate command has not been executed or the cir parameter is not explicitly specified, the default CIR (0) is assumed.</p> <p>Fractional values are not allowed and must be given as a positive integer.</p> <p>Values 0 to 2000000000, max</p> <p>Default 0</p>

policer

Syntax **policer** *policer-id* [**create**]

	no policer <i>policer-id</i>
Context	config>subscr-mgmt>sla-prof>ingress>qos config>subscr-mgmt>sla-prof>egress>qos config>subscr-mgmt>sub-profile>hsmda>ingress-qos>qos>policer
Description	<p>This command is used in the sap-ingress and sap-egress QoS policies to create, modify or delete a policer. Policers are created and used in a similar manner to queues. The policer ID space is separate from the queue ID space, allowing both a queue and a policer to share the same ID. The sap-ingress policy may have up to 32 policers (numbered 1 through 32) may be defined while the sap-egress QoS policy supports a maximum of 8 (numbered 1 through 8). While a policer may be defined within a QoS policy, it is not actually created on SAPs or subscribers associated with the policy until a forwarding class is mapped to the policer's ID.</p> <p>All policers must be created within the QoS policies. A default policer is not created when a sap-ingress or sap-egress QoS policy is created.</p> <p>Once a policer is created, the policer's metering rate and profiling rates may be defined as well as the policer's maximum and committed burst sizes (MBS and CBS respectively). Unlike queues which have dedicated counters, policers allow various stat-mode settings that define the counters that will be associated with the policer. Another supported feature—packet-byte-offset—provides a policer with the ability to modify the size of each packet based on a defined number of bytes.</p> <p>Once a policer is created, it cannot be deleted from the QoS policy unless any forwarding classes that are mapped to the policer are first moved to other policers or queues.</p> <p>The system will allow a policer to be created on a SAP QoS policy regardless of the ability to support policers on objects where the policy is currently applied. The system only scans the current objects for policer support and sufficient resources to create the policer when a forwarding class is first mapped to the policer ID. If the policer cannot be created due to one or more instances of the policy not supporting policing or having insufficient resources to create the policer, the forwarding class mapping will fail.</p> <p>The no form of this command is used to delete a policer from a sap-ingress or sap-egress QoS policy. The specified policer cannot currently have any forwarding class mappings for the removal of the policer to succeed. It is not necessary to actually delete the policer ID for the policer instances to be removed from SAPs or subscribers associated with the QoS policy once all forwarding classes have been moved away from the policer. It is automatically deleted from each policing instance although it still appears in the QoS policy.</p>
Parameters	<p><i>policer-id</i> — The policer-id must be specified when executing the policer command. If the specified ID already exists, the system enters that policer's context to allow the policer's parameters to be modified. If the ID does not exist and is within the allowed range for the QoS policy type, a context for the policer ID will be created (depending on the system's current create keyword requirements which may require the create keyword to actually add the new policer ID to the QoS policy) and the system will enter that new policer's context for possible parameter modification.</p> <p>Values 1to63</p>

cbs

Syntax	cbs { <i>size</i> [bytes kilobytes] default } no cbs
Context	config>subscr-mgmt>sla-prof>ingress>qos>policer config>subscr-mgmt>sla-prof>egress>qos>policer config>subscr-mgmt>sub-profile>hsmda>ingress-qos>qos>policer
Description	<p>This command is used to configure the policer's CIR leaky bucket's exceed threshold. The CIR bucket's exceed threshold represents the committed burst tolerance allowed by the policer. If the policer's forwarding rate is equal to or less than the policer's defined CIR, the CIR bucket depth hovers around the 0 depth with spikes up to the maximum packet size in the offered load. If the forwarding rate increases beyond the profiling rate, the amount of data allowed to be in-profile above the rate is capped by the threshold.</p> <p>The policer's cbs size defined in the QoS policy may be overridden on an sla-profile or SAP where the policy is applied.</p> <p>The no form of this command returns the policer to its default CBS size.</p>
Default	none
Parameters	<p>size [bytes kilobytes] — The size parameter is required when specifying cbs and is expressed as an integer representing the required size in either bytes or kilobytes. The default is kilobytes. The optional byte and kilobyte keywords are mutually exclusive and are used to explicitly define whether size represents bytes or kilobytes.</p> <p>byte — When byte is defined, the value given for size is interpreted as the queue's MBS value given in bytes.</p> <p>kilobyte — When kilobytes is defined, the value is interpreted as the queue's MBS value given in kilobytes.</p> <p>Values 0 to 16777216</p> <p>Default kilobyte</p>

cbs

Syntax	cbs { <i>size</i> [bytes kilobytes] default } no cbs
Context	config>subscr-mgmt>sub-profile>hsmda>egress-qos>qos>queue config>subscr-mgmt>sub-profile>hsmda>ingress-qos>qos>queue

Description	<p>This command is used to configure the policer's CIR leaky bucket's exceed threshold. The CIR bucket's exceed threshold represents the committed burst tolerance allowed by the policer. If the policer's forwarding rate is equal to or less than the policer's defined CIR, the CIR bucket depth hovers around the 0 depth with spikes up to the maximum packet size in the offered load. If the forwarding rate increases beyond the profiling rate, the amount of data allowed to be in-profile above the rate is capped by the threshold.</p> <p>The policer's cbs size defined in the QoS policy may be overridden on an sla-profile or SAP where the policy is applied.</p> <p>The no form of this command returns the policer to its default CBS size.</p>
Default	none
Parameters	<p>size [bytes kilobytes] — The size parameter is required when specifying cbs and is expressed as an integer representing the required size in either bytes or kilobytes. The default is kilobytes. The optional byte and kilobyte keywords are mutually exclusive and are used to explicitly define whether size represents bytes or kilobytes.</p> <p>byte — When byte is defined, the value given for size is interpreted as the queue's MBS value given in bytes.</p> <p>kilobyte — When kilobytes is defined, the value is interpreted as the queue's MBS value given in kilobytes.</p> <p>Values 1 to 4194304</p> <p>Default kilobyte</p>

mbs

Syntax	mbs { <i>size</i> [bytes kilobytes] default } no mbs
Context	config>subscr-mgmt>sla-prof>ingress>qos>policer config>subscr-mgmt>sla-prof>egress>qos>policer
Description	This command configures the MBS for the QoS policer.
Default	None
Parameters	<p>size [bytes kilobytes] — The size parameter is required when specifying mbs and is expressed as an integer representing the required size in either bytes or kilobytes. The default is kilobytes. The optional byte and kilobyte keywords are mutually exclusive and are used to explicitly define whether size represents bytes or kilobytes.</p> <p>byte — When byte is defined, the value given for size is interpreted as the queue's MBS value given in bytes.</p>

kilobyte — When **kilobytes** is defined, the value is interpreted as the queue's MBS value given in kilobytes.

Values 0 to 16777216

Default **kilobyte**

mbs

Syntax	mbs { <i>size</i> [bytes kilobytes] default } no mbs
Context	config>subscr-mgmt>sub-profile>hsmda>egress-qos>qos>queue config>subscr-mgmt>sub-profile>hsmda>ingress-qos>qos>queue
Description	<p>This command is used to configure the policer's PIR leaky bucket's high priority violate threshold. The high-prio-only command is applied to the MBS value to derive the bucket's low priority violate threshold. For ingress, trusted in-profile packets and un-trusted high priority packets use the policer's high priority violate threshold while trusted out-of-profile and un-trusted low priority packets use the policer's low priority violate threshold. At egress, in-profile packets use the policer's high priority violate threshold and out-of-profile packets use the policer's low priority violate threshold.</p> <p>The PIR bucket's violate threshold represent the maximum burst tolerance allowed by the policer. If the policer's offered rate is equal to or less than the policer's defined rate, the PIR bucket depth hovers around the 0 depth with spikes up to the maximum packet size in the offered load. If the offered rate increases beyond the metering rate, the amount of data allowed above the rate is capped by the threshold. The low priority violate threshold provides a smaller burst size for the lower priority traffic associated with the policer. Since all lower priority traffic is discarded at the lower burst tolerance size, the remaining burst tolerance defined by high-prio-only is available for the higher priority traffic.</p> <p>The policer's mbs size defined in the QoS policy may be overridden on an sla-profile or SAP where the policy is applied.</p> <p>The no form of this command returns the policer to its default MBS size.</p>
Default	None
Parameters	<p><i>size</i> [bytes kilobytes] — The size parameter is required when specifying mbs and is expressed as an integer representing the required size in either bytes or kilobytes. The default is kilobytes. The optional byte and kilobyte keywords are mutually exclusive and are used to explicitly define whether size represents bytes or kilobytes.</p> <p>byte — When byte is defined, the value given for size is interpreted as the queue's MBS value given in bytes.</p>

kilobyte — When **kilobytes** is defined, the value is interpreted as the queue's MBS value given in kilobytes.

Values 1 to 4194304

Default **kilobyte**

packet-byte-offset

Syntax **packet-byte-offset** {*add bytes* | **subtract bytes**}
no packet-byte-offset

Context config>subscr-mgmt>sla-prof>ingress>qos>policer
config>subscr-mgmt>sla-prof>egress>qos>policer

Description This command is used to modify the size of each packet handled by the policer by adding or subtracting a number of bytes. The actual packet size is not modified; only the size used to determine the bucket depth impact is changed. The **packet-byte-offset** command is meant to be an arbitrary mechanism that can be used to either add downstream frame encapsulation or remove portions of packet headers. Both the policing metering and profiling throughput is affected by the offset as well as the stats associated with the policer.

When child policers are adding to or subtracting from the size of each packet, the parent policer's **min-thresh-separation** value should also need to be modified by the same amount.

The policer's **packet-byte-offset** defined in the QoS policy may be overridden on an **sla-profile** or SAP where the policy is applied. Packet byte offset settings are not included in the applied rate when (queue) frame based accounting is configured and the policer is managed by HQoS, however the offsets are applied to the statistics.

The **no** version of this command is used to remove per packet size modifications from the policer.

Parameters **add bytes** — The **add** keyword is mutually exclusive to the **subtract** keyword. Either **add** or **subtract** must be specified. When **add** is defined the corresponding bytes parameter specifies the number of bytes that is added to the size each packet associated with the policer for rate metering, profiling and accounting purposes. From the policer's perspective, the maximum packet size is increased by the amount being added to the size of each packet.

Values 0 to 31

Default None

subtract bytes — The **subtract** keyword is mutually exclusive to the **add** keyword. Either **add** or **subtract** must be specified. When **b** is defined the corresponding bytes parameter specifies the number of bytes that is subtracted from the size of each packet associated with the policer for rate metering, profiling and accounting purposes. From the policer's perspective, the maximum packet size is reduced by the amount being subtracted from the size of each packet.

Note: The minimum resulting packet size used by the system is 1 byte.

Values	ingress 1to 32 egress: 1to 64
Default	None

rate

Syntax	rate {max kilobits-per-second} [cir {max kilobits-per-second}] no rate
Context	config>subscr-mgmt>sla-prof>ingress>qos>policer config>subscr-mgmt>sla-prof>egress>qos>policer
Description	<p>This command is used to configure the policer's metering and optional profiling rates. The metering rate is used by the system to configure the policer's PIR leaky bucket's decrement rate while the profiling rate configures the policer's CIR leaky bucket's decrement rate. The decrement function empties the bucket while packets applied to the bucket attempt to fill it based on the each packets size. If the bucket fills faster than how much is decremented per packet, the bucket's depth eventually reaches it's exceed (CIR) or violate (PIR) threshold. The cbs, mbs, and high-prio-only commands are used to configure the policer's PIR and CIR thresholds.</p> <p>If a packet arrives at the policer while the bucket's depth is less than the threshold associated with the packet, the packet is considered to be conforming to the bucket's rate. If the bucket depth is equal to or greater than the threshold, the packet is considered to be in the exception state. For the CIR bucket, the exception state is exceeding the CIR rate while the PIR bucket's exception state is violating the PIR bucket rate. If the packet is violating the PIR, the packet is marked red and will be discarded. If the packet is not red, it may be green or yellow based on the conforming or exceeding state from the CIR bucket.</p> <p>When a packet is red neither the PIR or CIR bucket depths are incremented by the packets size. When the packet is yellow the PIR bucket is incremented by the packet size, but the CIR bucket is not. When the packet is green, both the PIR and CIR buckets are incremented by the packet size. This ensures that conforming packets impact the bucket depth while exceeding or violating packets do not.</p> <p>The policer's adaptation-rule command settings are used by the system to convert the specified rates into hardware timers and decrement values for the policer's buckets.</p> <p>By default, the policer's metering rate is max and the profiling rate is 0 Kbps (all packets out-of-profile).</p> <p>The rate settings defined for the policer in the QoS policy may be overridden on an sla-profile or SAP where the policy is applied.</p>

The **no** form of this command is used to restore the default metering and profiling rate to a policer.

Parameters **{max | kilobits-per-second}** — Specifying the keyword **max** or an explicit kilobits-per-second parameter directly following the rate command is required and identifies the policer's metering rate for the PIR leaky bucket. When the policer is first created, the metering rate defaults to max. The kilobits-per-second value must be expressed as an integer and defines the rate in kilobits-per-second. The integer value is multiplied by 1,000 to derive the actual rate in bits-per-second. When max is specified, the maximum policer rate used will be equal to the maximum capacity of the card on which the policer is configured. If the policer rate is set to a value larger than the maximum rate possible for the card, then the PIR used is equivalent to max.

Values **max** or 1 to 2000000000

cir {max | kilobits-per-second} — The optional **cir** keyword is used to override the default CIR rate of the policer. Specifying the keyword max or an explicit kilobits-per-second parameter directly following the cir keyword is required and identifies the policer's profiling rate for the CIR leaky bucket. When the policer is first created, the profiling rate defaults to 0 Kbps. The kilobits-per-second value must be expressed as an integer and defines the rate in kilobits-per-second. The integer value is multiplied by 1,000 to derive the actual rate in bits-per-second. When max is specified, the maximum policer rate used will be equal to the maximum capacity of the card on which the policer is configured. If the policer rate is set to a value larger than the maximum rate possible for the card, then the CIR used is equivalent to max.

Values **max** or 0 to 2000000000

stat-mode

Syntax **stat-mode** *stat-mode*
no stat mode

Context config>subscr-mgmt>sla-prof>ingress>qos>policer
config>subscr-mgmt>sla-prof>ingress>qos>queue
config>subscr-mgmt>sla-prof>egress>qos>policer
config>subscr-mgmt>sla-prof>egress>qos>queue

Description This command is used to configure the forwarding plane octet and packet counters of a policer or queue to count packets of a specific type or state. For example separate counters for IPv4/IPv6 or separate counters for offered high and low priority policed traffic.

For policers, this command overrides the policer stat-mode configuration as defined in the sap-ingress or sap-egress qos policy. For details on sap-ingress and sap-egress policer stat-mode, refer to the Quality of Service Guide. For use in Enhanced Subscriber Management (ESM) context only, an additional stat-mode enables separate counters for IPv4 and IPv6 packets.

When a policer's stat-mode is changed while the sla profile is in use, any previous counter values are lost and any new counters are set to zero.

For queues, this command sets the stat-mode. Queue stat-mode is only available for use in Enhanced Subscriber Management (ESM) context to enable separate IPv4/IPv6 counters.

A queue's stat-mode cannot be changed while the SLA profile is in use.

Default no stat-mode

For policers, the default is **no stat-mode override**. The **sap-ingress** or **sap-egress stat-mode** is used instead.

For queues, the default is to count in-/out-of-profile octets and packets.

Parameters *statmode* — {v4-v6}
For ingress and egress qos queue stat-mode overrides
For ingress and egress qos policer stat-mode overrides, refer to the Quality of Service Guide for details on the **sap-ingress** and **sap-egress policer stat-mode** parameters.
For use in Enhanced Subscriber Management (ESM) context only:
v4-v6 — Count IPv4 and IPv6 forwarded/dropped Octets and Packets separately

9.24.2.1.10 Subscriber Identification Policy Commands

sub-ident-policy

Syntax [no] **sub-ident-policy** *sub-ident-policy-name*

Context config>subscr-mgmt

Description This command configures a subscriber identification policy. Each subscriber identification policy can have a default subscriber profile defined. The subscriber identification policy default subscriber profile overrides the system default and the subscriber SAP default subscriber profiles. Defining a subscriber identification policy default subscriber profile is optional.

The subscriber identification policy default subscriber profile cannot be defined with the subscriber profile name default.

Defining a subscriber profile as a subscriber identification policy default subscriber profile will cause all active subscribers currently associated with a subscriber SAP using the policy and associated with a subscriber policy through the system default or subscriber SAP default subscriber profiles to be reassigned to the subscriber policy defined as default on the subscriber identification policy.

Attempting to delete a subscriber profile that is currently defined as a default for a subscriber identification policy will fail.

When attempting to remove a subscriber identification policy default subscriber profile definition, the system will evaluate each active subscriber on all subscriber SAPs the subscriber identification policy is currently associated with that are using the default definition to determine whether the active subscriber can be either reassigned to a subscriber SAP default or the system default subscriber profile. If all active subscribers cannot be reassigned, the removal attempt will fail.

Parameters *sub-ident-policy-name* — Specifies the name of the subscriber identification policy.

app-profile-map

Syntax **app-profile-map**

Context config>subscr-mgmt>sub-ident-pol

Description This command enables the context to configure an application profile mapping.

entry

Syntax **entry key** *app-profile-string* **app-profile** *app-profile-name*
 no entry key *app-profile-string*

Context config>subscr-mgmt>sub-ident-pol>app-profile-map

Description This command configures an application profile string.

 The **no** form of the command removes the values from the configuration.

Parameters *app-profile-string* — Specifies the application profile string.
 app-profile-name — Specifies the application profile name.

use-direct-map-as-default

Syntax [**no**] **use-direct-map-as-default**

Context config>subscr-mgmt>sub-ident-pol>app-profile-map
 config>subscr-mgmt>sub-ident-pol>sla-profile-map

Description This command enables direct mapping of application profile as default. With this flag, a script returned string will be used as the named profile. If the named profile cannot be found, the default profile will be used.

 The **no** form of the command disables the direct mapping.

Default no use-direct-map-as-default

primary

Syntax	primary
Context	config>subscr-mgmt>sub-ident-pol
Description	This command configures a primary identification script.

script-url

Syntax	script-url <i>dhcp-script-url</i>
Context	config>subscr-mgmt>sub-ident-pol>primary config>subscr-mgmt>sub-ident-pol>secondary config>subscr-mgmt>sub-ident-pol>tertiary
Description	This command specifies the URL of the identification scripts.
Parameters	<i>dhcp-primary-script-url</i> — Specifies the URL of the primary identification script. <i>dhcp-secondary-script-url</i> — Specifies the URL of the secondary identification script. <i>dhcp-tertiary-script-url</i> — Specifies the URL of the tertiary identification script.

secondary

Syntax	secondary
Context	config>subscr-mgmt>sub-ident-pol
Description	This command configures a secondary identification script.

sla-profile-map

Syntax	sla-profile-map
Context	config>subscr-mgmt>sub-ident-pol
Description	This command configures an SLA profile mapping.

sub-profile-map

Syntax	sla-profile-map
Context	config>subscr-mgmt>sub-ident-pol
Description	This command configures a subscriber profile mapping.

entry

Syntax	entry key <i>sla-profile-string</i> sla-profile <i>sla-profile-name</i> no entry key <i>sla-profile-string</i>
Context	config>subscr-mgmt>sub-ident-pol>sla-profile-map
Description	<p>This command configures an SLA profile string. Each subscriber identification string can be provisioned into a subscriber mapping table providing an explicit mapping of the string to a specific subscriber profile. This allows certain subscribers to be directly mapped to the appropriate subscriber profile in the event that the default mappings are not desired for the subscriber.</p> <p>An explicit mapping of a subscriber identification string to a subscriber profile cannot be defined with the subscriber profile name default. It is possible for the subscriber identification string to be entered in the mapping table without a defined subscriber profile which can result in the explicitly defined subscriber to be associated with the subscriber profile named default.</p> <p>Explicitly mapping a subscriber identification string to a subscriber profile will cause an existing active subscriber associated with the string to be reassigned to the newly mapped subscriber profile. An explicit mapping overrides all default subscriber profile definitions.</p> <p>Attempting to delete a subscriber profile that is currently defined as in an explicit subscriber identification string mapping will fail.</p> <p>The system will fail the removal attempt of an explicit subscriber identification string mapping to a subscriber profile definition when an active subscriber is using the mapping and cannot be reassigned to a defined default non-provisioned subscriber profile.</p>
Parameters	<p><i>sla-profile-string</i> — Identifies the SLA profile string.</p> <p>Values 16 characters maximum</p> <p><i>sla-profile-name</i> — Identifies the SLA profile name.</p> <p>Values 32 characters maximum</p>

entry

Syntax	entry key <i>sub-profile-string</i> sub-profile <i>sub-profile-name</i> no entry key <i>sub-profile-string</i>
Context	config>subscr-mgmt>sub-ident-pol>sub-profile-map
Description	This command configures a subscriber profile string.
Parameters	<p><i>sub-profile-string</i> — Specifies the subscriber profile string.</p> <p>Values 16 characters maximum</p> <p><i>sub-profile-name</i> — Specifies the subscriber profile name.</p> <p>Values 32 characters maximum</p>

tertiary

Syntax	tertiary
Context	config>subscr-mgmt>sub-ident-pol
Description	This command configures a tertiary identification script.

Auto-Generated Subscriber Identification Key Commands

auto-sub-id-key

Syntax	auto-sub-id-key
Context	config>subscr-mgmt
Description	

ipoe-sub-id-key

Syntax	ipoe-sub-id-key <i>sub-id-key</i> [<i>sub-id-key</i> ...(up to 4 max)] no ipoe-sub-id-key
Context	config>subscr-mgmt>>auto-sub-id-key
Description	This command enables certain fields to become the base for auto-generation of the default sub-id name. The sub-id name will be auto generated if there is not a more specific method available. Such more specific methods would be a default sub-id name as a sap-id, a preconfigured static string or explicit mappings based on RADIUS/LUDB returned strings.

In case that a more specific sub-id name generation method is not available AND the auto-id keyword is defined under the def-sub-id hierarchy, the sub-id name will be generated by concatenating fields defined in this command separated by a “|” character.

The maximum sub-id name length is 32 characters while the concatenation of subscriber identification fields can easily exceed 32 characters. Subscriber host instantiation will fail in case that the sub-id name is based on subscriber identification fields whose concatenated length exceeds 32 characters. Failing the host creation rather than truncating sub-id name on a 32 character boundary will prevent collision of sub-ids (subscriber name duplication).

In case that a more specific sub-id name generation method is not available AND the auto-id keyword is NOT defined under the def-sub-id hierarchy, the sub-id name will be a random 10 character encoded string based on the fields defined under this command.

There is only one set of identification fields allowed per host type (IPoE or PPP) per chassis.

Parameters *sub-id-key* — Specifies the auto-generated sub-id keys for IPoE hosts.

Values **mac** — The MAC address can be combined with other subscriber host identification fields (circuit-id, remote-id, session-id or sap-id) to form a sub-id name in a user readable format or as a random 10 character encoded value.

In case that the mac address is used as a concatenation field in the sub-id name, then its format becomes a string xx:xx:xx:xx:xx:xx with the length 17B.

The MAC address as the subscriber host identification field is not applicable to PPPoA hosts or static hosts.

circuit-id — The circuit-id can be combined with other subscriber host identification fields (mac, remote-id, session-id or sap-id) to form a sub-id name in a user readable format or as a random 10 character encoded value.

In case that the circuit-id is used as a concatenation field in the sub-id name, then its format becomes access-node-id eth slot/port:[vlan-id] or access-node-id atm slot/port:vpi.vci with a variable length.

Note: If circuit-id contains any non printable ASCII characters, the entire circuit-id string will be formatted in hex in the sub-id name output. Otherwise all characters in circuit-id will be converted to ASCII. ASCII printable characters contain bytes in range 0x20 to 0x7E.

The circuit-id as the subscriber identification field is not applicable to PPPoA hosts, ARP hosts or static hosts.

remote-id — The remote-id can be combined with other subscriber host identification fields (mac, circuit-id, session-id or sap-id) to form a sub-id name in a user readable format or as a random 10 character encoded value.

In case that the remote-id is used as a concatenation field in the sub-id name, then its format becomes a remote-id string with a variable length.

Note: If remote-id contains any non printable ASCII characters, the entire remote-id string will be formatted in hex in the sub-id name output. Otherwise all characters in remote-id will be converted to ASCII. ASCII printable characters contain bytes in range 0x20 to 0x7E.

The remote-id as the subscriber identification field is not applicable to PPPoA hosts, ARP hosts or static hosts.

sap-id — The sap-id can be combined with other subscriber host identification fields (mac, circuit-id, remote-id, or session-id) to form a sub-id name in a user readable format or as a random 10 character encoded value.

In case that the circuit-id is used as a concatenation field in the sub-id name, then its format becomes : slot/mda:[outer-vlan].[inner-vlan] with a variable length.

The sap-id as the subscriber identification field is applicable to all hosts types with exception of static hosts.

Default ipoe-sub-id-key mac sap-id

ppp-sub-id-key

Syntax **ppp-sub-id-key** *sub-id-key* [*sub-id-key*...(up to 5 max)]
no ppp-sub-id-key

Context config>subscr-mgmt>>auto-sub-id-key

Description This command enable certain fields to become the base for auto-generation of default sub-id name. The sub-id name will be auto-generated if there is not a more specific method available. Examples of these specific methods would be a default sub-id name as a sap-id, a preconfigured static string or explicit mappings based on RADIUS/LUDB returned strings.

In case that a more specific sub-id name generation method is not available and the **auto-id** keyword is defined under the def-sub-id hierarchy, the sub-id name will be generated by concatenating fields defined in this command separated by a “|” character.

The maximum sub-id name length is 32 characters while the concatenation of subscriber identification fields can easily exceed 32 characters. The subscriber host instantiation will fail if the sub-id name is based on subscriber identification fields whose concatenated length exceeds 32 characters. Failing the host creation rather than truncating sub-id name on a 32 character boundary will prevent collision of sub-ids (subscriber name duplication).

In case that a more specific sub-id name generation method is not available and the **auto-id** keyword is not defined under the def-sub-id hierarchy, the sub-id name will be a random 10 character encoded string based on the fields defined under this command.

There is only one set of identification fields allowed per host type (IPoE or PPP) per chassis.

Parameters *sub-id-key* — Specifies the auto-generated sub-id keys for PPP hosts.

Values **mac** — The MAC address can be combined with other subscriber host identification fields (circuit-id, remote-id, session-id or sap-id) to form a sub-id name in a user readable format or as a random 10 character encoded value.

In case that the mac address is used as a concatenation field in the sub-id name, then its format becomes a string xx:xx:xx:xx:xx:xx with the length 17B.

The MAC address as the subscriber host identification field is not applicable to PPPoA hosts or static hosts.

circuit-id — The circuit-id can be combined with other subscriber host identification fields (mac, remote-id, session-id or sap-id) to form a sub-id name in a user readable format or as a random 10 character encoded value.

In case that the circuit-id is used as a concatenation field in the sub-id name, then its format becomes access-node-id eth slot/port:[vlan-id] or access-node-id atm slot/port:vpi.vci with a variable length.

Note: If circuit-id contains any non printable ASCII characters, the entire circuit-id string will be formatted in hex in the sub-id name output. Otherwise all characters in circuit-id will be converted to ASCII. ASCII printable characters contain bytes in range 0x20 to 0x7E.

The circuit-id as the subscriber identification field is not applicable to PPPoA hosts, ARP hosts or static hosts.

remote-id — The remote-id can be combined with other subscriber host identification fields (mac, circuit-id, session-id or sap-id) to form a sub-id name in a user readable format or as a random 10 character encoded value.

In case that the remote-id is used as a concatenation field in the sub-id name, then its format becomes a remote-id string with a variable length.

Note: If remote-id contains any non printable ASCII characters, the entire remote-id string will be formatted in hex in the sub-id name output. Otherwise all characters in remote-id will be converted to ASCII. ASCII printable characters contain bytes in range 0x20 to 0x7E.

The remote-id as the subscriber identification field is not applicable to PPPoA hosts, ARP hosts or static hosts.

sap-id — The sap-id can be combined with other subscriber host identification fields (mac, circuit-id, remote-id, or session-id) to form a sub-id name in a user readable format or as a random 10 character encoded value.

In case that the circuit-id is used as a concatenation field in the sub-id name, then its format becomes : slot/mda:[outer-vlan].[inner-vlan] with a variable length.

The sap-id as the subscriber identification field is applicable to all hosts types with exception of static hosts.

session-id — The session-id can be combined with other subscriber host identification fields (mac, circuit-id, remote-id, or sap-id) to form a sub-id name in a user readable format or as a random 10 character encoded value.

In case that the circuit-id is used as a concatenation field in the sub-id name, then its format becomes a decimal number with variable length.

The session-id as the subscriber identification field is applicable only to PPPoE/PPPoEoA type hosts.

Default ppp-sub-id-key mac sap-id session-id

9.24.2.1.11 Subscriber Profile Commands

sub-profile

Syntax	[no] sub-profile <i>subscriber-profile-name</i>
Context	config>subscr-mgmt
Description	This command enables the context to configure a subscriber profile. A subscriber profile is a template used to define the aggregate QoS for all hosts within a subscriber context. This is done through the definition of the egress and ingress scheduler policies that govern the aggregate SLA for subscribers using the subscriber profile. Subscriber profiles also allow for specific SLA profile definitions when the default definitions from the subscriber identification policy must be overridden.

Subscribers are either explicitly mapped to a subscriber profile template or are dynamically associated by one of various non-provisioned subscriber profile definitions.

A subscriber host can be associated with a subscriber profile in the following ways, listed from lowest to highest precedence:

1. The subscriber profile named default.
2. The subscriber profile defined as the subscriber SAP default.
3. The subscriber profile found by the subscriber identification policy sub-profile-map.
4. The subscriber profile found by the subscriber identification policy explicit map.

In the event that no defaults are defined and the subscriber identification string is not explicitly provisioned to map to a subscriber profile, either the static subscriber host creation will fail or the dynamic subscriber host DHCP ACK will be discarded.

Default Subscriber profile:

When a subscriber profile is created with the *subscriber-profile-name* default, it will be used when no other subscriber profile is associated with the subscriber host by the system. Creating a subscriber profile with the *subscriber-profile-name* default is optional. If a default subscriber profile is not created, all subscriber hosts subscriber identification strings must match either a non-provisioned default or be provisioned as an explicit match to a subscriber profile.

The default profile has no effect on existing active subscriber on the system as they exist due to higher precedence mappings.

Attempting to delete any subscriber profile (including the profile named default) while in use by existing active subscribers will fail.

Parameters *subscriber-profile-name* — Specify the name of the subscriber profile.

Values 32 characters maximum, default

accounting-policy

Syntax **accounting-policy** *acct-policy-id*
no accounting-policy

Context config>subscr-mgmt>sub-prof

Description This command specifies the policy to use to collect accounting statistics on this subscriber profile.

A maximum of one accounting policy can be associated with a profile at one time. Accounting policies are configured in the **config>log>accounting-policy** context.

The **no** form of this command removes the accounting policy association.

Default no accounting policy

Parameters *acct-policy-id* — Enter the accounting *policy-id* as configured in the **config>log>accounting-policy** context.

Values 1 to 99

collect-stats

Syntax [**no**] **collect-stats**

Context config>subscr-mgmt>sub-prof

Description When enabled, the agent collects non-RADIUS accounting statistics.

When the **no collect-stats** command is issued the statistics are still accumulated by the IOM cards. However, the CPU will not obtain the results and write them to the billing file. If a subsequent **collect-stats** command is issued then the counters written to the billing file include all the traffic while the **no collect-stats** command was in effect.

Default collect-stats

agg-rate-limit

Syntax **agg-rate-limit** {**max** | *kilobits-per-second*} [**queue-frame-based-accounting**]
no agg-rate-limit

Context config>subscr-mgmt>sub-prof>egress

Description This command define a subscriber aggregate limit when the subscriber profile is directly associated with an egress port based scheduler instead of a scheduler policy. The optional queue-frame-based-accounting keyword allows the subscriber queues to operate in the frame based accounting mode.

Once egress frame based accounting is enabled on the subscriber profile, all queues associated with the subscriber (created through the sla-profile associated with each subscriber host) will have their rate and CIR values interpreted as frame based values. When shaping, the queues will include the 12 byte Inter-Frame Gap (IFG) and 8 byte preamble for each packet scheduled out the queue. The profiling CIR threshold will also include the 20 byte frame encapsulation overhead. Statistics associated with the queue do not include the frame encapsulation overhead. Packet byte offset settings are not included in the applied rate when queue frame based accounting is configured, however the offsets are applied to the statistics.

The queue-frame-based-accounting keyword does not change the behavior of the egress-agg-rate-limit rate value. Since egress-agg-rate-limit is always associated with egress port based scheduling and egress port based scheduling is dependent on frame based operation, the egress-agg-rate-limit rate is always interpreted as a frame based value.

Enabling queue-frame-based-accounting will not cause statistics for queues associated with the subscriber to be cleared.

The **no** form of the command removes both an egress aggregate rate limit and egress frame based accounting for all subscribers associated with the sub-profile. If a subscriber's accounting mode is changed, the subscriber's queue statistics are cleared.

Parameters {**max** | *kilobits-per-second*} — The **max** keyword and *kilobits-per-second* parameter are mutually exclusive. Either max or a value for kilobits-per-second must follow the egress-agg-rate-limit command.

max — The max keyword specifies that the egress aggregate rate limit for the subscriber is unlimited. Scheduling for the subscriber queues will only be governed by the individual queue parameters and any congestion on the port relative to each queues scheduling priority.

kilobits-per-second — The kilobits-per-second parameter defines an actual egress aggregate rate to which all queues associated with the sub-profile will be limited. The limit will be managed per subscriber associated with the sub-profile. The value must be defined as an integer and is representative of increments of 1000 bits per second.

Values 1 to 800000000

Default max

queue-frame-based-accounting — The optional queue-frame-based-accounting keyword enables frame based accounting on all queues associated with the subscriber profile. If frame based accounting is required when a subscriber aggregate limit is not necessary, the max keyword should precede the queue-frame-based-accounting keyword. If frame based accounting must be disabled, execute egress-agg-rate-limit without the queue-frame-based-accounting keyword present.

Default Frame based accounting is disabled by default

queue-frame-based-accounting — Specifies whether to use frame-based accounting when evaluating the aggregation rate limit for the egress queues for this SAP.

avg-frame-size

Syntax **avg-frame-size** *bytes*
no avg-frame-size

Context config>subscriber-managemet>sub-profile>egress

Description This command specifies the average frame size used in the calculation of the fixed and variable encapsulation offset when the command encap-offset is enabled in the egress context of a subscriber profile.

If the user does not explicitly configure a value for the avg-frame-size parameter, then it will also be assumed the offset is zero.

The **no** form of the command removes the avg-frame-size parameter from the subscriber profile.

Default 0

Parameters *bytes* — specifies the average frame size value to be used in the adjustment of the subscriber aggregate rate to account for the per packet variable expansion of the last mile for the specific session used by the subscriber host.

Values 64 to 4096

encap-offset

Syntax **encap-offset** [*type type*]
no encap-offset

Context	config>subscriber-managemet>sub-profile>egress
Description	<p>This command enables the adjustment of the queue and subscriber aggregate rate based on the last mile Ethernet or ATM encapsulation.</p> <p>In R9.0, the data path computes the adjusted frame size real-time for each serviced packet from a queue by adding the actual packet size to the fixed offset provided by CPM for this queue and variable AAL5 padding.</p> <p>When this command is enabled, the fixed packet offset is derived from the encapsulation type value signaled in the Access-loop-encapsulation sub-TLV in the Vendor-Specific PPPoE Tags or DHCP Relay Options as per RFC 4679. If the user specifies an encapsulation type with the command, this value is used as the default value for all hosts of this subscriber until a host session signaled a valid value. The signaled value is applied to this host only and the remaining hosts of this subscriber continue to use the user entered default type value if configured, or no offset is applied. However, hosts of the same subscriber using the same SLA profile and which are on the same SAP will share the same instance of FC queues. In this case, the last valid encapsulation value signaled by a host of that same instance of the SAP egress QoS policy will override any previous signaled or configured value.</p> <p>If the user manually applied a constant byte offset to each packet serviced by the queue by configuring the packet-byte-offset, it will have no effect on the net offset computed for the packet. This net offset is stored in the subscriber host table.</p> <p>The procedures for handling signaling changes or configuration changes affecting the subscriber profile are as follows:</p> <p>The avg-frame-size parameter in the subscriber profile is ignored.</p> <p>If the user specifies an encapsulation type with the command, this value is used as the default value for all hosts of this subscriber until a host session signaled a valid value. The signaled value is applied to this host and other hosts of the same subscriber sharing the same SLA profile and which are on the same SAP. The remaining hosts of this subscriber continue to use the user entered default type value if configured, or no offset is applied.</p> <p>If the user enables/disables the encap-offset option, or changes the parameter value of the encap-offset option, CPM immediately triggers a re-evaluation of subscribers hosts using the corresponding subscriber profile and an update the IOM with the new fixed offset value.</p> <p>If a subscriber has a static host or an ARP host, the subscriber host continues to use the user-configured default encapsulation type value or the last valid encapsulation value signaled in the PPPoE tags or DHCP relay options by other hosts of the same subscriber which use the same SLA profile instance. If none was signaled or configured, then no rate adjustment is applied.</p> <p>When the encap-offset option is configured in the subscriber profile, the subscriber host queue rates, that is, CLI and operational PIR and CIR as well as queue bucket updates, the queue statistics, that is, forwarded, dropped, and HQoS offered counters use the last-mile frame-over-the-wire format. The scheduler policy CLI and operational rates also use LM-FoW format. The port scheduler max-rate and the priority level rates and weights, if a Weighted</p>

Scheduler Group is used, are always entered in CLI and interpreted as local port frame-over-the-wire rates. The same is true for an agg-rate-limit applied to a vport. Finally the subscriber agg-rate-limit is entered in CLI as last-mile frame-over-the-wire rate. The system maintains a running average frame expansion ratio for each queue to convert queue rates between these two formats.

Parameters	<p>type <i>type</i> — The name of the default encapsulation used for all host queues of a subscriber in the absence of a valid value signaled in the PPPoE tags.</p> <p>Values pppoa-llc pppoa-null pppoeoa-llc pppoeoa-llc-fcs pppoeoa-llc-tagged pppoeoa-llc-tagged-fcs pppoeoa-null pppoeoa-null-fcs pppoeoa-null-tagged pppoeoa-null-tagged-fcs ipoa-llc ipoa-null ipoeoa-llc ipoeoa-llc-fcs ipoeoa-llc-tagged ipoeoa-llc-tagged-fcs ipoeoa-null ipoeoa-null-fcs ipoeoa-null-tagged ipoeoa-null-tagged-fcs pppoe pppoe-tagged ipoe ipoe-tagged</p>
-------------------	---

scheduler

Syntax	<p>scheduler <i>scheduler-name</i> rate <i>pir-rate</i> [cir <i>cir-rate</i>]</p> <p>no scheduler <i>scheduler-name</i></p>
Context	<p>config>subscr-mgmt>sub-prof>egress>sched</p> <p>config>subscr-mgmt>sub-prof>ingress>sched</p>
Description	<p>This command provides a way to override parameters of the existing scheduler associated with the egress or ingress scheduler policy. A scheduler defines bandwidth controls that limit each child (other schedulers and queues) associated with the scheduler. Scheduler objects are created within the hierarchical tiers of the policy. It is assumed that each scheduler created will have queues or other schedulers defined as child associations. The scheduler can be a child (take bandwidth from a scheduler in a higher tier).</p>
Parameters	<p>scheduler <i>scheduler-policy-name</i> — Specify an existing scheduler policy name.</p> <p><i>pir-rate</i> — Specify the pir-rate, in kilobits, to override the administrative PIR used by the scheduler. When the rate command is executed, a valid PIR setting must be explicitly defined</p> <p>Fractional values are not allowed and must be given as a positive integer.</p> <p>Values 1 to 3200000000, max</p> <p>Default none</p> <p><i>cir-rate</i> — The cir parameter overrides the administrative CIR used by the scheduler. When the rate command is executed, a CIR setting is optional. The sum keyword specifies that the CIR be used as the summed CIR values of the children schedulers or queues.</p> <p>Fractional values are not allowed and must be given as a positive integer.</p> <p>Values 0 to 3200000000, sum, max</p> <p>Default sum</p>

scheduler-policy

Syntax	scheduler-policy <i>scheduler-policy-name</i> no scheduler-policy
Context	config>subscriber-mgmt>sub-profile>egress config>subscriber-mgmt>sub-profile>ingress
Description	This command specifies a scheduler policy to associate to the subscriber profile. Scheduler policies are configured in the configure>qos>scheduler>policy context. Each scheduler policy is divided up into groups of schedulers based on the tier each scheduler is created under. A tier is used to give structure to the schedulers within a policy and define rules for parent scheduler associations. The policy defines the hierarchy and operating parameters for virtual schedulers.
Parameters	<i>scheduler-policy-name</i> — Specify an existing scheduler policy name.

lag-per-link-hash

Syntax	lag-per-link-hash class { <i>class</i> } weight <i>weight</i> no lag-per-link-hash								
Context	config>subscr-mgmt>sub-profile>egress								
Description	<p>This command configures weight and class to be used on LAG egress when the LAG uses weighted per-link-hash by subscribers with the profile assigned. Subscribers using profile with lag-per-link-hash default configuration, inherit weight and class from the SAP configuration (1 and 1 respectively if none configured under SAP).</p> <p>The no form of this command restores default configuration.</p>								
Default	no lag-per-link-hash								
Parameters	<i>class</i> — Specifies the class to be used to select a LAG link. <table><tr><td>Values</td><td>1, 2, 3</td></tr><tr><td>Default</td><td>1</td></tr></table> <i>weight</i> — Specifies the weight to be associated with this SAP when selecting a LAG link. <table><tr><td>Values</td><td>1 to 1024</td></tr><tr><td>Default</td><td>1</td></tr></table>	Values	1, 2, 3	Default	1	Values	1 to 1024	Default	1
Values	1, 2, 3								
Default	1								
Values	1 to 1024								
Default	1								

policer-control-policy

Syntax	policer-control-policy <i>policy-name</i> [create] no policer-control-policy
---------------	---

Context	config>subscr-mgmt>sub-prof>ingress config>subscr-mgmt>sub-prof>egress
Description	This command is used to create, delete, or modify policer control policies. The policer-control-policy controls the aggregate bandwidth available to a set of child policers. Once created, the policy can be applied to ingress or egress SAPs. The policy can also be applied to the ingress or egress context of a sub-profile.
Default	no policer-control-policy
Parameters	<p><i>policy-name</i> — Each policer-control-policy must be created with a unique policy name. The name must given as policy-name must adhere to the system policy ASCII naming requirements. If the defined policy-name already exists, the system will enter that policy's context for editing purposes. If policy-name does not exist, the system will attempt to create a policy with the specified name. Creating a policy may require use of the create parameter when the system is configured for explicit object creation mode.</p> <p>Default None</p> <p>create — The create keyword is required when a new policy is being created and the system is configured for explicit object creation mode.</p>

max-rate

Syntax	max-rate { <i>kilobits-per-second</i> max } no max-rate
Context	config>subscr-mgmt>sub-prof>ingress>policer-control-policy config>subscr-mgmt>sub-prof>egress>policer-control-policy
Description	<p>The max-rate command defines the parent policer's PIR leaky bucket's decrement rate. A parent policer is created for each time the policer-control-policy is applied to either a SAP or subscriber instance. Packets that are not discarded by the child policers associated with the SAP or subscriber instance are evaluated against the parent policer's PIR leaky bucket.</p> <p>For each packet, the bucket is first decremented by the correct amount based on the decrement rate to derive the current bucket depth. The current depth is then compared to one of two discard thresholds associated with the packet. The first discard threshold (discard-unfair) is applied if the FIR (Fair Information Rate) leaky bucket in the packet's child policer is in the confirming state. The second discard threshold (discard-all) is applied if the child policer's FIR leaky bucket is in the exceed state. Only one of the two thresholds is applied per packet. If the current depth of the parent policer PIR bucket is less than the threshold value, the parent PIR bucket is in the conform state for that particular packet. If the depth is equal to or greater than the applied threshold, the bucket is in the violate state for the packet.</p>

If the result is “conform,” the bucket depth is increased by the size of the packet (plus or minus the per-packet-offset setting in the child policer) and the packet is not discarded by the parent policer. If the result is “violate,” the bucket depth is not increased and the packet is discarded by the parent policer. When the parent policer discards a packet, any bucket depth increases (PIR, CIR and FIR) in the parent policer caused by the packet are canceled. This prevents packets that are discarded by the parent policer from consuming the child policers PIR, CIR and FIR bandwidth.

The **policer-control-policy root max-rate** setting may be overridden on each SAP or sub-profile where the policy is applied.

Default	max
Parameters	<p><i>kilobits-per-second</i> — Defining a kilobits-per-second value is mutually exclusive with the max parameter. The kilobits-per-second value must be defined as an integer that represents the number of kilobytes that the parent policer will be decremented per second. The actual decrement is performed per packet based on the time that has elapsed since the last packet associated with the parent policer.</p> <p>Values Integer 0 – 2000000000</p> <p>max — The max parameter is mutually exclusive with defining a kilobits-per-second value. When max is specified, the parent policer does not enforce a maximum rate on the aggregate throughput of the child policers. This is the default setting when the policer-control-policy is first created and is the value that the parent policer returns to when no max-rate is executed. In order for the parent policer to be effective, a kilobits-per-second value should be specified.</p> <p>no max-rate — The no max-rate command returns the policer-control-policy’s parent policer maximum rate to max.</p>

priority-mbs-thresholds

Syntax	priority-mbs-thresholds
Context	config>subscr-mgmt>sub-prof>ingress>policer-control-policy config>subscr-mgmt>sub-prof>egress>policer-control-policy
Description	<p>The priority-mbs-thresholds command contains the root arbiter parent policer’s min-thresh-separation command and each priority level’s mbs-contribution command that is used to internally derive each priority level’s shared-portion and fair-portion values. The system uses each priority level’s shared-portion and fair-portion value to calculate each priority level’s discard-unfair and discard-all MBS thresholds that enforce priority sensitive rate-based discards within the root arbiter’s parent policer.</p> <p>The priority-mbs-thresholds CLI node always exists and does not need to be created.</p>

min-thresh-separation

Syntax	min-thresh-separation <i>size</i> [bytes kilobytes] no min-thresh-separation
Context	config>subscr-mgmt>sub-prof>ingress>policer-control-policy>priority-mbs-thresholds config>subscr-mgmt>sub-prof>egress>policer-control-policy>priority-mbs-thresholds
Description	The min-thresh-separation command defines the minimum required separation between each in-use discard threshold maintained for each parent policer context associated with the policer-control-policy. The min-thresh-separation value may be overridden on each SAP or sub-profile to which the policy is applied.

The system uses the default or specified min-thresh-separation value in order to determine the minimum separation required between each of the of the parent policer discard thresholds. The system enforces the minimum separation based on the following behavior in two ways. The first is determining the size of the shared-portion for each priority level (when the **mbs-contribution** command's optional fixed keyword is not specified):

- When a parent policer instance's priority level has less than two child policers associated, the shared-portion for the level will be zero.
- When a parent policer instance's priority level has two or more child policers associated, the shared-portion for the level will be equal to the current value of **min-thresh-separation**.

The second function the system uses the **min-thresh-separation** value for is determining the value per priority level for the fair-portion:

- When a parent policer instance's priority level has no child policers associated, the fair-portion for the level will be zero.
- When a parent policer instance's priority level has one child policer associated, the fair-portion will be equal to the maximum of the min-thresh-separation value and the priority level's mbs-contribution value.
- When a parent policer instance's priority level has two or more child policers associated, the fair-portion will be equal to the maximum of the following:
 - **min-thresh-separation** value
 - The priority level's **mbs-contribution** value less **min-thresh-separation** value

When the **mbs-contribution** command's optional fixed keyword is defined for a priority level within the policy, the system will treat the defined **mbs-contribution** value as an explicit definition of the priority level's MBS. While the system will continue to track child policer associations with the parent policer priority levels, the association counters will have no effect. Instead the following rules will be used to determine a fixed priority level's shared-portion and fair-portion:

- If a fixed priority level's **mbs-contribution** value is set to zero, both the shared-portion and fair-portion will be set to zero
- If the **mbs-contribution** value is not set to zero:
 - The shared-portion will be set to the current **min-thresh-separation** value

- The fair-portion will be set to the maximum of the following:

min-thresh-separation value

mbs-contribution value less **min-thresh-separation** value

Each time the **min-thresh-separation** value is modified, the thresholds for all instances of the parent policer created through association with this **policer-control-policy** are reevaluated.

Determining the Correct Value for the Minimum Threshold Separation Value

The minimum value for **min-thresh-separation** should be set equal to the maximum size packet that will be handled by the parent policer. This ensures that when a lower priority packet is incrementing the bucket, the size of the increment will not cause the bucket's depth to equal or exceed a higher priority threshold. It also ensures that an unfair packet within a priority level cannot cause the PIR bucket to increment to the discard-all threshold within the priority.

When evaluating maximum packet size, each child policer's per-packet-offset setting should be taken into consideration. If the maximum size packet is 1518 bytes and a per-packet-offset parameter is configured to add 20 bytes per packet, min-thresh-separation should be set to 1538 due to the fact that the parent policer will increment its PIR bucket using the extra 20 bytes.

In most circumstances, a value larger than the maximum packet size is not necessary. Management of priority level aggregate burst tolerance is intended to be implemented using the priority level **mbs-contribution** command. Setting a value larger than the maximum packet size will not adversely affect the policer performance, but it may increase the aggregate burst tolerance for each priority level.

Note: A priority level's shared-portion of the parent policer's PIR bucket depth is only necessary to provide some separation between a lower priority's discard-all threshold and this priority's discard-unfair threshold. It is expected that the burst tolerance for the unfair packets is relatively minimal since the child policers feeding the parent policer priority level all have some amount of fair burst before entering into an FIR exceed or unfair state. The fair burst amount for a priority level is defined using the mbs-contribution command.

The **no** form of this command returns the policy's **min-thresh-separation** value to the default value.

Default **no min-thresh-separation**

Parameters	<p>size [bytes kilobytes] — The size parameter is required when executing the min-thresh-separation command. It is expressed as an integer and specifies the shared portion in bytes or kilobytes that is selected by the trailing bytes or kilobytes keywords. If both bytes and kilobytes are missing, kilobytes is the assumed value. Setting this value has no effect on parent policer instances where the min-thresh-separation value has been overridden.</p> <p>Values 0 – 16777216</p> <p>Default none</p> <p>[bytes kilobytes] — The bytes keyword is optional and is mutually exclusive with the kilobytes keyword. When specified, size is interpreted as specifying the size of min-thresh-separation in bytes.</p> <p>The kilobytes keyword is optional and is mutually exclusive with the bytes keyword. When specified, size is interpreted as specifying the size of min-thresh-separation in kilobytes.</p> <p>Values bytes or kilobytes</p> <p>Default kilobytes</p>
-------------------	---

priority

Syntax	priority <i>level</i>
Context	config>subscr-mgmt>sub-prof>ingress>policer-control-policy>priority-mbs-thresholds config>subscr-mgmt>sub-prof>egress>policer-control-policy>priority-mbs-thresholds
Description	<p>The priority level command contains the mbs-contribution configuration command for a given strict priority level. Eight levels are supported numbered 1 through 8 with 8 being the highest strict priority.</p> <p>Each of the eight priority CLI nodes always exists and do not need to be created. While parameters exist for each priority level, the parameters are only applied when the priority level within a parent policer instance is currently supporting child policers.</p>

mbs-contribution

Syntax	mbs-contribution <i>size</i> [bytes kilobytes] [fixed] no mbs-contribution
Context	config>subscr-mgmt>sub-prof>ingress>policer-control-policy>priority-mbs-thresholds>priority config>subscr-mgmt>sub-prof>egress>policer-control-policy>priority-mbs-thresholds>priority

Description The **mbs-contribution** command is used to configure the policy-based burst tolerance for a parent policer instance created when the policy is applied to a SAP or subscriber context. The system uses the parent policer's **min-thresh-separation** value, the priority level's **mbs-contribution** value and the number of child policers currently attached to the priority level to derive the priority level's shared-portion and fair-portion of burst tolerance within the local priority level. The shared-portion and fair-portions for each priority level are then used by the system to calculate each priority level's discard-unfair threshold and discard-all threshold.

The value for a priority level's **mbs-contribution** within the policer-control-policy may be overridden on the SAP or subscriber sub-profile where the policy is applied in order to allow fine tuning of the discard-unfair and discard-all thresholds relevant to the needs of the local child policers on the object.

Accumulative Nature of Burst Tolerance for a Parent Policer Priority Level

When defining **mbs-contribution**, the specified size may only be a portion of the burst tolerance associated with the priority level. The packets associated with the priority level share the burst tolerance of lower within the parent policer. As the parent policer PIR bucket depth increases during congestion, the lower priority packets eventually experience discard based on each priority's discard-unfair and discard-all thresholds. Assuming congestion continues once all the lower priority packets have been prevented from consuming bucket depth, the burst tolerance for the priority level will be consumed by its own packets and any packets associated with higher priorities.

The Effect of Fair and Unfair Child Policer Traffic at a Parent Policer Priority Level

The system continually monitors the offered rate of each child policer on each parent policer priority level and detects when the policer is in a congested state (the aggregate offered load is greater than the decrement rate defined on the parent policer). As previously stated, the result of congestion is that the parent policer's bucket depth will increase until it eventually hovers around either a discard-unfair or discard-all threshold belonging to one of the priority levels. This threshold is the point where enough packets are being discarded that the increment rate and decrement rate begin to even out. If only a single child policer is associated to the priority level, the discard-unfair threshold is not used since fairness is only applicable when multiple child policers are competing at the same priority level.

When multiple child policers are sharing the congested priority level, the system uses the offered rates and the parenting parameters of each child to determine the fair rate per child when the parent policer is unable to meet the bandwidth needs of each child. The fair rate represents the amount of bandwidth that each child at the priority level should receive relative to the other children at the same level according to the policer control policy instance managing the child policers. This fair rate is applied as the decrement rate for each child's FIR bucket. Changing a child's FIR rate does not modify the amount of packets forwarded by the parent policer for the child's priority level. It simply modifies the forwarded ratio between the children on that priority level. Since each child FIR bucket has some level of burst tolerance before marking its packets as unfair, the current parent policer bucket depth may at times rise above the discard-unfair threshold. The mbs-contribution value provides a means to define how much separation is provided between the priority level's discard-unfair and discard-all threshold to allow the parent policer to absorb some amount of FIR burst before reaching the priority's discard-all threshold.

This level of fair aggregate burst tolerance is based on the decrement rate of the parent policer's PIR bucket while the individual fair bursts making up the aggregate are based on each child's FIR decrement rate. The aggregate fair rate of the priority level is managed by the system with consideration of the current rate of traffic in higher priority levels. In essence, the system ensures that for each iteration of the child FIR rate calculation, the sum of the child FIR decrement rates plus the sum of the higher priority traffic increment rates equals the parent policers decrement rate. This means that dynamic amounts of higher priority traffic can be ignored when sizing a lower priority's fair aggregate burst tolerance. Consider the following:

- The parent policer decrement rate is set to 20 Mbps (max-rate 20,000).
- A priority level's fair burst size is set to 30 Kbytes (mbs-contribution 30 kilobytes).
- Higher priority traffic is currently taking 12 Mbps.
- The priority level has three child policers attached.
- Each child's PIR MBS is set to 10 Kbytes, which makes each child's FIR MBS 10 Kbytes.
- The children want 10 Mbps, but only 8 Mbps is available,
- Based on weights, the children's FIR rates are set as follows:

	FIR Rate	FIR MBS
Child 1	4 Mbps	10 Kbytes
Child 2	3 Mbps	10 Kbytes
Child 3	1 Mbps	10 Kbytes

The 12 Mbps of the higher priority traffic and the 8 Mbps of fair traffic equal the 20 Mbps decrement rate of the parent policer.

It is clear that the higher priority traffic is consuming 12 Mbps of the parent policer's decrement rate, leaving 8 Mbps of decrement rate for the lower priority's fair traffic.

- The burst tolerance of child 1 is based on 10 Kbytes above 4 Mbps,
- The burst tolerance of child 2 is based on 10 Kbytes above 3 Mbps,
- The burst tolerance of child 3 is based on 10 Kbytes above 1 Mbps.

If all three children burst simultaneously (unlikely), they will consume 30 Kbytes above 8 Mbps. This is the same as the remaining decrement rate after the higher priority traffic.

Parent Policer Total Burst Tolerance and Downstream Buffering

The highest in-use priority level's discard-all threshold is the total burst tolerance of the parent policer. In some cases the parent policer represents downstream bandwidth capacity and the max-rate of the parent policer is set to prevent overrunning the downstream bandwidth. The burst tolerance of the parent policer defines how much more traffic may be sent beyond the downstream scheduling capacity. In the worst case scenario, when the downstream buffering is insufficient to handle the total possible burst from the parent policer, downstream discards based on lack of buffering may occur. However, in all likelihood, this is not the case.

In most cases, lower priority traffic in the policer will be responsible for the greater part of congestion above the parent policer rate. Since this traffic is discarded with a lower threshold, this lowers the effective burst tolerance even while the highest priority traffic is present.

Configuring a Priority Level's MBS Contribution Value

In the most conservative case, a priority level's **mbs-contribution** value may be set to be greater than the sum of child policer's mbs and one max-size-frame per child policer. This ensures that even in the absolute worst case where all the lower priority levels are simultaneously bursting to the maximum capacity of each child, enough burst tolerance for the priority's children will exist if they also burst to their maximum capacity.

Since simply adding up all the child policer's PIR MBS values may result in large overall burst tolerances that are not ever likely to be needed, you should consider some level of burst oversubscription when configuring the **mbs-contribution** value for each priority level. The amount of oversubscription should be determined based on the needs of each priority level.

Using the Fixed Keyword to Create Deterministic Parent Policer Discard Thresholds

In the default behavior, the system ignores the **mbs-contribution** values for a priority level on a subscriber or SAP parent policer when a child policer is not currently associated with the level. This prevents additional burst tolerance from being added to higher priority traffic within the parent policer.

This does cause fluctuations in the defined threshold values when child policers are added or removed from a parent policer instance. If this behavior is undesirable, the fixed keyword may be used which causes the **mbs-contribution** value to always be included in the calculation of parent policer's discard thresholds. The defined **mbs-contribution** value may be overridden on a subscriber sla-profile or on a SAP instance, but the fixed nature of the contribution cannot be overridden.

If the defined **mbs-contribution** value for the priority level is zero, the priority level will have no effect on the parent policer's defined discard thresholds. A packet associated with the priority level will use the next lower priority level's discard-unfair and discard-all thresholds.

Default **no mbs-contribution**

The **no mbs-contribution** command returns the policy's priority level's MBS contribution to the default value. When changed, the thresholds for the priority level and all higher priority levels for all instances of the parent policer will be recalculated.

Parameters *size* [**bytes** | **kilobytes**] — The size parameter is required when executing the **mbs-contribution** command. It is expressed as an integer and specifies the priority's specific portion amount of accumulative MBS for the priority level in bytes or kilobytes which is selected by the trailing **bytes** or **kilobytes** keywords. If both **bytes** and **kilobytes** are missing, **kilobytes** is assumed. Setting this value has no effect on parent policer instances where the priority level's **mbs-contribution** value has been overridden.

Values 0 to 16777216

Default none

bytes | kilobytes: — The **bytes** keyword is optional and is mutually exclusive with the **kilobytes** keyword. When specified, size is interpreted as specifying the size of **min-thresh-separation** in bytes.

The **kilobytes** keyword is optional and is mutually exclusive with the **bytes** keyword. Size is interpreted as specifying the size of min-thresh-separation in kilobytes.

Default **kilobytes**

fixed — This optional fixed keyword is used to force the inclusion of the defined **mbs-contribution** value in the parent policer's discard threshold calculations. If the **mbs-contribution** command is executed without the **fixed** keyword, the fixed calculation behavior for the priority level is removed.

policy

Syntax	policy <i>policy-name1</i> [<i>policy-name2</i>] [<i>policy-name3</i>] no policy
Context	config>subscr-mgmt>sub-prof>rad-acct
Description	This command specifies the radius accounting policy for the subscriber that is using this subscriber profile. This command allows up to three radius accounting policies. The three radius accounting policies will function according to their respective configuration, including their individual accounting mode, their own included attributes, the update interval, etc.
Default	no policy
Parameters	<i>policy-name1</i> — Specifies the name of the RADIUS accounting policy to be used for the subscriber profile (32 characters maximum). <i>policy-name2</i> — Specifies the name of the second RADIUS accounting policy to be used for the subscriber profile (32 characters maximum). <i>policy-name3</i> — Specifies the name of the third RADIUS accounting policy to be used for the subscriber profile (32 characters maximum).

session-optimized-stop

Syntax	[no] session-optimized-stop
Context	config>sub-mgmt>sub-prof>rad-acct
Description	This command optimizes a RADIUS Accounting Stop message for a PPPoE session termination (specifically for session accounting mode when the host update is enabled). By default when a PPPoE session terminates, the system removes a dual stack host in sequence, one host at a time. Therefore, the system will generate a RADIUS accounting interim for each host termination until only the final host is left. The final host will generate a final accounting stop message. Enabling this command will trigger a single Stop RADIUS accounting message and include information of all hosts without the host updates.

Default no session-optimized-stop

sla-profile-map

Syntax **sla-profile-map**

Context config>subscr-mgmt>sub-prof

Description This command enables the context to configure SLA profile mapping.

entry

Syntax **entry key** *sub-profile-string* **sub-profile** *sub-profile-name*
no entry key *sub-profile-string*

Context config>subscr-mgmt>sub-prof>sla-prof-map

Description This command configures SLA profile string mappings.

Parameters *sub-profile-string* — Specifies the subscriber profile string.
 Values 16 characters maximum
sub-profile-name — Specifies the subscriber profile name.
 Values 32 characters maximum

use-direct-map-as-default

Syntax **[no] use-direct-map-as-default**

Context config>subscr-mgmt>sub-prof>sla-prof-map

Description This command enables direct mapping of the SLA profile as default.
 The **no** form of the command disables direct mapping,

sub-mcac-policy

Syntax **sub-mcac-policy** *policy-name*
no sub-mcac-policy

Context config>subscr-mgmt>sub-prof

Description	<p>This command references the policy template in which the mcac bandwidth limits are defined. Mcac for the subscriber is effectively enabled with this command when the sub-profile is applied to the subscriber. The bandwidth of the channels is defined in a different policy (under the config>router>mcac context) and this policy is applied on the interface level as follows:</p> <ul style="list-style-type: none">• For group-interfaces under the config>service>vprn>igmp>grp-if>mcac context• For regular interfaces under the config>service/router>igmp>interface>mcac context <p>In case of HQoS Adjustment, it is mandatory that the sub-mcac-policy be created and applied to the subscriber. The sub-mac-policy does not have to contain any bandwidth constraints, but it has to be in a no shutdown state in order for HQoS Adjustment to work.</p>
Default	none
Parameters	<i>policy-name</i> — Specifies the policy name configured in the config>subscr-mgmt>sub-mcac-policy context.

volume-stats-type

Syntax	volume-stats-type {ip default} no volume-stats-type
Context	config>subscr-mgmt>sub-prof
Description	<p>This command enables the reporting of layer 3 (IP) based subscriber host volume accounting data.</p> <p>By default, subscriber host volume accounting data includes Layer 2 header octets and can be configured to include a fixed packet byte offset or last-mile encapsulation overhead.</p>
Default	volume-stats-type default
Parameters	<p>default — subscriber host volume accounting data is reported including the Layer 2 header octets and optional delta's introduced by configuration (for example: packet byte offset, last mile aware shaping, etc.)</p> <p>ip — subscriber host volume accounting data reporting is based on Layer 3 (IP) packet sizes. This includes subscriber host ingress/egress queue and policer stats in snmp, CLI show commands, RADIUS and XML accounting, and Diameter Gx usage monitoring. RADIUS and Diameter (DCCA) based credit control volume quota are interpreted as Layer 3 (IP).</p>

igmp-policy

Syntax	igmp-policy <i>policy-name</i> no igmp-policy
---------------	--

Context	config>subscr-mgmt>sub-prof
Description	<p>This command will enable IGMP processing per subscriber host. Without this command IGMP states will not be maintained per subscriber hosts. The referenced policy is defined under the configure>subscr-mgmt context and can be only applied via the sub-profile.</p> <p>The referenced policy contains entries such as:</p> <ul style="list-style-type: none">• description statement• import statement — IGMP filters• egress-rate-modify statement—HQoS Adjustment• mcast-redirection statement—redirection to alternate interface• static statement—definition of static IGMP groups• version statement —IGMP version• fast-leave statement• max-num-groups statement—t max number of multicast groups allowed
Parameters	<i>policy-name</i> — Name of the IGMP policy for the subscriber. The policy itself is defined under the configure>sub-mgmt context.

hsmdda

Syntax	hsmdda
Context	config>subscr-mgmt>sub-prof
Description	This command enables the context to configure egress and ingress HSMDDA queue parameters.

egress-qos

Syntax	egress-queues
Context	config>subscr-mgmt>sub-prof>hsmdda
Description	This command enables the context to configure SAP egress QOS policy for the HSMDDA egress queue.

ingress-qos

Syntax	ingress-queues
Context	config>subscr-mgmt>sub-prof>hsmdda>egress-queues

Description	This command enables the context to configure SAP egress QOS policy for the HSMDA ingress queue
--------------------	---

agg-rate

Syntax	agg-rate <i>rate</i> no agg-rate
Context	config>port>sonet-sdh>path>access>egress>vport config>port>ethernet>access>egress>vport
Description	This command configures an aggregate rate for the vport. The agg-rate <i>rate</i> , port-scheduler-policy and scheduler-policy commands are mutually exclusive. Changing between the use of a scheduler policy and the use of an agg-rate/port-scheduler-policy involves removing the existing command and applying the new command. Applying a scheduler-policy to a VPORT is only applicable to Ethernet interfaces.
Parameters	<i>rate</i> — Specifies the rate limit for the vport. Values 1 to 800000000, max

limit-unused-bandwidth

Syntax	limit-unused-bandwidth
Context	config>port>sonet-sdh>path>access>egress>vport config>port>ethernet>access>egress>vport
Description	Optional command used to enable (or disable) aggregate rate overrun protection on the agg-rate context.

agg-rate-limit

Syntax	agg-rate-limit <i>agg-rate</i> no agg-rate-limit
Context	config>subscr-mgmt>sub-prof>hsmda>egress-qos
Description	This command defines a maximum total rate for all subscriber egress queues for each subscriber associated with the sub-profile. The egress-agg-rate-limit command is mutually exclusive with the egress-scheduler-policy. When an egress-scheduler-policy is defined on the sub-profile, the egress-agg-rate-limit command will fail. If the egress-agg-rate-limit command is specified, an attempt to bind an egress-scheduler-policy to the sub-profile will fail.

A port scheduler policy must be applied on the egress port or channel the subscriber instance is bound to in order for the defined egress-aggregate-rate-limit to take effect. The egress port scheduler enforces the aggregate queue rate as it distributes its bandwidth at the various port priority levels. The port scheduler stops offering bandwidth to member queues once it has detected that the aggregate rate limit has been reached.

If a port scheduler is not defined on the egress port, the queues are allowed to operate based on their own bandwidth parameters.

The **no** form of the command removes the aggregate rate limit from the sub-profile.

Default	no agg-rate-limit
Parameters	<i>agg-rate</i> — Defines the maximum aggregate rate the egress queues associated with the subscriber profile may operate. The value is specified in kilobits per second in a base 10 context. A value of 1 indicates a rate of 1000 bits per second.
Values	1 to 40000000, max Kbps

qos

Syntax	qos <i>policy-id</i> no qos
Context	config>subscr-mgmt>sub-prof>hsmda>egress-qos
Description	This command assigns a SAP egress QoS policy to the HSMDA egress queue.
Parameters	<i>policy-id</i> — Specifies the policy ID of an existing QoS SAP egress policy.
Values	1 to 65535

qos

Syntax	qos <i>policy-id</i> no qos
Context	config>subscr-mgmt>sub-prof>hsmda>ingress-qos
Description	This command assigns a SAP ingress QoS policy to the HSMDA ingress queue.
Parameters	<i>policy-id</i> — Specifies the policy ID of an existing QoS SAP egress policy.
Values	1 to 65535

packet-byte-offset

Syntax	packet-byte-offset { add <i>add-bytes</i> subtract <i>sub-bytes</i> }
---------------	--

no packet-byte-offset

Context	config>subscr-mgmt>sub-prof>hsmda>egress-qos
Description	This command adds or subtracts the specified number of bytes to the accounting function for each packet handled by the HSMDA queue. Normally, the accounting and leaky bucket functions are based on the Ethernet DLC header, payload and the 4 byte CRC (everything except the preamble and inter-frame gap). As an example, the packet-byte-offset command can be used to add the frame encapsulation overhead (20 bytes) to the queues accounting functions.

The accounting functions affected include:

- Offered High Priority / In-Profile Octet Counter
- Offered Low Priority / Out-of-Profile Octet Counter
- Discarded High Priority / In-Profile Octet Counter
- Discarded Low Priority / Out-of-Profile Octet Counter
- Forwarded In-Profile Octet Counter
- Forwarded Out-of-Profile Octet Counter
- Peak Information Rate (PIR) Leaky Bucket Updates
- Committed Information Rate (CIR) Leaky Bucket Updates
- Queue Group Aggregate Rate Limit Leaky Bucket Updates

The secondary shaper leaky bucket, scheduler priority level leaky bucket and the port maximum rate updates are not affected by the configured packet-byte-offset. Each of these accounting functions are frame based and always include the preamble, DLC header, payload and the CRC regardless of the configured byte offset.

The packet-byte-offset command accepts either add or subtract as valid keywords which define whether bytes are being added or removed from each packet traversing the queue. An example use case for subtracting bytes from each packet is an IP based accounting function. Given a Dot1Q encapsulation, the command packet-byte-offset subtract 14 would remove the DLC header and the Dot1Q header from the size of each packet for accounting functions only. The 14 bytes are not actually removed from the packet, only the accounting size of the packet is affected.

As inferred above, the variable accounting size offered by the packet-byte-offset command is targeted at the queue and queue group level. The packet-byte-offset, when set, applies to all queues in the queue group. The accounting size of the packet is ignored by the secondary shapers, the scheduling priority level shapers and the scheduler maximum rate. The actual on-the-wire frame size is used for these functions to allow an accurate representation of the behavior of the subscriber's packets on an Ethernet aggregation network.

The packet-byte-offset value may be overridden at the queue-group level.

- Parameters** **add** *add-bytes* — Indicates that the byte value should be added to the packet for queue and queue group level accounting functions. Either the **add** or **subtract** keyword must be specified. The corresponding byte value must be specified when executing the packet-byte-offset command. The **add** keyword is mutually exclusive with the **subtract** keyword.
- Values** 0 to 31
- subtract** *sub-bytes* — Indicates that the byte value should be subtracted from the packet for queue and queue group level accounting functions. The **subtract** keyword is mutually exclusive with the **add** keyword. Either the **add** or **subtract** keyword must be specified. The corresponding byte value must be specified when executing the packet-byte-offset command.

Note: The minimum resulting packet size used by the system is 1 byte.

Values 1 to 64

queue

- Syntax** **queue** *queue-id* [**create**]
 no queue *queue-id*
- Context** config>subscr-mgmt>sub-prof>hsmda>ingress-qos>qos
- Description** This command specifies the HSMDA queue mapping for all packets in point-to-point services and unicast destined packets in multipoint services. Point-to-point services include epipe and other VLL type services. Multipoint services include IES, VPLS and VPRN services. The queue command does not apply to multicast, broadcast or unknown unicast packets within multipoint services (the multicast, broadcast and unknown commands must be used to define the queue mapping for non-unicast packets within a forwarding class). For Epipe services, the **queue** *queue-id* mapping applies to all packets, regardless of the packets destination MAC address.
- Each forwarding class has a default queue ID based on the intrinsic hierarchy between the forwarding classes. Executing the queue command within the HSMDA context of a forwarding class with a different queue ID than the default overrides the default mapping. Multiple forwarding classes may be mapped to the same HSMDA queue ID.
- The **no** form of the command returns the HSMDA queue mapping for queue to the default mapping for the forwarding class.
- Parameters** *queue-id* — Specifies the queue ID to override.
- Values** 1 to 8
- create** — This keyword is mandatory while creating a new queue override.

rate

Syntax	rate <i>pir-rate</i> [cir <i>cir-rate</i>] no rate
Context	config>subscr-mgmt>sub-prof>hsmda>egress-qos>qos>queue config>subscr-mgmt>sub-prof>hsmda>ingress-qos>queue config>subscr-mgmt>sub-prof>hsmda>ingress-qos>policer
Description	<p>This command can be used to override specific attributes of the specified queue's Peak Information Rate (PIR) and the Committed Information Rate (CIR) parameters. The PIR defines the maximum rate that the queue can transmit packets out an egress interface (for SAP egress queues). Defining a PIR does not necessarily guarantee that the queue can transmit at the intended rate. The actual rate sustained by the queue can be limited by oversubscription factors or available egress bandwidth.</p> <p>The CIR defines the rate at which the system prioritizes the queue over other queues competing for the same bandwidth. In-profile, then out-of-profile packets are preferentially queued by the system at egress and at subsequent next hop nodes where the packet can traverse. To be properly handled throughout the network, the packets must be marked accordingly for profiling at each hop.</p> <p>The CIR can be used by the queue's parent commands <i>cir-level</i> and <i>cir-weight</i> parameters to define the amount of bandwidth considered to be committed for the child queue during bandwidth allocation by the parent scheduler.</p> <p>The rate command can be executed at any time, altering the PIR and CIR rates for all queues created through the association of the SAP egress QoS policy with the <i>queue-id</i>.</p> <p>The no form of the command returns all queues created with the <i>queue-id</i> by association with the QoS policy to the default PIR and CIR parameters (max, 0).</p>
Default	<p>rate max cir 0</p> <p>The max default specifies the amount of bandwidth in kilobits per second (thousand bits per second). The max value is mutually exclusive to the pir-rate value.</p>
Parameters	<p><i>pir-rate</i> — Defines the administrative PIR rate, in kilobits, for the queue. When the rate command is executed, a valid PIR setting must be explicitly defined. When the rate command has not been executed, the default PIR of max is assumed.</p> <p>Fractional values are not allowed and must be given as a positive integer.</p> <p>The actual PIR rate is dependent on the queue's adaptation-rule parameters and the actual hardware where the queue is provisioned.</p> <p>Values 1 to 100000000</p> <p>Default max</p>

cir-rate — The **cir** parameter overrides the default administrative CIR used by the queue. When the **rate** command is executed, a CIR setting is optional. When the **rate** command has not been executed or the **cir** parameter is not explicitly specified, the default CIR (0) is assumed.

Fractional values are not allowed and must be given as a positive integer. The **sum** keyword specifies that the CIR be used as the summed CIR values of the children schedulers or queues.

Values 0 to 1000000000, **max**, **sum**

Default 0

slope-policy

Syntax	slope-policy <i>hsmda-slope-policy-name</i> no slope-policy
Context	config>subscr-mgmt>sub-prof>hsmda>egress-qos>qos>queue
Description	This command specifies an existing slope policy name. The policy contains the Maximum Buffer Size (MBS) that will be applied to the queue and the high and low priority RED slope definitions. The function of the MBS and RED slopes is to provide congestion control for an HSMDA queue. The MBS parameter defines the maximum depth a queue may reach when accepting packets. The low and high priority RED slopes provides for random early detection of congestion and slope based discards based on queue depth.

An hsmda-slope-policy can be applied to queues defined in the sap-ingress and sap-egress QoS policy hsmda-queues context. Once an HSMDA slope policy is applied to a SAP QoS policy queue, it cannot be deleted. Any edits to the policy are updated to all HSMDA queues indirectly associated with the policy.

Default HSMDA Slope Policy

An hsmda-slope-policy named **default** always exists on the system and does not need to be created. The default policy is automatically applied to all HSMDA queues unless another HSMDA slope policy is specified for the queue. The default policy cannot be modified or deleted. Attempting to execute no hsmda-slope-policy default will result in an error.

The **no** form of the command removes the slope policy from the subscriber profile HSMDA configuration.

stat-mode

Syntax	stat-mode {v4-v6} no stat-mode
Context	config>subscr-mgmt>sub-prof>hsmda>ingress-qos>qos>policer config>subscr-mgmt>sub-prof>hsmda>ingress-qos>qos>queue config>subscr-mgmt>sub-prof>hsmda>egress-qos>qos>queue

Description	<p>This command configures the forwarding plane octet and packet counters of a policer or queue to count packets of a specific type or state. For example separate counters for IPv4/IPv6.</p> <p>For HSM DA ingress policers, this command overrides the policer stat-mode configuration as defined in the sap-ingress qos policy. For details on sap-ingress and sap-egress policer stat-mode, refer to the Quality of Service Guide. For use in Enhanced Subscriber Management (ESM) context only, an additional stat-mode enables separate counters for IPv4 and IPv6 packets. stat-mode v4-v6 is the only mode that can be configured as an HSM DA ingress policer override.</p> <p>An HSM DA policer's stat-mode cannot be changed while the sub profile is in use.</p> <p>For queues, this command sets the stat-mode. Queue stat-mode is only available for use in ESM context to enable separate IPv4/IPv6 counters.</p> <p>An HSM DA queue's stat-mode cannot be changed while the sub profile is in use.</p>
Default	<p>no stat-mode</p> <p>For policers, the default is no stat-mode override. The sap-ingress stat-mode is used instead.</p> <p>For queues, the default is to count in-/out-of-profile octets and packets.</p>
Parameters	v4-v6 — Count IPv4 and IPv6 forwarded/dropped octets and packets separately

wrr-weight

Syntax	wrr-weight value no wrr-weight
Context	config>subscr-mgmt>sub-prof>hsm da>egress-qos>qos>queue
Description	<p>This command assigns the weight value to the HSM DA queue.</p> <p>The no form of the command returns the weight value for the queue to the default value.</p>
Parameters	<i>percentage</i> — Specifies the weight for the HSM DA queue. Values 1 to 32

wrr-policy

Syntax	wrr-policy hsm da-wrr-policy-name no wrr-policy
Context	config>subscr-mgmt>sub-prof>hsm da>egress-qos>qos

Description	This command associates an existing HSMDA weighted-round-robin (WRR) scheduling loop policy to the HSMDA queue.
Parameters	<i>hsmda-wrr-policy-name</i> — Specifies the existing HSMDA WRR policy name to associate to the queue.

9.24.2.1.12 Explicit Subscriber Mapping Commands

explicit-sub-map

Syntax	explicit-sub-map
Context	config>subscr-mgmt
Description	This command configures an explicit subscriber mapping

entry

Syntax	entry key <i>sub-ident-string</i> [sub-profile <i>sub-profile-name</i>] [alias <i>sub-alias-string</i>] [sla-profile <i>sla-profile-name</i>] no entry key <i>sub-profile-string</i>
Context	config>subscr-mgmt>explicit-sub-map
Description	This command configures a subscriber identification string.
Parameters	<i>sub-ident-string</i> — Specifies the profile string. <div> Values 16 characters maximum </div> <i>sub-profile-name</i> — Specifies an existing subscriber profile name. <div> Values 32 characters maximum </div> alias <i>sub-alias-string</i> — Specifies an alias for the subscriber identification string. sla-profile <i>sla-profile-name</i> — Specifies an existing SLA profile.

9.24.2.1.13 Subscriber Management Service Commands

SAP Subscriber Management Commands

sub-sla-mgmt

Syntax	[no] sub-sla-mgmt
Context	config>service>vpls>sap config>service>ies>if>sap config>service>ies>sub-if>grp-if>sap config>service>ies>sub-if>grp-if>sap-parameters config>service>vprn>if>sap config>service>vprn>sub-if>grp-if>sap config>service>ies>sub-if>grp-if>sap-parameters
Description	This command enables the context to configure subscriber management parameters for this SAP.
Default	no sub-sla-mgmt

def-sla-profile

Syntax	def-sla-profile <i>default-sla-profile-name</i> no def-sla-profile
Context	config>service>vpls>sap>sub-sla-mgmt config>service>ies>if>sap>sub-sla-mgmt config>service>ies>sub-if>grp-if>sap>sub-sla-mgmt config>service>ies>sub-if>grp-if>sap-param>sub-sla-mgmt config>service>vprn>sub-if>grp-if>sap-param>sub-sla-mgmt
Description	<p>This command specifies a default SLA profile for this SAP.</p> <p>An SLA profile is a named group of QoS parameters used to define per service QoS for all subscriber hosts common to the same subscriber within a provider service offering. A single SLA profile may define the QoS parameters for multiple subscriber hosts.</p> <p>The no form of the command removes the default SLA profile from the SAP configuration.</p>
Default	no def-sla-profile
Parameters	<i>default-sla-profile-name</i> — Specifies a default SLA profile for this SAP.

def-sub-profile

Syntax	def-sub-profile <i>default-subscriber-profile-name</i>
Context	config>service>vpls>sap>sub-sla-mgmt config>service>ies>if>sap>sub-sla-mgmt config>service>ies>sub-if>grp-if>sap>sub-sla-mgmt config>service>ies>sub-if>grp-if>sap-param>sub-sla-mgmt config>service>vprn>sub-if>grp-if>sap-param>sub-sla-mgmt
Description	<p>This command specifies a default subscriber profile for this SAP.</p> <p>A subscriber profile defines the aggregate QoS for all hosts within a subscriber context. This is done through the definition of the egress and ingress scheduler policies that govern the aggregate SLA for subscriber using the subscriber profile.</p> <p>The no form of the command removes the default SLA profile from the SAP configuration.</p>
Parameters	<i>default-sub-profile</i> — Specifies a default subscriber profile for this SAP.

sub-ident-policy

Syntax	sub-ident-policy <i>sub-ident-policy-name</i>
Context	config>service>vpls>sap>sub-sla-mgmt config>service>ies>if>sap>sub-sla-mgmt config>service>ies>sub-if>grp-if>sap>sub-sla-mgmt config>service>ies>sub-if>grp-if>sap-param>sub-sla-mgmt config>service>vprn>sub-if>grp-if>sap-param>sub-sla-mgmt
Description	<p>This command associates a subscriber identification policy to this SAP.</p> <p>Subscribers are managed by the system through the use of subscriber identification strings. A subscriber identification string uniquely identifies a subscriber. For static hosts, the subscriber identification string is explicitly defined with each static subscriber host.</p> <p>For dynamic hosts, the subscriber identification string must be derived from the DHCP ACK message sent to the subscriber host. The default value for the string is the content of Option 82 CIRCUIT-ID and REMOTE-ID fields interpreted as an octet sting. As an option, the DHCP ACK message may be processed by a subscriber identification policy which has the capability to parse the message into an alternative ASCII or octet string value.</p> <p>When multiple hosts on the same port are associated with the same subscriber identification string they are considered to be host members of the same subscriber.</p> <p>The no form of the command removes the default subscriber identification policy from the SAP configuration.</p>
Default	no sub-ident-policy

Parameters *sub-ident-policy-name* — Specifies a subscriber identification policy for this SAP.

multi-sub-sap

Syntax **multi-sub-sap** *number-of-sub*
no multi-sub-sap

Context config>service>vpls>sap>sub-sla-mgmt
 config>service>ies>sub-if>grp-if>sap>sub-sla-mgmt
 config>service>vprn>sub-if>grp-if>sap>sub-sla-mgmt

Description This command defines the maximum number of subscribers (dynamic + static) that can be simultaneously active on this SAP.

 If the limit is reached, a new host will be denied access and the corresponding DHCP ACK will be dropped.

 The **no** form of the command reverts back to the default setting.

Default 1

 no multi-sub-sap

Parameters *multi-sub-sap* — Specifies the maximum allowed. The operational maximum value may be smaller than the configured value due to equipped hardware dependencies.

Values 2 to 131071

single-sub-parameters

Syntax **single-sub-parameters**

Context config>service>vpls>sap>sub-sla-mgmt
 config>service>ies>sub-if>grp-if>sap>sub-sla-mgmt
 config>service>ies>if>sap>sub-sla-mgmt

Description This command configure single subscriber SAP parameters.

non-sub-traffic

Syntax **non-sub-traffic sub-profile** *sub-profile-name* **sla-profile** *sla-profile-name* [**subscriber** *sub-ident-string*]
no non-sub-traffic

Context config>service>vpls>sap>sub-sla-mgmt>single-sub
 config>service>ies>if>sap>sub-sla-mgmt>single-sub
 config>service>ies>sub-if>grp-if>sap>sub-sla-mgmt>single-sub

Description	<p>This command configures traffic profiles for non-IP traffic such as PPPoE. It is used in conjunction with the <code>profiled-traffic-only</code> on single subscriber SAPs and creates a subscriber host which is used to forward non-IP traffic through the single subscriber SAP without the need for SAP queues.</p> <p>The no form of the command removes any configured profile.</p>
Default	no non-sub-traffic
Parameters	<p><i>sub-profile-name</i> — Identifies the subscriber profile name.</p> <p>Values 32 characters maximum</p> <p><i>sla-profile-name</i> — Identifies the SLA profile name.</p> <p>Values 32 characters maximum</p>

profiled-traffic-only

Syntax	[no] profiled-traffic-only
Context	<pre>config>service>vpls>sap>sub-sla-mgmt>single-sub-parameters config>service>ies>if>sap>sub-sla-mgmt>single-sub config>service>ies>sub-if>grp-if>sap>sub-sla-mgmt>single-sub</pre>
Description	<p>This command specifies whether only profiled traffic is applicable for this SAP. The profiled traffic refers to single subscriber traffic on a dedicated SAP (in the VLAN-per-subscriber model). When enabled, subscriber queues are instantiated through the QOS policy defined in the <code>sla-profile</code> and the associated SAP queues are deleted. This can increase subscriber scaling by reducing the number of queues instantiated per subscriber (in the VLAN-per-subscriber model). In order for this to be achieved, any configured multi-sub-sap limit must be removed (leaving the default of 1).</p> <p>The no form of the command reverts to the default setting.</p>
Default	no profiled-traffic-only

srrp

Syntax	[no] srrp srrp-id
Context	config>service>vprn>sub-if>grp-if
Description	<p>This command creates an SRRP instance on a group IP interface. An SRRP instance manages all subscriber subnets within the group interfaces subscriber IP interface or other subscriber IP interfaces that are associated through a wholesale/retail relationship. Only one unique SRRP instance can be configured per group interface.</p>

The **no** form of the command removes an SRRP instance from a group IP interface. Once removed, the group interface ignores ARP requests for the SRRP gateway IP addresses that may exist on subscriber subnets associated with the group IP interface. Then the group interface stops routing using the redundant IP interface associated with the group IP interface and will stop routing with the SRRP gateway MAC address. Ingress packets destined to the SRRP gateway MAC will also be silently discarded. This is the same behavior as a group IP interface that is disabled (shutdown).

This command applies only to the 7750 SR.

Default no srrp

Parameters *srrp-id* — Specifies a 32 bit instance ID that must be unique to the system. The instance ID must also match the instance ID used by the remote router that is participating in the same SRRP context. SRRP is intended to perform a function similar to VRRP where adjacent IP hosts within local subnets use a default gateway to access IP hosts on other subnets.

Values 1 to 4294967295

gw-mac

Syntax **gw-mac** *mac-address*
no gw-mac

Context config>service>vprn>sub-if>grp-if>srrp

Description This command overrides the default SRRP gateway MAC address used by the SRRP instance. Unless specified, the system uses the same base MAC address for all SRRP instances with the last octet overridden by the lower 8 bits of the SRRP instance ID. The same SRRP gateway MAC address should be in-use by both the local and remote routers participating in the same SRRP context.

One reason to change the default SRRP gateway MAC address is if two SRRP instances sharing the same broadcast domain are using the same SRRP gateway MAC. The system will use the SRRP instance ID to separate the SRRP messages (by ignoring the messages that does not match the local instance ID), but a unique SRRP gateway MAC is essential to separate the routed packets for each gateway IP address.

The **no** form of the command removes the explicit SRRP gateway MAC address from the SRRP instance. The SRRP gateway MAC address can only be changed or removed when the SRRP instance is shutdown.

Parameters *mac-address* — Specifies a MAC address that is used to override the default SRRP base MAC address

Values Any MAC address except all zeros, broadcast or multicast addresses. The offset is expressed in normal Ethernet MAC address notation. The defined gw-mac cannot be 00:00:00:00:00:00, ff:ff:ff:ff:ff:ff or any multicast address.

If not specified, the system uses the default SRRP gateway MAC address with the last octet set to the 8 least significant bits of the SRRP instance ID.

keep-alive-interval

Syntax	keep-alive-interval <i>interval</i> no keep-alive-interval				
Context	config>service>vprn>sub-if>grp-if>srrp				
Description	<p>This command defines the interval between SRRP advertisement messages sent when operating in the master state. The interval is also the basis for setting the master-down timer used to determine when the master is no longer sending. The system uses three times the keep-alive interval to set the timer. Every time an SRRP advertisement is seen that is better than the local priority, the timer is reset. If the timer expires, the SRRP instance assumes that a master does not exist and initiates the attempt to become master.</p> <p>When in backup state, the SRRP instance takes the keep-alive interval of the master as represented in the masters SRRP advertisement message. Once in master state, the SRRP instance uses its own configured keep-alive interval.</p> <p>The keep-alive-interval may be changed at anytime, but will have no effect until the SRRP instance is in the master state.</p> <p>The no form of the command restores the default interval.</p>				
Parameters	<p><i>interval</i> — Specifies the interval, in milliseconds, between SRRP advertisement messages sent when operating in the master state.</p> <table><tr><td>Values</td><td>1 to 100</td></tr><tr><td>Default</td><td>10 milliseconds</td></tr></table>	Values	1 to 100	Default	10 milliseconds
Values	1 to 100				
Default	10 milliseconds				

message-path

Syntax	message-path <i>sap-id</i> no message-path
Context	config>service>vprn>sub-if>grp-if>srrp
Description	<p>This command defines a specific SAP for SRRP in-band messaging. A message-path SAP must be defined prior to activating the SRRP instance. The defined SAP must exist on the SRRP instances group IP interface for the command to succeed and cannot currently be associated with any dynamic or static subscriber hosts. Once a group IP interface SAP has been defined as the transmission path for SRRP Advertisement messages, it cannot be administratively shutdown, will not support static or dynamic subscriber hosts and cannot be removed from the group IP interface.</p>

The SRRP instance message-path command may be executed at anytime on the SRRP instance. Changing the message SAP will fail if a dynamic or static subscriber host is associated with the new SAP. Once successfully changed, the SRRP instance will immediately disable anti-spoof on the SAP and start sending SRRP Advertisement messages if the SRRP instance is activated.

Changing the current SRRP message SAP on an active pair of routers should be done in the following manner:

1. Shutdown the backup SRRP instance.
2. Change the message SAP on the shutdown node.
3. Change the message SAP on the active master node.
4. Re-activate the shutdown SRRP instance.

Shutting down the backup SRRP instance prevents the SRRP instances from becoming master due to temporarily using differing message path SAPs.

If an MCS peering is operational between the redundant nodes and the SRRP instance has been associated with the peering, the designated message path SAP will be sent from each member.

The **no** form of the command can only be executed when the SRRP instance is shutdown. Executing no message-path allows the existing SAP to be used for subscriber management functions. A new message-path SAP must be defined prior to activating the SRRP instance.

Parameters *sap-id* — Specifies the physical port identifier portion of the SAP definition.

policy

Syntax	[no] policy <i>vrrp-policy-id</i>
Context	config>service>vprn>sub-if>grp-if>srrp
Description	<p>This command associates one or more VRRP policies with the SRRP instance. A VRRP policy is a collection of connectivity and verification tests used to manipulate the in-use priorities of VRRP and SRRP instances. A VRRP policy can test the link state of ports, ping IP hosts, discover the existence of routes in the routing table or the ability to reach L2 hosts. When one or more of these tests fail, the VRRP policy has the option of decrementing or setting an explicit value for the in-use priority of an SRRP instance.</p> <p>More than one VRRP policy may be associated with an SRRP instance. When more than one VRRP policy is associated with an SRRP instance the delta decrement of the in-use priority is cumulative unless one or more test fail that have explicit priority values. When one or more explicit tests fail, the lowest priority value event takes effect for the SRRP instance. When the highest delta-in-use-limit is used to manage the lowest delta derived in-use priority for the SRRP instance.</p> <p>VRRP policy associations may be added and removed at anytime. A maximum of two VRRP policies can be associated with a single SRRP instance.</p>

The **no** form of the command removes the association with vrrp-policy-id from the SRRP instance.

Parameters *vrrp-policy-id* — Specifies one or more VRRP policies with the SRRP instance.

Values 1 to 9999

priority

Syntax **priority** *priority*
no priority

Context config>service>vprn>sub-if>grp-if>srrp

Description This command overrides the default base priority for the SRRP instance. The SRRP instance priority is advertised by the SRRP instance to its neighbor router and is compared to the priority received from the neighbor router. The router with the best (highest) priority enters the master state while the other router enters the backup state. If the priority of each router is the same, the router with the lowest source IP address in the SRRP advertisement message assumes the master state.

The base priority of an SRRP instance can be managed by VRRP policies. A VRRP policy defines a set of connectivity or verification tests which, when they fail, may lower an SRRP instances base priority (creating an in-use priority for the instance). Every time an SRRP instances in-use priority changes when in master state, it sends an SRRP advertisement message with the new priority. If the dynamic priority drops to zero or receives an SRRP Advertisement message with a better priority, the SRRP instance transitions to the *becoming backup* state.

When the priority command is not specified, or the no priority command is executed, the system uses a default base priority of 100. The priority command may be executed at anytime.

The **no** form of the command restores the default base priority to the SRRP instance. If a VRRP policy is associated with the SRRP instance, it will use the default base priority as the basis for any modifications to the SRRP instances in-use priority.

Parameters *priority* — Specifies a base priority for the SRRP instance to override the default.

Values 1 to 254

Default 100

srrp-enabled-routing

Syntax **srrp-enabled-routing** [*hold-time hold-time*]
no srrp-enabled-routing

Context config>service>ies>sub-if>grp-if

	config>service>vprn>sub-if>grp-if
Description	This command configures SRRP-enabled routing.
Parameters	hold-time <i>hold-time</i> — Specifies the hold time in seconds.
	Values 1 to 50 deci-seconds

tos-marking-state

Syntax	tos-marking-state {trusted untrusted} no tos-marking-state
Context	config>service>vprn>interface config>service>vprn>sub-if>grp-if
Description	<p>This command is used to alter the default trusted state to a non-trusted state. When unset or reverted to the trusted default, the ToS field will not be remarked by egress network IP interfaces unless the egress network IP interface has the remark-trusted state set, in which case the egress network interface treats all VPRN and network IP interface as untrusted.</p> <p>When the ingress interface is set to untrusted, all egress network IP interfaces will remark IP packets received on the network interface according to the egress marking definitions on each network interface. The egress network remarking rules also apply to the ToS field of IP packets routed using IGP shortcuts (tunneled to a remote next-hop). However, the tunnel QoS markings are always derived from the egress network QoS definitions.</p> <p>Egress marking and remarking is based on the internal forwarding class and profile state of the packet once it reaches the egress interface. The forwarding class is derived from ingress classification functions. The profile of a packet is either derived from ingress classification or ingress policing.</p> <p>The default marking state for network IP interfaces is trusted. This is equivalent to declaring no tos-marking-state on the network IP interface. When undefined or set to tos-marking-state trusted, the trusted state of the interface will not be displayed when using show config or show info unless the detail parameter is given. The save config command will not store the default tos-marking-state trusted state for network IP interfaces unless the detail parameter is also specified.</p> <p>The no tos-marking-state command is used to restore the trusted state to a network IP interface. This is equivalent to executing the tos-marking-state trusted command.</p>
Default	trusted
Parameters	<p>trusted — The default prevents the ToS field to not be remarked by egress network IP interfaces unless the egress network IP interface has the remark-trusted state set.</p> <p>untrusted — Specifies that all egress network IP interfaces will remark IP packets received on the network interface according to the egress marking definitions on each network interface.</p>

mac-da-hashing

Syntax	mac-da-hashing no mac-da-hashing
Context	config>service>vpls>sap>sub-sla-mgmt
Description	<p>This command specifies whether subscriber traffic egressing a LAG SAP has its egress LAG link selected by a function of the MAC destination address instead of the subscriber ID.</p> <p>The no form of the command reverts to the default setting.</p>
Default	no mac-da-hashing

diameter-auth-policy

Syntax	diameter-auth-policy <i>name</i> no diameter-auth-policy
Context	config>service>vpls>sap
Description	This command is used to configure the Diameter NASREQ application policy to use for authentication.
Parameters	<i>name</i> — Specifies the name of the Diameter NASREQ application policy to use for authentication.

host

Syntax	host {[ip <i>ip-address</i> [mac <i>mac-address</i>]} [subscriber-sap-id subscriber <i>sub-ident-string</i> [sub-profile <i>sub-profile-name</i> [sla-profile <i>sla-profile-name</i> [ancp-string <i>ancp-string</i>] [app-profile <i>app-profile-name</i>] [inter-dest-id <i>intermediate-destination-id</i>] no host {[ip <i>ip-address</i>] [mac <i>ieee-address</i>]} no host all
Context	config>service>vpls>sap config>service>ies>sub-if>grp-if>sap config>service>ies>if>sap config>service>vprn>sub-if>grp-if>sap
Description	<p>This command creates a static subscriber host for the SAP. Static subscriber hosts may be used by the system for various purposes. Applications within the system that make use of static host entries include anti-spoof, ARP reply agent and source MAC population into the VPLS forwarding database.</p> <p>Multiple static hosts may be defined on the SAP. Each host is identified by either a source IP address, a source MAC address or both a source IP and source MAC address. Every static host definition must have at least one address defined, IP or MAC.</p>

Static hosts can exist on the SAP even with anti-spoof and ARP reply agent features disabled. When enabled, each feature has different requirements for static hosts.

Use the **no** form of the command to remove a static entry from the system. The specified *ip-address* and *mac-address* must match the host's exact IP and MAC addresses as defined when it was created. When a static host is removed from the SAP, the corresponding anti-spoof filter entry and/or FDB entry is also removed.

Default	none
Parameters	<p>ip <i>ip-address</i> — Specify this parameter to associate a subscriber with the static subscriber host. Only one static host can be configured on the SAP with a given IP address.</p> <p>mac <i>mac-address</i> — Specify this optional parameter when defining a static host. The MAC address must be specified for anti-spoof mac, anti-spoof ip-mac and arp-reply-agent (the arp-reply-agent is supported by the 7450 ESS only). Multiple static hosts may be configured with the same MAC address given that each definition is distinguished by a unique IP address.</p> <p>Every static host definition must have at least one address defined, IP or MAC.</p> <p>subscriber <i>sub-ident-string</i> — Specify this parameter to configure an existing subscriber identification profile to be associated with the static subscriber host. The subscriber identification profile is configured in the config>subscr-mgmt>sub-ident-pol context. The subscriber information is used by the VPLS SAP arp-reply-agent to determine the proper handling of received ARP requests from subscribers. For VPLS SAPs with arp-reply-agent enabled with the optional <i>sub-ident</i> parameter, the static subscriber hosts <i>sub-ident-string</i> is used to determine whether an ARP request received on the SAP is sourced from a host belonging to the same subscriber as the destination host. When both the destination and source hosts from the ARP request are known on the SAP and the subscriber identifications do not match, the ARP request may be forwarded to the rest of the VPLS destinations.</p> <p>If the static subscriber hosts <i>sub-ident</i> string is not defined, the host is not considered to belong to the same subscriber as another host on the SAP.</p> <p>If source or destination host is unknown, the hosts are not considered to belong to the same subscriber. (ARP messages from unknown hosts are subject to anti-spoof filtering rules applied at the SAP.)</p> <p>If <i>sub-ident</i> is not enabled on the SAP arp-reply-agent, subscriber identification matching is not performed on ARP requests received on the SAP.</p> <p>ARP requests are never forwarded back to the same SAP or within the receiving SAP's Split Horizon Group.</p> <p>sub-profile <i>sub-profile-name</i> — Specify this parameter to configure an existing subscriber profile name to be associated with the static subscriber host. The subscriber profile is configured in the config>subscr-mgmt>sub-profile context.</p> <p>sla-profile <i>sla-profile-name</i> — Specify this parameter to configure an existing SLA profile name to be associated with the static subscriber host. The SLA profile is configured in the config>subscr-mgmt>sla-profile context.</p>

Note: If Enhanced Subscriber Management is enabled on a SAP using the **sub-sla-mgmt** command, the **sub-ident**, **sub-profile**, and **sla-profile** must be configured for all static hosts defined on this SAP.

Wireless Portal Protocol (WPP) Commands

wpp

Syntax	wpp
Context	config>service>ies>sub-if>grp-if config>service>vprn>sub-if>grp-if
Description	This command enables the context to configure Wireless Portal Protocol (WPP) parameters.

enable-triggered-hosts

Syntax	[no] enable-triggered-hosts
Context	config>service>vprn>sub-if>grp-if>wpp config>service>ies>sub-if>grp-if>wpp
Description	This command enables system to auto creates ESM hosts upon successful WPP authentication. Default host need to be configured under SAP on the subscriber SAP in order to redirection un-authentication client traffic to web portal.
Default	none

initial-app-profile

Syntax	initial-app-profile <i>app-profile-name</i> no initial-app-profile
Context	config>subscr-mgmt>loc-user-db>ipoe>host>wpp config>service>ies>sub-if>grp-if>wpp config>service>vprn>sub-if>grp-if>wpp
Description	This command specifies the initial app-profile for the hosts created on the group-interface. This initial app-profile will be replaced after hosts pass web portal authentication.
Default	none
Parameters	<i>app-profile-name</i> — Specifies the initial application profile, to be used during the WPP authentication phase of the IPoE hosts.

initial-sla-profile

Syntax	initial-sla-profile <i>sla-profile-name</i> no initial-sla-profile
Context	config>subscr-mgmt>loc-user-db>ipoe>host>wpp config>service>ies>sub-if>grp-if>wpp config>service>vprn>sub-if>grp-if>wpp
Description	This command specifies the initial sla-profile for the hosts created on the group-interface. This initial sla-profile will be replaced after hosts pass web portal authentication.
Default	none
Parameters	<i>sla-profile-name</i> — Specifies the initial SLA profile to be used during the WPP authentication phase of the IPOE host.

initial-sub-profile

Syntax	initial-sub-profile <i>sub-profile-name</i> no initial-sub-profile
Context	config>subscr-mgmt>loc-user-db>ipoe>host>wpp config>service>ies>sub-if>grp-if>wpp config>service>vprn>sub-if>grp-if>wpp
Description	This command specifies the initial sub-profile for the hosts created on the group-interface. This initial sub-profile will be replaced after hosts pass web portal authentication.
Default	none
Parameters	<i>sub-profile-name</i> — specifies the initial subscriber profile, to be used during the WPP authentication phase of the IPoE host.

portals

Syntax	portals
Context	config>router>wpp config>service>vprn>wpp
Description	This command enables the context to configure WPP portal server parameters.

portal

Syntax	portal router <i>router-instance name</i> <i>wpp-portal-name</i> no portal
---------------	---

Context	config>subscr-mgmt>loc-user-db>ipoe>host>wpp config>service>ies>sub-if>grp-if>wpp config>service>vprn>sub-if>grp-if>wpp
Description	This command specifies the web portal server that system talks to for the hosts on the group-interface.
Default	none
Parameters	router <i>router-instance</i> — Specifies the virtual router instance. Values router-name: Base, management service-id: 1 to 2147483647 service-name: Specifies the service name up to 64 characters in length Default Base name <i>wpp-portal-name</i> — Specifies the name of the web portal server.

lease-time

Syntax	lease-time [days <i>days</i>] [hrs <i>hours</i>] [min <i>minutes</i>] [sec <i>seconds</i>] no lease-time
Context	config>service>vprn>sub-if>grp-if>wpp
Description	This command specifies the lease time of the trigger created by the ESM host by WPP authentication.
Parameters	days <i>days</i> — Specifies the lease time in days. Values 0 to 3650 hrs <i>hours</i> — Specifies the lease time in hours. Values 1 to 23 min <i>minutes</i> — Specifies the lease time in minutes. Values 1 to 59 sec <i>seconds</i> — Specifies the lease time in seconds. Values 0 to 50

restore-disconnected

Syntax	restore-disconnected { restore no-restore } no restore-disconnected
---------------	--

Context	config>subscr-mgmt>loc-user-db>ipoe>host>wpp config>service>ies>sub-if>grp-if>wpp config>service>vprn>sub-if>grp-if>wpp
Description	This command specifies the behavior that system will restore the initial-sla-profile/initial-sub-profile/initial-aa-prfprofile when hosts disconnects instead of removing them.
Default	none
Parameters	restore — Specifies that the initial profiles must be restored after a DHCP host has disconnected. no-restore — Specifies that the initial profiles will not be restored after a DHCP host has disconnected.

user-db

Syntax	user-db <i>local-user-db-name</i> no user-db
Context	config>subscr-mgmt>loc-user-db>ipoe>host>wpp config>service>ies>sub-if>grp-if>wpp config>service>vprn>sub-if>grp-if>wpp
Description	This command configures the user database.

Note: If configured, the values configured under grp-if will only be used if there is no corresponding value returned from LUDB lookup.

This command specifies the LUDB system use to lookup while creating initial host before WPP authentication. LUDB could return WPP attributes such as portal name, initial-sla-profile, initial-sub-profile, etc. LUDB is configured in **config>subscr-mgmt>local-user-db** context.

Default	none
Parameters	<i>local-user-db-name</i> — Specifies the Local User Database name.

9.24.2.1.14 Subscriber Management Service Commands

Note: The commands described in this section apply only to the 7750 SR.

subscriber-interface

Syntax	subscriber-interface <i>ip-int-name</i> [create] subscriber-interface <i>ip-int-name</i> [create] fwd-service <i>service-id</i> fwd-subscriber-interface <i>ip-int-name</i> no subscriber-interface <i>ip-int-name</i>
Context	config>service>ies config>service>vpn
Description	<p>This command allows the operator to create special subscriber-based interfaces. It is used to contain multiple group interfaces. Multiple subnets associated with the subscriber interface can be applied to any of the contained group interfaces in any combination. The subscriber interface allows subnet sharing between group interfaces.</p> <p>Use the no form of the command to remove the subscriber interface.</p>
Default	no subscriber interfaces configured
Parameters	<p><i>ip-int-name</i> — Specifies the interface name of a subscriber interface. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.</p> <p>fwd-service <i>service-id</i> — specifies the wholesale service ID.</p> <p>Values</p> <p>fwd-subscriber-interface <i>ip-int-name</i> — specifies the wholesale subscriber interface.</p>

address

Syntax	[no] address { <i>ip-address/mask</i> <i>ip-address netmask</i> } [gw-ip-address <i>ip-address</i>] [populate-host-routes]
Context	config>service>ies>subscriber-interface config>service>vpn>subscriber-interface
Description	<p>This command creates or removes an IP address, IP subnet or broadcast address format for the interface. Multiple IP addresses can be associated with a subscriber-interface</p> <p>The IP address for the interface can be entered in either CIDR (Classless Inter-Domain Routing) or traditional dotted decimal notation. The show commands display CIDR notation and is stored in configuration files.</p>

In the IES subscriber interface context, this command is used to assign one or more host IP addresses and subnets. This differs from a normal IES interfaces where **secondary** command creates an additional subnet after the primary address is assigned. A user can then add or remove addresses without having to keep a primary address.

Use the **no** form of this command to remove the IP address assignment from the IP interface.

Default	no IP address or subnet associations configured
Parameters	<p><i>ip-address</i> — The IP address of the IP interface. The <i>ip-address</i> portion of the address command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).</p> <p><i>/</i> — The forward slash is a parameter delimiter and separates the <i>ip-address</i> portion of the IP address from the mask that defines the scope of the local subnet. No spaces are allowed between the <i>ip-address</i>, the “/” and the <i>mask-length</i> parameter. If a forward slash is not immediately following the <i>ip-address</i>, a dotted decimal mask must follow the prefix.</p> <p><i>mask</i> — The subnet mask in dotted decimal notation. When the IP prefix is not specified in CIDR notation, a space separates the <i>ip-address</i> from a traditional dotted decimal mask. The <i>mask</i> parameter indicates the complete mask that will be used in a logical AND function to derive the local subnet of the IP address. Allowed values are dotted decimal addresses in the range 128.0.0.0 – 255.255.255.252.</p>

Note: A mask of 255.255.255.255 is reserved for system IP addresses.

netmask — The subnet mask in dotted decimal notation.

Values 0.0.0.0 - 255.255.255.255

gw-ip-address *ip-address* — Specifies a separate IP address within the subnet for SRRP routing purposes. This parameter must be followed by a valid IP interface that exists within the subscriber subnet created by the address command. The defined gateway IP address cannot currently exist as a subscriber host (static or dynamic). If the defined *ip-address* already exists as a subscriber host address, the address command will fail. The specified *ip-address* must be unique within the system.

The *gw-address* parameter may be specified at anytime. If the subscriber subnet was created previously, executing the address command with a *gw-address* parameter will simply add the SRRP gateway IP address to the existing subnet.

If the address command is executed without the *gw-address* parameter when the subscriber subnet is associated with an active SRRP instance, the address will fail. If the SRRP instance is inactive or removed, executing the address command without the *gw-address* parameter will remove the SRRP gateway IP address from the specified subscriber subnet.

If the address command is executed with a new gw-address, all SRRP instances currently associated with the specified subscriber subnet will be updated with the new SRRP gateway IP address.

populate-host-routes — Specifies to populate subscriber-host routes in local FIB. Storing them in FIB benefits topologies only where the external router advertises more specific routes than the one corresponding to locally configured subscriber-interface subnets.

ipv6

Syntax	ipv6
Context	config>service>ies>sub-if>grp-if config>service>ies>sub-if config>service>vprn>sub-if
Description	This command enables the context to enable IPv6 IPoE bridged mode.

allow-unmatching-subnets

Syntax	[no] allow-unmatching-subnets
Context	config>service>ies>sub-if config>service>vprn>sub-if
Description	<p>This command allows address assignment for IPoEv4 and PPPoEv4 subscriber hosts in cases where the subscriber assigned IPv4 address falls outside of the subscriber-interface subnet configured under the same CLI hierarchy. Such subscriber host will be installed in the FIB as /32 hosts because the aggregated subscriber-interface route is not available for them (not configured under the subscriber-interface). Without the allow-unmatching-subnets command, such host are instantiated in the system but forwarding for them is disabled.</p> <p>This command can be only configured in case where the subscriber-interface has an IP address (and therefore subnet) configured. In case where the subscriber interface does not have explicitly configured and IP address, execution of this command will fail.</p> <p>IPv6 hosts are not affected by this command.</p>
Default	no allow-unmatching-subnets

allow-unmatching-subnets

Syntax	[no] allow-unmatching-subnets
Context	config>service>ies>sub-if>ipv6 config>service>vprn>sub-if>ipv6

Description	<p>This command will allow address assignment for IPoEv6 and PPPoEv6 hosts in cases where the subscriber host assigned IPv6 address or prefix falls outside of the subscriber-prefix range explicitly configured for the subscriber-interface (configure>service>vprn/ies>sub-if>ipv6) or the subscriber-prefix is not configured at all.</p> <p>SLAAC hosts will be installed in the FIB as /64 entries, the length of the installed DHCP-PD prefix will be dictated by the prefix-length and the DHCP-NA host will be installed as /128 entries.</p> <p>IPv4 subscriber hosts are unaffected by this command.</p>
Default	no allow-unmatching-subnets

allow-unmatching-prefixes

Syntax	[no] allow-unmatching-prefixes
Context	<p>config>service>ies>sub-if>ipv6</p> <p>config>service>vprn>sub-if>ipv6</p>
Description	<p>This command will allow address assignment for IPoEv6 and PPPoEv6 hosts in cases where the subscriber host assigned IPv6 address or prefix falls outside of the subscriber-prefix range explicitly configured for the subscriber-interface (configure>service>vprn/ies>sub-if>ipv6) or the subscriber-prefix is not configured at all.</p> <p>SLAAC hosts will be installed in the FIB as /64 entries, the length of the installed DHCP-PD prefix will be dictated by the prefix-length and the DHCP-NA host will be installed as /128 entries.</p> <p>IPv4 subscriber hosts are unaffected by this command.</p>
Default	no allow-unmatching-subnets

authentication-policy

Syntax	<p>authentication-policy <i>name</i></p> <p>no authentication-policy</p>
Context	<p>config>service>vprn>if</p> <p>config>service>vprn>sub-if>grp-if</p>
Description	<p>This command assigns an authentication policy to the interface.</p> <p>The no form of this command removes the policy name from the group interface configuration.</p>
Default	no authentication-policy

Parameters	<i>name</i> — Specifies the authentication policy name. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.
-------------------	---

arp-populate

Syntax	[no] arp-populate
Context	config>service>vprn>if config>service>vprn>sub-if>subscriber-interface config>service>vprn>sub-if>grp-if
Description	<p>This command enables populating static and dynamic hosts into the system ARP cache. When enabled, the host's IP address and MAC address are placed in the system ARP cache as a managed entry. Static hosts must be defined on the interface using the host command. Dynamic hosts are enabled on the system through enabling lease-populate in the IP interface DHCP context. In the event that both a static host and a dynamic host share the same IP and MAC address, the system's ARP cache retains the host information until both the static and dynamic information are removed. Both static and dynamic hosts override static ARP entries. Static ARP entries are marked as inactive when they conflict with static or dynamic hosts and will be repopulated once all static and dynamic host information for the IP address are removed. Since static ARP entries are not possible when static subscriber hosts are defined or when DHCP lease state table population is enabled, conflict between static ARP entries and the arp-populate function is not an issue.</p> <p>The arp-populate command will fail if an existing static subscriber host on the SAP does not have both MAC and IP addresses specified.</p> <p>Once arp-populate is enabled, creating a static subscriber host on the SAP without both an IP address and MAC address will fail.</p> <p>arp-populate can only be enabled on VPRN interfaces supporting Ethernet encapsulation.</p> <p>Use the no form of the command to disable ARP cache population functions for static and dynamic hosts on the interface. All static and dynamic host information in the systems ARP cache will be removed. Any existing static ARP entries previously inactive due to static or dynamic hosts will be populated in the system ARP cache.</p> <p>When arp-populate is enabled, the system will not send out ARP Requests for hosts that are not in the ARP cache. Only statically configured and DHCP learned hosts are reachable through an IP interface with arp-populate enabled.</p>
Default	not enabled

arp-timeout

Syntax	arp-timeout <i>seconds</i> no arp-timeout
---------------	--

Context	config>service>vprn>interface config>service>vprn>sub-if>grp-if
Description	<p>This command configures the minimum time in seconds an ARP entry learned on the IP interface will be stored in the ARP table. ARP entries are automatically refreshed when an ARP request or gratuitous ARP is seen from an IP host, otherwise, the ARP entry is aged from the ARP table. If arp-time-out is set to a value of zero seconds, ARP aging is disabled.</p> <p>The no form of this command restores arp-timeout to the default value.</p>
Default	14400 seconds
Parameters	<p><i>seconds</i> — The minimum number of seconds a learned ARP entry will be stored in the ARP table, expressed as a decimal integer. A value of zero specifies that the timer is inoperative and learned ARP entries will not be aged.</p> <p>Values 0 to 65535</p>

lease-populate

Syntax	lease-populate [<i>nbt-of-entries</i>] no lease-populate
Context	config>service>ies>sub-if>grp-if>dhcp
Description	<p>This command enables dynamic host lease state management for SAPs.</p> <p>For VPLS, DHCP snooping must be explicitly enabled (using the snoop command) at all points where DHCP messages requiring snooping enter the VPLS instance (both from the DHCP server and from the subscribers). Lease state information is extracted from snooped DHCP ACK messages to populate lease state table entries for the MSAP.</p> <p>The optional number-of-entries parameter is used to define the number lease state table entries allowed for an MSAP or IP interface. If number-of-entries is omitted, only a single entry is allowed. Once the maximum number of entries has been reached, subsequent lease state entries are not allowed and subsequent DHCP ACK messages are discarded.</p> <p>The retained lease state information representing dynamic hosts may be used to:</p> <ul style="list-style-type: none">• Populate an MSAP based anti-spoof filter table to provide dynamic anti-spoof filtering. If the system is unable to populate the dynamic host information in the anti-spoof filter table on the SAP, the DHCP ACK message must be discarded without adding new lease state entry or updating an existing lease state entry.• Generate dynamic ARP replies if arp-reply-agent is enabled. <p>The no form of the command disables dynamic host lease state management for the MSAP.</p>
Default	no lease-populate

delayed-enable

Syntax	delayed-enable <i>seconds</i> [init-only] no delayed-enable
Context	config>service>ies>subscriber-interface
Description	<p>This command delays making interface operational by the specified number of seconds.</p> <p>In environments with many subscribers, it can take time to synchronize the subscriber state between peers when the subscriber-interface is enabled (perhaps, after a reboot). To ensure that the state has time to be synchronized, the delayed-enable timer can be specified. The optional parameter init-only can be added to use this timer only after a reboot.</p>
Default	no delayed-enable
Parameters	<p><i>seconds</i> — Specifies the number of seconds to delay before the interface is operational.</p> <p>Values 1 to 1200</p> <p>init-only — Delays the initialization of the subscriber-interface to give the rest of the system time to complete necessary tasks such as allowing routing protocols to converge and/or to allow MCS to sync the subscriber information. The delay only occurs immediately after a reboot.</p>

export-host-routes

Syntax	[no] export-host-routes
Context	config>service>ies>subscriber-interface config>service>vprn>subscriber-interface
Description	<p>This command controls the export of subscriber management host routes from a retail service to the corresponding forwarding wholesale VPRN service.</p> <p>By default, subscriber management host routes are not exported.</p> <p>The presence of retail subscriber management host routes in the wholesale VPRN service is required for downstream traffic forwarding in multi-chassis redundancy scenario's with a redundant interface and when the retail subscriber subnets are not leaked in the wholesale VPRN service (allow-unmatching-subnets or unnumbered retail subscriber interface).</p> <p>This command will fail if the subscriber interface is not associated with a forwarding wholesale service subscriber interface or if the subscriber interface is not configured to support address allocation outside the provisioned subnets (allow-unmatching-subnets or unnumbered subscriber interface)</p>
Default	no export-host-routes

group-interface

Syntax	group-interface <i>ip-int-name</i> [create] group-interface <i>ip-int-name</i> [create] lns group-interface <i>ip-int-name</i> [create] wlangw no group-interface <i>ip-int-name</i> [create]
Context	config>service>ies>subscriber-interface config>service>vprn>subscriber-interface
Description	<p>This command creates a group interface. This interface is designed for triple-play services where multiple SAPs are part of the same subnet. A group interface may contain one or more SAPs.</p> <p>Use the no form of the command to remove the group interface from the subscriber interface.</p>
Default	no group interfaces configured
Parameters	<p><i>ip-int-name</i> — Specifies the interface name of a group interface. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.</p> <p>lns — Specifies to use LNS.</p> <p>wlangw — Specifies to use dynamic GRE encapsulation.</p>

data-trigger

Syntax	data-trigger
Context	config>service>vprn>sub-if>grp-if config>service>ies>sub-if>grp-if
Description	This command enabled the context to configure data-triggered subscriber management entities.

ingress

Syntax	ingress
Context	config>service>vprn>sub-if>grp-if
Description	This command configures ingress network filter policies for the interface.

policy-accounting

Syntax	policy-accounting <i>template-name</i>
---------------	---

no policy-accounting

Context	config>service>vprn>sub-if>grp-if>ingress
Description	This command enables/disables the specified policy accounting template.

ip-mtu

Syntax	ip-mtu <i>octets</i> no ip-mtu
Context	config>service>ies>sub-if>grp-if config>service>vprn>sub-if>grp-if
Description	<p>This command specifies the maximum size of ip packets on this group-interface. Packets larger than this will get fragmented.</p> <p>The ip-mtu applies to all IPoE host types (dhcp, arp, static). For PPP/L2TP sessions, the ip-mtu is not taken into account for the mtu negotiation; the ppp-mtu in the ppp-policy should be used instead.</p>
Default	none
Parameters	<i>octets</i> — Specifies the largest frame size (in octets) that this interface can handle.
Values	512 to 9000

enable-ingress-stats

Syntax	[no] enable-ingress-stats
Context	config>service>ies>sub-if>grp-if config>service>vprn>sub-if>grp-if
Description	<p>This command enables the collection of ingress interface IP stats. This command is only applicable to IP statistics, and not to uRPF statistics.</p> <p>If enabled, then the following statistics are collected:</p> <ul style="list-style-type: none">• IPv4 offered packets• IPv4 offered octets• IPv6 offered packets• IPv6 offered octets

Note: Octet statistics for IPv4 and IPv6 bytes at IP interfaces include the layer 2 frame overhead.

Default no enable-ingress-stats

host-connectivity-verify

Syntax	host-connectivity-verify [interval <i>interval</i>] [action { remove alarm }] [timeout <i>retry-timeout</i>] [retry-count <i>count</i>] [family <i>family</i>]
Context	config>service>ies>sub-if>grp-if config>service>vprn>sub-if>grp-if
Description	This command enables subscriber host connectivity verification on a given SAP within a service. This tool will periodically scan all known hosts (from dhcp-state) and perform UC ARP requests. The subscriber host connectivity verification will maintain state (connected vs. not-connected) for all hosts.
Default	no host-connectivity-verify
Parameters	<p>interval <i>interval</i> — The interval, in minutes, which specifies the time interval which all known sources should be verified. The actual rate is then dependent on the number of known hosts and interval.</p> <p>Values 1 to 6000</p> <p>A zero value can be used by the SNMP agent to disable host-connectivity-verify.</p> <p>action {remove alarm} — Defines the action taken on a subscriber host connectivity verification failure for a given host. The remove keyword raises an alarm and removes dhcp-state and releases all allocated resources (queues, table entries and etc.). DHCP-RELEASE will be signaled to corresponding DHCP server. Static hosts will be never removed. The alarm keyword raises an alarm indicating that the host is disconnected.</p> <p>timeout <i>retry-timeout</i> — Specifies the retry timeout.</p> <p>Values 10 to 60 seconds</p> <p>retry-count <i>count</i> — specifies the number of retry requests.</p> <p>Values 2 to 29</p> <p>family <i>family</i> — The family configuration allows the host connectivity checks to be performed for IPv4 endpoint, IPv6 endpoint or both. With family IPv6 configured, host connectivity checks will be performed on the global unicast address (assigned via SLAAC or DHCPv6 IA_NA) and link-local address of a Layer 3 RG or bridged hosts. In case of SLAAC assignment, host connectivity can only be performed if the /128 is known (via downstream ND). DHCPv6 PD assigned prefixes will be removed if link-local address is determined to be unreachable via “host connectivity check”. Reachability checks for GUA and link-local address will be done simultaneously.</p> <p>Values ipv4, ipv6, both</p>

ipoe-linking

Syntax	[no] ipoe-linking
Context	config>service>ies>sub-if config>service>vprn>sub-if config>service>ies>sub-if>grp-if config>service>vprn>sub-if>grp-if
Description	This command enables the context to configure IPoE host linking.

gratuitous-rtr-adv

Syntax	[no] gratuitous-rtr-adv
Context	config>service>ies>sub-if>ipoe-linking config>service>vprn>sub-if>ipoe-linking config>service>ies>sub-if>grp-if>ipoe-linking config>service>vprn>sub-if>grp-if>ipoe-linking
Description	If enabled, this command controls generation of unsolicited Router-advertisement on creation of v4 host. The no form of the command disables gratuitous-rtr-adv .
Default	gratuitous-rtr-adv

ipoe-session

Syntax	[no] ipoe-session
Context	config>service>ies>sub-if config>service>vprn>sub-if
Description	This command enables the context to configure IPoE session parameters.

shared-circuit-id

Syntax	[no] shared-circuit-id
Context	config>service>ies>sub-if>grp-if config>service>vprn>sub-if>grp-if

Description If configured, circuit-id in DHCPv4 option-82 is used to authenticate DHCPv6. If DHCPv6 is received before DHCPv4, it is dropped. Also, a SLAAC host is created based on DHCPv4 authentication if RADIUS returns IPv6 framed-prefix. IPv6oE host is deleted if the linked IPv4oE host is deleted due to DHCP release or lease time-out. The linkage between IPv4 and IPv6 is based on SAP and MAC address. The sharing of circuit-id from DHCPv4 for authentication of DHCPv6 (or SLAAC) allows 7750 SR to work around lack of support for LDRA on Access-nodes.

The **no** form of the command disables the feature.

Default no shared-circuit-id

ipv6

Syntax [no] ipv6

Context config>service>ies>if
config>service>vprn>if

Description This command enables the context to configure IPv6 for an IES interface.

urpf-check

Syntax [no] urpf-check

Context config>service>ies>if
config>service>ies>if>ipv6
config>service>ies>sub-if>grp-if>ipv6
config>service>ies>sub-if>grp-if
config>service>vprn>sub-if>grp-if

Description This command enables unicast RPF (uRPF) Check on this interface.

The **no** form of the command disables unicast RPF (uRPF) Check on this interface.

Default disabled

mode

Syntax mode {strict | loose | strict-no-ecmp}
no mode

Context config>service>ies>if>urpf-check
config>service>ies>sub-if>grp-if>ipv6>urpf-check

Description This command specifies the mode of unicast RPF check.

The **no** form of the command reverts to the default (strict) mode.

Default	strict
Parameters	<p>strict — When specified, uRPF checks whether incoming packet has a source address that matches a prefix in the routing table, and whether the interface expects to receive a packet with this source address prefix.</p> <p>loose — In loose mode, uRPF checks whether incoming packet has source address with a corresponding prefix in the routing table. However, the loose mode does not check whether the interface expects to receive a packet with a specific source address prefix. This object is valid only when urpf-check is enabled.</p> <p>strict-no-ecmp — When a packet is received on an interface in this mode and the SA matches an ECMP route the packet is dropped by uRPF.</p>

match-circuit-id

Syntax	[no] match-circuit-id
Context	config>service>vprn>sub-if>grp-if>dhcp
Description	<p>This command enables Option 82 circuit ID on relayed DHCP packet matching. For routed CO, the group interface DHCP relay process is stateful. When packets are relayed to the server the virtual router ID, transaction ID, SAP ID, and client hardware MAC address of the relayed packet are tracked.</p> <p>When a response is received from the server the virtual router ID, transaction ID, and client hardware MAC address must be matched to determine the SAP on which to send the packet out. In some cases, the virtual router ID, transaction ID, and client hardware MAC address are not guaranteed to be unique.</p> <p>When the match-circuit-id command is enabled this as part of the key is used to guarantee correctness in our lookup. This is really only needed when dealing with an IP aware DSLAM that proxies the client hardware MAC address.</p>
Default	no match-circuit-id

mac

Syntax	<p>mac <i>ieee-address</i></p> <p>no mac</p>
Context	config>service>ies>sub-if>grp-if
Description	<p>This command assigns a specific MAC address to a subscriber group interface.</p> <p>The no form of the command returns the MAC address of the group interface to the default value.</p>

Default	The physical MAC address associated with the Ethernet interface that the SAP is configured on (the default MAC address assigned to the interface, assigned by the system).
Parameters	<i>ieee-address</i> — Specifies the 48-bit MAC address for the static ARP in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee, and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.

oper-up-while-empty

Syntax	[no] oper-up-while-empty
Context	config>service>ies>sub-if>grp-if config>service>vprn>sub-if>grp-if
Description	<p>This command allows the subscriber interface to treat this group interface to be operationally enabled without any active SAPs.</p> <p>This command is typically used with MSAPs where advertising the subnet prior to having a MSAP dynamically created is needed.</p>

policy-control

Syntax	policy-control <i>diameter-policy-name</i> no policy-control
Context	config>service>ies>sub-if>grp-if config>service>vprn>sub-if>grp-if
Description	This command configures a policy-control policy for the interface.
Parameters	<i>diameter-policy-name</i> — Specifies the name of an existing diameter policy.

mode

Syntax	mode <i>mode</i>
Context	config>card>mda>atm
Description	<p>This command configures the ATM MDA into a mode with the increased VC scale (16k VCs, as opposed to 8K VCs). ESM is supported only in 16K VCs mode. In 16K VCs mode, there is only one queue allocated to each VC in the ATM MDA. In 8K VCs mode, there are two queues allocated per VC.</p> <p>The 16K VC mode is supported only on the 4 port oc-3/12c/STM-1/4c and the 16 port ATM oc-3/STM-1 ATM MDA.</p>

Changing the ATM MDA mode requires a reset of the MDA. A warning is issued asking for the confirmation before the command is executed.

Default	max8k-vc.
Parameters	<i>mode</i> — Specifies VC scale.
Values	max8k-vc max16k-vc

agg-rate

Syntax	[no] agg-rate
Context	config>service>ies>sub-if>grp-if>sap>egress config>service>vprn>sub-if>grp-if>sap>egress
Description	This command is used to control an HQoS aggregate rate limit. It is used in conjunction with the following parameter commands: rate , limit-unused-bandwidth , and queue-frame-based-accounting . When specified under a VPORT, the agg-rate rate, port-scheduler-policy and scheduler-policy commands are mutually exclusive. Changing between the use of a scheduler policy and the use of an agg-rate/port-scheduler-policy involves removing the existing command and applying the new command.

rate

Syntax	rate {max rate} no rate
Context	config>service>ies>sub-if>grp-if>sap>egress>agg-rate config>service>vprn>sub-if>grp-if>sap>egress>agg-rate config>port>ethernet>access>egress>vport>agg-rate
Description	This command defines the enforced aggregate rate for all queues associated with the agg-rate context. A rate must be specified for the agg-rate context to be considered to be active on the context's object (SAP, subscriber, VPORT etc.).
Parameters	<i>rate</i> — Specifies the rate limit for the VPORT. Values max , 1 to 3200000000, max

limit-unused-bandwidth

Syntax	[no] limit-unused-bandwidth
Context	config>service>ies>sub-if>grp-if>sap>egress>agg-rate

```
config>service>vprn>sub-if>grp-if>sap>egress>agg-rate
```

Description This command is used to enable (or disable) aggregate rate overrun protection on the agg-rate context.

queue-frame-based-accounting

Syntax **[no] queue-frame-based-accounting**

Context config>service>vprn>sub-if>grp-if>sap>egress>agg-rate
config>service>ies>sub-if>grp-if>sap>egress>agg-rate

Description This command is used to enabled (or disable) frame based accounting on all queues associated with the agg-rate context. Only supported on Ethernet ports. Not supported on HSM DA Ethernet ports. Packet byte offset settings are not included in the applied rate when queue frame based accounting is configured, however the offsets are applied to the statistics.

vpi

Syntax **vpi vpi egress-traffic-desc atm-td-profile-id**
no vpi vpi

Context config>port>sonet-sdh>path>atm

Description This command enables the ATM VP shaper under the ATM port. The type of ATM shaper are CBR or rt/nrt-VBR as defined by the traffic descriptor. It cannot be a UBR service-type.

All VCs within the shaper will degrade into a UBR type service class. For example, when a CBR type VC is associated with the shaper, it will degrade into a UBR type VC. Scheduling traffic amongst VCs within the shaper is based on WRR using the weight parameter.

If the VP shaper is deleted, the VCs that were under it is restored to their original service category.

The VP shaper is statically configured and instantiated upon configuration.

A VP shaper can be seamlessly added to or removed from the active VCs in the system.

Default none

Parameters *atm-td-profile-id* — Specifies ATM traffic description ID.

Values 1 to 1000

vpi — Specifies the VP identifier.

Values 0 to 4095

egress-traffic-desc — References an atm traffic descriptor profile.

traffic-desc

Syntax	traffic-desc <i>atm-td-profile-id</i> no traffic-desc
Context	config>service>vprn>sub-if>grp-if>sap>atm>egress config>service>vprn>sub-if>grp-if>sap>atm>ingress config>service>ies>sub-if>grp-if>sap>atm>egress config>service>ies>sub-if>grp-if>sap>atm>ingress config>subscr-mgmt>msap-policy>atm>egress config>subscr-mgmt>msap-policy>atm>ingress
Description	This command references traffic-descriptor id for VPs and VCs. The VP shaper cannot be of service-type UBR.
Default	Default traffic descriptor (id=1) of UBR type.
Parameters	<i>atm-td-profile-id</i> — Specifies traffic-descriptor id. Values 1 to 1000

weight

Syntax	weight <i>weight</i> no weight
Context	config>qos>atm-td-profile
Description	VCs within the VP tunnel are serviced by a single scheduler assigned to each VP tunnel. VCs within the shaped VP tunnel will be degraded from the originally assigned service category to a common UBR service category (default traffic descriptor). Scheduling between VCs will be based on WRR with a weight parameter that can be explicitly configured in the ATM traffic descriptor profile. If weight is not specifically configured, the defaults are taken. The explicitly configured weight parameter is honored only on the ATM MDA in the max16k-vc mode. On all other ATM capable MDAs (ASAP or ATM MDA in max8k-vc mode), the weight parameter is ignored.
Default	VC degraded from CBR = weight 10 VC degraded from rt-VBR = weight 7 VC degraded from nrt-VBR = weight 5 VC degraded from UBR+ = weight 2 VC degraded from UBR = weight 1

Parameters *weight* — Specifies the weight parameter value.
Values [1-255]

encapsulation

Syntax **encapsulation** [**aal5auto** | **aal5nlpid-ppp** | **aal5mux-ppp** | **aal5snap-bridged** | **aal5mux-bridged-eth-nofcs**]
 no encapsulation

Context config>service>ies>sub-if>grp-if>sap>atm
 config>service>vprn>sub-if>grp-if>sap>atm
 config>service>vpls>sap>atm

Description This command is a SAP level command and it will either statically set or enable dynamic detection of the encapsulation.

Default snap-bridged

Parameters **aal5auto** — This option is available only in max16k-vc mode on dynamic or static SAPs. It will enable automatic detection of one of the four supported encapsulation types.

aal5mux-bridged-eth-nofcs — This option already exist outside of the ESM context on regular interfaces. Within the ESM context (group-interfaces and capture SAPs), this option is available only in max16K-vc mode. The encapsulation is statically set to VC-MUX bridged Ethernet with no FCS. This is a valid encapsulation only for PPPoEoA.

aal5mux-ppp — This option is available only in max16k-vc mode on dynamic or static SAPs. The encapsulation is statically set VC-MUX PPP encapsulation. This is a valid encapsulation only for PPPoA.

aal5nlpid-ppp — dynamic or static SAPs. The encapsulation is statically set to NLPID (LLC) PPP encapsulation. This is a valid encapsulation only for PPPoA.

aal5snap-bridged — This option already exist outside of the ESM context on regular interfaces. Within the ESM context (group-interfaces and capture SAPs), this option is available only in max16k-vc mode. The encapsulation is statically set to bridged Ethernet with or without FCS. Both PIDs (0x 00-01 and 0x 00-07) are accepted on ingress and use this to determine whether to strip four bytes from the end of the encapsulated Ethernet frame. The inner FCS is not checked. This is a valid encapsulation only for PPPoEoA.

Note: On ATM frames with Ethernet FCS or without FCS are accepted but only frames with no Ethernet FCS are sent.

def-inter-dest-id

Syntax **def-inter-dest-id** **string** *interest-string*

	def-inter-dest-id {use-top-q use-vpi} no def-inter-dest-id
Context	config>service>ies>sub-if>grp-if>sap>sub-sla-mgmt config>service>vprn>sub-if>grp-if>sap>sub-sla-mgmt config>subscr-mgmt>msap-policy>sub-sla-mgmt
Description	This command is used to associate the vport with the subscriber. The association method will depend on the configured option.
Default	Disabled
Parameters	<p><i>string</i> — A RADIUS VSA (Alc-Int-Dest-Id-Str, type 28) obtained during the subscriber authentication phase will contain the destination string name that will be matched against the string defined under the vport. In this fashion the subscriber host will be associated with the corresponding vport.</p> <p>Alternatively, the destination string can be defined in LUDB.</p> <p>use-top-q — This is applicable only to Ethernet ports.</p> <p>use-vpi — VP Identifier (VPI) will be used to make the association between the subscriber and the vport automatically.</p> <p>Control Plane will be aware of the VPI during the session initiation phase. This VPI will be used to make the association between the host and the vport with the same name (VPI number).</p>

Note: In this case the vport name under the **configure>port>sonet-sdh>path>access>egress** context must be the VPI number.

pppoe-user-db

Syntax	pppoe-user-db lldb-name no pppoe-user-db
Context	config>services>vpls>sap
Description	<p>This command will enable LUDB authentication on capture SAPs for PPPoE(oA) clients. In case that this command is configured along with the authentication-policy command (RADIUS authentication), then the authentication-policy command will take precedence.</p> <p>Optionally, with a separate command (ppp-user-db) PPPoA clients can be authenticated under a separate LUDB.</p>
Default	Disabled
Parameters	<i>lldb-name</i> — Name of local user database.

ppp-user-db

Syntax	pppp-user-db <i>ludb-name</i> no pppp-user-db
Context	config>services>vpls>sap
Description	This command will enable LUDB authentication on capture SAPs for PPPoA clients. In case that this command is configured along with the authentication-policy command (RADIUS authentication), then the authentication-policy command will take precedence. Optionally, with a separate command (pppoe-user-db) PPPoE(oA) clients can be authenticated under a separate LUDB.
Default	Disabled
Parameters	<i>ludb-name</i> — Name of local user database.

ppp-policy

Syntax	ppp-policy <i>ppp-pol-name</i> no ppp-policy
Context	config>services>vpls>sap
Description	This command will reference a ppp-policy that will define session parameters (ppp-mtu, authentication options, etc.) during the session initiation phase. Normally, ppp-policy is referenced under the group-interface hierarchy. But with capture SAP is it not known at the session initiation phase to which group-interface the session belongs. This is why, with the capture SAP, the ppp-policy must be referenced directly under the capture SAP. The ppp-policy referenced under the group-interface must be the same as the ppp-policy referenced under the capture SAP. Otherwise the session will not come up.
Default	Disabled
Parameters	<i>ppp-pol-name</i> — Name of the ppp-policy.

pppoe-policy

Syntax	pppoe-policy <i>ppoe-pol-name</i> no pppoe-policy
Context	config>services>vpls>sap

Description	This command will reference a pppoe-policy that will define session parameters (ppp-mtu, authentication options, etc.) during the session initiation phase. Normally, pppoe-policy is referenced under the group-interface hierarchy. But with capture SAP is it not known at the session initiation phase to which group-interface the session belongs. This is why, with the capture SAP, the ppp-policy must be referenced directly under the capture SAP. The pppoe-policy referenced under the group-interface must be the same as the pppoe-policy referenced under the capture SAP. Otherwise the session will not come up.
Default	Disabled
Parameters	<i>pppoe-pol-name</i> — Name of the pppoe-policy

rtr-solicit-user-db

Syntax	rtr-solicit-user-db <i>local-user-db</i> no rtr-solicit-user-db
Context	config>service>vpls>sap
Description	This command enabled access to LUDB for SLAAC hosts under the capture SAP. The name of this ludb must match the name of ludb configured under the configure>service>vprn/ies>subscripntf>group-intf>ipv6>router-solicit> hierarchy.
Default	no rtr-solicit-user-db
Parameters	<i>local-user-db</i> — Specifies the name of the local-user-database. Up to 32 characters max.

vc-range

Syntax	vc-range <i>num</i> vpi-range <i>vpi-range</i> vci-range <i>vci-range</i> no vc-range <i>num</i>
Context	config>services>vpls>sap>atm
Description	This command is supported only in max16k-vc ATM MDA mode. An ATM MDA supports a number (see scaling guides for more info) of passive (or listening) VCs, of which a subset can be simultaneously active.
Default	Disabled
Parameters	<i>num</i> — Specifies the VC range. <div> Values 1 to 5 (Five ranges are supported to accommodate non-contiguous ranges of VPI/VCI pairs.) </div> <i>vci-range</i> <i>vci-range</i> — Specifies the VCI range. <div> Values 1, 2, 5 to 65535 (Contiguous VCI ranges in the form of 'x'- 'y'.) </div>

vpi-range vpi-range. — Specifies the VPI range.

Values 0 to 255 for UNI
 0 to 4095 for NNI
 (Contiguous VPI range in the form of 'x'-'y'.)

local-address-assignment

Syntax	local-address-assignment
Context	config>service>ies>sub-if config>service>vprn>sub-if config>service>ies>sub-if>grp-if config>service>vprn>sub-if>grp-if
Description	This command enables the context t configure the local address assignment.

ipv6

Syntax	[no] ipv6
Context	config>service>ies>sub-if>lcl-addr-assign config>service>vprn>sub-if>lcl-addr-assign
Description	This command configures the IPv6 local address assignment.

client-application

Syntax	client-application [ppp-v4] no client-application
Context	config>service>ies>sub-if>lcl-addr-assign config>service>vprn>sub-if>lcl-addr-assign config>service>ies>sub-if>grp-if>lcl-addr-assign config>service>ies>sub-if>grp-if>lcl-addr-assign
Description	This command enables local router DHCP server pool management for PPPoXv4 clients. A pool of IP addresses can be shared between IPoE clients that rely on DHCP protocol (lease renewal process) and PPPoX clients wehre address allocation is not dependent on DHCP messaging but instead an IP address allocation within the pool is tied to the PPPoX session.

client-application

Syntax **client-application [ppp-slaac] [ipoe-wan] [ipoe-slaac]
no client-application**

Context	config>service>vprn>sub-if>grp-if>lcl-addr-assign>ipv6 config>service>vprn>sub-if>grp-if>lcl-addr-assign>ipv6
Description	This defines the client application that will use the local address server to perform address assignment. This feature relies on RADIUS or local-user-database to return a pool name. The pool name is matched against the pools defined in the local-dhcp6-server. The name of the local-dhcp6-server must also be provisioned.
Parameters	<p>ppp-slaac — This parameter indicates using the local DHCPv6 prefix pool to assign SLAAC prefixes for hosts. The “pool name” where the prefixes are used for SLAAC prefix assignment are obtained from RADIUS or local-user-database during the authentication process. The RADIUS attribute “Alc-slaac-ipv6-pool” is used to indicate the SLAAC pool name for PPPoE hosts.</p> <p>ipoe-wan — This parameter indicates using the local DHCPv6 pool for IA_NA address assignment and a static pre-defined prefixes for IA_PD. Both the IA_NA “pool name” and the IA_PD static “framed-prefix” are either obtained from RADIUS or LUDB during authentication. In the case of RADIUS, it must return both IA_NA “Framed-IPv6-Pool” and IA_PD “Delegated-IPv6-Prefix” after a successful authentication. In the case of LUDB, it must have “ipv6-wan-address-pool” and “ipv6-delegated-prefix” populated. This feature is specific to this use case and is not required for other combinations of DHCPv6 assignments such as IA_NA and IA_PD address assignment through RADIUS or LUDB.</p> <p>ipoe-slaac — This parameter indicates using the local DHCPv6 prefix pool to assign SLAAC prefixes for hosts. The “pool name” where the prefixes are used for SLAAC prefix assignment are obtained from RADIUS or local-user-database during the authentication process. The RADIUS attribute “Alc-slaac-ipv6-pool” is used to indicate the SLAAC pool name for PPPoE hosts.</p>

default-pool

Syntax	default-pool pool-name [secondary pool-name] no default-pool
Context	config>service>ies>sub-if>lcl-addr-assign config>service>vprn>sub-if>lcl-addr-assign config>service>ies>sub-if>grp-if>lcl-addr-assign config>service>vprn>sub-if>grp-if>lcl-addr-assign
Description	This command references a default DHCP address pool for local PPPoX pool management in case that the pool-name is not returned via RADIUS or LUDB.
Parameters	<i>pool-name</i> — Name of the local router DHCP server pool.

server

Syntax	server server-name
---------------	---------------------------

no server

Context	config>service>ies>sub-if>lcl-addr-assign config>service>vprn>sub-if>lcl-addr-assign config>service>ies>sub-if>grp-if>lcl-addr-assign config>service>vprn>sub-if>grp-if>lcl-addr-assign
Description	This command designates a local router DHCPv4 server for local pools management where IPv4 addresses for PPPoXv4 clients will be allocated without the need for the internal router DHCP relay-agent. Those addresses will be tied to PPPoX sessions and they will be de-allocated when the PPPoX session is terminated.
Parameters	<i>server-name</i> — The name of the local 7450 ESS or 7750 SR DHCP server.

server

Syntax	server server-name no server
Context	config>service>ies>sub-if>grp-if>lcl-addr-assign>ipv6 config>service>vprn>sub-if>grp-if>lcl-addr-assign>ipv6
Description	This command designates a local router DHCPv6 server for local pools management where IPv6 prefixes or address for PPPoXv6 clients or IPoEv6 clients will be allocated without the need for the internal router DHCP relay-agent. Those addresses will be tied to PPPoX or IPoE sessions and they will be de-allocated when the PPPoX or IPoE session is terminated.
Default	none
Parameters	<i>server-name</i> — The name of the local router DHCPv6 server.

Layer 3 Subscriber Interfaces SAP Commands**accounting-policy**

Syntax	accounting-policy acct-policy-id no accounting-policy
Context	config>service>ies>sub-if>grp-if>sap config>service>vprn>if>sap config>service>vprn>if>spoke-sdp config>service>vprn>sub-if>grp-if>sap
Description	This command specifies the policy to use to collect accounting statistics on a subscriber profile. A maximum of one accounting policy can be associated with a profile at one time.

The **no** form of this command removes the accounting policy association.

Default	no accounting policy
Parameters	<i>acct-policy-id</i> — Enter the accounting <i>policy-id</i> as configured in the config>log>accounting-policy context.
Values	1 to 99

anti-spoof

Syntax	anti-spoof {ip ip-mac nh-mac} no anti-spoof
Context	config>service>ies>sub-if>grp-if>sap config>service>vprn>sub-if>grp-if>sap config>subscr-mgmt>msap-policy
Description	<p>This command configures the anti-spoof type of the MSAP.</p> <p>The type of anti-spoof filtering defines what information in the incoming packet is used to generate the criteria to lookup an entry in the anti-spoof filter table. The type parameter (ip, ip-mac) defines the anti-spoof filter type enforced by the SAP when anti-spoof filtering is enabled.</p> <p>The no form of the command reverts back to the default.</p>

Note: For IES and VPRN subscriber group interfaces, setting no anti-spoof will set the default anti-spoofing type which is **ip-mac**.

Default	no anti-spoof
Parameters	ip — Configures SAP anti-spoof filtering to use only the source IP address in its lookup. If a static host exists on the SAP without an IP address specified, the anti-spoof type ip command will fail.

Note: This parameter is not applicable in the **config>subscr-mgmt>msap-policy** context.

ip-mac — Configures SAP anti-spoof filtering to use both the source IP address and the source MAC address in its lookup. The anti-spoof type **ip-mac** command will fail if the default anti-spoof filter type of the SAP is **ip-mac** and the default is not overridden, or if the SAP does not support Ethernet encapsulation.

nh-mac — Indicates that the ingress anti-spoof is based on the source MAC and egress anti-spoof is based on the nh-ip-address.

app-profile

Syntax	app-profile <i>app-profile-name</i> no app-profile
Context	config>service>vprn>if>sap config>service>vprn>sub-if>grp-if>sap
Description	This command configures the application profile name.
Parameters	<i>app-profile-name</i> — Specifies an existing application profile name configured in the config>app-assure>group>policy context.

collect-stats

Syntax	[no] collect-stats
Context	config>service>ies>sub-if>grp-if>sap config>service>vprn>sub-if>grp-if>sap
Description	When enabled, the agent collects non-RADIUS accounting statistics on a subscriber profile. When the no collect-stats command is issued the statistics are still accumulated by the IOM cards. However, the CPU will not obtain the results and write them to the billing file. If a subsequent col-lect-stats command is issued then the counters written to the billing file include all the traffic while the no collect-stats command was in effect.
Default	collect-stats

default-host

Syntax	default-host <i>ipv4-prefix/mask</i> <i>ipv6-prefix/prefix-length</i> next-hop <i>ipv4-address</i> <i>ipv6-address</i> no default-host <i>ipv4-prefix/mask</i> <i>ipv6-prefix/prefix-length</i>				
Context	config>service>ies>sub-if>grp-if>sap config>service>vprn>sub-if>grp-if>sap				
Description	This command configures the default-host. More than one default host can be configured per SAP.				
Default	no lease-populate				
Parameters	<i>ipv64prefix/prefix-length</i> — Specifies an IPv4 prefix and prefix length. Values <table><tr><td>ipv4-prefix</td><td>x:x:x:x:x:x:x (eight 16-bit pieces)</td></tr><tr><td></td><td>x:x:x:x:x.d.d.d</td></tr></table>	ipv4-prefix	x:x:x:x:x:x:x (eight 16-bit pieces)		x:x:x:x:x.d.d.d
ipv4-prefix	x:x:x:x:x:x:x (eight 16-bit pieces)				
	x:x:x:x:x.d.d.d				

x - [0 to FFFF]H
d - [0 to 255]D
prefix-length - [0 to 128]

ipv6-prefix/prefix-length — Specifies an IPv6 prefix and prefix length.

Values

ipv6-prefix x:x:x:x:x:x:x (eight 16-bit
 pieces)
 x:x:x:x:x:d.d.d.d
 x - [0 to FFFF]H
 d - [0 to 255]D
prefix-length - [0 to 128]

next-hop — Assigns the next hop IP address.

cpu-protection

Syntax	cpu-protection <i>policy-id</i> [<i>mac-monitoring</i>] [<i>eth-cfm-monitoring</i> [<i>aggregate</i>] [<i>car</i>]] no cpu-protection
Context	config>service>ies>sub-if>grp-if>sap
Description	<p>This command assigns an existing CPU protection policy to the associated group interface. The CPU protection policies are configured in the config>sys>security>cpu-protection>policy <i>cpu-protection-policy-id</i> context.</p> <p>If no CPU-Protection policy is assigned to a group interface SAP, then the default policy is used to limit the overall-rate. The default policy is policy number 254 for access interfaces and 255 for network interfaces.</p> <p>The no form of the command removes the association of the CPU protection policy from the associated interface and reverts to the default policy values.</p>
Default	<p>cpu-protection 254 (for access interfaces)</p> <p>cpu-protection 255 (for network interfaces)</p> <p>The configuration of no cpu-protection returns the interface/SAP to the default policies as shown above.</p>
Parameters	<p><i>policy-id</i> — Specifies an existing CPU protection policy.</p> <p>Values 1 to 255</p> <p>mac-monitoring — This keyword enables MAC monitoring.</p>

eth-cfm-monitoring — This keyword enables Ethernet Connectivity Fault Management monitoring.

aggregate — This keyword applies the rate limit to the sum of the per peer packet rates.

car — (Committed Access Rate) This keyword causes Eth-CFM packets to be ignored when enforcing the overall-rate.

egress

Syntax	egress
Context	config>service>ies>sub-if>grp-if>sap config>service>vprn>sub-if>grp-if>sap
Description	<p>This command enables the context to configure egress SAP Quality of Service (QoS) policies and filter policies.</p> <p>If no sap-egress QoS policy is defined, the system default sap-egress QoS policy is used for egress processing. If no egress filter is defined, no filtering is performed.</p>

filter

Syntax	filter ip <i>ip-filter-id</i> filter no filter [<i>ip ip-filter-id</i>] no filter
Context	config>service>ies>sub-if>grp-if>sap>egress config>service>ies>sub-if>grp-if>sap>ingress config>service>vprn>sub-if>grp-if>sap>egress config>service>vprn>sub-if>grp-if>sap>ingress
Description	<p>This command associates an IP filter policy with an ingress or egress Service Access Point (SAP). Filter policies control the forwarding and dropping of packets based on the matching criteria.</p> <p>MAC filters are only allowed on Epipe and Virtual Private LAN Service (VPLS) SAPs.</p> <p>The filter command is used to associate a filter policy with a specified <i>ip-filter-id</i> with an ingress or egress SAP. The filter policy must already be defined before the filter command is executed. If the filter policy does not exist, the operation will fail and an error message returned.</p> <p>In general, filters applied to SAPs (ingress or egress) apply to all packets on the SAP. One exception is non-IP packets are not applied to the match criteria, so the default action in the filter policy applies to these packets.</p>

The **no** form of this command removes any configured filter ID association with the SAP. The filter ID itself is not removed from the system unless the scope of the created filter is set to local. To avoid deletion of the filter ID and only break the association with the service object, use the **scope** command within the filter definition to change the scope to **local** or **global**. The default scope of a filter is **local**.

Special Cases **IES** — Only IP filters are supported on an IES IP interface, and the filters only apply to routed traffic.

Parameters **ip** — Keyword indicating the filter policy is an IP filter.
ip-filter-id — Specifies the ID for the IP filter policy. Allowed values are an integer in the range of 1 and 65535 that corresponds to a previously created IP filter policy in the **configure>filter** context.

qos

Syntax **qos** *policy-id*
no qos

Context config>service>ies>sub-if>grp-if>sap>egress
config>service>vprn>sub-if>grp-if>sap>egress
config>service>vprn>sub-if>grp-if>sap>ingress

Description Associates a Quality of Service (QoS) policy with an egress Service Access Point (SAP) or IP interface.

QoS egress policies are important for the enforcement of SLA agreements. The policy ID must be defined prior to associating the policy with a SAP or IP interface. If the *policy-id* does not exist, an error will be returned.

The **qos** command is used to associate egress QoS policies. The **qos** command only allows egress policies on SAP or IP interface egress. Attempts to associate a QoS policy of the wrong type returns an error.

Only one ingress QoS policy can be associated with a SAP or IP interface at one time. Attempts to associate a second QoS policy of a given type will return an error.

By default, no specific QoS policy is associated with the SAP or IP interface for egress, so the default QoS policy is used.

The normal behavior is for queues to be created per destination.

The **no** form of this command removes the QoS policy association from the SAP or IP interface, and the QoS policy reverts to the default.

Parameters *policy-id* — The egress policy ID to associate with SAP or IP interface on egress. The policy ID must already exist.

Values 1 to 65535

qos

Syntax	qos <i>policy-id</i> [shared-queuing] no qos
Context	config>service>ies>sub-if>grp-if>sap>ingress
Description	<p>Associates a Quality of Service (QoS) policy with an ingress Service Access Point (SAP) or IP interface.</p> <p>QoS ingress policies are important for the enforcement of SLA agreements. The policy ID must be defined prior to associating the policy with a SAP or IP interface. If the <i>policy-id</i> does not exist, an error will be returned.</p> <p>This qos command is used to associate ingress QoS policies. The qos command only allows ingress policies to be associated on SAP or IP interface ingress.</p> <p>Only one ingress and one egress QoS policy can be associated with a SAP or IP interface at one time. Attempts to associate a second QoS policy of a given type will return an error.</p> <p>By default, no specific QoS policy is associated with the SAP or IP interface for ingress so the default QoS policy is used.</p> <p>The normal behavior is for queues to be created per destination. Shared and multipoint shared change this behavior creating either unicast or unicast and mcast shared queues.</p> <p>The no form of this command removes the QoS policy association from the SAP or IP interface, and the QoS policy reverts to the default.</p>
Parameters	<p><i>policy-id</i> — The ingress policy ID to associate with SAP or IP interface on ingress. The policy ID must already exist.</p> <p>Values 1 to 65535</p> <p>shared-queuing — This keyword can only be specified on SAP ingress. Specify the ingress shared queue policy used by a SAP. When the value of this object is null it means that the SAP will use individual ingress QoS queues, instead of the shared ones.</p>

scheduler-policy

Syntax	scheduler-policy <i>scheduler-policy-name</i> no scheduler-policy
Context	config>service>ies>sub-if>grp-if>sap>egress config>service>ies>sub-if>grp-if>sap>ingress config>service>vprn>sub-if>grp-if>sap>egress config>service>vprn>sub-if>grp-if>sap>ingress

Description	<p>This command applies an existing scheduler policy to an ingress or egress scheduler used by ingress SAP queues or egress SAP policers and queues associated with this multi-service customer site. The schedulers defined in the scheduler policy can only be created once the customer site has been appropriately assigned to a chassis port, channel or slot. Scheduler policies are defined in the config>qos>scheduler-policy <i>scheduler-policy-name</i> context.</p> <p>The no form of this command removes the configured ingress or egress scheduler policy from the multi-service customer site. When the policy is removed, the schedulers created due to the policy are removed also making them unavailable for the SAP policers or queues associated with the customer site. Policers and queues that lose their parent scheduler association are deemed to be orphaned and are no longer subject to a virtual scheduler. The SAPs that have policers or queues reliant on the removed schedulers enter into an operational state depicting the orphaned status of one or more policers or queues. When the no scheduler-policy command is executed, the customer site ingress or egress node will not contain an applied scheduler policy.</p>
Parameters	<p><i>scheduler-policy-name</i>: — The <i>scheduler-policy-name</i> parameter applies an existing scheduler policy that was created in the config>qos>scheduler-policy <i>scheduler-policy-name</i> context to create the hierarchy of ingress or egress virtual schedulers. The scheduler names defined within the policy are created and made available to any ingress queues or egress policers and queues created on associated SAPs.</p> <p>Values Any existing valid scheduler policy name.</p>

host

Syntax	<p>host ip <i>ip-address</i> [mac <i>ieee-address</i>] [subscriber <i>sub-ident-string</i>] [sub-profile <i>sub-profile-name</i>] [sla-profile <i>sla-profile-name</i>]</p> <p>no host {[ip <i>ip-address</i>] [mac <i>ieee-address</i>]}</p> <p>no host all</p>
Context	<p>config>service>ies>sub-if>grp-if>sap</p> <p>config>service>ies>if>sap</p> <p>config>service>ies>sub-if>grp-if>sap</p> <p>config>service>vprn>sub-if>grp-if>sap</p>
Description	<p>This command creates a static subscriber host for the SAP. Static subscriber hosts may be used by the system for various purposes. Applications within the system that make use of static host entries include anti-spoof filters and ARP cache population.</p> <p>Multiple static hosts may be defined on the SAP. Each host is identified by either a source IP address, a source MAC address or both a source IP and source MAC address. Every static host definition must have at least one address defined, IP or MAC.</p> <p>Static hosts can exist on the SAP even with anti-spoof and ARP populate features disabled. When enabled, each feature has different requirements for static hosts.</p>
Default	none

- Parameters**
- anti-spoof** — When enabled, this feature uses static and dynamic host information to populate entries into an anti-spoof filter table. The anti-spoof filter entries generated will be of the same type as specified in the anti-spoof type parameter. If the SAP anti-spoof filter is defined as **ip**, each static host definition must specify an IP address. If the SAP anti-spoof filter is defined as **ip-mac**, each static host definition must specify both an IP address and MAC address. If definition of a static host is attempted without the appropriate addresses specified for the enabled anti-spoof filter, the static host definition will fail.
- arp-populate** — When enabled, this feature uses static and dynamic host information to populate entries in the system ARP cache.
- Attempting to define a static subscriber host that conflicts with an existing DHCP lease state table entry will fail.
- Use the **no** form of the command to remove a static entry from the system. The specified *ip-address* and *mac-address* must match the host's exact IP and MAC addresses as defined when it was created. When a static host is removed from the SAP, the corresponding anti-spoof entry and/or ARP cache entry is also removed.
- ip ip-address* — Specify this optional parameter when defining a static host. The IP address must be specified for **anti-spoof ip**, **anti-spoof ip-mac** and **arp-populate**. Only one static host may be configured on the SAP with a given IP address.
- mac mac-address* — Specify this optional parameter when defining a static host. The MAC address must be specified for **anti-spoof ip-mac** and **arp-populate**. Multiple static hosts may be configured with the same MAC address given that each definition is distinguished by a unique IP address.
- subscriber sub-ident-string* — Specify this optional parameter to specify an existing subscriber identification profile to be associated with the static subscriber host. The subscriber identification profile is configured in the **config>subscr-mgmt>sub-ident-pol** context. The subscriber information is used by the VPRN SAP arp-reply-agent to determine the proper handling of received ARP requests from subscribers. For VPRN SAPs with **arp-reply-agent** enabled with the optional *sub-ident* parameter, the static subscriber hosts sub-ident-string is used to determine whether an ARP request received on the SAP is sourced from a host belonging to the same subscriber as the destination host. When both the destination and source hosts from the ARP request are known on the SAP and the subscriber identifications do not match, the ARP request may be forwarded to the rest of the VPRN destinations.
- If the static subscriber hosts *sub-ident* string is not defined, the host is not considered to belong to the same subscriber as another host on the SAP.
- If source or destination host is unknown, the hosts are not considered to belong to the same subscriber. (ARP messages from unknown hosts are subject to anti-spoof filtering rules applied at the SAP.)
- If *sub-ident* is not enabled on the SAP arp-reply-agent, subscriber identification matching is not performed on ARP requests received on the SAP.
- ARP requests are never forwarded back to the same SAP or within the receiving SAP's Split Horizon Group.

sub-profile *sub-profile-name* — Specify this optional parameter to specify an existing subscriber profile name to be associated with the static subscriber host. The subscriber profile is configured in the **config>subscr-mgmt>sub-profile** context.

sla-profile *sla-profile-name* — Specify this optional parameter to specify an existing SLA profile name to be associated with the static subscriber host. The SLA profile is configured in the **config>subscr-mgmt>sla-profile** context.

ingress

Syntax	ingress
Context	config>service>ies>sub-if>grp-if>sap config>service>vprn>sub-if>grp-if>sap
Description	<p>This command enables the context to configure ingress SAP Quality of Service (QoS) policies and filter policies.</p> <p>If no SAP ingress QoS policy is defined, the system default sap-ingress QoS policy is used for ingress processing. If no ingress filter is defined, no filtering is performed.</p>

multi-service-site

Syntax	[no] multi-service-site <i>customer-site-name</i>
Context	config>service>ies>sub-if>grp-if>sap config>service>vprn>sub-if>grp-if>sap
Description	<p>This command creates a new customer site or edits an existing customer site with the <i>customer-site-name</i> parameter. A customer site is an anchor point to create an ingress and egress virtual scheduler hierarchy. When a site is created, it must be assigned to a chassis slot or port. When scheduler policies are defined for ingress and egress, the scheduler names contained in each policy are created according to the parameters defined in the policy. Multi-service customer sites exist for the sole purpose of creating a virtual scheduler hierarchy and making it available to queues on multiple Service Access Points (SAPs).</p> <p>The scheduler policy association with the customer site normally prevents the scheduler policy from being deleted until after the scheduler policy is removed from the customer site. The multi-service-site object will generate a log message indicating that the association was deleted due to scheduler policy removal.</p> <p>When the multi-service customer site is created, an ingress and egress scheduler policy association does not exist. This does not prevent the site from being assigned to a chassis slot or prevent service SAP assignment. After the site has been created, the ingress and egress scheduler policy associations can be assigned or removed at anytime.</p>
Default	None — Each customer site must be explicitly created.

Parameters	<p><i>customer-site-name</i> — Each customer site must have a unique name within the context of the customer. If <i>customer-site-name</i> already exists for the customer ID, the CLI context changes to that site name for the purpose of editing the site scheduler policies or assignment. Any modifications made to an existing site will affect all SAPs associated with the site. Changing a scheduler policy association may cause new schedulers to be created and existing policers and queues on the SAPs to no longer be orphaned. Existing schedulers on the site may cease to exist, causing policers and queues relying on that scheduler to be orphaned.</p> <p>If the <i>customer-site-name</i> does not exist, it is assumed that an attempt is being made to create a site of that name in the customer ID context. The success of the command execution depends on the following:</p> <p>The maximum number of customer sites defined for the chassis slot has not been met.</p> <p>The <i>customer-site-name</i> is valid.</p> <p>The create keyword is included in the command line syntax (if the system requires it).</p> <p>When the maximum number of customer sites has been exceeded a configuration error occurs, the command will not execute and the CLI context will not change.</p> <p>If the <i>customer-site-name</i> is invalid, a syntax error occurs, the command will not execute and the CLI context will not change.</p> <p>Values Valid names consist of any string up to 32 characters long composed of printable, 7-bit ASCII characters excluding double quotes. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.</p>
------------	--

ATM Commands

Note: The commands described in this section apply only to the 7750 SR.

atm

Syntax	atm
Context	config>service>ies>sub-if>grp-if>sap config>service>vprn>if>sap config>service>vprn>sub-if>grp-if>sap
Description	This command enables access to the context to configure ATM-related attributes. This command can only be used when a given context (for example, a channel or SAP) supports ATM functionality such as:

- Configuring ATM port or ATM port-related functionality on MDAs supporting ATM functionality
- Configuring ATM-related configuration for ATM-based SAPs that exist on MDAs supporting ATM functionality.

If ATM functionality is not supported for a given context, the command returns an error.

egress

Syntax	egress
Context	config>service>ies>sub-if>grp-if>sap>atm config>service>vprn>if>sap>atm config>service>vprn>sub-if>grp-if>sap>atm
Description	This command enables the context to configure egress ATM attributes for the SAP.

encapsulation

Syntax	encapsulation <i>atm-encap-type</i>
Context	config>service>ies>sub-if>grp-if>sap>atm config>service>vprn>if>sap>atm config>service>vprn>sub-if>grp-if>sap>atm
Description	<p>This command configures RFC 2684, <i>Multiprotocol Encapsulation over ATM Adaptation Layer 5</i>, encapsulation for an ATM PVCC delimited SAP.</p> <p>This command specifies the data encapsulation for an ATM PVCC delimited SAP. The definition references RFC 2684 and to the ATM Forum LAN Emulation specification.</p> <p>Ingress traffic that does not match the configured encapsulation will be dropped.</p>
Default	The encapsulation is driven by the services for which the SAP is configured. For IES service SAPs, the default is aal5snap-routed .
Parameters	<p><i>atm-encap-type</i> — Specify the encapsulation type.</p> <p>Values</p> <p>aal5snap-routed — Routed encapsulation for LLC encapsulated circuit (LLC/SNAP precedes protocol datagram) as defined in RFC 2684.</p> <p>aal5mux-ip — Routed IP encapsulation for VC multiplexed circuit as defined in RFC 2684</p>

ingress

Syntax	ingress
Context	config>service>ies>sub-if>grp-if>sap>atm config>service>vprn>if>sap>atm config>service>vprn>sub-if>grp-if>sap>atm
Description	This command configures ingress ATM attributes for the SAP.

traffic-desc

Syntax	traffic-desc <i>traffic-desc-profile-id</i> no traffic-desc
Context	config>service>ies>sub-if>grp-if>sap>atm>egress config>service>ies>sub-if>grp-if>sap>atm>ingress config>service>vprn>if>sap>atm>egress config>service>vprn>if>sap>atm>ingress config>service>vprn>sub-if>grp-if>sap>atm>egress config>service>vprn>sub-if>grp-if>sap>atm>ingress
Description	<p>This command assigns an ATM traffic descriptor profile to a given context (for example, a SAP). When configured under the ingress context, the specified traffic descriptor profile defines the traffic contract in the forward direction. When configured under the egress context, the specified traffic descriptor profile defines the traffic contract in the backward direction.</p> <p>The no form of the command reverts the traffic descriptor to the default traffic descriptor profile.</p>
Default	The default traffic descriptor (trafficDescProfileId. = 1) is associated with newly created PVCC-delimited SAPs.
Parameters	<i>traffic-desc-profile-id</i> — Specify a defined traffic descriptor profile (see the QoS atm-td-profile command).

oam

Syntax	oam
Context	config>service>ies>sub-if>grp-if>sap>atm config>service>vprn>interface >sap>atm config>service>vprn>sub-if>grp-if>sap>atm
Description	This command enables the context to configure OAM functionality for a PVCC delimiting a SAP.

The ATM-capable MDAs support F5 end-to-end OAM functionality (AIS, RDI, Loopback):

- ITU-T Recommendation I.610 - B-ISDN Operation and Maintenance Principles and Functions version 11/95
- GR-1248-CORE - Generic Requirements for Operations of ATM Network Elements (NEs). Issue 3 June 1996
- GR-1113-CORE - Bellcore, Asynchronous Transfer Mode (ATM) and ATM Adaptation Layer (AAL) Protocols Generic Requirements, Issue 1, July 1994

alarm-cells

Syntax	[no] alarm-cells
Context	config>service>ies>sub-if>grp-if>sap>atm>oam config>service>vprn>if>sap>atm>oam config>service>vprn>sub-if>grp-if>sap>atm>oam
Description	<p>This command configures AIS/RDI fault management on a PVCC. Fault management allows PVCC termination to monitor and report the status of their connection by propagating fault information through the network and by driving PVCCs operational status.</p> <p>When alarm-cells functionality is enabled, PVCCs operational status is affected when a PVCC goes into AIS or RDI state because of an AIS/RDI processing (i.e. assuming nothing else affects PVCCs operational status, PVCC goes DOWN, when it enters a fault state and comes back UP, when it exits that fault state) and RDI cell are generated when PVCC is operationally DOWN. No OAM-specific SNMP trap is raised whenever an endpoint enters/ exits an AIS or RDI states, however, if as result of an OAM state change, the PVCC changes operational status, then a trap is expected from an entity the PVCC is associated with (for example a SAP).</p> <p>The no command disables alarm-cells functionality for a PVCC. When alarm-cells functionality is disabled, PVCCs operational status is no longer affected by PVCCs OAM state changes due to AIS/RDI processing (when alarm-cells is disabled, a PVCC will change operational status to UP, if it was DOWN because of the alarm-cell processing) and RDI cells are not generated as result of PVCC going into AIS or RDI state, however, PVCCs OAM status will record OAM faults as described above.</p>
Default	Enabled for PVCCs delimiting IES SAPs

periodic-loopback

Syntax	[no] periodic-loopback
Context	config>service>ies>sub-if>grp-if>sap>atm>oam config>service>vprn>if>sap>atm>oam config>service>vprn>sub-if>grp-if>sap>atm

Description	<p>This command enables periodic OAM loopbacks on this SAP. This command is only configurable on IES and VPRN SAPs. When enabled, an ATM OAM loopback cell is transmitted every period as configured in the <code>config>system>atm>oam>loopback-period</code> context.</p> <p>If a response is not received and consecutive retry-down retries also result in failure, the endpoint will transition to an alarm indication signal/loss of clock state. Then, an ATM OAM loopback cell will be transmitted every period as configured in the <code>loopback-period</code> context. If a response is received for the periodic loopback and consecutive retry-up retries also each receive a response, the endpoint will transition back to the up state.</p> <p>The no form of the command sets the value back to the default.</p>
Default	no periodic-loopback

Redundant Interface Commands

Note: The commands described in this section apply only to the 7750 SR.

redundant-interface

Syntax	[no] redundant-interface <i>ip-int-name</i>
Context	config>service>ies config>service>vprn config>service>ies>sub-if>grp-if config>service>vprn>sub-if>grp-if
Description	This command configures a redundant interface.
Parameters	<i>ip-int-name</i> — Specifies the name of the IP interface. Interface names can be from 1 to 32 alphanumeric characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

address

Syntax	address { <i>ip-address/mask</i> <i>ip-address netmask</i> } [remote-ip <i>ip-address</i>] no address
Context	config>service>vprn>redundant-interface
Description	This command assigns an IP address mask or netmask and a remote IP address to the interface.

- Parameters** *ip-address/mask* — Assigns an IP address/IP subnet format to the interface.
- ip-address netmask* — Specifies a string of 0s and 1s that mask or screen out the network part of an IP address so that only the host computer part of the address remains.
- Assigns an IP address netmask to the interface.
- remote-ip** *ip-address* — Assigns a remote IP to the interface.

spoke-sdp

- Syntax** **[no] spoke-sdp** *sdp-id*
- Context** config>service>vprn
- Description** This command binds a service to an existing Service Distribution Point (SDP).
- A spoke SDP is treated like the equivalent of a traditional bridge “port” where flooded traffic received on the spoke SDP is replicated on all other “ports” (other spoke and mesh SDPs or SAPs) and not transmitted on the port it was received.
- The SDP has an operational state which determines the operational state of the SDP within the service. For example, if the SDP is administratively or operationally down, the SDP for the service will be down.
- The SDP must already be defined in the **config>service>sdp** context in order to associate an SDP with a VPRN service. If the **sdp** *sdp-id* is not already configured, an error message is generated. If the *sdp-id* does exist, a binding between that *sdp-id* and the service is created.
- SDPs must be explicitly associated and bound to a service. If an SDP is not bound to a service, no far-end 7750 SRdevices can participate in the service.
- The **no** form of this command removes the SDP binding from the service. The SDP configuration is not affected; only the binding of the SDP to a service. Once removed, no packets are forwarded to the far-end router.
- Default** No *sdp-id* is bound to a service.
- Special Cases** **VPRN** — Several SDPs can be bound to a VPRN service. Each SDP must be destined to a different 7750 SR OS. If two *sdp-id* bindings terminate on the same 7750 SR, an error occurs and the second SDP binding is rejected.
- Parameters** *sdp-id* — The SDP identifier. Allowed values are integers in the range of 1 and 17407 for existing SDPs.
- vc-id* — The virtual circuit identifier.
- Values** 1 to 4294967295

egress

Syntax	egress
Context	config>service>vprn>red-if>spoke-sdp
Description	This command configures egress SDP parameters.

ingress

Syntax	ingress
Context	config>service>vprn>red-if>spoke-sdp
Description	This command configures ingress SDP parameters.

vc-label

Syntax	vc-label <i>egress-vc-label</i> no vc-label [<i>egress-vc-label</i>]
Context	config>service>vprn>red-if>spoke-sdp>egress
Description	This command configures the egress VC label.
Parameters	<i>vc-label</i> — A VC egress value that indicates a specific connection. Values 16 to 1048575

vc-label

Syntax	vc-label <i>ingress-vc-label</i> no vc-label [<i>ingress-vc-label</i>]
Context	config>service>vprn>red-if>spoke-sdp>ingress
Description	This command configures the ingress VC label.
Parameters	<i>vc-label</i> — A VC ingress value that indicates a specific connection. Values 2048 to 18431

filter

Syntax	filter { ip <i>ip-filter-id</i> }
	no filter

Context	config>service>vprn>red-if>spoke-sdp>ingress config>service>vprn>red-if>spoke-sdp>egress
Description	<p>This command associates an IP filter policy with an ingress or egress Service Access Point (SAP) or IP interface. An IP filter policy can be associated with spoke SDPs.</p> <p>Filter policies control the forwarding and dropping of packets based on IP or MAC matching criteria.</p> <p>The filter command is used to associate a filter policy with a specified ip-filter-id with an ingress or egress SAP. The ip-filter-id must already be defined before the filter command is executed. If the filter policy does not exist, the operation will fail and an error message returned.</p> <p>In general, filters applied to SAPs (ingress or egress) apply to all packets on the SAP. One exception is non-IP packets are not applied to IP match criteria, so the default action in the filter policy applies to these packets.</p> <p>The no form of this command removes any configured filter ID association with the SAP or IP interface. The filter ID itself is not removed from the system unless the scope of the created filter is set to local. To avoid deletion of the filter ID and only break the association with the service object, use scope command within the filter definition to change the scope to local or global. The default scope of a filter is local.</p>
Parameters	<p>ip <i>ip-filter-id</i> — Specifies IP filter policy. The filter ID must already exist within the created IP filters.</p> <p>Values 1 to 65535</p>

SDP Binding Commands

binding

Syntax	binding
Context	config>service>sdp
Description	The command enables the context to configure SDP bindings.

port

Syntax	port [<i>port-id</i> <i>lag-id</i>] no port
Context	config>service>sdp>binding

Description	This command specifies the port or lag identifier, to which the PW ports associated with the underlying SDP are bound. If the underlying SDP is re-routed to a port or lag other than the specified one, the PW ports on the SDP are operationally brought down. The no form of the command removes the value from the configuration.
Default	none
Parameters	<i>port-id</i> — The identifier of the port in the slot/mda/port format. <i>lag-id</i> — Specifies the LAG identifier.

pw-port

Syntax	pw-port <i>pw-port-id</i> [<i>vc-id vc-id</i>] [create] no pw-port
Context	config>service>sdp>binding
Description	This command creates a pseudowire port. The no form of the command removes the pseudowire port ID from the configuration.
Default	none
Parameters	<i>pw-port-id</i> — Specifies a unique identifier of the pseudowire port. Values 1 to 10239 <i>vc-id vc-id</i> — Specifies a virtual circuit identifier signaled to the peer. Values 1 to 4294967295

description

Syntax	description <i>description-string</i> no description
Context	config>service>sdp>binding>pw-port
Description	This command creates a text description stored in the configuration file for a configuration context. The description command associates a text string with a configuration context to help identify the content in the configuration file. The no form of the command removes the string from the configuration.
Default	no description

Parameters	<i>description-string</i> — Specifies the description character string of the configuration context.
Values	Any string up to 80 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

egress

Syntax	egress
Context	config>service>sdp>binding>pw-port
Description	This command enables the context to configure PW-port egress side parameters.

encap-type

Syntax	encap-type {dot1q qinq} no encap-type
Context	config>service>sdp>binding>pw-port
Description	This command sets the encapsulation type for the PW-port as dot1q or qinq.
Default	dot1q
Parameters	dot1q — Specifies dot1q encapsulation type. qinq — Specifies qinq encapsulation type.

shaper

Syntax	[no] shaper
Context	config>service>sdp>binding>pw-port>egress
Description	This command configures an egress shaping option for use by a PW port.
Default	no shaper.

int-dest-id

Syntax	[no] int-dest-id <i>int-dest-id</i>
Context	config>service>sdp>binding>pw-port>egress>shaper

Description	<p>This command specifies the intermediate destination string configured for dynamic vport selection.</p> <p>The no form of the command removes the configured intermediate destination string.</p> <p>This command is only valid for PW ports used for enhanced subscriber management (ESM on PW).</p>
Default	no .int-dest-id
Parameters	<i>int-dest-id</i> — A text string that describes the intermediate destination ID.

vport

Syntax	vport <i>vport-name</i> no vport
Context	config>service>sdp>binding>pw-port>egress>shaper
Description	<p>This command configures the name of the vport to be used for the PW port.</p> <p>The no form of the command removes the configured vport name.</p> <p>This command is valid for PW ports used for enhanced subscriber management (ESM on pseudowire) and pseudowire SAPs on Ethernet ports. It is not valid for pseudowire ports on the HSM DA.</p>
Default	no vport
Parameters	<i>vport-name</i> — Specifies a text string up to 32 characters in length representing the name of the vport.

vc-type

Syntax	vc-type {ether vlan} no vc-type
Context	config>service>sdp>binding>pw-port
Description	<p>This command sets the forwarding mode for PW-port. The vc-type is signaled to the peer, and must be configured consistently on both ends of the PW. vc-type VLAN is only configurable with dot1q encapsulation on the PW-port. The tag with vc-type vlan only has significance for transport, and is not used for service delineation or ESM. The top (provider tag) is stripped while forwarding out of the PW, and a configured vlan-tag (for vc-type vlan) is inserted when forwarding into the PW. With vc-type ether, the tags if present (max 2), are transparently preserved when forwarding in or out of the PW.</p> <p>The no form of the command reverts to the default value.</p>

Default	ether
Parameters	ether — Specifies ether as the virtual circuit (VC) associated with the SDP binding. vlan — Specifies vlan as the virtual circuit (VC) associated with the SDP binding.

vlan-vc-tag

Syntax	vlan-vc-tag <i>vlan-id</i> no vc-type
Context	config>service>sdp>binding>pw-port
Description	This command sets tag relevant for vc-type vlan mode. This tag is inserted in traffic forwarded into the PW. The no form of the command reverts to the default value.
Default	0
Parameters	<i>vlan-id</i> — Specifies the VLAN ID value. Values 0 to 4094

9.24.2.1.15 RIP Commands

rip-policy

Syntax	rip-policy <i>policy-name</i> [create] no rip- policy-name
Context	config>subscr-mgmt
Description	This command creates a RIP policy. This policy is applied to a subscriber IPv4 host to enable the BNG to learn RIP routes from the host. RIP routes are never sent to the hosts.
Default	none
Parameters	<i>policy-name</i> — Specifies the RIP policy name up to 32 characters in length.

neighbor

Syntax	[no] neighbor <i>ip-int-name</i>
Context	config>router>rip>group config>service>vprn>rip>group

Description	<p>This command creates a context for configuring a RIP neighbor interface. By default, group interfaces are not activated with RIP, unless explicitly configured. The BNG will only learn RIP routes from IPv4 host on the group interface. Hence, RIP neighbor group interface will default send to "none". The send operation is unchangeable for group-interface.</p> <p>The no form of the command deletes the RIP interface configuration for this group interface. The shutdown command in the config>router>rip>group group-name>neighbor context can be used to disable an interface without removing the configuration for the interface.</p>
Default	no neighbor — No RIP interfaces are defined.
Parameters	<p><i>ip-int-name</i> — The group interface name. Interface names must be unique within the group of defined group interfaces within config service vprn/ies sub-interface grp-interface commands. An interface name cannot be in the form of an IP address. Interface names can be any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes. If the group interface name does not exist, an error message will be returned.</p>

authentication-key

Syntax	authentication-key [<i>authentication-key</i> <i>hash-key</i>] [hash hash2] no authentication-key
Context	config>subscr-mgmt>rip-policy
Description	<p>This command configures the BGP authentication key.</p> <p>Authentication is performed between neighboring routers before setting up the BGP session by verifying the password. Authentication is performed using the MD-5 message-based digest. The authentication key can be any combination of letters or numbers from 1 to 16.</p> <p>The no form of the command removes the authentication password from the configuration and effectively disables authentication.</p>
Default	Authentication is disabled and the authentication password is empty.
Parameters	<p><i>authentication-key</i> — The authentication key. The key can be any combination of ASCII characters up to 255 characters in length (unencrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").</p> <p><i>hash-key</i> — The hash key. The key can be any combination of ASCII characters up to 342 characters in length (encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").</p> <p>This is useful when a user must configure the parameter, but, for security purposes, the actual unencrypted key value is not provided.</p>

hash — Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified

hash2 — Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

authentication-type

Syntax	authentication-type { none password message-digest message-digest-20 } no authentication-type
Context	config>sub-mgmt>rip-policy>
Description	This command sets the type of authentication to be used between RIP neighbors. The type and password must match exactly for the RIP message to be considered authentic and processed. The no form of the command removes the authentication type from the configuration and effectively disables authentication.
Default	no authentication-type — No authentication enabled.
Parameters	<p>none — The none parameter explicitly disables authentication at a given level (global, group, neighbor). If the command does not exist in the configuration, the parameter is inherited.</p> <p>password — Specify password to enable simple password (plain text) authentication. If authentication is enabled and no authentication type is specified in the command, simple password authentication is enabled.</p> <p>message-digest — Configures 16 byte message digest for MD5 authentication. If this option is configured, then at least one message-digest-key must be configured.</p> <p>message-digest-20 — Configures 20 byte message digest for MD5 authentication in accordance with RFC 2082, RIP-2 MD5 Authentication. If this option is configured, then at least one message-digest-key must be configured.</p>

retail-svc-id

Syntax	retail-svc-id <i>service-id</i> retail-svc-id
Context	config>service>ies vprn>sub-if>grp-if>sap>static-host

Description	This command specifies the service id of the retailer IES/VRN service to which the static IPv6 host belongs. A corresponding retailer subscriber interface must exist in the specified service.
Default	no retail-svc-id
Parameters	<i>service-id</i> — Specifies the retailer service ID. Values 1 to 2148007978

rip

Syntax	[no] rip
Context	config>service>vrn config>service>ies
Description	This command enables the RIP protocol on the given VRN IP interface. The no form of the command disables the RIP protocol from the given VRN IP interface.
Default	no rip

group

Syntax	[no] group <i>group-name</i>
Context	config>service>vrn>rip config>service>ies>rip
Description	This command creates a context for configuring a RIP group of neighbors. RIP groups are a way of logically associating RIP neighbor interfaces to facilitate a common configuration for RIP interfaces. The no form of the command deletes the RIP neighbor interface group. Deleting the group will also remove the RIP configuration of all the neighbor interfaces currently assigned to this group.
Default	no group — No group of RIP neighbor interfaces defined
Parameters	<i>group-name</i> — The RIP group name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

9.24.2.1.16 Vport Commands

ethernet

Syntax	ethernet
Context	config>port
Description	<p>This command enables access to the context to configure Ethernet port attributes.</p> <p>This context can only be used when configuring Fast Ethernet, gigabit or 10Gig Fast Ethernet or Ethernet LAN ports on an appropriate MDA.</p>

egress-scheduler-override

Syntax	[no] egress-scheduler-override
Context	config>port>ethernet
Description	<p>This command applies egress scheduler overrides. When a port scheduler is associated with an egress port, it is possible to override the following parameters:</p> <ul style="list-style-type: none">• The max-rate allowed for the scheduler.• The maximum rate for each priority level 8 through 1.• The CIR associated with each priority level 8 through 1. <p>See the SR OS Quality of Service Guide for command syntax and usage for the port-scheduler-policy command.</p> <p>The no form of this command removes all override parameters from the egress port or channel scheduler context. Once removed, the port scheduler reverts all rate parameters back to the parameters defined on the port-scheduler-policy associated with the port.</p>

level

Syntax	level <i>priority-level</i> rate <i>pir-rate</i> [<i>cir</i> <i>cir-rate</i>] no level <i>priority-level</i>
Context	config>port>ethernet>egress-scheduler-override

Description	<p>This command overrides the maximum and CIR rate parameters for a specific priority level on the port or channel's port scheduler instance. When the level command is executed for a priority level, the corresponding priority level command in the port-scheduler-policy associated with the port is ignored.</p> <p>The override level command supports the keyword max for the rate and cir parameter. When executing the level override command, at least the rate or cir keywords and associated parameters must be specified for the command to succeed.</p> <p>The no form of this command removes the local port priority level rate overrides. Once removed, the port priority level will use the port scheduler policies level command for that priority level.</p>
Parameters	<p><i>priority-level</i> — Identifies which of the eight port priority levels are being overridden.</p> <p>Values 1 to 8</p> <p>rate <i>pir-rate</i> — Overrides the port scheduler policy's maximum level rate and requires either the max keyword or a rate defined in kilobits-per-second to follow.</p> <p>Values 1 to 40000000, max</p> <p>cir <i>cir-rate</i> — Overrides the port scheduler policy's within-cir level rate and requires either the max keyword or a rate defined in kilobits-per-second to follow.</p> <p>Values 0 to 40000000, max</p> <p>max — removes any existing rate limit imposed by the port scheduler policy for the priority level allowing it to use as much total bandwidth as possible.</p>

access

Syntax	access
Context	config>port>ethernet
Description	This command configures Ethernet access port parameters.

egress

Syntax	egress
Context	config>port>ethernet>access
Description	This command configures Ethernet access egress port parameters.

vport

Syntax	vport <i>name</i> [create] no vport <i>name</i>
---------------	--

Context	config>port>ethernet>access>egress
Description	<p>This command configures a scheduling node, referred to as virtual port, within the context of an egress Ethernet port. The vport scheduler operates either like a port scheduler with the difference that multiple vport objects can be configured on the egress context of an Ethernet port, or it can be an aggregate rate when an egress port-scheduler policy is applied to the port.</p> <p>The vport is always configured at the port level even when a port is a member of a LAG.</p> <p>When a port scheduler policy is applied to a vport the following command is used:</p> <p>configure>port>ethernet>access>egress>vport>port-scheduler-policy <i>port-scheduler-policy-name</i></p> <p>The CLI will not allow the user to apply a port scheduler policy to a vport if one has been applied to the port. Conversely, the CLI will not allow the user to apply a port scheduler policy to the egress of an Ethernet port if one has been applied to any vport defined on the access egress context of this port. The agg-rate-limit, along with an egress port-scheduler, can be used to ensure that a given vport does not oversubscribe the port's rate.</p> <p>SAP and subscriber host queues can be port-parented to a vport scheduler in a similar way they port-parent to a port scheduler or can be port-parented directly to the egress port-scheduler if the agg-rate-limit is used.</p> <p>When the vport uses an aggregate rate, the following command is used:</p> <p>configure>port>ethernet>access>egress>vport>agg-rate-limit</p>
Parameters	<p><i>name</i> — Specifies the name of the vport scheduling node and can be up to 32 ASCII characters in length. This does not need to be unique within the system but is unique within the port or a LAG.</p>

agg-rate-limit

Syntax	agg-rate-limit <i>agg-rate</i> no agg-rate-limit
Context	config>port>ethernet>access>egress>vport
Description	This command configures an aggregate rate for the vport. This command is mutually exclusive with the port-scheduler-policy command.
Parameters	<p><i>agg-rate</i> — Specifies the rate limit for the vport.</p> <p>Values max, 1 to 10000000</p>

egress-rate-modify

Syntax	[no] egress-rate-modify
Context	config>port>ethernet>access>egress>vport
Description	This command is used to apply HQoS Adjustment to a vport. HQoS Adjustment refers to the dynamic adjustment of the rate limit at an QoS enforcement point within router when the multicast traffic stream is disjointed from the unicast traffic stream. This QoS enforcement point within router represents the physical point further down in the access part of the network where the two streams join each other and potentially can cause congestion.

An example would be a PON port which is shared amongst subscriber's multicast traffic (single copy of each channel) and subscriber's unicast traffic. The bandwidth control point for this PON port resides in the upstream router BNG node in the form of a vport. In case that the multicast delivery method in the router BNG utilizes redirection, the multicast traffic in the router BNG will flow outside of the subscriber or the vport context and thus will bypass any bandwidth enforcement in the router. To correct this, a vport bandwidth adjustment is necessary in the router that will account for the multicast bandwidth consumption that is bypassing vport in the router but is present in the PON port whose bandwidth is controlled by vport.

An estimate of the multicast bandwidth consumption on the PON port can be made at the vport level based on the IGMP messages sourced from the subscribers behind the PON port. This process is called HQoS Adjustment.

A multicast channel bandwidth is subtracted from or added to the vport rate limit according to the received IGMP Join/Leave messages and the channel bandwidth definition policy associated with the vport (indirectly through a group-interface). Since the multicast traffic on the PON port is shared amongst subscribers behind this PON port, only the first IGMP Join or the last IGMP Leave per multicast channel is tracked for the purpose of the vport bandwidth modification.

The vport rate that will be affected by this functionality depends on the configuration:

- In case the agg-rate-limit within the vport is configured, its value will be modified based on the IGMP activity associated with the subscriber under this vport.
- In case the port-scheduler-policy within the vport is referenced, the max-rate defined in the corresponding port-scheduler-policy will be modified based on the IGMP activity associated with the subscriber under this vport.

The channel bandwidth definition policy is defined in the mcac policy in the **configure>router>mcac>policy** context. The policy is applied under the group-interface or in case of redirection under the redirected-interface.

The rates in effect can be displayed with the following two commands:

```
show port 1/1/5 vport name
```

```
qos scheduler-hierarchy port port-id vport vport-name
```

The configuration of a scheduler policy under a Vport, which is only applicable to Ethernet interfaces, is mutually exclusive with the configuration of the egress-rate-modify parameter.

The configuration of a scheduler policy under a Vport, which is only applicable to Ethernet interfaces, is mutually exclusive with the configuration of the **egress-rate-modify** parameter.

Default HQoS Adjustment for vport is disabled.

host-match

Syntax	host-match dest <i>destination-string</i> [create] no host-match dest <i>destination-string</i>
Context	config>port>ethernet>access>egr>qgrp
Description	This command configures host matching for the Ethernet port egress queue-group. The no form of the command removes
Parameters	dest <i>destination-string</i> — Specify a host match destination string up to 32 characters in length. create — Keyword used to create the host match. The create keyword requirement can be enabled/disabled in the environment>create context.

port-scheduler-policy

Syntax	port-scheduler-policy <i>port-scheduler-policy-name</i> no port-scheduler-policy
Context	config>port>ethernet>access>egress>vport
Description	<p>This command specifies the destination and organization strings to be used for matching subscriber hosts with this vport.</p> <p>The parent vport of a subscriber host queue, which has the port-parent option enabled, is determined by matching the destination string dest string associated with the subscriber and the organization string org string associated with the subscriber host with the strings defined under a vport on the port associated with the subscriber.</p> <p>If a given subscriber host policers or queue does not have the port-parent option enabled, it will be foster-parented to the vport used by this subscriber and which is based on matching the dest string and org string. If the subscriber could not be matched with a vport on the egress port, the host policer or queue will not be bandwidth controlled and will compete for bandwidth directly based on its own PIR and CIR parameters.</p> <p>By default, a subscriber host policer or queue with the port-parent option enabled is scheduled within the context of the port's port scheduler policy.</p>

The **agg-rate rate**, **port-scheduler-policy** and **scheduler-policy** commands are mutually exclusive. Changing between the use of a scheduler policy and the use of an agg-rate/port-scheduler-policy involves removing the existing command and applying the new command. Applying a scheduler-policy to a VPORT is only applicable to Ethernet interfaces.

The **no** form of the command removes the port-scheduler-policy-name from the configuration.

The **agg-rate rate**, **port-scheduler-policy** and **scheduler-policy** commands are mutually exclusive. Changing between the use of a scheduler policy and the use of an **agg-rate/port-scheduler-policy** involves removing the existing command and applying the new command.

Parameters *port-scheduler-policy-name* — Specifies an existing port-scheduler-policy configured in the **config>qos** context.

scheduler-policy

Syntax **scheduler-policy** *scheduler-policy-name*
 no scheduler-policy

Context config>port>ethernet>access>egress>vport

Description This command specifies a scheduler policy to associate to the Vport. Scheduler policies are configured in the **configure>qos>scheduler>policy** context. Each scheduler policy is divided up into groups of schedulers based on the tier each scheduler is created under. A tier is used to give structure to the schedulers within a policy and define rules for parent scheduler associations. The policy defines the hierarchy and operating parameters for virtual schedulers.

The **no** form of this command removes the configured egress scheduler policy from the VPORT.

The **agg-rate rate**, **port-scheduler-policy** and **scheduler-policy** commands are mutually exclusive. Changing between the use of a scheduler policy and the use of an agg-rate/port-scheduler-policy involves removing the existing command and applying the new command.

The configuration of a scheduler policy under a Vport is mutually exclusive with the configuration of the egress-rate-modify parameter.

Parameters *scheduler-policy-name* — The *scheduler-policy-name* parameter applies an existing scheduler policy that was created in the **config>qos>scheduler-policy** *scheduler-policy-name* context to create the hierarchy of egress virtual schedulers.

parent-location

Syntax **parent-location** {default | sla}
 no parent-location

Context	config>qos>sap-egress
Description	<p>This command determines the expected location of the parent schedulers for queues configured with a parent command within the SAP egress policy. All parent schedulers must be configured within a scheduler policy applied at the location corresponding to the parent-location parameter.</p> <p>If a parent scheduler name does not exist at the specified location, the queue will not be parented and will be orphaned.</p>
Default	parent-location default
Parameters	<p>default — When the SAP egress policy is applied to an SLA profile for a subscriber, the parent schedulers of the queues need to be configured in the scheduler policy applied to the subscriber's SUB profile.</p> <p>When the SAP egress policy is applied to a SAP, the parent schedulers of the queues need to be configured in the scheduler policy applied to the SAP or the multi-service site.</p> <p>sla — When the SAP egress policy is applied to an SLA profile for a subscriber, the parent schedulers of the queues need to be configured in the scheduler policy applied to the same SLA profile.</p> <p>If this parameter is configured within a SAP egress policy that is applied to any object except of the egress of an SLA profile, the configured parent schedulers will not be found and so the queues will not be parented and will be orphaned.</p>

parent-location

Syntax	parent-location {none sub vport} no parent-location
Context	config>qos>scheduler-policy
Description	<p>This command determines the expected location of the parent schedulers for the tier 1 schedulers configured with a parent command within the scheduler policy. The parent schedulers must be configured within a scheduler policy applied at the location corresponding to the parent location parameter.</p> <p>If a parent scheduler name does not exist at the specified location, the schedulers will not be parented and will be orphaned.</p> <p>The configuration of parent-location and frame-based-accounting in a scheduler policy is mutually exclusive in to ensure consistency between the different scheduling levels.</p>
Default	parent-location none
Parameters	<p>none — This parameter indicates that the tier 1 schedulers do not have a parent scheduler and the configuration of the parent under a tier 1 scheduler is blocked. Conversely, this parameter is blocked when any tier 1 scheduler has a parent configured.</p>

sub — When the scheduler policy is applied to an SLA profile for a subscriber, the parent schedulers of the tier 1 schedulers need to be configured in the scheduler policy applied to the subscriber's SUB profile.

If this parameter is configured within a scheduler policy that is applied to any object except for the egress of an SLA profile, the configured parent schedulers will not be found and so the tier 1 schedulers will not be parented and will be orphaned.

vport — When the scheduler policy is applied to an SLA profile, a SUB profile for a subscriber or to the egress of a PW SAP, the parent schedulers of the tier 1 schedulers need to be configured in the scheduler policy applied to the VPORT to which the subscriber will be assigned.

If this parameter is configured within a scheduler policy that is applied to to any object except for the egress of an SLA profile or SUB profile, or to the egress of a PW SAP, the configured parent schedulers will not be found and so the tier 1 schedulers will not be parented and will be orphaned. This parameter is not supported when policers-hqos-manageable is configured in the SAP egress QoS policy.

MLD Policy Commands

mld-policy

Syntax	mld-policy <i>mld-policy-name</i> [create] no mld-policy <i>mld-policy-name</i>
Context	config>subscr-mgmt
Description	This command enables the context to create an MLD policy.

disable-router-alert-check

Syntax	[no] disable-router-alert-check
Context	config>subscr-mgmt>mld-policy
Description	This command disables router alert checking for MLD messages received on this interface. The no form of the command enables router alert checking.

egress-rate-modify

Syntax	egress-rate-modify agg-rate-limit egress-rate-modify scheduler <i>scheduler-name</i> no egress-rate-modify
Context	config>subscr-mgmt>mld-policy

Description	This command configures the egress rate modification. The no form of the command removes the values from the configuration.
Parameters	agg-rate-limit — specifies that the maximum total rate for all subscriber egress queues for each subscriber associated with the policy. scheduler <i>scheduler-name</i> — specifies the scheduler to be applied for egress rate modification.

fast-leave

Syntax	[no] fast-leave
Context	config>subscr-mgmt>mld-policy
Description	<p>This command enables fast leave. When fast leave processing is enabled, the router will immediately remove a SAP or SDP from the IP multicast group when it detects an MLD 'leave' on that SAP or SDP. Fast leave processing allows the switch to remove a SAP or SDP that sends a 'leave' from the forwarding table without first sending out group-specific queries to the SAP or SDP, and thus speeds up the process of changing channels ('zapping').</p> <p>Fast leave should only be enabled when there is a single receiver present on the SAP or SDP.</p> <p>When fast leave is enabled, the configured last-member-query-interval value is ignored.</p>
Default	no fast-leave

import

Syntax	import <i>policy-name</i> no import
Context	config>subscr-mgmt>mld-policy
Description	<p>This command specifies the import routing policy to be used. Only a single policy can be imported at a time.</p> <p>The no form of the command removes the policy association.</p>
Default	no import — No import policy is specified.
Parameters	<i>policy-name</i> — The import policy name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes. Routing policies are configured in the config>router>policy-options context. The router policy must be defined before it can be imported.

max-num-groups

Syntax	max-num-groups <i>count</i> no max-num-groups
Context	config>subscr-mgmt>mld-policy
Description	This command defines the maximum number of multicast groups that can be joined. If the router receives a join message that would exceed the configured number of groups, the request is ignored.
Default	no max-num-groups
Parameters	<i>count</i> — Specifies the maximum number of groups that can be joined. Values 1 to 1000

max-num-grp-sources

Syntax	max-num-grp-sources [<i>max-num-grp-sources</i>] no max-num-grp-sources
Context	config>subscr-mgmt>mld-policy
Description	<p>This command configures the maximum number of group sources for which MLD can have local receiver information based on received MLD reports on this interface. When this configuration is changed dynamically to a value lower than currently accepted number of group sources, the group sources that are already accepted are not deleted. Only new group sources will not be allowed. When this object has a value of 0, there is no limit to the number of group sources.</p> <p>The no form of the command removes the value from the configuration.</p>
Default	no max-num-grp-sources
Parameters	<i>max-num-grp-sources</i> — Specifies the maximum number of multicast sources allowed to be tracked per group. Values 1 to 32000

max-num-sources

Syntax	max-num-sources <i>max-num-sources</i> no max-num-sources
Context	config>subscr-mgmt>mld-policy
Description	<p>This command configures the maximum number of multicast sources allowed per group.</p> <p>The no form of the command removes the value from the configuration.</p>

Parameters	<i>max-num-sources</i> — Specifies the maximum number of multicast sources allowed per group.
Values	1 to 1000

per-host-replication

Syntax	[no] per-host-replication
Context	config>subscr-mgmt>mld-policy
Description	<p>This command enables per-host-replication. In the per-host-replication mode, multicast traffic is replicated per each host within the subscriber irrespective of the fact that some hosts may be subscribed to the same multicast stream. As a result, in case that multiple hosts within the subscriber are registered for the same multicast group, the multicast streams of that group will be generated. The destination MAC address of multicast streams will be changed to unicast so that each host receives its own copy of the stream. Multicast traffic in the per-host-replication mode can be classified via the existing QoS CLI structure. As such the multicast traffic will flow through the subscriber queues. HQoS Adjustment is not needed in this case.</p> <p>The alternative behavior for multicast replication in IPoE environment is per-SAP- replication. In this model, only a single copy of the multicast stream is sent per SAP, irrespective of the number of hosts that are subscribed to the same multicast group. This behavior applies to 1:1 connectivity model as well as on 1:N connectivity model (SAP centric behavior as opposed to subscriber centric behavior).</p> <p>In the per-SAP-replication model the destination MAC address is multicast (as opposed to unicast in the per-host-replication model). Multicast traffic is flowing via the SAP queue which is outside of the subscriber context. The consequence is that multicast traffic is not accounted in the subscriber HQoS. In addition, HQoS Adaptation is not supported in the per SAP replication model.</p>
Default	disabled

query-interval

Syntax	query-interval <i>seconds</i> no query-interval
Context	config>subscr-mgmt>mld-policy
Description	<p>This command specifies the frequency at which the querier router transmits general host-query messages. Host-query messages solicit group membership information and are sent to the link-scope all-node address, FF02::1. If nothing is configured, by default, the query-interval takes the value defined in the config>router>mld context or in the config>service>vpn>mld context. It is highly recommended that all three query intervals be configured together on each MLD policy.</p>

Parameters	<i>seconds</i> — specifies the frequency, in seconds, at which the router transmits general host-query messages
Values	2 to 1024

query-last-listener-interval

Syntax	query-last-listener-interval <i>seconds</i> no query-last-listener-interval
Context	config>subscr-mgmt>mld-policy
Description	This command configures the frequency at which the querier router sends a group-specific query messages, including the messages sent in response to leave-group messages. The shorter the interval, the faster the loss of the last member of a group can be detected. If nothing is configured, by default, the query-last-listener-interval takes the value defined in the config>router>mld context or in the config>service>vprn>mld context. It is highly recommended that all three query intervals be configured together on each MLD policy.
Parameters	<i>seconds</i> — specifies the frequency, in seconds, at which query messages are sent
Values	1 to 1024

query-response-interval

Syntax	query-response-interval <i>seconds</i> no query-response-interval
Context	config>subscr-mgmt>mld-policy
Description	This command configures the query response interval. If nothing is configured, by default, the query-response-interval takes the value defined in the config>router>mld context or in the config>service>vprn>mld context. It is highly recommended that all three query intervals be configured together on each MLD policy.
Parameters	<i>seconds</i> — specifies the length of time that the querier router waits to receive a response to from the host
Values	1 to 1023

redirection-policy

Syntax	redirection-policy <i>policy-name</i> no redirection-policy
Context	config>subscr-mgmt>mld-policy

Description	<p>This command will apply multicast redirection action to the subscriber. The redirection action along with the redirected interface (and possibly service id) is defined in the referenced policy-name. MLD messages will be redirected to an alternate interface if that alternate interface has MLD enabled. The alternate interface does not have to have any multicast groups registered via MLD. Currently all MLD messages are redirected and there is no ability to selectively redirect MLD messages based on match conditions (multicast-group address, source IP address, etc.). Multicast redirection is supported between VPRN services and also between interfaces within the Global Routing Context. Multicast Redirection is not supported between the VPRN services and the Global Routing Table (GRT).</p> <p>MLD state is maintained per subscriber host and per redirected interface. Traffic is however forwarded only on the redirected interface.</p>
Default	none
Parameters	<i>policy-name</i> — This is a regular policy defined under the configure>router>policy-option>policy-statement context.

static

Syntax	static
Context	config>subscr-mgmt>mld-policy
Description	This command adds an MLD static group membership.

group

Syntax	[no] group <i>grp-ipv6-address</i>
Context	config>subscr-mgmt>mld-policy>static
Description	This command configures a static multicast group.
Parameters	<i>grp-ipv6-address</i> — Specifies the IPv6 address.
Values	<p><grp-ipv6-address> : ipv6-address - x:x:x:x:x:x:x (eight 16-bit pieces) x:x:x:x:x:d.d.d.d</p> <p>x - [0 to FFFF]H</p> <p>d - [0 to 255]D</p> <p>- multicast group IPv6 address</p>

source

Syntax	[no] source <i>ipv6-address</i>
---------------	--

Context	config>subscr-mgmt>mld-policy>static>group
Description	This command adds or removes a static multicast source.
Parameters	<i>grp-ipv6-address</i> — Specifies the IPv6 address. Values <grp-ipv6-address> : ipv6-address - x:x:x:x:x:x:x (eight 16-bit pieces) x:x:x:x:x:x:d.d.d.d x - [0 to FFFF]H d - [0 to 255]D - multicast group IPv6 address

starg

Syntax	[no] starg
Context	config>subscr-mgmt>mld-policy>static>group
Description	This command adds a static (*,G) entry. This command can only be enabled if no existing source addresses for this group are specified. Use the no form of the command to remove the starg entry from the configuration.
Default	none

version

Syntax	version <i>version</i> no version
Context	config>subscr-mgmt>mld-policy#
Description	This command configures the MLD version.
Parameters	<i>version</i> — Specifies the MLD version. Values 1, 2

IPoE Session Commands

ipoe-session-policy

Syntax	ipoe-session-policy <i>policy-name</i> [create] no ipoe-session-policy <i>policy-name</i>
---------------	--

Context	config>subscr-mgmt
Description	This command configures an IPoE session policy. The policies are referenced from subscriber interfaces, group interfaces and capture SAPs. Multiple IPoE session policies can be configured.
Default	none
Parameters	<i>policy-name</i> — Specifies the IPoE policy name up to 32 characters in length

description

Syntax	description <i>description-string</i> no description
Context	config>subscr-mgmt>ipoe-policy
Description	<p>This command creates a text description stored in the configuration file for a configuration context.</p> <p>The description command associates a text string with a configuration context to help identify the context in the configuration file.</p> <p>The no form of this command removes any description string from the context.</p>
Default	no description
Parameters	<i>description-string</i> — A text string describing the entity. Allowed values are any string up to 80 characters long composed of printable, 7-bit ASCII characters excluding double quotes. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

session-key

Syntax	session-key sap mac [cid] [rid] no session-key
Context	config>subscr-mgmt>ipoe-policy
Description	<p>This command configures the key to logically group subscriber hosts that belong to the same dual stack end device in an IPoE session.</p> <p>The SAP and MAC address are always part of the IPoE session key. Optionally the Circuit-Id/Interface-Id or Remote-Id can be added to the session key.</p>
Default	session-key sap mac
Parameters	sap — Includes the SAP as part of the IPoE session key. The sap parameter is mandatory and cannot be removed from the key.

mac — Includes the MAC address as part of the IPoE session key. The **mac** parameter is mandatory and cannot be removed from the key.

cid — Optionally adds the DHCPv4 Relay Agent Circuit-Id (option 82, sub option 1) and DHCPv6 Interface-Id (option 18) field to the IPoE session key.

rid — Optionally adds the DHCPv4 Relay Agent Remote-Id (option 82, sub option 2) and DHCPv6 Remote-Id (option 37) field to the IPoE session key. For DHCPv6, the enterprise number is excluded from the key.

sap and **mac** are mandatory parameters while **cid** and **rid** are optional and mutually exclusive. Valid IPoE session key parameters are: **sap mac**, **sap mac cid** and **sap mac rid**.

session-timeout

Syntax	session-timeout <i>timeout</i> no session-timeout
Context	config>subscr-mgmt>ipoe-policy
Description	This command defines the time in seconds between 1 second and 360 days before the IPoE session will be disconnected. The default value is unlimited session timeout.
Default	no session-timeout
Parameters	<i>timeout</i> — Specifies the session timeout in seconds Values 1 to 31104000

sap

Syntax	sap <i>sap-id</i> [create] [capture-sap]
Context	Context
Description	This command declares a given SAP as a primary (or secondary) VPLS port.

ipoe-session

Syntax	[no] ipoe-session
Context	config>service>vpls>sap config>service>ies>sub-if>grp-if config>service>vprn>sub-if>grp-if config>service>ies>sub-if config>service>vprn>sub-if

Description	This command configures IPoE session parameters.
--------------------	--

Default	none
----------------	------

force-auth

Syntax	force-auth [cid-change] [rid-change] force-auth disabled no force-auth
Context	config>service>ies>sub-if>grp-if>ipoe-session config>service>vprn>sub-if>grp-if>ipoe-session
Description	<p>By default, if the circuit-id/interface-id or remote-id in the IPoE session re-authentication trigger packet (such as a DHCP renewal) is not empty and different from the circuit-id/interface-id or remote-id stored in the IPoE session data, a forced re-authentication is performed, ignoring the configured min-auth-interval. This default behavior can be changed with this command.</p> <p>The no form of the command resets the default behavior.</p>
Default	force-auth cid-change rid-change force-auth disabled on WLAN-GW group interfaces
Parameters	<p>cid-change — Perform a forced re-authentication upon a circuit-id/interface-id change. An empty circuit-id/interface-id is not considered a change.</p> <p>rid-change — Perform a forced re-authentication upon a remote-id change. an empty remote-id is not considered a change. For DHCPv6, the enterprise number is excluded from the comparison.</p> <p>disabled — Does not perform a forced re-authentication upon a circuit-id/interface-id or remote-id change.</p>

ipoe-session-policy

Syntax	ipoe-session-policy <i>policy-name</i> no ipoe-session-policy
Context	config>service>vpls>sap> ipoe-session config>service>ies>sub-if>grp-if>ipoe-session config>service>vprn>sub-if>grp-if>ipoe-session
Description	<p>This command specifies the IPoE session policy applicable for this group interface or capture SAP.</p> <p>On wlan-gw group interfaces, it is not possible to change this value.</p>

Default	no ipoe-session-policy ipoe-session-policy "default" on WLAN-GW group interfaces
Parameters	<i>policy-name</i> — Specifies the IPoE session policy name up to 32 characters in length

min-auth-interval

Syntax	min-auth-interval [days <i>days</i>] [hrs <i>hours</i>] [min <i>minutes</i>] [sec <i>seconds</i>] min-auth-interval infinite no min-auth-interval
Context	config>service>ies>sub-if>grp-if>ipoe-session config>service>vprn>sub-if>grp-if>ipoe-session
Description	<p>Re-authentication for IPoE sessions enable dynamic policy changes.</p> <p>This command configures the maximum frequency of re-authentications by specifying a minimum interval between two non-forced authentications for the same IPoE session.</p> <p>A forced authentication is by default triggered by a Circuit-Id/Interface-Id or Remote-Id change (see the force-auth command).</p> <p>Re-authentications are, by default, disabled and can be enabled by configuring a min-auth-interval.</p> <p>Setting the min-auth-interval to zero seconds will always re-authenticate on each trigger packet.</p>
Default	min-auth-interval infinite
Parameters	<p>days — Specifies the min number of days between two non-forced authentications for IPoE sessions</p> <p>Values 0 to 365</p> <p>hrs — Specifies the min number of hours between two non-forced authentications for IPoE sessions</p> <p>Values 0 to 23</p> <p>min — Specifies the min number of minutes between two non-forced authentications for IPoE sessions</p> <p>Values 0 to 59</p> <p>sec — Specifies the min number of seconds between two non-forced authentications for IPoE sessions</p> <p>Values 0 to 59</p> <p>infinite — Does not perform non-forced re-authentications for IPoE sessions (default).</p>

radius-session-timeout

Syntax	radius-session-timeout { backwards-compatible ignore absolute } no radius-session-timeout
Context	config>service>ies>sub-if>grp-if>ipoe-session config>service>vprn>sub-if>grp-if>ipoe-session
Description	<p>This command specifies how to interpret the session-timeout coming from a RADIUS VSA in an Access-Accept or CoA message.</p> <p>The value of this command can only be changed on WLAN-GW group interfaces.</p> <p>The no form of this command resets the default value.</p>
Default	absolute backwards-compatible on WLAN-GW group interfaces
Parameters	<p>backwards-compatible — Specifies that the VSA will be interpreted as an IPv4 lease time if the Alc-Lease-Time attribute is not present and an absolute timeout otherwise. The VSA will be treated the same as for non-ipoe session DHCP hosts.</p> <p>ignore — Specifies that the VSA meaning is irrelevant for IPoE session and should be ignored.</p> <p>absolute — Specifies that the the VSA would be treated as a timeout starting from the moment the IPoE session is set up.</p>

sap-session-limit

Syntax	sap-session-limit <i>sap-session-limit</i> no sap-session-limit
Context	config>service>ies>sub-if>grp-if>ipoe-session config>service>vprn>sub-if>grp-if>ipoe-session
Description	This command specifies the number of IPoE sessions per SAP allowed for this group-interface
Default	sap-session-limit 1
Parameters	<i>sap-session-limit</i> — Specifies the number of allowed IPoE sessions.

Note: The operational maximum value may be smaller due to equipped hardware dependencies.

Values 1 to 131071
131071 on WLAN-GW group interfaces

session-limit

Syntax	session-limit <i>session-limit</i> no session-limit
Context	config>service>ies>sub-if>grp-if>ipoe-session config>service>vprn>sub-if>grp-if>ipoe-session config>service>ies>sub-if>ipoe-session config>service>vprn>sub-if>ipoe-session
Description	This command specifies the number of IPoE sessions allowed for this group interface or retail subscriber interface.
Default	session-limit 1
Parameters	<i>session-limit</i> — Specifies the number of allowed IPoE sessions.

Note: The operational maximum value may be smaller due to equipped hardware dependencies.

Values	1 to 131071 1 – 500000 (retail subscriber interface)
---------------	---

user-db

Syntax	user-db <i>local-user-db-name</i> no user-db
Context	config>service>vpls>sap> ipoe-session config>service>ies>sub-if>grp-if>ipoe-session config>service>vprn>sub-if>grp-if>ipoe-session
Description	This command configures the local user database to use for IPoE session authentication.

When configured on a capture SAP, the group interface must have the same local user database configured.

On a WLAN-GW group interface, the **no** form of this command indicates that the user database will be picked from the following sources in the order shown:

1. dhcp
2. ipv6> dhcp6
3. ipv6> router-solicit

If no user database can be found in any of these locations, processing continues as if no user database was configured. This behavior is for backwards compatibility reasons only; when using a LUDB, it should be explicitly added to the IPoE session configuration.

Default	no user-db
Parameters	<i>local-user-db-name</i> — Specifies the local user database name up to 32 characters in length.

shutdown

Syntax	[no] shutdown
Context	config>service>vpls>sap> ipoe-session config>service>ies>sub-if>grp-if>ipoe-session config>service>vprn>sub-if>grp-if>ipoe-session
Description	<p>The shutdown command enables or disables IPoE session management on a group interface or capture SAP.</p> <p>A shutdown of the IPoE session CLI hierarchy on a group-interface will clear all active IPoE sessions on that interface, resulting in a deletion of all corresponding subscriber hosts.</p> <p>On WLAN-GW group interfaces it is not possible to disable an IPoE session.</p>
Default	shutdown no shutdown on WLAN-GW group interfaces

9.24.2.1.17 SHCV Policy Commands

shcv-policy

Syntax	shcv-policy <i>name</i> [create] no shcv-policy <i>name</i>
Context	config>subscr-mgmt
Description	<p>This command configures a Subscriber Host Connectivity Verification (SHCV) policy. An SHCV policy can be applied to both the subscriber management group interface and VPLS instances. All SHCV-related features inside a group interface and a VPLS service will follow the configuration specified in the SHCV policy. The SHCV policy and the SHCV configuration on a group interface are mutually exclusive. Only one can be applied to the group interface.</p> <p>The no form of the command removes the policy name from the configuration.</p>
Default	none
Parameters	<i>name</i> — Specifies the name of the SHCV policy up to 32 characters in length.

layer-3

Syntax	layer-3
Context	config>subscr-mgmt>shcv-policy
Description	This command enables the context to configure SHCV behavior parameters for IES and VPRN services.
Default	none

source-ip-origin

Syntax	source-ip-origin {interface vrrp} no source-ip-origin
Context	config>subscr-mgmt>shcv-policy>layer-3
Description	<p>This command selects the source IP address to be used for SHCV messages.</p> <p>The no form of the command reverts to the default.</p>
Default	default
Parameters	interface — Specifies to use the interface IP as the source address of SHCV. vrrp — Specifies to use the VRRP configured IP as the source address of SHCV.

periodic

Syntax	periodic
Context	config>subscr-mgmt>shcv-policy
Description	This command configures the periodic SHCV properties for the subscriber management group-interface. This tool will periodically scan all known DHCP hosts only and perform unicast ARP/NS requests. The subscriber host connectivity verification will maintain state (connected vs. not-connected) for all hosts.
Default	none

action

Syntax	action {alarm remove} no action
Context	config>subscr-mgmt>shcv-policy>periodic
Description	This command configures the action to take when the periodic connectivity verification failed. The no form of the command reverts to the default.
Default	alarm
Parameters	alarm — This keyword raises an alarm indicating that the host is disconnected. remove — This keyword raises an alarm and releases all allocated resources (addresses, prefixes, queues, table entries, etc.). Static hosts will never be removed.

interval

Syntax	interval <i>minutes</i> no interval
Context	config>subscr-mgmt>shcv-policy>periodic
Description	This command specifies the time interval which all known sources should be verified. The actual rate is dependent on the number of known hosts and intervals. The no form of the command reverts to the default.
Default	30 minutes
Parameters	<i>minutes</i> — Specifies the interval, in minutes, between periodic connectivity checks. Values 1 to 6000

retry-count

Syntax	retry-count [<i>count</i>] no retry-count
Context	config>subscr-mgmt>shcv-policy>periodic
Description	This command configures the number of retransmissions. The no form of the command reverts to the default.
Default	2
Parameters	<i>count</i> — Specifies the number of retransmissions in periodic connectivity verification. Values 2 to 29

timeout

Syntax	timeout <i>seconds</i> no timeout
Context	config>subscr-mgmt>shcv-policy>periodic
Description	This command configures the timeout before a retransmission in triggered connectivity verification. The no form of the command reverts to the default.
Default	10
Parameters	<i>seconds</i> — Specifies the timeout, in seconds, before a retransmission in triggered connectivity verification. Values 10 to 60

trigger

Syntax	trigger <i>trigger-type</i>
Context	config>subscr-mgmt>shcv-policy
Description	This command enables to context to configure SHCV triggers.
Default	none

Parameters *trigger-type* — Specifies the trigger SHCV properties for the subscriber management group-interface.

Values **ip-conflict** - Upon detecting an IP conflict for the new host, a trigger SHCV is sent using a unicast ARP/NS. The request will verify the old host's connectivity to the BNG. An unresponsive host will be removed from the system, allowing the new host to connect. The new host must resend its address request in order to be created as an ESM host in the system.

host-limit-exceeded - Upon exceeding the host-limit for (**sla-profile**, **ipoe-session** *sap-session-limit*, **ipoe-session** *session-limit*, and **arp-host**), a trigger SHCV is sent. The request will verify the old host's connectivity to the BNG. An unresponsive host will be removed from the system, allowing the new host to connect. The new host must resend its address request in order to be created as an ESM host in the system.

inactivity - A trigger SHCV is sent to the idle host to verify the host's connectivity to the BNG. An unresponsive host will be removed from the system.

mobility - Detects detects an IP or MAC conflict between different SAPs. Upon detecting a MAC or an IP conflict, a trigger SHCV is sent. The request will verify the old host's connectivity to the BNG. An unresponsive host will be removed from the system, allowing the new host to connect. The new host must resend its address request in order to be created as an ESM host in the system.

mac-learning - Specifies the trigger SHCV properties to learn the MAC address of static hosts. Upon a **no shutdown**, a trigger SHCV is sent to the host to learn the host's MAC address.

retry-count

Syntax **retry-count** [*count*]
no retry-count

Context config>subscr-mgmt>shcv-policy>trigger

Description This command configures the number of retransmissions in periodic connectivity verification.
The no form of the command reverts to the default.

Default 1

Parameters *count* — Specifies the number of retransmissions in periodic connectivity verification.

Values 1 to 29

timeout

Syntax	timeout <i>seconds</i> no timeout
Context	config>subscr-mgmt>shcv-policy>trigger
Description	This command configures the timeout before a retransmission. The no form of the command reverts to the default.
Default	1
Parameters	<i>seconds</i> — Specifies the retry timeout in seconds. Values 1 to 60

vpls

Syntax	vpls
Context	config>subscr-mgmt>shcv-policy
Description	This command enables the context to configure SHCV behavior in VPLS services.

source-ip

Syntax	source-ip <i>ip-address</i> no source-ip
Context	config>subscr-mgmt>shcv-policy>vpls
Description	This command configures the IPv4 address to be used as source address for connectivity verification in a VPLS service. The no form of the command reverts to the default.
Default	no source-ip
Parameters	<i>ip-address</i> — Specifies the IPv4 address to be used as source address for connectivity verification in a VPLS service.

source-mac

Syntax	source-mac <i>ieee-address</i> no source-mac
Context	config>subscr-mgmt>shcv-policy>vpls

Description	Specifies the MAC address to be used as source address for connectivity verification in a VPLS service. The no form of the command reverts to the default.
Default	no source-mac
Parameters	<i>ieee-address</i> — Specifies the 48-bit MAC address in the xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx format.

9.24.2.2 Show Commands

Note: The command outputs in the following section are examples only; actual displays may differ depending on supported functionality and user configuration.

diameter-peer-policy

Syntax	diameter-peer-policy [<i>peer-policy-name</i>] diameter-peer-policy <i>peer-policy-name</i> peer <i>peer-name</i> [statistics] diameter-peer-policy <i>peer-policy-name</i> client-side-peer-ip <i>ip-address</i> port <i>tcp-port</i> [statistics]
Context	show>aaa
Description	This command displays diameter peer policy information and diameter peer information and statistics. For the diameter proxy, the incoming peer can be specified with an IP address and port number.
Parameters	<i>peer-policy-name</i> — the diameter peer policy name, up to 32 characters in length peer <i>peer-name</i> — the diameter peer name, up to 32 characters in length client-side-peer-ip <i>ip address</i> — the IP address of the incoming peer (client side) of a diameter proxy port <i>tcp-port</i> — the TCP port number of the incoming peer (client side) of a diameter proxy statistics — displays the diameter peer statistics with details per diameter application, per message type, and per direction (rx/ tx)
Output	Table 87 provides a description of the counters in the output of the show aaa diameter-peer-policy command. and Table 88 provides the failure reasons for the aggregate Failed counter (Request Rx and Answer Rx). Sample output follows the tables.

Table 87 show aaa diameter-peer-policy Field Descriptions

Counter		Counts
Aggregates Total	Request Tx	Aggregated counter sum of all successfully transmitted diameter request messages (all applications, all message types)
	Answer Rx	Aggregated counter sum of all successfully received diameter answer messages (all applications, all message types)
	Request Rx	Aggregated counter sum of all successfully received diameter request messages (all applications, all message types)
	Answers Tx	Aggregated counter sum of all successfully transmitted diameter answer messages (all applications, all message types)
Aggregates Failed	Request Tx	Aggregated counter sum of all request messages that could not be sent for internal reasons, such as TCP socket error (for example, congestion), failure reported to application (for example, no retries left) Dropped by Python Timeouts (requests for which no answer was received within the configured timeout interval)
	Answer Rx	Aggregated counter sum of all Answer messages that failed to be successfully decoded, such as such as invalid header length or a violation against the Command Code Format (CCF) specification. See Aggregate Failed Request Rx and Answer Rx counters Aggregate Failed Request Rx and Answer Rx counters for more information.
	Request Rx	Aggregated counter sum of all Request messages that failed to be successfully decoded, such as invalid header length or a violation against the Command Code Format (CCF) specification See Aggregate Failed Request Rx and Answer Rx counters Aggregate Failed Request Rx and Answer Rx counters for more information.
	Answers Tx	Aggregated counter Sum of all answer messages that could not be sent for internal reasons such as TCP socket error (for example, congestion) Dropped by Python

Table 87 show aaa diameter-peer-policy Field Descriptions (Continued)

Counter		Counts (Continued)
Application ID <i>id</i> message type	Request Tx	successfully transmitted diameter request messages for the corresponding application and message type
	Answer Rx	successfully received diameter answer messages for the corresponding application and message type
	Request Rx	successfully received diameter request messages for the corresponding application and message type
	Answers Tx	successfully transmitted diameter answer messages for the corresponding application and message type

Table 88 Aggregate Failed Request Rx and Answer Rx counters

Role	Failed reasons
Proxy	proxy (message length too short / too long / version unsupported)
	Consistency check failed: header size, message length, illegal flag combination, AVP header too small, AVP present but not allowed (base RFC messages), etc.
	not a base message
	not a request
	Tx overload (message received to be send to client)
	dropped by python
	failed to create answer
	no transaction (answer to server, but request is not found - 5 min.)

Table 88 Aggregate Failed Request Rx and Answer Rx counters

Role	Failed reasons (Continued)
Diameter base / Diameter application	message dropped due to result code
	message too big / too small
	dropped by python
	consistency check failed
	end-2-end mismatch hop-to-hop command code (answer/ request mismatch)
	cool down sequence drop
	cc error request
	application id in header error
	T bit in header

isa-radius-policy

Syntax **isa-radius-policy** *policy-name*
isa-radius-policy *policy-name* **associations**

Context show>aaa

Description This command displays ISA RADIUS policy information.

Parameters *policy-name* — Displays information about the specified ISA RADIUS policy.

associations — Displays the information associated with the ISA RADIUS server policy.

Output

Sample Output

Table 89 Subscriber ISA RADIUS Policy Field Descriptions

Label	Description
Purposes Up	Indicates the RADIUS services that are up and running, and fully operational for this server.
Source IP address	Indicates the IP address of the RADIUS server.
Acct Tx Requests	Indicates the number of RADIUS transaction requests transmitted.
Acct TX Retries	Indicates the number of RADIUS transaction request retries.
Acct TX Timeouts	Indicates the number of RADIUS transaction requests that have timed out.
Acct RX Replies	Indicates the number of RADIUS transaction responses received.
Auth Tx Requests	Indicates the number of authentication requests transmitted.
Auth Tx Retries	Indicates the number of authentication request retries.
Auth Tx Timeouts	Indicates the number of RADIUS authentication requests that have timed out for the policy.
CoA RX Requests	Indicates the number of Change-of-Authorization message responses received.

Context	show>aaa
Description	This command displays RADIUS server policy configuration information.
Parameters	<i>policy-name</i> — Displays information for the specified RADIUS server policy. association — Displays the information configured with the RADIUS server policy. msg-buffer-stats — Displays statistics related to the RADIUS messages that are buffered for each specified RADIUS server policy. statistics — Displays statistics for the specified RADIUS server policy. act-on-off — Displays the admin state of the acct-on-off feature.
Output	

Sample Output

Table 90 **Subscriber RADIUS Server Policy Field Descriptions**

Label	Description
Tx transaction requests	Indicates the number of RADIUS transaction requests transmitted.
Rx transaction responses	Indicates the number of RADIUS transaction responses received.
Transaction requests timed out	Indicates the number of RADIUS transaction requests that have timed out.
Transaction requests send failed	Indicates the number of RADIUS transaction requests that could not be transmitted.
Packet retries	Indicates the number of times a RADIUS request packet was retransmitted to a server.
Transaction requests send rejected	Indicates the number of RADIUS transaction requests that were not transmitted due to unacceptable configuration.
Authentication requests failed	Indicates the number of authentication failures for this policy.
Accounting requests failed	Indicates the number of accounting failures for this policy.
Ratio of access-reject over auth responses	Indicates the ratio of access-rejects in the auth responses for this policy.
Transaction success ratio	Indicates the transaction success ratio for this policy.
Transaction failure ratio	Indicates the transaction failure ratio for this policy.
Statistics last reset at	Indicated the date and time at which the statistics for this policy were last reset.

ancp-string

- Syntax** **ancp-string**
 ancp-string *ancp-string*
 ancp-string **customer** *customer-id* **site** *customer-site-name*
 ancp-string **sap** *sap-id*
- Context** show>subscr-mgmt
- Description** This command displays subscriber Access Node Control Protocol (ANCP) string information.

Parameters *ancc-string* — Specifies an Access Node Control Protocol (ANCP) string up to 63 characters in length.

customer *customer-id* — Specifies an existing customer ID.

Values 1 to 2147483647

site *customer-site-name* — Specifies an existing customer site name up to 32 characters in length.

sap *sap-id* — Displays ANCP string information for the specified SAP ID.

authentication

- Syntax** **authentication** *policy-name* **association**
authentication [*policy-name*]
authentication [*policy-name*] **statistics**
authentication **coa-statistics**
- Context** show>subscr-mgmt
- Description** This command displays subscriber management RADIUS authentication policy information and statistics.
- Parameters** *policy-name* — Specifies the subscriber management RADIUS authentication policy name, up to 32 characters, for which information is requested.
- association** — Displays SAP, interface, local user database host, AA and L2TP associations of this policy.
- coa-statistics** — Displays the overall statistics for incoming RADIUS Change of Authorization (CoA) messages and Disconnect Messages. For dropped requests, a counter for different drop reasons is available.
- statistics** — Displays a list of policies with basic statistics (without specifying a policy name) or detailed statistics, including per-server statistics for the specified policy-name. These statistics apply only to the legacy RADIUS server configuration method where the servers are directly configured in the authentication policy.

Syntax	host-lockout-policy host-lockout-policy <i>policy-name</i> association host-lockout-policy <i>policy-name</i> host-lockout-policy <i>policy-name</i> <i>lockout-state</i> sap <i>sap-id</i> [summary] host-lockout-policy <i>policy-name</i> <i>lockout-state</i> [circuit-id <i>circuit-id</i>] [sap <i>sap-id</i>] [summary] host-lockout-policy <i>policy-name</i> <i>lockout-state</i> [mac <i>ieee-address</i>] [sap <i>sap-id</i>] [summary] host-lockout-policy <i>policy-name</i> <i>lockout-state</i> [remote-id <i>remote-id</i>] [sap <i>sap-id</i>] [summary]
Context	show>subscriber-mgmt
Description	This command displays host lockout policy information.
Parameters	<i>policy-name</i> — Specifies a specific subscriber host lockout policy name up to 32 characters. association — Specifies to display the association of the host lockout policy. <i>lockout-state</i> — Specifies to display information for hosts in a specific lockout state. Values all active graceful sap <i>sap-id</i> — Specifies to display SAP ID information.

circuit-id *circuit-id* — Specifies to display circuit ID information. The *circuit-id* is 256 characters maximum.

mac *ieee-address* — Specifies to display MAC address information. The *ieee-address* is 30 characters maximum.

remote-id *remote-id* — Specifies to display remote ID information. The *remote-id* is 256 characters maximum.

Output The following is a sample output for the **host-lockout-policy** command.

Sample Output

```

radius-accounting-policy

- Syntax** **radius-accounting-policy** *name* **association**
radius-accounting-policy [*name*]
radius-accounting-policy *name* **statistics**
- Context** show>subscr-mgmt
- Description** This command displays RADIUS accounting policy information.
- Parameters** *name* — Specifies the RADIUS accounting policy name.
association — Displays parameters associated with this RADIUS accounting policy.
statistics — Displays statistics associated with this RADIUS accounting policy

Output**Table 92 Subscriber RADIUS Accounting Policy Field Descriptions**

Label	Description
Tx Requests/TX Reqs	Displays the number of accounting requests transmitted for this policy.
Rx Responses/Rx Resps	Displays the number of accounting responses received for this policy.
Request Timeouts/Req Timeouts	Displays the number of accounting requests which have timed out for this policy.
Send Retries	Displays the number of retries to a different server for a single accounting request for this policy.
Send Failed Req Send Failed	Displays how many accounting requests failed because the packet could not be sent out for this policy.
Radius Servers	<p>Displays a table in which the statistics associated with this RADIUS accounting policy are broken down by individual RADIUS server.</p> <p>The table columns are:</p> <p>Index—displays the index number assigned to the RADIUS server. The index determines the sequence in which the servers are queried for authentication requests. Servers are queried in order from lowest to highest index.</p> <p>IP Address—the address of the RADIUS server.</p> <p>TX Reqs—see TX Requests in this table.</p> <p>Rx Resps—see RX Responses in this table.</p> <p>Req Timeouts—see Request Timeouts in this table.</p> <p>Req Send Failed—see Send Failed in this table.</p>

- Description** This command displays the subscriber's SLA profile scheduler stats.
- Parameters** **subscriber** *sub-ident-string* — Displays information for the specified subscriber profile name.
sla-profile *sla-profile-name* — Displays information for the specified sla-profile-name.
sap *sap-id* — Displays information for the specified SAP.
scheduler *scheduler-name* — Displays information for the specified scheduler-name.

Output

Sample Output

```
*A:BNG# show qos scheduler-stats subscriber "sub1" sla-profile "sla-profile.1" sap 1/1/1:1 scheduler

statistics

Syntax	statistics iom (<i>slot</i> all) [host session subscriber summary] [non-zero-value-only] statistics mda (<i>mda</i> all) [host session subscriber summary] [non-zero-value-only] statistics port (<i>port-id</i> all) [host session subscriber summary] [non-zero-value-only] statistics pw-port (<i>pw-port</i> all) [host session subscriber summary] [non-zero-value-only] statistics system [host session subscriber summary] [non-zero-value-only]
Context	show>subscr-mgmt
Description	This command displays enhanced subscriber management statistics per port/pw-port/MDA/IOM/system. For each statistic, there is current value and peak value, peak value is the highest value since last reset via system boot or command clear subscriber-mgmt peakvalue-stats .

Note: The peak values can be reset via the **clear subscriber-mgmt peakvalue-stats** command.

Parameters

iom *slot* — Displays specified IOM slot information.

mda *mda* — Displays specified slot/mda information.

port *port-id* — Specifies to display information for both the physical port ID and LAG.

pw-port *pw-port* — Specifies to display information for a pseudowire port ID.

Values 1 to 10239

all — displays statistics of all IOM or MDA or port or pseudowire port in the system.

host — Displays v4/v6 host statistics only.

session — Displays PPPoX/LAC/LNS session statistics only.

subscriber — Displays subscriber statistics only.

summary — Displays summary statistics only.

non-zero-value-only — Displays only non-zero value counters.

The following tables describe the counters available in the **show subscriber management statistics** command output.

The following terminology is used to indicate applicability of the stats:

- ESM — Enhanced Subscriber Management. Subscriber traffic forwarded via subscriber queues. Enabled with SAP sub-sla-mgmt in no shutdown state.
- BSM — Basic Subscriber Management. Subscriber traffic forwarded via SAP queues. SAP sub-sla-mgmt must be in shutdown state. For DHCP, dhcp lease-populate or dhcp6-relay lease-populate must be enabled to count the leases. For IPv4, if anti-spoof is enabled on the SAP, a subscriber host is instantiated.
- Routed CO — IES or VPRN service with subscriber-interface and group-interface constructs.
- Bridged CO — VPLS service with DHCPv4 lease management enabled (lease-populate)
- regular interface — IES or VPRN interface (none subscriber-interface or group-interface)
- Host (also subscriber host) — A resource in the system that is used for traffic forwarding and security related actions. The creation of a subscriber host entry is linked to anti-spoof being enabled on a SAP. For ESM, anti-spoof is mandatory and hence every connected {IP/MAC} consumes by default a subscriber host entry. A DHCP6 IA-PD can also be modeled as a managed route. In this case, no subscriber host is instantiated. For BSM, anti-spoof is optional on regular interfaces. An IPv4 static-host and DHCPv4 lease do not result in a subscriber host instantiation when anti-spoof is disabled on the SAP.

Table 93 Host And Protocol Statistics

Section	Counter	Counts	Applies to
IPv4	1. PPP Hosts - IPCP	IPv4 local terminated PPP hosts (PTA, LNS)	ESM, Routed CO
	2. IPOE Hosts - DHCP	DHCPv4 hosts (lease states)	ESM, Routed CO, Bridged CO
	3. IPOE Hosts - ARP	ARP hosts	ESM, Routed CO, Bridged CO
	4. IPOE Hosts – Static	IPv4 static hosts	ESM, Routed CO, Bridged CO
	5. IPOE Hosts BSM - DHCP	DHCPv4 hosts (lease states: anti-spoof and lease-populate enabled)	BSM, Routed CO, Bridged CO, regular interface
	6. IPOE Hosts BSM – Static	IPv4 static hosts (with anti-spoof enabled)	BSM, Routed CO, Bridged CO, regular interface
	7. IPOE BSM - DHCP	DHCPv4 lease states (with lease-populate enabled, no anti-spoof)	BSM, Routed CO, Bridged CO, regular interface
	8. IPOE BSM – Static	IPv4 static hosts (no anti-spoof)	BSM, Routed CO, Bridged CO, regular interface

Table 93 Host And Protocol Statistics (Continued)

Section	Counter	Counts	Applies to
IPv6	PPP Hosts – SLAAC	Local terminated IPv6 wan-host – SLAAC (PTA, LNS)	ESM, Routed CO
	PPP Hosts - DHCP6 (PD)	Local terminated IPv6 pd-host (PTA, LNS) – DHCP6 IA-PD leases over PPP (excluding PD as managed route)	ESM, Routed CO
	PPP Hosts - DHCP6 (NA)	Local terminated IPv6 wan-host (PTA, LNS) – DHCP6 IA-NA leases over PPP	ESM, Routed CO
	PPP Mngd Rt - DHCP6 (PD)	IPv6 (PTA, LNS) – DHCP6 IA-PD leases over PPP (PD as managed route only)	ESM, Routed CO
	IPOE Hosts – SLAAC	IPv6 wan-host – SLAAC	ESM, Routed CO
	IPOE Hosts - DHCP6 (PD)	IPv6 pd-host – DHCP6 IA-PD leases (excluding PD as managed route)	ESM, Routed CO
	IPOE Hosts - DHCP6 (NA)	IPv6 wan-host – DHCP6 IA-NA leases	ESM, Routed CO
	IPOE Mngd Rt - DHCP6 (PD)	IPv6 – DHCP6 IA-PD leases (PD as managed route only)	ESM, Routed CO
	IPOE Hosts – Static (PD)	IPv6 static hosts with prefix-length shorter than /128	ESM, Routed CO
	IPOE Hosts – Static (WAN)	IPv6 static hosts with prefix-length equal to /128	ESM, Routed CO
	IPOE BSM - DHCP6 (PD)	IPv6 – DHCP6 IA-PD leases (lease-populate)	BSM, regular interface
	IPOE BSM - DHCP6 (NA)	IPv6 – DHCP6 IA-NA leases (lease-populate)	BSM, regular interface

Table 93 Host And Protocol Statistics (Continued)

Section	Counter	Counts	Applies to
Total	PPP Hosts	Local terminated PPP hosts (PTA, LNS) Sum of counters 1, 9, 10 and 11	ESM
	IPOE Hosts	Total IPv4 and IPv6 IPOE hosts. Sum of counters 2, 3, 4, 5, 6, 13, 14, 15, 17 and 18	ESM
	IPv4 Hosts	Total IPv4 hosts. PPP (PTA, LNS) and IPOE. Sum of counters 1, 2, 3, 4, 5 and 6	ESM
	IPv6 Hosts	Total IPv6 hosts. PPP (PTA, LNS) and IPOE. Sum of counters 9, 10, 11, 13, 14, 15, 17 and 18	ESM
	IPv6 PD Mngd Routes	Total DHCP6 IA-PD leases modeled as a managed route. PPP (PTA, LNS) and IPOE. Sum of counters 12 and 16	ESM
	L2TP LAC Hosts	L2TP LAC hosts – single host per single or dual stack PPP session. Counter also increases for outgoing LTS sessions.	ESM, Routed CO
	Internal Hosts	Subscriber hosts for internal use. For example: LNS redirect hosts (for LTS, an LNS redirect host is also instantiated).	ESM

Table 93 Host And Protocol Statistics (Continued)

Section	Counter	Counts	Applies to
Total (Cont)	Non-Sub-Traffic L2-Hosts	<p>Host on a single subscriber SAP in a VPLS service that enables non-IP traffic to be forwarded using the specified SLA profile instance queues.</p> <p>Host on a single subscriber SAP attached to an IES/ VPRN group-interface that enables traffic normally forwarded via the SAP queues to flow via the specified SLA profile instance queues.</p> <p>configure service vpls <service-id> sap <sap-id> sub-sla-mgmt single-sub-parameters non-sub-traffic sub-profile <sub-profile-name> sla-profile <sla-profile-name> [subscriber <sub-ident-string>] [app-profile <app-profile-name>]</p>	ESM, Routed CO, Bridged CO
	DHCP leases	<p>Total number of DHCPv4 lease states.</p> <p>Sum of counters 2, 5 and 7</p>	ESM, BSM
	DHCPv6 leases	<p>Total number of DHCPv6 lease states.</p> <p>Sum of counters 10, 11, 12, 14, 15, 16, 19 and 20</p>	ESM, BSM
	Subscriber Hosts	<p>Counter displayed in the output of “show subscriber-mgmt statistics iom mda port pw-port”</p> <p>This counter matches the number of hosts accounted for in the per line card limit</p> <p>Sum of counters 1, 2, 3, 4, 5, 6, 9, 10, 11, 13, 14, 15, 17, 18 and 26</p>	ESM

Table 93 Host And Protocol Statistics (Continued)

Section	Counter	Counts	Applies to
Total (Cont)	System Hosts Scale	Counter displayed in the output of "show subscriber- mgmt statistics system" This counter matches the number of hosts accounted for in the system wide limit Sum of counters 1, 2, 3, 4, 5, 6, 9, 10, 11, 13, 14, 15, 17, 18, 26 and 27	ESM

Table 94 PPP Session Statistics

Section	Counter	Counts	Applies to
Local	PPP Sessions - PPPoE	Local terminated PPPoE sessions (PTA)	ESM, Routed CO
	PPP Sessions - PPPoEoA	Local terminated PPPoEoA sessions (PTA)	ESM, Routed CO
	.PPP Sessions - PPPoA	Local terminated PPPoA sessions (PTA)	ESM, Routed CO
	PPP Sessions - L2TP (LNS)	Local terminated PPP sessions (L2TP LNS)	ESM, Routed CO
LAC	PPP Sessions - PPPoE	Tunneled PPPoE session (L2TP LAC)	ESM, Routed CO
	PPP Sessions - PPPoEoA	Tunneled PPPoEoA session (L2TP LAC)	ESM, Routed CO
	PPP Sessions - PPPoA	Tunneled PPPoA session (L2TP LAC)	ESM, Routed CO
	PPP Sessions - L2TP (LTS)	Tunneled PPP session (L2TP LTS)	ESM, Routed CO

Table 94 PPP Session Statistics (Continued)

Section	Counter	Counts	Applies to
Total	PPP Sessions - established	PPP sessions that are established (at least one active host attached) – PTA/LAC/LTS/LNS	ESM, Routed CO
	PPP Sessions - in setup	PPP sessions in setup (session created, host setup in progress) – PTA/LAC/LTS/LNS	ESM, Routed CO
Total (Cont)	PPP Sessions - local	Local terminated PPPoX sessions (PTA, L2TP LNS) Sum of counters 33, 34, 35 and 36	ESM, Routed CO
	PPP Sessions - LAC	Tunneled PPPoX session (L2TP LAC, L2TP LTS) Sum of counters 37, 38, 39 and 40	ESM, Routed CO
L2TP	L2TP Tunnels - originator	Number of L2TP Tunnels originated on this node. (LAC/ LTS)	ESM, Routed CO
	L2TP Tunnels - receiver	Number of L2TP Tunnels terminated on this node. (LNS/ LTS)	ESM, Routed CO
	Total L2TP Tunnels	Number of L2TP Tunnels originated or terminated on this node Sum of counters 45 and 46	ESM, Routed CO

Table 95 **IPoE Session Statistics**

Section	Counter	Counts	Applies to
Total	IPOE Sessions - established	IPoE sessions that are established (at least one active host attached).	ESM, Routed CO
	IPOE Sessions- in setup	IPoE sessions in setup (session created, host setup in progress).	ESM, Routed CO

Table 96 **Subscriber Statistics**

Section	Counter	Counts	Applies to
Total	Subscribers	Total number of active subscribers.	ESM, Routed CO, Bridged CO

Table 97 **SubMgmt Statistics Summary**

Section	Counter	Counts
Hosts	IPv4	Total IPv4 hosts (counter 23 in tables above)
	IPv6	Total IPv6 hosts (counter 24 in tables above)
Sessions	PPP	Total PPP sessions - established (counter 41 in tables above)
	IPOE	Total IPOE sessions – established (counter 48 in tables above)
Subscribers		Total number of active subscribers (counter 50 in tables above)

pw-port

- Syntax** **pw-port** [*pw-port-id*] [**detail**]
pw-port sdp *sdp-id*
pw-port sdp none
- Context** show>pw-port
- Description** Displays pseudo-wire port information.
- If no optional parameters are specified, the command displays a summary of all defined PW ports. The optional parameters restrict output to only ports matching the specified properties.
- Parameters** *pw-port-id* — Specifies the pseudo-wire port identifier.
- Values** 1 to 10239
- detail** — Displays detailed port information that includes all the **pw-port** output fields.
- sdp** *sdp-id* — The SDP ID for which to display matching PW port information.
- Values** 1 to 17407
- Output** Show PW-Port
- The following table describes **show pw-port** output fields:

Table 98 Subscriber Show PW-Port Field Descriptions

Label	Description
PW Port	The PW Port identifier.
Encap	The encapsulation type of the PW Port.
SDP	The SDP identifier.
IfIndex	The interface index used for the PW Port.
VC-Id	The Virtual Circuit identifier.
Description	The description string for the PW Port.

Sample Output

```
*A:ALA-48>config>service# show pw-port
```

```

scheduler-hierarchy

Syntax	scheduler-hierarchy
Context	show>qos
Description	This command enables the context to display information about policies that use this scheduler.

customer

Syntax	customer <i>customer-id</i> site <i>customer-site-name</i> [scheduler <i>scheduler-name</i>] [ingress egress] [detail]
Context	show>qos>scheduler-hierarchy show>qos>scheduler-stats
Description	This command displays the scheduler hierarchy per customer multi-service-site.
Parameters	customer <i>customer-id</i> — Displays information for the specified customer ID. site <i>customer-site-name</i> — Displays information for the specified multi-service <i>customer-site-name</i> . scheduler <i>scheduler-name</i> — Displays information for the specified scheduler-name. ingress — Displays information for the ingress policy. egress — Displays information for the egress policy. detail — Displays detailed information.

sap

Syntax	sap <i>sap-id</i> [scheduler <i>scheduler-name</i>] [ingress egress] [detail]
Context	show>qos>scheduler-hierarchy show>qos>scheduler-stats
Description	This command displays the scheduler stats per SAP.
Parameters	<i>sap-id</i> — Specifies the physical port identifier portion of the SAP definition. scheduler <i>scheduler-name</i> — Displays information for the specified scheduler-name. ingress — Displays information for the ingress policy. egress — Displays information for the egress policy. detail — Displays detailed information.

subscriber

Syntax	subscriber <i>sub-ident-string</i> [scheduler <i>scheduler-name</i>] [ingress egress] [detail] subscriber <i>sub-ident-string</i> sla-profile <i>sla-profile-name</i> sap <i>sap-id</i> [scheduler <i>scheduler-name</i>] [detail]
Context	show>qos>scheduler-hierarchy
Description	This command displays the scheduler hierarchy rooted at the SLA profile scheduler.
Parameters	subscriber <i>sub-ident-string</i> — Displays information for the specified subscriber profile name. sla-profile <i>sla-profile-name</i> — Displays information for the specified sla-profile-name. sap <i>sap-id</i> — Displays information for the specified SAP. scheduler <i>scheduler-name</i> — Displays information for the specified scheduler-name. detail — Displays detailed information.

Note: If the SLA profile scheduler is orphaned (that is when the scheduler has a parent which does not exist) then the hierarchy is only shown when the show command includes the sla-profile and sap parameters.

Output

Sample Output

```

scheduler-name

- Syntax** scheduler-name scheduler-name
- Context** show>qos
- Description** This command displays information about the specified scheduler name.
- Parameters** scheduler-name — Displays information about the specified scheduler.

scheduler-policy

- Syntax** scheduler-policy [scheduler-policy-name] [association | sap-ingress policy-id | sap-egress policy-id]

Context	show>qos
Description	This command displays information about the specified scheduler policy.
Parameters	<i>scheduler-policy-name</i> — Displays information for the specified scheduler policy. sap-ingress <i>policy-id</i> — Displays information for the ingress policy. sap-egress <i>policy-id</i> — Displays information for the egress policy. association — Displays the information currently configured with the specified <i>scheduler-policy-name</i> .

Output**Sample Output**

Syntax **ancc-string**
ancc-string *ancc-string*
ancc-string customer *customer-id* **site** *customer-site-name*
ancc-string sap *sap-id*

Context show>subscriber-management

Description This command displays subscriber ANCP string information.

Parameters *ancc-string* — Specify the ASCII representation of the DSLAM circuit-id name.
customer *customer-id* — Specify the associated existing customer name.
site *customer-site-name* — Specify the associated customer’s configured MSS name.
sap *sap-id* — Specifies the physical port identifier portion of the SAP definition.

radius-proxy-server *server-name* **cache** *hex-key* *hex-string*
radius-proxy-server *server-name* **cache** *string-key* *string*
radius-proxy-server *server-name* **cache** **summary**

radius-proxy-server *server-name* **statistics**
radius-proxy-server

Context show>router

Description This command displays RADIUS proxy server information.

Parameters *server-name* — Specifies the default RADIUS proxy server name created in the **config>router>radius-proxy** context.

cache — Displays cached information.

hex-key *hex-string* — Displays

Values [0x0 to 0xFFFFFFFF (max 64 hex nibbles)]

string-key *string* — Displays the packet type of the RADIUS messages to use to generate the key for the cache of this RADIUS proxy server.

summary — Displays summarized information.

statistics — Displays statistics for the specified RADIUS proxy server.

Output

Table 99 Subscriber RADIUS Proxy Server Field Descriptions

Label	Description
Invalid response Authenticator Rx packet	Displays the number of packets received by this RADIUS proxy server.
Rx Access-Request	Displays the number of Access-Request packets received by this RADIUS proxy server.
Rx Accounting-Request	Displays the number of Accounting-Request packets received by this RADIUS proxy server.
Rx dropped	Displays the number of packets received by this RADIUS proxy server but dropped.
Retransmit	Displays the number of packets received by this RADIUS proxy server that were rejected because they are retransmitted.
Wrong purpose	Displays the number of packets received by this RADIUS proxy server that were rejected because the value of <code>tmnxRadProxSrvPurpose</code> is set to a value not matching the type of packet.
No UE MAC to cache	Displays the number of packets received by this RADIUS proxy server that were rejected because the UE MAC address was not present in the packet.

Table 99 **Subscriber RADIUS Proxy Server Field Descriptions (Continued)**

Label	Description (Continued)
Client context limit reached	Displays the number of packets received by this RADIUS proxy server that were rejected because the limit of client contexts was reached. For each RADIUS transaction a client context is created, and will be deleted once the transaction is finished.
No ISA RADIUS policy configured	Displays the number of packets received by this RADIUS proxy server that were rejected because it has no ISA RADIUS server policy configured for that type of packet.
Server admin down	Displays the number of packets received by this RADIUS proxy server that were rejected because it is administratively shut down.
No RADIUS policy configured	Displays the number of packets received by this RADIUS proxy server that were rejected because it has no RADIUS server policy configured for that type of packet.
No load-balance-key configured	Displays the number of packets received by this RADIUS proxy server that were rejected because the selected RADIUS server policy's algorithm is set to hashBased and no load balance key is configured.
Invalid length	Displays the number of packets received by this RADIUS proxy server that were rejected because their length was invalid.
Invalid Code field	Displays the number of packets received by this RADIUS proxy server that were rejected because they had an invalid Code field.
Invalid attribute encoding	Displays the number of packets received by this RADIUS proxy server that were rejected because one of the attributes was incorrectly encoded.
Invalid User-Name	Displays the number of packets received by this RADIUS proxy server that were rejected because they contained an invalid User-Name attribute.
Invalid password	Displays the number of packets received by this RADIUS proxy server that were rejected because the User-Password attribute could not be decoded.
Invalid accounting Authenticator	Displays the number of accounting packets received by this RADIUS proxy server that were rejected because they contained an invalid Authenticator field.
Invalid Message-Authenticator	Displays the number of packets received by this RADIUS proxy server that were rejected because they contained an invalid Message-Authenticator attribute.

Table 99 **Subscriber RADIUS Proxy Server Field Descriptions (Continued)**

Label	Description (Continued)
Management core overload	Displays the number of packets that were rejected by this RADIUS server because the ISA management core is not able to process any new RADIUS requests because of overload.
No memory	Displays the number of packets that were rejected by this RADIUS server because there was not enough memory to store them.
Accounting-Request with invalid Acct-Status-Type	Displays the number of accounting packets received by this RADIUS proxy server that were rejected because they contained an invalid Acct-Status-Type attribute.
Accounting-Request with no Acct-Status-Type	Displays the number of accounting packets received by this RADIUS proxy server that were rejected because they contained no Acct-Status-Type attribute.
Registered user overload	Displays the number of packets that were rejected by this RADIUS server because the registered user indicated to be in overload.
Dropped by Python	Displays the number of packets received by this RADIUS proxy server but dropped by Python.
Tx Access-Accept	Displays the number of Access-Accept packets transmitted by this RADIUS proxy server.
Tx Access-Reject	Displays the number of Access-Reject packets transmitted by this RADIUS proxy server.
Tx Access-Challenge	Displays the number of Access-Challenge packets transmitted by this RADIUS proxy server.
Tx Accounting-Response	Displays the number of Accounting-Response packets transmitted by this RADIUS proxy server.
Tx dropped	Displays the number of packets dropped by this RADIUS proxy server before transmission.
No key to cache	Displays the number of packets that could not be cached by this RADIUS proxy server because the key information was not present in the packet.
Cache key too long	Displays the number of packets that could not be cached by this RADIUS proxy server because the key information present in the packet was too long.
Cache attributes too long	Displays the number of packets that could not be cached by this RADIUS proxy server because the total length of the attributes is too long.

Table 99 Subscriber RADIUS Proxy Server Field Descriptions (Continued)

Label	Description (Continued)
Reached maximum number of cache entries	Displays the number of packets that could not be cached by this RADIUS proxy server because the limit has been reached.
No memory	Displays the number of packets that could not be transmitted by this RADIUS proxy server because there was not enough memory.
Server timeout	Displays the number of packets that were dropped because the RADIUS servers have timed out.
Server authentication failure	Displays the number of packets that were dropped because the RADIUS server replied with a packet which failed authentication (invalid response Authenticator or Message Authenticator attribute).
Server invalid Code	Displays the number of packets that were dropped because the RADIUS server replied with a packet with an invalid Code field.
Invalid attribute encoding	Displays the number of packets that were dropped because the RADIUS server replied with a packet with an invalid attribute.
Registered user overload	Displays the number of packets that were dropped because the registered user indicated to be in overload.
No RADIUS server configured	Displays the number of packets that were dropped by this RADIUS server because the RADIUS server policy has no servers configured.
RADIUS server send failure	Displays the number of packets that were dropped by this RADIUS server because the packet could not get transmitted to one of the servers in the RADIUS server policy.
Dropped by Python	Displays the number of packets that were dropped by this RADIUS server because the packet was dropped by the Python script.
Invalid response Authenticator	Displays the number of packets that were dropped because the RADIUS server replied with a packet which failed authentication

managed-hosts

Syntax **managed-hosts type {aaa | data-triggered} [ip ip-address] [mac ieee-address]**

Context	show>service>id
Description	This command displays information about hosts that are not yet linked to an in-band control plane protocol, such as DHCP or DHCPv6. Examples include hosts installed by data-triggers and hosts installed by RADIUS.
Parameters	aaa — shows information about managed hosts installed and removed only by RADIUS data-triggered — shows information about managed hosts installed by data-triggers <i>ip-address</i> — shows information about a managed host with the specified IP address <i>ieee-address</i> — shows information about a managed host with the specified MAC address
Output	The following output is an example of managed host information.

Sample Output

```
# show service id 100 managed-hosts type data-triggered
=====
Managed data-triggered hosts

9.24.2.3 Clear Commands

ancp-sub-string

Syntax	ancp-sub-string <i>string</i>
Context	clear>subscr-mgmt>ancp>ancp
Description	This command clears subscriber ANCP data.
Parameters	<i>string</i> — Clears the ANCP string corresponding to this subscriber ID.

arp

Syntax	arp {all <i>ip-address</i> } arp interface [<i>ip-int-name</i> <i>ip-address</i>]
Context	clear>router

Description	This command clears all or specific ARP entries. The scope of ARP cache entries cleared depends on the command line option(s) specified.
Parameters	all — Clears all ARP cache entries. <i>ip-addr</i> — Clears the ARP cache entry for the specified IP address. interface <i>ip-int-name</i> — Clears all ARP cache entries for the interface with the specified name. interface <i>ip-addr</i> — Clears all ARP cache entries for the specified interface with the specified address.

authentication

Syntax	authentication [<i>policy-name</i>] authentication coa-statistics
Context	clear
Description	This command clears subscriber authentication data.
Parameters	<i>policy-name</i> — Clears the authentication policy name. The policy must be already configured. coa-statistics — Clears statistics for incoming RADIUS Change of Authorization requests.

diameter-session

Syntax	diameter-session
Context	clear>subscr-mgmt
Description	This command clears diameter session data.

ccrt-replay

Syntax	ccrt-replay diameter-application-policy <i>name</i>
Context	clear>subscr-mgmt>diameter-session
Description	This command clears diameter Gx sessions that are in CCR Terminate replay mode.
Parameters	diameter-application-policy <i>name</i> — Specifies the application policy up to 32 characters in length for which orphaned Gx sessions will be deleted.

errors

Syntax	errors
Context	clear>subscriber-mgmt
Description	This command clears all errors in the circular buffer.

idle-only-msap

Syntax	idle-only-msap <i>msap-policy-name</i>
Context	clear>subscr-mgmt
Description	<p>This command removes all idle MSAPs associated with the MSAP policy.</p> <p>This command only removes idle MSAPs without active subscribers. This command is considered safer than the clear>subscr-mgmt>msap-policy <i>msap-policy-name</i> idle-only command because in that command, the parameter idle-only is optional. Not specifying idle-only will delete MSAPs with active subscribers.</p>
Parameters	<i>msap-policy-name</i> — Specifies the MSAP policy for which all associated idle MSAPs will be cleared

msap-policy

Syntax	msap-policy <i>msap-policy-name</i> [idle-only]
Context	clear>subscr-mgmt
Description	<p>This command deletes Managed SAPs (MSAPs) created by the MSAP policy.</p> <p>This command can remove an MSAP with active subscribers still associated with the MSAP. Use the idle-only parameter to remove only MSAPs in an idle state.</p>
Parameters	<p><i>msap-policy-name</i> — Specifies an existing managed SAP policy name. A string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.</p> <p>idle-only — Specifies to remove only the MSAPs in an idle state.</p>

peakvalue-stats

Syntax	peakvalue-stats iom (<i>slot</i> all) [recursive] peakvalue-stats mda (<i>mda</i> all) [recursive] peakvalue-stats port (<i>port-id</i> all)
---------------	--

peakvalue-stats pw-port (*pw-port* | **all**)
peakvalue-stats system [**recursive**]

Context clear> subscriber-mgmt

Description This command resets the most recent peak counter.

Note: Clearing one counter will not impact other counters. For example, clearing one IOM's most recent peak value will not impact chassis peak value.

Parameters

- iom slot** — Clears IOM host peak value statistics for the specified IOM.
- mda mda** — Clears MDA host peak value statistics for the specified MDA.
- port port-id** — Clears port host peak value statistics for the specified port ID.
- pw-port pw-port** — Clears pseudowire port host peak value statistics for the specified port.

Values 1 to 10239

- system** — Clears system host peak value statistics.
- all** — Clears all host peak value statistics.
- recursive** — Resets the sub-level counters. For example, clearing IOM counters with the **recursive** keyword will also clear counters of all ports counters on that IOM.

radius-accounting

Syntax **radius-accounting** [*policy-name*]

Context clear> subscriber-mgmt

Description This command clears RADIUS accounting data for the specified policy.

Parameters *policy-name* — The name of the policy. The string is case sensitive and limited to 32 ASCII 7-bit printable characters with no spaces

scheduler-stats

Syntax **scheduler-stats**

Context clear>qos

Description This command clears scheduler statistics.

subscriber

Syntax	subscriber <i>sub-ident-string</i> [scheduler <i>scheduler-name</i>] [ingress egress]
Context	clear>qos>scheduler-stats
Description	This command clears scheduler stats per subscriber.
Parameters	<i>sub-ident-string</i> — Clears information for the subscriber profile name. scheduler <i>scheduler-name</i> — Clears information for the specified scheduler-name. egress — Clears egress information for the subscriber. ingress — Clears ingress information for the subscriber.

sla-profile

Syntax	subscriber <i>sub-ident-string</i> sla-profile <i>sla-profile-name</i> sap <i>sap-id</i> [scheduler <i>scheduler-name</i>]
Context	clear>qos>scheduler-stats
Description	This command clears the subscriber's SLA profile scheduler stats.
Parameters	subscriber <i>sub-ident-string</i> — Clears information for the specified subscriber profile name. sla-profile <i>sla-profile-name</i> — Clears information for the specified sla-profile-name. sap <i>sap-id</i> — Clears information for the specified SAP. scheduler <i>scheduler-name</i> — Clears information for the specified scheduler-name.

srrp

Syntax	srrp
Context	clear>router
Description	This command enables the context to clear and reset SRRP virtual router instances.

interface

Syntax	interface <i>subscriber-interface</i> [id <i>srrp-id</i>]
Context	clear>router>srrp
Description	This command clears and resets SRRP interface instances.

Parameters	<i>subscriber-interface</i> — Specifies an existing subscriber interface name.
Values	32 chars max
id <i>srrp-id</i> — Specifies an existing SRRP ID.	
Values	1 to 4294967295

statistics

Syntax	statistics interface <i>subscriber-interface</i> [id <i>srrp-id</i>]
Context	clear>router>srrp
Description	This command clears statistics for SRRP instances.
Parameters	<i>subscriber-interface</i> — Specifies an existing subscriber interface name.
Values	32 chars max
id <i>srrp-id</i> — Specifies an existing SRRP ID.	
Values	1 to 4294967295

route-downloader

Syntax	route-downloader <i>name</i> [vprn <i>vprn</i>] [family <i>family</i>]
Context	clear>aaa
Description	<p>This command clears all the radius-downloaded routes from the internal downloader cache (or protocol RIB/db) (and thus eventually from the RTM itself). The parameters vprn and/or family allow to restrict the deletion of those routes learned in a particular address family (IPv4 or IPv6) and/or a particular VPRN.</p> <p>By default, all VPRNs and both IPv4 and IPv6 families are affected.</p>

Note: A clear of the internal protocol DB means the corresponding prefix that were deleted should be removed from the RTM (and from any other exports) as well.

Parameters	vprn — Specifies to limit the removal of prefixes to only the specific VPRN. The parameter can be either the service-id or service-name that identifies a VPRN.
	family <i>family</i> — Specifies to limit the removal of prefixes only belonging to the address family IPv4 or IPv6. Only these two values will be accepted.
Values	ipv4, ipv6

vport

Syntax	port <i>port-id</i> vport <i>name</i> [scheduler <i>scheduler-name</i>]
Context	clear>qos>scheduler-stats
Description	This command clears the vport scheduler stats.
Parameters	port <i>port-id</i> — Clears information for the specified port. vport <i>name</i> — Clears information for the specified vport. scheduler <i>scheduler-name</i> — Clears information for the specified scheduler-name.

ipoe session

Syntax	ipoe session [sap <i>sap-id</i>] [interface <i>ip-int-name</i> <i>ip-address</i>] [mac <i>ieee-address</i>] [circuit-id <i>circuit-id</i>] [remote-id <i>remote-id</i>] [inter-dest-id <i>intermediate-destination-id</i>] [no-inter-dest-id] [ip-address <i>ip-prefix[/prefix-length]</i>] [port <i>port-id</i>] [subscriber <i>sub-ident-string</i>] [sap-session-id <i>sap-session-index</i>] ipoe session all
Context	clear>service>id
Description	This commands clears all identified IPoE sessions for the specified service instance. All associated subscriber hosts will be deleted from the system.
Parameters	all — clears all active IPoE sessions for the specified service instance.

9.24.2.4 Tools Commands

tools

Syntax	tools
Context	root
Description	The context to enable useful tools for debugging purposes.
Default	none
Parameters	dump — Enables dump tools for the various protocols. perform — Enables tools to perform specific tasks.

avp-match-learned-session-id

Syntax	avp-match-learned-session-id
Context	tools>dump>debug>diameter
Description	This command displays the diameter session IDs that are learned by the AVP value matching in a diameter debug. Per avp-match <i>id</i> in a diameter peer policy, a single diameter session ID can be learned. "N/A" means no session ID is learned.
Output	The following is a sample output for the avp-match-learned-session-id command.

Sample output

```
# tools dump debug diameter avp-match-learned-session-id
=====
Learned Session-Id
=====
Diameter Peer Policy          ID Session-Id
-----
diameter-peer-policy-1        1  bng.domain.com;1452197100;13
diameter-peer-policy-1        2  N/A
-----
No. of AVP matches: 2
=====
```

perform

Syntax	perform
---------------	----------------

Context	tools
Description	This command enables the context to enable tools to perform specific tasks.
Default	none

credit-reset

Syntax	credit-reset sap <i>sap-id</i> subscriber <i>sub-ident-string</i> sla-profile <i>sla-profile-name</i> { category <i>category-name</i> all-categories } credit-reset sap <i>sap-id</i> ip <i>ip-address</i> { category <i>category-name</i> all-categories } credit-reset svc <i>service-id</i> ip <i>ip-address</i> { category <i>category-name</i> all-categories }
Context	tools>perform>subscr-mgmt
Description	This command resets the credit for an SLA-profile instance.
Parameters	sap <i>sap-id</i> — Specifies the physical port identifier portion of the SAP definition. ip <i>ip-address</i> — Modifies lease state information for the specified IP address. subscriber <i>sub-ident-string</i> — Modifies lease state information for the specified subscriber identification. sub-profile-string <i>sub-profile-string</i> — Modifies lease state information for the specified subscriber profile. sla-profile-string <i>sla-profile-string</i> — Modifies lease state information for the specified SLA profile. svc-id <i>service-id</i> — Modifies lease state information for the specified service ID. Values <i>service-id</i> : 1 2147483647 <i>svc-name</i> : up to 64 characters maximum.

persistence

Syntax	persistence
Context	tools>perform
Description	This command enables the context to configure downgrade parameters.

downgrade

Syntax	downgrade target-version <i>target</i> [reboot]
Context	tools>perform>persistence
Description	This command downgrades persistence files to a previous version.

Parameters **target-version** *target* — Specifies the downgrade version.
 reboot — Specifies to reboot the system after a successful conversion.

eval-msap

Syntax **eval-msap** {**policy** *msap-policy-name* | **msap** *sap-id*}

Context tools>perform>subscr-mgmt

Description This command re-applies the managed SAP policy to the managed SAP identified by the specified *sap-id* or to all managed SAPs associated with the specified *msap-policy name*.

Parameters **policy** *msap-policy-name* — Specifies an existing MSAP policy. The MSAP policy will be re-applied to all associated managed SAPs.
 msap *sap-id* — Specifies an MSAP sap-id. The MSAP policy will be re-applied to the specified MSAP.

Values [*port-id*||*lag-id*]:*qtag1*
 [*port-id*||*lag-id*]:*qtag1.qtag2*

eval-lease-state

Syntax **eval-lease-state** [**svc-id** *service-id*] [**sap** *sap-id*] [**subscriber** *sub-ident-string*] [**ip** *ip-address*] [**mac** *mac-address*]

Context tools>perform>subscriber-mgmt

Description This command evaluates lease state.

Parameters **sap-id** — Specifies the physical port identifier portion of the SAP definition.
 ip-address — Specifies the a server's IP address. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).
 sub-ident-string — Specifies the subscriber ID string, up to 32 characters, maximum.
 service-id — Specifies an existing service ID.

Values 1 to 2147483647

subscriber-mgmt

Syntax **subscriber-mgmt**

Context tools>perform

Description This command enables tools to control subscriber management.

edit-lease-state

Syntax	edit-lease-state sap <i>sap-id</i> ip <i>ip-address</i> [mac <i>ieee-address</i>] [subscriber <i>sub-ident-string</i>] [sub-profile-string <i>sub-profile-string</i>] [sla-profile-string <i>sla-profile-string</i>] [app-profile-string <i>app-profile-string</i>] [inter-dest-id <i>intermediate-destination-id</i>] [ancp-string <i>ancp-string</i>] edit-lease-state svc-id <i>service-id</i> ip <i>ip-address</i> [mac <i>ieee-address</i>] [subscriber <i>sub-ident-string</i>] [sub-profile-string <i>sub-profile-string</i>] [sla-profile-string <i>sla-profile-string</i>] [app-profile-string <i>app-profile-string</i>] [inter-dest-id <i>intermediate-destination-id</i>] [ancp-string <i>ancp-string</i>]				
Context	tools>perform>subscr-mgmt				
Description	This command provides the parameters to edit lease state information.				
Parameters	sap <i>sap-id</i> — Specifies the physical port identifier portion of the SAP definition. ip <i>ip-address</i> — Modifies lease state information for the specified IP address. <i>ieee-address</i> — Specifies the 48-bit MAC address for the static ARP in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee, and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses. subscriber <i>sub-ident-string</i> — Modifies the lease state information for the specified subscriber identification. sub-profile-string <i>sub-profile-string</i> — Modifies lease state information for the specified subscriber profile. sla-profile-string <i>sla-profile-string</i> — Modifies lease state information for the specified SLA profile. svc-id <i>service-id</i> — Modifies lease state information for the specified service ID.				
Values	<table> <tr> <td><i>service-id:</i></td><td>1 to 2147483647</td></tr> <tr> <td><i>svc-name:</i></td><td>64 characters maximum</td></tr> </table>	<i>service-id:</i>	1 to 2147483647	<i>svc-name:</i>	64 characters maximum
<i>service-id:</i>	1 to 2147483647				
<i>svc-name:</i>	64 characters maximum				

credit-reset

Syntax	credit-reset sap <i>sap-id</i> subscriber <i>sub-ident-string</i> sla-profile <i>sla-profile-name</i> { category <i>category-name</i> all-categories } credit-reset sap <i>sap-id</i> ip <i>ip-address</i> { category <i>category-name</i> all-categories } credit-reset svc <i>service-id</i> ip <i>ip-address</i> { category <i>category-name</i> all-categories }
Context	tools>perform>subscr-mgmt
Description	This command resets the credit for an SLA-profile instance.
Parameters	sap <i>sap-id</i> — Specifies the physical port identifier portion of the SAP definition. ip <i>ip-address</i> — Modifies lease state information for the specified IP address.

subscriber *sub-ident-string* — Modifies lease state information for the specified subscriber identification.

sub-profile-string *sub-profile-string* — Modifies lease state information for the specified subscriber profile.

sla-profile-string *sla-profile-string* — Modifies lease state information for the specified SLA profile.

svc-id *service-id* — Modifies lease state information for the specified service ID.

Values

<i>service-id:</i>	1 to 2147483647
<i>svc-name:</i>	64 characters maximum

edit-ppp-session

Syntax **edit-ppp-session sap** *sap-id* [**user-name** *user-name*] [**mac** *mac-address*] [**session-id** *session-id*] [**ip-address** *ip-address*] [**subscriber** *sub-ident-string*] [**sub-profile-string** *sub-profile-string*] [**sla-profile-string** *sla-profile-string*] [**inter-dest-id** *intermediate-destination-id*] [**ancp-string** *ancp-string*] [**app-profile-string** *app-profile-string*]
edit-ppp-session svc-id *service-id* [**user-name** *user-name*] [**mac** *mac-address*] [**session-id** *session-id*] [**ip-address** *ip-address*] [**subscriber** *sub-ident-string*] [**sub-profile-string** *sub-profile-string*] [**sla-profile-string** *sla-profile-string*] [**inter-dest-id** *intermediate-destination-id*] [**ancp-string** *ancp-string*] [**app-profile-string** *app-profile-string*]

Context tools>perform>subscr-mgmt

Description This command updates the data of the PPP session identified with the given MAC address and SAP identifier. Optionally the remote-id and circuit-id can be specified to identify the IPoE session to update.

Note: The changes take immediate effect.

edit-slaac-host

Syntax **edit-slaac-host sap** *sap-id* [**user-name** *user-name*] [**mac** *mac-address*] [**session-id** *session-id*] [**ip-address** *ip-address*] [**subscriber** *sub-ident-string*] [**sub-profile-string** *sub-profile-string*] [**sla-profile-string** *sla-profile-string*] [**inter-dest-id** *intermediate-destination-id*] [**ancp-string** *ancp-string*] [**app-profile-string** *app-profile-string*]
edit-slaac-host svc-id *service-id* [**user-name** *user-name*] [**mac** *mac-address*] [**session-id** *session-id*] [**ip-address** *ip-address*] [**subscriber** *sub-ident-string*] [**sub-profile-string** *sub-profile-string*] [**sla-profile-string** *sla-profile-string*] [**inter-dest-id** *intermediate-destination-id*] [**ancp-string** *ancp-string*] [**app-profile-string** *app-profile-string*]

Context tools>perform>subscr-mgmt

Description This command updates the data of the SLAAC host information

edit-ipoe-session

Syntax **edit-ipoe-session** **sap** *sap-id* **mac** *mac-address* [**subscriber** *sub-ident-string*] [**sub-profile-string** *sub-profile-string*] [**sla-profile-string** *sla-profile-string*] [**inter-dest-id** *intermediate-destination-id*] [**ancp-string** *ancp-string*] [**app-profile-string** *app-profile-string*] [**circuit-id** *circuit-id*] [**remote-id** *remote-id*]

Context tools>perform>subscr-mgmt

Description This command updates the data of the IPoE session identified with the given MAC address and SAP identifier. Optionally the remote-id and circuit-id can be specified to identify the IPoE session to update.

Note: The changes take immediate effect.

eval-ipoe-session

Syntax **eval-ipoe-session** [**svc-id** *service-id*] [**sap** *sap-id*] [**mac** *mac-address*] [**circuit-id** *circuit-id*] [**remote-id** *remote-id*] [**subscriber** *sub-ident-string*]

Context tools>perform>subscr-mgmt

Description This command re-evaluates the mapping between authentication strings such as the SLA profile string and the actual profiles for the identified IPoE sessions.

eval-ppp-session

Syntax **eval-ppp-session** [**svc-id** *service-id*] [**user-name** *user-name*] [**sap** *sap-id*] [**ip** *ip-address*] [**subscriber** *sub-ident-string*]
eval-ppp-session [**svc-id** *service-id*] [**user-name** *user-name*] [**sap** *sap-id*] **mac** *mac-address* [**session-id** *session-id*] [**ip** *ip-address*] [**subscriber** *sub-ident-string*]

Context tools>perform>subscr-mgmt

Description This command evaluates PPP sessions.

eval-slaac-host

Syntax **eval-slaac-host** [**svc-id** *service-id*] [**sap** *sap-id*] [**subscriber** *sub-ident-string*] [**ipv6-address** *ipv6-prefix*] [**mac** *ieee-address*]

Context	tools>perform>subscr-mgmt
Description	This command evaluates the SLAAC host.

remap-lease-state

Syntax	remap-lease-state old-mac <i>ieee-address</i> mac <i>ieee-address</i> remap-lease-state sap <i>sap-id</i> [mac <i>ieee-address</i>]
Context	tools>perform>subscr-mgmt
Description	This command allows the remapping of all existing hosts if network card on CMTS/WAC side is changed is required.

When this command is executed, the following restrictions apply:

- When **sap** is taken, all leases associated with the SAP are re-written.
 - For a SAP with a configured MAC in "lease-populate" command, this MAC will be taken.
 - For a SAP without a configured MAC the MAC from tools command will be taken.
 - For a SAP without a configured MAC and no MAC in tools command no action will be perform.
- When using the **old-mac** option, providing a new MAC *ieee-address* is mandatory.

This command is applicable only when dealing with DHCP lease states which were instantiated using I2header mode of DHCP operation.

Parameters	<p>old-mac <i>ieee-address</i> — Specifies the old MAC address to remap.</p> <p>mac <i>ieee-address</i> — Specifies that the provisioned MAC address will be used in the anti-spoofing entries for this SAP when I2-header is enabled. The parameter may be changed mid-session. Existing sessions will not be re-programmed unless a tools perform command is issued for the lease.</p> <p>sap <i>sap-id</i> — Specifies the physical port identifier portion of the SAP definition.</p> <p>When configured, the SAP parameter will remap all MAC addresses of DHCP lease states on the specified SAP. When no optional MAC parameter is specified, the sap sap-id command remaps all MAC addresses of lease states towards the MAC address specified in the I2-header configuration.</p>
-------------------	---

re-ident-sub

Syntax	re-ident-sub <i>old-sub-ident-string</i> to <i>new-sub-ident-string</i>
Context	tools>perform>subscr-mgmt
Description	This command renames a subscriber identification string.

Parameters *old-sub-ident-string* — Specifies the existing subscriber identification string to be renamed.
new-sub-ident-string — Specifies the new subscriber identification string name.

redundancy

Syntax **redundancy**
Context tools>dump
Description This command enables the context to dump redundancy parameters.

multi-chassis

Syntax **multi-chassis**
Context tools>dump>redundancy
Description This command enables the context to dump multi-chassis parameters.

mc-endpoint

Syntax **mc-endpoint peer** *ip-address*
Context tools>dump>redundancy>multi-chassis
Description This command dumps multi-chassis endpoint information.
Parameters **peer** *ip-address* — Specifies the peer's IP address.

force-switchover

Syntax **force-switchover tunnel-group** *local-group-id*
Context tools>dump>redundancy>multi-chassis
Description This command manually switches over mc-ipsec mastership of the specified tunnel-group.
Parameters *local-group-id* — Specifies the local tunnel-group ID configured under the **config>redundancy.multichassis>peer>mc-ipsec** context

mc-ring

Syntax	mc-ring mc-ring peer <i>ip-address</i> [ring <i>sync-tag</i>]
Context	tools>dump>redundancy>multi-chassis
Description	This command dumps multi-chassis ring information.
Parameters	peer <i>ip-address</i> — Specifies the peer's IP address. ring <i>sync-tag</i> — Specifies the ring's sync-tag created in the config>redundancy>mc>peer>mcr>ring context.

srrp-sync-database

Syntax	srrp-sync-database [instance <i>instance-id</i>] [peer <i>ip-address</i>]
Context	tools>dump>redundancy>multi-chassis
Description	This command dumps SRRP database information and only applies to the 7450 ESS and 7750 SR.
Parameters	peer <i>ip-address</i> — Specifies the peer's IP address. instance <i>instance-id</i> — Dumps information for the specified Subscriber Router Redundancy Protocol instance configured on this system. Values 1 to 4294967295

sync-database

Syntax	sync-database [peer <i>ip-address</i>] [port <i>port-id</i> <i>lag-id</i>] [sync-tag <i>sync-tag</i>] [application <i>application</i>] [detail] [type <i>type</i>]
Context	tools>dump>redundancy>multi-chassis
Description	This command dumps MCS database information.
Parameters	peer <i>ip-address</i> — Specifies the peer's IP address. port <i>port-id</i> <i>lag-id</i> — Indicates the port or LAG ID to be synchronized with the multi-chassis peer. Values <i>slot/mda/port</i> or <i>lag-lag-id</i> sync-tag <i>sync-tag</i> — Specifies a synchronization tag to be used while synchronizing this port with the multi-chassis peer.

application *application* — Specifies a particular multi-chassis peer synchronization protocol application.

Values

dhcp-server:	local dhcp server (7450 ESS and 7750 SR only)
igmp:	Internet group management protocol
igmp-snooping:	igmp-snooping
mc-ring:	multi-chassis ring
mld-snooping:	multicast listener discovery-snooping
srrp:	simple router redundancy protocol (7450 ESS and 7750 SR only)
sub-host-trk:	subscriber host tracking (7450 ESS and 7750 SR only)
sub-mgmt:	subscriber management (7450 ESS and 7750 SR only)

type *type* — Indicates the locally deleted or alarmed deleted entries in the MCS database per multi-chassis peer.

Values alarm-deleted, local-deleted

detail — Displays detailed information.

mc-ipsec

Syntax	mc-ipsec
Context	tools>perform>redundancy>multi-chassis
Description	This command enters the mc-ipsec context.

mc-endpoint

Syntax	mc-endpoint peer <i>ip-address</i>
Context	tools>dump>redundancy>multi-chassis
Description	This command dumps multi-chassis endpoint information.
Parameters	peer <i>ip-address</i> — Specifies the peer's IP address.

mc-ring

Syntax	mc-ring mc-ring peer <i>ip-address</i> [ring <i>sync-tag</i>]
Context	tools>dump>redundancy>multi-chassis

- Description** This command dumps multi-chassis ring information.
- Parameters** **peer** *ip-address* — Specifies the peer's IP address.
- ring** *sync-tag* — Specifies the ring's sync-tag created in the **config>redundancy>mc>peer>mcr>ring** context.

srrp-sync-database

- Syntax** **srrp-sync-database** [**instance** *instance-id*] [**peer** *ip-address*]
- Context** tools>dump>redundancy>multi-chassis
- Description** This command dumps SRRP database information and only applies to the 7450 ESS and 7750 SR.
- Parameters** **peer** *ip-address* — Specifies the peer's IP address.
- instance** *instance-id* — Dumps information for the specified Subscriber Router Redundancy Protocol instance configured on this system.
- Values** 1 to 4294967295

sync-database

- Syntax** **sync-database** [**peer** *ip-address*] [**port** *port-id* | *lag-id*] [**sync-tag** *sync-tag*] [**application** *application*] [**detail**] [**type** *type*]
- Context** tools>dump>redundancy>multi-chassis
- Description** This command dumps MCS database information.
- Parameters** **peer** *ip-address* — Specifies the peer's IP address.
- port** *port-id* | *lag-id* — Indicates the port or LAG ID to be synchronized with the multi-chassis peer.
- Values** *slot/mda/port* or *lag-lag-id*
- sync-tag** *sync-tag* — Specifies a synchronization tag to be used while synchronizing this port with the multi-chassis peer.
- application** *application* — Specifies a particular multi-chassis peer synchronization protocol application.
- Values**
- | | |
|----------------|---|
| dhcp-server: | local dhcp server (7450 ESS and 7750 SR only) |
| igmp: | Internet group management protocol |
| igmp-snooping: | igmp-snooping |
| mc-ring: | multi-chassis ring |
| mld-snooping: | multicast listener discovery-snooping |

srp:	simple router redundancy protocol (7450 ESS and 7750 SR only)
sub-host-trk:	subscriber host tracking (7450 ESS and 7750 SR only)
sub-mgmt:	subscriber management (7450 ESS and 7750 SR only)

type *type* — Indicates the locally deleted or alarmed deleted entries in the MCS database per multi-chassis peer.

Values alarm-deleted, local-deleted

detail — Displays detailed information.

forcerenew

Syntax	forcerenew svc-id <i>service-id</i> { ip <i>ip-address</i> [/ <i>mask</i>] mac <i>ieee-address</i> } forcerenew { interface <i>interface-name</i> sap <i>sap-id</i> sdp <i>sdp-id:vc-id</i> } [ip <i>ip-address</i> [/ <i>mask</i>] mac <i>ieee-address</i>]
Context	tools>perform>subscr-mgmt
Description	This command forces the renewal of lease state and only applies to the 7450 ESS and 7750 SR
Parameters	svc-id <i>service-id</i> — Forces renewal of the lease state for the specified service. Values 1 to 2147483647 sap <i>sap-id</i> — Forces renewal of the lease state for the specified SAP. ip <i>ip-address</i> — Forces renewal of the lease state for the specified IP address. mac <i>ieee-address</i> — Forces renewal of the lease state for the specified MAC address. interface <i>interface-name</i> — Forces renewal of the lease state for the specified interface name.

local-user-db

Syntax	local-user-db <i>local-user-db-name</i>
Context	tools>perform>subscr-mgmt
Description	This command provides tools to control the local user database.

ipoe

Syntax	ipoe
Context	tools>perform>subscr-mgmt>loc-user-db
Description	This command provides the tools to control IPoE entries in the local user database.

host-lookup

Syntax	host-lookup [mac <i>ieee-address</i>] [remote-id <i>remote-id-ascii</i>] [sap-id <i>sap-id</i>] [service-id <i>service-id</i>] [string <i>vso-string</i>] [system-id <i>system-id</i>] [option60 <i>option-60-ascii</i>] [circuit-id <i>circuit-id-ascii</i>] [circuit-id-hex <i>circuit-id-hex</i>] [option60-hex <i>option60-hex</i>] [remote-id-hex <i>remote-id-hex</i>] [derived-id <i>derived-id</i>] [ip-prefix <i>ip-prefix/ip-prefix-length</i>]
Context	tools>perform>subscr-mgmt>loc-user-db>ipoe
Description	This command performs a lookup in the local user database.

ppp

Syntax	ppp
Context	tools>perform>subscr-mgmt>loc-user-db
Description	This command provides the tools to control PPPoE entries in the local user database.

authentication

Syntax	authentication user-name <i>user-name</i> password <i>password</i> [circuit-id <i>circuit-id</i>] [circuit-id-hex <i>circuit-id-hex</i>] [derived-id <i>derived-id</i>] [mac <i>ieee-address</i>] [remote-id <i>remote-id</i>] [remote-id-hex <i>remote-id-hex</i>] [sap-id <i>sap-id</i>] [service-name <i>service-name</i>]
Context	tools>perform>subscr-mgmt>loc-user-db>ppp
Description	This command authenticates the PPPoE user name.

host-lookup

Syntax	host-lookup [circuit-id <i>circuit-id</i>] [circuit-id-hex <i>circuit-id-hex</i>] [derived-id <i>derived-id</i>] [mac <i>ieee-address</i>] [remote-id <i>remote-id</i>] [remote-id-hex <i>remote-id-hex</i>] [sap-id <i>sap-id</i>] [service-name <i>service-name</i>] [user-name <i>user-name</i>]
Context	tools>perform>subscr-mgmt>loc-user-db>ppp
Description	This command performs a lookup in the local user database.

mc-ring

Syntax	mc-ring
Context	tools>dump>redundancy>multi-chassis
Description	This command dumps multi-chassis ring data.

sync-database

Syntax	sync-database [peer <i>ip-address</i>] [port <i>port-id</i> <i>lag-id</i>] [sync-tag <i>sync-tag</i>] [application <i>application</i>] [detail] [type <i>type</i>]
Context	tools>dump>redundancy>multi-chassis
Description	This command dumps multi-chassis sync database information.
Parameters	peer <i>ip-address</i> — Dumps the specified address of the multi-chassis peer. port <i>port-id</i> — Dumps the specified port ID of the multi-chassis peer. port <i>lag-id</i> — Dumps the specified Link Aggregation Group (LAG) on this system. sync-tag <i>sync-tag</i> — Dumps the synchronization tag used while synchronizing this port with the multi-chassis peer. application — Dumps the specified application information that was synchronized with the multi-chassis peer. Values dhcps, igmp, igmp-snooping, mc-ring, srrp, sub-mgmt, mld-snooping, all detail — Displays detailed information. type <i>type</i> — Filters by the specified entry type. Values alarm-deleted, local-deleted

sync-database-reconcile

Syntax	sync-database-reconcile [peer <i>ip-address</i>] [port <i>port-id</i> <i>lag-id</i>] [sync-tag <i>sync-tag</i>] [application <i>application</i>] sync-database-reconcile [peer <i>ip-address</i>] [sdp <i>sdp-id</i>] [sync-tag <i>sync-tag</i>] [application <i>application</i>]
Context	tools>perform>redundancy>multi-chassis>mc-ipsec
Description	This command provides the paramwters to reconcile MCS database entries.

srrp-sync-data

Syntax	srrp-sync-database [instance <i>instance-id</i>] [peer <i>ip-address</i>]
Context	tools>dump>redundancy>multi-chassis
Description	This command dumps multi-chassis SRRP sync database information.
Parameters	<i>instance-id</i> — Specifies the instance ID. <div style="margin-left: 40px;">Values 1 to 4294967295</div> <i>ip-address</i> — Dumps the specified address (in the form of a.b.c.d).

route-downloader

Syntax	route-downloader start [force]
Context	tools>perform>aaa
Description	This command causes the download process to start immediately. If an ongoing download is already in progress then no further action is needed, except if the force keyword is added. In case the force keyword is added, then the current download is aborted and a new one is immediately restarted. If aborting the current download, the internal route table should not be emptied or cleared.
Parameters	start — Starts the download process immediately. force — Causes the current download to be aborted and a new one is immediately restarted.

router

Syntax	router [<i>router-instance</i>] router service-name <i>service-name</i>
Context	tools>dump
Description	This command enables the context for tools dump commands in the specified routing instance.
Parameters	<i>router-instance</i> — the router instance name (“Base” or “management”) or service ID <i>service-name</i> — the configured service name for the routing instance

ipoe-session

Syntax	ipoe-session
---------------	---------------------

Context	tools>dump>router
Description	This command enables the context for IPoE session-related tools dump commands in the specified routing instance.

migration

Syntax	migration [interface <i>ip-int-name</i>]
Context	tools>dump>router>ipoe-session
Description	This command displays details on the IPoE session migration progress. It shows per group interface the number of hosts per type (DHCPv4, DHCPv6 and SLAAC) that are associated with an IPoE session or that are not associated with an IPoE session.
Output	The following is a sample output for the <i>migration</i> command.

Sample Output

```
# tools dump router ipoe-session migration interface group-int-1-1
=====
Type                Total      IPoE session      Non IPoE session
=====
Group-interface: group-int-1-1 (IPoE session enabled)
-----
DHCPv4              2         1                 1
DHCPv6              3         2                 1
SLAAC               0         0                 0
-----
IPoE sessions       1
=====
```

9.24.2.5 Debug Commands

diameter

Syntax	[no] diameter
Context	debug>diameter
Description	This command enables debugging for diameter.

dest-realm

Syntax	dest-realm <i>realm</i> no dest-realm
Context	debug>diameter
Description	This command restricts the output to a specific destination-realm.
Parameters	<i>realm</i> — Specifies the realm up to 80 characters in length.

detail-level

Syntax	detail-level <i>level</i>
Context	debug>diameter
Description	This command configures the detail level of debug output.
Parameters	<i>level</i> — Specifies the detail level.
	Values low, medium, high

diameter-peer

Syntax	diameter-peer peer [<i>psm-events</i>] no diameter-peer
Context	debug>diameter
Description	This command restricts output to a specific peer.
Parameters	<i>psm-events</i> — Specifies to restrict output to the peer's state machine (PSM).

diameter-peer-policy

Syntax	diameter-peer-policy <i>policy</i> no diameter-peer-policy <i>policy</i>
Context	debug>diameter
Description	<p>This command restricts the debug output to messages on peers of a specific diameter peer policy. Up to eight diameter peer policies can be specified.</p> <p>The no form of the command removes the specified diameter peer policy and all debug statement under this policy from the debug configuration.</p>
Parameters	<i>policy</i> — Specifies the diameter peer policy name, up to 32 characters in length.

avp-match

Syntax	avp-match <i>id</i> no avp-match <i>id</i>
Context	debug>diameter>diameter-peer-policy
Description	<p>This command restricts the debug output to messages within the diameter peer policy that belong to a diameter session identified based on the AVP value matching in a diameter application message.</p> <p>At least the message type and one AVP match criteria must be specified in an avp-match <i>id</i> command.</p> <p>If a diameter application message matches all criteria within one AVP match ID, then the session ID is learned and all subsequent messages of that diameter session are shown until a relearning occurs. (OR function between avp-match <i>id</i> commands.)</p> <p>When the session ID is learned in an Answer message, an attempt is made to include the corresponding Request message in the debug output: The Request message should still be available in the system and must pass all debug filters (such as message-type).</p> <p>By default an avp-match <i>id</i> is disabled and must be configured with the debug>diameter>diam-peer-plcy>avp-match no shutdown to activate.</p>
Parameters	<i>id</i> — the AVP match ID, up to five per diameter peer policy
Values	1 to 5

avp

Syntax	avp <i>avp-id</i> type <i>type</i> [<i>ascii</i> <i>hex</i>] value <i>value</i> no avp <i>avp-id</i>
---------------	---

Context	debug>diameter>diameter-peer-policy>avp-match
Description	<p>This command specifies an AVP match criteria for AVP value matching. At least one and up to five AVP match criteria can be specified in an avp-match id command. When multiple AVP match criteria are specified, they must all match to be successful and result in a diameter session ID learning. (AND function between avp avp-id commands.)</p> <p>The AVP in an AVP match criteria is identified by its AVP ID. The AVP ID is specified as [<i>vendor-id</i>].<i>avp-code</i>[.<i>avp-id</i>] with nesting up to five levels deep.</p> <p>The format type of the AVP should match the standard documents in which the AVP is specified. Any AVP can be specified as an octet string in hex format.</p>
Parameters	<p><i>avp-id</i> — An AVP is specified as [<i>vendor-id</i>].<i>avp-code</i>[.<i>avp-id</i>], up to five levels deep. For example to specify the Multiple-Services-Credit-Control.Quota-Holding-Time AVP, use <i>avp-id</i> = 456.10415-871.</p> <p>Values</p> <p><i>vendor-id</i>: [1 to 4294967295] <i>avp-code</i>: [1 to 4294967295]</p> <p><i>type</i> — The format type of the AVP as octets tring, integer32, integer64, unsigned32, unsigned64 or address. The type should match the format as specified in the corresponding standard documents. Any AVP can be specified as octet string in hex.</p> <p>ascii hex — The value format. Ascii format is default. The hexadecimal format value should start with "0x". For example: 0x0000000a to specify a 4 byte integer value in hexadecimal format.</p> <p><i>value</i> — the actual value of the AVP that should be matched against (256 characters maximum; 127 characters maximum when specified in hex.)</p>

message-type

Syntax	message-type [<i>ccr</i>] [<i>cca</i>] [<i>rar</i>] [<i>raa</i>] [<i>asr</i>] [<i>asa</i>] [<i>aar</i>] [<i>aaa</i>] message-type all no message-type
Context	debug>diameter>diameter-peer-policy>avp-match
Description	<p>This command specifies the message type match criteria for AVP value matching. Only specified diameter application messages are used for AVP value matching. This is a mandatory criteria in an avp-match id command.</p> <p>This command does not restrict the debug output to the specified messages.</p>
Parameters	<p>ccr — credit control request</p> <p>cca — credit control answer</p> <p>rar — re-authentication request</p> <p>raa — re-authentication answer</p>

- asr** — abort session request
- asa** — abort session answer
- aar** — aa request
- aaa** — aa answer
- all** — all message types

shutdown

Syntax	[no] shutdown
Context	debug>diameter>diameter-peer-policy>avp-match
Description	<p>Enables or disables the avp-match <i>id</i> criteria for filtering debug output based on AVP value matching.</p> <p>A shutdown of the avp-match <i>id</i> will clear the learned diameter session ID.</p>

diameter-peer

Syntax	diameter-peer <i>peer</i> [psm-events] no diameter-peer
Context	debug>diameter>diameter-peer-policy
Description	<p>This command restricts the debug output to messages on a specific peer within the diameter peer policy. Overrides the debug>diameter>diameter-peer debug command for the specified diameter peer policy. A single peer can be specified per diameter peer policy.</p> <p>When no peer is specified at the diameter peer policy level, the debug output is restricted to the peer configured at the debug>diameter level.</p> <p>The no form of the command removes the peer from the debug>diameter>diameter-peer-policy debug output.</p>
Parameters	<p><i>peer</i> — the peer name, up to 32 characters in length</p> <p>psm-events — specifies to include Peer State Machine (PSM) events in the debug output</p>

message-type

Syntax	message-type [ccr] [cca] [cer] [cea] [dwr] [dwa] [dpr] [dpa] [rar] [raa] [asr] [asa] [aar] [aaa] message-type all no message-type
---------------	--

Context	debug>diameter>diameter-peer-policy debug>diameter
Description	<p>This command restricts the debug output to the specified message types.</p> <p>When specified within a diameter peer policy, it overrides the message type configuration at the debug>diameter level for messages received and sent on that diameter peer policy.</p> <p>The no form of the command removes the message type from the debug configuration.</p>
Parameters	<p>ccr — credit control request</p> <p>cca — credit control answer</p> <p>cer — capabilities exchange request</p> <p>cea — capabilities exchange answer</p> <p>dwr — device watchdog request</p> <p>dwa — device watchdog answer</p> <p>dpr — disconnect peer request</p> <p>dpa — disconnect peer answer</p> <p>rar — re-authentication request</p> <p>raa — re-authentication answer</p> <p>asr — abort session request</p> <p>asa — abort session answer</p> <p>aar — aa request</p> <p>aaa — aa answer</p> <p>all — all message types</p>

origin-realm

Syntax	origin-realm <i>realm</i> no origin-realm
Context	debug>diameter
Description	This command restricts output to a specific origin-realm.

arp-host

Syntax	[no] arp-host
Context	debug>service>id

Description This command enables and configures ARP host debugging.
The no form of the command disables ARP host debugging.

one-time-http-redirection

Syntax **one-time-http-redirection**

Context debug>service>id

Description This command produces one-time http redirection debug output.

ppp

Syntax [no] ppp

Context debug>service>id>

Description This command enables the PPP debug context.
event

event

Syntax [no] event

Context debug>service>id>ppp

Description This command enables the PPP event debug context.

dhcp-client

Syntax **dhcp-client [terminate-only]**
no dhcp-client

Context debug>service>id>ppp>event

Description This command enable PPP event debug for DHCP client.

Parameters **terminate-only** — Enables debug for local terminated PPP session

l2tp

Syntax **l2tp [terminate-only]**

no l2tp

Context	debug>service>id>ppp>event
Description	This command enables PPP L2TP event debug.
Parameters	terminate-only — Enables debug for local terminated PPP session.

local-address-assignment

Syntax	local-address-assignment [terminate-only] no local-address-assignment
Context	debug>service>id>ppp>event
Description	This command enables debugging for local-address-assignment events. The no form of the command disables debugging.
Parameters	terminate-only — Enables debugging for local address assignment.

ppp

Syntax	ppp [terminate-only] no ppp
Context	debug>service>id>ppp>event
Description	This command enables PPP event debug. The no form of the command disables debugging.
Parameters	terminate-only — Enables debugging for local terminated PPP session.

mac

Syntax	[no] mac <i>ieee-address</i>
Context	debug>service>id>ppp
Description	This command displays PPP packets for a particular MAC address. The no form of the command disables debugging.

msap

Syntax	[no] msap <i>msap-id</i>
Context	debug>service>id>ppp
Description	This command enables debugging for specific PPP MSAPs. The no form of the command disables debugging.

packet

Syntax	[no] packet
Context	debug>service>id>ppp
Description	This command enables the PPP packet debug context. The no form of the command disables debugging.

detail-level

Syntax	detail-level { low medium high } no detail-level
Context	debug>service>id>ppp>packet
Description	This command specify the detail level of PPP packet debug output. The no form of the command disables debugging.

dhcp-client

Syntax	[no] dhcp-client
Context	debug>service>id>ppp>packet
Description	This command enables packet debug output for DHCP client of the PPP session The no form of the command disables debugging.

discovery

Syntax	discovery [padi] [pado] [padr] [pads] [padt] no discovery
---------------	---

Context	debug>service>id>ppp>packet
Description	This command enables PPP discovery packet debug output. The no form of the command disables debugging.
Parameters	[padi] [pado] [padr] [pads] [padt] — Enables the corresponding type of PPP discovery packet.

mode

Syntax	mode {dropped-only ingr-and-dropped egr-ingr-and-dropped} no mode
Context	debug>service>id>ppp>packet
Description	This command specifies PPP packet debug mode. The no form of the command disables debugging.
Parameters	dropped-only — Only displays dropped packets. ingr-and-dropped — Only displays ingress packet and dropped packets. egr-ingr-and-dropped — Displays ingress, egress and dropped packets.

ppp

Syntax	ppp [lcp] [pap] [chap] [ipcp] [ipv6cp] no ppp
Context	debug>service>id>ppp>packet
Description	This command enables PPP discovery packet debug output for the specified PPP protocol. The no form of the command disables debugging.
Parameters	[lcp] [pap] [chap] [ipcp] [ipv6cp] — Enables debug for the specified protocol.

remote-id

Syntax	[no] remote-id remote-id
Context	debug>service>id>ppp
Description	This command enables debugging for specific PPP remote-ids. The no form of the command disables debugging.

sap

Syntax	[no] sap <i>sap-id</i>
Context	debug>service>id>ppp
Description	<p>This command enables PPP debug output for the specified SAP, this command allow multiple instances.</p> <p>The no form of the command disables debugging.</p>
Parameters	<i>sap-id</i> — Specifies the SAP ID.

username

Syntax	[no] username <i>username</i>
Context	debug>service>id>ppp
Description	<p>This command enable PPP debug for the specified username. since not all PPP packets contain username, so a mac debug filter will be created automatically when system sees a PPP packet contain the specified username.</p> <p>Multiple username filters can be specified in the same debug command.</p> <p>The no form of the command disables debugging.</p>
Parameters	<i>user-name</i> — Specifies the ppp username.

circuit-id

Syntax	[no] circuit-id <i>circuit-id</i>
Context	debug>service>id>ppp
Description	<p>This command enable PPP debug for the specified circuit-id.</p> <p>Multiple circuit-id filters can be specified in the same debug command.</p> <p>The no form of the command disables debugging.</p>
Parameters	<i>circuit-id</i> — Specifies the circuit-id in PADI.

remote-id

Syntax	[no] remote-id <i>remote-id</i>
Context	debug>service>id>ppp

Description	This command enable PPP debug for the specified remote-id. Multiple remote-id filters could be specified in the same debug command.
Parameters	<i>remote-id</i> — Specifies the remote-id in PADI.

msap

Syntax	[no] msap <i>msap-id</i>
Context	debug>service>id>ppp
Description	This command enable PPP debug for the specified managed SAP. Multiple msap filters could be specified in the same debug command.
Parameters	<i>msap-id</i> — Specifies the managed SAP ID.

authentication

Syntax	authentication [policy <i>policy-name</i>] [mac-addr <i>ieee-address</i>] [circuit-id <i>circuit-id</i>]
Context	debug>subscr-mgmt
Description	This command debugs subscriber authentication.
Parameters	policy <i>policy-name</i> — Specify an existing subscriber management authentication policy name. mac-addr <i>ieee-address</i> — Specifies the 48-bit MAC address xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx. circuit-id <i>circuit-id</i> — Specify the circuit-id, up to 256 characters.

sub-ident-policy

Syntax	[no] sub-ident-policy <i>policy-name</i>
Context	debug>subscr-mgmt
Description	This command debugs subscriber identification policies.
Parameters	<i>policy-name</i> — Specifies the subscriber identification policy to debug.

script-compile-error

Syntax	[no] script-compile-error
---------------	----------------------------------

Context	debug>subscr-mgmt>sub-ident-plcy
Description	This command send the traceback of the compile error to the logger. The traceback contains detailed information about where and why the compilation fails. The compilation takes place when the CLI user changes the admin state of the Python URL from shutdown to no-shutdown.

script-export-variables

Syntax	[no] script-export-variables
Context	debug>subscr-mgmt>sub-ident-plcy
Description	This command sends the result (the three output variables) of the Python script to the logger when the script ran successfully.

script-output

Syntax	[no] script-output
Context	debug>subscr-mgmt>sub-ident-plcy
Description	This command sends the output (such as from 'print' statements) of the Python script to the logger.

script-output-on-error

Syntax	[no] script-output-on-error
Context	debug>subscr-mgmt>sub-ident-plcy
Description	This command sends the output (such as from 'print' statements) of the Python script to the logger, but only when the script fails.

script-runtime-error

Syntax	[no] script-runtime-error
Context	debug>subscr-mgmt>sub-ident-plcy
Description	This command sends the traceback of the Python script failure to the logger.

script-all-info

Syntax	script-all-info
Context	debug>subscr-mgmt>sub-ident-plcy
Description	This command enables the script-compile-error, script-export-variables, script-output, script-output-on-error, and script-runtime-error functionalities.

srrp

Syntax	[no] srrp
Context	debug>router
Description	This command enables debugging for SRRP packets. The no form of the command disables debugging.

events

Syntax	[no] events [interface <i>ip-int-name</i>]
Context	debug>router>srrp
Description	This command enables debugging for SRRP packets. The no form of the command disables debugging.

packets

Syntax	[no] packets [interface <i>ip-int-name</i>]
Context	debug>router>srrp
Description	This command enables debugging for SRRP packets. The no form of the command disables debugging.

radius

Syntax	[no] radius
Context	debug>router
Description	This command enables the debug router RADIUS context.

detail-level

Syntax	detail-level {low medium high} no detail-level
Context	debug>router>radius
Description	This command specifies the output detail level of command debug router radius .
Default	medium
Parameters	low — Output includes packet type, server address, length, radius-server-policy name medium — All output in low level plus RADIUS attributes in the packet high — All output in medium level plus hex packet dump

packet-type

Syntax	packet-type [authentication] [accounting] [coa] no packet-type
Context	debug>router>radius
Description	This command specifies the RADIUS packet type filter of command debug router radius
Default	authentication accounting coa
Parameters	authentication — RADIUS authentication packet. accounting — RADIUS accounting packet. coa — RADIUS change of authorization packet.

radius-attr

Syntax	radius-attr type attribute-type [extended-type attribute-ext-type] [transaction] radius-attr type attribute-type [transaction] {address hex integer string} value <i>attribute-value</i> radius-attr vendor vendor-id type attribute-type [extended-type attribute-ext-type] [transaction] [encoding encoding-type] radius-attr vendor vendor-id type attribute-type [extended-type attribute-ext-type] [transaction] [encoding encoding-type] {address hex integer string} value attribute- <i>value</i> no radius-attr type attribute-type [extended-type attribute-ext-type] no radius-attr type attribute-type [extended-type attribute-ext-type] {address hex integer string} value attribute-value no radius-attr vendor vendor-id type attribute-type [extended-type attribute-ext-type] no radius-attr vendor vendor-id type attribute-type [extended-type attribute-ext-type] {address hex integer string} [0..16777215] attribute-value
---------------	--

Context	debug>router>radius																						
Description	This command specifies the RADIUS attribute filter of command debug router radius .																						
Default	n/a																						
Parameters	<p>type <i>attribute-type</i> — specifies the RADIUS attribute type</p> <p>Values 1 to 255</p> <p>extended-type <i>attribute-ext-type</i> — specifies the RADIUS attribute extended type (RFC6929)</p> <p>Values 1 to 255</p> <p>address — specifies the value is a IPv4 or IPv6 address/prefix/subnet</p> <p>string — specifies the value is a ASCII string</p> <p>integer — specifies the value is a integer</p> <p>hex — specifies the value is a binary string in hex format, e.g: “\0xAB01FE”</p> <p>value <i>attribute-value</i> — specifies the value of the RADIUS attribute</p> <p>Values</p> <table><tr><td>address</td><td><ipv4-address> <ipv6-address> <ipv6-prefix/prefix-length></td></tr><tr><td>ipv4-address</td><td>a.b.c.d</td></tr><tr><td>ipv6-address</td><td>x:x:x:x:x:x:x (eight 16-bit pieces)</td></tr><tr><td>ipv6-prefix</td><td>x:x:x:x:x:x:x (eight 16-bit pieces)</td></tr><tr><td></td><td>x:x:x:x:x:d.d.d.d</td></tr><tr><td></td><td>x - [0 to FFFF]H</td></tr><tr><td></td><td>d - [0 to 255]D</td></tr><tr><td>ipv6-prefix-length</td><td>[0 to 128]</td></tr><tr><td>hex</td><td>[0x0 to 0xFFFFFFFF (max 506 hex nibbles)]</td></tr><tr><td>integer</td><td>[0 to 4294967295]</td></tr><tr><td>string</td><td>ascii-string (max 253 chars)</td></tr></table> <p>transaction — With this parameter, the system will output both request and response packets in the same session even if the response packet doesn't include the filter attribute.</p> <p>vendor <i>vendor-id</i> — specifies the vendor id for the vendor specific attribute</p> <p>Values 0 to 16777215</p> <p>encoding <i>encoding-type</i> — specifies the size of the vendor-type and vendor-length in bytes. It is a two digitals string: “xy”, x is the size of vendor-type, range from 1 to 4; y is the size of vendor-length, range from 0 to 2; it is “11” by default.</p> <p>Values type-size:1 to 4, length-size: 0 to 2</p>	address	<ipv4-address> <ipv6-address> <ipv6-prefix/prefix-length>	ipv4-address	a.b.c.d	ipv6-address	x:x:x:x:x:x:x (eight 16-bit pieces)	ipv6-prefix	x:x:x:x:x:x:x (eight 16-bit pieces)		x:x:x:x:x:d.d.d.d		x - [0 to FFFF]H		d - [0 to 255]D	ipv6-prefix-length	[0 to 128]	hex	[0x0 to 0xFFFFFFFF (max 506 hex nibbles)]	integer	[0 to 4294967295]	string	ascii-string (max 253 chars)
address	<ipv4-address> <ipv6-address> <ipv6-prefix/prefix-length>																						
ipv4-address	a.b.c.d																						
ipv6-address	x:x:x:x:x:x:x (eight 16-bit pieces)																						
ipv6-prefix	x:x:x:x:x:x:x (eight 16-bit pieces)																						
	x:x:x:x:x:d.d.d.d																						
	x - [0 to FFFF]H																						
	d - [0 to 255]D																						
ipv6-prefix-length	[0 to 128]																						
hex	[0x0 to 0xFFFFFFFF (max 506 hex nibbles)]																						
integer	[0 to 4294967295]																						
string	ascii-string (max 253 chars)																						

wpp

Syntax	[no] wpp
Context	debug>router
Description	This command enables the context to configure WPP debugging parameters.

packet

Syntax	[no] packet
Context	debug>router>wpp debug>router>wpp>portal
Description	This command enables WPP packet debugging.

detail-level

Syntax	detail-level <i>detail-level</i>
Context	debug>router>wpp debug>router>wpp>packet debug>router>wpp>portal>packet
Description	This command specifies the detail level of WPP packet debugging.
Parameters	<i>detail-level</i> — specifies the detail level of WPP packet debugging Values high — Specifies a high detail level for WPP packet debugging. low — Specifies a low detail for WPP packet debugging.

portal

Syntax	[no] portal <i>wpp-portal-name</i>
Context	debug>router>wpp
Description	This command enables WPP debugging for the specified WPP portal.
Parameters	<i>wpp-portal-name</i> — Specifies the WPP portal name.

9.24.2.6 Monitor Commands

subscriber

Syntax	subscriber <i>sub-ident-string</i> sap <i>sap-id</i> sla-profile <i>sla-profile-name</i> [base ingress-queue-id <i>ingress-queue-id</i> egress-queue-id <i>egress-queue-id</i>] [interval <i>seconds</i>] [repeat <i>repeat</i>] [absolute rate]
Context	monitor>service
Description	This command monitors statistics for a subscriber.
Parameters	sub-ident-string — Specifies an existing subscriber identification profile to monitor. sap <i>sap-id</i> — Specifies the physical port identifier portion of the SAP definition. sla-profile <i>sla-profile-name</i> — Specifies an existing SLA profile. interval <i>seconds</i> — Configures the interval for each display in seconds. Default 11 Values 11 to 60 repeat <i>repeat</i> — Configures how many times the command is repeated. Default 10 Values 1 to 999 absolute — When the absolute keyword is specified, the raw statistics are displayed, without processing. No calculations are performed on the delta or rate statistics. Default mode delta rate — When the rate keyword is specified, the rate-per-second for each statistic is displayed instead of the delta. base — Monitor base statistics. ingress-queue-id <i>ingress-queue-id</i> — Monitors statistics for this queue. Values 1 to 32 egress-queue-id <i>egress-queue-id</i> — Monitors statistics for this queue. Values 1 to 8

Context show>service>id

Description	This command displays static host information configured on this service.		
Parameters	sap	<i>sap-id</i>	Displays SAP information for the specified SAP ID.
		<i>intermediate-destination-id</i>	Specifies the intermediate destination identifier which is encoded in the identification strings.
	Values	Up to 32 characters maximum	
	summary	Displays summary host information.	
	wholesaler	<i>service-id</i>	The VPRN service ID of the wholesaler. When specified in this context, SAP, SDP, interface, IP address and MAC parameters are ignored. This parameter applies only to the 7750 SR.
	Values	<i>service-id:</i>	1 to 2147483647
		<i>svc-name:</i>	64 characters maximum

10 Oversubscribed Multi-Chassis Redundancy (OMCR) in ESM

10.1 In This Section

This section describes features and functionality for the Oversubscribed Multi-Chassis Redundancy (OMCR) model.

Topics in this section include:

- [Overview](#)
- [Deploying Oversubscribed Multi-Chassis Redundancy](#)
- [OMCR Command Reference](#)

10.2 Overview

10.2.1 Terminology and Abbreviations

- **OMCR** — Oversubscribed Multi-Chassis Redundancy
- **Warm-Standby Node** or **Protecting Node** — Refers to the oversubscribed node that offers the protection of subscriber hosts spread over multiple BNGs. During the normal operation, the protecting node maintains the subscriber host in the form of an MCS record (Multi-Chassis Synchronization Record) in the control plane. Only when the failure occurs and the protecting node becomes active, are the subscriber-hosts fully instantiated in the data and control plane. This node is sometimes referred to as N:1 node.
- **Active/Active (1:1) Model** — This mode of operation refers to the model where subscribers host are fully synchronized between two chassis, regardless of the state of the underlying SRRP instance (Master/Standby). Each node can have MCS peering sessions with four another nodes where each peering session represent 1 to 1 mapping set of active subscriber hosts.

10.2.2 Restrictions

- The protecting node must use CPM-4 or higher (other protected nodes can continue to use CPM-3).
- The protecting node must use FP2 based cards or higher with chassis mode D.
- The protecting node functionality is not supported in mixed-mode in 7450 ESS chassis.
- All nodes in the OMCR cluster (central standby and the protected nodes) must run at the minimum SR OS R12.0R1.
- Warm-standby mode is a chassis-wide property. In other words, while in warm-standby mode, the chassis cannot operate in 1:1 (active-active) redundancy mode.
- OMCR is supported only for IPoEv4/v6 subscribers. However, non-synchronized PPPoEv4/v6 subscribers are supported in the OMCR cluster. PPPoEv4/v6 PTA (locally terminated) non-synchronized subscribers and the OMCR synchronized IPoE subscriber must be instantiated under separate group-interfaces. On the other hand, non-synchronized PPPoEv4/v6 LAC sessions are allowed to be under the same group interface as the OMCR synchronized IPoE subscribers. Non-synchronized PPPoEv4/v6 subscriber hosts will rely on ppp-keepalive timeouts to re-establish connectivity when the failure occurs.
- Pre-emption of already instantiated subscriber hosts in the protecting node by another subscriber hosts is not allowed.
- Redundant interface (shunting) is not supported for subscribers on the protecting node while they are not fully instantiated in the control/data plane (or while the underlying SRRP instance is in a non-Master state on the protecting node).
- Persistency in multi-chassis environment **must** be disabled since redundant nodes are protecting each other and they maintain up-to-date lease states.
- The failover trigger is based on SRRP only (no MC-LAG support).
- Unnumbered subscriber-interface model is not supported in OMCR.
- The protecting node supports 10 MCS peers, while the protected node (in active/active mode of operation) supports 4 MCS peers.
- Synchronization of the following MCS clients is not supported:
 - Host tracking
 - MC ring
 - Layer 2 subscriber hosts
 - Layer 3 IGMP/MLD
 - Layer 2 IGMP/MLD

- DHCP Server
- PPPoE Clients
- MC-LAG
- MC-IPSEC
- MC-ENDPOINT

10.3 Deploying Oversubscribed Multi-Chassis Redundancy

In order to optimize the cost, certain operators prefer oversubscribed model in which a single central standby BNG (protecting BNG) supports multiple other BNGs in a semi-stateful fashion.

In Oversubscribed Multi-Chassis Redundancy (OMCR) model, a large number of subscriber-hosts are backed up by a single central standby node. Standby subscriber-hosts within the protecting node are synchronized only within the control plane (CPM) in the form of a Multi-Chassis Synchronization (MCS) record. Such subscriber hosts are not instantiated in the data plane and therefore the data plane resources can be spared and used only on an **as needed** basis. This trait allows the protecting node to back up a large number of subscribers that are scattered over multiple active BNG nodes at the expense of slower convergence.

Only a subset of the subscribers, up to the available resource capacity of the data plane in the protecting node, would be activated on the protecting node at any given time during the failure.

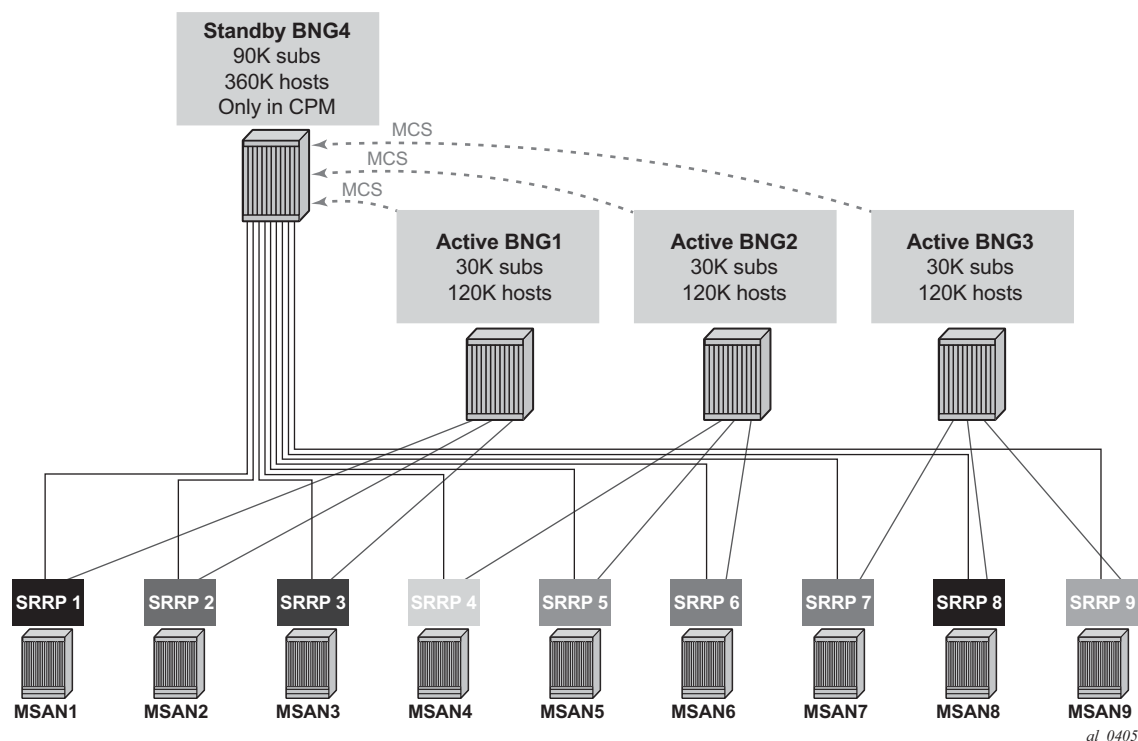

The failover trigger is based on SRRP (no MC-LAG support). The subscriber hosts under the corresponding group-interface will be switched over once the SRRP instance on the protecting node transitions into the Master SRRP state.

There are two possible models for this deployment:

1. Access nodes are directly connected to the BNGs. From the perspective of standby subscribers, in this model the line card is oversubscribed but the physical ports on it are not. For example each of the 10 physical ports on the same line card can be directly connected to respective access nodes. Assume that each physical port can support 64K subscriber hosts. Considering that the subscriber host limit per line card is also 64K (at the time of this writing), the oversubscription ratio in this case would be 10:1.

The concept of this deployment scenario is shown in [Figure 162](#).

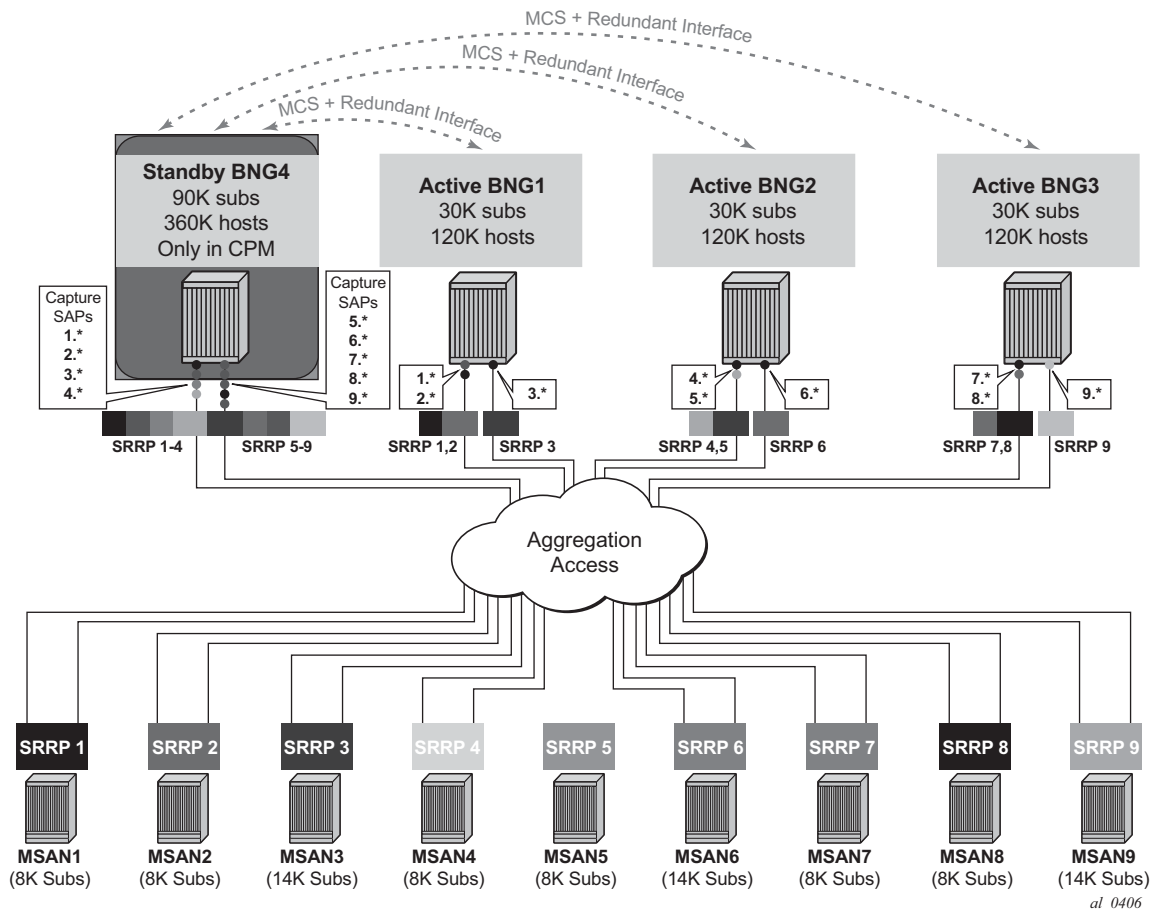

Figure 162 OMCR Scenario Without Aggregation Network

2. Aggregation network in the access (double VLAN tags). In this case a line card and a physical port can be oversubscribed with standby subscribers. For example multiple capture-saps (each capture sap containing 4K c-vlans) can be created on a single physical port on the protecting BNG, for the total of >>64K subscribers per physical port.

Conceptual model for this scenario is shown in [Figure 163](#) (although the number of SRRP instances and capture-saps is in this figure is reduced for simplification).

Figure 163 OMCR Scenario with Aggregation Network

In both cases, a maximum of 64K subscribers per line card can be activated on the protecting BNG during the switchover. This is something that the operator should plan around, and consequently group the access nodes in a way so that the eventual number of active subscribers per line card on the protecting node does not exceed the maximum number of supported subscribers per line card.

Note: One could have deployment scenario in which system wide ESM capacity is oversubscribed but the line card capacity is not. For example, on chassis with 10 line cards, each line card can be reserved to protect a total host count of 64k. This would yield a total of 640k protected hosts distributed across the 10 cards but only up to 256k hosts could be activated simultaneously should it be required due to SRRP transitions to Master.

10.3.1 Resource Exhaustion Notification and Simultaneous Failures

The protection success of the OMCR model relies on grouping protected entities (links and nodes) according to the likelihood of their failure within the timeframe required for their restoration. For example the same resource (IOM card or port) on the protecting node can be used to protect multiple entities in the network as long as their failures do not overlap in time. In other words, if one failure can be repaired before the next one contending for the same resource on the central standby node, the OMCR model will serve the purpose.

But since the oversubscribed model does not offer any guarantees, it is possible that the protecting node in certain cases runs out of resources and fails to offer protection. In this case, the protecting node will generate a SNMP trap identifying the SRRP instance on which subscriber protection has failed. One SNMP trap will be raised per SRRP instance in case where at least one subscriber under the corresponding group interface was not instantiated. The trap will be cleared either when all subscribers become instantiated or when the SRRP transition into a non-master state.

The number of the subscriber hosts that failed to instantiate, can also be determined via the operational **show redundancy multi-chassis omcr all** command. This command will show the number of subscribers that failed to instantiate along with SRRP instances on which the subscriber host are relaying for successful connectivity.

Pre-emption of already instantiated subscriber hosts in the protecting node by another subscriber hosts is not allowed.

10.3.2 Resource Monitoring

Management and conservation of resources is of utmost importance in OMCR. The resources consumed by the subscriber host depend on the type and the size of subscriber parameters (the number of strings, length of strings, etc.).

For these reasons it is crucial that the operator has a view of the amount of memory in the CPM utilized by subscribers and the amount of free memory that can be used for additional subscribers. The **MCS** line is of particular interest in this output. In addition, the **Subscriber Mgmt** line shows memory utilization for active subscribers in the CPM.

The **Available Memory** gives an indication about how much memory remains.

For example:

```
*A:right-21# show system memory-pools

10.3.3 Warm-Standby Mode Of Operation

The protecting node operates in a warm-standby mode. Warm-standby mode of operation is a property of the entire node. In other words, while in the central-standby mode of operation (warm-standby command), only subscribers under the SRRP instances that are in the Master state will be fully instantiated in the data plane on the central standby node (protecting node). All other subscribers (under the SRRP

instances that are in the standby state) will be synchronized only in the control plane. However, non-central standby nodes can have a peering connection with a protecting node (OMCR) and at the same time another peering connection with another active BNG node in active/active model. All nodes participating in the OMCR mode of operation must run SROS 12.0 or higher. This model is shown in [Figure 164](#).

Figure 164 Network Wide Mixing of OMCR and Active/Active (1:1) Model

The central backup property is configured with the following CLI:

```
configure
  redundancy
    multi-chassis
      peer 1.1.1.1
      warm-standby
```

The **warm-standby** keyword configures the chassis to be in the central standby mode of operation. Although the configuration option is configured per peer, the **warm-standby** functionality is applied per chassis.

Synchronization of IPoE subscribers (**config>redundancy>multi-chassis>peer>sync>sub-mgmt ipoe**) on the protecting node is only possible if all peers are configured for **warm-standby** or none are.

To transition from one mode to another (warm <--> hot), all peers must be administratively shutdown and the warm-standby keyword must be either removed or configured on all peers, depending on the direction of the transition.

Single-homed subscribers are supported in the central standby node, subject to resource limitations.

10.3.4 IPoE vs PPPoE

OMCR is supported only for IPoEv4/v6 subscribers. PPPoEv4/v6 subscriber hosts are not supported. However, non-synchronized PPPoE hosts can be hosted on the protecting node simultaneously with the protected IPoE subscribers. PPPoE PTA (locally terminated) non-synchronized subscribers and OMCR synchronized IPoE subscriber must not be configured under the same group-interfaces. On the other hand, non-synchronized PPPoE LAC sessions are allowed to be under the same group interface as the OMCR synchronized IPoE subscribers.

The recovery of PPPoE subscriber host in non-synchronized environment is based on the timeout of ppp-keepalives.

10.3.5 Persistency

Persistency in the multi-chassis environment **must** be disabled since redundant nodes are protecting each other and they maintain up-to-date lease states. Otherwise, race conditions resulting in stale lease states caused by contention between MCS data and persistency data may occur.

10.3.6 Routing and Redundant Interface in OMCR

Support for redundant interface is limited and can be used only in cases where subscribers are activated in the protecting node. In other words, the shunting over the redundant interface cannot be used if subscriber hosts are not fully instantiated (in the data and control plane). For this reason, downstream traffic must not be attracted (via routing) to the protecting node while the subscriber hosts are in the standby mode (SRRP is in a backup state).

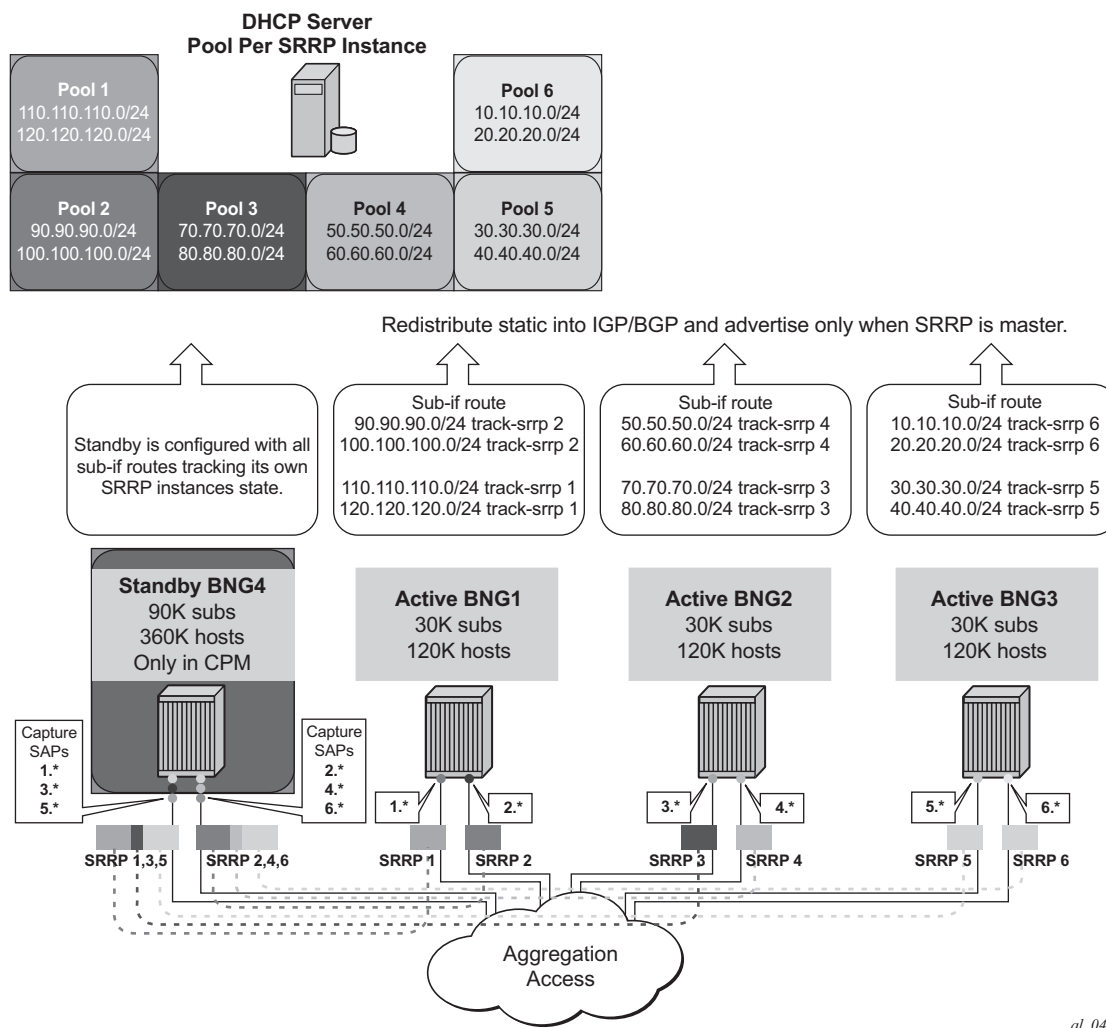

During the transient period while the switchover is in progress, subscriber hosts are being instantiated or withdrawn (depending on the direction of the switchover) in the data plane on the protecting node. The duration of this process is dependent on the number of the hosts that needs to be instantiated/withdrawn and it is proportional to the regular host setup/tear-down rates. The redundant interface in this case can be used only for the hosts that are present in the data plane during the switchover transitioning period (from the moment that they are instantiated in the dataplane when protecting node is assuming activity, or up the moment when they are withdrawn from the data plane when the protecting node is relinquishing activity).

The following routing models are supported:

Case 1 — SRRP-Aware routing where subnets can be assigned per group-interfaces (SRRP instances). In a steady state, the redundant interface is not needed since the downstream traffic is attracted to the master node. During switchover periods (routing convergence transitioning periods), redundant interface can be used only for the subscriber hosts that are instantiated in the data plane (from the moment that they are instantiated in the dataplane when protecting node is assuming activity, or up the moment when they are withdrawn from the data plane when the protecting node is relinquishing activity). See [Figure 165](#).

Case 2 — SRRP-Aware routing where subnets spawn (are aggregated) over multiple group-interfaces (SRRP instances). In case of a switchover, /32 IPv4 addresses and /64 IPv6 addresses/prefixes are advertised from the protecting node. In a steady state, the redundant interface is not needed since the downstream traffic is attracted via more specific routes (/32s and /64s) to the master node. During switchover periods (routing convergence transitioning periods), the redundant interface can be used only for the subscriber-hosts that are instantiated in the data plane (from the moment that they are instantiated in the dataplane when protecting node is assuming activity, or up the moment when they are withdrawn from the data plane when the protecting node is relinquishing activity). To reduce the number of routes on the network side, /32s and /64s should only be activated on the protecting node.

Figure 165 Subnet per Group Interface

A deployment case that is not supported is the one where subnets spawn (are aggregated) over multiple group-interfaces (SRRP instances) and at the same time /32s are not allowed to be advertised from the protecting node. This scenario would require redundant interface support while subscriber-hosts are not necessarily instantiated in the protecting node.

10.3.7 Revertive Behavior

In case that failure is repaired on the original active node (non-central standby node) while SRRP preemption (**preempt**) is configured, the corresponding active subscribers on the protecting node will be withdrawn from the data plane and the activity (mastership) will be switched to the original node.

This behavior will ensure that the resources in the central backup are freed upon failure restoration and are available for protection of other entities in the network (other links/nodes).

In the preemption case, the upstream traffic is steered towards the newly active BNG via gratuitous ARP (GARP). In other words, the virtual MAC is advertised from the newly active node, and consequently the access and aggregation nodes will update their Layer 2 forwarding entries. This action should cause NO interruption in the upstream traffic.

In the downstream direction, the service interruption is equivalent to the time it takes to withdraw the routes from the network side on the standby node. In this case, there are two scenarios:

- A route per group interface (SRRP) is advertised in the network from the central standby node. In this case, downstream traffic interruption is a function of the convergence time of the routing protocol deployed on the network side. Once the routing is converged, all downstream subscriber traffic will be attracted to the newly active node. In the meantime, the redundant interface can be used to shunt traffic from the central standby node to the newly master, but only for the subscriber hosts that have not yet been withdrawn from the data plane on the protecting node. This withdrawal process may take some time and therefore downstream traffic for some subscriber hosts is restored before the others during the routing convergence period.
- /32 subscriber-host routes are advertised from the protecting node. The total recovery time for downstream traffic will depend on the routing convergence. The routing convergence might be slower than in the previous case since more routes (/32s) need to be withdrawn from the network. The redundant interface can be used in the meantime for the subscriber hosts that have not yet been withdrawn from the data plane in protecting node.

10.3.8 Service Restoration Times

Service restoration times depends on the scale of the outage. The factors that affect the restoration times are:

- Failure detection time based on SRRP (could be in a sub second range, also supported based on BFD).
- Time needed to instantiate/withdraw subscriber host in/from the data plane.
- Routing convergence (based on SRRP aware routing).

10.3.9 Processing of the SRRP Flaps

When multiple srrp instances fail at the same time, they will be processed one at the time on first come first serve basis. The subscriber instantiation processing during the switchover is divided into 1seconds intervals. In-between those intervals, the state of the SRRP are checked to ensure that it has not changed while the subscriber instantiation is in progress. This mechanism will break the inertia (snowball effect) that can be caused by SRRP instance flaps. Furthermore, an SRRP flap is handled by not requesting a withdrawal followed by an instantiation request for the same SRRP instance.

10.3.10 Accounting

The OMCR accounting follows the active/active (1:1) redundancy model.

One difference in accounting behavior between the OMCR model and 1:1 redundancy model is in the processing of the accounting session-time attribute which on the protecting node denotes the time when the host was instantiated on the protecting node.

In contrast, the session-time attribute in 1:1 redundancy model is recorded almost simultaneously on both BNG nodes at the time when the host is originally instantiated.

As a result, the session-time attribute is for the most part uninterrupted during the switchover in 1:1 model whereas in OMCR model, the session-time attribute will be reset on the switchover to the protecting node.

10.3.11 Configuration Guidelines

- For all protected SRRP instances, the protected node should be the **preferred Master**. To achieve this, the SRRP priority should be higher in the protected node than in the protecting node. SRRP preemption is recommended in the protecting node to force it to become Master when possible.

Note: An SRRP switch from nonMaster to Master in the protected node does not suffer the slow convergence observed when the nonMaster -> Master transition takes place in the protecting node. This is because the protected node always has the hosts instantiated in the data plane.

- ARP hosts configuration is strongly discouraged in protected group interfaces, unless the operator is ready to tolerate an incomplete redundancy mechanism for these hosts.
- SRRP tracking is strongly recommended to expedite the routing convergence upon an SRRP transition from non-Master to Master in the protecting node.
- It is recommended to have a 1:1 relationship between SRRP and subscriber subnets in order to have smooth routing advertisements based on SRRP state tracking.
- The use of M-SAPs should be preferred over the use of static SAPs. Static SAPs are supported in the OMCR mode but they are consuming resources in the protecting node even when the underlying SRRP instance is in a non-Master state.
- It is recommended that the capture-sap configuration include the **track-srrp** statement (at least for the protecting node). With this configuration the CPM will not process trigger packets when the leases cannot be created because the SRRP is not in the Master state. Configuring SRRP tracking at the capture-sap will offload the CPM from performing false authentication and MSAP creation attempts.
- Load balancing between Master and non-Master via export policies for SRRP must not be configured as the hosts are not instantiated in the protecting node when the corresponding SRRP state is non-Master.
- In order to minimize traffic impact in the event of node reboot, it is recommended to use **delayed-enable seconds** command under the subscriber-interface and allow enough time for the MCS database to reconcile. This is particularly important in the protected node. If the SRRP becomes master in the protected node before the database has been reconciled, the protecting node will remove the leases (non-Master state) which have not been synchronized. This would create partial outage.

- In order to avoid SRRP collisions, lack of resources and partial subscriber host instantiation, the use of fate-sharing-groups is not recommended. As long as an SRRP instance can be served by the protected node, it is preferred to keep it in the Master state in there, instead of switching it to the protecting node as part of the operation-group.

10.3.12 Troubleshooting Commands

Some of the commands that can assist in troubleshooting are listed below.

Note: To get a summary view of SRRPs and their OMCR status use the following command as shown below (the **domain** concept is reserved for future use):

```
*A:right-21# show redundancy multi-chassis omcr all

10.4 OMCR Command Reference

10.4.1 Command Hierarchies

Refer to the Basic System Configuration Guide for information about redundancy CLI command descriptions and syntax.

```
config
├─ redundancy
│   └─ multi-chassis
│       └─ [no] peer ip-address
│           └─ warm-standby
```

10.4.2 OMCR Configuration Commands

10.4.2.1 OMCR Configuration Commands

warm-standby

Syntax	warm-standby
Context	config>redundancy> multi-chassis>peer
Description	<p>This command enables Oversubscribed Multi-Chassis Redundancy (OMCR) model where subscriber hosts are synchronized between the two chassis only in the control plane and are kept there (as part of the Multi-Chassis Synchronization (MCS) state) until the switchover occurs. Link or nodal failure will trigger the switchover at which point the subscriber hosts are being fully instantiated in the control and the forwarding plane. This approach allows oversubscription of the resources in the central standby (or protecting) node that is backing-up a number of other active nodes. The total number of protected subscribers in the OMCR cluster exceeds the forwarding capacity of the protecting node. This is achievable by not fully occupying the resources for the subscriber hosts until the failure occurs.</p> <p>The restoration times depend on the amount of the subscriber hosts that are affected by the switchover and it is related to the time needed for the full instantiation of the subscribers in the forwarding plane.</p>

Although this command is configured on a peer level, the warm-standby property is a nodal characteristic. In other words, mixing of N:1 and 1:1 (hot standby) mode in the central standby node is not supported. Consequently all peers on the central standby node must be configured for warm-standby (N:1), or all peers must be configured for hot-standby (1:1) by omitting the warm-standby keyword from the configuration.

The peer of the central-backup node is not aware of the redundancy model supported. In other words, the peer of the central-backup node does not know whether it peers with a warm-standby peer or host-standby-peer. All nodes participating in this protection model must run SR OS R12.0 or higher.

Default no warm-standby

11 WIFI Aggregation and Offload

11.1 In This Section

This section describes features and functionality for the 7750 SR to act as a WLAN-GW providing subscriber management (ESM), mobility and 3G/4G interworking functions for WIFI subscribers gaining access from WLANs in hot-spots and home-spots.

Topics in this section include:

- [WIFI Aggregation and Offload Overview](#)
- [Layer 2 over Soft-GRE Tunnels](#)
- [Tunnel Level Egress QoS](#)
- [Authentication](#)
- [Address Assignment](#)
- [WIFI Mobility Anchor](#)
- [Wholesale](#)
- [CGN on WLAN-GW](#)
- [Lawful Intercept on WLAN-GW](#)
- [3G/4G Interworking](#)
- [Migrant User Support](#)
- [Layer 2 Wholesale](#)
- [Distributed Subscriber Management \(DSM\)](#)
- [Distributed RADIUS Proxy](#)
- [IPv6-only Access](#)
- [Layer 2 Wholesale](#)
- [VLAN to WLAN-GW IOM/IMM Steering via Internal Epipe](#)

11.2 WIFI Aggregation and Offload Overview

This solution set adds support for managing subscribers gaining network access over WLAN. The WLAN access enables a service provider to offer a mobile broadband service to its subscribers or to offload traffic on its or a partners macro cellular (3G/4G) network. The WLAN access can be from public hot-spots (indoor or outdoor APs), venues, enterprises, or home-spots (with public SSID).

The 7750 SR serves as a WLAN Gateway (WLAN-GW) providing Layer 3 termination and ESM for these subscribers. The connectivity from WLAN AP or AC can be over any existing access technology (DSL, PON, Fiber, DOCSIS, etc.), with Ethernet based connectivity from the access node (DSLAM, OLT, Eth MTU, Layer 2 CMTS) to the WLAN-GW. WLAN-GW functions could be on a standalone 7750 as shown in Figure 166 or could be an add-on functionality on existing 7750 based BNG as shown in Figure 167. WLAN connectivity to the WLAN-GW could be over a Layer 2 aggregation or an Layer 3 aggregation network (typical when WLAN-GW is upstream of an existing BNG or CMTS). In case of Layer 2 aggregation the connectivity to the WLAN-GW could be tagged or untagged Ethernet. In case of Layer 3 aggregation, supported connectivity option is Ethernet over GRE (or Eth-over-MPLS over GRE) tunnel originating from the AP/AC, and terminating on the WLAN-GW. The WLAN AP acts as a bridge, switching Ethernet frames into a GRE tunnel terminating on an MS-ISA in the WLAN-GW.

Figure 166 Standalone WLAN-GW

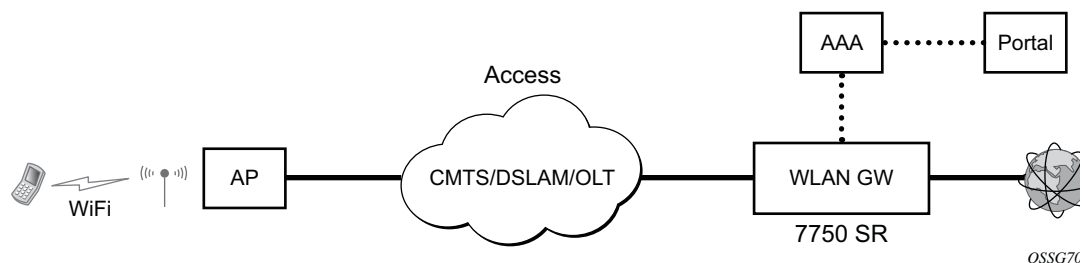

Figure 167 WLAN-GW Functions on Existing BNG

AP Connectivity to the WLAN-GW could be direct Ethernet (tagged or untagged) or could be Ethernet over GRE. In future releases, other tunnels encapsulations will be considered. With the bridged AP using GRE tunnels, the WLAN-GW solution elements are discussed in the following sections.

11.3 Layer 2 over Soft-GRE Tunnels

Soft-GRE refers to stateless GRE tunneling, whereby the AP forwards GRE encapsulated traffic to the WLAN-GW, and the GW reflects back the encapsulation in the downstream traffic towards the AP. WLAN-GW does not require any per-AP end-point IP address configuration. The WLAN-GW learns the encapsulation as part of creating the subscriber state on processing the encapsulated control and data traffic. Following are some of the advantages of soft-GRE:

- Resources are only consumed on the WLAN-GW if there is one or more active subscriber on the AP. Merely broadcasting an SSID from an AP does not result in any state on the WLAN-GW.
- No per-AP tunnel end-point configuration on WLAN-GW. This is important as the AP can get renumbered.
- No control protocol to setup and maintain tunnel state on WLAN-GW.

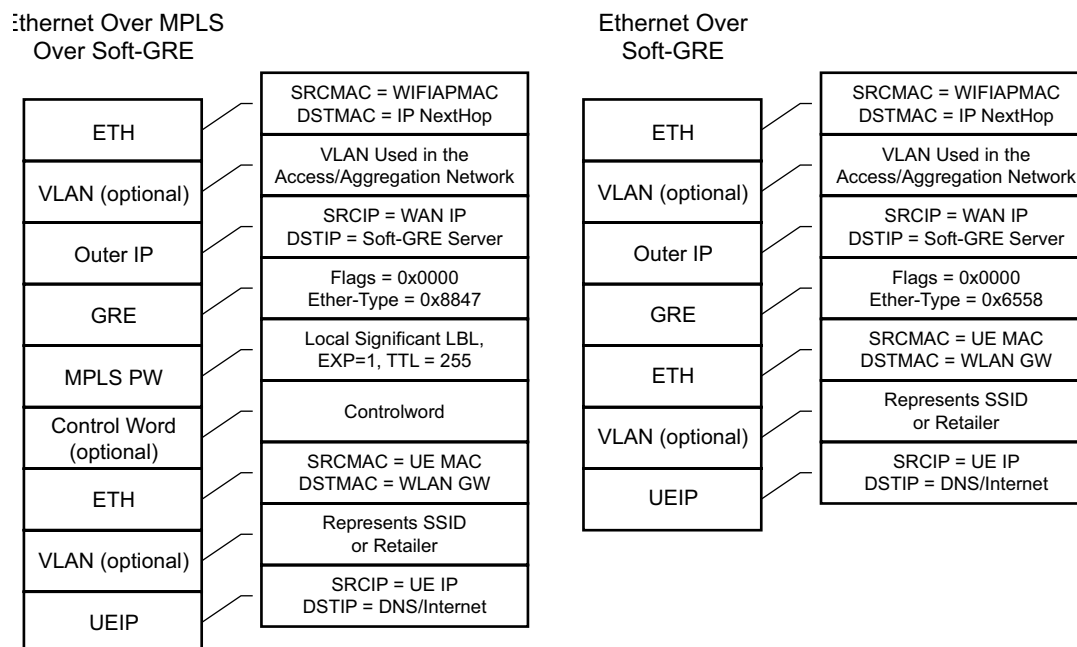

Soft-GRE tunnel termination is performed on dedicated IOMs with MS-ISAs (referred to as WLAN-GW IOM). Each slot requires two MS-ISAs dedicated for soft-GRE tunnel termination. MS-ISA provides tunnel encapsulation/de-encapsulation, bandwidth shaping per tunnel (or per-tunnel per SSID), and anchor point for inter-AP mobility. The ESM function such as per-subscriber anti-spoofing (IP and MAC), filters, hierarchical policing, and lawful intercept are provided on the carrier IOM corresponding to the ISA where the subscriber is anchored.

In future releases, other tunnels encapsulations will be considered.

11.3.1 Encapsulation

The GRE encapsulation is based on RFC 1701/2784, *Generic Routing Encapsulation (GRE)*, WLAN-GW will encapsulate according to RFC 1701 with all the flag fields set to 0, and no optional fields present. WLAN-GW is able to receive both encapsulation specified in RFC 1701 and RFC 2784, with all flag fields set to 0, and no optional fields present in the header.

Figure 168 Encapsulation Example

OSSG702

The encapsulation is built as follows:

- Outer Ethernet header: (14 bytes)
 - Source MAC: MAC address of the WIFI AP/RG/HGW HW address
 - Destination MAC: MAC address of the first IP NH the WIFI AP/RG/HGW is connected to (for example, CMTS, IP aggregation router, BNG, etc.)
- Outer VLAN: (4 bytes): optional, typically used for service delineation in the access or aggregation network.
- Outer IPv4 Header: (20 bytes)
 - Source IP — IP address used for WAN addressing which is retrieved by the AP/RG from the ISP through DHCP, PPPoX, etc.
 - Destination IP — Soft-GRE server address which can be retrieved by a DHCP Option, PPPoX option or configured by TR69 or configured statically in a boot file (in cable environment).
 - DSCP — Reflects QoS used in the access/aggregation network.
 - TTL — Should be set to 255 or should reflect the amount of IP hops in the access/aggregation network

- GRE: (4 bytes)
 - All flags are set to 0, such as checksum, sequence number and keys are not present.
 - The Ether-Type is set to 0x6558 for native Ethernet is used, and 0x8847 when MPLS encapsulation is used.
- MPLS Pseudowire Label (4 bytes)
 - Label Value, statically assigned in the WiFi AP/Controller and reflected back from the soft-GRE server to the WIFI AP/Controller. The Label is unique within the context of the source IP address of the tunnel.
 - EXP: 0 (not used)
 - TTL: 255 (not used)
- Inner Ethernet header: (14 bytes)
 - Source MAC: MAC address of the UE
 - Destination MAC: MAC address of the soft-GRE server/WLAN-GW.
- Inner VLAN: (4 bytes): optional, inserted by AP/RG per unique SSID (typically, when the AP is providing SSID per retailer). WLAN-GW allows mapping the VLAN to a service context per retailer, in the data plane.
- Inner IPv4 Header: (20 bytes)
 - Source IP: Client's IP address obtained via DHCP (tunneled).
 - Destination IP: IP address of the destination client trying to reach.
 - DSCP: set by the client/application
 - TTL: set by the client/application

Soft-GRE tunnel termination is performed on dedicated IOMs with MS-ISAs (referred to as WLAN-GW IOM). Each WLAN-GW IOM requires both MS-ISAs to be plugged in for soft-GRE tunnel termination. MS-ISA provides tunnel encapsulation/de-encapsulation and anchor point for inter-AP mobility. The carrier IOMs of the ISA where the tunnel is terminated performs bandwidth shaping per tunnel (or per-tunnel per SSID). ESM function such as per-subscriber anti-spoofing (IP and MAC), filters, hierarchical policing, and lawful intercept are provided on the carrier IOM corresponding to the ISA where the subscriber is anchored.

N:M warm standby redundancy is supported for WLAN-GW IOM slots. Up to 4 WLAN-GW IOMs can be configured per 7750 SR. A maximum 3 WLAN-GW IOMs can be active. One or more WLAN-GW group can be configured with set of WLAN-GW IOMs, and a limit of active IOMs. Incoming soft-GRE tunnel contexts and corresponding subscribers are load-balanced amongst the MS-ISAs on active IOMs. Tunnel load-balancing is based on outer source IP address of the tunnel. Subscriber

load-balancing is based on UE's MAC address in the source MAC of the Ethernet payload in the tunnel. IOM(s) beyond the active limit act as warm standby, and take over the tunnel termination and subscriber management functions from failed WLAN-GW slot. MS-ISAs on WLAN-GW IOMs can also be configured to perform NAT function.

```

config isa wlan-gw-group <group-id>
  [no] active-iom-limit <number>
  [no] description <description-string>
  [no] distributed-sub-mgmt
    [no] isa-aa-group <aa-group-id>
  [no] * iom <slot-number>
  nat
    [no] radius-accounting-policy <nat-accounting-policy>
    [no] session-limits
      [no] reserved <num-sessions>
      [no] watermarks high <percentage> low <percentage>
  [no] shutdown

```

An ESM and soft-gre configuration is required for wlan-gw functions. Subscriber and group interfaces are configured as part of normal ESM configuration. The group interface is enabled for wlan-gw by configuration. L2oGRE is the currently supported soft tunnel types. The wlan-gw related configuration includes the following:

- Tunnel end-point IP address.
- Service context for tunnel termination.
- TCP MSS segment size. This is set in TCP SYN and SYN-ACKs by wlan-gw to adjust to the MTU on access/aggregation network in order to prevent fragmentation of upstream and downstream TCP packets.
- Mobility related configuration, including mobility trigger packet types (normal data or special Ethernet IAPP fame), and hold-down time between successive mobility triggers.
- VLAN to retailer mapping. The AP typically inserts a unique dot1Q tag per retail service provider in the Ethernet payload. The mapping of dot1Q tag to retail service context is configured under wlan-gw tunnel. The subscriber is then created in the configured retail service context. The retail service context can also be provided by AAA server in authentication-accept message based on subscriber credentials or SSID information contained in DHCP Option82.
- Egress QoS configuration for downstream traffic entering the wlan-gw module for tunnel encapsulation. This includes type of aggregate bandwidth shaping (per-tunnel or per-retailer), aggregate-rate-limit, egress QoS policy and scheduler policy. The tunnel shaping can be configured to be applied only when there is more than one subscriber on the tunnel. By default the shaping if configured is applied when first subscriber on the tunnel logs in.

11.3.2 Data Path

In the upstream direction, the ingress IOM receiving the GRE tunneled packets from the WIFI AP or AC, load-balances tunnel processing amongst the set of MS-ISAs on the active WLAN-GW IOMs in the WLAN-GW group. The load-balancing is based on a hash of source IP address in the outer IP header. The MS-ISA receiving the GRE encapsulated packets removes the tunnel encapsulation, and internally tunnels (MAC-in-MAC, using BVPLS) the packet to an anchor MS-ISA on the WLAN-GW IOM. All traffic from a given UE is always forwarded to the same anchor MS-ISA based on hashing on UE's MAC address. The MS-ISA provides a mobility anchor point for the UE. The UE MAC's association to the GRE tunnel identifier is created or updated. The corresponding IOM provides ESM functions including ESM lookup, ingress ACLs and QoS. DHCP packets are forwarded to the CPM from the anchor IOM.

In the downstream direction, the IP packets are forwarded as normal from the network IOM (based on route lookup yielding subscriber subnet) to the IOM where the ESM host is anchored. ESM processing including per UE hierarchical policing and LI is performed on the anchor IOM. Configured MTU on the group-interface is enforced on the IOM, and if required packets are fragmented. The packets are then forwarded to the appropriate anchor MS-ISA housed by this IOM. Lookup based on UE's MAC address is performed to get the tunnel identification, and the packets are MAC-in-MAC tunneled to the MS-ISA terminating the GRE tunnel. Aggregate shaping on the tunneled traffic (per tunnel or per retailer) is performed on the carrier IOM housing the tunnel termination MS-ISA. The tunnel termination MS-ISA removes MAC-in-MAC encapsulation, and GRE encapsulates the Layer 2 packet, which exits on the Layer 3 SAP to the carrier IOM. The GRE tunneled packet is forwarded to the right access IOM toward the WIFI AP based on a routing lookup on IP DA in the outer header.

11.4 Tunnel Level Egress QoS

Downstream traffic can be subjected to aggregate rate-limit per tunnel or per tunnel and per retailer combination (in case of wholesale). Typically a unique SSID is used per retailer for wholesale on the AP, and is reflected via unique dot1Q tag. In the case of a wlan-gw tunnel per AP, the tunnel encapsulation is performed on the tunnel ISA. The downstream traffic on the tunnel IOM is received over B-VPLS from the anchor IOM, and is MAC-in-MAC (802.1ah) encapsulated. I-SID in the packet represents the GRE tunnel or tunnel and retailer combination. SAP-egress QoS policy defining queues (with rates), and FC to queue mapping, can be specified under the wlan-gw interface. This policy is applicable to all tunnels (or tunnel and SSID combinations) associated with the wlan-gw interface, and is attached to corresponding I-SIDs on the B-VPLS SAP. Traffic is shaped into these queues based on configured queue rates. An aggregate rate-limit applied across queues on an I-SID (representing tunnel or tunnel and retailer combination) can be configured under the wlan-gw interface (represented by the wlan-gw node under the group-interface configuration). The aggregate rate-limit works in conjunction with a port-scheduler. The port-scheduler corresponds to the internal port between tunnel ISA and its carrier IOM, and is specified at the wlan-gw IOM group level. The rate-limit includes the B-VPLS encapsulation overhead. The configuration is shown in [Figure 170](#). Queues per I-SID also work with virtual-scheduler (with or without a port scheduler). Virtual-scheduling and aggregate-rate enforcement are mutually exclusive. Configuration is shown in [Figure 171](#). Egress SAP QoS policy, aggregate rate-limit, port-scheduler, and virtual-schedulers are described in the SR OS QoS Guide. The SAP egress QoS policy associated with a wlan-gw interface implicitly creates queues (and scheduler association) on ISIDs as corresponding wlan-gw tunnels are created. General ISID queuing and shaping is defined in the SR OS Services Guide.

A configuration node under wlan-gw interface (egress) controls where the egress shaping is applied, and can specify either tunnel or retailer (tunnel and retailer combination in case of wholesale). Per I-SID shaping resources can be held after the last subscriber on the tunnel is deleted, for a configurable amount of time (hold-time) configured under the wlan-gw interface. During ISA or IOM failover the tunnel resources on the IOM kept due to hold-time are reclaimed. ISID shaping can be configured (via knob shape-multi-client) to be applied only when there is more than one UE on the corresponding tunnel (or tunnel and retailer combination). A total of 40,000 shaped tunnels (or shaped tunnel & retailer combinations) are supported per WLAN-GW IOM. Hardware resources for tunnel (ISID) shapers are shared with subscribers. With 3 WLAN-GW IOMs per chassis, a maximum of 98,000 ($3 * 64K / 2$) shaped tunnels and subscribers can be supported per chassis.

The following output depicts per tunnel or per tunnel/SSID egress QoS (with aggregate-rate and port-scheduler).

// Port-scheduler

```
config>qos#
  port-scheduler-policy "lo-gre-port-sched"
    max-rate 5000
    level 1 rate 1000 cir-rate 1000
    level 8 rate 500 cir-rate 500
  exit
exit
```

// Egress queues (per ISID) parented by port-scheduler specified under associated wlan-gw interface

```
config>qos>
  sap-egress 3 create
    queue 1 create

  qos 3
  scheduler-policy "virt-sched-policy"
  shaping per-tunnel
  shape-multi-client
exit
```

11.4.1 QoS Overrides

Per-tunnel QoS overrides can be provided in order to have more specific values for certain tunnels. This allows the WLAN gateway to accommodate a heterogeneous set of access points in one WiFi network; for example, provisioning different bandwidth for homespots and hotspots. For a detailed list of allowed overrides and values, refer to the *RADIUS Attributes Reference Guide*.

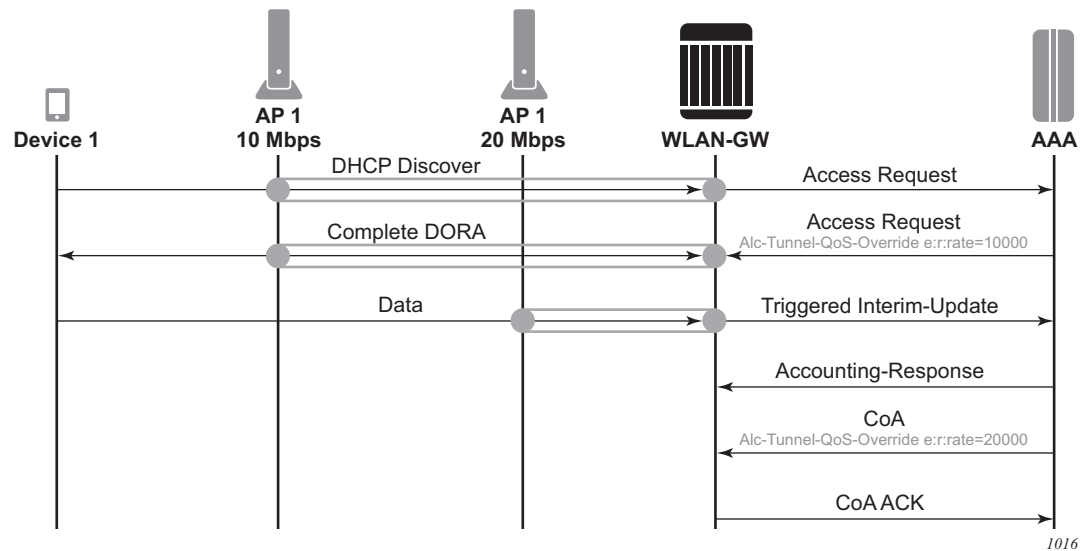

QoS overrides can be signaled via RADIUS in UE authentication and in UE CoA. The override is applied to the tunnel where the UE is currently active. Therefore, two scenarios should be considered:

- If the first UE on a tunnel is also a new UE that will be authenticated, any tunnel QoS override can be signaled in the Access-Accept message for that UE.

- If the first UE on a tunnel is a previously authenticated UE that moved from another tunnel, a mobility triggered Interim Update can be sent and used as a trigger to send a CoA with the per-tunnel QoS overrides.

Figure 169 shows flows for both scenarios.

Figure 169 QoS Override Flows

To guarantee that the CoA is applied to the correct tunnel, use the CoA key consisting of the *nas-port-id* and the UE IP address; both can be derived from the interim update. In the WLAN gateway, the *nas-port-id* identifies the tunnel to which the UE is linked, and, if a mismatch is detected, the CoA is not applied. Other CoA keys are also supported but do not offer this guarantee.

11.4.2 Operational Commands

Egress per tunnel (or per tunnel, per SSID) QoS with aggregate rate-limit and port-scheduler.

11.5 Authentication

The solution supports multiple authentication mechanisms. Type of authentication support depends on the WIFI AP, UE capabilities and customer preference. In case of 802.1x/EAP capable WIFI APs, supporting secure SSIDs via 802.11i/WPA2, various EAP based authentication such as SIM/uSIM based (SIM/AKA/AKA'), TTLS, PEAP, certs, etc., are supported. The solution also supports web-portal based authentication with or without WISPr client on the UE. EAP and portal authentication works independent of the type of connectivity from the AP (tunneled or native IP).

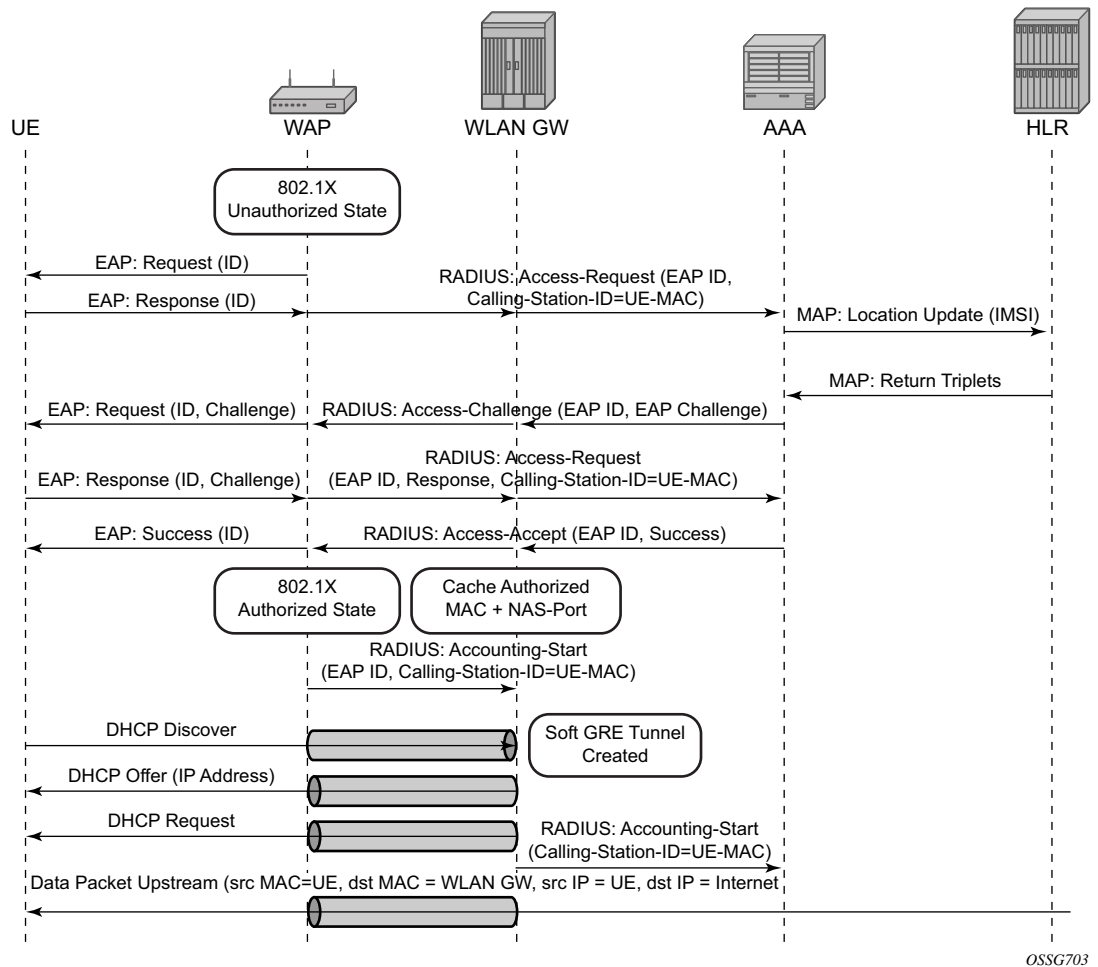

The SR OS WLAN-GW uses the IPoE session concept to authenticate and manage UEs in ESM. Every WLAN-GW group interface uses a pre-defined default `ipoe-session policy` that cannot be changed or disabled. The contents of the default policy also cannot be changed and always uses `sap-mac` as a key. The `ipoe-session session-timeout` can optionally be ignored in a `wlan-gw` context. This is to support closed SSID authentication where the `session-timeout` is relative to the last re-authentication while for `ipoe-session` the timeout is absolute to the start of the session.

11.5.1 EAP-Based Authentication

In this model the WIFI AP supports a RADIUS client, and originates RADIUS messages based on 802.1x/EAP exchange with the UE. It sends EAP payload in RADIUS messages towards the RADIUS server or RADIUS proxy. 7750 WLAN-GW can be configured as a RADIUS proxy for the WIFI APs. The WIFI AP should be configured with the IP address of the RADIUS proxy, and should send authentication and accounting messages non-tunneled, natively routed to the RADIUS proxy. See [Figure 170](#).

The RADIUS proxy function allows 7750 SR to look at the RADIUS authentication and accounting messages and create or update corresponding subscriber state. RADIUS proxy transparently forwards RADIUS messages between AP (authenticator) and the AAA server. The access-request message contains standard RADIUS attributes (including user-name), and the EAP payload. Standard authentication algorithms negotiated with EAP involve multiple round-trips (challenge/response) between AP (and UE) and the AAA server.

Once authentication is complete, AAA server passes back subscriber related configuration parameters as well as the computed session keys (aka pair-wise master key) for 802.11i to the AP. These keys are encrypted using shared secret between AP (authenticator) and the AAA server. 7750 WLAN-GW can optionally cache authentication information of the subscriber from access-request and access-accept messages. The cached information allows local authorization of subsequent DHCP messages from the UEs behind the AP against the cached state on the 7750 RADIUS proxy, and avoids another trip to the RADIUS server.

Figure 170 EAP Authentication Call Flow with WLAN-GW RADIUS Proxy

11.5.1.1 RADIUS Proxy

RADIUS proxy can be configured per service router (base or VPRN). The proxy acts as a server towards the WIFI AP RADIUS clients, and as a client towards RADIUS server(s). Therefore, both client and server parts of the RADIUS proxy need to be configured. The attribute from access-request or response message that serves as the key for the cache is configurable. The key configuration is mandatory for enabling the cache. Commonly the key is the MAC address of the UE, which is available in subsequent DHCP request, and used to locate the cache entry. The UE's MAC address is typically available in the Calling-station-Id attribute (31) in the RADIUS

access-request message from the AP. The proxy can be configured for both authentication and accounting. The radius server policies referred by RADIUS proxy are configured under “aaa” context. If caching is enabled in the RADIUS proxy, the subscriber attributes returned in access-accept are cached. These can include 802.1x credentials/keys, IP address or pool, DNS information, default gateway information, retail-service-id, SLA-profile, filter parameters, charging information, session keys (MS-MPPE-RECV-KEY, MS-MPPE-SEND-KEY) etc. If subsequent DHCP DISCOVER is not received within the configured timeout, the cache entry is removed.

The following output displays a RADIUS proxy configuration.

```
config>service>ies>
config>service>vprn>
    description "Default Description For VPRN ID 50"
    interface "listening_radius_server" create
        address 9.9.9.9/32
        loopback
    exit

    radius-proxy
        server "radius_proxy" purpose accounting authentication create
            cache
                key packet-type request attribute-type 31
                timeout min 5
                track-accounting stop interim-update accounting-on accounting-off
                no shutdown
            exit
            default-accounting-server-policy "radius_acct_server_policy"
            default-authentication-server-policy "radius_auth_server_policy"
            interface "listening_radius_server"
            load-balance-key attribute-type 102 vendor 5
            secret "AQepKzndDzjRI5g38L3LbbN3E8qualtn" hash2
            send-accounting-response
            no shutdown
        exit
    exit
```

11.5.1.1.1 RADIUS Proxy — Server Load-Balancing

RADIUS proxy can be configured for load-balancing to multiple authentication and accounting servers. Load-balancing can be “round-robin” or “hash” based, and is configured via access-algorithm under RADIUS policy. With round-robin the first RADIUS request is sent to the first server, the second request to the second server and so on. With hash, it is possible to load-balance subscribers across a set of servers. Based on the configured hash key, configured in the RADIUS proxy, it can be ensured that all RADIUS messages for a single subscriber are sent to the same server. The hash key can include any specified standard or vendor-specific RADIUS attribute. An example is calling-station-id which contains subscriber’s MAC address).

If the hash lookup causes the request to be sent to a server that is currently known to be unresponsive, a second hash lookup is performed that only takes the servers into account that are not known to be unresponsive. This is done to maximize the likelihood that all requests will end on the same server. If all configured servers are known to be unresponsive, the RADIUS proxy will fall back to the round-robin algorithm with the starting point determined by the first hash lookup to maximize the chance of getting any response to the request.

The following output displays a RADIUS server and policy configuration for servers referred from the RADIUS proxy.

```
config>service>vprn
  radius-server
    server "radius_server" address 100.100.100.2 secret "9OkclHYDDbo9eHrzFmuxiaO/
LAft3Pw"
                                hash2 port 1812 create
  exit
exit

config>aaa
  radius-server-policy "radius_server_policy" create
  servers
    router 50
    access-algorithm hash-based
    source-address 10.1.1.1
    timeout min 1
    hold-down-time 2
    server 1 name "radius_server"
  exit
```

11.5.1.1.2 RADIUS Proxy — Cache Lookup

Local-user-database can be programmed to associate a host match with the RADIUS proxy cache instance. The host-match criterion is configurable, based on a subscriber attribute from the DHCP request.

The following output displays a RADIUS proxy cache lookup configuration.

```
config>subscriber-mgmt
  local-user-db "radius_ludb" create
  dhcp
    match-list service-id
    host "default" create
    auth-policy "auth_policy_1"
    match-radius-proxy-cache
      fail-action continue
      match mac
      server router 50 name "radius_proxy"
    exit
  no shutdown
```

```

        exit
    no shutdown
exit
exit

```

If caching is enabled in the RADIUS proxy, then the actions on receiving DHCP message for the authenticated client includes the following:

- A host lookup is done in the local-user-database to find the RADIUS proxy cache for the subscriber.
- The field used to lookup the cache is configurable. It can include circuit-id or remote-id (present in sub-option in DHCP option-82), MAC@ or one of the other options in the DHCP packet. If a match is not found, the configured fail-action is executed. The default match field is MAC@. If the configured fail-action is "drop", the DHCP DISCOVER is dropped. If the configured fail-action is "continue", then the ESM host creation proceeds based on the authentication policy configured under the group-interface on which the DHCP packet is received.
- If a match is found, the parameters from original authentication accept in the cache are used to create the ESM host. If the group-interface is wlan-gw, then the ESM host is associated with the wlan-gw tunnel the (AP's WAN IP@) and corresponding AP (MAC@ from the called-station-id in the authentication state).

11.5.1.1.3 RADIUS Proxy — Accounting

An ESM accounting-start is generated once the ESM host is created on successful authorization of DHCP against cached authentication state, and IP@ allocation is complete. The accounting-start contains information from locally cached 802.1x/EAP authentication such as calling-station-id, called-station-id, NAS-port-id, Subscriber-profile, SLA-profile, NAT port range for subscriber-aware NAT etc.

If RADIUS proxy is configured as an accounting proxy in addition to authentication proxy, then the RADIUS proxy transparently forwards the accounting messages to the authentication server(s) referred from the RADIUS proxy, and can also load-balance. If caching is enabled, then the proxy can be configured to also track and locally act on the accounting messages, while still transparently forwarding these messages. The possible actions if accounting messages are tracked include the following:

- Accounting-start — The WIFI AP RADIUS client generates an accounting-start when a UE has successfully authenticated and associated with the AP. In cases where after mobility, the new AP does not re-authenticate due to key caching, accounting-start can be used as a mobility trigger on the WLAN-GW. Also, in cases where a UE associates with a single AP but pre-authenticates with

multiple APs in range, tracking mobility based on authentication can falsely associate a UE with incorrect AP. Mobility tracking based on authentication can be disabled via CLI (no track-authentication under radius-proxy cache), and instead be performed based on accounting-start. On receiving accounting-start, the RADIUS proxy on WLAN-GW finds the corresponding ESM host based on the calling-station-id attribute (typically the MAC@) of the subscriber) in accounting-start and associates the UE with the RADIUS client (for example, WIFI AP).

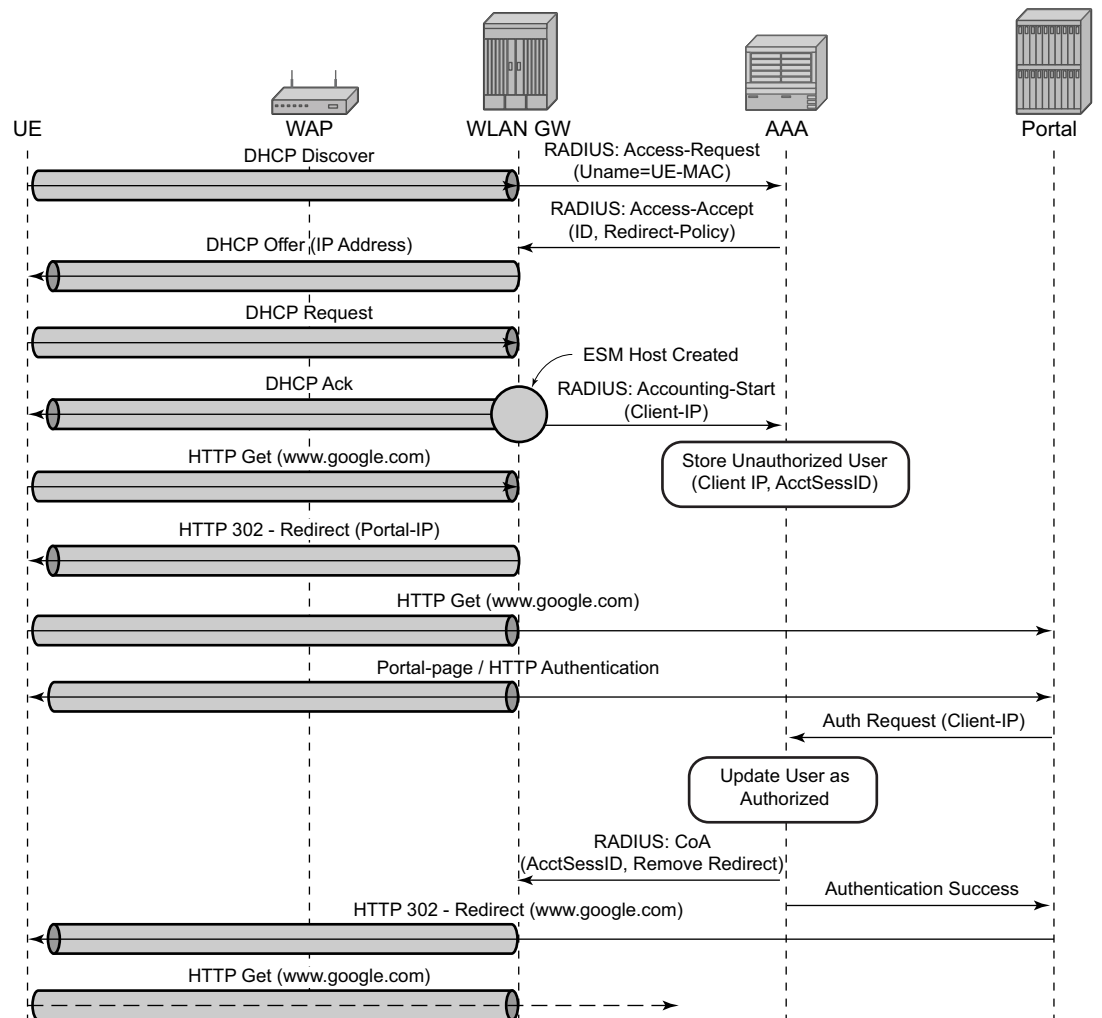

- Accounting-stop — The WIFI AP RADIUS client generates an accounting stop if it detects the UE has disassociated or is deleted due to inactivity or session timeout. The RADIUS proxy finds the corresponding ESM host based on the calling-station-id (typically the MAC@) of the subscriber. Note that if the called-station-id is filled out this must also match with what is currently stored as a security measure. When a UE moves the called-station-id should get updated and as such an accounting-stop from a previous AP cannot delete this UE anymore.
- The ESM host is deleted, an ESM accounting-sop message is sent, and the accounting-stop message from the AP is forwarded to the accounting-server.
- Accounting-ON or Accounting-OFF — This would be received from the AP if the AP has restarted. The RADIUS proxy will find all the impacted subscribers for the AP based on the called-station-id attribute (the AP's MAC@) in the accounting message, and delete all the corresponding ESM hosts.
- Interim Accounting Updates — If the client moves and re-associates with a new AP, the RADIUS client in the new AP generates interim-update. The RADIUS-proxy will locate the impacted ESM host, and update its state to point to the new AP's MAC@ (as available in called-station-id in the accounting message). The ESM interim-updates to accounting servers are sent on scheduled interval configured in accounting-policy, but with the updated information from the interim updates received from the AP.

11.5.2 Portal Authentication

For SSIDs without 802.11i/WPA2-based key exchange and encryption, it is common to authenticate the user by directing user's HTTP traffic to a portal, where the user is prompted for its credentials, which are verified against a subscriber database. The backend can optionally remember the MAC@ and subscriber credentials for a set period of time such that subsequent logins of the user do not require portal redirection. Some UEs support a client application (aka WISPr client), which automatically posts subscriber credentials on redirect, and parse HTTP success or failure response from the portal sever.

7750 WLAN-GW uses existing http-redirect action in IP filter to trigger redirect port-80 traffic. In case of open SSID, on receiving DHCP DISCOVER, MAC based authentication is performed with the RADIUS server as per configured authentication policy. The SLA-profile returned from RADIUS server in authentication-accept (or the default SLA-profile) contains the filter with http-redirect. Redirect via HTTP 302 message to the UE is triggered from the CPM. Once the user posts its credentials, RADIUS server generates a CoA-request message removing the http-redirect by specifying an SLA-profile without redirect action. If the portal authentication fails, the RADIUS server generates a disconnect-request message to remove the ESM host. In case of wlan-gw tunnel from the AP, the DHCP messages and data are both tunneled to the WLAN-GW. See [Figure 171](#).

Figure 171 Portal Authentication for Open SSIDs

OSSG704

The following output displays a portal authentication for open SSIDs configuration example.

```
config>subscriber-mgmt
  sla-profile "portal-redirect" create
    ingress
      ip-filter 10
    exit
  exit
exit
exit

system>config>filter
  ip-filter 10 create
    entry 1 create
      match protocol udp
        dst-port range 67 68
      exit
      action forward
    exit
  entry 2 create
    match protocol tcp
      dst-port eq 80
    exit
    action http-redirect "http://www.google.ca"
  exit
exit
exit
```

It is possible to view the subscriber HTTP redirect statistics by using the **show service id subscriber-hosts statistics** command. The statistics are captured per host and supports both IPv4 and IPv6. This command is only supported from CPM5 and up and SR-e platforms.

11.6 Address Assignment

The address to the UEs can be assigned via local DHCP server from locally defined pools, or from RADIUS server via local DHCP proxy, or from an external DHCP server. Subscriber-interface and group-interface are configured as part of normal ESM configuration. In case of wlan-gw, the group interface is wlan-gw enabled. Subnets on the subscriber interface are used for the pools from which the DHCP local server assigns addresses to UEs.

The following output displays an address assignment configuration example.

```
config>service>vprn
  dhcp
    local-dhcp-server "dhcp" create      #### create local DHCP server
    pool "1" create                      #### define Pool
    options
```

```

        dns-server 8.8.8.8 8.8.4.4
        lease-time min 5
    exit
    subnet 128.203.254.180/30 create
        options
            subnet-mask 255.255.0.0
            default-router 128.203.254.181
        exit
        address-range 128.203.254.182 128.203.254.183
    exit
exit
exit
exit

interface "DHCP-
lb" create          ##### loopback interface with DHCP server
    address 10.1.1.1/32
    local-dhcp-server "dhcp"
    loopback
exit

relation
            no shutdown
        exit
    exit

```

11.7 WIFI Mobility Anchor

7750 WLAN-GW supports seamless handling for UE mobility, when a UE moves from one AP to another, where the new AP is broadcasting the same SSID, and is anchored on the same WLAN-GW. In case of open SSID, when the UE re-associates with the same SSID on the new AP and already has an IP@ from association with previous AP, the UE can continue to send and receive data. The WLAN-GW learns the association of the UE's MAC address to the GRE tunnel corresponding to the new AP, and updates its state on the MS-ISA as well as on the CPM. The UE continues to be anchored on the same anchor MS-ISA, thereby avoiding any disruption in ESM functions (SLA enforcement and accounting). State update based on data learning results in fast convergence after mobility and minimal packet loss. The data-triggered mobility can be turned on via configuration. Mobility trigger can be configured to be restricted to special Ethernet IAPP frame (originated by the AP with the source MAC of UE).

For 802.1x/EAP based SSIDs, by default the AP requires re-authentication to learn the new session keys (PMK). 7750 SR as WLAN-GW RADIUS proxy infers mobility from the re-authentication, and updates the ESM host to point to the new AP. The new AP's IP address is derived from the RADIUS attribute NAS-IP-address. The re-authentication also provides the new session keys to the AP in access-accept RADIUS response. In case the WIFI AP or ACs are capable of PMK key caching or standard 802.11r (or OKC, the opportunistic key caching pre-802.11r), the re-authentication on re-association can be avoided. In this case the UE can continue to send data, and the WLAN-GW can provide fast data-triggered mobility as defined in context of open SSIDs.

The following output provides a mobility anchor configuration example.

```
config>service>ies>
config>service>vprn>
subscriber-interface <if-name>
group-interface <if-name> wlangw
wlan-gw
    [no] router (base | <vprn-id>) # tunnel service context
    [no] wlan-gw-group <group-id>
    ...snip
    mobility
        [no] trigger {data | iapp}
        [no] hold-time <seconds> // [0..255 secs]
    exit
exit
exit
```

11.8 Wholesale

With EAP the AAA server can look at the realm from the user credential (IMSI) in authentication request and appropriately provide the service context in retail-service-id, for the ESM host corresponding to the UE.

For open SSID, the decision can be made by the AAA server based on the SSID. The SSID is encapsulated in circuit-id sub-option of option-82. The recommended format for the circuit-id is a string composed of multiple parts (separated by a delimiter) as shown below.

AP-MAC;SSID-STRING;SSID-TYPE

Delimiter is the character ';', and MUST not be allowed in configured SSIDs. AP-MAC sub-string MUST contain the MAC address of the AP in the format "xx:xx:xx:xx:xx:xx"

SSID-TYPE is "o" for open, and "s" for secure.

For example, if AP-MAC is "00:10:A4:23:19:C0", SSID is "SP1-wifi", and SSID-type is secure, then the value of circuit-id would be the string "00:10:A4:23:19:C0;SP1-wifi;s".

The circuit-id is passed to the AAA server in initial MAC based authentication on DHCP DISCOVER. The retail-service-id can be returned in access-accept. This assumes the AP broadcasts unique SSID per retail provider, and inserts it in Option82 as a DHCP relay-agent. As an alternative to SSID in option-82, the AP can insert a unique dot1Q tag per retail provider, before tunneling the Ethernet frame, using single GRE tunnel per AP to the WLAN-GW. 7750 supports configuring a map of .dot1Q tags to retail-service-id. Therefore, the determination of the retail provider for the subscriber can be made in the data plane when DHCP is received, and the subscriber state can be created and processed in the right service context.

The following output displays a wholesale configuration example.

```
config>service>ies>
config>service>vprn>
subscriber-interface <if-name>
group-interface <if-name> wlangw
wlan-gw
[no] router (base | <vprn-id>) # tunnel service context
[no] wlan-gw-group <group-id>
...snip
vlan-tag-ranges # Precedence for retail-service-id:
# RADIUS, vlan-retail-service-map, default-retail-
svc
[no] vlan start <start-tag> end <end-tag> retail-svc-id <svc-id>
[no] default-retail-svc-id
exit
exit
```

exit

11.9 CGN on WLAN-GW

Both LSN and L2-aware NAT for WIFI subscribers over wlan-gw tunnels is supported. NAT on WLAN-GW is only supported for locally terminated subscribers and not for GTP tunneled subscribers. NAT can be performed on the same set of ISAs that are used for WLAN-GW functions, by referring to the WLAN-GW ISA group from NAT configuration. Alternatively, dedicated set of ISAs can be used for NAT function by creating and referencing a separate NAT-group. Configuration related to LSN and L2-aware NAT is provided in SROS MS-ISA guide.

11.10 Lawful Intercept on WLAN-GW

Mirroring traffic for WIFI subscribers to a mediation device, when the subscriber is under legal intercept is supported. The mirroring function is performed on the anchor IOM where the subscriber is anchored. Both Ether and IP-only mirror is supported. With Ether mirror, VLAN tags which are part of internal SAP between ISA and IOM, are included in the mirrored Ethernet frame of the subscriber. IP-only mirror includes the IP header and the payload. Conventional IP-only mirror service can be used with direct p2p or MPLS (for remote mirroring) connection to the mediation device. In addition, routable-encapsulation added in 10R1 is also supported. Both IP/UDP encapsulation with optional shim-header for subscriber correlation on the mediation device, and IP/GRE encapsulation is supported with routable-encapsulation of mirrored data. LI can be triggered via CLI, SNMPv3 or RADIUS, as supported with ESM. RADIUS triggered LI can be via LI related VSAs in access-accept or in CoA. The CoA is keyed on accounting-session-id. LI is supported for both local and GTP tunnelled subscribers.

Existing LI support with ESM is described in the SROS OAM and diagnostics guide.

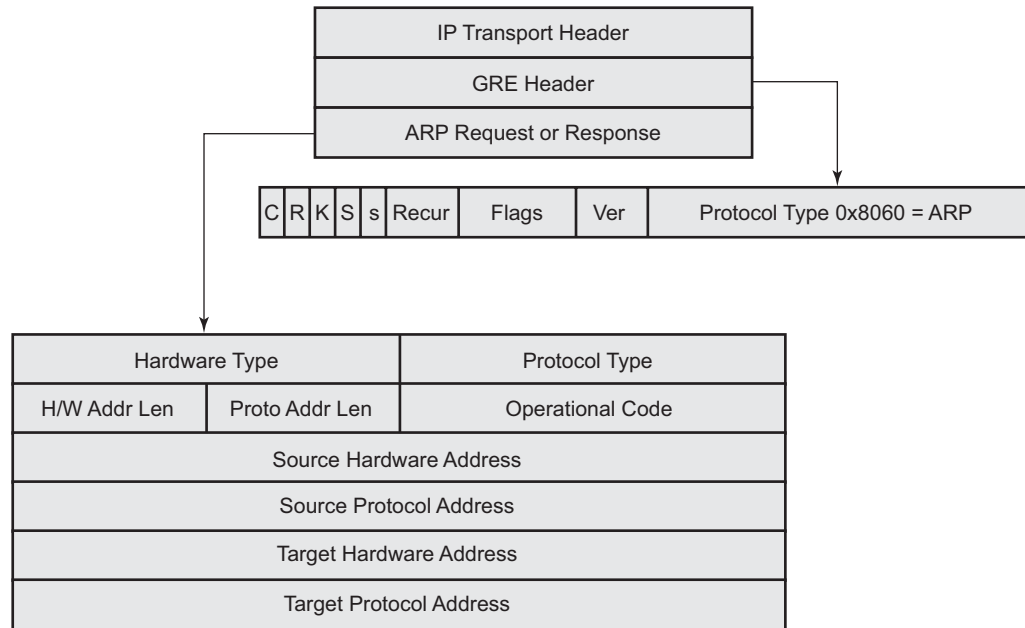

11.11 WLAN Location Enhancements

This feature adds configurable support for learning and reporting AP's MAC address (which represents WLAN location of the UE), to the AAA server. Support is also added for triggered interim accounting-updates to report the AP's MAC@ to the AAA server.

11.11.1 Triggered Interim Accounting-Updates

Using location based policy for WIFI subscribers is important. The business logic in AAA could use the location of the subscriber. Therefore, it is important to notify location change of the subscriber to AAA. Standard way to do this is by generating an interim accounting update when the WLAN-GW learns of the location change for a subscriber. The location for a WIFI subscriber can be inferred from MAC@ (preferred) or WAN IP@ of the AP.

For open-SSID, learning about mobility could be "data-triggered" or "IAPP packet triggered." If triggered, interim accounting-update is configured via CLI, then on detecting a location change for the UE, an interim accounting-update is sent immediately to the AAA server with the new AP's MAC@ (if already known to WLAN-GW). The accounting-update contains NASP-port-id (which contains the AP's IP@), and circuit-id (from DHCP option-82) which contains AP's MAC@ and SSID. In case of data-triggered mobility, if the new AP's MAC@ is not already known to WLAN-GW, a GRE encapsulated ARP packet is generated towards the AP to learn the MAC@ of the AP. The AP is expected to reply with a GRE encapsulated ARP response containing its MAC@. The generation of ARP to learn the AP's MAC@ is controlled via CLI. The GRE encapsulated ARP packet is shown in [Figure 172](#).

Figure 172 GRE Encapsulated ARP Request

al_0411

The standard ARP request must be formatted as follows:

- Hardware Type = Ethernet (1)
- Protocol Type = 0x0800 (IPv4)
- H/W Addr Len = 6
- Proto Addr Len = 4
- Operational code (1 = request)
- Source hardware address = WLAN-GW MAC@
- Source protocol address = Tunnel endpoint IP@ on WLAN-GW
- Target hardware address = Unknown
- Target protocol address = WAN IP@ of the AP (source IP in GRE packet)

The AP MUST generate a GRE encapsulated ARP response when it receives the GRE encapsulated ARP request for its WAN IP@ (that is used to source tunneled packets). The standard ARP response should be formatted as follows:

- Hardware Type = Ethernet (1)
- Protocol Type = 0x0800 (IPv4)

- H/W Addr Len = 6
- Proto Addr Len = 4
- Operational code (2 = response)
- Source hardware address = AP MAC@
- Source protocol address = WAN IP@ of AP (used for sourcing tunneled packets)
- Target hardware address = source hardware address from the request
- Target protocol address = source protocol address from ARP request

For 802.1x/EAP SSID, the location change (mobility) is learnt from an interim-accounting update from the AP. The called-station-Id (containing the AP MAC@) is compared against the current stored called-station-Id that the subscriber is associated with. If the called-station-id is different then the received interim accounting update is immediately forwarded to the accounting server, if triggered interim accounting-update is configured via CLI. In previous releases, the interim-update received from the AP is not immediately forwarded by the accounting proxy. Only a regularly scheduled interim-update is sent.

11.11.2 Operational Support

Following command shows if GRE encapsulated ARP request is enabled.

11.12 3G/4G Interworking

The WLAN-GW supports 3G/4G interworking based on a per-UE GTP tunnel from WLAN-GW to the mobile packet core (GGSN or P-GW). For more details on the GTP uplink setup, see [GTP](#). The bridged WiFi AP connectivity with the WLAN-GW can be WLAN-GW-based (soft-tunnel/I2-ap), or it can be a native L2 (regular group-interface).

11.12.1 Signaling Call Flow

The decision to setup a GTP tunnel for a subscriber or locally breakout subscriber's traffic is AAA based, and received in authentication response. If the traffic is to be tunneled to the PGW or GGSN, the signaling interface or PGW/GGSN interface would be provided via AAA. Absence of these attributes in the authentication response implicitly signifies local-breakout.

11.12.1.1 GTP Setup with EAP Authentication

Once the EAP authentication completes as described in the section on authentication, the RADIUS proxy caches the authentication response, including any attributes related to GTP signaling. Subsequently DHCP is initiated from the UE. On receiving DHCP DISCOVER, the RADIUS proxy cache is matched to get the AAA parameters related to the UE from the original authentication response. If PGW/GGSN (mobile gateway) IP address is not present in cached authentication, DNS resolution as described in section 1.2 is initiated for the WLAN APN obtained from AAA (in the cache) or for locally configured APN in the service associated with the UE. The DNS resolution provides a set of IP addresses for the mobile gateways. The GTP tunnel setup is attempted to the selected mobile gateway. The IP address provided by PGW/GGSN in the GTP response is returned in DHCP offer to the UE. The WLAN-GW acts as a DHCP to GTP proxy. The WLAN-GW is the default-GW for the UE. Any packets from the UE are then GTP tunneled to the mobile gateway. If

the UE requests an IP address (for which it may have an existing lease on one of its interface) via DHCP option 50 in the DHCP request, then WLAN-GW sets the “handover bit” in the GTP session create message, and indicates the requested address in the PDN Address Allocation (PAA) field. This allows the PGW to look for existing session corresponding to the signaled IMSI and APN (with potentially different RAT-Type) and return its existing IP address in session create response. The old session and bearer is deleted by the PGW. The signaling of “handover bit” is supported with S2a and S2b (release 10 and beyond). The IP address cannot be preserved over the Gn interface. The call flow in [Figure 176](#) shows basic GTP setup (with S2a), the output provided on [Figure 176](#) show IP address preservation across inter-access (WIFI <-> 4G) moves.

DHCP release or lease timeout on WLAN-GW will result in deletion of the GTP tunnel corresponding to the UE. The session or PDP context deactivation from PGW/GGSN will also result in removal of the GTP state for the UE and the corresponding ESM host on WLAN-GW. In this SR-OS release, only default bearer (or primary PDP context) for single default APN is handled over WIFI. GTP path-management messages (echo request and reply) are supported. Mandatory IEs are supported in GTP signaling. Hard coded default values are signaled for QoS and charging related IEs. For GTPv2, the bearer is signaled as non-GBR bearer with QCI value of 8, and MBR/GBR values of 0. APN-AMBR default values signaled are 20Mbps/10Mbps downstream/upstream. For GTPv1, reliability and priority classes default to “best-effort”, allocation/retention priority defaults to 1, and the default peak-rate corresponds to class 9 (bit-wise 1001) which is slightly over 2Mbps. Charging characteristics IE which contains a 16 bit flag defaults to 0. In the future, RADIUS returned values or locally configurable values will be signaled in QoS and charging IEs.

The IP address is returned in the create PDP context response or Create session response. The DNS server addresses for the UE are returned in IP control protocol (IPCP) option in a PCO IE in the response. The default gateway address provided to the UE in DHCP is auto-generated algorithmically on the WLAN-GW from the IP address returned by the PGW/GGSN for the UE. The WIFI AP is required to provide a split-horizon function, where there is no local switching on the AP, and all communication to/from any AP is via WLAN-GW. The WLAN-GW implements proxy-ARP and forwards all received traffic from the UE into the GTP tunnel. In the future, the default-GW address to be returned to the UE could be obtained in a PCO from the PGW/GGSN. The GTP-U processing of data packets is done in the IOM.

11.12.2 Location Notification in S2a

This feature adds support on WLAN-GW for reporting UE's WLAN location (TWAN Identifier IE) and cellular location (ULI IE) over S2a interface to PGW and UE's cellular location (ULI IE) to GGSN (over Gn interface). Location information is useful for charging on PGW/GGSN.

11.12.2.1 WLAN Location over S2a

The WLAN location information consists of the *TWAN Identifier IE* as described in 29 274 V11.6.0 (2013-04) and is sent in GTPv2 "create session request" message. If present, this IE carries BSSID (MAC address of the AP) and the SSID. WLAN-GW learns the AP's MAC@ from calling-station-id attribute in the RADIUS messages from the AP (both authentication and accounting messages) or from circuit-id in DHCP DISCOVER or REQUEST messages. In this release, the IE is only sent at session creation time. Therefore, it reports location on initial attach, on handover from LTE to WIFI, and on AP mobility across WLAN-GWs. Mobility across APs anchored on the same WLAN-GW does not result in location update. 3GPP release 11 does not define location update mechanism for S2a.

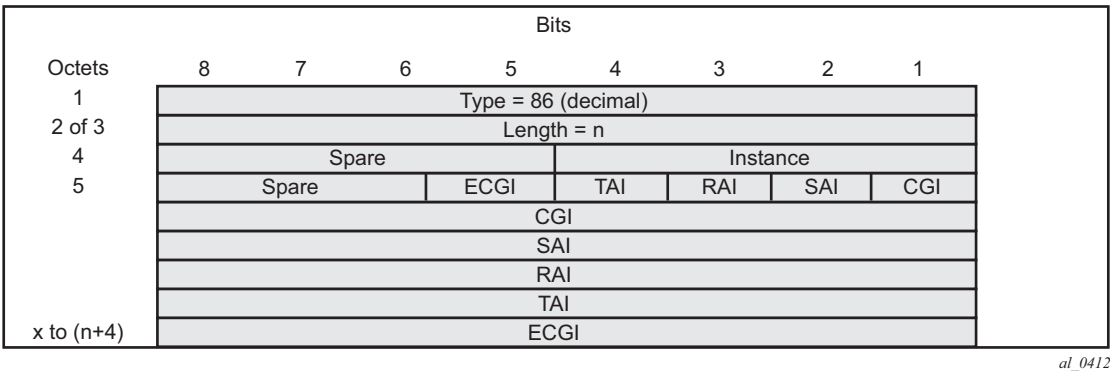

By default, location is not reported. It can be enabled via CLI.

```
config>subscriber-mgmt>wlan-gw>  
  mgw-profile "pgw-west-mn01"  
    [no] report-wlan-location
```

11.12.2.2 Cellular Location over S2a

The "User Location Info" IE is included in "Create Session Request" and is described in 3GPP TS 29.274 version 8.1.1 Release 8. The encoding for individual location identifiers (CGI, SAI, RAI, TAI, and ECGI) is also defined in the same reference (as shown in [Figure 173](#)).

Figure 173 User Location Information

The AP’s MAC@ and IP@ are provided to AAA server in RADIUS messages during EAP authentication and accounting. If AAA provides the cellular location (corresponding to this AP) in 3GPP attribute *3GPP-User-Location-Info* in access-accept, and location reporting is enabled via CLI. The ULI IE will be included in GTPv2 “create session request”. The *3GPP-User-Location-Info* attribute is described in 3GPP TS 29.061 v9.3.0.

11.12.2.3 Cellular Location over Gn Interface

The “User Location Info” IE (as shown in Figure 174) can be included in create-pdp-context message as described in 3GPP TS 29.060 V10.1.0. The geographic location type field describes the type of location included in the “Geographic Location” field that follows. The location can be CGI (cell global identification), SAI (service area identity), or RAI (routing area identity). The formats for these location identifiers are defined in the same reference *3GPP TS 29.060 V10.1.0*.

Figure 174 User Location Information IE

AP MAC address and SSID is reported to AAA (including changes on mobility). AAA can then specify the ULI IE contents based on static mapping of AP’s MAC address to one of the cellular location types (CGI, SAI or RAI). AAA should provide the cellular location in 3GPP attribute *3GPP-User-Location-Info* (below) in access-accept. The attribute is described in 3GPP TS 29.061 v9.3.0.

In case a UE moves to a different WLAN-GW, UE is authenticated based on data-trigger. In this case, the AAA server can provide the WLAN location (AP's MAC@ and SSID) in called-station-ID attribute and cellular location in 3GPP-User-Location-Info attribute. The WLAN location is then encoded in TWAN identifier in "create session request" message, and the cellular location is encoded in the ULI IE.

11.12.2.4 Operational Support

The following command shows state of location reporting (enabled/disabled).

```

11.13 Migrant User Support

“Migrant users” are UEs that connect to an SSID, but move out of the range of the access-point before initiating or completing authentication. For open-SSIDs, a migrant user may stay in the range of the access-point just enough to get a DHCP lease from the WLAN-GW. In real WIFI deployments with portal authentication, it has been observed that a large percentage of users are migrant, such as get a DHCP lease but do not initiate or complete authentication. Prior to this feature, an ESM host is created when DHCP completes. This results in consumption of resources on both CPM and IOM, limiting the ESM scale and performance for fully authenticated active users. This feature adds support to only create an ESM host after a user has been fully authenticated, either via web portal or with a AAA server based on completing EAP exchange. In addition, with this feature L2-aware NAPT is enabled on the ISA, such that each UE gets the same shared configured inside IP@ from the ISA via DHCP. Until a user is authenticated, forwarding of user traffic is constrained (via policy) to only access DNS and portal servers. Each user is allocated a small number of configured NAT outside ports to minimize public IP address consumption for unauthenticated users. Once the user is successfully authenticated, as indicated via a RADIUS COA on successful portal authentication, an ESM host is created, and the L2-aware NAT is applied via a normal per-subscriber NAT policy. The inside IP address of the user does not change. The outside IP pool used is as per the NAT policy, and the L2-aware NAT could be 1:1 or NAPT with larger number of outside ports than in the un-authenticated phase. If a user is already pre-authenticated (for example, if RADIUS server remembers the MAC@ of the UE from previous successful portal authentication), then the initial access-accept from RADIUS will trigger the creation of the ESM host.

Migrant user support is only applicable to EAP based closed SSIDs when RADIUS-proxy is not enabled on WLAN-GW. This is described in [Migrant User Support with EAP Authentication](#).

11.13.1 Migrant User Support with Portal-Authentication

11.13.1.1 DHCP

Based on DHCP and L2 NAT configuration on the ISA, IP address is assigned to the user via DHCP. A different DHCP lease-time can be configured for an un-authenticated user and an authenticated user for which an ESM host has been created. DHCP return options, for example, DNS and NBNS server addresses can be configured. This configuration can be per wlan-gw group interface or per VLAN

range (where a VLAN tag corresponds to an SSID). Once the DHCP ACK is sent back to the UE from the ISA, the UE will be created on the ISA in “migrant (or unauthenticated) state”. ARP requests coming from the UE in migrant state will be responded to from the ISA. The authentication to RADIUS is triggered on receiving first L3 data-packet as opposed to on DHCP DISCOVER.

11.13.1.2 Authentication and Forwarding

The authentication is initiated from RADIUS client on the ISA anchoring the user, based on an isa-radius-policy (configured under aaa) and specified on the wlan-gw group-interface. The initial access-accept from RADIUS can indicate if a user needs to be portal authenticated or is a pre-authenticated user. The indication is based on inclusion of a “redirect policy” applicable to the user, in a VSA (Alc-Wlan-Portal-Redirect, type = string). The access-accept can also include a redirect URL VSA (Alc-Wlan-Portal-Url, type = string) for the user. An empty Alc-Wlan-Portal_redirect VSA forces the use of locally configured redirect policy. Also, if neither of the above two VSAs are included, then this indicates a “pre-authenticated user”, and an ESM host is created for the subscriber with subscriber-profile and other subscriber configuration from access-accept, and from here normal ESM based forwarding occurs for the subscriber.

However, if a user needs portal authentication (as indicated in access-accept), then while the user is pending authentication, forwarding is restricted to DNS and portal servers via the redirect policy. The redirect policy is an IP ACL that restricts forwarding based on IP destination, destination port, and protocol, and also specifies http-redirect for http traffic that does not match any of the forwarding rules. The URL for re-redirect is configured in the redirect policy or can be provided in authentication-accept. A maximum of 16 redirect policies can be created in the system, with a maximum of 64 forward rules across all redirect policies. During this “authentication pending” phase all forwarded traffic is subjected to L2-aware NAT on the ISA. The NAT policy to use for these users can be configured on the wlan-gw interface or per VLAN range under the wlan-gw interface. After an access-accept has been received from RADIUS for such a user, the next http packet triggers a redirect function from the ISA, and an http 302 is sent to the client. The redirect can be configured to append original-URL, subscriber’s MAC address and IP address to the redirect URL sent back in http 302. The client presents its credentials to the portal and once it is successfully authenticated, a COA is generated from the RADIUS server (triggered by the portal). The COA message triggers creation of an ESM host with the subscriber configuration contained in the COA such as subscriber-profile, SLA-profile, NAT-profile and application-profile. From this point normal ESM based forwarding occurs for the subscriber.

See, [Migrant User NAT Configuration](#) for configuration information related to migrant users.

11.13.2 Migrant User Support with EAP Authentication

Migrant user support can only be used for closed SSIDs when there is no RADIUS-proxy configured on WLAN-GW. If no RADIUS proxy is configured, then initial RADIUS request carrying EAP from the AP is normally forwarded to a RADIUS server. The RADIUS exchange is between AP and the AAA server, and no information from EAP authentication is cached on the WLAN-GW. The subsequent DHCP DISCOVER after successful EAP authentication is received on the ISA. However, for subscriber that needs to be GTP tunneled to PGW/GGSN, the DHCP is forwarded to the CPM, where it triggers a RADIUS authorization. RADIUS correlates the MAC address with calling-station-id from EAP authentication for the user. GTP tunnel initiation, and ESM host creation then follows after receiving an access-accept. However, for a “local-breakout” subscriber DHCP and L2-aware NAT is handled on the ISA (as in the case for migrant users with portal based authentication). Shared inside IP address can be handed out to each subscriber. The first L3 packet triggers MAC address based RADIUS authorization from the ISA. RADIUS server can correlate the EAP authentication with the MAC address of the user and send an access-accept. This triggers ESM host creation as normal.

For closed SSIDs with EAP authentication, if a RADIUS proxy function is configured on WLAN-GW, then the initial EAP authentication from the AP is processed by the RADIUS-proxy on the CPM, and is forwarded to the RADIUS server based on configured authentication policy. Based on authentication response, ESM host creation with local DHCP address assignment or GTP tunnel initiation proceeds as usual.

11.13.3 Data Triggered Subscriber Creation

With **data-triggered-ue-creation** configured under wlan-gw group interface or per VLAN range (such as, per one or more SSIDs), the first UDP or TCP packet received on WLAN-GW ISA from an unknown subscriber (with no prior state, such as an unknown MAC address) will trigger RADIUS authentication from the ISA. The authentication is based on configured isa-radius-policy (under aaa context). If RADIUS authentication succeeds, then ESM host is created from the CPM. The ESM host can get deleted based on idle-timeout. Data-triggered authentication and subscriber creation enables stateless inter WLAN-GW redundancy, as shown in [Figure 175](#). If the AP is configured with a backup WLAN-GW address (or FQDN), it can tunnel subscriber traffic to the backup WLAN-GW, when it detects failure of the primary WLAN-GW (based on periodic liveness detection). With “data-triggered-ue-creation” configured, the first data packet results in authentication and ESM host creation on the backup WLAN-GW. If the subscriber had obtained an IP address via DHCP with L2-aware NAT on the primary WLAN-GW, it can retain it with L2 aware NAT on the backup WLAN-GW. The NAT outside pool for the subscriber changes on

the backup WLAN-GW based on local configuration. For a subscriber that needs to be anchored on GGSN/PGW (as indicated via RADIUS access-accept), RADIUS server will return the IP address of PGW/GGSN where the UE was anchored before the switch-over. GTP tunnel is then signaled with “handover indication” set. The PGW/GGSN must return the requested IP address of the UE, which is the address with which the UE originated data packet that triggered authentication.

The same data-triggered authentication and subscriber creation is also used to support inter WLAN-GW mobility, such as when a UE moves from one AP to another AP such that the new AP is anchored on a different WLAN-GW. This is shown in [Figure 176](#).

Figure 175 N:1 WLAN-GW Redundancy Based on “Data-Triggered” Authentication and Subscriber Creation

11.14 Distributed Subscriber Management (DSM)

With this feature, once the UE is successfully authenticated (portal, auto-signed-in, or EAP), the corresponding subscriber can be created on the anchor ISA, and both control plane and forwarding plane for the subscriber are handled on the ISA. This mode of subscriber management is henceforth referred to as **Distributed Subscriber Management (DSM)**.

Prior to this feature, only ESM is supported for WLAN UEs, where the ESM host state is created on the IOM/IMMs from the CPM (triggered by the ISA on successful authentication). With ESM, the initial DHCP process and authentication could be triggered from the ISA (based on a per VLAN-range configuration for DHCP) under the group-interface with of type **wlangw**. However, control plane operations after the ESM host creation (such as accounting and DHCP renewals) are handled on the CPM.

With DSM, in addition to initial DHCP and authentication, once the subscriber state exists on the anchor ISA, accounting and DHCP renewals are also handled from the anchor ISA for the UE. This allows a higher UE scale and better control plane performance (including DHCP transactions per second, rate of authentications, and web redirects) due to load-balancing amongst set of ISAs in the WLAN-GW group. With DSM, the UE data-plane functions (such as per UE IP filtering, ingress/egress policing, legal intercept, per UE counters, and web-redirect) are performed on the ISA.

The decision to create an authenticated UE as an ESM or DSM UE can be controlled from RADIUS via inclusion of *Alc-Wlan-Ue-Creation-Type* VSA. The VSA can be included in access-accept for a UE that is auto-signed-in (for example, it does not need web redirect to portal), or in a COA message triggered to remove web redirect for a UE after successful portal authentication. The VSA is described in the RADIUS guide. If *Alc-Wlan-Ue-Creation-Type* is not present in access-accept (for auto-signed UE) or in the COA message (for UE creation of portal authenticated UE), then the UE is created as an ESM host. In this release DSM is not supported for dual-stack UEs or UEs which require a GTP host. If *Alc-Wlan-Ue-Creation-Type* indicates a DSM UE then any IPv6 or GTP related parameters in access-accept or COA will be ignored, and the UE will be created as a DSM host. *Alc-Wlan-Ue-Creation-Type* cannot be changed mid-session via COA. A COA containing *Alc-Wlan-Ue-Creation-Type* for an existing UE does not result in any change of state, and is NACK'ed.

11.14.1 DHCP

Based on DHCP and L2 NAT configuration on the ISA, the configured IP address (l2-aware-ip-address configured under vlan-range or default vlan-range) is assigned to the user via DHCP. A different DHCP lease-time can be configured for an un-authenticated and an authenticated user for which an ESM or DSM host has been created. DHCP return options, for example, DNS and NBNS server addresses can be configured. This configuration can be per soft-wlan-gw group interface (by explicitly configuring it under vlan-range default), or per VLAN range (where a VLAN tag corresponds to an SSID). By default, for open SSIDs, DHCP DORA is completed, and authentication request is sent to AAA server only on reception of the first Layer 3 packet. However, with a **authenticate-on-dhcp** command configured under vlan-range (default or specific range), authentication can be triggered on received DHCP DISCOVER or REQUEST when no UE state is present. If UE anchoring on GGSN/PGW is required, then **authenticate-on-dhcp must** be enabled, since the decision to setup GTP tunnel (in which case the IP@ for the UE comes from the GGSN/PGW) is based on RADIUS response.

In order to support unique inside IP addresses, the ISA Pool Manager can be used. Pools are allocated to each ISA in large blocks, requiring an IPv4 subnet with prefix-length 16. From this prefix, the subnet address (x.x.0.0), broadcast address (x.x.255.255), and gateway address (x.x.0.1) are reserved and not allocated to UEs, reducing the total number of available addresses by three. NAT pools are only available in non-retailer subscriber interfaces. Any retail service ID derived from configuration or AAA is only used for IPv6 pool selection and is ignored for IPv4 NAT pools. Forwarding in a different VRF can be achieved by selecting a different NAT policy and outside VRF.

11.14.2 Authentication and Accounting

The authentication is initiated from RADIUS client on the ISA anchoring the user, based on an isa-radius-policy (configured under **aaa**) and specified on the wlan-gw group-interface. This support exists in prior releases and is described in [Authentication and Forwarding](#). The auth-policy can contain up to ten servers, five of which can be for authentication and all ten can be COA servers.

In order to generate accounting updates for DSM UEs, an accounting policy (type isa-radius-policy) must be configured under the **aaa** node and specified under **vlan-range (default or specific range)** on the wlan-gw interface. Accounting for DSM UEs includes **accounting-start**, **accounting-stop** and **interim-updates**. Interim-update interval is configurable under vlan-range on wlan-gw interface. The user-name format to be included in RADIUS messages is configurable in the auth-policy and accounting-policy via the **user-name-format** command. By default, the user-name contains the UE MAC address, but can be configured to include the UEs MAC address and IP address, or circuit-id or DHCP vendor options. If **authenticate-on-dhcp** is enabled, then the IP address for the UE is not known prior to authentication, and, if the user-name is configured to contain both MAC and IP address, then only the MAC address will be included.

The accounting-policy can be configured with attributes to be included in the accounting messages. The details of the attributes are covered in the *7750 SR-OS RADIUS Attributes Reference Guide*. The attributes are included here for reference.

```

exit
```

The **isa-radius-policy** for auth/COA and accounting specifies the server selection method for the servers specified in the policy with respect to load-balancing and failure of one or more servers. The three methods implemented include:

- Direct — Specifies that the first server will be used as primary for all RADIUS messages, the second server will be used as secondary (that is, used for all RADIUS messages if primary server fails), and so on.
- Round-Robin — RADIUS messages across accounting-sessions are distributed in a round-robin manner amongst the list of configured servers. All accounting messages for a given session are sent to the selected server for that session, until that server fails. If a server fails, then the sessions targeted to that server are distributed in a round-robin manner amongst the remaining servers. If the failed server comes back up, the sessions that were originally assigned to the failed server revert to the original server.
- Hash — Server is picked via hash on UE MAC. The hash list consists of all configured servers that are up. If a server fails, then the UEs hashed to that server are re-hashed over the remaining servers that are up.

If a response is not received for a RADIUS message from a particular server for a configurable timeout value (per server), and the time elapsed since the last packet received from this RADIUS server is longer than this configured timeout value, then the server is deemed to be down. Periodically an accounting-on message is sent to a server that is marked as down, to probe if it has become responsive. If a response is received then the server is marked as up.

11.14.2.1 DSM Data-Plane

In this release NAT on the anchor ISA is required for forwarding of traffic to/from a DSM UE. There is no UE state in the IOM/IMM for a DSM UE. The downstream forwarding is based on FIB lookup that should match a route corresponding to the NAT outside pool, and get the downstream traffic to the right anchor ISA, where NAT is performed for the UE. The inside IP address assigned to the UE is the configured l2-aware-ip-address on the vlan-range (default or specific range) under wlan-gw interface. Therefore every UE corresponding to the default or specific vlan-range will get the same inside IP@. The NAT is L2-aware, and uses UE MAC to de-multiplex.

11.14.3 IP Filtering

Filtering based on protocol, destination IP, destination port or any combination is supported for traffic to and from the UE. The match entries and corresponding actions can be specified within the **dsm-ip-filter** which can be created in the **subscriber-mgmt>wlan-gw>dsm** context. The filter can be associated with a vlan-range (default or specific vlan-range) on wlan-gw interface, in which case all subscribers associated with the vlan-range will be associated with an instance of this filter.

The supported filter actions include drop and forward. The first match will cause corresponding action to be executed and no further match entries will be executed. In case there is no match or no action configured for a match, configurable default action for the filter will be executed. The filter can be overridden on a per UE basis via RADIUS access-accept or COA. The new VSA *Alc-Wlan-Dsm-Ip-Filter* is defined for specifying the per UE filter from RADIUS. The VSA is defined in the RADIUS guide.

```

        exit
      exit
    exit
  exit
exit
-----
```

11.14.3.1 Policing

Per UE policing for both ingress and egress direction is supported. Policers can be created under **subscriber-mgmt>wlan-gw>dsm**. The policers can be of type single-bucket (PIR) bandwidth limiting or dual-bucket (PIR and CIR) bandwidth limiting. In this release only policer action supported is permit-deny i.e. non-conformant traffic is dropped, as opposed to marked out-of-profile. The administrative peak and committed rates and peak and committed burst sizes are configurable. For single-bucket bandwidth policers, cir and cbs are not applicable, and only pir and mbs are configurable.

```
*A:vsim>config>subscr-mgmt>wlan-gw>distributed-sub-mgmt>dsm-policer# info detail
-----
no description
action permit-deny
cbs 100
mbs 200
rate 1000 cir 500
```

The policers can be associated with a vlan-range (default or specific vlan-range) on wlan-gw interface, in which case all subscribers associated with the vlan-range will be associated with an instance of these policers. These ingress and egress policers can be overridden on per UE basis via RADIUS access-accept or COA. The new VSAs *Alc-Wlan-Dsm-Ingress-Policer* and *Alc-Wlan-Dsm-Egress-Policer* are defined for specifying the per UE policers from RADIUS. The VSAs are defined in the *7750 SR-OS RADIUS Attributes Reference Guide*. If the policers specified in access-accept are not found the message is dropped. If the policers specified in COA are not found, a NACK is sent back.

```
*A:vsim>config>service>vprn# info

exit
-----
```

11.14.3.2 Lawful Intercept (LI)

LI can be triggered for a DSM UE LI via CLI or RADIUS, and is performed post-NAT. Only routable encaps (IP/UDP/LI-shim) and IP-only mirror-dest are supported. A maximum of 2K DSM UEs per-chassis can be under LI simultaneously. LI mirror dest (service in which mirrored packets are injected) along with other required mirror information (mirror-dest type, encapsulation-type e.g. ip-udp-shim, and encapsulation information e.g. IP and UDP header information) is configurable. A DSM UE identified by its MAC address can be associated with the mirror-dest (service in which mirrored packets for the host are injected) via li-source command. For routable encapsulation (IP/UDP/LI-Shim), the session-id and transaction-id to be inserted in the LI-Shim are configured under **li-source**.

```
A:Dut-1>config>mirror# info
-----
mirror-dest 60000 type ip-only create
  encaps
    layer-3-encap ip-udp-shim create
      gateway create
        ip src 1.1.1.1 dest 2.2.2.2
        udp src 2048 dest 2049
      exit
    exit
  exit
  no shutdown
exit

-----
A:Dut-1>config>li# info
-----
li-source 60000
  wlan-gw
    dsm-subscriber mac 00:00:00:07:02:03
    intercept-id 10000
    session-id 20000
  exit
  no shutdown
exit
```

LI can be enabled or disabled from RADIUS via inclusion of the *Alc-LI-Action* VSA in access-accept or COA. The *Alc-LI-Destination* VSA is required to indicate the mirror-dest service that the DSM UE under LI is associated with. The Intercept-Id and Session-Id for a DSM UE can be provided from RADIUS access-accept or COA via inclusion of Alc-LI-Intercept-Id and Alc-LI-Session-Id VSAs. These LI related VSAs are described in the RADIUS guide.

Information for a particular li-source, and its associated mirror-dest can be shown via CLI.

11.14.3.3 Data-Triggered UE Creation

Similar to data-triggered UE creation with ESM, a DSM UE can also be created based on data-triggered authentication discussed in [Data Triggered Subscriber Creation](#). The decision to create ESM versus DSM UE is based on the value of RADIUS VSA Alc-Wlan-Ue-Creation-Type present in the access-accept message. The data-triggered authentication and UE creation if configured provides for WLAN-GW IOM redundancy. The DSM UE is created on the standby ISA based on successful data-triggered authentication. Also, inter-chassis redundancy is supported for DSM UE based on data-triggered authentication, and is identical to ESM (as described in [Data Triggered Subscriber Creation](#)).

11.14.4 Idle-Timeout and Session-Timeout Management

The per UE idle-timeout value can be provided in RADIUS access-accept or COA for a DSM UE in standard Idle-Timeout attribute. The minimum idle-timeout allowed is 150 seconds. The idle-timeout is enforced on the ISA for a DSM UE. If there is no data to/from a UE for up to idle-timeout value, the UE is removed and accounting-stop is sent. Subsequently, if a UE re-associates and connects to an open SSID on an AP, and has an IP address with a valid lease, then the first data packet from the UE triggers authentication. Successful authentication results in creation of DSM UE.

To improve idle-timeout behavior an optional SHCV check can be performed after idle-timeout expires. This check verifies connectivity to all of the DHCP, DHCPv6 and /128 SLAAC addresses using ARP and/or NDP. While the check is performed for every address, the result is applied to the whole UE. The UE is only deleted when verification of all addresses fails. When at least one connectivity verification succeeds the UE and all of the allocated addresses are kept and the idle-timeout process is restarted.

The per UE session timeout value can be provided in RADIUS access-accept or COA in standard Session-Timeout attribute. The value is interpreted as “absolute value”, and the UE is unconditionally deleted regardless of activity. The minimum allowed value for session-timeout is 300 seconds.

11.14.5 Operational Commands

The following shows the command usage to dump information on UE under LI (only allowed to users with LI privilege).

```
A:Dut-1# tools dump li wlan-gw ue
```

11.14.6 Pool Manager

To support allocations of unique IP addresses each ISA is assigned pools from a centralized pool manager on the CPM. The ISA can subsequently assign addresses from these pools to UEs, but this state is not synchronized back to the CPM. Different applications have different pools, for example, SLAAC and DHCPv6 IA_NA cannot share a single pool. To support Wholesale/Retail scenarios a pool-manager can be configured per subscriber-interface.

The allocation of additional pools and freeing up unused pools is based on configurable high and low watermarks. When the usage level of all pools combined on an ISA reaches the high watermark, a new pool is allocated. When the usage level of a single pool reaches zero and the usage level of the other pools combined is below the low watermark, this pool is freed.

In the case of redundancy the pool manager will signal the pools that were allocated to the failed ISA back to the new active ISA. These pools can no longer be used to allocate new addresses because allocations are lost. However, these can still be used to forward traffic based on data-triggered UE creation. This is supported both for IOM redundancy and Active/Standby WLAN-GW redundancy. The new active ISA will also receive new pools that it can use for new allocations.

The Pool Manager uses DHCPv6 Prefix Delegation to allocate pools to the ISAs. Each ISA is represented by a separate DHCPv6 Client ID. These clients request fixed prefix sizes to accommodate up to 64K UEs. In the case of Active/Standby redundancy the Pool Manager uses a DHCPv6 Lease Query Message to retrieve the prefixes that were allocated to the failed WLAN-GW. In order to identify the correct PD leases in the DHCPv6 server, a configurable virtual-chassis-name is added to the DHCPv6 client-id, this value should be identical on both WLAN-GWs and unique otherwise. The Pool Manager will always send out a DHCPv6 Relay message and supports up to eight DHCPv6 servers.

IPv4 pools are supported by encoding an IPv4 subnet into an IPv6 prefix. The least significant 32 bits of the prefix are treated as an IPv4 address and the allocated prefix-length is subtracted with 96 to obtain an IPv4 prefix length. It is recommended to use the special IPv6 prefix "::ffff:/96" to provision these pools.

```

```

11.14.7 DHCPv6 and SLAAC

DHCPv6 and SLAAC support can be configured per VLAN range. Authentication can be triggered by a Router Solicit, DHCPv6 or DHCP packet but will only be triggered once per UE. Each UE can be assigned a unique DHCPv6 IA_NA address (/128) or SLAAC prefix (/64) from the ISA pools. The IPv6 pools are installed by the centralized pool manager. SLAAC privacy extensions are supported and up to three /128 SLAAC addresses can be learned via either Duplicate Address Detection or upstream data. Wholesale/retail is supported (IPv6 only) both via radius and per vlan-range CLI, the applicable pool is selected from the retailer service. ESM and DSM IPv6 are not supported in the same vlan-range context.

```
A:system>config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range# info
-----
...
authenticate-on-dhcp
...
dhcp6
    active-preferred-lifetime hrs 1
    active-valid-lifetime hrs 1
    no shutdown
exit
slaac
    active-preferred-lifetime hrs 1
    active-valid-lifetime hrs 1
    no shutdown
exit
...
-----
```

Configuration of other DHCPv6/SLAAC parameters, such as server DUID and RA flags is taken from the **wlan-gw group-interface** configuration. For DSM only the configuration of the **wlan-gw group interface** applies, the retailer interface cannot override this configuration.

```
A:system>config>service>vprn>sub-if>grp-if>ipv6# info
-----
router-advertisements
    other-stateful-configuration
    prefix-options
    autonomous
exit
exit
dhcp6
    proxy-server
        server-id duid-en string "example_duid"
exit
exit
```

A subset of DHCPv6 options retrieved by the pool-manager in the PD process is reflected in DHCPv6 towards the client. For IA_NA leases these are included in the associated DHCPv6 messages. For SLAAC allocations, the DNS option can be reflected in the Router Advertisement and all options can also be reflected in a stateless DHCPv6 Information Reply message.

When using a captive portal, different valid/preferred lifetimes can be configured for authenticated and un-authenticated UEs. The DHCPv6 lease time will be equal to the applied valid-lifetime and can be extended via the regular renew process. SLAAC lifetime is equal to the applied valid-lifetime and will be extended when sending an RA including the SLAAC prefix. To avoid infinite SLAAC allocations, when sending an unsolicited RA, SHCV will be performed for all learned /128 addresses. If SHCV fails for all addresses, the unsolicited RA will not contain the SLAAC prefix and the SLAAC lifetime will not be extended.

In redundancy scenarios the new active ISA will migrate the leases in the old pools as soon as possible to a lease in the new pools. For SLAAC this is done by sending an unsolicited RA to deprecate the old prefix (lifetimes 0) and include a new prefix. For DHCPv6 this is done during the first Renew, that will again deprecate the old address (lifetimes 0) and include a new address in the same IA.

11.14.8 Call Trace

The call trace feature is an enhanced debugging feature that allows an operator to monitor the full control plane (like the setup) of a single entity. When call trace is enabled all protocols related to this entity are captured. This allows an operator to easily debug problematic entities (like a WiFi UE) instead of debugging and verify every separate protocol (like DHCP, ARP, RADIUS, DHCPv6, ICMPv6, and so on). Call trace can present the captured packets for further processing in one of following ways.

- Send the captured packets as live output over a tunnel to an external monitoring device.
- Store as a PCAP on a pre-provisioned compact-flash. If the system already uses the compact flash intensively, for example, for ESM persistency, this method is not recommended in a live network.

For DSM, call trace can be enabled on a per UE basis by providing the UE's exact MAC address. When enabled, all protocols as seen by the ISA will be traced.

11.15 Distributed RADIUS Proxy

The distributed RADIUS proxy acts just like the regular RADIUS proxy but runs on an ISA and is designed for high scale and high performance. It can handle a high number of RADIUS transactions, therefore it is able to keep up with EAP authentications that consists of many RADIUS transactions (EAP-PEAP) and all the accounting messages sent by an Access Point for a particular UE. The distributed RADIUS proxy is designed to handle the scale and performance of Distributed Subscriber Management (DSM) but can also be used as a performance improvement for Enhanced Subscriber Management (ESM). All common server-selection mechanisms are supported (direct, round-robin, hash-based) and both IPv4 and IPv6 RADIUS clients can communicate with the proxy. Important differences with the CPM based proxy are no IPv6 support towards the RADIUS server and no python support on any of the interfaces.

The distributed proxy also supports caching an access-accept to aid authentication of Layer 3 setup (DHCP/SLAAC/DHCPv6). After UE creation the cache supports tracking of both accounting and authentication messages. Contrary to the CPM-based RADIUS proxy the key used in the cache is always the calling-station-id attribute and it is expected to contain the UE MAC address, as specified in RFC 3580, *IEEE 802.1X Remote Authentication Dial In User Service (RADIUS) Usage Guidelines*. Accounting-on and accounting-off messages are not supported. The RADIUS proxy cache works with both ESM and DSM UEs.

For caching to work, the distributed proxy makes sure that all packets are routed via the anchor ISA tied to the UE. An AP will send a RADIUS packet to the radius-proxy IP address shared by all ISAs, the WLAN-GW will forward the packet to a distributor ISA based on the source IP address of the radius packet. That ISA then looks for the calling-station-id and forwards the packet to the correct anchor-isa to handle proxy functionality and caching. If no calling-station-id is found (such as acct-on/acct-off), the packet is always forwarded to a fixed ISA that is chosen at startup. The chosen ISA will forward the packet with a per-ISA IP as source-ip, this source-ip is assigned at startup from the range configured under **configure aaa isa-radius-policy policy-name**. From server to client the packet is sent back to that IP address and therefore immediately arrives at the correct anchor ISA, which subsequently forwards the packet straight to the AP without an additional ISA pass through.

Figure 177 Distributed RADIUS Packet Forwarding

The following is a distributed proxy configuration example.

```

11.15.1 Enhanced Subscriber Management

For ESM support `authenticate-on-dhcp` must be enabled under **`configure>service>vprn|ies svc>subscriber-interface sub-if>group-interface grp-it>wlan-gw vlan-tag-ranges range start start end end`**. When receiving DHCPv4 the ISA will send the DHCP message and the cached access-accept to the CPM which will further process the setup sequence. On the CPM a regular radius authentication policy should be picked up for the UE either through configuration on the group-interface or via the LUDB. Typically this policy will reflect the ISA-policy. This policy will be used as a context to store the access-accept on the CPM for 10s.

IPv6 hosts are supported but can only be authenticated after DHCPv4 has triggered the promote from ISA to CPM. When `ipoe-linking` is enabled a SLAAC host will be created together with the DHCPv4 host as usual. If an additional IPv6 host would arrive after the 10s timeout, a regular radius authentication will be started from the CPM using the previously mentioned radius policy.

When tracking is enabled, the radius messages are handled on the ISA and specific tracking actions (`mobility`, `delete`) are sent directly to the CPM

11.15.2 Distributed Subscriber Management

For DSM support the radius-proxy cache is directly tied to the UE record on the anchor ISA and is automatically used during UE creation. Tracking immediately executes the associated actions (`mobility`, `timed host-delete`) on the UE record. If a cached accept would time out before DHCP is received, a regular radius authentication will be used using the configuration under **`configure>service>vprn|ies svc>subscriber-interface sub-if>group-interface grp-it>wlan-gw vlan-tag-ranges range start start end end>authentication`**.

11.15.3 VLAN Awareness

The distributed RADIUS proxy optionally allows inclusion of the `Alc-WLAN-SSID-VLAN` attribute in an Access-Accept message. When this attribute is received, any subsequent traffic, including control plane traffic, must match the VLAN or VLAN-range, otherwise it will be dropped. When an Access-Accept message with this attribute is received for a UE, one of the following scenarios may occur.

- The VLAN in authentication matches the current UE VLAN or VLAN-range. This is assumed to be a re-authentication within the same SSID and no further action is taken.
- The VLAN in authentication does not match the current VLAN or VLAN-range. It is assumed that the UE moved between SSIDs and that this is a new initial authentication. The UE is returned to an authenticated-only state from which the UE can be recreated with the correct new SSID parameters. If the UE was in the ESM or DSM state, it is gracefully removed. Any allocated IP addresses are released and final accounting data is sent.

The DRP checks on the exact VLAN or VLAN-range based on configuration of inter-VLAN mobility. When inter-VLAN mobility is enabled, it is assumed that an SSID maps to a VLAN-range instead of a single VLAN, and all comparisons are adapted accordingly. Additionally, when receiving an Access-Accept message for a UE with a different VLAN in the same VLAN range, the UE will start using the new VLAN to send downstream traffic.

This is recommended for deployment models where there are multiple SSIDs. Without specifying the VLAN, every authentication for a UE would be considered as a re-authentication for the same SSID and would make no changes to the WLAN-GW state. After authentication, the UE would send control-plane messages on the new SSID with a different VLAN or VLAN-range. The WLAN-GW would see this as a non-seamless change and trigger SHCV to remove the UE. Only after the UE is removed would control-plane traffic on the new VLAN or VLAN-range succeed, and it would also require an additional authentication trigger.

11.15.4 Operational Commands

The following commands will display all statistics related to the radius-proxy, both for communication towards the client and for communication towards the server.

show router router-id radius-proxy-server server-name statistics

clear router router-id radius-proxy-server server-name statistics

Example output:

```
*A:Dut-C# show router 50 radius-proxy-server "radius_proxy_isa" statistics
...
Group 1 member 3
-----
Rx packet                               : 2

11.16 WLAN-GW 1:1 Active-Backup Redundancy

This feature provides support for 1:1 inter WLAN-GW active-backup redundancy. The failure detection and switchover mechanism is contained in WLAN-GWs, and there is no dependency on the AP to detect failure of WLAN-GW and switch traffic to tunnel endpoint on a different WLAN-GW. There is also no dependency on NAT or a particular flavor of NAT on WLAN-GW. If local DHCP servers are used for address allocation, then DHCP leases in the server are synchronized to the backup WLAN-GW via MCS. However, ESM state for the UE is created on the backup WLAN-GW based on data-triggered authentication after switchover. The granularity of switchover is subscriber-interface. Both WLAN-GWs are required to be configured with the same tunnel endpoint address. Also, the subscriber-interfaces on both WLAN-GW must be configured with the same subnets. Only the WLAN-GW that is deemed as active announces the tunnel endpoint address in routing towards the APs.

Active-backup decision is based on monitor and export route concept (same as what is used with NAT redundancy). Monitor and export routes are configured on the subscriber-interface on both WLAN-GWs. These should be complementary with respect to the ones on the other WLAN-GW. When WLAN-GW group goes up operationally, check is made in the FIB for presence of monitor route (which is the route exported by the other WLAN-GW). If it is not found, then the WLAN-GW assumes active state with respect to ownership of the tunnel end-point address, and the tunnel end-point address is announced in IGP towards the AP (subject to configured IGP and routing policy). The active WLAN-GW also announces the aggregate subscriber subnets upstream in routing. When WLAN-GW group comes up operationally, and detects the monitor route in the FIB, it assumes standby state with respect to the tunnel endpoint address. It does not announce the tunnel endpoint or the subscriber subnets in routing.

Each WLAN-GW will need to track the monitor route in the FIB. If the monitor route is no longer in the FIB, and the WLAN-GW is in standby state, it will transition to active, and announce the tunnel end-point towards APs, and subscriber subnets upstream. This will draw the traffic from the AP to the backup WLAN-GW. Redundancy will be non-revertive. The monitor and export routes are configured on the subscriber-interface.

```
config>service>ies>sub-if
wlan-gw
redundancy
    [no] export <ip-prefix/length>
    [no] monitor <ip-prefix/length>
exit
exit
```

If the number of operationally up WLAN-GW IOMs in wlan-gw group drops below the number of active IOMs configured, the WLAN-GW group will be brought down (based on the configuration **oper-down-on-group-degrade** command under wlan-gw interface), and switchover procedures for the subscriber-interface are triggered (export route, tunnel endpoint address and subscriber subnets are withdrawn from routing).

```
config>service>vprn>sub-if>grp-if
config>service>ies>sub-if>grp-if
wlan-gw
[no] oper-down-on-group-degrade
```

The switchover can also be triggered administratively on per subscriber-interface basis using the **tools perform** command.

```
*A:vsim-07-cpm# tools perform wlan-gw redundancy force-switchover service <service-id> interface <ip-int-name>
```

11.16.1 DHCP Server Redundancy

1:1 redundancy provided with this feature only handles complete failure of WLAN-GW (either due to chassis reboot or due to number of operational WLAN-GW IOMs in WLAN-GW group falling below the number of active WLAN-GW IOMs, which will operationally bring down the WLAN-GW group, and trigger switchover). For any partial failures (port, MDA or IOM failure), it is assumed there is network level redundancy, such that the soft-GRE tunnel will be re-routed to the primary WLAN-GW. This ensures there is only one active WLAN-GW owning the subnets defined on the two WLAN-GWs (that is, allows local/local subnets). The DHCP server(s) state will be synchronized between the two WLAN-GWs using MCS.

Supported access includes:

- DHCPv4 Relay to external server.
- DHCPv4 Relay to local server.
 - Pool name could be returned by AAA (framed-pool) in access-accept.
 - Pool name could come from LUDB (as relay we would set use-pool-from-client). LUDB could be specified under group-interface or under DHCP server. LUDB or AAA returned pool allows support for per SSID pool selection. SSID is contained in circuit-id.
 - Local pool selection based on giaddr.
- DHCPv4 proxy (IP@ from AAA or IP@ from PGW/GGSN).

Unnumbered case should work both in relay and proxy scenarios. IPv6 is not supported in this release (as we don't support data-triggered auth and subscriber creation for IPv6). Therefore, DHCPv6 server synchronization is not applicable. Also, IPv4 address from LUDB is not supported in this release (as data-triggered authentication against LUDB is not supported).

11.16.2 Subscriber Creation after Switchover

When standby WLAN-GW transitions to active state, and receives data on the anchor ISA there will not be any UE state on the anchor ISA. Data-triggered authentication [Data Triggered Subscriber Creation](#) will be used to create the subscriber. In order to infer how the UE originally obtained the IP@ (DHCP relay versus proxy, such as AAA or GTP), the following holds:

1. If any GTP related parameters are returned in access-accept, then it is assumed the IP@ comes from GGSN/PGW, and the origin for the IP@ is assumed to be "GTP".
2. If no GTP parameter is returned, and access-accept contains framed-IP, then proxy case will be assumed (that is, the origin as AAA).
3. If no GTP parameter or framed-IP is returned, then DHCP relay is assumed. The remaining lease time will be set to initial lease-time (if it was originally provided from AAA on primary WLAN-GW, it could be provided in access-accept for data-triggered auth on backup WLAN-GW). If AAA does not provide it, then it will be initialized to default value of 7 days.

If authentication indicates GTP for the subscriber, then create-session-request will be signaled with Handover indication. Data-triggered subscriber creation based on IPv6 packet is not supported in R12. However, for dual-stack subscriber over soft-GRE, if AAA returns the SLAAC prefix in access-accept (in response to IPv4 data-triggered auth), and linking is configured, RA message will be sent (unicast to client's MAC@), and a SLAAC host is created.

11.17 WLAN-GW Triggered Stateless Redundancy (N:1)

Existing stateless redundancy, described in [Data Triggered Subscriber Creation](#), is enhanced to support WLAN-GW based failure detection and switchover based on monitor and export route mechanism described above. The AP is not required to be configured with different tunnel endpoint addresses for active and standby WLAN-GWs. Single tunnel endpoint address is configured on the APs. The tunnel endpoint address is only announced in routing by the primary WLAN-GW as described in the section above. This form of redundancy as described in [Data Triggered Subscriber Creation](#), required L2-aware NAT. After failure, the subscriber on the standby WLAN-GW that transitions to primary is based on data-triggered authentication. This is supported for both ESM and DSM.

11.18 AP Triggered Stateless WLAN-GW Redundancy (N:1)

Existing AP controlled redundancy, described in [Data Triggered Subscriber Creation](#), is enhanced to trigger switchover on primary WLAN-GW if the number of WLAN-GW IOMs in the WLAN-GW group fall below number of active WLAN-GW IOMs. Based on a configuration **configure>service>vpn|ies svc>subscriber-interface sub-if>group-interface grp-it>wlan-gw** command, the WLAN-GW group is operationally brought down if a WLAN-GW IOM fails and the number of WLAN-GW IOMs fall below number of active WLAN-GW IOMs configured for the WLAN-GW group. This results in loss of route to the tunnel endpoint from the active WLAN-GW. The AP will detect this as WLAN-GW failure, and start tunneling the data to a configured backup WLAN-GW, where the subscriber will be created based on data-triggered authentication. This is supported for both ESM and DSM.

11.19 IPv6-only Access

In order to accommodate IPv6 only AP/CPEs, IPv6 wlan-gw tunnel transport, and IPv6 client-side support for RADIUS-proxy have been added.

11.19.1 IPv6 GRE Tunnels

Support for IPv6 GRE tunnels require configuration of local IPv6 tunnel end-point address under wlan-gw configuration on the group-interface. The transport for L2oGRE (or L2VPNNoGRE) packet is IPv6 as shown below. The outer IPv6 header contains the value 0x2F (GRE) in its Next Header field. GRE header contains protocol Ethernet (0x6558) or Ethernet-over-MPLS (0x8847) as in the case IPv4 GRE.

IPv6 Transport for L2oGRE Packet:

A single wlan-gw endpoint instance on the group-interface can have both IPv4 and IPv6 address configured as shown below. Inter-AP mobility between IPv4 and IPv6 only APs is supported in this scenario.

IPv6 Endpoint Configuration for WLAN-GW:

```
service
  vprn 300 customer 1 create
    group-interface "grp-intf-1" wlangw create
      wlan-gw
        gw-address 50.1.1.4
        gw-ipv6-address 2032::1:1:7
        mobility
          hold-time 0
          trigger data iapp
        exit
      egress
        shaping per-tunnel
      exit
      tcp-mss-adjust 1000
      vlan-tag-ranges
        range start 100 end 100
        data-triggered-ue-creation
        retail-svc-id 402
      exit
    exit
  router 30
  wlan-gw-group 1
```

```

        no shutdown
    exit
exit
exit
exit

```

The data-path for IPv6 GRE tunneled packets, including load-balancing of tunneled packets amongst set of ISAs in the WLAN-GW group, and anchoring after tunnel de-capsulation remains unchanged. Per tunnel traffic shaping is supported similar to IPv4 tunnels. All existing per tunnel configuration on the group-interface described in previous sections (including mobility, egress shaping, VLAN ranges, etc.) is supported identically for IPv6 tunnels. Tunnel reassembly for upstream tunneled traffic is not supported for IPv6 tunnels in this release. TCP mss-adjust is supported for IPv6 tunnels, and is configurable under wlan-gw mode on group-interface. APs must use globally routable addresses for GRE IPv6 transport. Packets with extension headers are dropped.

11.19.2 IPv6 Client-Side RADIUS Proxy

RADIUS proxy is extended to listen for incoming IPv6 RADIUS messages from IPv6 RADIUS clients on AP/CPEs. The listening interface that the RADIUS proxy binds to must be configured with an IPv6 address as shown below. The IPv6 RADIUS proxy is solely for DHCPv4-based UEs behind IPv6 only AP/CPEs (IPv6-capable UEs are not supported in this release). All RADIUS-proxy functions (including caching, correlation with DHCPv4, and mobility tracking) are supported identically to existing IPv4 client-side RADIUS-proxy.

Configuration for IPv6 Client-Side RADIUS Proxy:

```

service
  vprn 300 customer 1 create
  shutdown
  interface "listening_radius_server" create
    address 9.9.9.9/32
    ipv6
      address 9::9:9:9/128
    exit
  loopback
  exit
radius-proxy
  server "radius-proxy" purpose accounting authentication create
  shutdown
  cache
    key packet-type request attribute-type 31
    track-accounting stop interim-update accounting-on accounting-off
    no shutdown
  exit
  default-accounting-server-policy "radius_server_policy"
  default-authentication-server-policy "radius_server_policy"

```

```
interface "listening_radius_server"  
load-balance-key attribute-type 102 vendor 5  
secret "AQepKzndDzjRI5g38L3LbbN3E8qualtn" hash2  
send-accounting-response  
no shutdown  
exit  
exit
```

11.19.3 Dual-Stack UEs over WLAN-GW

This feature adds support for dual-stack UEs over wlan-gw. Each dual-stack UE appears to WLAN-GW as a bridged client. Dual-stack UE support includes both SLAAC and DHCPv6, with and without linking with DHCPv4. Handling of DHCPv6, RS/RA, and NS/NA messages over wlan-gw has been added. WLAN-GW can assign /128 GUA to the UE via DHCPv6 and/or assign a /64 prefix in SLAAC to each UE. Each UE can be handed via DHCPv6, a /128 IA_NA from a unique /64 prefix, with the “on-link” flag is off in the RA message. This is because the public WIFI users are distinct subscribers, and the communication must always be via WLAN-GW. The CPE MUST prevent local-switching on the WIFI link even if the /64 prefix is signaled as “on-link” or if the UEs are handed out /128 from the same /64 prefix.

Existing ESMv6 support on normal group-interface is applicable to wlan-gw group-interface, and is already documented in general ESMv6 sections in this guide. There are a few exceptions that are mentioned in sections below.

11.19.3.1 SLAAC Prefix Assignment

SLAAC prefix assignment to the UE can be from local prefix pool, where pool name can come from RADIUS in Alc-SLAAC-IPv6-Pool VSA or from LUDB (see general section on ESMv6 SLAAC pool assignment). Alternatively, the SLAAC prefix can be provided from RADIUS (in standard Framed-IPv6-Prefix attribute) or from LUDB. SLAAC with stateless DHCPv6 (DHCPv6 information-request) is supported. DNS can be sent in RA messages (per RFC 6106). RS authentication (based on MAC address) can be configured (as described in general ESMv6 section on “SLAAC only ESM hosts”). SLAAC host is created on successful RS authentication. For successfully authenticated SLAAC host, an RA is sent in response to every received RS message (subject to a configured min-auth-interval). RA messages are sent to unicast MAC address of the UE.

SLAAC host creation can be linked to DHCPv4 by configuring **ipoe-linking** under group-interface. With **ipoe-linking** enabled, any received RS messages are dropped till DHCPv4 successfully authenticates and ESMv4 host is created. If **gratuitous-rtr-adv** is configured under ipoe-linking context then an RA is sent when ESMv4 host is created. If available, the SLAAC-prefix is included in the RA message. **shared-circuit-id** command under wlan-gw is not supported on wlan-gw interfaces. The O-Bit (other-stateful-configuration) is configurable on the group-interface.

11.19.3.2 DHCPv6 IA_NA Assignment

If UE requests DHCPv6 IA_NA, a /128 address can be provided from a unique /64 prefix per UE from a local-pool. The pool name can be provided from LUDB or from RADIUS (in Framed-IPv6-Pool attribute). The address could also be provided via LUDB or RADIUS (in Alc-IPv6-Address VSA). DHCPv6 can also be linked with DHCPv4 by enabling **ipoe-linking** command. The M-bit in RA message is configurable. DHCPv6 IA_NA is allowed if it is received after a SLAAC host exists, if **allow-multiple-wan-addresses** is enabled under group-interface ipv6 configuration. In previous releases, this is precluded. This however consumes two hosts (one each for IA_NA and SLAAC) per UE. Based on a configuration command **override-slaac**, SLAAC host can be deleted if DHCPv6 IA_NA host is successfully created. Prefix-delegation is not supported with DHCPv6 on wlan-gw interfaces.

11.19.3.3 Migrant User Support

Migrant user support is only applicable to IPv4. However, if linking is configured for SLAAC or DHCPv6 with DHCPv4 then RS and DHCPv6 messages are dropped till IPv4 ESM host exists (that is, the UE is out of migrant state). Once the IPv6 ESM host exists, that is, UE is out of migrant state, RA is sent to the UE (unicast MAC), and subsequent RS or DHCPv6 messages can result in creation of IPv6 ESM host. Therefore, with migrant UEs, linking should be enabled. SLA-profile instance accounting (with interim-updates), and per-host accounting (w/ interim-updates) are supported.

11.19.3.4 Accounting

Per SLA-profile instance accounting (with interim-updates) and per SLA-profile instance accounting (with interim-updates) with host accounting enabled is supported. The interim-updates are scheduled updates, and carry IPv4 address and IPv6 address or prefix are assigned to the UE.

A sample sequence with per SLA-profile instance accounting (with interim-updates) is shown below:

0. IPv4oE host created based on DHCPv4.
1. Acct-start generated (contains framed-ip-address).
2. SLAAC host comes up.
3. Next scheduled interim-update (contains framed-ip-address and framed-IPv6-Prefix, that is, SLAAC-prefix).
4. DHCPv6 IA_NA gets assigned and corresponding host is created.
5. Next Scheduled interim-update (contains framed-ip-address, framed-IPv6-Prefix and Alc-Ipv6-Address).
6. SLAAC host times out.
7. Next Scheduled interim-update (contains only Alc-IPv6-Address and will NOT contain framed-IPv6-Prefix).
8. DHCPv6 IA_NA lease times out.
9. Next Scheduled interim-update (contains only framed-ip-address).

A sample sequence with per SLA-profile instance accounting (with interim-updates) with host accounting enabled is shown below:

0. IPv4oE host created based on DHCPv4.
1. Acct-start for sla-profile instance generated (contains framed-ip-address).
2. Acct-start for DHCPv4 host will be generated (contains framed-ip-address).
3. SLAAC host comes up.
4. Acct-start for SLAAC host will be generated (this should contain framed-IPv6-Prefix, that is, SLAAC-prefix)
5. Next scheduled interim-update for sla-profile instance accounting (contains framed-ip-address and framed-IPv6-Prefix, that is, SLAAC-prefix).
6. DHCPv6 IA_NA gets assigned and corresponding host is created.
7. Acct-start for DHCPv6 IA_NA host will be generated (contains Alc-Ipv6-Address).

8. Next Scheduled interim-update (contains framed-ip-address, framed-IPv6-Prefix and Alc-Ipv6-Address).
9. SLAAC host times out.
10. Acct-stop (SLACC-host-acct-session-id) will be generated.
11. Next Scheduled interim-update for sla-profile instance accounting (contains only Alc-IPv6-Address).
12. DHCPv6 IA_NA lease times out.
13. Acct-stop (DHCPv6-IA_NA-host-acct-session-id) will be generated.
14. Next Scheduled interim-update for sla-profile instance accounting (contains framed-ip-address).
15. DHCPv4 lease times out.
16. Acct-stop (DHCPv4-host-acct-session-id) will be generated.
17. Acct-stop for sla-profile instance accounting will be generated.

11.20 Layer 2 Wholesale

This feature adds support for mapping a UE to a VPLS instance based on configuration. The mapping is explicitly created by assigning a Layer 2 service instance (limited to VPLS only in R. 13) to an SSID that the UE is connected to. The SSID is represented by the .1q tag in the received Layer 2 frames from the UE. A VPLS instance is configured per vlan-range on wlan-gw group-interface (as shown in [Standalone WLAN-GW](#)). This feature therefore enables Layer 2 wholesale, where traffic from all UEs on a particular SSID is transparently forwarded into the corresponding VPLS instance associated with the retail ISP. UE authentication, address assignment, Layer 3 classification and QOS are managed by the retail provider terminating the subscriber. There is no local-switching on the WLAN-GW providing the wholesale service. When a VPLS instance is configured under a VLAN-range, an internal SAP is implicitly created in the VPLS instance between each ISA and corresponding carrier IOM in the WLAN-GW group. The internal SAP is associated with an implicitly created SHG to constrain broadcast and multicast traffic received from UEs, such that it is not forwarded back on the SAP. Layer 2 wholesale and Layer 3 termination are possible simultaneously on same wlan-gw interface, since Layer 2 wholesale or Layer 3 termination is a per SSID decision. UE state on the ISA is removed when the UE MAC in the VPLS instance ages out based on local-age configured under VPLS service.

A vpls-sap-template (described in the SR OS Services Guide) can be defined under **service>template** and associated with the VPLS service for Layer 2 wholesale via **config>service>vpls>wlan-gw>sap-template** command. Ingress/egress filter and QoS specified in the vpls-sap-template for the VPLS service is applied to the implicitly created internal SAP (between ISA and carrier IOM) in the VPLS service.

```
*A:vsim>config>service>vprn# info
-----
subscriber-interface "s1" create
  group-interface "g1" wlangw create
    wlan-gw
      vlan-tag-ranges
        range start 100 end 100
          l2-service 600
            no shutdown
          exit
        exit
      exit
    exit
  exit
exit
-----

*A:vsim>config>service>vpls# info
-----
wlan-gw
  shutdown
  sap-template "foo"
exit
-----
```

11.21 VLAN to WLAN-GW IOM/IMM Steering via Internal Epipe

This feature provides the steering of traffic received on an access VLAN or spoke SDP from a WIFI AP/AC to a WLAN-GW IOM/IMM via an internal Epipe. The benefit of this internal steering is that all existing features available with native soft GRE tunnels on WLAN-GW IOM/IMM are now available to pure Layer 2 access via VLANs or spoke SDPs. The access SAP can be null, .1q, or q-in-q. Access SAPs aggregating WIFI APs or ACs can and be configured in the **configure>service>ies>sub-if>grp-if>wlan-gw>l2-access-points>l2-ap** or **configure>service>vprn>sub-if>grp-if>wlan-gw>l2-access-points>l2-ap** context

The aggregation network can insert up to two **AP identifying** VLAN tags, and the AP can insert a .1q tag (typically for identifying the SSID). The number of AP identifying tags sent on the internal epipe depends on the encapsulation on the access SAP. For example, if an aggregation network inserts two AP identifying tags, and an access SAP is configured with null encaps, then the traffic sent on the internal Epipe will carry two AP identifying tags. The number of AP identifying tags in the frame forwarded over the internal Epipe must be configured via the **l2-ap-encap-type** command.

```
configure service (vprn|ies) <svc-id> subscriber-interface <sub-itf> group-
interface <grp-itf> wlan-gw
    l2-access-points
        [no] l2-ap <sap-id> [create]
        [no] encap-type {default|null|dot1q|qinq}
        [no] epipe-sap-template <name>
        [no] shutdown
    exit
exit
[no] l2-ap-encap-type {null|dot1q|qinq}
exit
```

The traffic on an internal Epipe is load-balanced among ISAs in the WLAN-GW group. The load balancing uses a hash based on AP identifying tags that remain on the frame after being received on the access SAP (based on the SAP encapsulation). This ensures all traffic from a particular AP is Epipied to the same ISA. Ingress and egress QoS and filters can be defined in an **epipe-sap-template** as displayed in the configuration shown below, and associated with the access sap or spoke SDP. IP filters and DSCP remarking are not supported if more than two tags are present in the frame ingressing the SAP. Also, downstream filters and DSCP remarking is not applied if a retail tag is present. Both Layer 3 ESM and DSM as well as Layer 2 wholesale are supported for steered traffic.

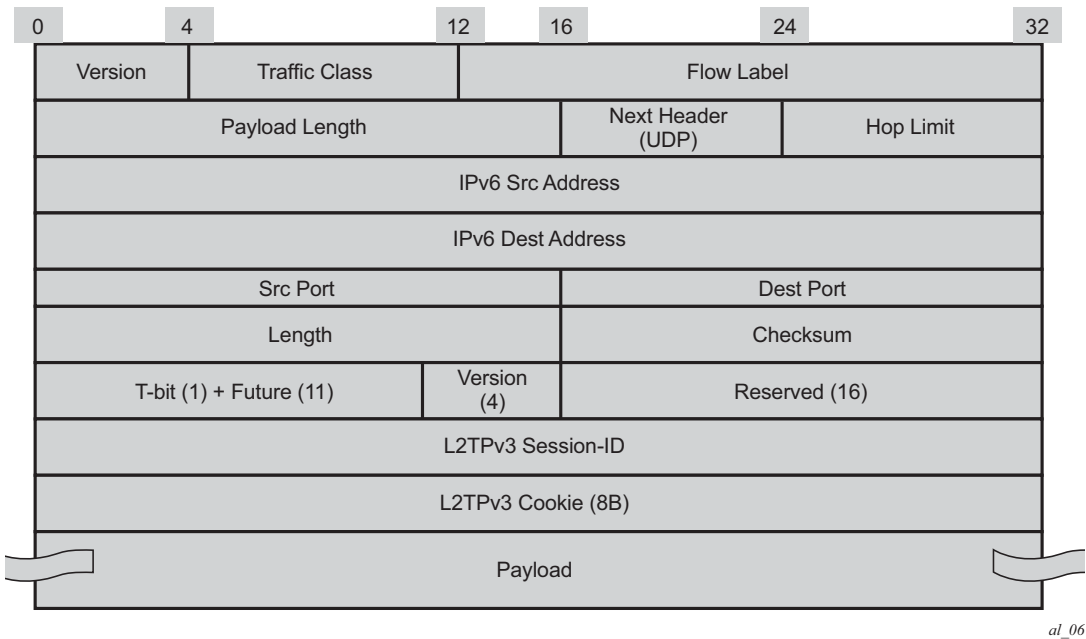

```
configure service template epipe-sap-template <name> [create]
    egress
        [no] filter
            [no] ip <filter-id>
            [no] ipv6 <filter-id>
            [no] mac <filter-id>
        exit
        [no] qos <policy-id>
    exit
    ingress
        [no] filter
            [no] ip <filter-id>
            [no] ipv6 <filter-id>
            [no] mac <filter-id>
        exit
        [no] qos <policy-id> {shared-queuing|multipoint-shared}
    exit
exit
```

Currently, mobility from an AP that is reached over a VLAN or spoke SDP to an AP that is reached over a soft GRE or soft L2TPv3 tunnels are not supported. Each internal Epipe takes away two SAPs on each WLAN-GW IOM (one per ISA) in WLAN-GW group. With 64K SAPs per IOM, the maximum number of internal Epipes supported per chassis is 32K.

11.22 Soft-L2TPv3 Tunnels

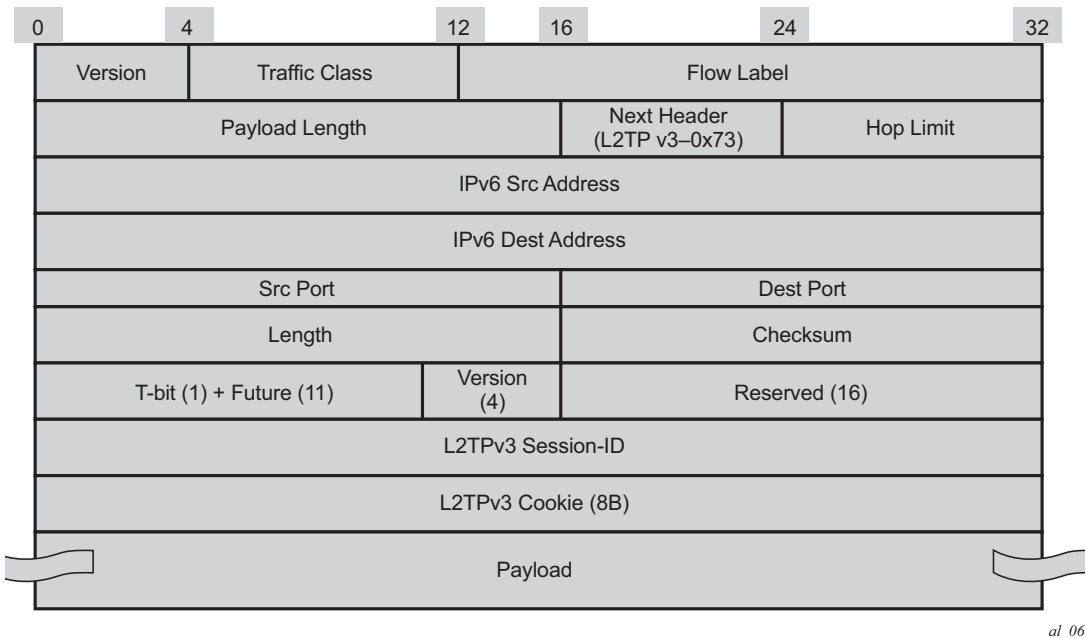

This feature adds support for Layer 2 over soft-L2TPv3 tunnels. L2TPv3 is over UDP and both IPv4 and IPv6 transport is supported. The encapsulation with UDP allows NAT traversal. Soft-L2TPv3 tunnels are terminated on WLAN-GW IOM/IMM. All features supported with soft-GRE tunnels are supported identically with soft-L2TPv3 tunnels. L2TPv3 tunnels are stateless and there is no support for control channel, dynamic exchange of session-id and cookie, and L2-specific sub-layer for sequencing. Received cookie in L2TPv3 is reflected back. The AP can encode its MAC address in 8-byte cookie. Based on configuration, the cookie can be ignored and just reflected back, or parsed to interpret AP-MAC from the least significant 6 bytes. Both L2TPv3 over IP and L2TPv3 over UDP encapsulation is supported. L2TPv3 tunnels are load-balanced from ingress IOMs to WLAN-GW IOMs based on source IP address. [Figure 178](#) and [Figure 179](#) shows these encapsulations with IPv6.

Figure 178 L2TPv3 over UDP (IPv6 Transport)

al_06

Figure 179 L2TPv3 over IP (IPv6 Transport)

al_06

Enabling multi-tunnel-type on a wlan-gw group-interface allows multiple tunnel types (such as soft-GRE and L2TPv3) to the same gateway tunnel endpoint. Mobility between APs reachable via soft-L2TPv3 tunnels and APs reachable via soft-GRE tunnels is supported. There is feature and scale parity between soft-GRE and soft-L2TPv3 tunnels. The local tunnel gateway endpoint and other configurations parameters are shown below.

```

11.23.1.1 WLAN-GW Commands

Note: The **wlan-gw** commands apply only to the 7750 SR platform.

```

config
  — subscriber-mgmt
    — wlan-gw
      — distributed-sub-mgmt
      — virtual-chassis-identifier dual-homing-key
      — no virtual-chassis-identifier

configure
  — router
    — wlan-gw
      — distributed-sub-mgmt
        — ipv6-tcp-mss-adjust segment-size
        — no ipv6-tcp-mss-adjust
      — mobility-triggered-acct
        — interim-update
        — no interim-update
  
```

11.23.1.1.1 Subscriber Management BRG Commands

```

configure
— subscriber-mgmt
— brg-profile profile-name [create]
— no brg-profile profile-name
— connectivity-verification [count nr-of-attempts] [timeout timeout-seconds]
  [retry-time retry-seconds]
— no connectivity-verification
— description description-string
— no description
— dhcp-pool
— lease-time seconds
— no lease-time
— options
— custom-option option-number address [ip-address (up to 4
  max)]
— custom-option option-number hex hex-string
— custom-option option-number string ascii-string
— no custom-option option-number
— standby-ip-lifetime [seconds]
— no standby-ip-lifetime
— subnet ip-prefix/prefix-length start ip-address end ip-address
— hold-time seconds
— no hold-time
— initial-hold-time seconds
— no initial-hold-time
— radius-authentication
— password password [hash | hash2]
— no password
— radius-server-policy policy-name
— no radius-server-policy
— [no] radius-proxy-server router router-instance name server-name
— radius-server-policy string
— no radius-server-policy

11.23.2 WIFI Aggregation and Offload Commands

11.23.2.1 WIFI Aggregation and Offload Commands

11.23.2.1.1 Generic Commands

description

Syntax	description <i>description-string</i> no description
Context	config>aaa>acct-on-off-grp config>aaa>radius-srv-plcy config>isa>wlan-gw-group config>router>radius-server>server config>router>radius-proxy>server config>service>vprn>radius-proxy>server config>service>vprn>radius-server>server config>subscr-mgmt>wlan-gw>mgw-profile config>service>ies>sub-if>grp-if>wlan-gw config>service>vprn>sub-if>grp-if>wlan-gw config>service>ies>sub-if>grp-if>sap-parameters config>service>vprn>sub-if>grp-if>sap-parameters config>subscr-mgmt>wlan-gw>dsm>dsm-ip-filter config>subscr-mgmt>wlan-gw>dsm>dsm-ip-filter>ipv6 config>call-trace>trace-profile
Description	<p>This command creates a text description stored in the configuration file for a configuration context.</p> <p>The description command associates a text string with a configuration context to help identify the context in the configuration file.</p> <p>The no form of this command removes any description string from the context.</p>
Default	No description is associated with the configuration context.
Parameters	<i>description-string</i> — A text string describing the entity. Allowed values are any string up to 80 characters long composed of printable, 7-bit ASCII characters excluding double quotes. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

shutdown

Syntax	[no] shutdown
Context	<pre> config>router>radius-proxy>cache config>router>radius-proxy>server>cache config>router>radius-proxy>server config>service>vprn>radius-proxy>server>cache config>service>vprn>radius-proxy>server config>service>ies>sub-if>grp-if>wlan-gw config>service>vprn>sub-if>grp-if>wlan-gw config>service>ies>sub-if>grp-if>wlan-gw>pool-mgr>dhcpv6-clnt>slaac config>service>vprn>sub-if>grp-if>wlan-gw>pool-mgr>dhcpv6-clnt>slaac config>service>ies>sub-if>grp-if>wlan-gw>pool-mgr>dhcpv6-clnt>ia-na config>service>vprn>sub-if>grp-if>wlan-gw>pool-mgr>dhcpv6-clnt>ia-na config>service>ies>sub-if>grp-if>wlan-gw>pool-manager>dhcpv6-clnt>dhcpv4-nat config>service>vprn>sub-if>grp-if>wlan-gw>pool-manager>dhcpv6-clnt>dhcpv4-nat config>service>vprn>sub-if>grp-if>wlan-gw>vlan-ranges>range>brg config>service>ies>sub-if>grp-if>wlan-gw>vlan-ranges>range>brg config>service>vprn>sub-if>grp-if>brg config>service>ies>sub-if>grp-if>brg </pre>
Description	<p>The shutdown command administratively disables the entity. When disabled, an entity does not change, reset, or remove any configuration settings or statistics. Many entities must be explicitly enabled using the no shutdown command.</p> <p>The shutdown command administratively disables an entity. The operational state of the entity is disabled as well as the operational state of any entities contained within. Many objects must be shut down before they can be deleted.</p> <p>Unlike other commands and parameters where the default state is not indicated in the configuration file, shutdown and no shutdown are always indicated in system generated configuration files.</p> <p>The no form of the command puts an entity into the administratively enabled state.</p>
Default	no shutdown

subscriber-mgmt

Syntax	subscriber-mgmt
Context	config
Description	<p>This command enables the context to configure subscriber management entities. A subscriber is uniquely identified by a subscriber identification string. Each subscriber can have several DHCP sessions active at any time. Each session is referred to as a subscriber host and is identified by its IP address and MAC address.</p>

All subscriber hosts belonging to the same subscriber are subject to the same hierarchical QoS (HQoS) processing. The HQoS processing is defined in the sub-profile (the subscriber profile). A sub-profile refers to an existing scheduler policy (configured in **the config>qos>scheduler-policy** context) and offers the possibility to overrule the rate of individual schedulers within this policy.

Because all subscriber hosts use the same scheduler policy instance, they must all reside on the same complex.

11.23.2.1.2 WLAN-GW Commands

Note: The **wlan-gw** commands apply only to the 7750 SR platform.

wlan-gw

Syntax	[no] wlan-gw
Context	config>subscriber-mgmt config>router config>service>vprn
Description	This command enables the context to configure WLAN Gateway parameters.

distributed-sub-mgt

Syntax	distributed-sub-mgmt
Context	config>subscr-mgmt>wlan-gw
Description	This command enables the context to configure profiles, templates, and policies that can be applied to DSM subscribers.

dsm-ip-filter

Syntax	dsm-ip-filter <i>filter-name</i> no dsm-ip-filter <i>filter-name</i>
Context	config>subscr-mgmt>wlan-gw>dsm
Description	This command configures a set of filter rules that can be applied to a DSM UE.

The **no** form of the command can only be executed if no entries are configured under this filter.

Default	none
Parameters	<i>filter-name</i> — Specifies the name of the filter.

description

Syntax	description <i>description-string</i> no description
Context	config>subscr-mgmt>wlan-gw>dsn>dsm-ip-filter config>subscr-mgmt>wlan-gw>dsm>dsm-ip-filter>ipv6>entry config>subscr-mgmt>wlan-gw>dsm>dsm-policer
Description	This command creates a text description stored in the configuration file for a configuration context. The description command associates a text string with a configuration context to help identify the context in the configuration file. The no form of the command removes any description string from the context.
Default	none
Parameters	<i>description-string</i> — A text string describing the entity. Allowed values are any string up to 80 characters long composed of printable, 7-bit ASCII characters, excluding double quotation marks (" "). If the string contains special characters (such as #, \$, spaces, etc.), the entire string must be enclosed in double quotation marks (" ").

default-action

Syntax	default-action { drop forward } no default-action
Context	config>subscr-mgmt>wlan-gw>dsm>dsm-ip-filter config>subscr-mgmt>wlan-gw>dsm>dsm-ip-filter>ipv6
Description	This command specifies what should happen to packets that do not match any of the configured entries. The no form of the command reverts to the default value.
Default	default-action drop
Parameters	drop — Specifies that packets matching the filter entry are dropped. forward — Specifies that packets matching the filter entry are forwarded.

entry

Syntax	entry <i>entry-id</i> [create] no entry <i>entry-id</i>
Context	config>subscr-mgmt>wlan-gw>dsm>dsm-ip-filter config>subscr-mgmt>wlan-gw>dsm>dsm-ip-filter>ipv6
Description	This command creates a new entry for this filter. When processing a packet, entries are matched in order, starting with the lowest entry-id. A maximum of 128 IPv4 and 128 IPv6 DSM filter entries are allowed. The no form of the command reverts to the default value.
Default	none
Parameters	<i>entry-id</i> — The numeric identifier for the filter entry.

action

Syntax	action { drop forward none } no action
Context	config>subscr-mgmt>wlan-gw>dsm>dsm-ip-filter config>subscr-mgmt>wlan-gw>dsm>dsm-ip-filter>ipv6>entry
Description	This command specifies what should happen to packets that do match this entry. If the configured action is none, this entry is not applied and processing continues to match against subsequent entries. The no form of the command reverts to the default value.
Default	action none
Parameters	drop — Drops the packet. forward — Forwards the packet. none — Disables this entry. Packet processing continues with the next entry.

match

Syntax	match <i>protocol</i> { any icmp tcp udp gre} no match
Context	config>subscr-mgmt>wlan-gw>dsm>dsm-ip-filter config>subscr-mgmt>wlan-gw>dsm>dsm-ip-filter>ipv6>entry
Description	This command creates a match context for this entry. The <i>protocol</i> value specifies which Layer-4 protocol the packet should match.

The **no** form of the command removes the match context of this entry.

Default	no match
Parameters	<p><i>protocol</i> — The only supported match context is protocol.</p> <p>any — Specifies to match any protocol.</p> <p>icmp — Specifies to match ICMP packets in a v4 filter.</p> <p>tcp — Specifies to match TCP packets.</p> <p>udp — Specifies to match UDP packets.</p> <p>gre — Specifies to match GRE over IP packets.</p>

dst-port

Syntax	dst-port <i>operator port-number</i> no dst-port
Context	config>subscr-mgmt>wlan-gw>dsm>dsm-ip-filter>entry>match config>subscr-mgmt>wlan-gw>dsm>dsm-ip-filter>ipv6>entry>match
Description	<p>This command specifies that the packet's UDP/TCP dst-port must match a specific value. This command is not valid in a match context that is not specific to UDP or TCP.</p> <p>The no form of the command removes matching of the layer-4 port.</p>
Default	no dst-port
Parameters	<p><i>operator</i> — The only supported value is eq (equal to); the destination port value must be equal to the <i>port-number</i> value.</p> <p><i>port-number</i> — [0..65535] The number of the port to match.</p>

dst-ip

Syntax	dst-ip <i>ip-prefix/length</i> no dst-ip
Context	config>subscr-mgmt>wlan-gw>dsm>dsm-ip-filter>entry
Description	<p>This command specifies that the packet's destination IP address must match the specified IP prefix and mask.</p> <p>The no form of the command disables the match on the destination IP.</p>
Default	no dst-ip
Parameters	<i>ip-prefix/length</i> — The IP prefix to match.

dsm-policer

Syntax	dsm-policer <i>policer-name</i> [type <i>policer-type</i>] [create] no dsm-policer <i>policer-name</i>
Context	config>subscr-mgmt>wlan-gw>dsm
Description	This command creates a policer profile that can be applied to a DSM host. When creating a profile the first time, the create and type parameters are required. The WLAN-GW allows configuration of single-rate and dual-rate bucket policers. The no form of the command removes the profile.
Default	none
Parameters	<i>policer-name</i> — The name by which this policer is referenced. type <i>policer-type</i> — Specifies the policer type. The dual-bucket-bandwidth policer applies both a CIR and PIR. Values single-bucket-bandwidth, dual-bucket-bandwidth

action

Syntax	action { <i>permit-deny</i> <i>priority-mark</i> } no action
Context	config>subscr-mgmt>wlan-gw>dsm>dsm-policer
Description	This command specifies what happens to packets that are in-profile and out-of-profile. The no form of the command reverts to the default value.
Default	action permit-deny
Parameters	<i>permit-deny</i> — Drop all packets that are out of profile (do not conform to the PIR). <i>priority-mark</i> — Currently not supported. The policer will take no action.

adaptation-rule

Syntax	adaptation-rule pir { <i>max</i> <i>min</i> <i>closest</i> } [cir { <i>max</i> <i>min</i> <i>closest</i> }] no adaptation-rule
Context	config>subscr-mgmt>wlan-gw>dsm>dsm-policer
Description	This command specifies what happens to packets that are in-profile and out-of-profile. The no form of the command reverts to the default value.

Default	action permit-deny
Parameters	<p><i>max</i> — The operational rate at its maximum may be the configured rate. The first operational value that is smaller or equal to the configured rate will be chosen.</p> <p><i>min</i> — The operational rate at its minimum must be the configured rate. The first operational value that is bigger or equal to the configured rate will be chosen.</p> <p><i>closest</i> — The system chooses the operational value—either lower or higher—that is closest to the configured value.</p>

cbs

Syntax	cbs <i>burst-size</i> no cbs
Context	config>subscr-mgmt>wlan-gw>dsm>dsm-policer
Description	<p>This command specifies the committed burst-size value of this policer. This can only be set on dual-bucket-bandwidth policers.</p> <p>The no form of the command reverts to the default value.</p>
Default	cbs 0
Parameters	<i>burst-size</i> — [0..131071] The committed burst-size in kilobytes.

mbs

Syntax	mbs <i>burst-size</i> no mbs
Context	config>subscr-mgmt>wlan-gw>dsm>dsm-policer
Description	<p>This command specifies the maximum burst-size value of this policer. This can only be set on dual-bucket-bandwidth policers.</p> <p>The no form of the command reverts to the default value.</p>
Default	mbs 0
Parameters	<i>burst-size</i> — [0..131071] The maximum burst-size in kbytes.

rate

Syntax	rate <i>rate</i> [<i>cir rate</i>] no rate
---------------	---

Context	config>subscr-mgmt>wlan-gw>dsm>dsm-policer
Description	<p>This command specifies the rate at which the policer drains packets. The cir <i>rate</i> value is only supported on dual-bucket-bandwidth policers. If rate max is configured, no rate limitations are applied.</p> <p>The no form of the command reverts to the default value.</p>
Default	rate max
Parameters	<i>rate</i> — [1..100000000 max] the rate in kb/s

virtual-chassis-identifier

Syntax	virtual-chassis-identifier <i>dual-homing-key</i> no virtual-chassis-identifier
Context	config>subscr-mgmt>wlan-gw>mgw-profile
Description	<p>This command specifies a virtual chassis identifier that can link two wlan-gw's together.</p> <p>The no form of the command removes the dual-homing-key</p>
Default	none
Parameters	<i>dual-homing-key</i> — Specifies the name of the dual homing key up to 16 characters.

distributed-sub-mgmt

Syntax	distributed-sub-mgmt
Context	config>router>wlan-gw config>service>vprn>wlan-gw
Description	This command enables the context to configure profiles, templates and policies that can be applied to DSM subscribers.

ipv6-tcp-mss-adjust

Syntax	ipv6-tcp-mss-adjust <i>segment-size</i> no ipv6-tcp-mss-adjust
Context	config>router>wlan-gw>dsm config>service>wlan-gw>dsm

Description	<p>This command specifies the value used for TCP-MSS-adjust in the IPv6 upstream direction for DSM. The downstream direction for both IPv4 and IPv6 are both configured under the group-interface. The upstream direction for IPv4 NAT hosts is configured under the NAT policy.</p> <p>The defined segment size is inserted in a TCP SYN message if there is no existing MSS option or the value in the MSS option is bigger than the configured value.</p> <p>The no form of the command disables upstream TCP MSS adjust for IPv6 DSM.</p>
Default	no ipv6-tcp-mss-adjust
Parameters	<i>segment-size</i> — Specifies the segment size to be inserted.
	Values 160 to 10240

mobility-triggered-acct

Syntax	mobility-triggered-acct
Context	config>router>wlan-gw config>service>vprn>wlan-gw
Description	This command enters the configuration context of mobility-triggered-accounting in wlan-gw context under router or VPRN service.
Default	none

interim-update

Syntax	interim-update no interim-update
Context	config>router>wlan-gw>mobility-triggered-acct config>service>vprn>wlan-gw>mobility-triggered-acct
Description	<p>This command enables generation of a flash interim accounting-update to the accounting service when change in location of the UE is detected.</p> <p>The no form of the command disables generation of flash interim accounting- update to RADIUS when change in location of the UE is detected.</p>
Default	Not enabled

Bridged Residential Gateway Commands

brg-profile

Syntax	brg-profile <i>profile-name</i> [create]
Context	config>subscr-mgmt
Description	<p>This command creates the profile Bridged Residential Gateway (BRG) devices. The BRG profile specifies default parameters that are used for host management under a single BRG.</p> <p>The no form of the command removes the profile name from the configuration.</p>
Default	none
Parameters	<i>profile-name</i> — Specifies the name of the BRG profile.

connectivity-verification

Syntax	connectivity-verification [count <i>nr-of-attempts</i>] [timeout <i>timeout-seconds</i>] [retry-time <i>retry-seconds</i>]
Context	config>subscr-mgmt>brg-profile
Description	<p>This command configures the BRG connectivity verification. The system uses ICMP Echo request messages for connectivity verification.</p> <p>When the last host associated to a BRG is removed, a ping mechanism is used to verify if the BRG is still active. This command specifies the parameters used in this mechanism.</p> <p>The no form of this command disables the BRG ping mechanism and removes the BRG without verification. Any configured hold-time still applies.</p>
Default	count 3 timeout 30 retry-time 900
Parameters	<p>count <i>nr-of-attempts</i> — Specifies the number of connectivity verification attempts this system makes before a BRG is considered down.</p> <p>Values 1 to 5</p> <p>timeout <i>timeout-seconds</i> — Specifies the time, in seconds, after which an unanswered ping is considered failed.</p> <p>Values 5 to 60</p> <p>retry-time <i>retry-seconds</i> — Specifies the time, in seconds, that the system waits while it considers a BRG down, before it starts a new connectivity verification cycle. If a ping succeeds, the mechanism will be retried after this time.</p> <p>Values 300 to 3600</p>

dhcp-pool

Syntax	dhcp-pool
Context	config>subscr-mgmt>brg-profile
Description	This command enables the context to configure per-subscriber IPv4 address pool parameters to be used for address allocation. Pools for different subscribers can overlap. Specific pool parameters can be overridden by RADIUS.

lease-time

Syntax	lease-time <i>seconds</i> no lease-time
Context	config>subscr-mgmt>brg-profile>dhcp-pool
Description	This command configures the lease time, in seconds, to be used when allocating addresses from the pool. This time should always be larger than the renew/rebind time. The no form of the command reverts to the default.
Default	600
Parameters	<i>seconds</i> — Specifies the lease time. Values 300 to 315446399

options

Syntax	options
Context	config>subscr-mgmt>brg-profile>dhcp-pool
Description	This command enables the context to configure options that are reflected in DHCP.
Default	none

custom-option

Syntax	custom-option <i>option-number</i> address [<i>ip-address</i> (up to 4 max)] custom-option <i>option-number</i> hex <i>hex-string</i> custom-option <i>option-number</i> string <i>ascii-string</i> no custom-option <i>option-number</i>
Context	config>subscr-mgmt>brg-profile>dhcp-pool>options
Description	This command configures DHCP options.

Default	none
Parameters	<i>option-number</i> — Specifies the number of this DHCP option. address [<i>ip-address...</i> (upto 4 max)] — Specifies the IP address. hex <i>hex-string</i> — Specifies a hex string. string <i>ascii-string</i> — Specifies the ASCII string.

standby-ip-lifetime

Syntax	standby-ip-lifetime [<i>seconds</i>] standby-ip-lifetime
Context	config>subscr-mgmt>brg-profile>dhcp-pool
Description	This command defines how long these addresses will be kept aside when standby addresses are signaled to the pool. During this time these addresses can only be used by devices explicitly requesting the IP (for example datatrigger or DHCP renew/rebind). When the timer expires the addresses will again become available for dynamic allocation.
Default	21600
Parameters	<i>seconds</i> — Specifies the lifetime in seconds Values 300 to 315446399

subnet

Syntax	subnet <i>ip-prefix/prefix-length</i> start <i>ip-address</i> end <i>ip-address</i>
Context	config>subscr-mgmt>brg-profile>dhcp-pool
Description	<p>This command configures the subnet that will be used for the I2aware-subscriber. This subnet is only locally significant and can overlap with other subscribers. The subnet is derived by ignoring the host-bits of the ip-address. The ip address specifies the default gateway that will be signaled in DHCP along with the netmask derived from the prefix-length.</p> <p>The start and end addresses specify the addresses that are suitable for allocation within the given subnet, the start and end address included. If the subnet address (host-bits 0), broadcast address (host-bits 1) or default-gw address fall in this range, they will not be considered for allocation.</p> <p>Changing the subnet will only have effect for new subscribers. New and existing hosts for existing subscribers will keep allocating from the original subnet.</p> <p>The no form of this command removes the subnet configuration. New I2-aware subscribers will no longer use this pool and fall back to a pool from radius. Existing subscribers will keep using the original subnet.</p>

Default	no subnet
Parameters	<i>ip-prefix/prefix-length</i> — Specifies the IP prefix and prefix length. start <i>ip-address</i> — Specifies the starting IP address. end <i>ip-address</i> — Specifies the ending IP address.

hold-time

Syntax	hold-time seconds no hold-time
Context	config>subscr-mgmt>brg-profile
Description	When the BRG should be deleted this still holds the BRG object for the specified time. This applies when connectivity-verification fails or when the last host is removed and no connectivity-verification is enabled. Hold time does not apply to an explicit removal via radius or clear commands. The no form of the command deletes the hold-time.
Default	no hold-time
Parameters	<i>seconds</i> — Specifies the time to hold on to a BRG after this system considered it down. Values 30 to 86400

initial-hold-time

Syntax	initial-hold-time <i>seconds</i> no initial-hold-time
Context	config>subscr-mgmt>brg-profile
Description	This command configures the time to hold on to a BRG immediately after the system detected its presence. The hold time does not apply in case this system removes the BRG context upon an explicit request
Default	300
Parameters	<i>seconds</i> — Specifies the initial time, in seconds, to hold on to a BRG after this system considered it down. Values 0 to 900

radius-authentication

Syntax	radius-authentication
---------------	------------------------------

Context	config>subscr-mgmt>brg-profile
Description	This command configures RADIUS authentication of the BRG.

radius-proxy-server

Syntax	[no] radius-proxy-server router <i>router-instance</i> name <i>server-name</i>
Context	config>subscr-mgmt>brg-profile
Description	<p>This command enables BRG processing on the specified RADIUS proxy server. Whenever an Access-Accept is received with the attribute Alc-BRG-Id present, this will trigger the creation of a BRG. The BRG will use the BRG profile specified in Access-Accept or otherwise fall-back to this BRG profile. When the specified radius-proxy-server has a cache enabled, no cache entries will be created for a transaction identified as BRG. A RADIUS proxy server can only be listed in one BRG profile.</p> <p>This command can be executed multiple times.</p> <p>The no form of this command removes BRG processing for the specified RADIUS proxy server.</p>
Default	none
Parameters	router <i>router-instance</i> — Specifies the ID of the VRF where the proxy server is located. name <i>server-name</i> — Specifies the name of the RADIUS proxy server.

radius-server-policy

Syntax	radius-server-policy <i>policy-name</i> no radius-server-policy
Context	config>subscr-mgmt>brg-profile>radius-authentication
Description	<p>This command is used if the BRG needs to be authenticated to the PCMP by the BRG. This is required if the BRG does not perform radius authentication via the proxy itself. The BRG will originate a valid Access Request using the BRG ID as username.</p> <p>The no form of this command removes the radius-server-policy from the configuration. Setup of an unauthenticated BRG will now fail.</p>
Default	no radius-server-policy
Parameters	<i>policy-name</i> — Specifies the RADIUS server policy up to 32 characters in length to be applied in this subscriber authentication policy.

sla-profile-string

Syntax	sla-profile-string <i>string</i> no sla-profile-string
Context	config>subscr-mgmt>brg-profile
Description	<p>This command configures the SLA profile string which will be used as a default for SLA-profile lookup. This string can be overridden during BRG or host authentication.</p> <p>The no form of the command removes the string from the configuration.</p>
Default	no sla-profile-string
Parameters	<i>string</i> — Specifies the string to use to look up the subscriber profile.

sub-profile-string

Syntax	sub-profile-string <i>string</i> no sub-profile-string
Context	config>subscr-mgmt>brg-profile
Description	<p>This string will be used as a default for subscriber-profile lookup. This string can be overridden during BRG or host authentication.</p> <p>The no form of the command removes the string from the configuration.</p>
Default	no sub-profile-string
Parameters	<i>string</i> — Specifies the string used to look up the subscriber profile.

11.23.2.1.3 DSM Call Trace Commands

call-trace

Syntax	call-trace
Context	config
Description	This command enables the context to configure parameters related to the call trace debugging tool

location

Syntax	location {cf1 cf2}
Context	config>call-trace
Description	This command specifies the compact flash (CF) configuration to store call trace files.

disable

Syntax	[no] disable
Context	config>call-trace>location
Description	When configured, the specified compact flash will not be used by call-trace. The no form of this command enables the compact flash for use by call-trace.
Default	no disable

size-limit

Syntax	size-limit <i>limit-value</i> no size-limit
Context	config>call-trace>location
Description	This command limits the total size of call-trace files on the specified compact flash card. The no form of this command removes the size restriction.
Default	1000

Parameters	<i>limit-value</i> — Specifies the total size of call-trace files on the specified compact flash card.
Values	1 to 65536

max-files-number

Syntax	max-files-number <i>number</i>
Context	config>call-trace
Description	This command configures the maximum number of files call-trace can create.
Default	200
Parameters	<i>number</i> — Specifies the maximum number of all call trace log files stored on all compact flash cards together.
Values	1 to 1024

primary-cf

Syntax	primary-cf <i>cflash-id</i>
Context	config>call-trace
Description	This command specifies which compact-flash will be used as the primary CF for call-trace operation.
Default	cf1
Parameters	<i>cflash-id</i> — Specifies the compact flash card to be used as the primary local storage location to save the generated call trace log files.
Values	cf1, cf2

trace-profile

Syntax	trace-profile <i>profile-name</i> [create] no trace-profile <i>profile-name</i>
Context	config>call-trace
Description	This command creates a profile that can be applied to a specific trace job.
Default	none
Parameters	<i>profile-name</i> — Specifies the unique name of the call trace profile.

live-output

Syntax	live-output <i>ip-address</i> fqdn [port <i>port</i>] [router { <i>router-instance</i> service-name <i>service-name</i> }] no live-output				
Context	config>call-trace>trace-profile				
Description	<p>This command specifies a live output destination for this trace. When configured, captures will not be stored locally but sent (over UDP) to the server in the specified routing context. The destination can be specified as either an IP address or a DNS FQDN.</p> <p>The no form of this command disables live output streaming.</p>				
Default	no live-output				
Parameters	<p><i>ip-address</i> — Specifies the IPv4 or IPv6 address of the server to stream to.</p> <p>fqdn — Specifies the FQDN that represents the server in DNS.</p> <p>port <i>port</i> — Specifies the UDP port on which the server will be listening.</p> <table><tr><td>Values</td><td>1 to 65535</td></tr><tr><td>Default</td><td>10</td></tr></table> <p>router <i>router-instance</i> — Specifies the router instance in which the live output will be forwarded.</p> <p>service-name <i>service-name</i> — The name of the L3 service in which the live output will be forwarded.</p>	Values	1 to 65535	Default	10
Values	1 to 65535				
Default	10				

size-limit

Syntax	size-limit <i>limit-value</i>		
Context	config>call-trace>trace-profile		
Description	This command specifies a maximum of how big a trace may grow before it is stopped.		
Default	10		
Parameters	<p><i>limit-value</i> — Specifies the maximum data volume generated by a single call trace job to the output in megabytes. After reaching the limit the call trace job for a given host is automatically terminated.</p> <table><tr><td>Values</td><td>1 to 1000</td></tr></table>	Values	1 to 1000
Values	1 to 1000		

time-limit

Syntax	time-limit <i>limit-value</i>
---------------	--------------------------------------

Context	config>call-trace>trace-profile
Description	This command specifies how long a trace may run before it is stopped.
Default	86400
Parameters	<i>limit-value</i> — Specifies the maximum duration of a single call trace job in seconds. After reaching the limit the call trace job for a given host is automatically terminated.
Values	1 to 604800

11.23.2.1.4 RADIUS Server Policy Commands

acct-on-off-group

Syntax	acct-on-off-group <i>group-name</i> [create] no acct-on-off-group <i>group-name</i>
Context	config>aaa
Description	This command creates an acct-on-off-group. An acct-on-off-group can be referenced by: <ul style="list-style-type: none"> • A single radius-server-policy as controller — The acct-on-off oper-state of the acct-on-off-group is set to the acct-on-off oper-state of the radius-server-policy (acts as master). • Multiple radius-server-policies as monitor — The acct-on-off oper-state of the radius-server-policy is inherited from the acct-on-off oper-state of the acct-on-off group. (acts as a slave). <p>The no form of the command deletes the acct-on-off-group.</p>
Default	none
Parameters	<i>group-name</i> — Specifies the name of an acct-on-off group up to 32 characters in length.

radius-server-policy

Syntax	radius-server-policy <i>policy-name</i> [create] no radius-server-policy <i>policy-name</i>
Context	config>aaa
Description	This command creates a radius-server-policy. A radius-server-policy can be used in <ul style="list-style-type: none"> • radius-proxy, for application like EAP authentication for WIFI access • authentication policy, for Enhanced Subscriber Management authentication • radius accounting policy, for Enhanced Subscriber Management accounting • dynamic data service RADIUS accounting • AAA route downloader <p>The no form of the command removes the policy name from the configuration.</p>
Default	none

Parameters	<i>policy-name</i> — Specifies the name of the radius-server-policy up to 32 characters in length. create — Keyword used to create a radius-server-policy name. The create keyword requirement can be enabled/disabled in the environment>create context.
-------------------	--

accept-script-policy

Syntax	accept-script-policy <i>policy-name</i> no accept-script-policy
Context	config>aaa>radius-srv-plcy
Description	This command specifies name of the radius-script-policy to be applied for access-accept.
Default	none
Parameters	<i>policy-name</i> — Specifies the name of the accept-script-policy up to 32 characters in length.

acct-on-off

Syntax	acct-on-off acct-on-off monitor-group <i>group-name</i> acct-on-off oper-state-change [group <i>group-name</i>]
Context	config>aaa>radius-srv-plcy
Description	<p>This command controls the sending of Accounting-On and Accounting-Off messages and the acct-on-off oper-state of the radius-server-policy:</p> <p>acct-on-off: enables the sending of Accounting-On and Accounting-Off messages for this radius-server-policy. The acct-on-off oper-state is always not blocked.</p> <p>acct-on-off oper-state-change [group <i>group-name</i>]: enables the sending of Accounting-On and Accounting-Off messages for this radius-server-policy. The acct-on-off oper-state is function of the Accounting-response received for the Accounting-On and Accounting-Off. Optionally, sets the acct-on-off oper-state of the acct-on-off-group.</p> <p>acct-on-off monitor-group <i>group-name</i>: no Accounting-On and Accounting-Off messages are sent for this radius-server-policy. The acct-on-off oper-state is inherited from the acct-on-off-group.</p> <p>The no form of the command disables the sending of Accounting-On and Accounting-Off messages.</p>
Default	no acct-on-off
Parameters	<i>group-name</i> — Specifies the name of an acct-on-off group up to 32 characters in length.

acct-on-off-group

Syntax	acct-on-off-group <i>group-name</i> [create] no acct-on-off-group <i>group-name</i>
Context	config>aaa
Description	This command creates an acct-on-off-group. An acct-on-off-group can be referenced by: -a single radius-server-policy as controller: the acct-on-off oper-state of the acct-on-off-group is set to the acct-on-off oper-state of the radius-server-policy (acts as master) -multiple radius-server-policies as monitor: the acct-on-off oper-state of the radius-server-policy is inherited from the acct-on-off oper-state of the acct-on-off group . (acts as a slave) The no form of the command deletes the acct-on-off-group.
Default	none
Parameters	<i>group-name</i> — Specifies the name of an acct-on-off group up to 32 characters in length.

acct-request-script-policy

Syntax	acct-request-script-policy <i>policy-name</i> no acct-request-script-policy
Context	config>aaa>radius-srv-plcy
Description	This command specifies the name of the acct-request-script-policy pointing to the Python script to be applied for RADIUS accounting request messages.
Default	no acct-request-script-policy
Parameters	<i>policy-name</i> — Specifies the name of the acct-request-script-policy up to 32 characters in length.

auth-request-script-policy

Syntax	uth-request-script-policy <i>policy-name</i> no auth-request-script-policy
Context	config>aaa>radius-srv-plcy
Description	This command specifies the name of the auth-request-script-policy pointing to the Python script to be applied for RADIUS access request messages.

Default	no auth-request-script-policy
Parameters	<i>policy-name</i> — Specifies the name of the auth-request-script-policy up to 32 characters in length.

buffering

Syntax	[no] buffering
Context	config>aaa>radius-srv-plcy
Description	This command enables the context to configure RADIUS message buffering. The no form of the command disables RADIUS message buffering.
Default	none

acct-interim

Syntax	acct-interim min <i>min-val</i> max <i>max-val</i> lifetime <i>lifetime</i> no acct-interim
Context	config>aaa>radius-srv-plcy>servers>buffering
Description	<p>This command enables RADIUS accounting interim update message buffering.</p> <ol style="list-style-type: none">1. The message is stored in the buffer, a lifetime timer is started and the message is sent to the RADIUS server2. If after <i>retry*timeout</i> seconds no RADIUS accounting response is received for the interim update then a new attempt to send the message is started after minimum[(<i>min-val</i>*2n), <i>max-val</i>] seconds.3. Repeat step 2 until for one of the following:<ol style="list-style-type: none">a. a RADIUS accounting response is received.b. the lifetime of the buffered message expires.c. a new RADIUS accounting interim-update or a RADIUS accounting stop for the same accounting session-id and radius-server-policy is stored in the buffer.d. the message is manually purged from the message buffer via a clear command.4. The message is purged from the buffer. <p>The no form of the command disables RADIUS accounting interim update message buffering.</p>
Default	no acct-interim

Parameters	<p><i>min-val</i> — Specifies the minimum interval in seconds between attempts to resend the RADIUS accounting interim update</p> <p>Values 1 – 3600</p> <p><i>max-val</i> — Specifies the maximum interval in seconds between attempts to resend the RADIUS accounting interim update</p> <p>Values 1 – 3600</p> <p><i>lifetime</i> — Specifies the lifetime in hours</p> <p>Values 1 – 25</p>
-------------------	--

acct-stop

Syntax	<p>acct-stop min <i>min-val</i> max <i>max-val</i> lifetime <i>lifetime</i></p> <p>no acct-stop</p>
Context	config>aaa>radius-srv-plcy>servers>buffering
Description	<p>This command enables RADIUS accounting stop message buffering.</p> <ol style="list-style-type: none"> 1. The message is stored in the buffer, a lifetime timer is started and the message is sent to the RADIUS server 2. If after retry*timeout seconds no RADIUS accounting response is received for the accounting stop, then a new attempt to send the message is started after minimum[(min-val*2n), max-val] seconds. 3. Repeat step 2 until <ol style="list-style-type: none"> a. a RADIUS accounting response is received, or b. the lifetime of the buffered message expires, or c. the message is manually purged from the message buffer via a clear command 4. The message is purged from the buffer. <p>The no form of the command disables RADIUS accounting stop message buffering.</p>
Default	no acct-interim
Parameters	<p><i>min-val</i> — Secifies the minimum interval in seconds between attempts to resend the RADIUS accounting stop</p> <p>Values 1 – 3600</p> <p><i>max-val</i> — Specifies the maximum interval in seconds between attempts to resend the RADIUS accounting stop.</p> <p>Values 1 – 3600</p> <p><i>max-val</i> — Specifies the lifetime in hours.</p> <p>Values 1 – 25</p>

servers

Syntax	servers
Context	config>aaa>radius-srv-plcy
Description	This command enables the context to configure radius-server-policy parameters.

access-algorithm

Syntax	access-algorithm {direct round-robin hash-based} no access-algorithm
Context	config>aaa>radius-srv-plcy>servers
Description	This command configures the algorithm used to select a RADIUS server from the pool of configured RADIUS servers.
Default	direct
Parameters	direct — Specifies that the first server will be used as primary server for all requests, the second as secondary and so on. round-robin — Specifies that the first server will be used as primary server for the first request, the second server as primary for the second request, and so on. If the router gets to the end of the list, it starts again with the first server. hash-based — Select a RADIUS server based on the calculated hash result of the configured load-balance-key under the radius-proxy server hierarchy. This parameter is only applicable for radius-proxy server scenarios and results in an unpredictable RADIUS server selection if used in other scenarios.

disable-stickiness

Syntax	[no] disable-stickiness
Context	config>aaa>radius-srv-plcy>servers
Description	This command disables a subscriber RADIUS accounting session from sticking with a single server under normal working conditions. If a direct algorithm is used, all subscriber RADIUS sessions will go directly to the server with the lowest configured index. If a failure occurs, a new in-service server with the next lowest index will be used. When the original server recovers, if stickiness is not disabled, all existing sessions will continue to use the new server. This command disables stickiness, and as a result, the recovered original RADIUS server will again service every subscriber. If a round-robin algorithm is used and stickiness is not disabled, an accounting session for a particular subscriber (or host, depending on the accounting mode) will stay with the same server. This command removes the stickiness and all subscriber accounting messages will go through the list of servers in a round-robin manner.

Default n/a

health-check

Syntax **health-check**

Context config>aaa>radius-server-policy>servers

Description This command performs a health check of the RADIUS server.

test-account

Syntax **test-account**

Context config>aaa>radius-srv-plcy>servers>health-check

Description This command sets up a test account as a probing mechanism to check the connectivity of all configured RADIUS authentication servers within the RADIUS server policy.

interval

Syntax **interval** *seconds*
no interval

Context config>aaa>radius-srv-plcy>servers>health-check>test-account

Description This command specifies the intervals at which the test account will send its access requests to probe the RADIUS servers.

Default no interval

Parameters *seconds* — specifies the probing interval

Values 1 to 60

password

Syntax **password** *password* [**hash** | **hash2**]
no password

Context config>aaa>radius-srv-plcy>servers>health-check>test-account
config>subscr-mgmt>brg-profile>radius-authentication

Description This command specifies the password that the test account will use to send access requests to probe the RADIUS servers.

Default	no password
Parameters	<i>password</i> — specifies the probing password
Values	64-character maximum string
	hash — Specifies the key is entered in an encrypted form. If the hash or hash2 parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the hash or hash2 parameter specified
	hash2 — Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the hash2 encrypted variable cannot be copied and pasted. If the hash or hash2 parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the hash or hash2 parameter specified.

shutdown

Syntax	[no] shutdown
Context	config>aaa>radius-srv-plcy>servers>health-check>test-account
Description	This command disables the test account that probes the RADIUS server.
Default	no shutdown

user-name

Syntax	user-name <i>user-name</i> no user-name
Context	config>aaa>radius-srv-plcy>servers>health-check>test-account
Description	This command specifies the username that the test account will use to send its access requests to probe the RADIUS servers.
Default	no user-name
Parameters	<i>user-name</i> — the probing username, up to 64 characters in length

retry

Syntax	retry <i>count</i> no retry
Context	config>aaa>radius-srv-plcy>servers

Description	This command configures the number of times the router attempts to contact the RADIUS server, if not successful the first time.
Default	3
Parameters	<i>count</i> — Specifies the number of times a signalling request message is transmitted towards the same peer.
Values	1 to 256

router

Syntax	router <i>router-instance</i> router service-name <i>service-name</i> no router								
Context	config>aaa>radius-srv-plcy>servers								
Description	This command specifies the virtual router instance applicable for the set of configured RADIUS servers. This value cannot be changed once a RADIUS server is configured for this policy.								
Default	no router								
Parameters	<i>router-instance</i> — Specifies the router instance.								
Values	<table> <tr> <td>service-name</td><td>Service name up to 64 characters.</td></tr> <tr> <td>router-instance:</td><td>router-name, service-id</td></tr> <tr> <td>router-name:</td><td>Base, management</td></tr> <tr> <td>service-id:</td><td>1 to 2147483647</td></tr> </table>	service-name	Service name up to 64 characters.	router-instance:	router-name, service-id	router-name:	Base, management	service-id:	1 to 2147483647
service-name	Service name up to 64 characters.								
router-instance:	router-name, service-id								
router-name:	Base, management								
service-id:	1 to 2147483647								
	<i>service-name</i> — Specifies the router name service-id up to 64 characters.								

server

Syntax	server <i>server-index</i> name <i>server-name</i> no server <i>server-index</i>
Context	config>aaa>radius-srv-plcy>servers
Description	This command adds a RADIUS server. The no form of the command removes a RADIUS server.
Default	none

Parameters *index* — The index for the RADIUS server. The index determines the sequence in which the servers are queried for authentication requests. Servers are queried in order from lowest to highest index.

Values 1 to 5

server-name — Specifies the server name up to 32 characters in length.

source-address

Syntax **source-address** *ip-address*
no source-address

Context config>aaa>radius-srv-plcy>servers

Description This command configures the source address of the RADIUS packet. The system IP address must be configured in order for the RADIUS client to work. See Configuring a System Interface in the 7750 SR OS Configuration Guide.

Note: The system IP address must only be configured if the source-address is not specified. When the no source-address command is executed, the source address is determined at the moment the request is sent. This address is also used in the nas-ip-address attribute: over there it is set to the system IP address if no source-address was given.

The no form of the command reverts to the default value.

Default no source-address

Parameters *ip-address* — Specifies the source address of radius packet.

timeout

Syntax **timeout** [**sec** *seconds*] [**min** *minutes*]
no timeout

Context config>aaa>radius-srv-plcy>servers

Description This command configures the time the router waits for a response from a RADIUS server.

The no form of the command reverts to the default value.

Default 5 seconds

Parameters *seconds* — Specifies the number of seconds for the timeout.

Values 1 to 59

minutes — Specifies the number of minutes for the timeout.

Values 1 to 1

Values Max. value = 5 min 40 sec

hold-down-time

Syntax	hold-down-time [sec <i>seconds</i>] [min <i>minutes</i>] [hrs <i>hours</i>] [days <i>days</i>] no hold-down-time
Context	config>aaa>radius-srv-plcy>servers
Description	This command configures the hold time before re-using a RADIUS server. The no form of the command reverts to the default value.
Default	30 seconds
Parameters	<i>seconds</i> — Specifies the number of seconds for the hold down time. Values 1 to 59 <i>minutes</i> — Specifies the number of minutes for the hold down time. Values 1 to 59 <i>hours</i> — Specifies the number of hours for the hold down time. Values 1 to 23 <i>days</i> — Specifies the number of days for the hold down time. Values 1 to 1

ipv6-source-address

Syntax	ipv6-source-address <i>ipv6-address</i> no ipv6-source-address
Context	config>aaa>radius-srv-plcy>servers
Description	This command configures the source address of an IPv6 RADIUS packet. When no <i>ipv6-source-address</i> is configured, the system IPv6 address (inband RADIUS server connection) or Boot Option File (BOF) IPv6 address (outband RADIUS server connection) must be configured in order for the RADIUS client to work with an IPv6 RADIUS server. This address is also used in the NAS-IPv6-Address attribute. The no form of the command reverts to the default value.

Default no ipv6-source-address

Parameters *ipv6-address* — Specifies the source address of an IPv6 RADIUS packet.

11.23.2.2 CLI Command Description for RADIUS Server

radius-server

Syntax	radius-server
Context	config>router config>service>vpn
Description	This command enters the radius-server configuration context under router or VPRN service.
Default	none

server

Syntax	server <i>server-name</i> [address <i>ip-address</i>] [secret <i>key</i>] [hash hash2] [create] no server <i>server-name</i>
Context	config>router>radius-server config>service>vpn>radius-server
Description	<p>This command either specifies an external RADIUS server in the corresponding routing instance or enters configuration context of an existing server. The configured server could be referenced in the radius-server-policy.</p> <p>The no form of the command removes the parameters from the server configuration.</p>
Default	no
Parameters	<p><i>server-name</i> — Specifies the name of the external RADIUS server</p> <p>address <i>ip-address</i> — Specifies the IPv4 or IPv6 IP address of the external RADIUS server.</p> <p>secret <i>key</i> — Specifies the shared secret key of the external RADIUS server</p> <p>hash — Specifies the key is entered in an encrypted form. If the hash or hash2 parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the hash or hash2 parameter specified</p> <p>hash2 — Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the hash2 encrypted variable cannot be copied and pasted. If the hash or hash2 parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the hash or hash2 parameter specified.</p>

accept-coa

Syntax	[no] accept-coa
Context	config>router>radius-server>server config>service>vpn>radius-server>server
Description	This command configures this server for Change of Authorization messages. The system will process the CoA request from the external server if configured with this command; otherwise the CoA request will be dropped. The no form of the command disables the command.

acct-port

Syntax	acct-port <i>port</i> no acct-port
Context	config>router>radius-server>server config>service>vpn>radius-server>server
Description	This command specifies the UDP listening port for RADIUS accounting requests. The no form of the commands resets the UDP port to its default value (1813)
Default	acct-port 1813
Parameters	<i>port</i> — Specifies the UDP listening port for accounting requests of the external RADIUS server. Values 1 to 65535

auth-port

Syntax	auth-port <i>port</i> no auth-port
Context	config>router>radius-server>server config>service>vpn>radius-server>server
Description	This command specifies the UDP listening port for RADIUS authentication requests. The no form of the commands resets the UDP port to its default value (1812)
Default	auth-port 1812
Parameters	<i>port</i> — Specifies the UDP listening port for accounting requests of the external RADIUS server. Values 1 to 65535

coa-script-policy

Syntax	coa-script-policy <i>policy-name</i> no coa-script-policy
Context	config>router>radius-server>server config>service>vprn>radius-server>server
Description	This command specifies radius-script-policy for CoA-Request sent from this RADIUS server. The no form of the command removes the policy name from the configuration.
Default	none
Parameters	<i>policy-name</i> — Specifies the name of radius-script-policy up to 80 characters in length.

pending-requests-limit

Syntax	pending-request-limit <i>limit</i> no pending-request-limit
Context	config>router>radius-server>server config>service>vprn>radius-server>server
Description	This command specifies the per-server maximum number of outstanding requests sent to the RADIUS server. If the maximum number is exceeded, the next RADIUS server in the pool is selected. The no form of the command removes the limit value from the configuration.
Default	none
Parameters	<i>limit</i> — Specifies the maximum number of outstanding requests sent to the RADIUS server Values 1 to 4096

11.23.2.3 CLI Command Description for RADIUS Proxy Server

radius-proxy

Syntax	radius-proxy
Context	config>router config>service>vprn
Description	This command context to configure RADIUS proxy parameters.

server

Syntax	server <i>server-name</i> [create] [purpose {[accounting authentication]}] [wlan-gw-group <i>group-id</i>] no server <i>server-name</i>
Context	config>router>radius-proxy config>service>vpn>radius-proxy
Description	<p>This command creates a RADIUS-proxy server in the corresponding routing instance. The proxy server can be configured for the purpose of proxying authentication or accounting or both.</p> <p>If a WLAN-GW ISA group is specified, then the RADIUS proxy server is instantiated on the set of ISAs in the specified wlan-gw group. The RADIUS messages from the AP are load-balanced to these ISAs. The ISA that processes the RADIUS message then hashes this message to the ISA that anchors the UE. The hash is based on UE MAC address (required to be present in the calling-station-id attribute) in the RADIUS message.</p> <p>If the create parameter is not specified, then this command enters configuration context of the specified RADIUS-proxy server.</p> <p>The no form of the command removes the server-name and parameters from the radius-proxy configuration.</p>
Default	purpose authentication
Parameters	<p><i>server-name</i> — Specifies the name of the RADIUS-proxy server.</p> <p>create — The creation parameter. The system will create the specified RADIUS-proxy server.</p> <p>purpose — Specifies the purpose the RADIUS-proxy server,</p> <p style="padding-left: 40px;">Values</p> <p style="padding-left: 80px;">accounting — proxy accounting packets.</p> <p style="padding-left: 80px;">authentication — proxy authentication packets .</p> <p style="padding-left: 80px;">both — Specifies both accounting and authentication proxy accounting packets.</p> <p>wlan-gw-group <i>group-id</i> — Specifies the WLAN-GW isa group.</p>

attribute-matching

Syntax	attribute-matching
Context	config>router>radius-proxy>server config>service>vpn>radius-proxy>server
Description	This command enables the context for selecting the RADIUS policy for authentication and accounting based on the RADIUS attribute. This feature is supported for both the ESM RADIUS proxy and the ISA RADIUS proxy.

entry

Syntax	entry [1 to 32] [prefix-string <i>prefix-string</i>] [accounting-server-policy <i>policy-name</i>] [authentication-server-policy <i>policy-name</i>] [suffix-string <i>suffix-string</i>] [no] entry [1 to 32]
Context	config>router>radius-proxy>server>attribute-matching config>service>vpn>radius-proxy>server>attribute-matching
Description	This command matches the specified prefix or suffix string with the selected accounting server policy or authentication server policy.
Default	n/a
Parameters	1 to 32 — specifies the entry number; up to 32 matching entries can be specified <i>prefix-string</i> — specifies the prefix string for matching up to 128 characters maximum; if the suffix-string is also used, the combined length cannot exceed 126 characters <i>suffix-string</i> — specifies the suffix string for matching up to 126 characters maximum; if the prefix-string is also used, the combined length cannot exceed 126 characters accounting-server-policy <i>policy-name</i> — specifies the RADIUS accounting policy up to 32 characters maximum authentication-server-policy <i>policy-name</i> — specifies the RADIUS authentication policy up to 32 characters maximum

type

Syntax	type [1 to 255] [vendor-id <i>vendor-id</i>] no type
Context	config>router>radius-proxy>server>attribute-matching config>service>vpn>radius-proxy>server>attribute-matching
Description	This command specifies the RADIUS VSA type for the entries to be matched with.
Default	no type
Parameters	1 to 255 — the VSA number <i>vendor-id</i> — the vendor ID number Values 1 to 16777215 alu

cache

Syntax	cache
Context	config>router>radius-proxy>server

```
config>service>vpn>radius-proxy>server
```

Description This command enters the cache configuration context under radius-proxy server. The cache contains per-subscriber authentication information learned from RADIUS authentication messages, and is used to authorize subsequent DHCP requests.

Default none

default-accounting-server-policy

Syntax **default-accounting-server-policy** *policy-name*
no default-accounting-server-policy

Context config>router>radius-proxy>server
config>service>vpn>radius-proxy>server

Description This command specifies the default radius-server-policy for RADIUS accounting. This policy will be used when there is no specific match based on username.

The **no** form of the command removes the policy name from the configuration.

Default none

Parameters *policy-name* — Specifies the name of the default RADIUS server policy associated with this RADIUS Proxy server for accounting purposes.

default-authentication-server-policy

Syntax **default-authentication-server-policy** *policy-name*
no default-authentication-server-policy

Context config>router>radius-proxy>server
config>service>vpn>radius-proxy>server

Description This command specifies the default radius-server-policy for RADIUS authentication. This policy will be used when there is no specific match based on username.

The **no** form of the command removes the policy name from the configuration.

Default none

Parameters *policy-name* — Specifies the name of the default RADIUS server policy associated with this RADIUS proxy server for authentication purposes.

interface

Syntax [**no**] **interface** *ip-int-name*

Context	config>router>radius-proxy>server config>service>vprn>radius-proxy>server
Description	This command configures the IP interface the RADIUS-proxy server will bind to. One RADIUS-proxy server could bind to multiple interfaces.
Default	none
Parameters	<i>ip-int-name</i> — Specifies the name of IP interface.

load-balance-key

Syntax	load-balance-key [vendor <i>vendor-id</i> [<i>vendor-id...</i> (up to 5 max)]] attribute-type <i>attribute-type</i> [<i>attribute-type...</i> (up to 5 max)] load-balance-key source-ip-udp no load-balance-key
Context	config>router>radius-proxy>server config>service>vprn>radius-proxy>server
Description	This command specifies the key(s) used in calculating a hash to select an external RADIUS server from the pool of configured servers. The key(s) can be the source ip and source udp port tuple, or the specified radius attribute(s) in radius packets. The no form of the command removes the parameters from the configuration.
Default	no load-balance-key
Parameters	vendor <i>vendor-id</i> — Specifies the vendor-id of vendor-specific attribute. Values 0 to 16777215 attribute-type <i>attribute-type</i> — Specifies that the key is constructed with the attributes in the RADIUS message. Values 1 to 255 source-ip-udp — Specifies that the key consists of the source IP address and source UDP port of the RADIUS message.

python-policy

Syntax	python-policy <i>name</i> no python-policy
Context	config>router>radius-proxy>server
Description	This command specifies the Python policy used to change the RADIUS attributes of the different RADIUS messages.

secret

Syntax	secret <i>secret</i> [hash hash2] no secret
Context	config>router>radius-proxy>server config>service>vpn>radius-proxy>server
Description	<p>This command configures the shared secret key. The RADIUS client must have the same key to communicate with the RADIUS-proxy server.</p> <p>The no form of the command removes the parameters from the configuration.</p>
Default	none
Parameters	<p>secret <i>key</i> — The secret key to access the RADIUS server. This secret key must match the password on the RADIUS server.</p> <p>Values</p> <ul style="list-style-type: none">secret-key: Up to 20 characters in length.hash-key: Up to 33 characters in length.hash2-ke: Up to 55 characters in length. <p>hash — Specifies the key is entered in an encrypted form. If the hash or hash2 parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the hash or hash2 parameter specified</p> <p>hash2 — Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the hash2 encrypted variable cannot be copied and pasted. If the hash or hash2 parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the hash or hash2 parameter specified.</p>

send-accounting-response

Syntax	[no] send-accounting-response
Context	config>router>radius-proxy>server config>service>vpn>radius-proxy>server
Description	<p>This command results in the system to always generate RADIUS accounting-response to acknowledge RADIUS accounting-request received from the RADIUS client.</p> <p>The no form of the command disables the command.</p>
Default	no send-accounting-response

key

Syntax	key packet-type { accept request } attribute-type <i>attribute-type</i> [vendor <i>vendor-id</i>] no key
Context	config>router>radius-proxy>server>cache config>service>vpn>radius-proxy>server>cache
Description	This command specifies the RADIUS cache key that is used to match the information in subsequent DHCP requests for authorization.
Default	no key
Parameters	<p>packet-type — Specifies the packet type of the RADIUS messages to use to generate the key for the cache of this RADIUS proxy server.</p> <p>Values accept, request</p> <p>attribute-type <i>attribute-type</i> — Specifies the RADIUS attribute type to cache for this RADIUS proxy server.</p> <p>Values 1 to 255 the type value of RADIUS attribute</p> <p>vendor <i>vendor-id</i> — Specifies the RADIUS vendor ID.</p> <p>Values 1 to 16777215, alu</p>

timeout

Syntax	timeout [hrs <i>hours</i>] [min <i>minutes</i>] [sec <i>seconds</i>] no timeout
Context	config>router>radius-proxy>server>cache config>service>vpn>radius-proxy>server>cache
Description	<p>This command configures the time for which the cache entry is kept if there is no corresponding DHCP DISCOVER. At the expiry of this time, the cache entry is deleted.</p> <p>The no form of the command reverts to the default value.</p>
Default	timeout min 5
Parameters	<p>hrs <i>hours</i> — Specifies, in seconds, the timeout after which an entry in the cache will expire.</p> <p>min <i>minutes</i> — Specifies, in seconds, the timeout after which an entry in the cache will expire.</p> <p>sec <i>seconds</i> — Specifies, in seconds, the timeout after which an entry in the cache will expire.</p>

track-accounting

Syntax	track-accounting [start] [stop][interim-update][accounting-on] [accounting-off] no track-accounting
Context	config>router>radius-proxy>server>cache config>service>vpn>radius-proxy>server>cache
Description	<p>This command specifies the type of RADIUS accounting packets from RADIUS client (a WIFI AP) that the router should track.</p> <p>The no form of the command removes the parameters from the configuration.</p>
Default	no track-accounting
Parameters	<p>start — The router will update the associated ESM-host with the RADIUS client (for example, a WIFI AP) that generated the accounting-start. This is required in cases where a UE roams to a new AP that does not re-authenticate due to key caching.</p> <p>stop — The router will remove the corresponding ESM host and forward the accounting-stop packet to the external RADIUS server.</p> <p>accounting-on accounting-off — The router will remove all ESM hosts associated with the RADIUS client (a WIFI AP), and forward the accounting-on packet to the external RADIUS server.</p> <p>interim-update — The router will update the associated ESM-host with the RADIUS client (e.g. a WIFI AP) that generated the interim-update. The interim-updates with the updated information are sent to the RADIUS server as scheduled.</p>

track-authentication

Syntax	track-authentication [accept] no track-authentication
Context	config>router>radius-proxy>server>cache config>service>vpn>radius-proxy>server>cache
Description	<p>This command specifies if RADIUS authentication (from the AP) should be tracked in order to update the ESM host with the RADIUS client (for example, WIFI AP) on UE mobility. It also specifies the authentication packet from RADIUS client (for example, a WIFI AP) that the router should track for mobility.</p> <p>The no form of this command stops tracking authentication for UE mobility.</p>
Default	Not enabled
Parameters	<p>accept — Indicates access-accept is tracked for mobility.</p>

track-delete-hold-time

Syntax	track-delete-hold-time <i>seconds</i> no track-delete-hold-time
Context	config>router>radius-proxy>server>cache
Description	This command specifies the delete hold-time in case the DHCP host gets a trigger to delete from the matched RADIUS Proxy server.
Default	0
Parameters	<i>seconds</i> — Specifies the delete hold time, in seconds. Values 0 to 600

11.23.2.4 LUDB Matching of RADIUS Proxy Cache Commands

local-user-db

Syntax	local-user-db <i>local-user-db-name</i> [create] no local-user-db <i>local-user-db-name</i>
Context	config>subscr-mgmt
Description	This command enables the context to configure a local user database.
Default	not enabled
Parameters	<i>local-user-db-name</i> — Specifies the name of a local user database.

dhcp

Syntax	dhcp
Context	config>subscr-mgmt>loc-user-db
Description	This command configures DHCP host parameters.

host

Syntax	host
Context	config>subscr-mgmt>loc-user-db

Description This command enables the context to configure DHCP host parameters.

match-radius-proxy-cache

Syntax **match-radius-proxy-cache**

Context config>subscr-mgmt>loc-user-db>ipoe>host

Description This command enables the context to configure match-radius-proxy-cache parameters.

fail-action

Syntax **fail-action {continue | drop}**
no fail-action

Context config>subscr-mgmt>loc-user-db>ipoe>host>match-radprox-cache

Description This command specifies the router's action when failed to find matched radius-proxy-server cache entry.

The **no** form of the command reverts to the default.

Default drop

Parameters **continue** — Specifies that the will proceed with ESM authentication without dropping the DHCP packet.

drop — Specifies that the router will drop the DHCP packet.

mac-format

Syntax **mac-format** *format*
no mac-format

Context config>subscr-mgmt>loc-user-db>ipoe>host>match-radprox-cache

Description This command specifies the format of MAC address used for matching incoming DHCP DISCOVER against the RADIUS proxy cache.

The **no** form of the command reverts to the default.

Default mac-format "aa:"

Parameters *format* — Specifies the format string that specifies the format of MAC address.

Values

mac-format: (only when match is equal to mac)
like ab: for 00:0c:f1:99:85:b8

or XY- for 00-0C-F1-99-85-B8
or mmmm. for 0002.03aa.abff
or xx for 000cf19985b8

match

Syntax	match {circuit-id mac remote-id} match option [1 to 254] no match
Context	config>subscr-mgmt>loc-user-db>ipoe>host>match-radprox-cache
Description	This command specifies the field/option of DHCP packet that is used to match against the radius-proxy-server cache. The no form of the command reverts to the default.
Default	mac
Parameters	circuit-id — Specifies to match the circuit-id in DHCP option82 remote-id — Specifies to match the remote-id in DHCP option82 mac — Specifies to match the MAC address of DHCP client option — Specifies to use specified DHCP option, 1 to 254

server

Syntax	server [service service-id] name server-name no server
Context	config>subscr-mgmt>loc-user-db>ipoe>host>match-radprox-cache
Description	This command specifies the name of radius-proxy-server and optionally id of the service that the radius-proxy-server resides in. The no form of the command removes the parameters from the configuration.
Default	no server
Parameters	service service-id — Specifies the ID or name of the service. Values 1 to 214748365 svc-name up to 64 char maximum name server-name — Specifies the name of radius-proxy-server up to 32 characters in length.

11.23.2.5 WLAN-GW-Group Commands

wlan-gw-group

Syntax	wlan-gw-group <i>group-id</i> [create] no wlan-gw-group <i>group-id</i>
Context	config>isa
Description	This command creates a WLAN GW group.

Note: The wlan-gw-group ID shares the same number space with the nat-group.

The **no** form of the command removes the group

Default	none
Parameters	<i>group-id</i> — Specifies WLAN Gateway Integrated Service Adaptor (ISA) Groups. Values 1 to 4

active-iom-limit

Syntax	active-iom-limit <i>number</i> no active-iom-limit
Context	config>isa>wlan-gw-group
Description	This command specifies the number of WLAN-GW IOMs used as active IOMs from the total number of configured WLAN-GW IOMs. If there are more configured IOM than active-iom-limit, then the remaining number of IOMs will be designated as backup(s). The no form of the command removes the number from the configuration.
Parameters	<i>number</i> — Specifies the number of IOM's in this WLAN Gateway ISA group that are intended for active use. Values 1 to 3

distributed-sub-mgmt

Syntax	[no] distributed-sub-mgmt
Context	config>isa>wlan-gw-group

Description	This command configures the WLAN gateway distributed subscriber management.
--------------------	---

isa-aa-group

Syntax	isa-aa-group <i>aa-group-id</i> no isa-aa-group
Context	config>isa>wlan-gw-group>distributed-sub-mgmt
Description	This command configures an ISA application assurance group for WLAN gateway DSM subscribers.

iom

Syntax	iom <i>slot-number</i> type {[load-balancer] [ue-anchor]} no iom <i>slot-number</i>
Context	config>isa>wlan-gw-group
Description	<p>This command designates the specified IOM as a WLAN-GW IOM. Each WLAN-GW IOM must be provisioned with two ISA-BB modules on a hardware chassis and with an ISA-BB module in the first MDA slot in the VSR.</p> <p>The no form of the command removes the IOM from the configuration.</p>
Default	none
Parameters	<p><i>slot-number</i> — Indicates the IOM slot to be used in the WLAN-GW group.</p> <p>Values 1 to 10</p> <p>type {[load-balancer] [ue-anchor]} — This parameter is supported on the VSR only. It determines if an IOM slot will be used for load-balancing or UE anchoring and processing, or both. When the wlan-gw-group has only a single IOM, it is required to put this IOM in both modes at the same time.</p>

nat

Syntax	nat
Context	config>isa>wlan-gw-group
Description	This command enables the context to configure NAT parameters under wlan-gw-group.

radius-accounting-policy

Syntax	radius-accounting-policy <i>nat-accounting-policy</i> no radius-accounting-policy
Context	config>isa>wlan-gw-group>nat
Description	This command configures the RADIUS accounting policy to use for each MDA in this ISA group. The no form of the command removes the accounting policy from the configuration.
Default	none
Parameters	<i>nat-accounting-policy</i> — Specifies the RADIUS accounting policy up to 32 characters in length.

session-limits

Syntax	session-limits
Context	config>isa>wlan-gw-group>nat
Description	This command configures the ISA NAT group session limits.

reserved

Syntax	reserved <i>num-sessions</i> no reserved
Context	config>isa>nat>session-limits
Description	This command configures the number of sessions per block that will be reserved for prioritized sessions.
Parameters	<i>num-sessions</i> — Specifies the number of sessions reserved for prioritized sessions. Values 0 to 4194303

watermarks

Syntax	watermarks high <i>percentage</i> low <i>percentage</i> no watermarks
Context	config>isa>nat>session-limits
Description	This command configures the ISA NAT group watermarks.

Parameters	high <i>percentage</i> — Specifies the high watermark of the number of sessions for each MDA in this NAT ISA group.
	Values 2 to 100
	low <i>percentage</i> — Specifies the low watermark of the number of sessions for each MDA in this NAT ISA group.
	Values 1 to 99

11.23.2.6 Port Policy Commands

port-policy

Syntax	port-policy <i>port-policy-name</i> [create] no port-policy <i>port-policy-name</i>
Context	config
Description	This command either creates a new port-policy with create parameter or enters the configuration context of an existing port-policy.
Default	none
Parameters	<i>port-policy-name</i> — Specifies the name of port-policy. create — Keyword used to create a port-policy.

egress-scheduler-policy

Syntax	egress-scheduler-policy <i>port-sched-plcy</i> egress-scheduler-policy
Context	config>port-policy
Description	This command specifies the port-scheduler-policy to use in the egress direction for the internal port connecting the WLAN-GW IOM to the MS-ISA.
Default	none
Parameters	<i>port-sched-plcy</i> — Specifies the name of the port-scheduler-policy up to 32 characters in length.

11.23.2.7 WLAN-GW Group Interface Commands

Note: The **wlan-gw** commands apply only to the 7750 SR platform.

group-interface

Syntax	group-interface <i>ip-int-name</i> [create] group-interface <i>ip-int-name</i> [create] lns group-interface <i>ip-int-name</i> [create] wlangw no group-interface <i>ip-int-name</i> [create]
Context	config>service>ies>subscriber-interface config>service>vpn>subscriber-interface
Description	<p>This command creates a group interface. This interface is designed for triple-play services where multiple SAPs are part of the same subnet. A group interface may contain one or more SAPs.</p> <p>Use the no form of the command to remove the group interface from the subscriber interface.</p>
Default	no group interfaces configured
Parameters	<p><i>ip-int-name</i> — Specifies the interface name of a group interface. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.</p> <p>lns — Specifies to use LNS.</p> <p>wlangw — Specifies the group interface for wlan-gw.</p>

ip-mtu

Syntax	ip-mtu <i>octets</i> no ip-mtu
Context	config>service>ies>subscriber-interface config>service>vpn>subscriber-interface
Description	<p>This command specifies the maximum size of frames on this group-interface. Packets larger than this will get fragmented.</p> <p>The no form of the command removes this functionality.</p>
Default	none

Parameters	<i>octets</i> — Specifies the largest frame size (in octets) that this interface can handle.
Values	512 to 9000

sap-parameters

Syntax	sap-parameters
Context	config>service>ies>sub-if>grp-if config>service>vprn>sub-if>grp-if
Description	This command enables the context to configure parameters that can be applied to automatically-generated internal SAPs.
Default	N/A

anti-spoof

Syntax	anti-spoof {ip-mac nh-mac} no anti-spoof
Context	config>service>ies>sub-if>grp-if>sap-parameters config>service>vprn>sub-if>grp-if>sap-parameters
Description	<p>This command configures the anti-spoof type of the SAP.</p> <p>The type of anti-spoof filtering defines what information in the incoming packet is used to generate the criteria to lookup an entry in the anti-spoof filter table. The type parameter (ip-mac or nh-mac) defines the anti-spoof filter type enforced by the SAP when anti-spoof filtering is enabled.</p> <p>The no form of the command reverts back to the default.</p>
Default	no anti-spoof
Parameters	<p>ip-mac — Configures SAP anti-spoof filtering to use both the source IP address and the source MAC address in its lookup. The anti-spoof ip-mac command will fail if the default anti-spoof filter type of the SAP is ip-mac and the default is not overridden, or if the SAP does not support Ethernet encapsulation.</p> <p>nh-mac — Indicates that the ingress anti-spoof is based on the source MAC address and egress anti-spoof is based on the nh-ip-address.</p>

wlan-gw

Syntax	wlan-gw
Context	config>service>ies>sub-if>group-interface

```
config>service>vprn>sub-if> group-interface
```

Description This command enables the context to configure wlan-gw parameters.

Default none

egress

Syntax **egress**

Context config>service>ies>sub-if>grp-if>wlan-gw

Description This command enables the context to configure egress QoS parameters for wlan-gw tunnels.

agg-rate-limit

Syntax **agg-rate-limit** *kilobits-per-second*
no agg-rate-limit

Context config>service>ies>sub-if>grp-if>wlan-gw>egress
config>service>vprn>sub-if>grp-if>wlan-gw>egress

Description This command is used to control an HQoS aggregate rate limit. It is used in conjunction with the following parameter commands: **rate**, **limit-unused-bandwidth**, and **queue-frame-based-accounting**.

Parameters *kilobits-per-second* — Specifies the aggregate rate limit.

Values 1 to 100000000, max

rate

Syntax **rate** {**max** | **rate**}
no rate

Context config>service>ies>sub-if>grp-if>wlan-gw>egress>agg-rate
config>service>vprn>sub-if>grp-if>wlan-gw>egress>agg-rate

Description This command defines the enforced aggregate rate for all queues associated with the agg-rate context. A rate must be specified for the agg-rate context to be considered to be active on the context's object (SAP, subscriber, Vport, etc.).

limit-unused-bandwidth

Syntax [**no**] **limit-unused-bandwidth**

Context	config>service>ies>if>sap>egress>agg-rate config>service>ies>sub-if>grp-if>sap>egress>agg-rate config>service>vprn>if>sap>egress>agg-rate config>service>vprn>sub-if>grp-if>sap>egress>agg-rate
Description	This command is used to enable (or disable) aggregate rate overrun protection on the agg-rate context.

queue-frame-based-accounting

Syntax	[no] queue-frame-based-accounting
Context	config>service>ies>if>sap>egress>agg-rate config>service>ies>sub-if>grp-if>sap>egress>agg-rate config>service>vprn>if>sap>egress>agg-rate config>service>vprn>sub-if>grp-if>sap>egress>agg-rate
Description	This command is used to enabled (or disable) frame based accounting on all policers and queues associated with the agg-rate context. Only supported on Ethernet ports. Not supported on HSMDA Ethernet ports. Packet byte offset settings are not included in the applied rate when queue frame based accounting is configured, however the offsets are applied to the statistics.

hold-time

Syntax	hold-time infinite hold-time [1 to 86400] no hold-time
Context	config>service>ies>sub-if>grp-if>wlan-gw>egress config>service>vprn>sub-if>grp-if>wlan-gw>egress
Description	This command configures the time for which egress shaping resources associated with a wlan-gw tunnel are held after the last subscriber on a tunnel is deleted.
Parameters	1 to 86400 — Specifies the time, in seconds, for which shaping resources are held in seconds after last subscriber is deleted.
Values	infinite to 1 to 86400

qos

Syntax	qos <i>policy-id</i> no qos
Context	config>service>ies>sub-if>grp-if>wlan-gw>egress

Description	<p>This command configures the identifier of the egress QoS policy associated with each wlan-gw tunnel of this interface.</p> <p>The no form of the command removes the policy ID from the configuration.</p>				
Default	1				
Parameters	<p><i>policy-id</i> — Specifies to apply the specified sap-egress-policy-id.</p> <table><tr><td>Values</td><td>1 to 65535</td></tr><tr><td></td><td>name: A string up to 64 characters.</td></tr></table>	Values	1 to 65535		name: A string up to 64 characters.
Values	1 to 65535				
	name: A string up to 64 characters.				

scheduler-policy

Syntax	scheduler-policy <i>scheduler-policy-name</i> no scheduler-policy
Context	config>service>ies>sub-if>grp-if>wlan-gw>egress
Description	<p>This command configures the identifier of the egress scheduler policy associated with each wlan-gw tunnel of this interface.</p> <p>The no form of the command removes the scheduler policy name from the configuration.</p>
Default	none
Parameters	<i>scheduler-policy-name</i> — Specifies the identifier of the egress scheduler policy associated with each wlan-gw tunnel of this interface

shape-multi-client-only

Syntax	[no] shape-multi-client-only
Context	config>service>ies>sub-if>grp-if>wlan-gw>egress
Description	<p>This command enables the egress shaping is only enabled for a wlan-gw tunnel while there are multiple UE (User Equipment) using it.</p> <p>The no form of the command disables the egress shaping.</p>

shaping

Syntax	shaping { per-retailer per-tunnel } no shaping
Context	config>service>ies>sub-if>grp-if>wlan-gw>egress

Description	This command configures the the granularity of the egress shaping for wlan-gw on this group interface. The no form of the command removes the parameter from the configuration.
Parameters	per-tunnel — Specifies that a separate shaper is applied to each wlan-gw tunnel. per-retailer — Specifies that a separate shaper is applied to each retailer Mobile Network Operator's fraction of the wlan-gw tunnel payload.

gw-address

Syntax	gw-address <i>ip-address</i> no gw-address
Context	config>service>ies>sub-if>grp-if>wlan-gw config>service>vprn>sub-if>grp-if>wlan-gw
Description	This command specifies gateway endpoint address for the wlan-gw tunnel. The no form of the command removes the value from the wlan-gw configuration.
Default	none
Parameters	<i>ip-address</i> — Specifies the IP address of the wlan-gw tunnels on this group interface.

gw-ipv6-address

Syntax	gw-ipv6-address <i>ipv6-address</i> no gw-ipv6-address
Context	config>service>ies>sub-if>grp-if>wlan-gw config>service>vprn>sub-if>grp-if>wlan-gw
Description	This command specifies a gateway IPv6 endpoint address for the wlan-gw tunnel. The no form of the command removes the IPv6 the gateway IPv6 endpoint address for the wlan-gw tunnel.
Default	none
Parameters	<i>ipv6-address</i> — Specifies the gateway IPv6 endpoint address

Values

ipv6-address : x:x:x:x:x:x:x (eight 16-bit pieces)
 x:x:x:x:x:d.d.d.d
 x - [0 to FFFF]H
 d - [0 to 255]D

learn-ap-mac

Syntax	learn-ap-mac [delay-auth] no learn-ap-mac
Context	config>service>vprn>sub-if>grp-if>wlan-gw config>service>ies>sub-if>grp-if>wlan-gw
Description	<p>This command enables the sending of ARP or ND packets on the wlan-gw GRE tunnel upon certain events. The target IP address in the ARP/ND packet will be the endpoint IP address of the AP. The ARP/ND response from the AP should contain the AP MAC, which subsequently can be reported in called-station-id. When enabled this will be sent for following events:</p> <ul style="list-style-type: none"> • CPM: Mobility to an AP for which the AP-MAC is not yet known. • CPM: RS-triggered authentication on an AP for which the AP-MAC is not yet known • ISA: Any mobility event • ISA: Any authentication where the AP-MAC is not yet known (e.g. from radius proxy cache, DHCP circuit-id, etc.). If the optional keyword delay-auth is provided the authentication will be delayed until the ARP/ND is answered or timed out, after which the AP-MAC can be included in authentication. <p>This configuration is ignored for l2-ap and l2tpv3 access.</p>
Default	The no form of this command disables this mechanism.
Parameters	delay-auth — Specifies that authentication will be delayed until the ARP/ND is answered or timed out, after which the AP-MAC can be included in authentication.

l2-access-points

Syntax	l2-access-points
Context	config>service>ies>sub-if>grp-if>wlan-gw config>service>vprn>sub-if>grp-if>wlan-gw
Description	This command enables the context to configure Layer 2 Access Points in WLAN Gateway Group-Interfaces.

l2-ap

Syntax	l2-ap sap-id [create] no l2-ap sap-id
Context	config>service>vprn>sub-if>grp-if>wlan-gw>l2-access-points config>service>ies >sub-if>grp-if>wlan-gw>l2-access-points

Description	<p>This command adds a specific SAP where Layer-2 WLAN-GW aggregation will be performed. The following SAPs are supported.</p> <ul style="list-style-type: none">• Ethernet• LAG• MPLS pseudowire SDPs <p>This command can be repeated multiple times to create multiple Layer-2 access points.</p> <p>The no form of the command removes the Layer-2 access point. This is only allowed if the l2-ap SAP is shutdown.</p>
Default	No SAPs are defined
Parameters	<p>sap-id — Specifies SAP to be created. For the exact syntax, see the common CLI command description of the 7750 Services Guide.</p> <p>create — Keyword used to create the Layer-2 WLAN-GW aggregation instance. The create keyword requirement can be enabled/disabled in the environment>create context.</p>

encap-type

Syntax	encap-type {default null dot1q qinq} no encap-type
Context	config>service>vprn>sub-if>grp-if>wlan-gw>l2-access-points>l2-ap config>service>ies >sub-if>grp-if>wlan-gw>l2-access-points>l2-ap
Description	<p>If different from default, this command overrides the value specified by l2-ap-encap-type on wlan-gw level. See the description of l2-ap-encap-type for more detail. This value can only be changed while the l2-ap is shutdown.</p> <p>The no form of the command sets the default value.</p>
Default	default
Parameters	<p>default — Specifies to use the value specified by l2-ap-encap-type.</p> <p>null — Specifies to use both the SAP and the AP are not VLAN-tagged.</p> <p>dot1q — Specifies to use either the AP or the SAP uses one VLAN tag.</p> <p>qinq — Up to two VLAN tags are used by the AP or SAP.</p>

epipe-sap-template

Syntax	epipe-sap-template <i>name</i> no epipe-sap-template
---------------	---

Context	config>service>vprn>sub-if>grp-if>wlan-gw>l2-access-points>l2-ap config>service>ies >sub-if>grp-if>wlan-gw>l2-access-points>l2-ap
Description	This command specifies which SAP parameter template should be applied to the l2-ap SAP. This can only be changed when the l2-ap is shutdown. The no form of the command removes the template, the SAP will use default parameters.
Default	none
Parameters	<i>name</i> — Specifies the name of the template to use.

shutdown

Syntax	shutdown <i>sap-id</i> [create] no shutdown <i>sap-id</i>
Context	config>service>vprn>sub-if>grp-if>wlan-gw>l2-access-points>l2-ap config>service>ies >sub-if>grp-if>wlan-gw>l2-access-points>l2-ap
Description	This command administratively enables this SAP to begin accepting Layer 2 packets for WIFI offloading. The no form of the command disables this SAP.
Default	shutdown

l2-ap-encap-type

Syntax	2-ap-encap-type { null dot1q qinq }
Context	config>service>vprn>sub-if>grp-if>wlan-gw config>service>ies >sub-if>grp-if>wlan-gw
Description	This parameter specifies the number of AP identifying VLAN tags for an AP. This is the default value that can be overridden per SAP. This value should at least be equal to the number of VLANs configured in the SAP or enabling a SAP will fail. A SAP VLAN is explicitly configured, for example l2-ap 1/1/1:25 . Other VLANs on the same port can still be used in other contexts. The number of VLAN tags Epiped to WLAN-GW IOM equal the l2-ap-encap-type minus the encaps of the SAP. Upon receipt of a packet these VLANs will be stored as a Layer 2 tunnel identifier, and are only used in context of WLAN-GW. The no form of the command sets the default value.
Default	null

Parameters **null** — Both the SAP and the AP are not VLAN-tagged.
 dot1q — Either the AP or the SAP uses one VLAN tag.
 qinq — Up to two VLAN tags are used by the AP or SAP.

mobility

Syntax **mobility**

Context config>service>ies>sub-if>grp-if>wlan-gw
 config>service>vprn>sub-if>grp-if>wlan-gw

Description This command enables the context to configure mobility parameters.

hold-time

Syntax **hold-time** *time in s*
 no hold-time

Context config>service>ies>sub-if>grp-if>wlan-gw>mobility
 config>service>vprn>sub-if>grp-if>wlan-gw>mobility

Description This command configures the minimum time that a User Equipment will be held associated with its current Access Point (AP) before being associated with a new AP.

 The hold time is used to prevent overwhelming the system with mobility triggers, by limiting the rate at which a UE can move from one AP to another while the system is very busy already.

Default no default

Parameters *time in s* — Specifies a hold-down time, in seconds, for handling of successive mobility triggers for a UE. It is the minimal time a UE stays associated with an AP.

Values 0 to 255

trigger

Syntax **trigger** [**data**] [**iapp**] [**control**]
 no trigger

Context config>service>ies>sub-if>grp-if>wlan-gw>mobility
 config>service>vprn>sub-if>grp-if>wlan-gw>mobility

Description This command specifies the type of packet used as a mobility trigger.

This **no** form of the command removes the parameters from the configuration and disables data-plane mobility.

- Parameters**
- data** — Specifies that data traffic be used as a trigger.
 - iapp** — Specifies that Inter Access Point Protocol (IAPP) messages be used as a trigger.
 - control** — Specifies that control traffic can be used as a trigger.

multi-tunnel-type

- Syntax** **[no] multi-tunnel-type**
- Context** config>service>ies>sub-if>grp-if>wlan-gw>mobility
config>service>vprn>sub-if>grp-if>wlan-gw>mobility
- Description** This command enables terminating multiple types of tunnels.
- The **no** form of the command disables terminating multiple types of tunnels.

oper-down-on-group-degrade

- Syntax** **[no] oper-down-on-group-degrade**
- Context** config>service>ies>sub-if>grp-if>wlan-gw
config>service>vprn>sub-if>grp-if>wlan-gw
- Description** This command operationally brings down the WLAN-GW group if the total number of operational WLAN-GW IOMs in the WLAN-GW group fall below the configured number of active WLAN-GW IOMs. This triggers withdrawal of the route to tunnel endpoint and subscriber subnets in routing.
- Default** none

router

- Syntax** **router** *router-instance*
no router
- Context** config>service>ies>sub-if>grp-if>wlan-gw
config>service>vprn>sub-if>grp-if>wlan-gw
- Description** This command specifies the routing instance that wlan-gw gateway endpoint resides in.
- The **no** form of the command removes the value from the wlan-gw configuration.
- Default** none

Parameters *router-instance* — Specifies the identifier of the virtual router instance where the tunneled User Equipment traffic is routed.

tcp-mss-adjust

Syntax **tcp-mss-adjust** *segment-size*
no tcp-mss-adjust

Context config>service>ies>sub-if>grp-if>wlan-gw
 config>service>vprn>sub-if>grp-if>wlan-gw

Description This command configures the TCP Maximum Segment Size (MSS) adjustment for the wlan-gw gateway.

 The **no** form of the command disables adjusting tcp-mss values.

Default none

Parameters *segment-size* — Specifies the value to put into the TCP Maximum Segment Size (MSS) option if not already present, or if the present value is higher.

Values 160 to 10240

tunnel-encaps

Syntax **tunnel-encaps**

Context config>service>ies>sub-if>grp-if>wlan-gw
 config>service>vprn>sub-if>grp-if>wlan-gw

Description This command enables the context to configure tunnel encapsulation parameters.

learn-l2tp-cookie

Syntax **learn-l2tp-cookie** {if-match | never | always} [**cookie** *hex string*]
no learn-l2tp-cookie

Context config>service>ies>sub-if>grp-if>wlan-gw
 config>service>vprn>sub-if>grp-if>wlan-gw

Description This command specifies when this system will learn the cookie from L2TP tunnels terminating on this interface. Learning the cookie means that the value of the octets 3-8 of the cookie is interpreted as an access point's MAC address, and used as such, for example in the Called-Station-Id attribute of RADIUS Interim-Update messages.

Parameters	<p>if-match — Specifies that the cookie will be interpreted only if the value of the first two octets of the cookie is equal to the value of the object <code>tmnxWlanGwSoftGrelfL2tpCookie</code>.</p> <p>cookie <i>hex string</i> — Only valid if <code>if-match</code> is used. Specifies the value used to compare the first two bytes of the cookie. Specified in HEX format, possible range [0x0000 to 0xFFFF]</p> <p>Values [0x0000 to 0xFFFF...(4 hex nibbles)]</p> <p>never — Specifies that the cookie value will always be ignored.</p> <p>always — Always learn the AP-MAC from the cookie, no matter what the value of the first two bytes is.</p>
-------------------	--

vlan-tag-ranges

Syntax	vlan-tag-ranges
Context	<pre>config>service>ies>sub-if>grp-if>wlan-gw config>service>vprn>sub-if>grp-if>wlan-gw</pre>
Description	This command enables the context to configure <code>vlan-to-retail-map</code> parameters to map dot1Q tags to retail-service-id. The WIFI AP could insert a dot1Q tag in the Layer 2 frame within the GRE tunnel to indicate the retail service provider for the subscriber.
Default	none

default-retail-svc-id

Syntax	default-retail-svc-id <i>service-id</i> no default-retail-svc-id
Context	<pre>config>service>ies>sub-if>grp-if>wlan-gw>vlan-tag-ranges config>service>vprn>sub-if>grp-if>wlan-gw>vlan-tag-ranges</pre>
Description	This command specifies the id of default retail service if there is no match found in VLAN to retail map configuration (specified by the vlan command). For DSM and migrant, this command is only applicable for non-NAT stacks.
Default	none
Parameters	<p><i>service-id</i> — specifies the identifier of the retail service to be used by default of a value in the retail service map of this interface.</p> <p>Values 1 to 2147483650 svc-name: up to 64 characters in length.</p>

retail-svc-id

Syntax	retail-svc-id <i>service-id</i> no retail-svc-id
Context	config>service>vprn>sub-if>grp-if>wlan-gw config>service>ies>sub-if>grp-if>wlan-gw
Description	This command configures the retailer service.
Parameters	<i>service-id</i> — specifies the identifier of the retail service.
Values	1 to 2147483650 svc-name: up to 64 characters in length.

router-advertisements

Syntax	[no] router-advertisements
Context	config>service>vprn>sub-if>grp-if>wlan-gw>vlan-ranges>range config>service>ies>sub-if>grp-if>wlan-gw>vlan-ranges>range
Description	This command configures IPv6 router advertisements for this group-interface.

current-hop-limit

Syntax	[no] current-hop-limit <i>limit</i>
Context	config>service>vprn>sub-if>grp-if>wlan-gw>vlan-ranges>range>router-advertisements config>service>ies>sub-if>grp-if>wlan-gw>vlan-ranges>range>router-advertisements
Description	This command configures the hop-limit advertised for this group-interface.
Default	64
Parameters	<i>limit</i> — Specifies the default value to be placed in the current hop limit field in router advertisements sent from this interface.
Values	0 to 255

vlan

Syntax	vlan start [0 to 4095] end [0 to 4095] retail-svc-id <i>service-id</i> no vlan start [0 to 4095] end [0 to 4095]
Context	config>service>ies>sub-if>grp-if>wlan-gw>retailer config>service>vprn>sub-if>grp-if>wlan-gw>retailer

Description	<p>This command creates a mapping from a range of VLANs (appearing in the wlan-gw encapsulated Layer 2 frame) to a retail service ID.</p> <p>The no form of the command removes the parameters from the configuration.</p>
Default	none
Parameters	<p>start [0 to 4095] — Specifies the start VLAN tag of this range.</p> <p>Values</p> <p>end [0 to 4095] — Specifies the end VLAN tag of this range.</p> <p>Values</p> <p>retail-svc-id <i>service-id</i> — Specifies the identifier of the retail service to be used by default of a value in the retail service map of this interface.</p> <p>Values 1 to 2147483650</p> <p>svc-name: up to 64 characters in length.</p>

wlan-gw-group

Syntax	wlan-gw-group <i>group-id</i> no wlan-gw-group
Context	config>service>ies>sub-if>grp-if>wlan-gw config>service>vprn>sub-if>grp-if>wlan-gw
Description	<p>This command specifies the id of wlan-gw-group that the wlan-gw gateway binds to.</p> <p>The no form of the command removes the value from the wlan-gw configuration.</p>
Default	none
Parameters	<p><i>group-id</i> — Specifies the ISA WLAN-GW group.</p> <p>Values 1 to 4</p>

pool-manager

Syntax	pool-manager
Context	config>service>ies>sub-if>grp-if>wlan-gw config>service>vprn>sub-if>grp-if>wlan-gw
Description	This command enables the context to configure pool manager data for a WLAN GW subscriber interface.

dhcpv6-client

Syntax	dhcpv6-client
Context	config>service>ies>sub-if>grp-if>wlan-gw>pool-manager config>service>vprn>sub-if>grp-if>wlan-gw>pool-manager
Description	This command configures the DHCPv6 client for the pool manager.

dhcpv4-nat

Syntax	dhcpv4-nat
Context	config>service>ies>sub-if>grp-if>wlan-gw>pool-manager>dhcpv6-client config>service>vprn>sub-if>grp-if>wlan-gw>pool-manager>dhcpv6-client
Description	This node enables address pools for DHCPv4 NAT inside addresses. This configuration is only available in wholesale interfaces.

ia-na

Syntax	ia-na
Context	config>service>ies>sub-if>grp-if>wlan-gw>pool-manager config>service>vprn>sub-if>grp-if>wlan-gw>pool-manager
Description	This command configures the DHCPv6 client for the pool manager.

link-addr

Syntax	link-addr <i>ipv6-address</i> no link-addr
Context	config>service>ies>sub-if>grp-if>wlan-gw>pool-mgr>dhcpv6-clnt>slaac config>service>vprn>sub-if>grp-if>wlan-gw>pool-mgr>dhcpv6-clnt>slaac config>service>ies>sub-if>grp-if>wlan-gw>pool-mgr>dhcpv6-clnt>ia-na config>service>vprn>sub-if>grp-if>wlan-gw>pool-mgr>dhcpv6-clnt>ia-na config>service>ies>sub-if>grp-if>wlan-gw>pool-manager>dhcpv6-clnt>dhcpv4-nat config>service>vprn>sub-if>grp-if>wlan-gw>pool-manager>dhcpv6-clnt>dhcpv4-nat
Description	This command specifies the ipv6-address that should be included in the link-address field of the relay header. This can be used for pool-selection by the DHCPv6 server. The no form of this command falls back to the default.
Default	0::0

Parameters *ipv6-address* — Specifies the IPv6 address up to 32 characters.

pool-name

Syntax **pool-name** *name*
no pool-name

Context config>service>ies>sub-if>grp-if>wlan-gw>pool-mgr>dhcpv6-clnt>slaac
config>service>vprn>sub-if>grp-if>wlan-gw>pool-mgr>dhcpv6-clnt>slaac
config>service>ies>sub-if>grp-if>wlan-gw>pool-mgr>dhcpv6-clnt>ia-na
config>service>vprn>sub-if>grp-if>wlan-gw>pool-mgr>dhcpv6-clnt>ia-na
config>service>ies>sub-if>grp-if>wlan-gw>pool-manager>dhcpv6-clnt>dhcpv4-nat
config>service>vprn>sub-if>grp-if>wlan-gw>pool-manager>dhcpv6-clnt>dhcpv4-nat

Description This command specifies the pool name that should be sent in the DHCPv6 messages. This will be reflected in the Nokia vendor specific pool option (vendor-id 6527, option-id 0x02).

The **no** form of this command removes pool-name and the option will not be sent in DHCPv6.

Parameters *name* — Specifies the pool name up with 32 characters.

lease-query

Syntax **lease-query** [**max-retry** **Max nbr of retries**]
no lease-query

Context config>service>vprn>sub-if>wlan-gw>pool-mgr>dhcpv6-clnt
config>service>ies>sub-if>wlan-gw>pool-mgr>dhcpv6-clnt

Description This command enables lease-query. If this is specified the dhcpv6-client will retrieve any existing addresses when becoming active. The lease-query is performed for all of the configured servers

The **no** form of this command disables lease-query.

Parameters *max-retry* — Specifies the maximum number of retries before the lease query assumes no existing subnets were allocated.

Values 0 to 10

server

Syntax **server** *ipv6-address* [*ipv6-address...*(upto 8 max)]
no server [*ipv6-address* [*ipv6-address...*(upto 8 max)]]

Context config>service>vprn>sub-if>wlan-gw>pool-mgr>dhcpv6-clnt
config>service>ies>sub-if>wlan-gw>pool-mgr>dhcpv6-clnt

Description	<p>This specifies the DHCPv6 servers that are used for requesting addresses. Up to 8 servers can be used simultaneously.</p> <p>The no form of this command removes the server. This cannot be executed while any dhcpv6 client application is not shutdown.</p>
Default	none
Parameters	<i>ipv6-address</i> — Specifies the unicast IPv6 address of a DHCPv6 server.

slaac

Syntax	slaac
Context	config>service>vprn>sub-if>wlan-gw>pool-mgr>dhcpv6-clnt config>service>ies>sub-if>wlan-gw>pool-mgr>dhcpv6-clnt
Description	This command configures SLAAC for the DHCPv6 client.

source-ip

Syntax	source-ip <i>ipv6-address</i> no source-ip
Context	config>service>vprn>sub-if>wlan-gw>pool-mgr>dhcpv6-clnt config>service>ies>sub-if>wlan-gw>pool-mgr>dhcpv6-clnt
Description	<p>This command specifies the source-ip to be used by the DHCPv6 client.</p> <p>The no form of this command removes the specific source-ip. In this case the DHCPv6 client will fall back to the IP address configured on the outgoing interface.</p>
Parameters	<i>ipv6-address</i> — Specifies the IPv6 address up to 32 characters.

watermarks

Syntax	watermarks high <i>high-percentage</i> low <i>low-percentage</i> no watermarks
Context	config>service>vprn>sub-if>wlan-gw>pool-mgr config>service>ies>sub-if>wlan-gw>pool-mgr
Description	This command configures the watermarks used to determine if a new prefix should be allocated or an old prefix should be removed. A new prefix will be allocated when the total usage level for the ISA reaches the high watermark. A prefix will be freed if no addresses are currently in use and the usage level without this prefix would be below the low watermark.

The **no** form of this command resets the watermarks to its default values of 95% high and 90% low.

Default	watermarks high 95 low 90
Parameters	high <i>high-percentage</i> — Specifies the high watermark. Values 80 to 99 low <i>low-percentage</i> — Specifies the low watermark. The value must be lower than the high percentage value. Values 50 to 98

wlan-gw-group

Syntax	wlan-gw-group <i>nat-group-id</i> no wlan-gw-group
Context	config>service>vprn>sub-if>wlan-gw>pool-mgr config>service>ies>sub-if>wlan-gw>pool-mgr
Description	This command specifies the ISA WLAN Gateway group.
Default	none
Parameters	<i>nat-group-id</i> — Specifies the identifier of the WLAN Gateway group. Values 1 to 4

redundancy

Syntax	redundancy
Context	config>service>ies>sub-if>wlan-gw
Description	This command enables the context to configure WLAN-GW redundancy-related parameters.
Default	none

export

Syntax	export <i>ip-prefix/length</i> no export
Context	config>service>ies>sub-if>wlan-gw>redundancy

Description	This command specifies an IPv4 route (prefix/length) per subscriber-interface to be exported (announced) to indicate liveness of the subscriber-interface on the WLAN-GW. This route is the one that is monitored in routing by the peer WLAN-GW to decide its state with respect.
Default	none
Parameters	<i>ip-prefix/length</i> — Specifies the IP prefix and length.
Values	ip-prefix:a.b.c.d ip-prefix-length: 0 to 32

monitor

Syntax	monitor <i>ip-prefix/length</i> no monitor
Context	config>service>ies>sub-if>wlan-gw>redundancy
Description	This command specifies an IPv4 route (prefix/length) per subscriber-interface to be monitored in the FIB to determine liveness of the subscriber-interface (and consequently all associated group-interfaces of type wlangw) on a peer WLAN-GW. This route is the one that is advertised in routing by the peer WLAN-GW when the subscriber-interface and WLAN-GW group are operationally up
Default	none
Parameters	<i>ip-prefix/length</i> — Specifies the IP prefix and length.
Values	ip-prefix:a.b.c.d ip-prefix-length: 0 to 32

11.23.2.8 Migrant User Support Commands

http-redirect-policy

Syntax	http-redirect-policy <i>policy-name</i> no http-redirect-policy
Context	config>subscr-mgmt
Description	This command configures the redirect policy to constrain forwarding of an unauthenticated “migrant” WIFI user.
Default	none
Parameters	<i>policy-name</i> — Specifies the HTTP redirect policy name up to 32 characters in length.

forward-entries

Syntax	forward-entries
Context	config>subscr-mgmt>http-rdr-plcy
Description	Enters the context to configure entries that need to be forwarded
Default	none

dst-port

Syntax	dst-port <i>tcp-port</i> no dst-port
Context	config>subscr-mgmt>http-rdr-plcy
Description	This command specifies the port to match the destination port in the HTTP request. HTTP traffic that does not match this port, is not redirected.
Default	80
Parameters	<i>tcp-port</i> — Specifies the TCP port. Values 1 to 65535

dst-ip

Syntax	dst-ip <i>ip-address</i> protocol <i>ip-protocol</i> dst-port <i>port-number</i> dst-ip <i>ip-address</i> protocol <i>ip-protocol</i> dst-port <i>port-number</i> prefix-length <i>prefix-length</i> no dst-ip <i>ip-address</i> protocol <i>ip-protocol</i> dst-port <i>port-number</i>
Context	config>subscr-mgmt>http-rdr-plcy
Description	This command configures traffic flow to be forwarded via match in the redirect policy.
Default	none
Parameters	<i>ip-address</i> — Specifies the IPv4 or IPv6 address to match the destination address in the IP header of the traffic received from the subscriber. <i>prefix-length</i> — Specifies the length of the prefix specified by the ip-address. Values 1 to 128 for IPv6 1 to 32 for IPv4 protocol <i>ip-protocol</i> — Specifies the protocol to match the IP protocol in the IP header of the traffic received from the subscriber. Values tcp, udp

dst-port

port-number — Specifies the port to match the destination port in the HTTP request.

Values
1 to 65535

portal-hold-time

Syntax

portal-hold-time *seconds*
no portal-hold-time

Context

config>subscr-mgmt>http-rdr-plcy

Description

This command configures the time for which the forwarding state applicable during redirect phase is held in the system, after the user has been authenticated on the portal. This allows the http response from the portal to be forwarded back on the existing connection.

none

Parameters

seconds — Specifies how long the system holds on to re-direct forwarding resources of a subscriber, after it has left the re-direct portal.

Values
1 to 60

url

Syntax

url *rdr-url-sting*
no url

Context

config>subscr-mgmt>http-rdr-plcy

Description

This command configures the HTTP URL to re-direct the matching traffic to. It also can specify inclusion of original URL, MAC address and IP address of the subscriber in the redirect URL.

none

Parameters

rdr-url-sting — Specifies the URL to redirect to.

Values

rdr-url-string
[255 chars max]

macro substitutions:

\$URL
Request-URI in the HTTP GET Request received

\$MAC
A string that represents the MAC address of the subscriber host

\$IP
A string that represents the IP address of the subscriber host

wlan-gw

Syntax	wlan-gw
Context	config>service>vprn>sub-if>grp-if config>service>ies>sub-if>grp-if
Description	This command enables the context to configure wlan-gw parameters.

vlan-tag-ranges

Syntax	vlan-tag-ranges
Context	config>service>vprn>sub-if>grp-if>wlan-gw config>service>ies>sub-if>grp-if>wlan-gw
Description	This command enters the context for per vlan range configuration.
Default	none

default-retail-svc-id

Syntax	default-retail-svc-id <i>service-id</i>
Context	config>service>vprn>sub-if>grp-if>wlan-gw>ranges config>service>ies>sub-if>grp-if>wlan-gw>ranges
Description	This command configures the default retailer service for WIFI users.
Default	none

range

Syntax	range start [0 to 4096] end [0 to 4096] range default no range start [0 to 4096] end [0 to 4096]
Context	config>service>vprn>sub-if>grp-if>wlan-gw>ranges config>service>ies>sub-if>grp-if>wlan-gw>ranges
Description	This command creates or enters the context of specified VLAN range for configuration applicable to that range of VLANs.
Default	none
Parameters	start [0 to 4096] — Specifies the start of the vlan range. end [0 to 4096] — Specifies the end of vlan the range.

default — Configures defaults for the interface.

distributed-sub-mgmt

Syntax	distributed-sub-mgmt
Context	config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range config>service>ies>sub-if>grp-if>wlan-gw>ranges>range
Description	This command enables the context to configure distributed-sub-mgmt configuration per vlan-range. This also includes vlan-range default, which makes this configuration applicable to the wlan-gw group-interface.
Default	none

accounting-policy

Syntax	accounting-policy <i>policy-name</i> no accounting-policy
Context	config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range>distrib-sub-mgmt config>service>ies>sub-if>grp-if>wlan-gw>ranges>range>distrib-sub-mgmt
Description	This command specifies the isa-radius-policy used for accounting messages originated from the ISAs in the wlan-gw group. The policy can specify up to five accounting servers and configuration-specific to these accounting servers. It also specifies configuration specific to RADIUS client on ISAs and RADIUS attributes to be included in accounting messages.
Default	none
Parameters	<i>policy-name</i> — Specifies the name of the account policy up to 32 characters in length.

accounting-update-interval

Syntax	accounting-update-interval [5 to 259200] no accounting-update-interval
Context	config>service>ies>sub-if>grp-if>wlan-gw>ranges>range>distrib-sub-mgmt config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range>distrib-sub-mgmt
Description	This command enables the interim accounting and specifies the interim accounting interval.
Default	none
Parameters	5 to 259200 — Specifies the interim accounting interval in seconds.

collect-aa-acct-stats

Syntax	[no] collect-aa-acct-stats
Context	config>service>ies>sub-if>grp-if>wlan-gw>ranges>range>distrib-sub-mgmt config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range>distrib-sub-mgmt
Description	This command enables Application Assurance account statistics collection.

def-app-profile

Syntax	def-app-profile <i>profile-name</i> no def-app-profile
Context	config>service>ies>sub-if>grp-if>wlan-gw>ranges>range>distrib-sub-mgmt config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range>distrib-sub-mgmt
Description	This command configures the default application profile.

dsm-ip-filter

Syntax	dsm-ip-filter <i>dsm-ip-filter-name</i> no dsm-ip-filter
Context	config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range>distrib-sub-mgmt config>service>ies>sub-if>grp-if>wlan-gw>ranges>range>distrib-sub-mgmt
Description	<p>This command configures an IP filter that is distributed on ISA cards.</p> <p>This command specifies the IP filter applied to all UEs corresponding to default vlan-range (such as a group-interface) or the specified vlan-range. The IP filter can be created in the subscr-mgmt>wlan-gw>distributed-sub-mgmt context, and can contain up to 1024 match entries. The IP filter can be overridden per UE from RADIUS via access-accept or COA.</p>
Default	none
Parameters	<i>dsm-ip-filter-name</i> — Specifies the identifier of the distributed-sub-mgmt IP filter.

egress-policer

Syntax	egress-policer [256 chars max] no egress-policer
Context	config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range>distrib-sub-mgmt config>service>ies>sub-if>grp-if>wlan-gw>ranges>range>distrib-sub-mgmt

Description	This command specifies the egress policer applied to all UEs corresponding to default vlan-range (such as, group-interface) or the specified vlan-range. The policer can be created in the subscr-mgmt>wlan-gw>distributed-sub-mgmt context. The egress policer can be overridden per UE from RADIUS via access-accept or COA.
Default	none
Parameters	<i>256 chars max</i> — Specifies the identifier of the distributed-sub-mgmt policer for egress traffic.

ingress-policer

Syntax	ingress-policer <i>policer-name</i> no ingress-policer
Context	config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range>distrib-sub-mgmt config>service>ies>sub-if>grp-if>wlan-gw>ranges>range>distrib-sub-mgmt
Description	.This command specifies the ingress policer applied to all UEs corresponding to default vlan-range (such as group-interface) or the specified vlan-range. The policer can be created in the subscr-mgmt>wlan-gw>distributed-sub-mgmt context. The ingress policer can be overridden per UE from RADIUS via access-accept or COA.
Default	none
Parameters	<i>policer-name</i> — Specifies the identifier of the distributed-sub-mgmt policer for ingress traffic.

one-time-redirect

Syntax	one-time-redirect url <i>rdr-url-string</i> port <i>port-num</i> no one-time-redirect
Context	config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range>distrib-sub-mgmt config>service>ies>sub-if>grp-if>wlan-gw>ranges>range>distrib-sub-mgmt
Description	This command enables one-time http-redirect to specified redirect URL for traffic matching the specified destination port.
Default	none
Parameters	url <i>rdr-url-string</i> — Specifies the HTTP web address that will be sent to the user's browser. port <i>port-num</i> — Specifies the destination port number as a decimal hex or binary. Values 1 to 65535

dhcp

Syntax	dhcp
Context	config>service>vprn>sub-if>grp-if>wlan-gw>ranges config>service>ies>sub-if>grp-if>wlan-gw>ranges
Description	Enters the context to create DHCP configuration for WLAN-GW ISA subscribers (e.g. migrant subscribers).
Default	none

dhcp6

Syntax	dhcp6
Context	config>service>vprn>sub-if>grp-if>wlan-gw>ranges config>service>ies>sub-if>grp-if>wlan-gw>ranges
Description	Enters the context to create DHCP6 configuration for WLAN-GW ISA subscribers.
Default	none

active-preferred-lifetime

Syntax	active-preferred-lifetime [<i>hrs hours</i>] [<i>min minutes</i>] [<i>sec seconds</i>] no active-preferred-lifetime
Context	config>service>vprn>sub-if>grp-if>wlan-gw>vlan-ranges>range>dhcp6 config>service>ies>sub-if>grp-if>wlan-gw>vlan-ranges>range>dhcp6 config>service>vprn>sub-if>grp-if>wlan-gw>vlan-ranges>range>slaac config>service>ies>sub-if>grp-if>wlan-gw>vlan-ranges>range>slaac
Description	This command specifies the signaled preferred lifetime in DHCPv6 or SLAAC after full authentication. This is only applicable to DSM.
Default	min 10
Parameters	<p>hrs <i>hours</i> — Specifies the number of active preferred lifetime hours.</p> <p>Values 1 to 1</p> <p>min <i>minutes</i> — Specifies the number of active preferred lifetime minutes.</p> <p>Values 5 to 59</p> <p>sec <i>seconds</i> — Specifies the number of active preferred lifetime seconds.</p> <p>Values 1 to 59</p> <p>Combined values: min 5 – hrs 1</p>

active-valid-lifetime

Syntax	active-valid-lifetime [<i>hrs hours</i>] [<i>min minutes</i>] [<i>sec seconds</i>] no active-valid-lifetime
Context	config>service>vprn>sub-if>grp-if>wlan-gw>vlan-ranges>range>dhcp6 config>service>ies>sub-if>grp-if>wlan-gw>vlan-ranges>range>dhcp6 config>service>vprn>sub-if>grp-if>wlan-gw>vlan-ranges>range>slaac config>service>ies>sub-if>grp-if>wlan-gw>vlan-ranges>range>slaac
Description	This command specifies the signaled valid lifetime in DHCPv6 or SLAAC after full authentication. This is only applicable to DSM.
Default	min 10
Parameters	<p>hrs <i>hours</i> — Specifies the number of active-valid-lifetime hours.</p> <p>Values 1 to 1</p> <p>min <i>minutes</i> — Specifies the number of active-valid-lifetime minutes.</p> <p>Values 5 to 59</p> <p>sec <i>seconds</i> — Specifies the number of active-valid-lifetime seconds.</p> <p>Values 1 to 59</p>

active-lease-time

Syntax	active-lease-time [<i>hrs hours</i>] [<i>min minutes</i>] [<i>sec seconds</i>] no active-lease-time
Context	config>service>vprn>sub-if>grp-if>wlan-gw>dhcp config>service>ies>sub-if>grp-if>wlan-gw>dhcp config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range>dhcp config>service>ies>sub-if>grp-if>wlan-gw>ranges>range>dhcp
Description	This command configures the lease time for an authenticated user.
Default	none
Parameters	<p>hrs <i>hours</i> — Specifies the number of initial lease time hours.</p> <p>Values 1 to 1</p> <p>min <i>minutes</i> — Specifies the number of initial lease time minutes.</p> <p>Values 5 to 59</p> <p>sec <i>seconds</i> — Specifies the number of initial lease time seconds.</p> <p>Values 1 to 59</p>

initial-preferred-lifetime

Syntax	initial-preferred-lifetime [<i>hrs hours</i>] [<i>min minutes</i>] [<i>sec seconds</i>] no initial-preferred-lifetime
Context	config>service>vprn>sub-if>grp-if>wlan-gw>vlan-ranges>range>dhcp6 config>service>ies>sub-if>grp-if>wlan-gw>vlan-ranges>range>dhcp6 config>service>vprn>sub-if>grp-if>wlan-gw>vlan-ranges>range>slaac config>service>ies>sub-if>grp-if>wlan-gw>vlan-ranges>range>slaac
Description	This command specifies the signaled preferred lifetime in DHCPv6 or SLAAC after full authentication (DSM and/or ESM).
Default	min 10
Parameters	<p>hrs <i>hours</i> — Specifies the number of initial preferred lifetime hours.</p> <p>Values 1 to 1</p> <p>min <i>minutes</i> — Specifies the number of initial preferred lifetime minutes.</p> <p>Values 5 to 59</p> <p>sec <i>seconds</i> — Specifies the number of initial preferred lifetime seconds.</p> <p>Values 1 to 59</p> <p>Combined values: min 5 – hrs 1</p>

initial-valid-lifetime

Syntax	initial-valid-lifetime [<i>hrs hours</i>] [<i>min minutes</i>] [<i>sec seconds</i>] no initial-valid-lifetime
Context	config>service>vprn>sub-if>grp-if>wlan-gw>vlan-ranges>range>dhcp6 config>service>ies>sub-if>grp-if>wlan-gw>vlan-ranges>range>dhcp6 config>service>vprn>sub-if>grp-if>wlan-gw>vlan-ranges>range>slaac config>service>ies>sub-if>grp-if>wlan-gw>vlan-ranges>range>slaac
Description	This command specifies the signaled preferred lifetime in DHCPv6 or SLAAC during a migrant phase.
Default	min 5
Parameters	<p>hrs <i>hours</i> — Specifies the number of initial preferred lifetime hours.</p> <p>Values 1 to 1</p> <p>min <i>minutes</i> — Specifies the number of initial preferred lifetime minutes.</p> <p>Values 5 to 59</p> <p>sec <i>seconds</i> — Specifies the number of initial preferred lifetime seconds.</p> <p>Values 1 to 59</p>

Combined values: min 5 – hrs 1

initial-lease-time

Syntax	initial-lease-time [hrs <i>hours</i>] [min <i>minutes</i>] [sec <i>seconds</i>] no initial-lease-time
Context	config>service>vpn>sub-if>grp-if>wlan-gw>dhcp config>service>ies>sub-if>grp-if>wlan-gw>dhcp config>service>vpn>sub-if>grp-if>wlan-gw>ranges>range>dhcp config>service>ies>sub-if>grp-if>wlan-gw>ranges>range>dhcp
Description	This command configures the lease time for a user which is migrant (unauthenticated).
Default	none
Parameters	hrs <i>hours</i> — Specifies the number of initial lease time hours. Values 1 to 1 min <i>minutes</i> — Specifies the number of initial lease time minutes. Values 5 to 59 sec <i>seconds</i> — Specifies the number of initial lease time Biteme#24ds. Values 1 to 59

l2-aware-ip-address

Syntax	l2-aware-ip-address <i>ip-address</i> l2-aware-ip-address from-pool no l2-aware-ip-address
Context	config>service>vpn>sub-if>grp-if>wlan-gw>dhcp config>service>ies>sub-if>grp-if>wlan-gw>dhcp config>service>vpn>sub-if>grp-if>wlan-gw>ranges>range>dhcp config>service>ies>sub-if>grp-if>wlan-gw>ranges>range>dhcp
Description	<p>This command configures the l2-aware NAT inside IP address to be assigned via DHCP on WLAN-GW ISA.</p> <p>If the from-pool parameter is specified instead of an IPv4 address, a unique address is allocated to each UE. The pool used is managed by the dhcpv4-nat pool manager, configured under the same subscriber interface. This option is only available when auth-on-dhcp is also configured.</p>
Default	none
Parameters	<i>ip-address</i> — Specifies the l2-aware NAT inside IP address

from-pool — Specifies that the I2-aware IP address will be allocated from a pool

primary-dns

Syntax	primary-dns <i>ip-address</i> no primary-dns
Context	config>service>vprn>sub-if>grp-if>wlan-gw>dhcp config>service>ies>sub-if>grp-if>wlan-gw>dhcp config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range>dhcp config>service>ies>sub-if>grp-if>wlan-gw>ranges>range>dhcp
Description	This command configures the primary DNS address to be returned via DHCP on WLAN-GW ISA.
Default	none
Parameters	<i>ip-address</i> — Specifies the primary DNS address

secondary-dns

Syntax	secondary-dns <i>ip-address</i> no secondary-dns
Context	config>service>vprn>sub-if>grp-if>wlan-gw>dhcp config>service>ies>sub-if>grp-if>wlan-gw>dhcp config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range>dhcp config>service>ies>sub-if>grp-if>wlan-gw>ranges>range>dhcp
Description	This command configures the secondary DNS address to be returned via DHCP on WLAN-GW ISA.
Default	none
Parameters	<i>ip-address</i> — Specifies the secondary DNS address.

primary-nbns

Syntax	primary-nbns <i>ip-address</i> no primary-nbns
Context	config>service>vprn>sub-if>grp-if>wlan-gw>dhcp config>service>ies>sub-if>grp-if>wlan-gw>dhcp config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range>dhcp config>service>ies>sub-if>grp-if>wlan-gw>ranges>range>dhcp

Description	This command configures the primary NBNS address to be returned via DHCP on WLAN-GW ISA.
Default	none
Parameters	<i>ip-address</i> — Specifies the primary NBNS address.

secondary-nbns

Syntax	secondary-nbns <i>ip-address</i> no secondary-nbns
Context	config>service>vprn>sub-if>grp-if>wlan-gw>dhcp config>service>ies>sub-if>grp-if>wlan-gw>dhcp config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range>dhcp config>service>ies>sub-if>grp-if>wlan-gw>ranges>range>dhcp
Description	This command configures the secondary NBNS address to be returned via DHCP on WLAN-GW ISA.
Default	none
Parameters	<i>ip-address</i> — Specifies the secondary NBNS address.

idle-timeout

Syntax	idle-timeout action <i>idle-timeout-action</i> no idle-timeout
Context	config>service>vprn>sub-if>grp-if>wlan-gw>vlan-ranges>range config>service>ies >sub-if>grp-if>wlan-gw>vlan-ranges>range
Description	This command specifies idle-timeout behavior for DSM UEs and UEs undergoing (ISA-based) portal authentication. This knob only specifies the desired action, idle-timeout is activated by RADIUS on a per-UE basis. The no form of the command resets the idle-timeout to its default
Default	idle-timeout action remove
Parameters	<i>action</i> — Specifies which action to perform when the idle-timeout timer goes off. Values remove, shcv

http-redirect-policy

Syntax	http-redirect-policy <i>policy-name</i>
---------------	--

no http-redirect-policy

Context	config>service>vprn>sub-if>grp-if>wlan-gw config>service>ies>sub-if>grp-if>wlan-gw config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range config>service>ies>sub-if>grp-if>wlan-gw>ranges>range
Description	This command specifies http redirect policy on ISA to redirect http traffic to the URL specified in the policy.
Default	none
Parameters	<i>policy-name</i> — Specifies the name of the http redirect policy under subscriber-management context.

l2-service

Syntax	l2-service <i>service-id</i> no l2-service
Context	config>service>vprn>sub-if>grp-if>wlan-gw>vlan-ranges>range config>service>ies>sub-if>grp-if>wlan-gw>vlan-ranges>range
Description	This command specifies the VPLS service used for L2 wholesale. When such a service is configured no other configuration is allowed under the vlan-range. The no form of the command removes the L2 wholesale service, this is only allowed if the l2-service node is shutdown.
Parameters	<i>service-id</i> — Specifies the VPLS service ID to use for Layer 2 wholesale.

nat-policy

Syntax	nat-policy <i>policy-name</i> no nat-policy
Context	config>service>vprn>sub-if>grp-if>wlan-gw config>service>ies>sub-if>grp-if>wlan-gw config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range config>service>ies>sub-if>grp-if>wlan-gw>ranges>range
Description	This command specifies the NAT policy for WLAN-GW ISA subscribers.
Default	none

authentication

Syntax	authentication
Context	config>service>vprn>sub-if>grp-if>wlan-gw config>service>ies>sub-if>grp-if>wlan-gw config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range config>service>ies>sub-if>grp-if>wlan-gw>ranges>range
Description	Enters the context to create configuration for authenticating a user from the WLAN-GW ISA.
Default	none

authenticate-on-dhcp

Syntax	[no] authenticate-on-dhcp
Context	config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range config>service>ies>sub-if>grp-if>wlan-gw>ranges>range
Description	This command enables initial authentication (when there is no state for the UE on the ISA), to be triggered by DHCP DISCOVER or REQUEST. The default behavior is authentication based on first Layer 3 packet.
Default	none

authentication-policy

Syntax	authentication-policy <i>policy-name</i> no authentication-policy
Context	config>service>vprn>sub-if>grp-if>wlan-gw>authentication config>service>ies>sub-if>grp-if>wlan-gw>authentication config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range>authentication config>service>ies>sub-if>grp-if>wlan-gw>ranges>range>authentication
Description	This command specifies authentication policy configured under aaa context for authenticating users on WLAN-GW ISA.
Default	none
Parameters	<i>policy-name</i> — Specifies the name of the authentication policy up to 32 characters in length.

hold-time

Syntax	hold-time [hrs <i>hours</i>] [min <i>minutes</i>] [sec <i>seconds</i>]
---------------	--

no hold-time

Context	config>service>vpn>sub-if>grp-if>wlan-gw>authentication config>service>ies>sub-if>grp-if>wlan-gw>authentication config>service>vpn>sub-if>grp-if>wlan-gw>ranges>range>authentication config>service>ies>sub-if>grp-if>wlan-gw>ranges>range>authentication
Description	This command configures the minimum time that a user is held down after a failed authentication attempt.
Default	.none
Parameters	hrs <i>hours</i> — Specifies the minimum time that a user is held down in hours. Values 1 to 1 min <i>minutes</i> — Specifies the minimum time that a user is held down in minutes Values 5 to 59 sec <i>seconds</i> — Specifies the minimum time that a user is held down in seconds. Values 1 to 59

vlan-mismatch-timeout

Syntax	vlan-mismatch-timeout <i>seconds</i> no vlan-mismatch-timeout
Context	config>service>ies>sub-if>grp-if>wlan-gw>ranges>range>authentication config>service>vpn>sub-if>grp-if>wlan-gw>ranges>range>authentication
Description	<p>This command configures the timeout value for the RADIUS proxy cache if a packet is received with a non-matching VLAN tag. The new timeout value will be the lesser of the vlan-mismatch-timeout value and the currently remaining proxy cache timeout value.</p> <p>The no form of the command disables the timeout behavior. The cache timeout value will remain unchanged.</p>
Default	no vlan-mismatch-timeout
Parameters	<i>seconds</i> — The timeout value for the RADIUS proxy cache, in seconds Values 5 to 60

brg

Syntax	brg
Context	config>service>ies>sub-if>grp-if>wlan-gw>ranges>range config>service>vpn>sub-if>grp-if>wlan-gw>ranges>range

	<pre>config>service>ies>sub-if>grp-if config>service>vprn>sub-if>grp-if</pre>
Description	This command enables the context to configure BRG parameters. In the config>service>ies>sub-if>grp-if and config>service>vprn>sub-if>grp-if contexts, these commands are only available in the vlan-range level.

authenticated-brg-only

Syntax	[no] authenticated-brg-only
Context	<pre>config>service>vprn>sub-if>grp-if>wlan-gw>vlan-ranges>range>brg config>service>ies>sub-if>grp-if>wlan-gw>vlan-ranges>range>brg config>service>vprn>sub-if>grp-if>brg config>service>ies>sub-if>grp-if>brg</pre>
Description	<p>This command indicates that only BRGs that are pre-authenticated using the RADIUS proxy are allowed in this context.</p> <p>The no form of the command removes the restriction</p>
Default	no authentication-brg-only

default-brg-profile

Syntax	default-brg-profile <i>profile-name</i> no default-brg-profile
Context	<pre>config>service>vprn>sub-if>grp-if>wlan-gw>vlan-ranges>range>brg config>service>ies>sub-if>grp-if>wlan-gw>vlan-ranges>range>brg config>service>vprn>sub-if>grp-if>brg config>service>ies>sub-if>grp-if>brg</pre>
Description	This command indicates that the default BRG profile must be used for new BRGs. This profile can be overridden by RADIUS.
Default	no default-brg-profile
Parameters	<i>profile-name</i> — Specifies the name of the brg-profile to be applied.

data-triggered-ue-creation

Syntax	[no] data-triggered-ue-creation
Context	<pre>config>service>vprn>sub-if>grp-if>wlan-gw config>service>ies>sub-if>grp-if>wlan-gw config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range</pre>

```
config>service>ies>sub-if>grp-if>wlan-gw>ranges>range
```

Description This command enables or disables data-triggered subscriber creation for WIFI subscribers. Data triggered UE creation is currently only supported for UDP and TCP packets.

Default none

track-mobility

Syntax **track-mobility**

Context

```
config>service>vpn>sub-if>grp-if>wlan-gw
config>service>ies>sub-if>grp-if>wlan-gw
config>service>vpn>sub-if>grp-if>wlan-gw>ranges>range
config>service>ies>sub-if>grp-if>wlan-gw>ranges>range
```

Description This command enters the context to configure RADIUS-proxy cache information required for subscribers that are created via “data-triggered” authentication. The RADIUS proxy cache enables efficient handling of UE mobility.

none

mac-format

Syntax **mac-format** *mac-format*
no mac-format

Context

```
config>service>vpn>sub-if>grp-if>wlan-gw>track-mobility
config>service>ies>sub-if>grp-if>wlan-gw>track-mobility
config>service>vpn>sub-if>grp-if>wlan-gw>ranges>range>track-mobility
config>service>ies>sub-if>grp-if>wlan-gw>ranges>range>track-mobility
```

Description This command configures how the MAC address is represented by the RADIUS proxy server.

Default none

Parameters *mac-format* — Specifies how the MAC address is represented by the RADIUS proxy server

Values

mac-format	like ab: for 00:0c:f1:99:85:b8
	or XY- for 00-0C-F1-99-85-B8
	or mmmm. for 0002.03aa.abff
	or xx for 000cf19985b8

radius-proxy-cache

Syntax	radius-proxy-cache <i>router router-instance</i> server <i>server-name</i> no radius-proxy-cache				
Context	config>service>vprn>sub-if>grp-if>wlan-gw>track-mobility config>service>ies>sub-if>grp-if>wlan-gw>track-mobility config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range>track-mobility config>service>ies>sub-if>grp-if>wlan-gw>ranges>range>track-mobility				
Description	This command specifies the RADIUS-proxy server to allow subscribers created via data-triggered authentication to create an entry. This RADIUS proxy cache entry allows efficient handling of UE mobility.				
Default	none				
Parameters	router <i>router-instance</i> — Specifies the router instance. Values <table><tr><td>router-name</td><td>Base</td></tr><tr><td>service-id</td><td>1 to 2147483647</td></tr></table> server <i>server-name</i> — Specifies the server name up to 32 characters in length.	router-name	Base	service-id	1 to 2147483647
router-name	Base				
service-id	1 to 2147483647				

sap-template

Syntax	sap-template <i>sap template</i> no sap-template
Context	config>service>vpls>wlan-gw
Description	This command specifies the vpls-sap-template that will be applied on the internal SAPs created for communication between the VPLS and the ISAs. The no form of the command removes the SAP template.
Parameters	<i>sap-template</i> — Specifies the SAP template to apply. The template is a vpls-sap-template created in the service>template context.

11.23.2.8.1 Distributed Subscriber Management Commands

dsm-ip-filter

Syntax	dsm-ip-filter <i>name</i> [create] no dsm-ip-filter <i>name</i>
---------------	--

Context	config>subscr-mgmt>wlan-gw>dsm
Description	<p>This command configures a set of filter rules that can be applied to a DSM UE.</p> <p>The no form of this command can only be executed if no entries are configured under this filter.</p>
Parameters	<p><i>filter-name</i> — Specifies the name of the filter as it will be referred to in other contexts.</p> <p>create — Keyword used to create a dsm-ip-filter name. The create keyword requirement can be enabled/disabled in the environment>create context.</p>

default-action

Syntax	default-action {drop forward} no default-action
Context	config>subscr-mgmt>wlan-gw>dsm>dsm-ip-filter config>subscr-mgmt>wlan-gw>dsm>dsm-ip-filter>ipv6
Description	<p>The default action specifies what should happen to packets that do not match any of the configured entries.</p> <p>The no form of this command reverts to the default.</p>
Default	default-action drop
Parameters	<p>drop — Drops the packet.</p> <p>forward — Forwards the packet.</p>

entry

Syntax	entry entry-id [create] no entry entry-id
Context	config>subscr-mgmt>wlan-gw>dsm>dsm-ip-filter config>subscr-mgmt>wlan-gw>dsm>dsm-ip-filter>ipv6
Description	<p>This command configures a new entry for this filter. When processing a packet, entries are matched in order, starting with the lowest entry-id. A maximum of 128 IPv4 and 128 IPv6 DSM filter entries are allowed box-wide.</p> <p>The no form of this command reverts to the default.</p>
Parameters	<i>entry-id</i> — Specifies the id of this filter entry.

action

Syntax	action {drop forward none} no action
Context	config>subscr-mgmt>wlan-gw>dsm>dsm-ip-filter>entry config>subscr-mgmt>wlan-gw>dsm>dsm-ip-filter>ipv6>entry
Description	The action specifies what should happen to packets that do match this entry. If the configured action is none, this entry is not applied and processing will continue to match against subsequent entries. The no form of this command reverts to the default.
Default	action none
Parameters	drop — Drops the packet. forward — Forwards the packet. none — Disables this entry. Packet processing continues with the next entry.

match

Syntax	match protocol {any icmp tcp udp gre} no match
Context	config>subscr-mgmt>wlan-gw>dsm>dsm-ip-filter>entry config>subscr-mgmt>wlan-gw>dsm>dsm-ip-filter>ipv6>entry
Description	This command creates a match context for this entry. The protocol specifies which Layer-4 protocol the packet should match. The no form of this command removes the match context of this entry.
Default	no match
Parameters	any — Matches any protocol. icmp — Matches ICMP packets in a v4 filter. tcp — Matches TCP packets. udp — Matches UDP packets. gre — Matches GRE over IP packets.

dst-ip

Syntax	dst-ip ip-prefix/length no dst-ip
---------------	--

Context	config>subscr-mgmt>wlan-gw>dsm>dsm-ip-filter>entry
Description	<p>This command specifies that the packet's destination IP address must match the specified IP prefix + mask.</p> <p>The no form of this command disables the match on destination IP.</p>
Default	no dst-ip
Parameters	<i>ip-prefix/length</i> — Specifies the IP prefix to match on.

dst-port

Syntax	dst-port <i>operator port-number</i> no dst-port
Context	config>subscr-mgmt>wlan-gw>dsm>dsm-ip-filter>entry
Description	<p>This command specifies that the packet's destination IP address must match the specified IP prefix + mask.</p> <p>The no form of this command disables the match on destination IP.</p>
Default	no dst-ip
Parameters	<i>ip-prefix/length</i> — Specifies the IP prefix to match on.

dsm-policer

Syntax	dsm-policer <i>policer-name</i> [type <i>policer-type</i>] [create] no dsm-policer <i>policer-name</i>
Context	config>subscr-mgmt>wlan-gw>dsm
Description	<p>This command creates a policer profile that can be applied to a DSM host. When creating a profile the first time, both the create and type parameters are required.</p> <p>The WLAN-GW allows configuration of both single-rate and dual-rate bucket policers.</p> <p>The no form of this command removes the profile.</p>
Parameters	<p><i>policer-name</i> — The name by which this policer will be referenced.</p> <p>type <i>policer-type</i> — Specifies the policer type. The dual-bucket-bandwidth policer applies both a CIR and PIR.</p> <p>Values single-bucket-bandwidth, dual-bucket-bandwidth</p>

action

Syntax	action {permit-deny priority-mark} no action
Context	config>subscr-mgmt>wlan-gw>dsm>dsm-policer
Description	This command specifies what should happen with packets that are in-profile and out-of-profile. The no value of this command reverts to its default.
Default	action permit-deny
Parameters	permit-deny — Drop all packets that are out of profile (do not conform to the PIR). priority-mark — Currently not supported, the policer will take no action.

adaptation-rule

Syntax	adaptation-rule pir {max min closest} [cir {max min closest}] no adaptation-rule
Context	config>subscr-mgmt>wlan-gw>dsm>dsm-policer
Description	For operational efficiency, the operational rate of a policer cannot take on every value in the configurable range. This configuration defines a rule that must be followed when mapping a configured rate to an operational rate. The cir adaptation-rule can only be set on dual-bucket-bandwidth policers. The no form of this command reverts to its default.
Default	adaptation-rule pir closest cir closest
Parameters	min — The operational rate must minimally be the configured rate. The first operational value bigger or equal to the configured rate will be chosen. max — The operational rate may maximally be the configured rate. The first operational value smaller or equal to the configured rate will be chosen. closest — Chooses the operational value closest to the configured value, lower or higher

cbs

Syntax	cbs <i>burst-size</i> no cbs
Context	config>subscr-mgmt>wlan-gw>dsm>dsm-policer

Description	This command specifies the committed burst-size value of this policer. This can only be set on dual-bucket-bandwidth policers. The no form of this command reverts to its default.
Default	cbs 0
Parameters	<i>burst-size</i> — The committed burst-size in kilobytes. Values 0 to 131071

mbs

Syntax	mbs <i>burst-size</i> no mbs
Context	config>subscr-mgmt>wlan-gw>dsm>dsm-policer
Description	This command specifies the maximum burst-size value of this policer. The no form of this command reverts to its default.
Default	mbs 0
Parameters	<i>burst-size</i> — The maximum burst-size in kilobytes. Values 0 to 131071

rate

Syntax	rate <i>rate</i> [<i>cir rate</i>] no rate
Context	config>subscr-mgmt>wlan-gw>dsm>dsm-policer
Description	This command specifies at which rate the policer drains packets. The cir value is only supported on dual-bucket-bandwidth policers. If rate max is configured, no actual rate limitations are applied. The no form of this command reverts to the default.
Default	rate max
Parameters	<i>rate</i> — Specifies the rate in Kbps. Values 1 to 100000000, max

11.23.2.8.2 Show Commands

Note: The command outputs in the following section are examples only; actual displays may differ depending on supported functionality and user configuration.

call-trace

Syntax	call-trace
Context	show
Description	This command enables the context to display information related to the call-trace module.

files

Syntax	files [running finished] [detail]
Context	show>call-trace
Description	This command gives an overview of all the files in use by the call-trace module, either for running or finished jobs.
Parameters	running — Displays the active jobs that are tracing events triggered by the host being monitored. finished — Displays the jobs that have already finished and not tracing events generated by the host anymore. detail — Displays detailed information about the files.
Output	The following output displays call trace local log files information.

Sample Output

```
Node# show call-trace files
=====
Call trace files of running jobs
=====
File path                                                    File size
                                                                (bytes)
-----
cf1-A:/calltrace/running/mac_00-02-00-00-00-19_160119_1557.pcap      1575
-----
No. of call trace files of running jobs: 1
=====
Call trace files of finished jobs
=====

```

(bytes)

```
-----
No. of call trace files of finished jobs: 0
=====
```

status

Syntax	status
Context	show>call-trace
Description	This command gives a router-wide overview of call-trace operational data, such as number of configured profile, number of jobs and status of the compact flash.
Output	The following output displays call trace status information.

Sample Output

```
=====
Call trace status
=====
No. of trace profiles: 1
No. of trace jobs      : 0
-----
Primary CF             : CF1             Max files number      : 200

CF2 state              : enabled          CF2 volume limit       : 1000 MB
```

trace-profile

Syntax	trace-profile [detail] trace-profile <i>profile-name</i>
Context	show>call-trace
Description	This command provides an overview of all configured profiles or details of a specific profile. If the detail option is specified the full information for all configured profiles will be displayed.
Output	The following output displays call-trace trace-profile information.

Sample Output

```
Node# show call-trace trace-profile "default"
=====
Call-trace  trace profile
=====
Profile name           : default
Description            : none

=====
```

wlan-gw

Syntax	wlan-gw
Context	show>call-trace
Description	The command enables the context to display information related to the wlan-gw call-trace functionality.

ue

Syntax	ue [<i>ieee-address</i>] [detail]
Context	show>call-trace
Description	This command gives an overview of either all traces or a specific trace on the WLAN-GW.
Parameters	<i>ieee-address</i> — Displays information about the MAC address of this UE. detail — Displays detailed information about the job.
Output	This command displays information about the traces of the UE being monitored.

Sample Output

```
Node# show call-trace hosts
=====

acct-on-off-group

Syntax **acct-on-off-group** [*group-name*]

Context show>aaa

Description This command displays Acct-On-Off group information and the associated RADIUS server policies.

Parameters *group-name* — Displays information pertaining to the specified acct-on-off group.

Output

Table 100 WiFi Acct-On-Off Field Descriptions

Label	Description
acct on off group name	Displays the name of a RADIUS server policy Accounting-On-Off-Group.
controlling Radius-Server-policy	Specifies the RADIUS policy that controls the Acct-On-Off group.
monitored by Radius-Server-policy	Specifies the RADIUS policy that monitors the Acct-On-Off group.
Nbr of Acct-on-off-groups displayed	Displays the number of acct-on-off-group.

Sample Output

```
# show aaa acct-on-off-group "group-1"

radius-proxy-server

Syntax **radius-proxy-server** *server-name*
radius-proxy-server *server-name* **cache**
radius-proxy-server *server-name* **cache hex-key** *hex-string*
radius-proxy-server *server-name* **cache string-key** *string*
radius-proxy-server *server-name* **cache summary**
radius-proxy-server *server-name* **statistics**
radius-proxy-server

Context show>router

Description This command displays summary of RADIUS-proxy cache or specific entries.

Parameters *server-name* — Displays information about the specified server name.
cache — Displays messages used to generate the key for the cache of this RADIUS proxy server.
hex-key *hex-string* — Displays information about the specified hex string.
 Values 0x0 to 0xFFFFFFFF (maximum of 64 hex nibbles)]
string-key *string* — Displays information about the specified string.
summary — Displays a summary of the cache of the RADIUS proxy servers.
statistics — Displays statistics about the RADIUS proxy servers of this system.

Output

Table 101 RADIUS Proxy Server Field Descriptions

Label	Description
Description	Displays the description of this RADIUS proxy server.
Purpose	Displays the purpose of the RADIUS server, either accounting or authentication.
Administrative state	Displays the administrative state of this RADIUS server.
Default acct server policy	Displays the name of the default RADIUS server policy associated with this RADIUS proxy server for accounting purposes.
Default auth server policy	Displays the name of the default RADIUS server policy associated with this RADIUS proxy server for authentication purposes.
Send accounting response	Specifies if this RADIUS Proxy server itself responds with an Accounting-Response message to each received Accounting-Request instead of proxying them to a configured RADIUS server.

Table 101 RADIUS Proxy Server Field Descriptions (Continued)

Label	Description
Last management change	Displays the sysUpTime at the time of the most recent management-initiated change
Key packet type	Displays the packet type of the RADIUS messages to use to generate the key for the cache of this RADIUS proxy server, access-request, access-accept, access-reject, access-challenge
Key attribute type	Displays the RADIUS attribute type to cache for this RADIUS proxy server. Refer to RFC 2865, Remote Authentication Dial In User Service (RADIUS), Section 5 Attributes.
Key vendor ID	Displays the RADIUS Vendor-Id. Refer to RFC 2865, Remote Authentication Dial In User Service (RADIUS), Section 5.25 Vendor-Specific.
Timeout (s)	Displays, in seconds, the timeout after which an entry in the cache will expire.
Track accounting	Displays the RADIUS accounting packets that have impact on the cache of this RADIUS proxy server.
Load balance key	Displays the key for load-balancing RADIUS messages between RADIUS servers.
Id	Displays the specifies the RADIUS Vendor-Id.
Username	Displays the user name.
RADIUS-server-policy	Displays the RADIUS server name.
Purpose	Displays the purpose of the RADIUS server, either accounting or authentication.

Sample Output

```

wlan-gw

Syntax	wlan-gw
Context	show>router
Description	This command displays Wireless LAN Gateway information.

isa-subnets

Syntax	isa-subnets [detail] isa-subnets [detail] interface <i>interface-name</i> isa-subnets prefix <i>ipv6-address/prefix-length</i>
Context	show>router>wlan-gw
Description	This command outputs all the prefixes in use by the wlan-gw pool-manager.
Parameters	detail — Displays detailed information for each prefix. interface <i>interface-name</i> — Displays only the prefixes associated with this subscriber-interface. <i>ipv6-address/prefix-length</i> — Displays details of a specific ipv6 address and prefix.
Output

mgw-address-cache

- Syntax

mgw-address-cache [arec] [snaptr] [srv]
mgw-address-cache apn *apn-domain-string*
- Context

show>router>wlan-gw
- Description

This command displays the mobile gateway's DNS lookup address cache.
- Parameters

arec — Displays A-records/

snaptr — Displays Straightforward-NAPTR information.

srv — Displays SRV records.

apn *apn-domain-string* — Specifies the APN (Access Point Name) of this DNS cache entry.

Output

Sample Output

```

mobile-gateway

Syntax	mobile-gateway [mgw-profile <i>profile-name</i>] [local-address <i>ip-address</i>] [control protocol] [interface-type <i>interface-type</i>] mobile-gateway remote-address <i>ip-address</i> [udp-port <i>port</i>] mobile-gateway remote-address <i>ip-address</i> [udp-port <i>port</i>] statistics
Context	show>router>wlan-gw
Description	This command displays Mobile Gateway information.
Parameters	mgw-profile <i>profile-name</i> — Specifies the name that identifies the profile.

local-address *ip-address* — Specifies the local IP address.

Values

ip-address: ipv4-address - a.b.c.d
 ipv6-address : x:x:x:x:x:x:x (eight 16-bit pieces)
 x:x:x:x:x:d.d.d.d
 x - [0 to FFFF]H
 d - [0 to 255]D

control *protocol* — Specifies the control plane protocol used for the connection with this Mobile Gateway.

Values gtpv1-c, gtpv2-c

interface-type *interface-type* — Specifies the interface type of the connection between WLAN Gateway and Mobile Gateway.

Values gn — Gn interface
 s2a — S2a interface
 s2b —S2b interface

remote-address *ip-address* — Specifies the remote IP address.

Values

ip-address: ipv4-address - a.b.c.d
 ipv6-address : x:x:x:x:x:x:x (eight 16-bit pieces)
 x:x:x:x:x:d.d.d.d
 x - [0 to FFFF]H
 d - [0 to 255]D

udp-port *port* — Specifies the UDP port.

Values 1 to 65535

statistics — Displays statistics information about the Mobile Gateways connected to this system.

Output

Sample Output

```
*A:Dut-C# show router 300 wlan-gw mobile-gateway mgw-profile "Ivo"

soft-gre-tunnel-qos

Syntax **soft-gre-tunnel-qos [detail]**
soft-gre-tunnel-qos remote-ip *ip-address* [**local-ip** *ip-address*] [**detail**]

Context show>router>wlan-gw

Description This command displays soft-GRE tunnel-QoS resource information.

Parameters **remote-address** *ip-address* — Specifies the IP address of the Mobile Gateway, that is the source IP address in the tunnel header of received packets.

Values

```

ip-address:      ipv4-address  - a.b.c.d
ipv6-address :   x:x:x:x:x:x:x (eight 16-bit pieces)
                  x:x:x:x:x:d.d.d.d
                  x - [0 to FFFF]H
                  d - [0 to 255]D

```

local-address *ip-address* — Specifies the IP address of this system, that is the destination IP address in the tunnel header of received packets.

Values

```

ip-address:      ipv4-address  - a.b.c.d
ipv6-address :   x:x:x:x:x:x:x (eight 16-bit pieces)
                  x:x:x:x:x:d.d.d.d
                  x - [0 to FFFF]H
                  d - [0 to 255]D

```

detail — Displays detailed information.

soft-gre-tunnels

Syntax **soft-gre-tunnels local-ip** *ip-address* **remote-ip** *ip-address* **ue**
soft-gre-tunnels [**local-ip** *ip-address*] [**remote-ip** *ip-address*] [**isa-group** *wlan-gw-group-id*]
[member [1 to 255]] **[summary]** **[detail]**

Context show>router>wlan-gw

Description This command displays soft-GRE tunnel-QoS resource information.

Parameters **remote-address** *ip-address* — Specifies the IP address of the Mobile Gateway, that is the source IP address in the tunnel header of received packets.

Values

ip-address:	ipv4-address - a.b.c.d
ipv6-address :	x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:d.d.d.d
	x - [0 to FFFF]H
	d - [0 to 255]D

local-address *ip-address* — Specifies the IP address of this system, that is the destination IP address in the tunnel header of received packets.

Values

ip-address: ipv4-address - a.b.c.d
 ipv6-address : x:x:x:x:x:x:x (eight 16-bit pieces)
 x:x:x:x:x:d.d.d.d
 x - [0 to FFFF]H
 d - [0 to 255]D

ue — Displays information for the specified user equipment.

isa-group *wlan-gw-group-id* — Specifies the identifier of the WLAN Gateway ISA group that terminates GRE for this group interface.

Values 1 to 4

member [1 to 255] — Specifies the identifier of this WLAN Gateway ISA Group member.

summary — Displays a summary of the specified parameters.

detail — Displays detailed information.

Output

Sample Output

```

tunnels

Syntax	tunnels [local-ip <i>ip-address</i>] [remote-ip <i>ip-address</i>] [isa-group <i>wlan-gw-group-id</i>] [member [1 to 255]] [summary] [detail] tunnels local-ip <i>ip-address</i> remote-ip <i>ip-address</i> ue
Context	show>router>wlan-gw
Description	This command displays tunnel operation information.
Parameters	local-address <i>ip-address</i> — Specifies the IP address of this system,that is the destination IP address in the tunnel header of received packets. Values <div>ip-address: ipv4-address - a.b.c.d ipv6-address : x:x:x:x:x:x:x (eight 16-bit pieces) x:x:x:x:x:x:d.d.d.d x - [0 to FFFF]H d - [0 to 255]D</div> remote-address <i>ip-address</i> — Specifies the IP address of the Mobile Gateway,that is the source IP address in the tunnel header of received packets. Values <div>ip-address: ipv4-address - a.b.c.d ipv6-address : x:x:x:x:x:x:x (eight 16-bit pieces) x:x:x:x:x:x:d.d.d.d x - [0 to FFFF]H d - [0 to 255]D</div>

isa-group *wlan-gw-group-id* — Specifies the identifier of the WLAN Gateway ISA group that terminates GRE for this group interface.

Values 1 to 4

member [1 to 255] — Specifies the identifier of this WLAN Gateway ISA Group member.

summary — Displays a summary of the specified parameters.

detail — Displays detailed information.

ue — Displays information for the specified user equipment.

Output

Sample Output

Note: The remote/local IP addresses are locally generated for VLAN tunnels.

radius-server-policy [**acct-on-off**]

Context show>aaa

Description This command displays RADIUS server policy information.

- Parameters**
- policy-name* — Displays information pertaining to the specified policy name.
 - associations** — Displays the association between the RADIUS server policy and the applications referencing the policy (RADIUS proxy, route downloader, authentication policy, accounting policy, dynamic services policy).
 - statistics** — Displays statistics of the RADIUS server policy and RADIUS servers referenced in the policy.
 - acct-on-off** — Displays the acct-on-off operational state for the RADIUS server policy.
 - msg-buffer-stats** — Displays statistics for the RADIUS message buffering.

wlan-gw-group

Syntax **wlan-gw-group** *wlan-gw-group-id*
wlan-gw-group *wlan-gw-group-id* **associations**
wlan-gw-group *wlan-gw-group-id* **member** [1 to 255] [**statistics**]
wlan-gw-group

Context show>isa

Description This command displays WLAN-GW group information including wlan-gw tunnels.

Parameters *wlan-gw-group-id* — Displays information about the specified wlan-gw-group-id.
associations — Displays information about association for the specified wlan-gw-group-id.
member [1 to 255] — Displays information about the WLAN-GW-specific status and basic statistics information about the specified member.
statistics — Displays statistics information about the members of the specified WLAN-GW group.

Output

Sample Output

```
system# show isa wlan-gw-group 1

11.23.2.8.3 Debug Commands

call-trace

Syntax	call-trace
Context	debug
Description	This command enables the context to set up various call-trace debug sessions.

wlan-gw

Syntax	[no] wlan-gw
Context	debug>call-trace
Description	<p>This node will contain all the parameters to set up specific call-trace debug sessions for wlan-gw.</p> <p>The no form of this command will stop all configured wlan-gw traces.</p>

ue

Syntax	ue <i>ieee-address</i> [profile <i>trace-profile-name</i>] no ue <i>ieee-address</i>
Context	debug>call-trace>wlan-gw
Description	<p>This command will start tracing of the UE with the specified MAC address. The trace will be started with default parameters or optionally parameters specified in the trace-profile.</p> <p>The no form of this command will stop the trace and make sure no new traces are started.</p>
Parameters	<p><i>ieee-address</i> — Displays information about the MAC address of this UE.</p> <p>profile <i>trace-profile-name</i> — Specifies the name of a configured trace profile.</p>

11.23.2.8.4 Tools Commands

acct-on

Syntax	acct-on [radius-server-policy <i>policy-name</i>] [force]
Context	tools>perform>aaa
Description	<p>This command triggers a RADIUS Accounting-On message:</p> <ul style="list-style-type: none"> • for all radius-server-policies that have acct-on-off configured. • for the specified radius-server-policy if the acct-on-off is configured <p>The Accounting-On message is not sent when the last successful event for the radius server policy was an Accounting-On message. In this case, an Accounting-Off should be sent first. By specifying the keyword “force”, this is overruled.</p>
Parameters	<p>radius-server-policy <i>policy-name</i> — Specifies the radius-server-policy for which the Accounting-On should be sent.</p> <p>force — Sends an Accounting-On also if the last successful event was an Accounting-On.</p>

acct-off

Syntax	acct-off [radius-server-policy <i>policy-name</i>] [force] [acct-terminate-cause <i>number</i>]
Context	tools>perform>aaa
Description	<p>This command triggers a RADIUS Accounting-Off message:</p> <ul style="list-style-type: none"> • for all radius-server-policies that have acct-on-off configured. • for the specified radius-server-policy if the acct-on-off is configured <p>The Accounting-Off message is not sent when the last successful event for the radius server policy was an Accounting-Off message. In this case, an Accounting-On should be sent first. By specifying the keyword “force”, this is overruled.</p>
Parameters	<p>radius-server-policy <i>policy-name</i> — Specifies the radius-server-policy for which the Accounting-Off should be sent.</p> <p>force — Sends an Accounting-On also if the last successful event was an Accounting-Off.</p> <p>acct-terminate-cause <i>number</i> — Overrides the default Acct-Terminate-Cause (User-Request) in the Accounting-Off message.</p>

radius-acct-terminate-cause

Syntax	radius-acct-terminate-cause
Context	tools>dump>aaa
Description	This command shows all available termination causes and their respective number values. The TermCause is equivalent to VSA 226 alc-error-code numeric values. The description is equivalent to VSA 227 alc-error-message string.

radius-server-policy

Syntax	radius-server-policy <i>policy-name</i> msg-buffer [session-id <i>acct-session-id</i>]
Context	tools>perform>aaa tools>dump>aaa
Description	This command dumps the RADIUS message buffer content for the specified radius-server-policy: <ul style="list-style-type: none"> • message-type (acct-interim or acct-stop) • Acct-Session-Id • Remaining lifetime <p>When specifying the session-id, the message details are displayed.</p>
Parameters	<i>policy-name</i> — Specifies the radius-server-policy for which the message buffer content should be displayed. session-id <i>acct-session-id</i> — Displays the RADIUS message details for the message with specified session-id that is stored in the RADIUS message buffer.

ue

Syntax	ue
Context	tools>dump>wlan-gw
Description	This command dumps user equipment (UE) information.
Output	This command displays UE information.

11.23.2.8.5 Clear Commands

radius-server-policy

Syntax	radius-server-policy <i>policy-name</i> msg-buffer [acct-session-id <i>acct-session-id</i>] radius-server-policy <i>policy-name</i> statistics [msg-buffer-only] radius-server-policy <i>policy-name</i> server <i>server-index</i> statistics
Context	clear>aaa
Description	<p>This command dumps the RADIUS message buffer content for the specified radius-server-policy:</p> <ul style="list-style-type: none"> • message-type (acct-interim or acct-stop) • Acct-Session-Id • Remaining lifetime <p>When specifying the session-id, the message details are displayed.</p>
Parameters	<p><i>policy-name</i> — Specifies the radius-server-policy for which the information should be cleared.</p> <p>msg-buffer [acct-session-id <i>acct-session-id</i>] — Deletes all RADIUS messages or the RADIUS message with specified session-id from the RADIUS message buffer.</p> <p>statistics [msg-buffer-only] — Clears all statistics for the specified radius-server-policy: radius-server-policy statistics, RADIUS server statistics and RADIUS message buffer statistics. With the optional keyword “msg-buffer-only”, only the RADIUS message buffer statistics are cleared.</p> <p>server <i>server-index</i> statistics — Clears the RADIUS server statistics for the specified server-index in the specified radius-server-policy.</p>

isa-subnets

Syntax	isa-subnets all isa-subnets interface <i>ip-int-name</i> isa-subnets prefix <i>ipv6-address/prefix-length</i>
Context	clear>router>wlan-gw
Description	<p>This command clears specific subnets from the pool-manager. Associated UE's will be removed from the system.</p> <p>When clearing the last subnet on an ISA the pool-manager will automatically allocate a new subnet with allocation-level 0%.</p>
Parameters	all — Clears all the isa-subnets.

interface *ip-int-name* — Clears all the isa-subnets of a specific subscriber-interface.

ipv6-address/prefix-length — Clears a specific IPv6 address and prefix length.

12 GTP

12.1 In This Chapter

This chapter provides information about using GTP tunnels in TPSDA, including a configuration process overview.

Topics in this chapter include:

- [GTP Uplink](#)
 - [Identification Attributes](#)
 - [P-GW/GGSN Selection](#)
 - [Configuration](#)
 - [QoS Support](#)
 - [GTP Session Hold](#)
 - [Selective Breakout](#)
 - [IPoE Support](#)
 - [PPPoE Support](#)
- [GTP Peering](#)
- [Operational Commands](#)
 - [show router wlan-gw mobile-gateway](#)
 - [show router 300 wlan-gw mgw-address-cache](#)
 - [show subscriber-mgmt wlan-gw gtp-session detail](#)
 - [show subscriber-mgmt wlan-gw mgw-profile "default"](#)
 - [show subscriber-mgmt wlan-gw gtp-statistics](#)

12.2 GTP Uplink

SR OS supports subscriber traffic forwarding over an uplink GTP tunnel towards a GGSN or P-GW. This requires a per-subscriber GTP tunnel based on authentication to be configured. Each subscriber may access only a single APN. Both GTPv1 (Gn) and GTPv2 (S2a/S2b) are supported. A single primary PDP context per subscriber is supported on the Gn interface (3GPP TS 29.060 Release 8) from SR OS to the GGSN. A single default-bearer per subscriber is supported on the S2b interface (3GPP TS 29.274 Release 10), and S2a interface (3GPP TS 29.274 Release 11) from SR OS to the P-GW.

GTP-U encapsulation requires IOM3 or better.

12.2.1 Identification Attributes

GTP requires at least an IMSI and an APN to set up a connection. The IMSI is required to identify the user, and the APN is required to identify the network the user is connecting to.

There is a 1:1 relationship between IMSI and subscriber ID. It is possible to provision only one of these and the other will be accepted as the same value. If both are provisioned, they must be equal. Therefore, it is not possible to set up more than one GTP tunnel per subscriber.

APN can be provisioned explicitly per subscriber, or a default APN can be provisioned per VRF. If this APN does not contain an Operator Identifier (OI), it will be added automatically based on the IMSI.

12.2.2 P-GW/GGSN Selection

The initial address of the P-GW or GGSN can either be provided during authentication, or, in absence of authentication, resolved dynamically via DNS. For DNS, a FQDN is generated based on the APN as specified in 3GPP 29.303. This FQDN always consists of both the Network-ID (NI) portion and the OI portion, and is formatted as "NI.apn.epc.mnc<MNC>.mcc<MCC>.3gppnetwork.org". The system will perform an S-NAPTR lookup with this FQDN.

When multiple GW addresses are returned as part of this lookup, load-balancing is performed according to regular NAPTR and SRV rules. If no addresses are returned, or the S-NAPTR lookup failed, the system tries a regular A host lookup with the same FQDN. In this case, SR OS load-balances over multiple GW addresses using a round-robin mechanism. DNS servers can be configured per VPRN, except for the base router where the servers defined in the BOF are used.

```
config>router
config>service>vprn
    apn "internet.mnol.apn"
config>service>vprn>dns
    primary-dns 130.1.1.1
    secondary-dns 131.1.1.1
    tertiary-dns 132.1.1.1
    ipv4-source-address 170.1.1.1
exit
```

After initial GTP setup, it is possible for the P-GW or GGSN to return another address as a GTP-C or GTP-U destination. All data plane traffic is sent using the signaled GTP-U address. All subsequent control plane traffic is forwarded to the new GTP-C address.

The VRF used for GTP tunneling can be selected via provisioning a retain service ID for the subscriber. The source IP for GTP tunneling is taken from a loopback interface with the name "system" in that VRF. If no such interface is present, the tunnel setup fails.

12.2.3 Configuration

Profiles with signaling-related configuration per mobile gateway can be created locally on the SR OS router. These profiles include configuration for the interface type used between the router and the mobile gateway, path management parameters, retransmission parameters, and default values for GTP information elements such as AMBR. Each profile can be mapped to a specific GW IP address or subnet per VRF. Most of the per-session/context parameters can be overridden via RADIUS authentication. See the *RADIUS Attributes Reference Guide* for more information.

```
config>subscr-mgmt>wlan-gw>mgw-profile
    no description
    interface-type s2a

        address 203.0.113.0/24 "ggsn-policy"
    exit
```

12.2.4 QoS Support

SR OS provides appropriate traffic treatment and remarking based on DSCP bits in the outer and inner header in GTP packets.

Downstream from PGW/GGSN, the DSCP bits from the outer header in a GTP packet can be mapped to a forwarding class on network ingress, which can be preserved through the chassis as the packet passes to the egress IOM. On egress, reclassification can be done based on either the inner or outer DSCP bits, depending on the configuration value of the **use-ingress-l2tp-dscp** option in the SLA profile.

In the upstream direction, regular ESM FC classification is used. This FC is carried through the IOM to the egress complex. In the egress complex, this FC can be used for remarking of the outer DSCP values.

DSCP and default FC values for egress GTP-C packets can be configured under sgt-qos.

It is possible to signal the subscriber's aggregate rate or the rate of a specific scheduler in the downlink AMBR IE in both GTPv1-C and GTPv2-C. This uses the **report-rate** configuration of the SLA profile; the pppoe-actual-rate and rfc5515-actual-rate values are not applicable for GTP. This value can be subtracted with a value signaled during authentication to take into account an average use for selective breakout.

```
config>subscr-mgmt>sla-prof>egress  
report-rate
```

Other signed QoS IE values are taken from static configuration or values signaled in authentication.

12.2.5 GTP Session Hold

Deletion of an IPoE or PPPoE session also triggers deletion of any corresponding GTP sessions. This deletion is subject to a configurable hold time. When the subscriber returns with the same GGSN/P-GW parameters within the hold time, the GTP connection will not be resignaled. This avoids releasing resources (such as IP addresses) too quickly on the GGSN/P-GW. This is useful in the following cases:

- Non-seamless control plane mobility with WLAN-GW. Due to SHCV usage, the UE will be completely removed, but should reconnect quickly, preferably with the same IP address. Having a short hold time avoids the P-GW releasing the IP address.
- IP handover from WiFi-GW to RAN. In some cases, WiFi connectivity is lost before wireless data connectivity is established. By holding the GTP session active on the WLAN-GW, the IP address is also held on the GGSN/P-GW until the RAN connection is complete.

While a GTP session is in hold, all downstream traffic is dropped, but no error indication messages are sent.

12.2.6 Selective Breakout

This feature adds support for selecting a subset of traffic from a host (via IP filter) for local forwarding, while tunneling the remaining traffic to GGSN/PGW. This allows selected traffic to bypass the mobile packet core. The IP address for the host still comes from the GGSN/PGW during GTP session setup. Therefore, the selected traffic for local breakout from SR OS requires NAT functionality in order to draw the return traffic back to the router. To support address overlap within GTP, the NAT functionality is L2-aware. The selection of traffic for local breakout (local forwarding and NAT) is based on a net action in an upstream Ip filter applied to the host.

Selective breakout can be enabled on a per-host basis via RADIUS VSA (ALC-GTP-Local-Breakout) in access-accept. It is not possible to change this during a host's lifetime, such as via CoA. AA functionality is supported for local breakout traffic. Also, LI (after NAT) is supported for local breakout traffic, and is enabled via existing secure CLI, as stated in the *OAM and Diagnostics Guide*.

```
system>config>filter
  ip-filter 10 create
    entry 1 create
      match protocol udp
      dst-port eq 4000
    exit
    action gtp-local-breakout
  exit
```

On traffic ingress from the host UE, normal ESM host lookup and CAM lookup with the ingress host filter is performed. If there is a match in the filter indicating "gtp-local-breakout", the traffic is forwarded within the chassis to an ISA-BB, where it is subjected to L2-aware NAT function, and afterwards is forwarded using regular routing in the NAT outside VRF. The inside IP address is the address returned in GTP, and may not match a NAT L2-aware inside prefix. The outside IP is an address belonging to the NAT outside IP address range on the ISA. If the filter action results in a "forward" action (default), the traffic is GTP-tunneled without performing NAT functionality. The traffic received from the network can be a normal L3 packet or a GTP encapsulated packet. The normal Layer 3 packet is expected to be destined to the NAT outside IP and is normally routed to the NAT ISA.

By default, per-host accounting includes counters that are aggregated across GTP and local breakout traffic. Separate counters can be obtained by directing the GTP and local breakout traffic into different queues associated with the corresponding ESM host based on QoS IP classification. NAT information (outside IP and port range) associated with an ESM host subjected to selective breakout is included in accounting-updates.

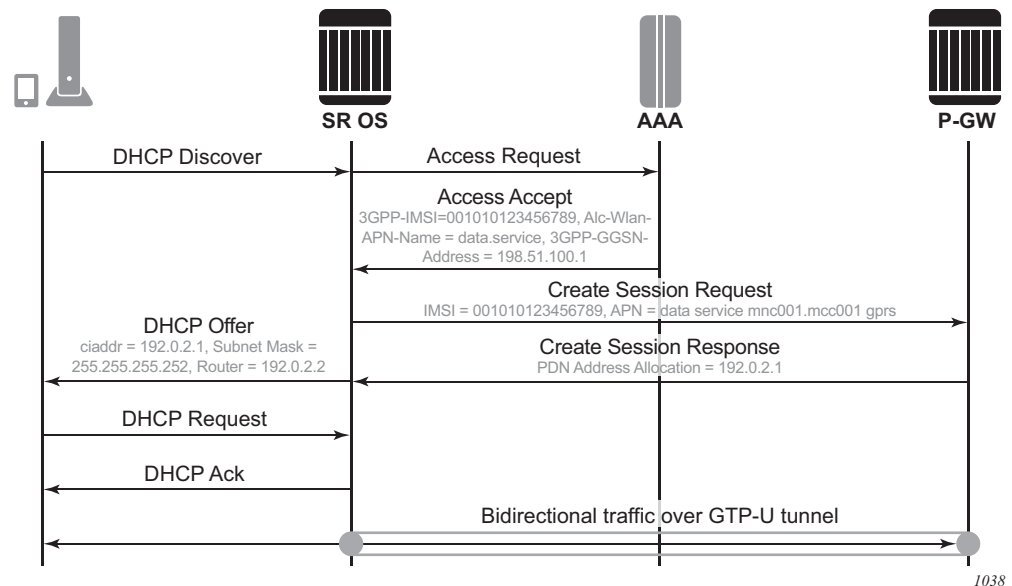

Selective breakout is supported for IPv4 only.

12.2.7 IPoE Support

A GTPv2 session or GTPv1 PDP context will be set up when IPoE session authentication includes any GTP parameters. The GTP session provides the IPv4 and IPv6 address used for the connecting host. Currently only DHCPv4 and SLAAC are supported to deliver these addresses back to the client. If DHCP is used, SR OS automatically derives a standards-compliant subnet mask and default GW from the signaled IP address. It is important that all GTP subscribers are in a shared split-horizon domain and that there is no L2 switching between GTP subscribers. Only a single IPoE session is supported per GTP subscriber. Additionally, DNS and NBNS can be signaled via GTP (A)PCO and reflected in DHCP, SLAAC, and stateless DHCPv6. Control plane packets such as DHCP and ICMPv6 RS are always terminated on the BNG and are not forwarded over GTP.

Figure 180 shows a sample IPoE session for GTP.

Figure 180 IPoE Session

1038

GTP without an IPoE session is available for IPv4 DHCP leases only for backwards compatibility. It may not be used for new deployments; existing deployments should move to the IPoE session concept.

12.2.8 PPPoE Support

A GTPv2 session or GTPv1 PDP context is set up when PPPoE session authentication includes any GTP parameters. The GTP session provides the IPv4 and IPv6 address to be used for the connecting host. IPCP and IPv6CP with SLAAC are supported to signal these addresses to the client. Only a single PPPoE session is supported per GTP subscriber. Additionally, DNS and NBNS can be signaled via GTP (A)PCO and reflected in IPCP, SLAAC, and stateless DHCPv6. Control plane packets such as ICMPv6 RS are always terminated on the BNG and are not forwarded over GTP.

12.3 GTP Peering

SR OS tracks each GTP-C peer for which it has at least a single GTP session or PDP context active. It tracks the peer's operational state with the following mechanisms:

- Regular GTP echo messages and parameters are configurable on a per-mgw-profile basis. When the echo mechanism fails, the peer is considered down.
- Active route entries towards the peer are monitored. If no route towards the peer is available, the peer is considered down.
- The Restart counter value of the peer is monitored. This is initially learned when the first active session or context is created. If the value is not available in regular messaging, an echo request is sent out immediately to learn the correct value. If the Restart counter is incremented during any later messaging exchange, the peer is considered rebooted.

When a peer is considered down or rebooted, all active GTP sessions and PDP contexts are forcefully removed.

SR OS also keeps a recovery counter in a persistent state, and increments this value on every reboot. This value is kept in the restcntr.txt file on CF3 and may not be modified or removed. This value is included in every control plane message.

SR OS responds to GTP echo messages for both active peers and unknown sources. This can be restricted via CPM filters if required. An incoming echo request from an unknown source will not create a peer; this can only be done by setting up GTP sessions or PDP contexts.

12.4 Operational Commands

These commands show state related to mobile gateways and GTP sessions.

```
show router wlan-gw
    mobile-gateway - Display mobile gateway information
    mgw-map - Display the mobile gateway map
    mgw-address-cache -
        Display the mobile gateway's DNS lookup address cache.

show router wlan-gw mgw-address-cache [apn <apn-string>]
                                <apn-string>          : [80 chars max]

show router wlan-gw mobile-gateway
    [mgw-profile <profile-name>] [local-address <ip-
address>] [control <protocol>]
    remote-address <ip-address> [udp-port <port>]
    remote-address <ip-address> [udp-port <port>] statistics
```

```

12.5.2 GTP Command Descriptions

12.5.2.1 GTP Commands

12.5.2.1.1 Generic Commands

description

Syntax	description <i>description-string</i> no description
Context	config>subscr-mgmt>wlan-gw>mgw-profile
Description	<p>This command creates a text description stored in the configuration file for a configuration context.</p> <p>The description command associates a text string with a configuration context to help identify the context in the configuration file.</p> <p>The no form of this command removes any description string from the context.</p>
Default	No description is associated with the configuration context.
Parameters	<i>description-string</i> — A text string describing the entity. Allowed values are any string up to 80 characters long composed of printable, 7-bit ASCII characters excluding double quotes. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

subscriber-mgmt

Syntax	subscriber-mgmt
Context	config
Description	This command enables the context to configure subscriber management entities. A subscriber is uniquely identified by a subscriber identification string. Each subscriber can have several DHCP sessions active at any time. Each session is referred to as a subscriber host and is identified by its IP address and MAC address.

All subscriber hosts belonging to the same subscriber are subject to the same hierarchical QoS (HQoS) processing. The HQoS processing is defined in the sub-profile (the subscriber profile). A sub-profile refers to an existing scheduler policy (configured in **the config>qos>scheduler-policy** context) and offers the possibility to overrule the rate of individual schedulers within this policy.

Because all subscriber hosts use the same scheduler policy instance, they must all reside on the same complex.

Default N/A

12.5.2.1.2 GTP Commands

wlan-gw

Syntax	wlan-gw
Context	config>subscriber-mgmt config>router config>service>vprn
Description	This command enables the context to configure WLAN Gateway parameters.
Default	N/A

max-held-sessions

Syntax	max-held-sessions <i>sessions</i> no max-held-sessions
Context	config>subscr-mgmt>wlan-gw
Description	This command configures the maximum number of GTP sessions to be held while their UE are disconnected.
Default	max-held-sessions 2000
Parameters	<i>sessions</i> — Specifies the maximum number of GTP sessions. Values 0 to 262144

mgw-profile

Syntax	mgw-profile <i>profile-name</i> [create] no mgw-profile <i>profile-name</i>
---------------	---

Context	config>subscr-mgmt>wlan-gw
Description	<p>This command creates a new mobile gateway profile or configures an existing mobile gateway profile.</p> <p>Mobile gateway profile is used to configure signaling interface between WLAN-GW and mobile gateway (PGW or GGSN) and GTP related signaling parameters per mobile gateway.</p> <p>The no form of the command removes the profile name from the configuration.</p>
Default	N/A
Parameters	<p><i>profile-name</i> — Specifies the Mobile Gateway profile up to 32 characters in length.</p> <p>create — Keyword used to create a profile name. The create keyword requirement can be enabled/disabled in the environment>create context.</p>

charging-characteristics

Syntax	charging-characteristics
Context	config>subscr-mgmt>wlan-gw>mgw-profile
Description	<p>This command configures the charging characteristics.</p> <p>The no form of the command reverts to the default.</p>
Default	N/A

home

Syntax	home <i>bit</i> [<i>bit</i> ... (up to 16 max)] no home
Context	config>subscr-mgmt>wlan-gw>mgw-profile>charging
Description	This command configures the charging characteristics for home UE.
Default	N/A
Parameters	<i>bit</i> — Specifies the bits to set in the Charging Characteristics Information Element (IE) for home UE, if not known by other means such as RADIUS.

roaming

Syntax	roaming <i>bit</i> [<i>bit</i> ... (up to 16 max)] no roaming
---------------	---

Context	config>subscr-mgmt>wlan-gw>mgw-profile>charging
Description	This command configures the charging characteristics for roaming UE.
Default	N/A
Parameters	<i>bit</i> — Specifies the bits to set in the Charging Characteristics Information Element (IE) for roaming UE, if not known by other means such as RADIUS.

ggsn

Syntax	ggsn
Context	config>subscr-mgmt>wlan-gw>mgw-profile
Description	This command enables the context to configure communication with a GGSN Mobile Gateway.
Default	N/A

qos

Syntax	qos
Context	config>subscr-mgmt>wlan-gw>mgw-profile>ggsn
Description	This command enables the context to configure QoS for a GGSN Mobile Gateway.
Default	N/A

ambr

Syntax	ambr down-link <i>kbps</i> up-link <i>kbps</i> no ambr
Context	config>subscr-mgmt>wlan-gw>mgw-profile>ggsn>qos
Description	This command configures the Aggregated Maximum Bit Rate (AMBR) to be sent in the APN AMBR IE. The contents of this IE can be overridden by RADIUS or report-rate mechanisms. If those mechanisms specify a partial value, such as only specifying the down-link parameter, the other value is picked up from the ambr configuration.

For GTPv1, the **no** form of the command implies that the IE will not be sent. If a partial value is received from another source, the missing value will use the following defaults:

- 10000 kbps up-link
- 20000 kbps down-link

For GTPv2, the **no** form of the command reverts to the default of 10000 kbps up-link and 20000 kbps down-link.

Default	no ambr
Parameters	down-link kbps — Specifies the downlink Aggregated Maximum Bit Rate (AMBR). Values 0 to 10000000 up-link kbps — Specifies the uplink Aggregated Maximum Bit Rate (AMBR). Values 0 to 10000000

arp

Syntax	arp <i>arp-value</i> no arp
Context	config>subscr-mgmt>wlan-gw>mgw-profile>ggsn>qos config>subscr-mgmt>wlan-gw>mgw-profile>pgw>qos
Description	The command configures the allocation/retention priority to be used in the GTP messages as QOS IE (for a Gn interface) or Bearer QOS (for an S2a/S2b interface). The no form of the command reverts to the default.
Default	arp-value 1
Parameters	<i>arp-value</i> — Specifies the Allocation/Retention Priority (ARP).

down-link

Syntax	down-link gbr <i>rate</i> mbr <i>rate</i> no down-link
Context	config>subscr-mgmt>wlan-gw>mgw-profile>ggsn>qos config>subscr-mgmt>wlan-gw>mgw-profile>pgw>qos
Description	This command configures the down-link bitrate in Kbps to be used in the GTP messages. The no form of the command reverts to the default.
Default	down-link gbr 2000 mbr 2000

up-link

Syntax	up-link gbr <i>rate</i> mbr <i>rate</i> no up-link
---------------	--

Context	config>subscr-mgmt>wlan-gw>mgw-profile>ggsn>qos config>subscr-mgmt>wlan-gw>mgw-profile>pgw>qos
Description	This command configures the up-link bitrate in Kbps to be used in the GTP messages. The no form of the command reverts to the default.
Default	up-link gbr 5000 mbr 5000
Parameters	gbr rate — Specifies the uplink Guaranteed Bit Rate (GBR) to be used in the GTP messages as QOS IE (for a Gn interface) or Bearer QOS (for an S2a/S2b interface). mbr rate — Specifies the uplink Maximum Bit Rate (MBR) to be used in the GTP messages as QOS IE (for a Gn interface) or Bearer QOS (for an S2a/S2b interface).

pgw

Syntax	pgw
Context	config>subscr-mgmt>wlan-gw>mgw-profile
Description	This command enables the context to configure communication with a Packet Data Network Gateway.
Default	N/A

qci

Syntax	qci <i>qci-value</i> no qci
Context	config>subscr-mgmt>wlan-gw>mgw-profile>pgw>qos
Description	This command configures the QoS Class Identifier (QCI) to send in the Bearer Level QoS IE in GTP messages on the S2a/S2b interface. The no form of the command reverts to the default.
Default	qci 8
Parameters	<i>qci-value</i> — Specifies the QCI value to send. Values 0 to 9

interface-type

Syntax	interface-type {gn s2a s2b} no interface-type
---------------	--

Context	config>subscriber-mgmt>wlan-gw >mgw-profile
Description	This command specifies the signaling interface between the WLAN-GW and the mobile gateway (PGW or GGSN).
Default	interface-type s2a
Parameters	gn — Signaling interface between the WLAN-GW and the mobile gateway is Gn as specified in 3GPP TS 29.060. S2a — Signaling interface between the WLAN-GW and the mobile gateway is S2a as specified in SAMOG. S2b — Signaling interface between the WLAN-GW and the mobile gateway is S2b as specified in 3GPP TS 29.274.

ip-ttl

Syntax	ip-ttl <i>hops</i> no ip-ttl
Context	config>subscr-mgmt>wlan-gw>mgw-profile
Description	This command configures the value to put in the IP header's TTL field for GTP control messages. The no form of the command reverts to the default value.
Default	ip-ttl 255
Parameters	<i>hops</i> — Specifies the IP TTL. Values 1 to 255

keep-alive

Syntax	keep-alive [<i>interval seconds</i>] [<i>retry-count value</i>] [<i>timeout retry-seconds</i>] no keep-alive
Context	config>subscr-mgmt>wlan-gw>mgw-profile
Description	This command configures Echo-Request messages. The no form of the command reverts to the default values.
Default	keep-alive interval 60 retry-count 5 timeout 5

Parameters	<p>interval <i>seconds</i> — Specifies, in seconds, the interval between keep-alive Echo-Request messages towards the same peer.</p> <p>Values 0, 60 to 180</p> <p>Default 60</p> <p>retry-count <i>value</i> — Specifies, in seconds, the interval between keep-alive Echo-Request messages towards the same peer.</p> <p>Values 1 to 15</p> <p>Default 4</p> <p>timeout <i>retry-seconds</i> — Specifies the retry timeout, in seconds.</p> <p>Values 1 to 20</p> <p>Default 5</p>
-------------------	---

message-retransmit

Syntax	message-retransmit [<i>timeout timeout</i>] [<i>retry-count value</i>] no message-retransmit
Context	config>subscr-mgmt>wlan-gw>mgw-profile
Description	This command configures the retry-count and response-timeout for GTP messages. The no form of the command reverts to the default values.
Default	message-retransmit timeout 5 value 3
Parameters	<p><i>timeout</i> — Specifies the interval, in seconds, between retransmission of signaling request messages towards the same peer Mobile Gateway.</p> <p>Values 1 to 30</p> <p>Default 5</p> <p><i>value</i> — Specifies the number of times a signaling request message is transmitted towards the same peer Mobile Gateway.</p> <p>Values 1 to 8</p> <p>Default 3</p>

protocol-configuration-options

Syntax	protocol-configuration-options { <i>apco</i> <i>pco</i> } no protocol-configuration-options
Context	config>subscr-mgmt>wlan-gw>mgw-profile

Description	This command configures the Information Element to use for the Protocol Configuration Options. The no form of the command reverts to the default value.
Default	protocol-configuration-options pco
Parameters	apco — Specifies that the system uses the Protocol Configuration Options Information Element. pco — Specifies that the system uses the Additional Protocol Configuration Options Information Element.

python-policy

Syntax	python-policy <i>name</i> no python-policy
Context	config>subscr-mgmt>wlan-gw>mgw-profile
Description	This command specified the python-policy for MGW profile packets sent/received on the group interface The no form of the command reverts to the default value.
Default	N/A
Parameters	<i>name</i> — Specifies an existing Python policy name.

rat-type

Syntax	rat-type { utran geran wlan gan hspa eutran virtual <i>id</i> }
Context	config>subscr-mgmt>wlan-gw>mgw-profile
Description	This command configures the default Radio Access Type (RAT) signaled during GTP setup. RAT is the underlying physical connection method for a radio-based communication network. This can be overridden by RADIUS. The no form of the command reverts to the default value.
Default	rat-type wlan
Parameters	utran — The signaled RAT type is UTRAN (1). geran — The signaled RAT type is GERAN (2). wlan — The signaled RAT type is WLAN (3). gan — The signaled RAT type is GAN (4).

hspa — The signaled RAT type is HSPA Evolution (5).

eutran — The signaled RAT type is EUTRAN (6).

virtual — The signaled RAT type is virtual (7).

id — Numerically specifies the RAT type to be used.

Values 0 to 255

report-wlan-location

Syntax	[no] report-wlan-location
Context	config>subscr-mgmt>wlan-gw>mgw-profile
Description	<p>This command enables reporting the WLAN location or cellular location of the UE in the signaling interface (S2a or Gn) between wlan-gw and mobile gateway (PGW or GGSN).</p> <p>The no form of the command disables location reporting.</p>
Default	no report-wlan-location

session-hold-time

Syntax	session-hold-time remaining-lease-time session-hold-time <i>seconds</i> no session-hold-time
Context	config>subscr-mgmt>wlan-gw>mgw-profile
Description	<p>This command configures , in seconds, the time that a GTP session context is held after the corresponding User Equipment is disconnected. If the same User Equipment re-connects to this system before this time has elapsed, its GTP session context is re-used. When the timer expires, the GTP session context is cleared.</p> <p>The no form of the command reverts to the default.</p>
Default	30
Parameters	<p>remaining-lease-time — Specifies that the timer is equal to the User Equipment's DHCP remaining lease time.</p> <p><i>seconds</i> — Specifies the time, in seconds, to hold a GTP session after its UE is disconnected.</p> <p>Values 0 to 3600</p>

signalling-protocol

Syntax	signalling-protocol <i>protocol</i> no signalling-protocol
Context	config>subscr-mgmt>wlan-gw>mgw-profile
Description	This command specifies the GTP (GPRS Tunneling Protocol) control protocol. The no form of the command reverts to the default value.
Default	signalling-protocol gtpv1-c
Parameters	<i>protocol</i> — Specifies the the GTP control protocol variant. Values gtpv1-c, gtpv2-c, gtp-auto

serving-network

Syntax	serving-network mcc <i>mcc-value</i> mnc <i>mnc-value</i> no serving-network
Context	config>subscr-mgmt>wlan-gw>mgw-profile
Description	This command configures the Operator Identifier part (MCC and MNC) of the APN. The no form of the command removes the values from the profile.
Default	no serving-network
Parameters	<i>mcc-value</i> — Specifies the Mobile Country Code (MCC) portion of the Serving Network. Values 2 digits <i>mnc-value</i> — Specifies the Mobile Network Code (MNC) portion of the Serving Network. Values 2 or 3 digits

apn

Syntax	apn <i>apn</i> no apn
Context	config>router>wlan-gw config>service>vprn>wlan-gw
Description	This command configures the Network Identifier part of the APN. The no form of the command removes the string from the configuration.
Default	no apn

Parameters *apn* — Specifies the APN (Access Point Name) used for this IMSI to connect to this Mobile Gateway up to 80 characters in length.

mgw-map

Syntax **mgw-map** *ip-prefix* [/prefix-length] **mgw-profile** *profile-name*
no mgw-map

Context config>router>wlan-gw
 config>service>vprn>wlan-gw

Description This command configures the mappings of MGW IP address and GTP profile.

Default N/A

Parameters *ip-prefix*[/prefix-length] — Specifies the IP prefix and prefix length.

Values *ip-prefix* a.b.c.d (host bits must be 0)
 length [0..32]

profile-name — specifies the profile associated with this address prefix.

Values 32 characters max

address

Syntax **address** *ip-prefix*[/prefix-length] [**mgw-profile** *profile-name*]
no address *ip-prefix*[/prefix-length]

Context config>router>wlan-gw>mgw-map
 config>service>vprn>wlan-gw>mgw-map

Description This command specifies the address.

 The **no** form of the command removes the parameters from the configuration.

Default N/A

Parameters *ip-prefix*[/prefix-length] — Specifies the IP prefix and prefix length of the subnet.

Values

<i>ip-prefix</i> [/prefix-length]	<i>ip-prefix</i>	a.b.c.d (host bits must be 0)
	<i>length</i>	[0..32]

profile-name — specifies the Mobile Gateway profile associated with this address prefix up to 32 characters in length.

pdn-type

Syntax	pdn-type {ipv4 ipv6 ipv4v6} no pdn-type
Context	config>router>wlan-gw config>service>vprn>wlan-gw
Description	<p>This command configures the PDP type to be signaled in GTP, determining which addresses are requested from the P-GW/GGSN and which hosts are set up afterwards. This can be overridden by RADIUS. If the ipv4v6 keyword is used, the P-GW/GGSN can fall back to either IPv4 or IPv6.</p> <p>The no form of the command reverts to the default configuration.</p>
Default	pdn-type ipv4
Parameters	<p>ipv4 — The GTP connection requests an IPv4 address.</p> <p>ipv6 — The GTP connection requests an IPv6 address.</p> <p>ipv4v6 — The GTP connection requests both an IPv4 and an IPv6 address.</p>

13 virtual Residential Gateway

13.1 In This Section

This section describes features and functionality for the router to act as a virtual Residential Gateway providing bridged home connectivity.

Topics in this section include:

- [virtual Residential Gateway Overview](#)
 - [Access Modes](#)
 - [Home Context on the vRGW](#)
 - [Device Context on the vRGW](#)
 - [Dynamic Configuration Changes](#)
 - [Per-Home Pool Management and L2-Aware NAT](#)
 - [IPv6](#)
 - [QoS and Filter Support](#)
 - [Data-Triggered Authentication](#)
 - [BRG and vRG Caveats](#)
 - [Per-Host NAT Port Ranges](#)
 - [Inter-Chassis Redundancy](#)

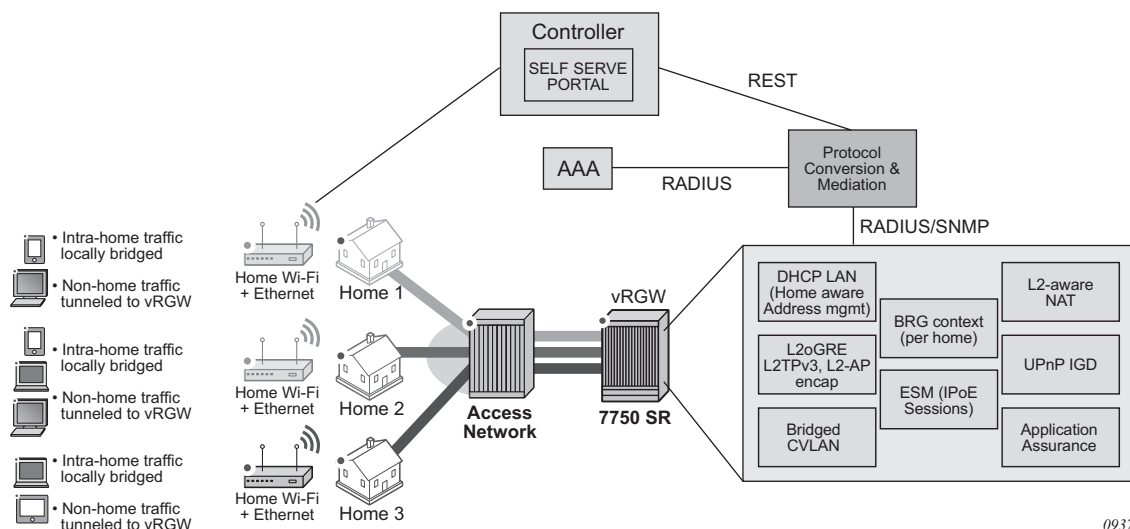

13.2 virtual Residential Gateway Overview

A virtualized residential gateway transforms the Layer 3 routed Residential Gateway (RGW) in the home into a bridged Residential Gateway, by moving the Layer 3 functions of an RGW into the network resides on a node hereby referred to as a “virtual Residential Gateway” (vRGW). The Layer 3 functionality, such as address management (DHCP server, and static or sticky address assignment), routing, Internet connectivity, NAT, UPnP, Firewall and application awareness provides functions such as URL filtering and parental control, is moved to the network and resides on the vRGW. The Residential Gateway then operates in a bridged mode and performs local switching of intra-home traffic that originates and terminates on devices within the home. Bridged traffic destined for outside the home (such as to the Internet, or to the provider’s content, or to another home) over the WAN toward the vRGW is hereby referred to as a “Bridged Residential Gateway” (BRG).

This mode of operation allows an operator visibility of the connected devices on the home LAN, instead of just a single IP address per home as is the case for a Layer 3 routed Residential Gateway. This allows operational improvements through per-device control and troubleshooting, and the ability to offer new services faster and on a more granular device specific-basis.

The router, as a dedicated gateway or as a BNG, serves as a vRGW providing Layer 3 termination and ESM functionality for bridged homes, as shown in [Virtualized Residential Gateway \(vRGW\)](#).

Figure 181 Virtualized Residential Gateway (vRGW)

0937

13.2.1 Access Modes

All vRGW functionality is supported on both regular group interfaces (SAPs, LAGs, PW-SAPs, and so on) and WLAN GW group interfaces (soft-GRE, soft-L2TPv3, VLAN).

A new configuration sub-node for the BRG is provided under the **group-interface** context for regular group interfaces and under the **vlan-range** context for WLAN-GW group interfaces. A regular group interface with a BRG sub-node does not support any non-BRG configuration and must operate in the **ipoe-bridged** mode.

In a WLAN-GW group interface, the BRG is configured in the **vlan-range** level. With a **vlan-range** it is not possible to mix BRG and other existing functionalities, but it is possible to mix BRG and other functionalities (such as WLAN-GW) on the same group interface. If a BRG also supports public WIFI, the expectation is that the BRG will have different SSIDs for public WIFI and for private home traffic on the BRG, each represented by a different VLAN tag.

Contrary to WLAN-GW UEs, which require anchoring based on their MAC addresses (for mobility), devices associated with a BRG are anchored based on the tunnel source IP address of the BRG. The system therefore load-balances on a per-BRG granularity basis across a set of configured ISAs. Anchoring based on the source IP address of the BRG allows all devices in the home to be anchored on the same ISA and IOM. This enables aggregate QoS functionality within a single home.

Tunnel QoS is not supported as this will be performed by regular subscriber QoS in the BRG scenario. WLAN-GW IOM (N:M) redundancy is supported. Data-triggered authentication (IPv4 only) is supported. All WLAN-GW access types (GRE, L2TPv3, L2-AP) are supported.

13.2.2 Home Context on the vRGW

The system keeps a management context for each connected home or BRG, which is identified by a BRG ID. This context is used for authentication, configuration, and retrieval of operational data. Authentication can be performed explicitly by the BRG, in which case the vRGW acts as a RADIUS proxy. Alternatively, the vRGW can implicitly authenticate on the BRG's behalf when the first host from the BRG connects.

Initial configuration parameters are provided as RADIUS attributes during authentication. Configuration parameters provided on the home level will be used as defaults on the host level can be overridden on a per-host basis. Home-level configuration can be dynamically overridden by means of a RADIUS CoA message. For more details on the available configuration parameters, see the vRGW section in the RADIUS Attributes Reference Guide.

Operational data provides information on the BRG such as the number of connected devices, how long the BRG has been active, and which configuration parameters were provided. This can be retrieved via MIBs or show commands.

The vRGW communicates with a classic AAA server mainly to perform the authentication and with a separate configuration/operational platform. This separate configuration/operational platform referred to as a “controller” and can be combined in a single management control system.

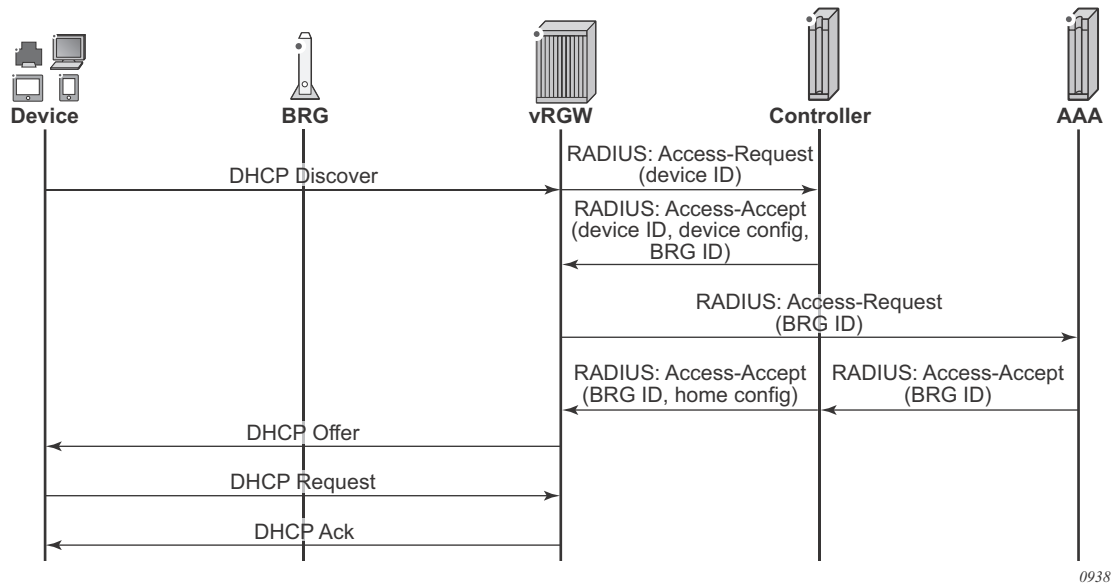

13.2.2.1 Implicit Home Authentication

with implicit home authentication ([Implicit Home Authentication](#)), the vRGW will authenticate a new BRG when the first associated device connects. In order to not impose restrictions on the connectivity model, the vRGW will not try to identify a BRG based on tunnel or VLAN data. The vRGW will always perform authentication of a new host and this authentication should return the BRG ID with which this host is associated. If this BRG ID is not yet known, the vRGW will trigger BRG-level authentication. This allows an operator flexibility to identify a home. For example, one deployment might use CVLANs as an identifier while another might use a BRG MAC as an identifier.

A home can be optionally authenticated with an AAA server. Each device in the home, on the other hand, is not typically authenticated with an AAA server, but merely authorized with a controller (via regular RADIUS messages and configured authentication policy) to get its configuration. This authorization is handled by the controller, which will identify and return the associated BRG ID and, optionally, any device-level configuration.

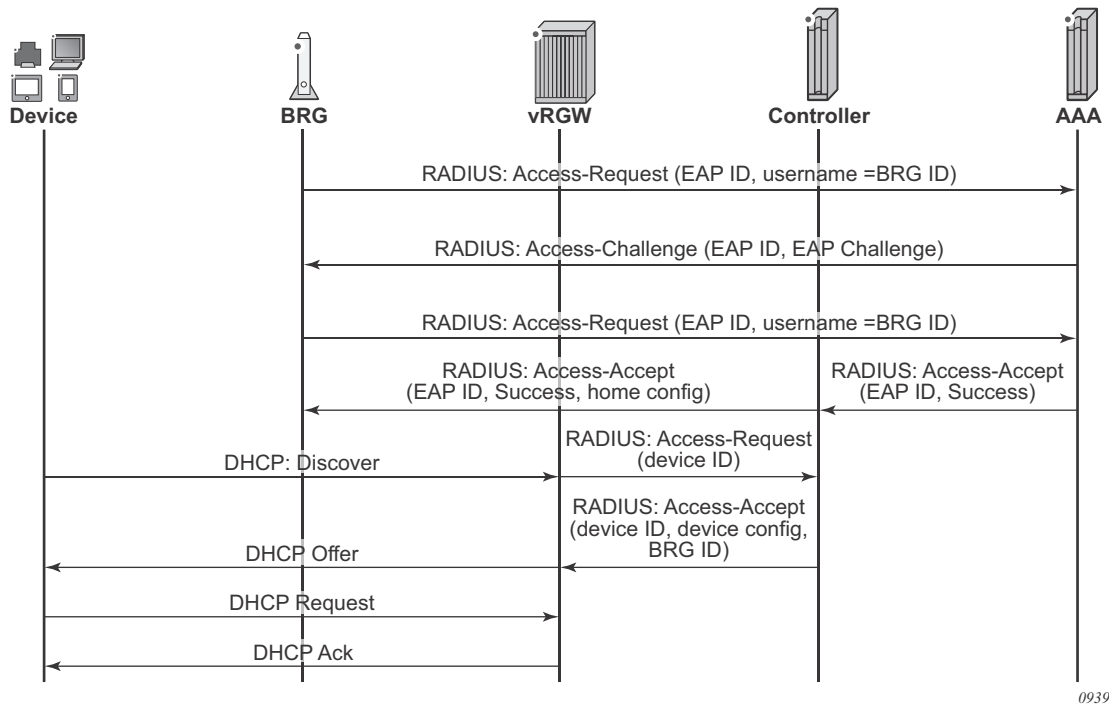

Per-home authentication is forwarded to the AAA server to be fully authenticated. In this case, it is expected that the controller performs an AAA proxy functionality so it can insert home configuration data in the final Access-Accept message. After both device and BRG authentication have been completed the resulting RADIUS attributes will be used to set up all required ESM objects (hosts, subscribers, SLA profile instances, filters, and so on).

Figure 182 Implicit Home Authentication

13.2.2.2 Explicit Home Authentication

With explicit home authentication ([Explicit Home Authentication](#)), the BRG authenticates itself at boot time before allowing connectivity of any devices. The vRGW will act as a proxy for this authentication, and upon receipt of a successful authentication, the BRG context will be created and store all home parameters. As with implicit authentication, the vRGW performs authentication for each device and expects the BRG ID as a result.

Figure 183 Explicit Home Authentication

0939

On the router, this functionality is obtained by including a RADIUS proxy in the vRGW configuration. This RADIUS proxy can be used for both WLAN-GW and vRGW scenarios and will determine the difference based on the presence of a BRG-ID attribute in the Access-Accept message. Proxy transactions in the context of a BRG will not be cached. Instead, a fully functional BRG context will already be created. Track accounting is not supported in the context of a BRG. Reauthentication is supported and behaves the same as on a CoA at the BRG level.

13.2.2.3 Change of Configuration

It is possible to change the configuration on a home level with the use of a RADIUS CoA. The CoA should use the BRG ID as a key and contain attributes for all new or updated parameters. For all correctly specified parameters, the vRGW will overwrite the existing configuration on the home level and update all devices connected to the BRG.

13.2.2.4 Home Lifetime

A configurable ping based on a smart connectivity-verification mechanism is provided to detect whether a BRG is alive. The BRG state is removed if it is not deemed alive (subject to a configurable hold time). A BRG is always considered to be alive as long as there are connected non-static devices. Static devices are not considered because there is no control plane to track whether they are alive or not. When no sessions are present, the home context can still be in one of the following three states.

- On explicit authentication, where there is no session connected yet, the BRG state should be kept alive. To handle this, an initial hold time applies during which the BRG context cannot be removed. Any connected device will cancel the timer. If the timer expires and there are still no connections present, the BRG falls back to the behavior as if the last session was removed.
- If the last session was removed and connectivity verification is configured, the vRGW will try to ping the BRG. This ping mechanism uses ICMP or ICMPv6 ping toward the tunnel source IP or, if not present, toward the RADIUS source IP address. As long as the pinging is successful, the BRG context is kept. If the pinging is unsuccessful or impossible to perform (such as no IP known), the BRG falls back to the hold time. If during the connectivity verification a host connects to the BRG, the verification is stopped and the BRG is assumed to be alive again.
- If the last session was removed and connectivity verification failed or was not configured, a configurable hold time applies during which time the BRG is not removed. If during the hold time a new device connects, the timer is canceled. If the timer is not canceled, the BRG is removed when the timer expires. The configured hold time can be zero and can be different from the initial hold time.

13.2.3 Device Context on the vRGW

The router maps every device in a home to an IPoE session, which can contain one or more ESM hosts depending on the number of IP stacks active on the device. The vRGW will still authorize every single device and store the resulting configuration data with the IPoE session. Whenever the session is created or updated, the vRGW will combine the configuration data of the home context with the configuration data of the device. When the same configuration object is present on both levels, the device level will apply. The resulting combined configuration data will be used to install or update the ESM objects.

13.2.4 Dynamic Configuration Changes

It is possible to dynamically change the configuration on both the home level and the device level by means of a RADIUS CoA. A CoA on the home level should use the BRG ID as key. The included attributes will overwrite the existing stored configuration on the home level and subsequently update all devices connected to the home. All devices will pick up the new home-level configuration unless a more specific configuration exists on the device level.

A CoA on the device level can use all existing ESM keys as detailed in the RADIUS Attributes Reference Guide. This will update the existing configuration on the device level. If the device inherited the specified parameter from the home level, this parameter will only be updated on the device level; the existing home-level configuration will stay intact and will be used as the default for other devices.

In certain cases, the configuration can be removed on the device level to be able to fall back to the home level. To support this, the RADIUS attribute “Alc-Remove-Override” has been created. This attribute lists which overrides must be removed on the session level and fall back (revert) to the home-level configuration. If the home parameter changes, the device will also pick up this new configuration.

For more details on RADIUS configuration attributes, refer to the RADIUS Attributes Reference Guide.

13.2.5 Per-Home Pool Management and L2-Aware NAT

This feature allows the provisioning of a DHCP pool per home in a vRGW context. The addresses in a per-home pool are unique, so local bridging within the home functions. Devices in different homes can, however, be allocated the same address. L2-aware NAT is then used to handle address translation and connectivity toward the network and between homes. Per-home default GW, subnet and address range (out of which addresses are allocated to home devices) can be configured via the CLI. The address range can be overridden from RADIUS. The subnet associated with the home pool must be within the configured L2-aware inside subnet. L2-aware source NAT can optionally be combined with destination NAT to support enhanced traffic redirection (such as for stateful DNS overwrite function). More details on network address translation forwarding can be found in the Multiservice Integrated Service Adapter Guide.

In addition to the IPv4 addresses from the home pool, the following hosts can be set up:

- IPv4 DHCP proxy hosts using an AAA-provisioned address
Note that only non L2-aware hosts can get a framed IP address from RADIUS
- IPv6 SLAAC hosts using an AAA-provisioned address or a Local Address Assignment
- IPv6 IA_NA hosts using DHCPv6 relay, an AAA-provisioned address, or a Local Address Assignment

13.2.5.1 Sticky IP Addresses

The vRGW can be programmed with a list of sticky IP addresses per BRG. A sticky IP address is an IPv4 address from the home pool allocation range that is set aside for a specific device based on the MAC address and will never be allocated to any other device. This can be used for devices where a persistent IP address is desirable but configuring a static IP address on the device is too cumbersome (such as a network printer). The device will still use DHCP to gain connectivity but will always be assigned the same IP address.

Public (non-NAT) sticky IP addresses are not directly supported in pool management but can be provisioned in the following manner.

1. Create a local DHCP server and pool to manage the public address space.

2. For each public sticky IP address that must be provisioned, create a sticky lease in this pool. See [Address Reservation for Sticky Leases](#) in the DHCP server section for further details. Both the user identification and hostname can be the MAC address of the associated device.
3. When the device linked to the sticky lease authorizes with the controller, it returns the allocated address as a framed IP address. This address will take precedence over any home pool configuration and a DHCP proxy host will be installed.

13.2.5.2 Managed Static IPv4 Addresses

Similar to sticky IP addresses, the vRGW can be programmed with a list of static IP addresses per BRG. However, for static IP addresses, DHCP is not expected from clients and will be dropped. The vRGW will automatically install all of these addresses as IPv4 hosts contained in IPoE sessions. Because every host must be linked to a specific point of access (such as a SAP or tunnel) the vRGW does need to wait on a data-trigger or the first non-static host in a home before static hosts can be created. Similar to regular (DHCP-triggered) hosts, a device-level authorization will be performed for each static host in order to retrieve the per-device level configuration.

This type of static host can cover both private (inside the home subnet) and public (non-L2-aware NAT) addresses. The created hosts can only be explicitly removed by the management interface, and mechanisms such as session-timeout and idle-timeout are not supported.

13.2.5.3 DMZ

A single DMZ address can be provisioned per home via RADIUS (VSA Alc-DMZ-Address), which can be any address inside the home subnet except for the default gateway. When a host exists with this address, the DMZ mode will be activated. Note that DMZ will be activated if a host exists with the address and the subscriber uses only 1 port range per IP. Without DMZ mode enabled, any traffic arriving for the NAT outside IP that does not match an existing flow, pinhole, or port-forward, will be dropped. With DMZ mode enabled, this traffic will be forwarded to the provisioned DMZ host.

13.2.6 IPv6

The vRGW feature set supports the following IPv6 host types:

- IPv6 SLAAC hosts using an AAA-provisioned address or a Local Address Assignment.
- IPv6 IA_NA hosts using DHCPv6 relay, an AAA-provisioned address, or a Local Address Assignment.

The vRGW only operates in IPoE bridge mode. For regular group interfaces, IPoE bridge mode must be explicitly enabled before the BRG can be enabled. For WLAN-GW group interfaces, IPoE bridge mode is implicitly assumed for a VLAN the range with BRG enabled. This has the following consequences:

- SLAAC hosts from the same home can share a /64 prefix.
- When a local address assignment is used, SLAAC hosts from the same home are automatically assigned the same /64 prefix.
- IA_NA hosts from the same BRG can get unique addresses from a shared /64 prefix. This prefix is automatically signaled in an RA.

13.2.7 QoS and Filter Support

The vRGW is based on existing ESM QoS configurations on the router where each home maps to a single subscriber instance. Home-level bandwidth can be provided by an aggregate rate or scheduler policy on the subscriber level. Groups of home devices (such as telephones, computers, televisions, and security systems) can be given a shared bandwidth by assigning a different SLA profile per such group. Individual device-level QoS can be provisioned by mapping a specific device to a specific forwarding class using IP classifiers based on the device IP. This forwarding class can then be mapped to its own individual queue.

Dynamic QoS overrides can be provisioned on both the home level and the device level. While QoS overrides are represented by a single RADIUS attribute, the device level does not override the whole attribute but only the QoS objects specified on that level. For example, if on the home level, the scheduler bandwidth is overridden, and on the device level, queue bandwidth is overridden. The resulting override is a combination of both.

13.2.8 Data-Triggered Authentication

ISA-based IPv4 data-triggered authentication ([Data-Triggered Authentication](#)) and host creation is supported on WLAN-GW group interfaces. When authenticating a data-triggered device, the controller has less data to derive the BRG from connection data only unlike DHCP where the BRG can insert its identifier, such as a circuit-id. For pure Layer 2 access, a BRG ID can be hard-coded to a port and VLANs, although for tunneled access, this is not always possible as the corresponding value would be the tunnel source IP address. This IP address can be dynamically assigned and changed with a BRG reboot. The following alternatives are suggested.

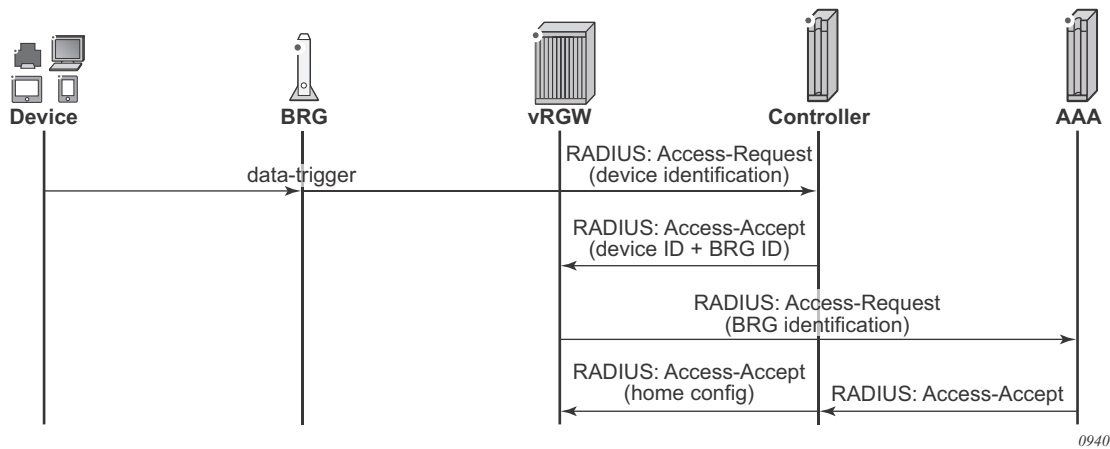

- Use the “AP MAC” as the identifier. This can be signaled in DHCP and DHCPv6 as specified in the [WIFI Aggregation and Offload](#) section. For data-trigger purposes, it can also be sent as part of the L2TPv3 header or if a GRE, it can be learned upon data-trigger via an ARPoGRE/NDoGRE message.
- Use a custom identifier that is sent in DHCP in a circuit-id option or a vendor-specific option. While a DHCP lease is active, a controller keeps state to map the device MAC to the BRG identifier in order for the data-trigger can be handled.

If the data-triggered device is the first device to come up in the home and the BRG did not perform explicit authentication, the vRGW will also trigger an implicit authentication. After authentication, two possibilities exist to install the data-triggered host.

- It is determined that the data trigger was for a static IP address. This is usually the case when the static device is the first to send upstream data in the home. In this case, the triggering static host and any other provisioned static hosts will be installed.
- The trigger was sent for a dynamic host (sticky/not sticky). This usually occurs when connection with a device was lost (based on an idle-timeout) but the lease was still valid. A DHCP lease will be re created using the provisioned lease time (on the home level). This installed lease time is usually excessive compared to the actual remaining lease time on the device, but this is corrected when the lease performs DHCP renew or rebind procedures.

Note however the actual remaining lease time will be used if known. Normally if a host goes idle and sends a data trigger, the actual remaining lease time will be used.

Figure 184 Data-Triggered Authentication

13.2.9 Per-Host NAT Port Ranges

Carriers want to offer "opt-in" value-added services (VASs) through dedicated DPI-based appliances or VMs in data-centers. This functionality requires vRGW support to forward traffic (ideally, only for subscribers who have subscribed to the VAS) to the external appliance. The appliance implements per-subscriber and per-device policies, and must be able to determine the subscriber and device from the received packets. Because address space across homes can overlap, subscriber-aware NAT is a requirement in the vRGW architecture. When subscriber-aware NAT is used, the outside IP address is unique and corresponds to the subscriber but, by default, the device information is lost. However, the device can be determined for the external appliance from the Layer 3 packet if a unique NAT outside port range is used per device on the vRGW.

By default, the subscriber-aware NAT allows the entire port range (other than the port range for static port forwarding) to be available for dynamic NAT flows and dynamic port forwarding (via UPnP). The feature adds support for allocating per-host NAT outside port ranges, and reporting per-host port-range allocation and deallocation in RADIUS accounting. External VAS appliances can then track RADIUS accounting to determine device to port-range mapping.

The port range for a host is allocated and deallocated when the host is created and deleted, respectively. A single port range per host is supported. The RADIUS attribute **Alc-Per-Host-Port-Range** provides the count of ports per host for a subscriber. See the 7750 SR RADIUS Attributes Reference Guide for information about the attribute format. In case of multiple NAT policies per subscriber, the attribute value is required to be the same for all policies.

The presence of the VSA implicitly enables the per-host NAT port-range allocation mode. The **ports-per-host** mode is only enabled (via the VSA) if vRGW is enabled (as indicated by the presence of BRG in **no-shutdown**) under the VLAN range on the WLAN-GW interface, or on the group interface. The VSA can be present in **access-accept** for BRG authentication (implicit or explicit), and in COA (with **Alc-BRG-Id** as the key). If a COA is received with the **Alc-Per-Host-Port-Range** set to 0, it indicates the disabling of the per-host port-range mode.

In cases where the **Alc-Per-Host-Port-Range** VSA is changed, the flows in the overlapping region between the new and old port ranges remain intact; remaining flows (if any) are removed.

- When the **ports-per-host** mode is disabled (via the VSA), the new port range includes all ports except the SPFs, and in accordance with the preceding rule, no ports are deleted.

- When **ports-per-host** mode is enabled mid-session (via the VSA), the new port range falls within the old port range (where the old range contained all ports except the SPFs).

ISA is updated from the CPM for all hosts when the **ports-per-host** mode changes, and cleanup occurs in accordance with the preceding rule.

The **per-host port-range** is included in the **Alc-Nat-Port-Range** attribute in per-host or per-session RADIUS accounting (in accordance with the currently supported format of the **Alc-Nat-Port-Range** VSA for L2-aware NATs).

When a new port block for a host is allocated or freed, an interim-update message with a **Nat-Port-Range-Event** reason is sent. The interim update is sent only when interim updates are enabled and the configured **include-attributes** contain the **alc-port-range** VSA.

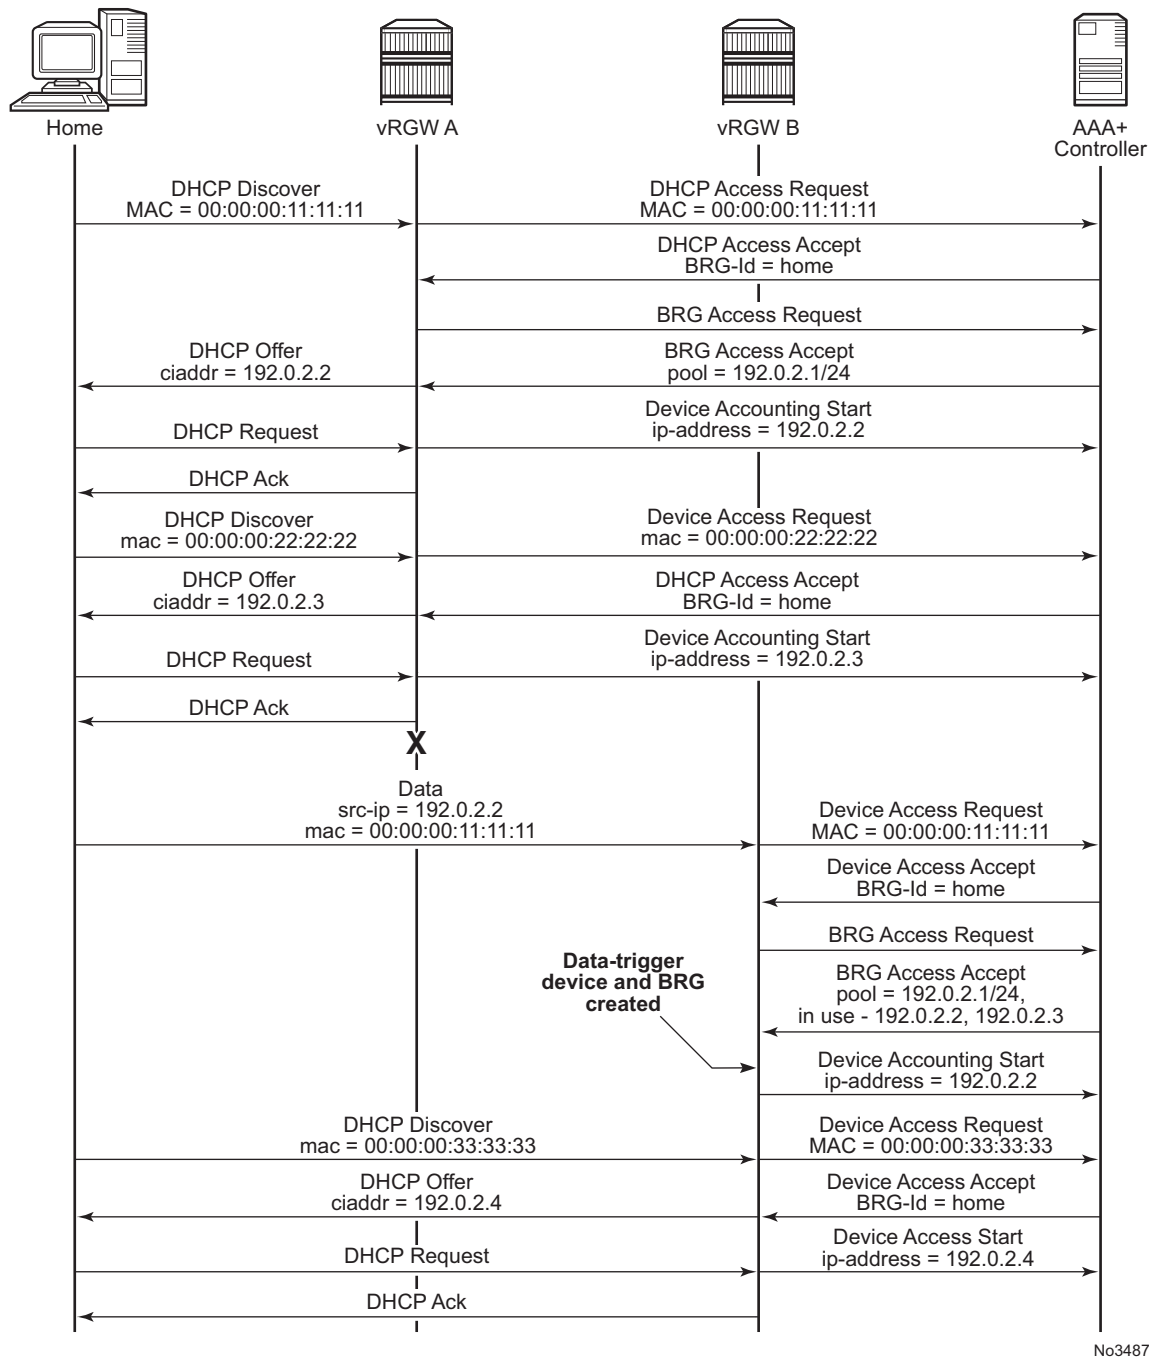

The port range for a host remains allocated for the lifetime of the host (unless explicitly removed using the VSA). Per-host reserved ports (for prioritized sessions), and watermarks to indicate exhaustion of **per-host port-range**, are not supported.

13.2.10 Inter-Chassis Redundancy

vRGW supports stateless inter-chassis redundancy, where the home and device state is not explicitly synchronized between the two virtual residential gateways. After a redundancy switchover event, Data Triggered Authentication (DTA) is used to download the correct home and device state back from the controller.

The controller should always have the latest configuration state of a given home, including any overrides after the home was activated. Additionally, the controller maintains a minimal state for DHCP pool management that can be reflected to the vRGW in case of a redundancy event.

Figure 185 Inter-Chassis Redundancy

13.2.10.1 Pool State Synchronization

Because there is no stateful synchronization between pairs of redundant gateways, all pool state is lost also in a switchover event. The new gateway creates a new pool with state information for all configured reserved and static address, but has no knowledge of dynamic addresses. When a data-triggered host is authenticated, the pool tries to recreate the lease corresponding with this source-ip. However, this is subject to race conditions. If a data-trigger is delayed (for example, the device is not active upon switchover) the DHCP pool might already have given out the IP address to a new device in the home. This not only blocks the data-trigger for the old device, but might lead to address duplication issues inside the home.

To solve this issue the controller keeps track of allocated dynamic IP addresses. After a switchover event, these addresses can be sent to the vRGW as part of the BRG configuration. In this case, the per-home pool only allocates these addresses to data-triggered devices or DHCP renew triggered devices that request this specific IP address. New devices will receive addresses not present on this list. After a configurable timeout, the pool relinquishes any unclaimed IP addresses back to the pool for general use. The currently unclaimed addresses can be displayed using the following command.

```
show subscriber-mgmt brg gateway brg-id "00:00:5e:00:53:05" standby-ip-addresses
=====
Bridged Residential Gateway home-aware pool standby IP addresses
=====
Home-aware pool : 00:00:5e:00:53:05
-----
192.0.2.10
192.0.2.11
192.0.2.12
-----
No. of standby IP addresses: 3
=====
```

It is recommended to keep the pool state on the controller simple, by marking an address as used when a device is connected and unused when it is disconnected. The controller should also periodically synchronize explicitly with the vRGW to remove addresses for which a device disconnect notification may have been lost.

13.2.10.2 Regular Group Interfaces

On regular group interfaces, redundancy is supported by enabling SRRP and IPoE session stateless redundancy. For more information on stateless redundancy see [Stateful Multi-Chassis Redundancy \(MCS\)](#) in the [Triple Play Enhanced Subscriber Management](#) section of this guide. The backup router will always be in the backup-routing mode. There is no support for shunting traffic via a redundant interface from the backup to master router.

IPv6 traffic and public IPv4 will be attracted to the correct master router via the regular track-SRRP mechanism. L2-aware NAT outside pools cannot use track-SRRP and should be configured distinctly on both routers making up the redundant pair. After a redundancy event, each home will gain a new outside IP address on the new master router.

Traffic from the BRGs is attracted to the correct master router via sending out Gratuitous ARP (GARP) messages. These GARPs update the FDB of the dual-homed Layer 2 aggregation nodes. This GARP is not supported for L2-aware inside prefixes. At least one subscriber interface subnet must be explicitly configured to send a GARP.

When using MSAP deployments, the managed SAPs are not synchronized and must be recreated on the new master router via data-triggered authentication. Because there are no managed SAPs present, no GARPs can be sent when a backup router becomes master. If the aggregation node has a shared FDB for all c-vlans (FDB per s-vlan) or for all s-vlans (FDB per switch), it is recommended to configure a single static SAP per s-vlan or per port over which a single ARP can be sent.

13.2.10.3 WLAN-GW Group Interfaces

Redundancy on WLAN GW group interfaces reuses the WLAN-GW monitor route mechanism to determine active/standby state of each router in a pair of redundant routers. For more information refer to the [WLAN-GW 1:1 Active-Backup Redundancy](#) section. When using the BRG MAC as a BRG identifier, an ARPoGRE (IPv4 GRE tunnel) or NDoGRE (IPv6 GRE tunnel) is triggered when receiving a data-trigger for an unknown device. Authentication of the data trigger will be delayed until the ARP/ND is answered or timed out.

```
config>service>vprn>sub-if>grp-if>wlan-gw
      learn-ap-mac delay-auth
```

IPv6 and public IPv4 traffic from the network will be attracted to the active router because a subscriber-interface on a standby router is operationally disabled and its associated subnets are not exported to the route table. L2-aware NAT outside pools stay active on both routers and should be configured distinctly on both routers making up the redundant pair. After a redundancy event each home will gain a new outside IP address on the new master router.

Traffic from the BRG is attracted by regular routing as only the active router will export the configured tunnel endpoints.

Access via the Layer 2 access point is not supported in a redundant setup.

Alternatively, vRGW with tunnel access also supports active and active redundancy using two different tunnel endpoint addresses. In this setup, each vRGW acts independently and does not synchronize any state. Each BRG is responsible for determining which vRGW is considered active, for example by sending ICMP/ICMP6 echo requests toward the tunnel endpoints. After detecting a failover, the BRG will direct traffic toward the alternate tunnel endpoint. The state on this vRGW will be re-created using data-trigger. This is similar to the monitor-route active/backup redundancy previously discussed. Explicit BRG authentication is supported in this use case if the BRG keeps track of a pair of tunnel endpoints and RADIUS server (proxy) addresses.

Redundancy of public IPv4 addresses and IPv6 addresses is not supported with an active/active deployment. After a failover event, it is not possible to send traffic for these addresses until the BRG restores connectivity to its original vRGW.

13.2.11 BRG and vRG Caveats

- Static IPv6 hosts are not supported in vRGW. It is possible to provide a static IPv4 host with a SLAAC prefix and use IPoE linking to automatically create an associated IPv6 host.
- Wholesale/retail is not supported in vRGW.
- Subnets provisioned for BRG pool management must lie in a pre-configured L2-aware NAT inside prefix. The dynamic range of a BRG pool must not contain the configured L2-aware NAT inside IP address.
- BRG connectivity verification is limited to a maximum of 50000 BRGs. If more
- BRGs are connected, connectivity verification will not be performed for the excess numbers and only hold-time will apply before the BRG instance is deleted from the vRGW.
- On regular group interfaces, only a single BRG is supported per SAP.
- There is a maximum of one SLAAC prefix per BRG.
- There is a maximum of 128 IPoE sessions per BRG, and a maximum of 8 static hosts per BRG.
- There is a maximum of 32 SLAAC hosts per shared prefix.
- The idle timeout is based on SLA profile instance, not per host. For hosts under the same BRG sharing an SLA profile, it is not possible to detect early disconnect of a single host. This restriction may be fixed in a future release.
- All SLAAC hosts under a BRG sharing the same prefix will use a common forwarding context downstream. For predictable behavior, the same SLA profile should be used for each SLAAC host. This restriction may be fixed in a future release.

13.3 vRGW Command Reference

13.3.1 Command Hierarchies

13.3.1.1 Subscriber Management BRG Profile Commands

```

configure
— subscriber-mgmt
  — brg-profile profile-name [create]
  — no brg-profile profile-name
    — connectivity-verification [count nr-of-attempts] [timeout timeout-seconds]
      [retry-time retry-seconds]
    — no connectivity-verification
    — description description-string
    — no description
    — dhcp-pool
      — lease-time seconds
      — no lease-time
      — options
        — custom-option option-number address [ip-address...(up to 4
          max)]
        — custom-option option-number hex hex-string
        — custom-option option-number string ascii-string
        — no custom-option option-number
      — subnet ip-prefix/prefix-length start ip-address end ip-address
    — hold-time seconds
    — no hold-time
    — initial-hold-time seconds
    — no initial-hold-time
    — radius-authentication
      — password password [hash | hash2]
      — no password
      — radius-server-policy policy-name
      — no radius-server-policy
    — [no] radius-proxy-server router router-instance name server-name
    — sla-profile-string string
    — no sla-profile-string
    — sub-profile-string string
    — no sub-profile-string
  
```

13.3.1.2 Subscriber Management Commands

```
configure
— subscriber-mgmt
  — authentication-policy name [create]
  — no authentication-policy name
    — [no] include-radius-attribute
    — [no] wifi-num-attached-ues
  — radius-accounting-policy name [create]
  — no radius-accounting-policy name
    — [no] include-radius-attribute
    — [no] wifi-num-attached-ues
    — [no] brg-num-active-sessions
```

13.3.1.3 Service Commands

```

config
  — service
    — ies service-id/vprn service-id
      — subscriber-interface ip-int-name [create]
      — no subscriber-interface ip-int-name
      — group-interface ip-int-name [create]
      — no group-interface ip-int-name
      — brg
        — [no] authenticated-brg-only
        — default-brg-profile profile-name
        — no default-brg-profile
        — [no] shutdown
      — wlan-gw
        — vlan-tag-ranges
          — [no] data-triggered-ue-creation
          — range start [0 to 4096] end [0 to 4096]
          — range default
          — no range start [0 to 4096] end [0 to 4096]
          — brg
            — [no] authenticated-brg-only
            — default-brg-profile profile-name
            — no default-brg-profile
            — [no] shutdown
        — learn-ap-mac [delay-auth]
        — no learn-ap-mac

```

13.3.1.4 Show Commands

```
show
  — subscriber-mgmt
    — brg
      — brg-hosts [mac ieee-address] [ip ip-address]
      — gateway brg-id brg-ident
        — bindings [mac ieee-address]
        — host mac ieee-address ip ip-address
        — hosts
      — gateways
      — gateways brg-profile profile-name
    — brg-profile
    — brg-profile name
    — brg-profile name associations
```

13.3.1.5 Clear Commands

```
clear
  — subscriber-mgmt
    — brg
      — gateway brg-id brg-ident
      — gateway brg-id brg-ident idle-bindings [binding ieee-address]
      — gateway all-gateways
      — gateway brg-id brg-ident all-hosts
      — gateway brg-id brg-ident host ieee-address
```

13.3.2 Command Descriptions

13.3.2.1 Generic Commands

description

Syntax	description <i>description-string</i> no description
Context	config>sub-mgmt>brg-prof
Description	This command creates a text description stored in the configuration file for a configuration context. This associates a text string with a configuration context to help identify the context in the configuration file. The no form of this command removes any description string from the context.
Default	No description is associated with the configuration context.
Parameters	<i>description-string</i> — A text string describing the entity. Allowed values are any string up to 80 characters long composed of printable, 7-bit ASCII characters excluding double quotes. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

shutdown

Syntax	[no] shutdown
Context	config>service>ies>sub-if>grp-if>wlan-gw>vlan-ranges>range>brg config>service>vprn>sub-if>grp-if>wlan-gw>vlan-ranges>range>brg config>service>ies>sub-if>grp-if>brg config>service>vprn>sub-if>grp-if>brg
Description	This command administratively disables the entity. When disabled, an entity does not change, reset, or remove any configuration settings or statistics. Many entities must be explicitly enabled using the no shutdown command. The operational state of the entity is disabled as well as the operational state of any entities contained within. Many objects must be shut down before they can be deleted. Unlike other commands and parameters where the default state is not indicated in the configuration file, shutdown and no shutdown are always indicated in system-generated configuration files. The no form of the command puts an entity into the administratively enabled state.

13.3.2.2 vRGW Commands

brg-profile

Syntax	brg-profile <i>profile-name</i> [create] no brg-profile <i>profile-name</i>
Context	config>subscr-mgmt
Description	<p>This command creates the profile for Bridged Residential Gateway (BRG) devices. The BRG profile specifies default parameters that are used for host management under a single BRG.</p> <p>The no form of the command removes the profile name from the configuration.</p>
Default	none
Parameters	<p><i>profile-name</i> — Specifies the name of the BRG profile.</p> <p>create — Keyword used to create a BRG profile. The create keyword requirement can be enabled/disabled in the environment>create context.</p>

connectivity-verification

Syntax	connectivity-verification [count <i>nr-of-attempts</i>] [timeout <i>timeout-seconds</i>] [retry-time <i>retry-seconds</i>] no connectivity-verification
Context	config>subscr-mgmt>brg-profile
Description	<p>This command configures the BRG connectivity verification. The system uses ICMP Echo request messages for connectivity verification.</p> <p>When the last host associated with a BRG is removed, a ping mechanism is used to verify if the BRG is still active. This command specifies the parameters used in this mechanism.</p> <p>The no form of this command disables the BRG ping mechanism and removes the BRG without verification. Any configured hold time still applies.</p>
Default	count 3 timeout 30 retry-time 900
Parameters	<p>count <i>nr-of-attempts</i> — Specifies the number of connectivity verification attempts this system makes before a BRG is considered down.</p> <p>Values 1 to 5</p> <p>timeout <i>timeout-seconds</i> — Specifies the time, in seconds, after which an unanswered ping is considered failed.</p> <p>Values 5 to 60</p>

retry-time *retry-seconds* — Specifies the time, in seconds, that the system waits while it considers a BRG down before it starts a new connectivity verification cycle. If a ping succeeds, the mechanism will be retried after this time.

Values 300 to 3600

dhcp-pool

Syntax	dhcp-pool
Context	config>subscr-mgmt>brg-profile
Description	This command enables the context to configure per-subscriber IPv4 address pool parameters to be used for address allocation. Pools for different subscribers can overlap. Specific pool parameters can be overridden by RADIUS.

lease-time

Syntax	lease-time <i>seconds</i> no lease-time
Context	config>subscr-mgmt>brg-profile>dhcp-pool
Description	This command configures the lease time, in seconds, to be used when allocating addresses from the pool. This time value should always be longer than the renew/rebind time. The no form of the command reverts to the default.
Default	600
Parameters	<i>seconds</i> — Specifies the lease time. Values 10 to 315446399

options

Syntax	options
Context	config>subscr-mgmt>brg-profile>dhcp-pool
Description	This command enables the context to configure options that are reflected in DHCP.
Default	none

custom-option

Syntax	custom-option <i>option-number</i> address [<i>ip-address...</i> (up to 4 max)] custom-option <i>option-number</i> hex <i>hex-string</i> custom-option <i>option-number</i> string <i>ascii-string</i> no custom-option <i>option-number</i>
Context	config>subscr-mgmt>brg-profile>dhcp-pool>options
Description	This command configures DHCP options.
Default	none
Parameters	<i>option-number</i> — Specifies the number of this DHCP option. address [<i>ip-address...</i> (up to 4 max)] — Specifies the IP address. hex <i>hex-string</i> — Specifies the hex string. string <i>ascii-string</i> — Specifies the ASCII string.

subnet

Syntax	subnet <i>ip-prefix/prefix-length</i> start <i>ip-address</i> end <i>ip-address</i>
Context	config>subscr-mgmt>brg-profile>dhcp-pool
Description	<p>This command configures the subnet that will be used for the L2aware-subscriber. This subnet is only locally significant and can overlap with other subscribers. The subnet is derived by ignoring the host bits of the IP address. The IP address specifies the default gateway that will be signaled in DHCP along with the netmask derived from the prefix length.</p> <p>The start and end addresses specify the range of addresses that are suitable for allocation within the given subnet. If the subnet address (host bits 0), broadcast address (host bits 1) or default-gw address fall in this range, they will not be considered for allocation.</p> <p>Changing the subnet will only affect new subscribers. New and existing hosts for existing subscribers will keep allocating from the original subnet.</p>
Default	no subnet
Parameters	<i>ip-prefix/prefix-length</i> — Specifies the IP prefix and prefix length. start <i>ip-address</i> — Specifies the starting IP address. end <i>ip-address</i> — Specifies the ending IP address.

hold-time

Syntax	hold-time <i>seconds</i>
---------------	---------------------------------

no hold-time

Context	config>subscr-mgmt>brg-profile
Description	<p>This command holds the BRG object for the specified time. This applies when the connectivity verification fails or when the last host is removed and no connectivity-verification is enabled. Hold time does not apply to an explicit removal via the radius or clear commands.</p> <p>The no form of the command disables the hold time.</p>
Default	no hold-time
Parameters	<p><i>seconds</i> — Specifies the time to hold on to a BRG after the system considered it down.</p> <p>Values 30 to 86400</p>

initial-hold-time

Syntax	initial-hold-time <i>seconds</i> no initial-hold-time
Context	config>subscr-mgmt>brg-profile
Description	<p>This hold time applies to BRG instances that are created without any hosts; for example, triggered due to proxy authentication. During this initial hold-time the BRG is not deleted and no connectivity-verification is started. When this timer expires, connectivity verification is started. If connectivity verification is disabled and no hosts are associated with the BRG upon expiry, the regular hold time is started and the BRG instance will be removed.</p> <p>This command allows an operator to have fast BRG removal (no connectivity-verification and no hold-time) but still use BRG proxy authentication. Without an initial hold time the BRG would be removed immediately after creation.</p> <p>This command does not apply to BRG instances that are created through host setup.</p>
Default	300
Parameters	<p><i>seconds</i> — Specifies the initial time, in seconds, to hold on to a BRG after the system considered it down.</p> <p>Values 0 to 900</p>

radius-authentication

Syntax	radius-authentication
Context	config>subscr-mgmt>brg-profile

Description	This command enables the context to configure parameters related to RADIUS authentication performed for the BRG.
--------------------	--

Default	none
----------------	------

password

Syntax	password <i>password</i> [hash hash2] no password
---------------	--

Context	config>subscr-mgmt>brg-prof>radius-authentication
----------------	---

Description	This command configures the value of the user password as signaled in RADIUS. The no form of this command indicates that no password field should be sent in RADIUS.
--------------------	--

Default	none
----------------	------

Parameters	hash — Specifies the key is entered in an encrypted form. If the hash or hash2 parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the hash or hash2 parameter specified. hash2 — Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the hash2 encrypted variable cannot be copied and pasted. If the hash or hash2 parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the hash or hash2 parameter specified.
-------------------	---

radius-server-policy

Syntax	radius-server-policy <i>policy-name</i> no radius-server-policy
---------------	--

Context	config>subscr-mgmt>brg-prof>radius-authentication
----------------	---

Description	This command is used if the BRG needs to be authenticated to the controller/PCMP by the vRGW. This is required if the BRG does not perform RADIUS authentication via the proxy server. The vRGW will originate a valid Access Request using the BRG ID as the username. The no form of this command removes the radius-server-policy from the configuration. Setup of an unauthenticated BRG will now fail.
--------------------	--

Default	no radius-server-policy
----------------	-------------------------

Parameters	<i>policy-name</i> — Specifies the RADIUS server policy up to 32 characters in length to be applied to this subscriber authentication policy.
-------------------	---

radius-proxy-server

Syntax	[no] radius-proxy-server router <i>router-instance</i> name <i>server-name</i>
Context	config>subscr-mgmt>brg-profile
Description	<p>This command enables BRG processing on the specified RADIUS proxy server. Whenever an Access-Accept message is received with the attribute Alc-BRG-Id present, this will trigger the creation of a BRG. The BRG will use the brg-profile specified in the Access-Accept message or fall back to this BRG profile. When the specified radius-proxy-server has a cache enabled, no cache entries will be created for a transaction identified as BRG. A RADIUS proxy server can only be listed in one BRG profile.</p> <p>This command can be executed multiple times.</p> <p>The no form of this command removes BRG processing for the specified radius-proxy server.</p>
Default	none
Parameters	router <i>router-instance</i> — Specifies the ID of the VRF where the proxy server is located. name <i>server-name</i> — Specifies the name of the RADIUS proxy server.

sla-profile-string

Syntax	sla-profile-string <i>string</i> no sla-profile-string
Context	config>subscr-mgmt>brg-profile
Description	<p>This command configures the SLA profile string that will be used as a default for SLA profile lookup. This string can be overridden during BRG or host authentication.</p> <p>The no form of the command removes the string from the configuration.</p>
Default	no sla-profile-string
Parameters	<i>string</i> — Specifies the string to use to look up the SLA profile.

sub-profile-string

Syntax	sub-profile-string <i>string</i> no sub-profile-string
Context	config>subscr-mgmt>brg-profile
Description	This command is used as a default for subscriber profile lookup. This string can be overridden during BRG or host authentication.

The **no** form of the command removes the string from the configuration.

Default no sub-profile-string

Parameters *string* — Specifies the string used to look up the subscriber profile.

13.3.2.3 Subscriber Management Commands

radius-accounting-policy

Syntax	radius-accounting-policy <i>name</i> [create] no radius-accounting-policy <i>name</i>
Context	config>subscr-mgmt
Description	This command specifies a subscriber RADIUS-based accounting policy.
Parameters	<i>name</i> — The name of the policy. The string is case-sensitive and limited to 32 ASCII 7-bit printable characters with no spaces. create — Keyword used to create a RADIUS accounting policy instance. The create keyword requirement can be enabled/disabled in the environment>create context.

include-radius-attribute

Syntax	[no] include-radius-attribute
Context	config>subscr-mgmt>auth-plcy config>subscr-mgmt>acct-plcy
Description	This command enables the context to specify the RADIUS parameters that the system should include in RADIUS authentication-request messages.

authentication-policy

Syntax	authentication-policy <i>name</i> [create] no authentication-policy <i>name</i>
Context	config>subscr-mgmt
Description	This command specifies authentication policy configured under the aaa context for authenticating users on the WLAN-GW ISA.
Default	none
Parameters	<i>name</i> — Specifies the name of the authentication policy up to 32 characters in length. create — Keyword used to create a authentication policy instance. The create keyword requirement can be enabled/disabled in the environment>create context.

wifi-num-attached-ues

Syntax	[no] wifi-num-attached-ues
Context	config>subscr-mgmt>acct-plcy>include config>subscr-mgmt>auth-plcy>include
Description	<p>This command includes the Alc-Num-Attached-UEs attribute. For session/host accounting, this is the tunnel of the associated UE. For queue-instance accounting, this attribute will not be included.</p> <p>The no form of the command removes the attribute from inclusion.</p>
Default	no wifi-num-attached-ues

brg-num-active-sessions

Syntax	[no] brg-num-active-sessions
Context	config>subscr-mgmt>acct-plcy>include
Description	<p>This command indicates the number of IPoE sessions that are currently active on the BRG to which this accounting message relates.</p> <p>The no form of the command removes the attribute from inclusion.</p>
Default	disabled

subscriber-mgmt

Syntax	subscriber-mgmt
Context	config
Description	<p>This command enables the context to configure subscriber management entities. A subscriber is uniquely identified by a subscriber identification string. Each subscriber can have several DHCP sessions active at any time. Each session is referred to as a subscriber host and is identified by its IP address and MAC address.</p> <p>All subscriber hosts belonging to the same subscriber are subject to the same hierarchical QoS (HQoS) processing. The HQoS processing is defined in the sub-profile (the subscriber profile). A sub-profile refers to an existing scheduler policy (configured in the configure>qos>scheduler-policy context) and offers the possibility to overrule the rate of individual schedulers within this policy.</p> <p>Because all subscriber hosts use the same scheduler policy instance, they must all reside on the same complex.</p>

13.3.2.4 Service Commands

brg

Syntax	brg
Context	config>service>ies>sub-if>grp-if>wlan-gw>ranges>range config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range config>service>ies>sub-if>grp-if config>service>vprn>sub-if>grp-if
Description	This command enables the context to configure BRG parameters. In the config>service>ies>sub-if>grp-if and config>service>vprn>sub-if>grp-if contexts, these commands are only available in the vlan-tag-ranges level.

authenticated-brg-only

Syntax	[no] authenticated-brg-only
Context	config>service>ies>sub-if>grp-if>wlan-gw>vlan-ranges>range>brg config>service>vprn>sub-if>grp-if>wlan-gw>vlan-ranges>range>brg config>service>ies>sub-if>grp-if>brg config>service>vprn>sub-if>grp-if>brg
Description	This command indicates that only BRGs that are pre-authenticated using the RADIUS proxy are allowed in this context. The no form of the command removes the restriction.
Default	no authentication-brg-only

default-brg-profile

Syntax	default-brg-profile <i>profile-name</i> no default-brg-profile
Context	config>service>vprn>sub-if>grp-if>wlan-gw>vlan-ranges>range>brg config>service>ies>sub-if>grp-if>wlan-gw>vlan-ranges>range>brg config>service>vprn>sub-if>grp-if>brg config>service>ies>sub-if>grp-if>brg
Description	This command indicates that the default BRG profile must be used for new BRGs. This profile can be overridden by RADIUS.
Default	no default-brg-profile

Parameters *profile-name* — Specifies the name of the brg-profile to be applied.

learn-ap-mac

Syntax **learn-ap-mac** [**delay-auth**]
no learn-ap-mac

Context config>service>ies>sub-if>grp-if>wlan-gw
config>service>vpn>sub-if>grp-if>wlan-gw

Description This command enables the sending of ARP or ND packets on the WLAN-GW GRE tunnel for certain events. The target IP address in the ARP/ND packet is the endpoint IP address of the AP. The ARP/ND response from the AP should contain the AP MAC, which subsequently can be reported in a called-station-id message. When enabled, a message will be sent for following events:

- CPM: Mobility to an AP for which the AP-MAC is not yet known
- CPM: RS-triggered authentication on an AP for which the AP-MAC is not yet known
- ISA: Any mobility event
- ISA: Any authentication where the AP-MAC is not yet known (for example, from a RADIUS proxy cache or a DHCP circuit-id). If the optional keyword **delay-auth** is configured, then the authentication will be delayed until the ARP/ND is answered or timed out, after which the AP-MAC can be included in the authentication.

This configuration is ignored for L2-AP and L2TPv3 access.

Default The **no** form of this command disables this mechanism.

Parameters **delay-auth** — Specifies that authentication will be delayed until the ARP/ND is answered or timed out, after which the AP-MAC can be included in the authentication.

data-triggered-ue-creation

Syntax [**no**] **data-triggered-ue-creation**

Context config>service>vpn>sub-if>grp-if>wlan-gw>ranges>range
config>service>ies>sub-if>grp-if>wlan-gw>ranges>range

Description This command enables or disables data-triggered subscriber creation for WIFI subscribers. Data- triggered UE creation is currently only supported for UDP and TCP packets.

Default none

subscriber-interface

Syntax **subscriber-interface** *ip-int-name* [**create**]

no subscriber-interface *ip-int-name*

Context	config>service>ies config>service>vprn
Description	<p>This command allows the operator to create special subscriber-based interfaces. It is used to contain multiple group interfaces. Multiple subnets associated with the subscriber interface can be applied to any of the contained group interfaces in any combination. The subscriber interface allows subnet sharing between group interfaces.</p> <p>The no form of the command removes the subscriber interface.</p>
Default	none
Parameters	<p><i>ip-int-name</i> — Specifies the interface name of a subscriber interface. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.</p> <p>fwd-service <i>service-id</i> — specifies the wholesale service ID.</p>

group-interface

Syntax	group-interface <i>ip-int-name</i> [create] no group-interface <i>ip-int-name</i>
Context	config>service>ies>sub-if config>service>vprn>sub-if
Description	<p>This command creates a group interface. This interface is designed for triple-play services where multiple SAPs are part of the same subnet. A group interface may contain one or more SAPs.</p> <p>The no form of the command removes the group interface from the subscriber interface.</p>
Default	no group interfaces configured
Parameters	<i>ip-int-name</i> — Specifies the interface name of a group interface. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

wlan-gw

Syntax	wlan-gw
Context	config>service>ies>sub-if>grp-if config>service>vprn>sub-if>grp-if
Description	This command enables the context to configure WLAN GW parameters.
Default	none

range

Syntax	range start [0 to 4096] end [0 to 4096] range default no range start [0 to 4096] end [0 to 4096]
Context	config>service>vprn>sub-if>grp-if>wlan-gw>ranges config>service>ies>sub-if>grp-if>wlan-gw>ranges
Description	This command creates or enters the context of specified VLAN range for configuration applicable to that range of VLANs.
Default	none
Parameters	start [0 to 4096] — Specifies the start of the VLAN range. end [0 to 4096] — Specifies the end of the VLAN range. default — Configures defaults for the interface.

vlan-tag-ranges

Syntax	vlan-tag-ranges
Context	config>service>ies>sub-if>grp-if>wlan-gw config>service>vprn>sub-if>grp-if>wlan-gw
Description	This command enables the context to configure VLAN-to-retail-map parameters to map dot1q tags to the retail service ID. The WIFI AP inserts a dot1Q tag in the Layer 2 frame within the GRE tunnel to indicate the retail service provider for the subscriber.
Default	none

13.3.2.5 Show Commands

brg

Syntax	brg
Context	show>subscr-mgmt
Description	This command enables the context to display operational information for connected BRGs and related hosts.

brg-hosts

Syntax	brg-hosts [mac <i>ieee-address</i>] [ip <i>ip-address</i>]
Context	show>subscr-mgmt>brg
Description	This command displays operational information for connected BRGs and related hosts.
Parameters	mac <i>ieee-address</i> — Displays detailed information for each prefix. ip <i>ip-address</i> — Displays only the prefixes associated with this subscriber interface.

Output

Sample Output

```
Node# show subscriber-mgmt brg brg-hosts
=====

brg-profile

Syntax	brg-profile brg-profile <i>name</i> brg-profile <i>name associations</i>
Context	show>subscr-mgmt
Description	This command displays BRG profile information.
Parameters	<i>name</i> — Specifies an existing BRG profile name. associations — Displays information associated with the specified BRG profile name.

13.3.2.6 Clear Commands

brg

Syntax	brg
Context	clear>subscr-mgmt
Description	This command clears BRG data.

gateway

Syntax	gateway brg-id <i>brg-ident</i> gateway brg-id <i>brg-ident</i> idle-bindings binding <i>ieee-address</i> gateway all-gateways gateway brg-id <i>brg-ident</i> all-hosts gateway brg-id <i>brg-ident</i> host <i>ieee-address</i>
Context	clear>subscr-mgmt>brg
Description	This command clears BRG gateway data.
Parameters	<p>brg-id <i>brg-ident</i> — Clears the specified BRG and all related hosts from the system.</p> <p>idle-bindings — Clears a specific idle binding or all idle binding from the BRG. An idle binding is a DHCP lease that has not been expired but for which the host has been removed due to idle timeout.</p> <p>binding <i>ieee-address</i> — Specifies the MAC address of the binding to remove.</p> <p>all-gateways — Clears all BRGs and related hosts from the system.</p> <p>all-hosts — Clears all hosts belonging to a specified BRG.</p> <p>host <i>ieee-address</i> — Clears a specific host belonging to a specified BRG.</p>

14 Dynamic Data Services

14.1 In This Section

Topics in this section include:

- [Introduction to Dynamic Data Services](#)
- [RADIUS-Triggered Dynamic Data Services Associated With a PPPoE or IPoE Session as Control Channel](#)

 - [RADIUS Authentication](#)
 - [Local Authentication](#)
 - [Data-Triggered Dynamic Service Provisioning](#)
 - [Control Plane Protection](#)
 - [Debugging](#)

14.2 Introduction to Dynamic Data Services

Dynamic Data Services enables a zero-touch, single-ended provisioning model for business services. Two deployment models are available:

- **With control channel:** triggered by the authentication of a single or dual-stack PPPoE or IPoE session as a business CPE control channel, parameters are passed in a RADIUS Access-Accept or CoA message to set up a Layer 2 or Layer 3 data service.
- **Without control channel:** RADIUS or local authentication of a Dynamic Data Service data trigger provides the required parameters to set up a Layer 2 or Layer 3 data service.

Dynamic Data Services support includes Epipe VLL services, Epipe VLL services with dynamic MS-PWs (FEC 129) or spoke-sdp, VPLS services, VPLS services with BGP-AD pseudowire, VPLS service with spoke-sdp or mesh-sdp, IES, and VPRN services. Dynamic Data Service SAPs must be located on dot1q- or qinq-encapsulated Ethernet, anchoring or satellite ports and can be part of a LAG.

A Python script interface adds a flexible abstraction layer that reduces the OSS integration cost; only the business user specific service parameters, such as service type, IP address, QoS, and filter parameters, are required from RADIUS or local authentication. These parameters are then used in the Python script to generate a CLI template to set up the target Dynamic Data Service.

Dynamic Data Services configuration can be updated via a RADIUS CoA message.

Both XML accounting and RADIUS accounting for up to two different RADIUS destinations can be activated on a dynamic data service SAP.

14.3 RADIUS-Triggered Dynamic Data Services Associated With a PPPoE or IPoE Session as Control Channel

Refer to the “RADIUS-Triggered Dynamic Data Service Provisioning” section in the *Advanced Configuration Guide* for a detailed description.

14.4 Data-Triggered Dynamic Data Services

In the data-triggered dynamic data services model, any frame arriving on a dynamic data services capture SAP can result in RADIUS or local authentication. The dynamic data service is then created from a Python script that generates CLI snippets using parameters obtained from authentication.

Figure 186 Data-Triggered Dynamic Data Services

14.4.1 Data Trigger

A dynamic services data trigger is an object that is created when a frame received on a dynamic services capture SAP is sent to the control plane for authentication. A dynamic services data trigger is uniquely identified with its SAP ID. If the dynamic services data trigger was received on capture SAP $x / y / z : * . *$ with outer-tag = a and inner-tag = b, then the dynamic service data trigger SAP ID is “x / y / z:a.b”.

For each dynamic services data trigger, the following information is stored.

Table 102 Data Trigger Information

Data Trigger Information	Description
Acct-Session-ID	The RADIUS accounting session ID for this dynamic services data trigger. This accounting session ID is used as accounting multi-session ID in RADIUS accounting for associated dynamic services. It can also be used as a key in CoA or Disconnect Messages to set up or terminate associated dynamic services.
MAC	The MAC address learned to set up this dynamic service data trigger. The MAC address is included in the Access-Request message for RADIUS authentication.
IP	The IPv4 or IPv6 address learned to set up this dynamic service data trigger. If the data trigger packet was not an IP packet, then this field is empty. When available, the IP address is included in the RADIUS authentication and accounting messages.

Table 102 Data Trigger Information (Continued)

Data Trigger Information	Description
State	<p>The current state of the dynamic service data trigger:</p> <p>Pending: (initial state) data trigger received and authentication started</p> <p>Accepted: (transient state) authentication succeeded; dynsvc script started but not yet completed</p> <p>sapCreated: (final state) corresponding dynamic services SAP created</p>

The dynamic services data trigger information can be displayed as follows:

```
# show service dynamic-services data-triggers
=====
Dynamic Services Data-triggers
=====
SAP                               : 1/1/4:1214.101
-----
Acct session-ID                   : 144DFF0000009156A24138
MAC                               : 00:51:00:dd:01:01
IP                                :
State                             : sapCreated
-----
No. of Data-triggers: 1
=====
```

For a data-triggered dynamic data service to be successfully set up, a dynamic services SAP equal to the data trigger SAP ID must be created.

In the same way as the control channel model, multiple dynamic data services can be associated with a single dynamic services data trigger: up to 32 dynamic services during data trigger authentication or up to 4000 in total via CoA. When the dynamic services SAP that corresponds to a data trigger is deleted (teardown action), then all dynamic services associated with that dynamic services data trigger are deleted (teardown action).

14.4.2 Dynamic Services Data Trigger Capture SAP

In the same way as an Enhanced Subscriber Management (ESM) capture SAP is configured, a dynamic services data trigger capture SAP is configured in a VPLS service and captures frames for authentication. A dynamic service data trigger capture SAP does not forward traffic within the VPLS service, and no MAC learning occurs.

A VPLS capture SAP becomes a dynamic services data trigger capture SAP when a dynamic services policy is configured and the **dynamic-services** context is enabled (no shutdown). The dynamic services policy specifies the authentication mechanism to be used as detailed in the authentication sections below.

For example:

```
configure
  service
    vpls 10 customer 1 create
    sap 1/1/4:1214.* capture-sap create
      description "Dynamic Services Data Trigger capture-sap"
      dynamic-services
        dynamic-services-policy "dyn-svc-1"
        no shutdown
      exit
    no shutdown
  exit
no shutdown
exit
```

trigger-packet type needs to be configured. A dynamic services data trigger **capture-sap** will capture any valid Ethernet frames, including non-IP frames.

Valid dynamic services data trigger capture SAPs are:

- dot1q-encapsulated Ethernet, anchoring, satellite ports or LAGs
 - sap x/y/z.*
 - lag-x.*
 - pxc-x.a.*
 - esat-x/y/z.*
- qinq-encapsulated Ethernet, anchoring, satellite ports or LAGs:
 - sap x/y/z:.*.*
 - sap lag-x:.*.*
 - sap x/y/z:tag.*
 - sap lag-x:tag.*
 - pxc-x.a:.*.*
 - pxc-x.a:tag.*
 - esat-x/y/z:.*.*
 - esat-x/y/z:tag.*

Enhanced Subscriber Management (ESM) and dynamic services data trigger cannot be enabled simultaneously on a single capture SAP: a “no shutdown” of the **dynamic-services** CLI context is mutually exclusive when configuring an ESM trigger-packet type.

Use the following CLI commands to display capture SAP statistics:

- To display the number of data trigger packets forwarded to the CPM and dropped on the IOM:

```
# show service id <service-id> sap <sap-id> sap-stats
=====
Service Access Points(SAP)
=====
--- snip ---
-----
Sap Statistics
-----
Last Cleared Time      : N/A
                        Packets          Octets
CPM Ingress            : 108              6696
Forwarding Engine Stats
Dropped                : 6144              405504
```

Table 103 **Data Trigger Packets Forwarded/Dropped Counters**

Counter	Description
CPM Ingress	Number of dynamic service data triggers received on the capture SAP that are forwarded to CPM
Forwarding Engine Stats Dropped	Number of dynamic service data triggers is received on the capture SAP that are dropped on IOM

- To display the dynamic services capture SAP control plane statistics (data triggers received and data trigger drop reason counters):

```
# show service id 10 dynamic-services capture-sap 1/1/4:1214.* statistics
=====
Dynamic Services Capture SAP 1/1/4:1214.* Statistics
=====
Data packets received by SAP                               : 3
-----
Drop Reason Counters
-----
No policy configured at capture SAP level                  : 0
No authentication configured in policy                     : 0
Data-trigger already exists                                : 0
Lockout is active                                           : 0
Reached data-trigger system limit                          : 0
No memory available                                         : 0
Unsuccessful authentication                                : 1
No data-trigger SAP-id in authentication                   : 0
Corresponding dynamic SAP is not created                   : 0
```

Table 104 Data Triggers Received/Dropped Reason Counters

Counter	Description
Data packets received by SAP	Number of dynamic service data triggers received on the capture-sap that reached the CPM
No policy configured at capture SAP level	No dynamic services policy configured at the capture-sap ; required to determine the authentication destination.
No authentication configured in policy	The authentication section in the specified dynamic services policy is missing or incomplete.
Data-trigger already exists	A new data trigger frame is received for an existing data trigger that is authenticated, but the corresponding dynamic SAP is not yet created. The new data trigger packet is dropped.
Lockout is active	The data trigger for this managed SAP is currently in a lockout state due to previous authentication failures.
Reached data-trigger system limit	The maximum number of dynamic service data triggers supported on the system is reached. Additional data triggers are dropped.
No memory available	There is not enough system memory available to process the data trigger.
Unsuccessful authentication	The authentication for a data trigger on this capture SAP failed or timed out.
No data-trigger SAP-id in authentication	The dynamic services data trigger SAP ID is not provided in authentication. This is a mandatory parameter.
Corresponding dynamic SAP is not created	The data trigger successfully authenticated but the corresponding dynamic SAP was not created. This is typically caused by a dynamic services script error.

- to clear the dynamic services capture SAP control plane statistics:

```
# clear service id <service-id> dynamic-services capture-sap <sap-id> statistics
```

14.4.3 RADIUS Authentication

When a valid Ethernet frame is received on a dynamic services data trigger capture SAP, it is sent to the control plane for authentication. The dynamic services policy configured at the capture SAP specifies the RADIUS authentication parameters, as shown in the following example:

```
configure service
  vpls 10 customer 1 create
    sap 1/1/4:1214.* capture-sap create
      description "Dynamic Services Data Trigger capture-sap"
      dynamic-services
        dynamic-services-policy "dyn-svc-1"
        no shutdown
      exit
    no shutdown
  exit
  no shutdown
exit
dynamic-services
  dynamic-services-policy "dyn-svc-1" create
    ---snip---
    authentication
      password "RwXx4x0jao776C3CGlDBKVaNOd//ySXw" hash2
      server-policy "aaa-server-policy-1"
    exit
    ---snip---
  exit
exit
```

Local authentication and RADIUS authentication are mutually exclusive and cannot be configured simultaneously in a **config>service>dynsvc>plcy>authentication** context.

The **server-policy** CLI command references the **config>aaa>radius-server-policy policy-name** to be used for authentication.

The **password** CLI command specifies the password that is used in all RADIUS Access-Request messages.

[RADIUS Access-Request Message Attributes](#) specifies the attributes that are included in the RADIUS Access-Request message for dynamic services data triggers.

Table 105 RADIUS Access-Request Message Attributes

RADIUS Attribute	Description
[1] User-Name	The username format for dynamic services data trigger authentication is fixed to <i>nas-port-id</i> (SAP).

Table 105 RADIUS Access-Request Message Attributes (Continued)

RADIUS Attribute	Description
[2] Password	The password as configured in the authentication section of the dynamic-services-policy .
[4] NAS-IP-Address	The outband management interface or system interface IPv4 address. Only included if the RADIUS server is reachable via an IPv4 address.
[95] NAS-IPv6-Address	The outband management interface or system interface IPv6 address. Only included if the RADIUS server is reachable via an IPv6 address.
[44] Acct-Session-Id	A unique accounting session ID (number format) per dynamic service data trigger. Included as [50] Acct-Multi-Session-Id in radius accounting for all dynamic services that are associated with this data trigger.
[87] NAS-Port-Id	The dynamic service data trigger sap-id
[32] NAS-Identifier	The system name of the router
[26-6527-27] Alc-Client-Hardware-Addr	The MAC address of the data trigger frame that resulted in the authentication. Fixed format (xx:xx:xx:xx:xx:xx)
[8] Framed-IP-Address	The IPv4 source address of the IPv4 data trigger frame that resulted in the authentication. Not included if the data trigger frame is not an IPv4 packet.
[26-6527-99] Alc-Ipv6-Address	The IPv6 source address of the IPv6 data trigger frame that resulted in the authentication. Not included if the data trigger frame is not an IPv6 packet.

The attributes that must be returned in the Access-Accept message are the same as for RADIUS-triggered Dynamic Data Services associated with an IPoE or PPPoE session as a control channel.

14.4.4 Local Authentication

Local authentication is available for data-triggered dynamic services deployments where RADIUS is used for accounting and dynamic changes (CoA) but cannot provide the actual service provisioning parameters.

When a valid Ethernet frame is received on a dynamic services data trigger capture SAP, it is sent to the control plane for authentication. The dynamic services policy configured at the capture SAP specifies the local authentication parameters, as shown in the following example:

```
configure service
  vpls 10 customer 1 create
    sap 1/1/4:1214.* capture-sap create
      description "Dynamic Services Data Trigger capture-sap"
      dynamic-services
        dynamic-services-policy "dyn-svc-2"
        no shutdown
      exit
    no shutdown
  exit
  no shutdown
exit
dynamic-services
  dynamic-services-policy "dyn-svc-2" create
  ---snip---
  authentication
    local-auth-db "dynsvc-db-1"
  exit
  ---snip---
exit
exit
```

Local authentication and RADIUS authentication are mutually exclusive and cannot be configured simultaneously in a **config>service>dynsvc>plcy>authentication** context.

The **local-auth-db** CLI command references the local authentication database to be used for authentication, as shown in the following example:

```
configure service
  dynamic-services
    local-auth-db "dynsvc-db-1" create
    user-name "1/1/4:1214.101" create
      description "dynsvc: epipe"
      index 1 create
        dynamic-services-policy "dyn-svc-2"
        sap-id "1/1/4:1214.101"
        script-parameters-1 "epipe_1={'t':('dynsvc-epipe-1',None,None,10,11)}"
      accounting 1 create
        stats-type volume-time
        update-interval min 30
      exit
    exit
    no shutdown
  exit
  no shutdown
exit
exit
exit
```

A username is used as a key for a lookup in the local authentication database. The username format for dynamic service data triggers is fixed to the SAP ID of the data trigger. For each username entry (data trigger **sap-id**), multiple dynamic service SAPs can be specified (indexes). The index enables multiple dynamic service SAPs to be associated with a single dynamic service data trigger.

The following data can be specified for each index (dynamic service SAP) in a **user-name** entry:

- **dynamic service sap-id** (mandatory)
The dynamic service SAP ID that will be created. The SAP ID of one of the indexes must match the dynamic service data trigger **sap-id**.
- **dynamic-services-policy dynsrv-policy-name** (optional)
Specifies the policy to use for setting up the dynamic service. If not specified, the policy provisioned at the dynamic service data trigger **capture-sap** is used.
- **script-parameters** (mandatory)
Script parameters are used as input to the dynamic data service Python script. They are specified as four strings of up to 250 characters each. The concatenation of all four script parameter strings are passed to the Python script and must be formatted as **function-key dictionary**. The **function-key** specifies which Python functions will be called, and *dictionary* contains the actual parameters in a Python dictionary structure format. The format should match the format of the [26-6527-165] Alc-Dyn-Serv-Script-Params attribute when RADIUS authentication is used.
- **accounting overrides** (optional)
For each of the two RADIUS accounting destinations, the **stats-type** and **update-interval** can be specified. These parameters override the configured value in the dynamic services policy:
 - **stats-type**: specifies if dynamic service RADIUS accounting should be enabled or disabled. RADIUS accounting is enabled by specifying the statistics type: volume and time or time only. RADIUS accounting is disabled when **no stats-type** is specified.
 - **update-interval**: specifies the time between each dynamic data service accounting interim update. The generation of interim accounting updates is disabled when **no update-interval** is specified.

A local authentication database can only be used to authenticate a dynamic service data trigger and provide parameters to set up associated dynamic services. The script action cannot be specified and is always set to “setup”.

The setup timeout for Access=Accept (CLI command: **configure service dynamic-services timers setup-timeout access-accept timeout**) also applies for local authenticated dynamic services.

14.4.5 Data-Triggered Dynamic Service Provisioning

Once authenticated, the mechanism to set up, modify, and tear down a data triggered dynamic service is the same as for RADIUS-triggered Dynamic Data Services associated with an IPoE or PPPoE session as a control channel.

The auto-provisioning of a data-triggered dynamic service is initiated by the RADIUS messages or local authentication as listed in [Table 106](#).

Notes:

- Using the Nas-Port-Id as a key in a CoA or Disconnect-Message targets the corresponding dynamic services SAP; this also occurs when the Nas-Port-Id corresponds with the SAP ID of a data trigger.
- Using the Acct-Session-Id as a key in a CoA or Disconnect-Message targets:
 - the corresponding dynamic services SAP if the Acct-Session-Id belongs to a dynamic services SAP that is not a dynamic services data trigger SAP
 - the data trigger SAP if the Acct-Session-Id belongs to the dynamic services data trigger SAP
- In the event of a tear down, if the dynamic services SAP ID is a dynamic service data trigger SAP ID, all dynamic services associated with that dynamic services data trigger are also removed.

Table 106 **Dynamic Service Script Actions**

Action	Dynamic Service Script Action	Comments
Rx Access-Accept or local authentication (dynamic services data trigger authentication)	Setup	Up to 32 dynamic data services SAPs in a single message The dynamic services SAP that corresponds with the data trigger (also referred to as the dynamic services data trigger sap-id) must be part of this list. The Alc-Dyn-Serv-Script-Action VSA is optional for RADIUS authentication.
	Modify / Teardown	Not supported

Table 106 Dynamic Service Script Actions (Continued)

Action	Dynamic Service Script Action	Comments
Rx CoA (Nas-Port-Id or Acct-Session-Id of a dynamic service SAP different from the data trigger)	Setup	Not supported
	Modify	Only a single dynamic data service per message Mandatory VSAs: Alc-Dyn-Serv-Script-Action Alc-Dyn-Serv-Script-Params
	Teardown	Tear down the dynamic service of the dynamic services SAP identified by the Acct-Session-Id or Nas-Port-Id. Alc-Dyn-Serv-Script-Action VSA is mandatory
Rx CoA (Nas-Port-Id of a data trigger)	Setup	Not supported. Nas-Port-Id always targets the dynamic services SAP and not the data trigger.
	Modify	Only a single dynamic data service per message Mandatory VSAs: Alc-Dyn-Serv-Script-Action Alc-Dyn-Serv-Script-Params
	Teardown	Tear down the dynamic service of the dynamic services SAP identified by the Nas-Port-Id. Because this is the data trigger SAP that is deleted, all dynamic services SAPs associated with the data trigger are also deleted. Alc-Dyn-Serv-Script-Action VSA is mandatory

Table 106 Dynamic Service Script Actions (Continued)

Action	Dynamic Service Script Action	Comments
Rx CoA (Acct-Session-Id of a data trigger)	Setup	Only a single dynamic service SAP per message When successful, the dynamic services SAP is associated with the data trigger identified by the specified Acct-Session-Id. Mandatory VSAs: Alc-Dyn-Serv-Script-Action Alc-Dyn-Serv-SAP-Id Alc-Dyn-Serv-Script-Params Alc-Dyn-Serv-Policy (if no “default” policy configured)
	Modify	Only a single dynamic service per message Modify the dynamic service of the dynamic services SAP identified by the Alc-Dyn-Serv-SAP-Id. The dynamic services SAP must be associated with the data trigger identified with the specified Acct-Session-Id. Mandatory VSAs: Alc-Dyn-Serv-Script-Action Alc-Dyn-Serv-SAP-Id Alc-Dyn-Serv-Script-Params
	Teardown	Tear down the dynamic service of the dynamic services SAP identified by the Alc-Dyn-Serv-SAP-Id. The dynamic services SAP must be associated with the data trigger identified with the specified Acct-Session-Id. If the dynamic services SAP identified by the Alc-Dyn-Serv-SAP-Id is a data trigger sap, then teardown the dynamic services of all dynamic services saps associated with that data trigger Mandatory VSAs: Alc-Dyn-Serv-Script-Action Alc-Dyn-Serv-SAP-Id
Rx Disconnect Message (Nas-Port-Id or Acct-Session-Id of a dynamic service SAP different from a data trigger)	N/A	Tear down the dynamic service of the dynamic services SAP identified by the Acct-Session-Id or Nas-Port-Id

Table 106 **Dynamic Service Script Actions (Continued)**

Action	Dynamic Service Script Action	Comments
Rx Disconnect Message (Nas-Port-Id or Acct-Session-Id of a data trigger)	N/A	Tear down the dynamic services of all dynamic services SAPs associated with the data trigger identified by the Acct-Session-Id or Nas-Port-Id

A data-triggered dynamic service must be explicitly removed by one of the following:

- with a RADIUS Disconnect message containing the Acct-Session-Id or NAS-Port-Id as key
- with a RADIUS CoA message containing the Acct-Session-Id or NAS-Port-Id as key and Alc-Dyn-Serv-Script-Action VSA with value 3 (teardown)
- with a CLI clear command: **clear service dynamic-services data-trigger sap sap-id**
All dynamic service SAPs associated with the dynamic services data trigger will be removed.
- with a CLI tools command: **tools perform service dynamic-services evaluate-script sap sap-id control-session acct-session-id action teardown**
The control session accounting session ID corresponds to the dynamic services data trigger accounting session ID.

The removal of a dynamic service SAP that is a data trigger SAP will result in the removal (teardown) of all dynamic service SAPs associated with that dynamic services data trigger.

To prevent a data-triggered dynamic service from being immediately set up again after it was removed (because traffic is still being received), the following procedures can be used:

- Authentication failure
 - Update the configuration of the RADIUS server or local authentication such that the authentication for the dynamic service data trigger will fail
 - Tear down the dynamic service
 - The dynamic service will not be set up again because the data trigger authentication will fail, resulting in a host-lockout when provisioned.
- VID filter on the **capture-sap**

- Add the data trigger encapsulation to a VID filter (ingress MAC filter of type **vid**) that is applied on the data trigger **capture-sap**
- Tear down the dynamic service
- The dynamic service will not be set up again because the data trigger is now dropped by the VID filter applied on the **capture-sap**

14.4.6 Control Plane Protection

As a dynamic services data trigger **capture-saps** potentially forward all valid Ethernet frames for authentication to the control plane, control plane protection mechanisms are required to prevent overload conditions.

1. **capture-sap** data trigger packet throttling (frames dropped at IOM)

The number of data trigger packets sent to the control plane via the ingress forwarding complex is rate-limited based on a hash using {sap-id, outer tag, inner-tag} as the key. The per-hash result is that a maximum of 1 frame/s is forwarded to the control plane.

This throttling mechanism is always enabled and has no configuration options. It guarantees fairness between different encapsulation while limiting the frame rate sent to the control plane.

2. Blocking certain VLANs from authenticating (frames dropped at IOM)

This can be achieved by applying ingress MAC filters of type vid with the **capture-sap** command. In the example below, frames with encaps 1/1/4:1214.20 will be dropped by the VID filter.

```
configure
service
  service
    vpls <service-id> customer <customer-id>
    sap 1/1/4:1214.* capture-sap
    dynamic-services
      dynamic-services-policy <dynsvc-policy-name>
      no shutdown
    exit
    ingress
      filter mac 10
    exit
  exit
exit
filter
  mac-filter 10 create
  default-action forward
  type vid
  entry 10 create
    match frame-type ethernet_II
      outer-tag 20 4095
  exit
```

```

        action
        drop
    exit
exit
exit
exit
exit

```

3. Dynamic service data trigger rate-limiting in the control plane (frames dropped at the CPM)

An overall rate limit of dynamic service data triggers limits the number of frames that come from the different IOMs to an acceptable rate for the control plane to handle.

Control plane rate-limiting for dynamic service data triggers is always enabled and has no configuration options.

4. Using a lockout mechanism to protect the RADIUS infrastructure from overload as a result of permanent failing authentications of Python script errors.

The existing Enhanced Subscriber Management (ESM) host lockout mechanism can be enabled on a dynamic services data trigger **capture-sap**.

The dynamic services data trigger **sap-id** is used as a key for the **host-lockout** context. A **host-lockout** context is created whenever a data trigger is deleted:

- Authentication failures: RADIUS Access Reject, RADIUS Access-Accept with a wrong or missing data trigger SAP ID, timeout, local authentication lookup failure, local authentication returns a wrong or **no data-trigger sap-id**.
- No data trigger SAP created within the configured dynamic services **access-accept setup timeout** (30 seconds by default):

```
configure service dynamic-services timers setup-timeout access-accept <timeout>
```

- A dynamic services Python script failure
- A **clear** command on a data trigger:

```
clear service dynamic-services data-trigger sap <sap-id>
```

- A tear down of a data trigger initiated via a CoA or Disconnect Message

The last two bullets are tear down operations that occur infrequently and should not result in an actual lockout; only the host lockout context is created and should disappear again when the **lockout-reset-time** expires. This is configured in the **host-lockout-policy**:

```
configure subscriber-mgmt host-lockout-policy <policy-name> lockout-reset-time
<seconds> (default 60 seconds).
```

To enable host lockout for dynamic services data trigger, configure a **host-lockout-policy** at the dynamic services data trigger **capture-sap**:

```
configure service
    vpls <service-id> customer <customer-id>
```

```

sap <sap-id> capture-sap
dynamic-services
dynamic-services-policy <dynsvc-policy-name>
no shutdown
exit
host-lockout-policy <policy-name>
exit
exit

```

The **host-lockout-policy** is configured in the **config>subscr-mgmt** CLI context. For data-triggered dynamic services, the **host-key** in the policy must be set to **all** which is achieved with the **no host-key** CLI command (default). Configuring the host key to **mac** in a host lockout policy associated with a dynamic service data trigger **capture-sap** is a configuration error and results in a faulty host lockout behavior.

Use the following show command to display active dynamic services data trigger capture SAP lockouts (the capture SAP must be used as the **sap-id**):

```

# show subscriber-mgmt host-lockout-policy "host-lockout-1" all sap 1/1/4:1214.*
=====
Host Lockout Policy "host-lockout-1"
=====
Description                               Host lockout policy

Nr of lockouts in grace period             0
Nr of total lockouts:                     1
=====

```

Use following command to clear active dynamic services data trigger capture SAP lockouts (the capture SAP must be used as the **sap-id**):

```

# clear subscriber-mgmt host-lockout-policy [policy <host-lockout-policy-
name>] <lockout-state>
# clear subscriber-mgmt host-lockout-policy sap <sap-id> [lockout-state]

```

5. You can use the **cpu-protection** and **dist-cpu-protection** commands on the platforms that support it.

When using the **cpu-protection** command, you will need a **cpu-protection policy** that you apply on the capture SAP.

```
configure
system
security
cpu-protection
policy 200 create
overall-rate 100
out-profile-rate 50
exit
exit
exit
service
vpls <service-id> customer <customer-id>
sap 1/1/1:.* capture-sap create
cpu-protection 200
dynamic-services
dynamic-services-policy "dynServPolicy"
no shutdown
exit
no shutdown
exit
exit
exit
```

When using the **dist-cpu-protection** command, you will need a **dist-cpu-protection policy** that you can also apply on the capture SAP.

```
configure
system
security
dist-cpu-protection
policy "distCpuProt" create
static-policer "dcpuStatPol" create
rate packets 50 within 1
exceed-action discard
detection-time 5
exit
protocol all-unspecified create
enforcement static "dcpuStatPol"
exit
exit
exit
exit
service
vpls <service-id> customer <customer-id>
sap 1/1/1:.* capture-sap create
dynamic-services
dynamic-services-policy "dynServPolicy"
no shutdown
exit
dist-cpu-protection "distCpuProt"
no shutdown
```

```
exit
exit
exit
```

14.4.7 Debugging

To enable dynamic services data trigger debugging, use the following debug commands:

```
debug
dynamic-services
data-triggers
# multiple capture-sap commands allowed
capture-sap <sap-id> [encap-val <qtag[.qtag]>] [mode <mode>]
capture-sap <sap-id> [encap-val <qtag[.qtag]>] [mode <mode>]
exit
exit
```

This will log data trigger events such as:

- data trigger received
- data trigger authentication events
- data trigger SAP created
- dynamic service SAP created
- dropped data trigger with drop reason such as data trigger already exists or lockout active

The **encap-val** command limits the debug output to data trigger events for specific encapsulation values.

The mode specifies which data trigger events are logged: all events or dropped data trigger events only.

14.5 RADIUS Triggered Dynamic Data Services Command Reference

14.5.1 Command Hierarchies

14.5.1.1 RADIUS Triggered Dynamic Data Services Commands

```

14.5.2 RADIUS Triggered Dynamic Data Services Commands

14.5.2.1 Configuration Commands

dynamic-services

Syntax	dynamic-services
Context	config>service>vpls>sap
Description	This command enables the context to configure dynamic services parameters on a capture SAP.

shutdown

Syntax	shutdown no shutdown
Context	config>service>vpls>sap>dyn-svc
Description	This command disables or enables data-triggered dynamic services on this capture-sap .

dynamic-services

Syntax	dynamic-services
Context	config>service
Description	This command enables the context to configure dynamic data services. Only available on systems with multi-core CPM (CPM3 or up).

dynamic-services-policy

Syntax	dynamic-services-policy <i>dynsrv-policy-name</i> [create] no dynamic-services-policy <i>dynsrv-policy-name</i>
Context	config>service>dynsvc
Description	This command creates a new dynamic services policy that can be used to create dynamic data services.

The **no** form of the command removes the dynamic services policy from the configuration. This is only allowed when there are no active dynamic data services referencing this policy.

Default none

Parameters *dynsrv-policy-name* — Specifies a unique name of a dynamic services policy up to 32 characters in length.

accounting-1

Syntax **accounting-1**

Context config>service>dynsvc>policy

Description This command enables the context to configure the first RADIUS accounting destination and corresponding RADIUS accounting parameters for dynamic data services.

accounting-2

Syntax **accounting-2**

Context config>service>dynsvc>policy

Description This command enables the context to configure the second RADIUS accounting destination and corresponding RADIUS accounting parameters for dynamic data services.

server-policy

Syntax **server-policy** *policy-name*
no server-policy

Context config>service>dynsvc>acct-1
config>service>dynsvc>acct-2

Description This command configures the radius server policy to be used for dynamic data services RADIUS accounting.

The **no** form of the command removes the radius server policy from the configuration. This is only allowed when there are no active dynamic data services referencing this policy.

Default no server-policy

Parameters *policy-name* — Specifies the name of the radius server policy.

Values Up to 32 characters maximum

stats-type

Syntax	stats-type { <i>time</i> <i>volume-time</i> } no stats-type
Context	config>service>dynsvc>acct-1 config>service>dynsvc>acct-2
Description	<p>This command configures the type of statistics to be reported in dynamic data services RADIUS accounting. A RADIUS specified Stats Type overrides the CLI configured value.</p> <p>The no form of the command resets the default value.</p>
Default	volume-time
Parameters	<p><i>time</i> — Only report Session-Time in the RADIUS Accounting Interim-Update and Stop message.</p> <p><i>volume-time</i> — Report both Session-Time and Volume counter attributes in the RADIUS Accounting Interim-Update and Stop messages.</p>

update-interval

Syntax	update-interval [<i>hrs hours</i>] [<i>min minutes</i>] [<i>days days</i>] no update-interval
Context	config>service>dynsvc>acct-1 config>service>dynsvc>acct-2
Description	<p>This command specifies the interval between each RADIUS Accounting Interim-Update message (minimum 5 minutes; maximum 180 days).</p> <p>The no form of the command disables the sending of Accounting Interim-Update messages.</p> <p>A RADIUS specified Accounting Interim Interval overrides the CLI configured value.</p>
Default	no update-interval (do not send Accounting Interim-Update messages)
Parameters	<p><i>hrs</i> — specifies the interval in hours.</p> <p>Values 1 to 23</p> <p><i>min</i> — Specifies the interval in minutes.</p> <p>Values 1 to 59</p> <p><i>days</i> — specifies the interval in days.</p> <p>Values 1 to 180</p>

update-interval-jitter

Syntax	update-interval-jitter absolute <i>seconds</i> no update-interval-jitter
Context	config>service>dynsvc>acct-1 config>service>dynsvc>acct-2
Description	<p>This command specifies the absolute maximum random delay introduced on the update interval between two RADIUS Accounting Interim Update messages. The effective maximum random delay value is the minimum of the configured absolute jitter value and 10% of the configured update-interval.</p> <p>A value of zero will send the accounting interim update message without introducing an additional random delay.</p> <p>The no form of the command sets the default to 10% of the configured update-interval.</p>
Default	no update-interval-jitter (10% of the configured update-interval)
Parameters	<i>seconds</i> — Specifies the absolute maximum jitter value in seconds. Values 0 to 3600

authentication

Syntax	authentication
Context	config>service>dynsvc>policy
Description	This command enables the context to configure authentication parameters for data-triggered dynamic services.

local-auth-db

Syntax	local-auth-db <i>name</i> no local-auth-db
Context	config>service>dynsvc>policy>auth
Description	<p>This command configures the local authentication database to be used for local authentication of data-triggered dynamic services.</p> <p>Local authentication and RADIUS authentication are mutually exclusive.</p> <p>The no form of the command removes the local authentication database from the configuration and disables local authentication.</p>
Default	no local-auth-db

Parameters *name* — local authentication database name, up to 32 characters

password

Syntax **password** *password* [**hash** | **hash2**]
no password

Context config>service>dynsvc>policy>authentication

Description This command configures the password to be used for RADIUS authentication of data-triggered dynamic services.

 The **no** form of the command removes the password from the configuration.

Default no password

Parameters *password* — Specifies the password that is used in RADIUS authentication of a data-triggered dynamic service. The maximum length is 20 characters if unhashed, 32 characters if hashed, and 54 characters if the **hash2** keyword is specified.

hash — Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified

hash2 — Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

server-policy

Syntax **server-policy** *policy-name*
no server-policy

Context config>service>dynsvc>policy>authentication

Description This command configures the RADIUS server policy to be used for RADIUS authentication of data-triggered dynamic services.

 Local authentication and RADIUS authentication are mutually exclusive.

 The **no** form of the command removes the server policy from the configuration and disables RADIUS authentication.

Default no server-policy

Parameters *policy-name* — Specifies a RADIUS server policy name, up to 32 characters in length.

local-auth-db

Syntax	local-auth-db <i>name</i> [create] no local-auth-db <i>name</i>
Context	config>service>dynsvc
Description	<p>This command creates a local authentication database that can be used for local authentication of data-triggered dynamic services.</p> <p>The no form of the command removes the local authentication database from the configuration.</p>
Default	no local-auth-db
Parameters	<i>name</i> — Specifies a local authentication database name, up to 32 characters in length.

shutdown

Syntax	[no] shutdown
Context	config>service>dynsvc>policy>ladb
Description	This command disables or enables the local authentication database. When disabled, the database cannot be used for authentication.

user-name

Syntax	user-name <i>name</i> [create] no user-name <i>name</i>
Context	config>service>dynsvc>policy>ladb
Description	<p>This command creates a user name entry in the local authentication database. The user name entry is used to match with the user name of a local authenticated dynamic service data trigger. The user name of a dynamic service data trigger is fixed to the sap-id. When matched, the corresponding authentication data is used to set up the dynamic data services.</p> <p>The no form of the command removes the user name entry from the local authentication database configuration.</p>
Parameters	<i>name</i> — Specifies the user name entry name, up to 64 characters in length.

shutdown

Syntax	[no] shutdown
---------------	----------------------

Context config>service>dynsvc>policy>ladb>user

Description This command disables or enables a user name entry in the local authentication database. When disabled, the entry will not be matched.

index

Syntax **index** *index* [create]
no index *index*

Context config>service>dynsvc>policy>ladb>user

Description This command creates an index entry containing authentication data for a dynamic service SAP. Up to 32 indexes can be created per user name entry, representing up to 32 dynamic service SAPs that can be instantiated with a single dynamic service data trigger. One of the dynamic service SAPs must be the data trigger SAP.

The **no** form of the command removes the index entry from the user name entry in the local authentication database configuration.

Parameters *index* — Specifies the index entry identifier.

Values 1 to 32

accounting

Syntax **accounting** {1 | 2} [create]
no accounting {1 | 2}

Context config>service>dynsvc>policy>ladb>user>idx

Description This command creates a context for one of the two accounting destinations specified in the dynamic services policy. In this context, overrides of RADIUS accounting parameters can be specified.

The **no** form of the command removes the RADIUS accounting overrides context from the configuration

Default no accounting

Parameters {1 | 2} — Indicates one of the two RADIUS accounting destinations

stats-type

Syntax **stats-type** {volume-time | time}
no stats-type

Context config>service>dynsvc>policy>ladb>user>idx>acct

Description	<p>This command specifies whether dynamic service accounting should be enabled or disabled for this destination. RADIUS accounting is enabled by specifying the stats type: volume and time or time only. This command overrides the local configured value in the dynamic services policy.</p> <p>The no form of the command disables RADIUS accounting (stats-type off).</p>
Default	no stats-type
Parameters	volume-time time — Enables RADIUS accounting for this dynamic service and specifies if volume counters should be included (volume-time) or time only (time) in the RADIUS accounting messages.

update-interval

Syntax	update-interval [hrs <i>hours</i>] [min <i>minutes</i>] [days <i>days</i>] no update-interval
Context	config>service>dynsvc>policy>ladb>user>idx>acct
Description	<p>This command specifies the time between each dynamic data service accounting interim update for this accounting destination. This command overrides the local configured value in the dynamic services policy.</p> <p>The no form of the command disables the generation of interim accounting updates to this destination.</p> <p>The minimum update interval is 5 minutes.</p>
Default	no update-interval (disable interim updates)
Parameters	<p><i>hours</i> — Specifies the interval in hours.</p> <p>Values 1 to 23</p> <p><i>minutes</i> — Specifies the interval in minutes.</p> <p>Values 1 to 59</p> <p><i>days</i> — Specifies the interval in days.</p> <p>Values 1 to 180</p>

dynamic-services-policy

Syntax	dynamic-services-policy <i>name</i> no dynamic-services-policy
Context	config>service>dynsvc>policy>ladb>user>idx config>service>vpls>sap>dyn-svc

Description	This command specifies the local configured dynamic data service policy to use for provisioning (local authentication database context) or authentication (capture-sap context) of this dynamic service. If not specified, the dynamic services policy with the name “default” is used. If the default policy does not exist, then the dynamic data service setup or authentication will fail. The no form of the command removes the dynamic services policy from the configuration.
Default	no dynamic-services-policy
Parameters	<i>name</i> — Specifies a dynamic services policy name, up to 32 characters in length.

sap-id

Syntax	sap-id <i>sap-string</i> no sap-id
Context	config>service>dynsvc>policy>ladb>user>idx
Description	This command specifies the dynamic data service SAP that will be created. A dynamic service SAP ID uniquely identifies a dynamic data service instance. For a local authenticated dynamic service data trigger, one of the dynamic service SAP IDs must be the data trigger SAP. The no form of the command removes the sap-id from the configuration.
Default	no sap-id
Parameters	<i>sap-string</i> — Specifies a string representing the dynamic service SAP ID (only SAPs on Ethernet ports and LAGs are valid), up to 64 characters in length

script-parameters-1

Syntax	script-parameters-1 <i>param-string1</i> no script-parameters-1
Context	config>service>dynsvc>policy>ladb>user>idx
Description	This command specifies the first part of parameters as input to the dynamic data service Python script. The concatenation of all four script-parameters strings are passed to the Python script and must be formatted as function-key <dictionary>. The function-key specifies which Python functions will be called, and <dictionary> contains the actual parameters in a Python dictionary structure format. The no form of the command removes script-parameters-1 from the configuration.
Default	no script-parameters-1

Parameters *param-string1* — Specifies a string representing parameters that are used as input for the dynamic service Python script, up to 250 characters in length

script-parameters-2

Syntax **script-parameters-2** *param-string2*
no script-parameters-2

Context config>service>dynsvc>policy>ladb>user>idx

Description This command specifies the second part of parameters as input to the dynamic data service Python script. The concatenation of all four script-parameters strings are passed to the Python script and must be formatted as function-key <dictionary>. The function-key specifies which Python functions will be called, and <dictionary> contains the actual parameters in a Python dictionary structure format.

 The **no** form of the command removes the **script-parameters-2** from the configuration.

Default no script-parameters-2

Parameters *param-string2* — Specifies a string representing parameters that are used as input for the dynamic service Python script, up to 250 characters in length.

script-parameters-3

Syntax **script-parameters-3** *param-string3*
no script-parameters-3

Context config>service>dynsvc>policy>ladb>user>idx

Description This command specifies the third part of parameters as input to the dynamic data service Python script. The concatenation of all four script-parameters strings are passed to the Python script and must be formatted as function-key <dictionary>. The function-key specifies which Python functions will be called, and <dictionary> contains the actual parameters in a Python dictionary structure format.

 The **no** form of the command removes the **script-parameters-3** from the configuration

Default no script-parameters-3

Parameters *param-string3* — Specifies string representing parameters that are used as input for the dynamic service Python script, up to 250 characters in length.

script-parameters-4

Syntax **script-parameters-4** *param-string4*
no script-parameters-4

Context	config>service>dynsvc>policy>ladb>user>idx
Description	<p>This command specifies the fourth part of parameters as input to the dynamic data service Python script. The concatenation of all four script-parameters strings are passed to the Python script and must be formatted as function-key <dictionary>. The function-key specifies which Python functions will be called, and <dictionary> contains the actual parameters in a Python dictionary structure format.</p> <p>The no form of the command removes the script-parameters-4 from the configuration.</p>
Default	no script-parameters-4
Parameters	<i>param-string4</i> — Specifies a string representing parameters that are used as input for the dynamic service Python script, up to 250 characters in length.

cli-user

Syntax	cli-user <i>name</i> no cli-user
Context	config>service>dynsvc>policy
Description	<p>This command specifies the CLI user to be used to execute the dynamic data services CLI scripts. With the specified user's profile, it is possible to further restrict the internal list of allowed commands to be executed via dynamic data service CLI scripts.</p> <p>The no form of the command sets the CLI user to an internal user with all configuration rights.</p>
Default	no cli-user
Parameters	<i>name</i> — Specifies the CLI user name that must exist in the >config>system>security CLI context.

description

Syntax	description <i>description-string</i> no description
Context	config>service>dynsvc>policy config>service>dynsvc>ladb config>service>dynsvc>ladb>user
Description	<p>This command associates a text string with a configuration context to help identify the content in the configuration file.</p> <p>The no form of this command removes the string from the configuration.</p>
Default	no description

Parameters	<i>description-string</i> — The description character string. Allowed values are any string up to 80 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.
-------------------	---

sap-limit

Syntax	sap-limit [<i>limit</i>] no sap-limit
Context	config>service>dynsvc>policy
Description	<p>This command specifies a limit for the number of dynamic data service instances (SAPs) that can be setup simultaneously using a given dynamic services policy.</p> <p>A value of zero (0) means the policy will be drained: existing dynamic data services can be modified and torn down but no new dynamic data services can be setup.</p>
Default	sap-limit 1
Parameters	[0 to 131072] — Specifies the number of dynamic data service SAPs that can be setup simultaneously using this dynamic services policy.
Values	0 to 131072

script-policy

Syntax	script-policy <i>name</i> no script-policy
Context	config>service>dynsvc>policy
Description	<p>This command specifies the radius script policy to be used to setup the dynamic data services. The script-policy configuration cannot be changed when there are active dynamic data services referencing the policy.</p> <p>The no form of this command removes the script-policy from the configuration. This is only allowed when there are no active dynamic data services referencing this policy.</p>
Default	no script-policy
Parameters	<i>name</i> — Specifies the RADIUS script policy name.

service-range

Syntax	service-range <i>service-id</i> <i>service-id</i> no service-range
---------------	---

Context	config>service>dynsvc
Description	<p>This command specifies the service id range that is reserved for dynamic data service creation. The range cannot overlap with existing static configured services. Once configured with active dynamic services in the range, the service-range can only be extended at the end.</p> <p>The no form of this command removes the service-range from the configuration. This is only allowed when there are no active dynamic data services.</p> <p>When no service-range is specified, the setup of dynamic data services will fail.</p>
Default	no service-range
Parameters	<p><i>service-id</i> — Specifies the start and end service-id to define the service-range for dynamic services.</p> <p>Values 1 to 2147483647</p>

timers

Syntax	timers
Context	config>service>dynsvc
Description	This command enables the context to configure dynamic data services related timers.

setup-timeout

Syntax	setup-timeout access-accept <i>timeout</i> no setup-timeout
Context	config>service>dynsvc>timers
Description	<p>This command specifies the time that dynamic data services setup requests from a RADIUS Access-Accept are hold in an internal work queue waiting to be processed. If after the timeout, the dynamic data service setup request is still in the queue (meaning it is not setup), then the dynamic service setup request will be removed from the queue and the setup fails.</p> <p>The no form of this command resets the timeout to 2 seconds.</p>
Default	no setup-timeout (30 seconds)
Parameters	<p><i>timeout</i> — Specifies the setup-timeout in seconds for setup requests of dynamic services received via Access-Accept.</p> <p>Values 2 to 3600 seconds</p>

dynsvc-password

Syntax **dynsvc-password** *password* [**hash**|**hash2**]
no dynsvc-password

Context config>system>security>password

Description

Note: See also the description for the **enable-dynamic-services-config** command.

This command allows a user with admin permissions to configure a system wide password which enables a user to enter a special dynamic services configuration mode.

The minimum length of the password is determined by the **minimum-length** command. The complexity requirements for the password are determined by the **complexity** command.

The **no** form of the command removes the dynsvc password from the configuration

Default no dynsvc-password

Parameters *password* — Configures the password which enables a user to enter a special dynamic services configuration mode. The maximum length can be up to 20 characters if unhashed, 32 characters if hashed, 54 characters if the hash2 keyword is specified.

hash — Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified

hash2 — Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

enable-dynamic-services-config

Syntax [**no**] **enable-dynamic-services-config**

Context <global>

Description

Note: See also the description for the **dynsvc-password** command.

If the `dynsvc-password` is configured in the `config>system>security>password` context, then any user can enter a special dynamic services configuration mode by entering the `enable-dynamic-services-config` command.

The `enable-dynamic-services-config` command is not in the default profile. To give access to this command, the user must belong to the administrative profile or a new profile should be created.

Once the `enable-dynamic-services-config` command is entered, the user is prompted for a password. If the password matches, the user is given access to the dynamic services configuration. Access to static configuration is in this case prohibited.

To verify that a user is in the `enable-dynamic-services-config` mode, use the `show users` command. Users in the `enable-dynamic-services-config` mode lists the letter “D” next to the user’s CLI session.

The `no` form of this command disables the dynamic services configuration mode for this user.

Default no enable-dynamic-services-config

14.5.2.2 **Basic System Command**

info

Syntax	<code>info [detail] [objective]</code>
Context	any configuration context
Description	<p>This command displays the running configuration for the configuration context where it is entered and all branches below that context level.</p> <p>By default, the command only enters the configuration parameters that vary from the default values.</p> <p>The detail keyword causes all configuration parameters to be displayed. The include-dynamic objective keyword includes configuration parameters from dynamic sources such as VSD or dynamic data services Python scripts. These dynamic configuration parameters are not saved in the configuration file.</p>
Default	none
Parameters	detail — Displays all configuration parameters including parameters at their default values.

objective — Provides an output objective that controls the configuration parameters to be displayed.

Values **include-dynamic:** includes configuration parameters from dynamic sources such as VSD or dynamic data services Python scripts.

14.5.2.3 Show Commands

Note: The command outputs in the following section are examples only; actual displays may differ depending on supported functionality and user configuration.

dynamic-services

Syntax	dynamic-services
Context	show>service show>service>id
Description	This command enables the context to show dynamic services information.

data-triggers

Syntax	data-triggers [sap sap-id] [summary]
Context	show>service>dynsvc
Description	This command displays the active dynamic services data trigger details.
Parameters	<i>sap-id</i> — Specifies the dynamic services SAP for which the details are shown. summary — Limits the output to one line per data trigger SAP.
Output	

Table 107 Data Trigger Field Descriptions

Output field	Description
Acct session-ID	The RADIUS accounting session ID for this dynamic services data trigger. This accounting session ID is used as an accounting multi-session ID in RADIUS accounting for the associated dynamic services. It can also be used as a key in CoA or Disconnect Messages to set up or terminate associated dynamic services.
MAC	The MAC address learned to set up this dynamic service data trigger. The MAC address is included in the Access-Request message for RADIUS authentication.

Table 107 Data Trigger Field Descriptions (Continued)

Output field	Description
IP	The IPv4 or IPv6 address learned to set up this dynamic service data trigger. If the data trigger packet was not an IP packet, then this field is empty. When available, the IP address is included in the RADIUS authentication and accounting messages.
State	The current state of the dynamic service data trigger: Pending—(initial state) data trigger received and authentication started Accepted—(transient state) authentication succeeded; dynsvc script started but not yet completed sapCreated—(final state) corresponding dynamic services sap created

Sample Output

```
# show service dynamic-services data-triggers
=====
Dynamic Services Data-triggers
=====
SAP                               : 1/1/4:1214.101

capture-sap

- Syntax** capture-sap [statistics] sap-id
- Context** show>service>id>dynsvc
- Description** This command displays the status and statistics of a dynamic services capture. Statistics include counters for the number of data triggers received and data trigger drop reasons.
- Parameters** sap-id — Specifies the dynamic services capture SAP.
statistics — Displays data trigger receive and drop reason counters for this dynamic services capture SAP.
- Output**

Table 108 Capture SAP Field Descriptions

Counter	Description
Data packets received by SAP	The number of dynamic service data triggers received on the capture SAP that reached the CPM.

Table 108 Capture SAP Field Descriptions (Continued)

Counter	Description
No policy configured at capture SAP level	There is no dynamic-services-policy configured at the capture SAP. This is required to determine the authentication destination.
No authentication configured in policy	The authentication section in the specified in dynamic services policy is missing or incomplete.
Data-trigger already exists	A new data trigger frame is received for an existing data trigger that is authenticated, but the corresponding dynamic SAP is not yet created. The new data trigger packet is dropped.
Lockout is active	The data trigger for this managed SAP is currently in a lockout state due to previous authentication failures.
Reached data-trigger system limit	The maximum number of dynamic service data triggers supported on the system is reached. Additional data triggers are dropped.
No memory available	There is not enough system memory available to process the data trigger.
Unsuccessful authentication	The authentication for a data trigger on this capture SAP failed or timed out.
No data-trigger SAP-id in authentication	The dynamic services data trigger SAP ID is not provided in authentication. This is a mandatory parameter.
Corresponding dynamic SAP is not created	The data trigger successfully authenticated but the corresponding dynamic SAP was not created. This is typically caused by a dynamic services script error.

Sample Output

```
# show service id 10 dynamic-services capture-sap 1/1/1:10.*
=====
Dynamic Services Capture SAP 1/1/1:10.*

root-objects

Syntax	root-objects
Context	show>service>dynsvc
Description	<p>This command displays the root objects created by dynamic data services.</p> <p>OID prefix and index — The corresponding SNMP OID prefix and index for this root object.</p> <p>Snippet name — The name of the python function that created this root object. The name is set to N/A when the root-object is orphaned.</p> <p>Snippet instance — The instance for which the python function with “Snippet name” created this root object. If the snippet is a result from a dynamic reference, then the snippet instance is the reference-id string passed in the dyn.reference(). If the snippet is not the result from a dynamic reference, then the snippet instance is the dynamic data service SAP-ID. The instance is set to N/A when the root object is orphaned.</p> <p>Orphan time — Shows the timestamp when the root-object became orphaned (root-object not deleted when corresponding teardown function is called) or N/A if the root-object is not orphaned.</p>

Output

Sample Output

```
# show service dynamic-services root-objects
=====
Dynamic Service Root Objects
=====
OID prefix      : svcRowStatus
OID index       : .100000
Snippet name     : vprn

script

Syntax	script
Context	show>service>dynsvc
Description	This command enables the context to show dynamic services script information.

snippets

Syntax **snippets [detail]**

snippets name *snippet-name* [**instance** *snippet-instance*] [**detail**]

Context show>service>dynsvc>script

Description This command displays the dynamic services snippets information.

The CLI output generated by a single dynamic service python function call is a snippet instance.

The name of the snippet instance is the function key in the dyn.action() dictionary that caused this function to be called. This name is the dictionary name passed via RADIUS for top-level snippets or the first parameter to dyn.reference() for the others.

The snippet instance is either the dynamic data service SAP id or if the function is called via dynamic reference, the reference-id (that is, second parameter) provided in the dyn.reference() call.

Parameters *detail* — display detailed dynamic services snippet information.

Filtering options, display dynamic services snippets information that matches:

name *snippet-name* — Specifies the snippet name.

instance *snippet-instance* — Specifies the snippet instance.

Output

Sample Output

```
# show service dynamic-services script snippets

14.5.2.4 Clear Commands

dynamic-services

Syntax	dynamic-services
Context	clear>service>stats
Description	This command resets the dynamic services script statistics. See also show service dynamic-services script statistics .

data-trigger

Syntax	data-trigger sap sap-id
Context	clear>service>dynsvc
Description	This command deletes all dynamic services associated with a dynamic services data trigger.
Parameters	<i>sap-id</i> — Specifies the dynamic services data trigger SAP to delete.

14.5.2.5 Debug Commands

dynamic-services

Syntax	[no] dynamic-services
---------------	------------------------------

Context	debug
Description	This command enables the context to configure dynamic services debugging.

data-triggers

Syntax	[no] data-triggers
Context	debug>dynsvc
Description	<p>This command enables the context to configure dynamic services data trigger capture SAP debugging.</p> <p>The no form of the command removes all dynamic services data trigger capture SAP debug configurations.</p>

capture-sap

Syntax	capture-sap <i>sap-id</i> [encap-val <i>qtag[.qtag]</i>] [mode <i>mode</i>] no capture-sap <i>sap-id</i>
Context	debug>dynsvc>data-triggers
Description	<p>This command enables or disables the generation of dynamic services data trigger debug events, such as:</p> <ul style="list-style-type: none"> • data trigger received • authentication • data trigger SAP created • dynamic service SAP created • dropped data trigger with drop reason such as data trigger exists or lockout active. <p>Multiple capture SAPs can be specified simultaneously.</p> <p>Optionally, a single encap-val per capture-sap can be specified to limit the output of the debug events to the data trigger events with the specified encapsulation.</p> <p>Optionally, the debug output can be restricted to dropped data trigger events only.</p>
Parameters	<p><i>sap-id</i> — Specifies the dynamic services data trigger capture SAP for which debug events should be logged.</p> <p>encap-val <i>qtag[.qtag]</i> — Optionally restrict the debug output to data trigger events with the specified encapsulation.</p> <p>Values 1 to 4094</p> <p><i>mode</i> — Optionally restrict the debug output to specific events.</p> <p>Values all—log all data trigger events</p>

dropped-only—log only dropped data trigger events

scripts

Syntax	scripts
Context	debug>dynsvc
Description	This command enables the context to configure dynamic services script debugging.

event

Syntax	[no] event
Context	debug>dynsvc>scripts debug>dynsvc>scripts>inst debug>dynsvc>scripts>script
Description	This command enables/disables the generation of all dynamic data service script debugging events output: cli, errors, executed-cmd, warnings, state-change.

cli

Syntax	[no] cli
Context	debug>dynsvc>scripts>event debug>dynsvc>scripts>inst>event debug>dynsvc>scripts>script>event
Description	This command enables/disables the generation of a specific dynamic data service script debugging event output: cli.

errors

Syntax	[no] errors
Context	debug>dynsvc>scripts>event debug>dynsvc>scripts>inst>event debug>dynsvc>scripts>script>event
Description	This command enables/disables the generation of a specific dynamic data service script debugging event output: errors.

executed-cmd

Syntax	[no] executed-cmd
Context	debug>dynsvc>scripts>event debug>dynsvc>scripts>inst>event debug>dynsvc>scripts>script>event
Description	This command enables/disables the generation of a specific dynamic data service script debugging event output: executed-cmd.

state-change

Syntax	[no] state-change
Context	debug>dynsvc>scripts>event debug>dynsvc>scripts>inst>event debug>dynsvc>scripts>script>event
Description	This command enables/disables the generation of a specific dynamic data service script debugging event output: state-change.

warnings

Syntax	[no] warnings
Context	debug>dynsvc>scripts>event debug>dynsvc>scripts>inst>event debug>dynsvc>scripts>script>event
Description	This command enables/disables the generation of a specific dynamic data service script debugging event output: warnings.

instance

Syntax	instance <i>instance</i>
Context	debug>dynsvc>scripts
Description	This command enables the context to configure dynamic services script debugging for a specific instance.
Parameters	<i>instance</i> — Specifies the instance name.

script

Syntax	script <i>script</i>
Context	debug>dynsvc>scripts
Description	This command enables the context to configure dynamic services script debugging for a specific script.
Parameters	<i>script</i> — Specifies the script name.

14.5.2.6 Tools Commands

dynamic-services

Syntax	dynamic-services
Context	tools>perform>service
Description	This command enables the context to execute dynamic services tools perform commands.

evaluate-script

Syntax	evaluate-script sap <i>sap-id</i> control-session <i>acct-session-id</i> action <i>script-action</i> [dynsvc-policy <i>name</i>] [param-string <i>string</i>]
Context	tools>perform>service>dynamic-services
Description	This tools command performs the execution of a dynamic service script action as if the corresponding RADIUS attributes were received from RADIUS. It is possible to setup, modify or teardown a dynamic service associated with the specified control channel.
Parameters	<p><i>sap sap-id</i> — specifies the dynamic service SAP id.</p> <p>control-session <i>acct-session-id</i> — Specifies the accounting session id of the control channel associated with this dynamic service</p> <p>action <i>script-action</i> — Specifies the requested action: setup, modify or teardown.</p> <p>dynsvc-policy <i>name</i> — Specifies the dynamic services policy to use for this action. Mandatory parameter for setup and modify actions. In case of a modify action, the dynamic services policy must be the same as the policy used at setup.</p> <p>param-string <i>string</i> — Specifies the dynamic service parameter list. Mandatory parameter for setup and modify actions.</p>

dynamic-services command-list

Syntax	dynamic-services command-list
Context	tools>dump>service
Description	<p>This command displays the list of supported commands that are allowed to be used in dynamic service CLI scripts.</p> <p>There are two types of CLI nodes in this list:</p> <ul style="list-style-type: none">• Pass through nodes: navigation is allowed but attributes creation or attribute changes are prohibited in this node.• Allowed nodes: navigation, attribute creation and attribute changes are allowed in this node.

15 Diameter and Diameter Applications

15.1 In This Section

This section provides information pertaining to the Diameter authentication, authorization, and accounting protocol, and Diameter applications. The features in this section are supported in the system.

15.2 Restrictions

Diameter-Based Restrictions:

- Accounting (RFC 6733, *Diameter Base Protocol*) via Diameter is not supported in this release.
- Accounting-Request (ACR), Accounting-Answer (ACA), Session-Termination-Requests (STR) and Session-Termination-Answer (STA) messages are not supported.
- SCTP and IPSec as transport protocols are not supported. TCP is supported.

Gx-Based Restrictions:

- Static hosts L2-Aware NAT hosts, PPPoA hosts, PPPoEoA hosts, MLPPP sessions and LAC/LNS (L2TP) hosts are not supported in Gx.
- Bridged homes and AA subscribers — Since there is no concept of a subscriber host in AA, the last AA policy submitted via Gx for any ESM subscriber host within the home will be applied to the AA subscriber as a whole and overwrite any previously active AA policy.
- The <SAP, MAC> combination must be unique for each host (single stack or dual-stack).
- When an SLA profile instance contains multiple subscriber hosts, it is mandatory that all hosts have the same PCC rules applied.
- The Charging-Rule-Name within the Charging-Rule-Definition cannot contain a double colon (::) set of characters in the name string. The use of double colon in the name string itself is reserved for future use.
- Reporting about successful rule activation on the node (3GPP 29.212, §4.5.2) is not supported. The rule report is sent only if the rule instantiation fails.
- Time-based Usage-Monitoring is not supported.
- Gx persistency is not supported. However, upon reboot with ESM persistency enabled, the node will re-initiate Gx sessions (new CCR-I will be generated for each Gx enabled host).
- Gy and Usage-Monitoring cannot be enabled for the same host and the same category-map at the same time. Gy is pre-configured at the time of the host instantiation. If a Usage-Monitoring request is received while Gy is enabled, the node will ignore the Usage-Monitoring request.

- Each ESM host can have up to sixteen Usage-Monitoring entities enabled simultaneously. Static configured categories and the internal category required for session level Usage-Monitoring are counted against this limit. The instantiation of the internal category for session level Usage-Monitoring is controlled with the **gx-session-level-usage** CLI command in the category map. If sixteen categories are configured, then Usage-Monitoring cannot be enabled per session (host) since this would exceed the limit of sixteen Usage-Monitoring entities per host.
- Per-session Usage-Monitoring is not supported for subscriber hosts (or IP-CAN sessions) that share the same sla-profile instance.

15.3 Terminology

The term Gx interface (or simply Gx) is used to refer to the implementation of the Gx reference point on the node. Gx reference points are defined in the 3GPP 29.212 document.

The Enhanced Subscriber Management (ESM) subscriber is a host or a collection of hosts instantiated on the Broadband Network Gateway. The ESM subscriber represents a household or a business entity for which various services with committed Service Level Agreements (SLA) can be delivered.

AA Subscriber is a representation of ESM subscriber in MS-ISA for the purpose of managing its traffic based on applications (Layer 7 awareness). An AA subscriber has no concepts of ESM hosts.

BNG refers to the network element on which a Gx interface is implemented and policy rules are enforced (PCEF).

Flow – A flow in Gx context represents traffic matching criteria (traffic classification or traffic identification) based on any combination of the following fields:

- source IP address
- destination IP address
- source port or port ranges
- destination port or port ranges
- protocol field
- DSCP bits

A Gx flow is defined in the Flow-Information AVP:

```
Flow-Information ::= < AVP Header: 1058 > 3GPP 29.212 §5.3.53
```

```
[ Flow-Description ]      3GPP 29.214 §5.3.8
[ ToS-Traffic-Class ]    3GPP 29.212 §5.3.15
[ Flow-Direction ]       3GPP 29.212 §5.3.65
*[ AVP ]
```

Gx flows are similar to dynamically created filter/ip-criteria (QoS) entries and are inserted within the entry range configured for the base filter/qos-policy.

IP criterion – These fields are used in IPv4/v6 packet header used as a match criterion. The supported fields are DSCP bits and 5 tuple. This is part of traffic classification (or traffic identification) within the PCC rule or within the static qos-policy/filter entry.

Gx policy rule – There are three types of Gx policy rules supported:

- Gx based overrides — Subscriber related overrides (sub/sla/aa-profile, subscriber-id, QoS, filter, category-map, and so on).
- NAS filter entry inserts via Gx — Basic permit/deny entries, similar to ACL filter entries.
- PCC rules or IP-criterion based rules which are fully constructed Policy and Charging Control (PCC) rules with multiple QoS/filter actions per rule and its own traffic classification.

PCC rule represents a single or a set of IP based classifiers (DSCP bits or 5 tuple) associated with a single or multiple actions.

For example:

Each PCC rule can be removed via Gx from the node by referencing its name (Charging-Rule-Name AVP).

The PCC rule can contain a combination of QoS and IPv4/v6 filter actions as they pertain to the node.

PCC Rule Classifier — A flow-based (5 tuple) or a DSCP classifier defined in the Flow-Information AVP within the PCC Rule. There can be a single classifier or multiple classifiers (Flow-Information AVPs) within a single PCC rule. A PCC classifier (Flow-Information AVP) corresponds to an entry (match criteria) within the filter/ip-criteria definition.

CAM entry – A single entry in the CAM that counts toward the CAM scaling limit. For example a match condition within ip-criteria in a filter or qos-policy can evaluate into a single CAM entry or into multiple entries (where port-ranges are configured in the classifier, or where matching against UDP and TCP protocols are enabled simultaneously).

Subscriber Host Policy – A collection of PCC rules (classifiers and actions), Gx overrides, NAS filter inserts and statically configured rules (CLI defined QoS or filter) that are together applied to the subscriber host.

15.4 3GPP-Based Diameter Credit Control Application (DCCA) - Online Charging

The 3GPP-based Diameter Credit Control Online charging applications allow the control of subscriber access to services based on a pre-paid credit. The volume and time accounting on the node supports online charging using the Diameter Credit-Control Application (DCCA). The node supports Session Charging with Unit Reservation (SCUR), allowing the node to reserve volume and time quotas for rating-groups. Furthermore, the node supports centralized unit determination and centralized rating: it requests quotas and reports usage against the quota provided by the Online Charging Server (OCS). Credit control is always on a per-rating group basis. A rating group maps to a category inside a category map of the node volume-based and time-based accounting function.

The following are the basic configuration steps:

1. Configure a diameter policy

In the **config>aaa** CLI context, configure a Diameter peer policy with one or multiple Diameter peers.

```
configure
aaa
    diameter-peer-policy "diameter-peer-policy-1" create
        description "Diameter peer policy"
        applications gy
        connection-timer 5
        origin-host "bng.domain.com"
        origin-realm "domain.com"
        source-address 10.0.0.1
        peer "peer-1" create
            address 10.1.0.1
            destination-host "server.domain.com"
            destination-realm "domain.com"
            no shutdown
        exit
    exit
exit
```

When the diameter peer is reachable from IPv6, then the peer address should be specified as an IPv6 address. Optionally, an IPv6 source address can be specified:

```
configure
aaa
    diameter-peer-policy "diameter-peer-policy-1" create
    ---snip---
    ipv6-source-address 2001:db8::1
    peer "peer-1" create
        address 2001:db8:100::1
    ---snip---
```

2. Configure a diameter application policy.

In the **config>subscriber-mgmt** CLI context, configure a diameter application policy:

- Set the application to Gy (Diameter Credit Control Application),
- Specify the Diameter peer policy to use and optionally specific additional Gy application specific parameters (for example AVP format).

```
configure
subscriber-mgmt
    diameter-application-policy "diameter-gy-policy-1" create
        description "Diameter Gy policy"
        application gy
        diameter-peer-policy "diameter-peer-policy-1"
        gy
            avp-subscription-id subscriber-id type e164
            include-avp
                radius-user-name
            exit
        exit
    exit
exit
```

3. Create a category-map in which you define:

- The credit type (time or volume).
- A category defining the queues to monitor for quota consumption and the rating-group this category maps to in DCCA.

```
configure
subscriber-mgmt
    category-map "cat-map-1" create
        description "Category Map"
        credit-type time
        category "cat-1" create
            rating-group 1
            queue 1 ingress-egress
            exhausted-credit-service-level
                pir 256
            exit
        exit
    exit
exit
```

```
exit
```

4. Create a credit control policy.

Define the credit control servers to use by specifying the diameter application policy. Optionally, specify the default-category-map and an out-of-credit-action.

```
configure
  subscriber-mgmt
    credit-control-policy "cc-policy-1" create
      description "Credit Control Policy"
      credit-control-server diameter "diameter-gy-policy-1"
      default-category-map "cat-map-1"
      out-of-credit-action change-service-level
    exit
  exit
```

5. Configure the diameter credit-control-policy in the sla-profile of the subscriber host for which credit control should be activated.

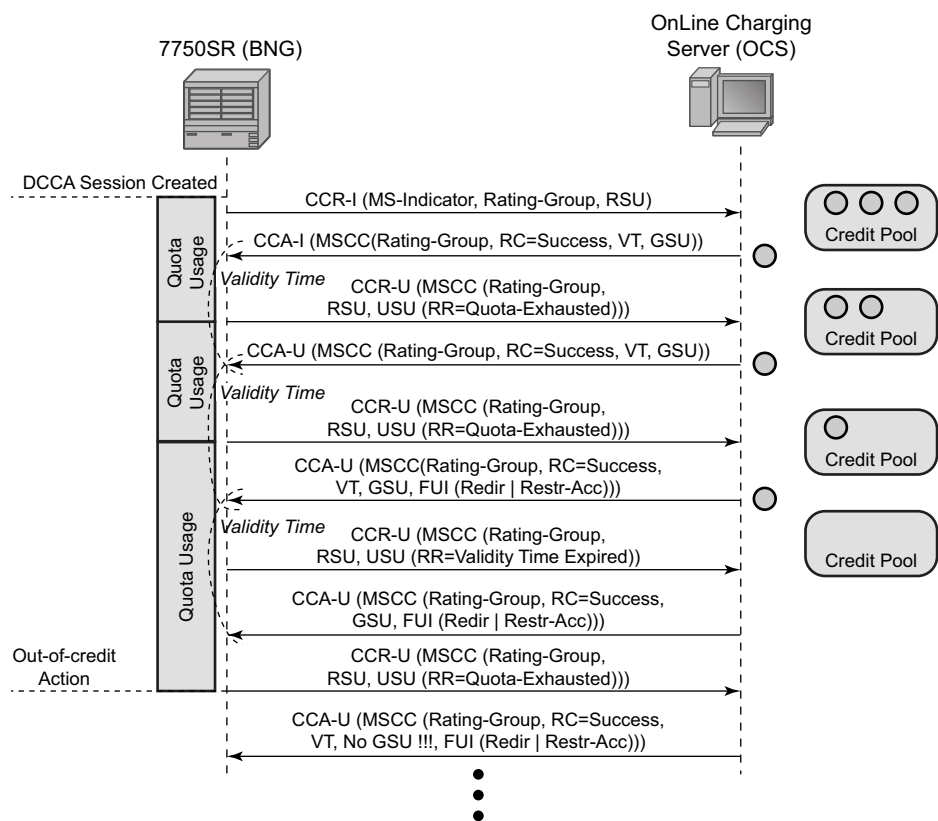

```
configure
  subscriber-mgmt
    sla-profile "sla-profile-3" create
      description "SLA profile"
      credit-control-policy "cc-policy-1"
    exit
  exit
```

The following are examples of Diameter online charging flows:

Scenario 1 — Depicts a redirect use-case:

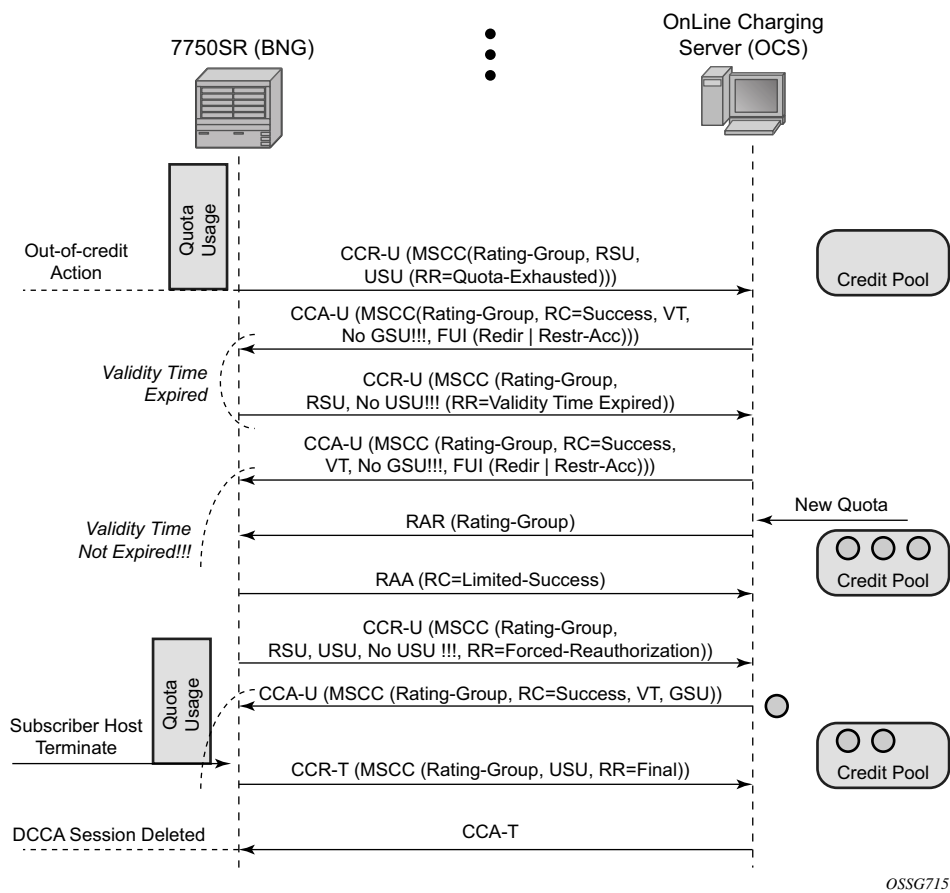

When the quota is depleted, the subscriber is redirected to a web portal. When the credit is refilled, the OCS server will notify the BNG and provide new quota. The configured out-of-credit-action when receiving a Final Unit Indication with action different from Terminate will be installed.

Figure 187 Online Charging Scenario 1 - Redirect (1/2)

OSSG714

Figure 188 Online Charging Scenario 1 - Redirect (2/2)

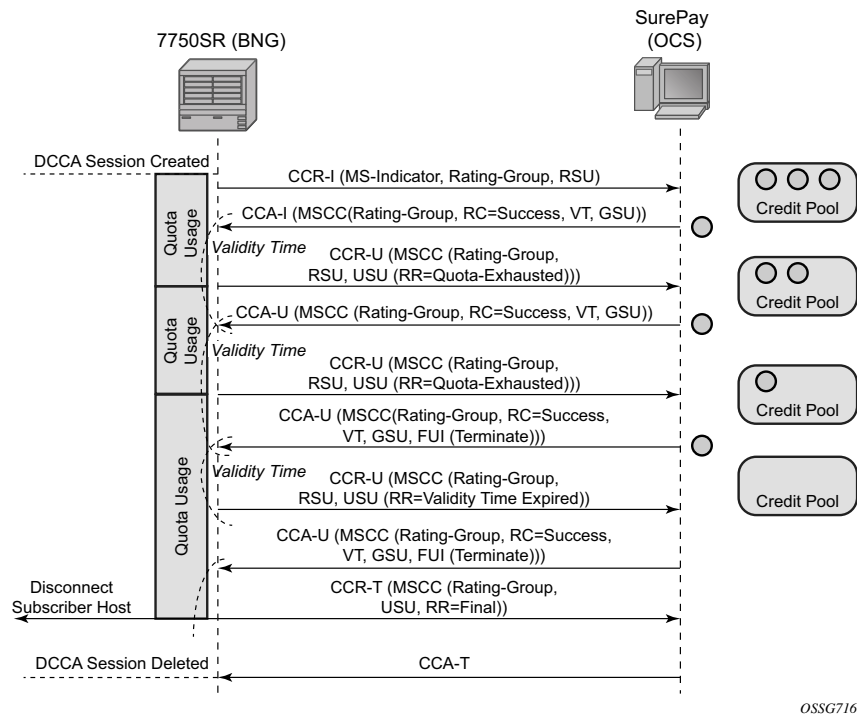

OSSG715

Scenario 2 — Depicts a terminate use case:

When the quota is depleted after reception of a Final Unit Indication with action set to Terminate, the subscriber host is disconnected. The configured out-of-credit-action is ignored in this case.

Figure 189 Online Charging Scenario 2 – Terminate

Abbreviations used in the previous drawings:

Table 109 Online Charging Scenario Legend

Abbreviation	Expansion
CCR	Credit Control Request (-Initial, -Update, -Terminate)
CCA	Credit Control Answer (-Initial, -Update, -Terminate)
RAR	Re-Authentication Request
RAA	Re-Authentication Answer
MSCC	Multiple Services Credit Control
GSU	Granted Service Unit
RSU	Requested Service Unit
USU	Used Service Unit
RC	Result Code

Abbreviation	Expansion
RR	Reporting Reason
VT	Validity Time

15.4.1 Extended Failure Handling (EFH)

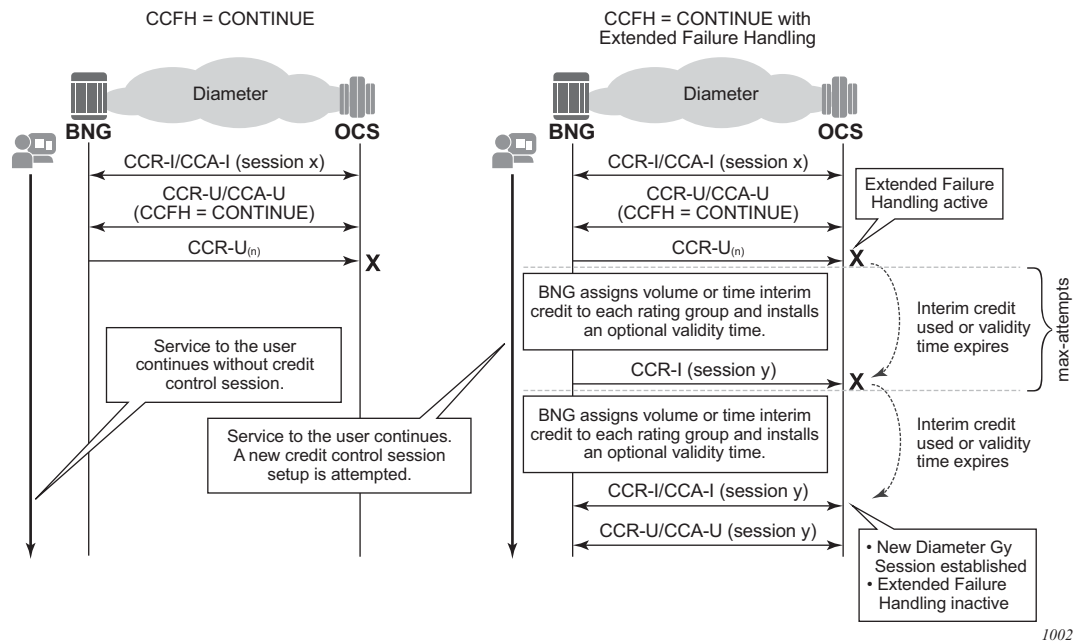

In a Diameter Gy application, that is, a Diameter Credit Control Application (DCCA), Credit Control Failure Handling (CCFH) determines the behavior of a credit control client in fault situations. When the CCFH value is set to CONTINUE and a failure occurs, the credit control client first attempts a failover procedure. If failover is not enabled or not supported by both client and server, or the failover is not successful, the client deletes the credit control session and continues the service to the end user without the Diameter Gy session until the user disconnects.

Extended Failure Handling (EFH) enables the credit control client to establish a new Diameter Gy session with the Online Charging Server (OCS) in failure situations where CCFH is triggered and the CCFH value is set to CONTINUE.

The following occurs when EFH is enabled and the CCFH value is set to CONTINUE.

- Service to the end user continues during failures (such as lost connectivity to the OCS).
- A new Diameter Gy session is established when the failure is restored.
- Usage information is kept up-to-date for reporting purposes (optional).

Figure 190 Extended Failure Handling (EFH)

If a failure occurs when EFH is active, a preconfigured time interim credit or volume interim credit with an optional validity time is assigned to all rating groups. A new Diameter Gy session setup is attempted each time the interim credit is used or the validity time expires. The following occurs when an attempt to re-establish the Diameter Gy session is made.

- The user session continues normally and EFH becomes inactive when the Diameter Gy session is successfully established with the OCS.
- A new interim credit with optional validity time is assigned to all rating groups if the Diameter Gy session is not established with the OCS.
- The user session is terminated if the Diameter Gy session is still not established with the OCS after a configurable maximum number of attempts.

15.4.1.1 Extended Failure Handling Example Call Flow

Figure 191 Extended Failure Handling - Example Call Flow

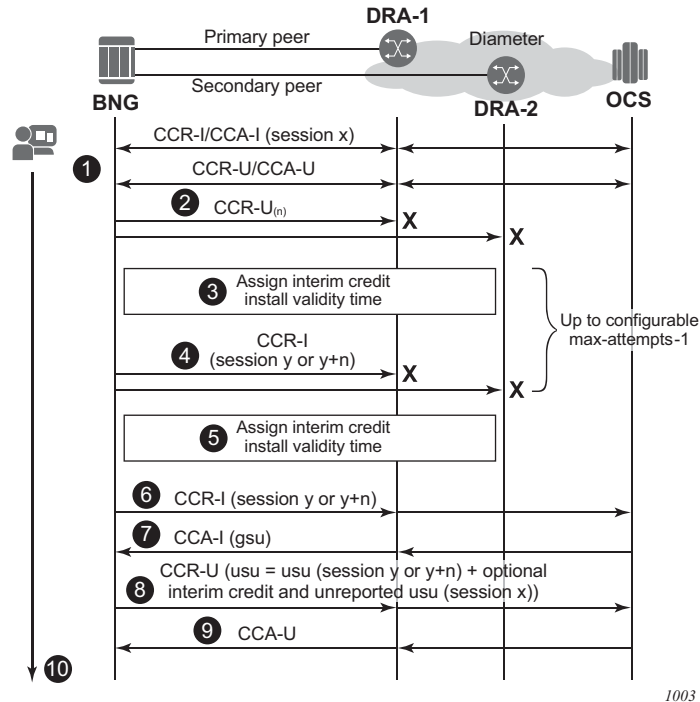

Figure 191 shows a sample call flow with EFH enabled. The following describes the call flow.

1. A Diameter Gy session is established between the Broadband Network Gateway (BNG), or credit control client, and the OCS, or credit control server.
2. A Credit Control Request Update (CCR-U) message is sent via the primary peer but no answer (CCA-U) is received. A timeout occurs which triggers a failover to the secondary peer. The same CCR-U is sent via the secondary peer. Again no answer is received. Because the CCFH value is set to CONTINUE for this session, EFH is activated.
3. The following EFH actions occur:
 - Service to the user continues uninterrupted.
 - If this is the first attempt to re-establish a Diameter Gy session:
 - i. The failed Diameter Gy session (session ID x) is terminated without sending a CCR-T (Terminate) message.
 - ii. The unreported used credits for each rating group are stored in an EFH unreported credit counter.

- iii. A new Diameter Gy session (new session ID y) is created internally but is not yet established with the OCS; the CCR-I (Initial) message is sent later.
 - For all subsequent attempts to re-establish a Diameter Gy session:
 - i. The failed Diameter Gy session (session ID y or y+n) is terminated without sending a CCR-T (Terminate) message.
 - ii. The unreported used interim credit for each rating group is added to the EFH unreported credit counter.
 - iii. A new Diameter Gy session is created internally but not yet established with the OCS: the CCR-I (Initial) message is sent later. The internal Diameter session is created with the same session ID (y) or a new session ID (y+n) based on a configuration knob.
 - Pre-configured interim credit is assigned to all rating groups and an optional validity time is installed.
4. If either all interim credit is used or the validity time expires for one of the rating group, an attempt is made to establish the new Diameter Gy session (session ID y or y+n) with the OCS.
- A CCR-I message is sent via the primary peer but no answer (CCA-I) is received. A timeout occurs which triggers a failover to the secondary peer. The same CCR-I is sent via the secondary peer. Again no answer is received.
- EFH stays active for this user session.
- Steps 3 and 4 can be repeated multiple times until the maximum number of interim credit allocations is reached and the user session is terminated (not shown in this example call flow).
5. The EFH actions are as follows:
- Service to the user continues uninterrupted.
 - The failed Diameter Gy session (session ID y or y+n) is terminated without sending a CCR-T (Terminate) message.
 - The unreported used interim credit for each rating group is added to the EFH unreported credit counter.
 - A new Diameter Gy session is created internally but is not yet established with the OCS: the CCR-I (Initial) message is sent later. The Diameter session is created with the same session ID (y) or a new session ID (y+n) based on the configuration.
 - Pre-configured interim credits are assigned to all rating groups and an optional validity time is installed.
6. If either all interim credits are used or the validity time expires for one of the rating groups, an attempt is made to establish the new Diameter Gy session (session ID y or y+n) with the OCS.
- A CCR-I message is sent via the primary peer.

7. An answer (CCA-I) is received with new granted service units (credit). Because communication with the OCS is restored, EFH becomes inactive.
8. The new Diameter Gy session resumes normal operation. Optionally, the EFH unreported credit usage is reported together with the usage from the newly granted credit in the next CCR-U credit negotiation for the rating group.
9. An answer (CCA-U) is received.
10. The service to the user continues and is uninterrupted during the OCS connectivity failure.

15.4.1.2 Extended Failure Handling Triggers

For EFH to become active, the Credit Control Failure Handling (CCFH) value must be set to CONTINUE.

For a new session, the CCFH value is set in the configuration:

```
configure
  subscriber-mgmt
    diameter-application-policy <application-policy-name> [create]
      on-failure [failover {enabled|disabled}] handling continue
```

For ongoing sessions, the CCFH value is determined from the configuration or can be overridden by the OCS by including the following AVP in an answer message (CCA-I or CCA-U):

```
[427] Credit-Control-Failure-Handling AVP = CONTINUE (1)
```

EFH is triggered when the CCFH value is set to CONTINUE and one of the following conditions occurs:

- a transmit failure—failure to send a CCR-I or CCR-U message

Figure 192 EFH Trigger: Transmit Failure

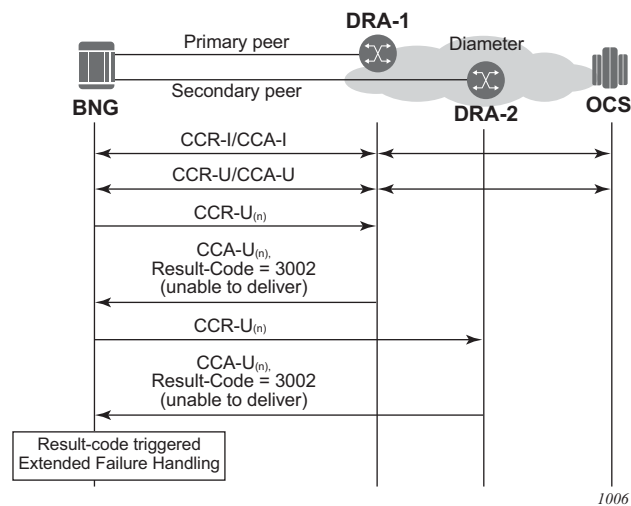

- a timeout—failure to receive an answer (CCA-I or CCA-U) within the configured timeout

Figure 193 EFH Trigger: Timeout

- a protocol error—failure due to a protocol error; seen as a Result-Code at command level in an answer message (CCA-I or CCA-U)

Figure 194 EFH Trigger: Protocol Error

Other cases where CCFH CONTINUE is triggered will not result in the activation of EFH.

15.4.1.3 Assigning Interim Credit

EFH interim credit can be specified in two ways:

- as a single volume interim credit value that is assigned to all rating groups of the Diameter Gy session with active EFH and that have no default credits configured

```
configure subscriber-mgmt
  diameter-application-policy <application-policy-name> create
    gy
      extended-failure-handling
        interim-credit
          volume <credits> {bytes|kilobytes|megabytes|gigabytes}
```

- as a single volume or time interim credit value per rating group (default credit)

The activity threshold configured in the category map also applies to all rating groups that have time-based interim credit assigned while EFH is active.

```
configure subscriber-mgmt
  category-map <category-map-name> create
    activity-threshold <kilobits-per-second>
  category <category-name> create
    default-credit time <seconds>
    default-credit volume <credits> <bytes|kilobytes|megabytes|gigabytes>
```

A single validity time value can be specified and applied to all rating groups that have interim credit assigned, regardless of whether the interim credit is configured for all rating groups in the Diameter application policy or per rating group in the category map.

```
configure subscriber-mgmt
  diameter-application-policy <application-policy-name> create
    gy
      extended-failure-handling
        interim-credit
          validity-time <seconds>
```

The maximum number of times that interim credit is assigned to all rating groups of a Diameter Gy session when EFH is active can be limited in the configuration. The **max-attempts** value also corresponds with the maximum number of attempts to establish a new Diameter Gy session with the OCS (the default maximum attempts = 10).

```
configure subscriber-mgmt
  diameter-application-policy <application-policy-name> create
    gy
      extended-failure-handling
        interim-credit
          max-attempts <count>
          max-attempts infinite
```

An attempt to establish a new Diameter Gy session with the OCS is made when one of the following conditions occurs.

- The assigned interim credit for one of the rating groups is used.
- The validity time of the interim credit for one of the rating groups expires.

When the maximum number of attempts is reached and a new Diameter Gy session is not yet successfully established, then the user session is terminated; that is, the corresponding subscriber hosts are deleted from the system.

The reporting of used EFH interim credit can be enabled using the following CLI command:

```
configure subscriber-mgmt
  diameter-application-policy <application-policy-name> create
    gy
      extended-failure-handling
        interim-credit
          [no] reporting
```

With reporting enabled, the following accumulated used credit is reported when a new Diameter Gy session is established with the OCS and usage reporting is triggered for a rating group:

- unreported used credit granted via the initial Diameter Gy session that caused the EFH activation
- used interim credit when EFH was active
- used credit granted via the new Diameter Gy session

By default, reporting is disabled and all the used credit from the initial Gy session and all used interim credit are discarded.

15.4.1.4 Enabling Extended Failure Handling

EFH is enabled by specifying **no shutdown** in the **extended-failure-handling** CLI context in a Gy Diameter application policy.

```
configure subscriber-mgmt
  diameter-application-policy <application-policy-name> create
    gy
      extended-failure-handling
        no shutdown
```

[Table 110](#) lists the EFH states for a Diameter Gy session.

Table 110 Extended Failure Handling States

Extended Failure Handling State	Description
Disabled	EFH is disabled (shutdown). EFH cannot be triggered for the Diameter Gy session.

Table 110 Extended Failure Handling States (Continued)

Extended Failure Handling State	Description
Enabled - active	EFH is enabled (no shutdown) and active. A failure event occurred that triggered EFH. Interim credit is assigned to all rating groups and when either the validity time expires or the interim credit is used for a rating group, a new attempt is made to establish a Diameter Gy session with the OCS.
Enabled - inactive	EFH is enabled (no shutdown) and inactive. A Diameter Gy session with the OCS is established. EFH will be activated for the Diameter Gy session if a trigger condition occurs.

15.4.1.5 Configuration Example 1 - Single Volume Interim Credit Value

```

configure subscriber-mgmt
  diameter-application-policy gy-1 create
    --- snip ---
    on-failure handling continue
    gy
      --- snip ---
      extended-failure-handling
        no new-session-id          # default
        interim-credit
          no reporting             # default
          volume 100 megabytes
          validity-time 900
          max-attempts 96
        exit
      no shutdown
    exit
  exit
exit

```

In this example, EFH is enabled and when active, 100 Mbytes of volume interim credit is assigned to all rating groups of the Diameter Gy session with a validity time of 900 s. The maximum number of attempts to establish a Diameter Gy session with the OCS is 96.

Therefore, a maximum of 96 x 100 Mbytes or 9.6 Gbytes can be consumed before the user session is terminated (that is, the subscriber host is deleted from the system) when the OCS remains unreachable. Alternatively, when less than 100 Mbytes per rating group is consumed every 15 minutes (900 s), the user will be disconnected after 900 s x 96 = 24 hours when the OCS remains unreachable.

15.4.1.6 Configuration Example 2 - Interim Credit Values Per Rating Group

```
configure subscriber-mgmt
  category-map "cat-map-1" create
    activity-threshold 10
    category "cat-1" create
      description "Time interim credit per category"
      default-credit time 900
      rating-group 1
      queue 1 ingress-egress
    exit
  category "cat-2" create
    description "Volume interim credit per category"
    default-credit volume 10 megabytes
    rating-group 2
    queue 2 ingress-egress
  exit
  category "cat-3" create
    no default-credit
    rating-group 3
    queue 3 ingress-egress
  exit
exit
diameter-application-policy gy-1 create
  --- snip ---
  on-failure handling continue
  gy
    --- snip ---
    extended-failure-handling
      new-session-id
      interim-credit
        reporting
        volume 100 megabytes
        validity-time 900
        max-attempts 96
      exit
    no shutdown
  exit
exit
exit
```

In this example, EFH is enabled and when active, the following interim credit is assigned:

- 900 s of time interim credit to rating group 1 (category cat-1) with a validity time of 900 s. The activity threshold applies. When the usage stays below 10 kbytes/s, no time credit is used.
- 10 Mbytes of volume interim credit to rating group 2 (category cat-2) with a validity time of 900 s
- 100 Mbytes of volume interim credit to rating group 3 (category cat-3) with a validity time of 900 s

For inactive users, the validity time ensures that new Diameter Gy session connection attempts with the OCS are made at regular intervals.

For each attempt to establish a Diameter Gy session with the OCS, a new session ID is used.

When a new Diameter Gy session is successfully established, the EFH unreported credit for each rating group is included in the used service units when reporting is triggered for that rating group on the new Diameter Gy session.

When no new Diameter Gy session is established after 96 attempts, the user session is terminated; that is, the subscriber hosts are deleted from the system.

15.4.1.7 Monitoring the Extended Failure Handling State

Subscribers with Diameter Gy sessions that have EFH enabled can be displayed with the following CLI command:

```
# show service active-subscribers credit-control extended-failure-  
handling [state] [summary]
```

where the EFH state can be set to:

- active—show subscribers with Diameter Gy sessions that have EFH enabled and EFH is active;
- inactive—show subscribers with Diameter Gy sessions that have EFH enabled and EFH is inactive; or
- all—show subscribers with Diameter Gy sessions that have EFH enabled and EFH is either active or inactive.

Example output:

```
A:BNG-1# show service active-subscribers credit-control extended-failure-handling  
=====
```

```

Number of active subscribers : 1

The following information is displayed In the Extended Failure Handling (EFH) section of the example:

```

Extended Failure Handling (EFH)
  State           : active

```

State indicates that EFH is enabled and active. Another possible state is “inactive”. When EFH is disabled, no EFH information is included.

```

Attempts           : 1                      Maximum Attempts   : 10

```

Attempts indicates the number of times interim credit has been assigned to all categories followed by an attempt to establish a new Diameter Gy session with the OCS. When the attempt to establish a new Diameter Gy session with the OCS is still failing after the Maximum Attempts value is reached, then the user session is terminated (that is, the subscriber hosts are deleted from the system).

```
Active time          : 0d 00:00:10
```

Active time indicates the time since the EFH state became active for this subscriber session.

```
Total Active time   : 0d 00:00:10
Total Active Count   : 1
```

Total Active time indicates the accumulative time of all occurrences that EFH was active during the lifetime of this subscriber session.

Total Active Count indicates the number of times that EFH was active during the lifetime of this subscriber session.

For each category (rating group), the EFH Unreported Credit is displayed:

```
EFH Unreported Credit
Current Volume      : 0                Current Time      : 601
Total Volume        : 0                Total Time         : 601
```

The Current Volume and Current Time counters contain, respectively, the unreported volume and time credit for the current occurrence of the EFH in an active state. These counters include the unreported used credit for the initial Diameter Gy session that caused the EFH state to become active and the unreported interim credit from previous attempts. Used interim credit for the current attempt per category (rating group) is shown in the following counters:

```
Credit Volume Used   : 0                Credit Time Used    : 11
Credit Volume Avail. : 0                Credit Time Avail.  : 589
```

The Total Volume and Total Time counters contain respectively the accumulated total unreported volume and time credit for the previous occurrences of EFH active state. The total counters are updated when the EFH state toggles from active to inactive. When interim credit reporting is enabled, the counters are reset to zero when the actual usage reporting happens for that rating group. When interim credit reporting is disabled, the counters are accumulating the total unreported credit during the lifetime of the subscriber session.

Current and Total Volume EFH Unreported Credit counters are the sum of used ingress and egress octets.

For each category (rating group), the validity time is displayed:

Validity Time Used : 13

Validity Time Avail. : 587

The following fields are only displayed when the EFH state is active:

- Extended Failure Handling (EFH): “Attempts”, “Max Attempts” and “Active time”
- EFH Unreported Credit: “Current Volume” and “Current Time”

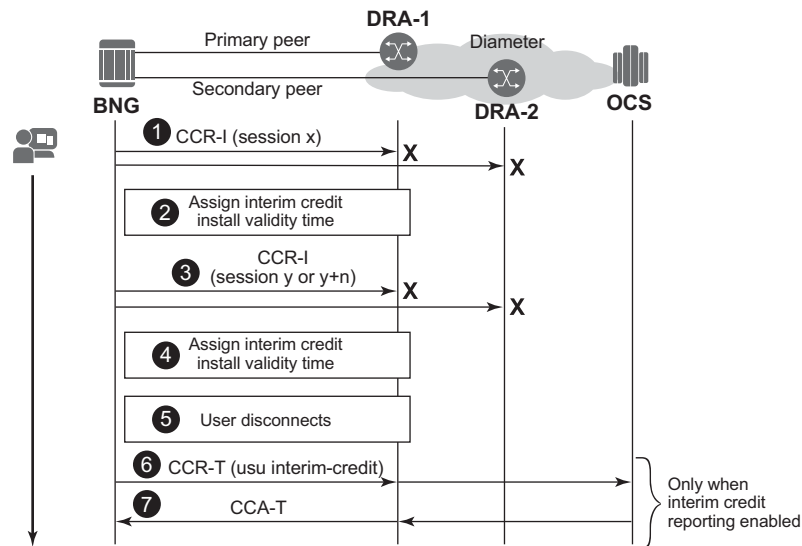

When EFH is disabled (shutdown), then the EFH information is not included in the credit control output.

15.4.1.8 Additional Call Flow Examples

15.4.1.8.1 User Disconnects While EFH is Active

The call flow in [Figure 195](#) shows a scenario where EFH is activated before the session is established with the OCS. The scenario is similar when EFH is activated by a CCR-U message.

Figure 195 EFH Call Flow - User Disconnects During EFH

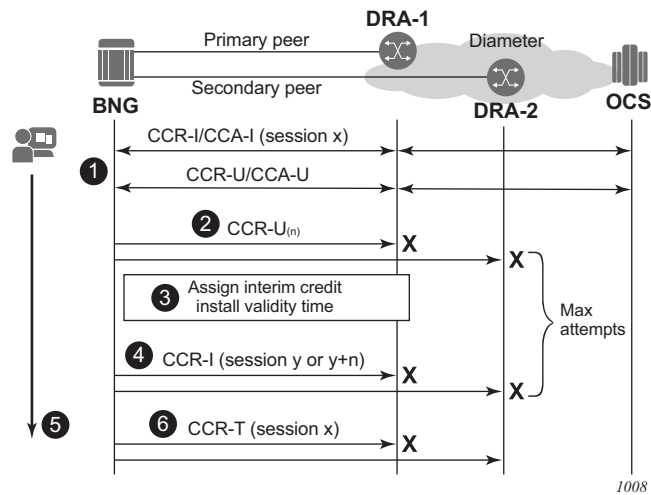

1007

1. The initial Diameter Gy session setup fails: the CCR-I message sent to the primary peer times out or an error condition occurs that triggers Diameter Gy EFH. If failover is enabled, the CCR-I message is resent on the secondary peer. The CCR-I message sent to the secondary peer times out or an error condition occurs that triggers Diameter Gy EFH.
2. EFH becomes active for this user session. Interim credit is assigned to all rating groups and, optionally, a validity time is installed.
3. Interim credit is exhausted for a rating group or a validity time expires. A new attempt is made to establish the Diameter Gy session with the OCS; a CCR-I message is sent to the primary peer. A timeout or an error condition occurs that triggers Diameter Gy EFH to become active. If failover is enabled, the CCR-I message is resent on the secondary peer. The CCR-I message sent to the secondary peer times out or an error condition occurs that triggers EFH.
4. Interim credit is assigned to all rating groups and, optionally, a validity time is installed.
5. The user disconnects, resulting in a termination of the user session.
6. If interim credit reporting is enabled, a CCR-T is sent reporting the accumulated consumed interim credit.
7. If the OCS becomes reachable, a CCA-T may be received. Because the Diameter Gy session was not established with the OCS, the result code is `DIAMETER_UNKNOWN_SESSION_ID`.

15.4.1.8.2 The Maximum Number of Attempts is Reached

The call flow in [Figure 196](#) shows a scenario where the maximum attempts is reached to establish a Diameter Gy session with the OCS.

Figure 196 EFH Call Flow - Maximum Attempts Reached

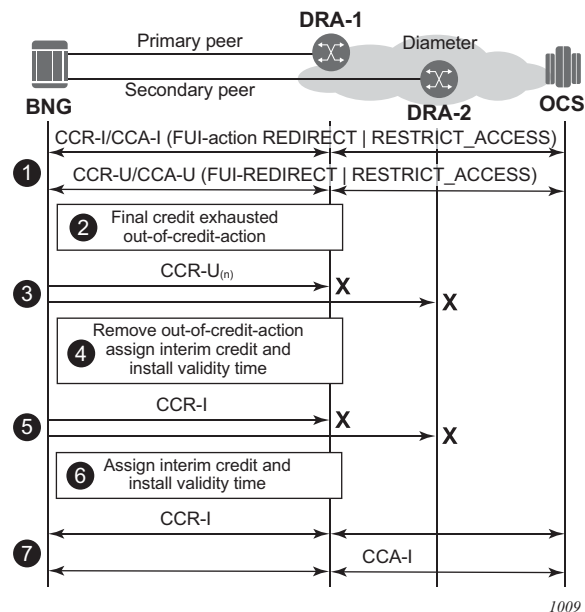

1. A Diameter Gy session is in progress.
2. An update message sent to the primary peer times out or an error condition occurs that triggers Diameter Gy EFH. If failover is enabled, the CCR-U message is resent on the secondary peer. The CCR-U message sent to the secondary peer times out or an error condition occurs that triggers Diameter Gy EFH.
3. EFH becomes active for this user session. Interim credit is assigned to all rating groups and, optionally, a validity time is installed.
4. Interim credit is exhausted for a rating group or a validity time expires. A new attempt is made to establish the Diameter Gy session with the OCS; a CCR-I message is sent to the primary peer. A new session ID is used for the first attempt. For subsequent attempts, a configuration command determines if a new or the same session ID will be used. A timeout or an error condition occurs that triggers Diameter Gy EFH to become active. If failover is enabled, the CCR-I message is resent on the secondary peer. The CCR-I message sent to the secondary peer times out or an error condition occurs that triggers EFH. Steps 3 and 4 are repeated until the maximum attempts for interim credit is reached.
5. The user session is disconnected; that is, the subscriber hosts are deleted from the system.
6. When interim credit reporting is enabled, a CCR-T is sent, reporting the accumulated consumed interim credit: the unreported quota from the initial session x and the accumulated interim credit.

15.4.1.8.3 EFH Activation Triggered During Final Unit Indication (FUI)

This section describes two scenarios where EFH is activated during a graceful service termination initiated by the OCS with a FUI AVP. A graceful service termination with FUI action equal to REDIRECT or RESTRICT_ACCESS relies on a validity time or RAR to trigger a new credit negotiation with the OCS. Since the OCS is unreachable, it cannot be verified if a new quota has been granted. With EFH enabled, interim credit is assigned to guarantee service to the user until the connectivity with OCS is restored.

In the first scenario shown in [Figure 197](#), the OCS initiates the graceful service termination with the Final-Unit-Action AVP = REDIRECT or RESTRICT_ACCESS. EFH is activated immediately after the out-of-credit action is installed.

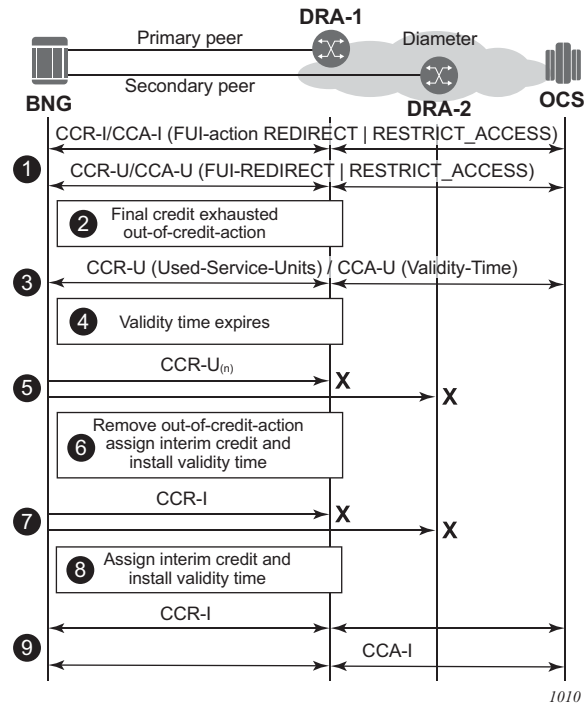

Figure 197 EFH Call Flow - Final Unit Indication Scenario 1

1. A Diameter Gy session is in progress. Either the CCA-I or a CCA-U contains the Final-Unit-Indication AVP and the Final-Unit-Action AVP is set to REDIRECT or RESTRICT_ACCESS.
2. The final assigned credit is exhausted and because the Final-Unit-Action AVP is different from TERMINATE, the provisioned out-of-credit action is installed. A CCR-U is sent to the OCS to notify it that the Final-Unit-Action has started.

3. The CCR-U message sent to the primary peer times out or an error condition occurs that triggers diameter Gy EFH. If failover is enabled, the CCR-U message is resent on the secondary peer. The CCR-U message sent to the secondary peer times out or an error condition occurs that triggers Diameter Gy EFH.
4. EFH becomes active for this user session. Interim credit is assigned to all rating groups and, optionally, a validity time is installed. The out-of-credit action is removed.
5. Interim credit is exhausted for a rating group or a validity time expires. A new attempt is made to establish the Diameter Gy session with the OCS and a CCR-I message (new session ID) is sent to the primary peer. A timeout or an error condition occurs that triggers Diameter Gy EFH to become active. If failover is enabled, the CCR-I message is resent on the secondary peer. The CCR-I message sent to the secondary peer times out or an error condition occurs that triggers EFH.
6. A new interim credit is assigned to all rating groups and, optionally, a validity time is installed.
7. Interim credit is exhausted for a rating group or a validity time expires. A new attempt is made to establish the Diameter Gy session with the OCS. A CCR-I is sent with the same or a new session ID to the primary peer. Whether the same or a new session ID is used is determined by a configuration command.
A CCA-I answer message is received. EFH becomes inactive and the user session continues with the new established credit control session. Optionally, the used interim credit can be reported via the new established session.

In the second scenario shown in [Figure 198](#), the OCS initiates the graceful service termination with the Final-Unit-Action AVP = REDIRECT or RESTRICT_ACCESS. EFH is activated after the FUI validity time expires.

Figure 198 EFH Call Flow - Final Unit Indication Scenario 2

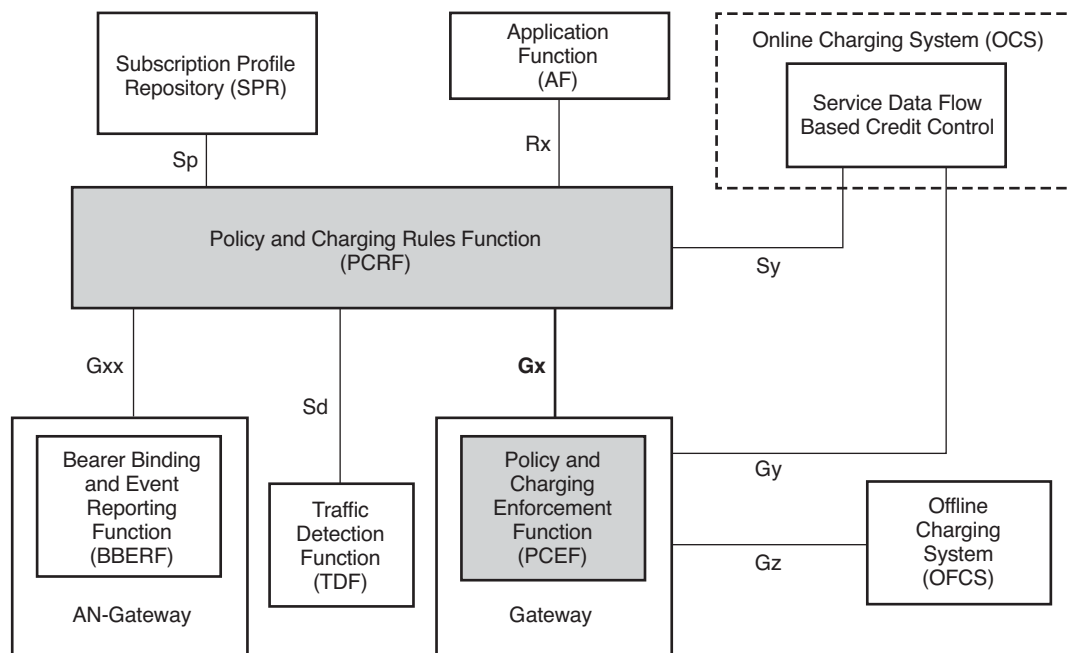

1. A diameter Gy session is in progress. Either the CCA-I or a CCA-U, contains the FUI AVP and Final-Unit-Action AVP = REDIRECT or RESTRICT_ACCESS.
2. The final assigned credit is exhausted and because the Final-Unit-Action is different from TERMINATE, the configured out-of-credit action is installed.
3. A CCR-U is sent to the OCS to notify that the Final-Unit-Action has started. The server responds with CCA-U containing a validity time.
4. The validity time expires.
5. The subsequent CCR-U message sent to the primary peer times out or an error condition occurs that triggers Diameter Gy EFH. If failover is enabled, the CCR-U message is resent on the secondary peer. The CCR-U message sent to the secondary peer times out or an error condition occurs that triggers Diameter Gy EFH.
6. EFH becomes active for this user session. Interim credit is assigned to all rating groups and, optionally, a validity time is installed. The out-of-credit action is removed.

7. Interim credit is exhausted for a rating group or a validity time expires. A new attempt is made to establish the Diameter Gy session with the OCS; a CCR-I message is sent to the primary peer. For the first attempt, a new session ID is used. For subsequent attempts, a configuration command determines if a new or the same session ID will be used. A timeout or an error condition occurs that triggers Diameter Gy EFH to become active. If failover is enabled, the CCR-I message is resent on the secondary peer. The CCR-I message sent to the secondary peer times out or an error condition occurs that triggers EFH.
8. A new interim credit is assigned to all rating groups and, optionally, a validity time is installed.
9. Interim credit is exhausted for a rating group or a validity time expires. A new attempt is made to establish the Diameter Gy session with the OCS—a CCR-I message is sent to the primary peer.
A CCA-I answer message is received. EFH becomes inactive and the user session continues with the new established credit control session. Optionally, the used interim credit can be reported via the new established session.

15.5 Policy Management via Gx Interface

Gx is a reference point in the network architecture model describing mobile service delivery. The network elements are described in various technical documents under the umbrella of 3GPP and are used to deliver, manage, report on and charge end-user traffic for mobile users. The Gx reference point is used for policy control and charging control. As shown in [Figure 199](#), it is placed between a policy server (Policy and Rule Charging Function (PCRF)) and a traffic forwarding node (Policy and Charging Enforcement Function) that enforces rules set by the policy server.

Figure 199 Gx Reference Point

al_0464

The Gx reference point is defined in the Policy and Charging Control (PCC) architecture within 3GPP standardization body. The PCC architecture is defined in the document 23.203 while the Gx functionality is defined in the document 29.212. Gx is an application of the Diameter protocol (RFC 3588/6733).

Although the Gx reference point is defined within 3GPP standardization body (spurred by mobile/wireless industry) its applicability has spread to wire-line operation as well. For example, mobile operators that also have fixed line customers (residential + business) would like to streamline policy management in their mobile and non-mobile domains with a single and already existing Gx based policy management infrastructure. In other words they want to integrate policy management of nodes serving fixed line subscribers into the system that is currently managing mobile subscriber base.

In such mixed environments, the node plays the role of a PCEF with an integrated TDF (Traffic Detection Function, or Application Awareness [AA] in ALU terminology) where policies and charging rules can be managed via PCRF.

With WiFi Offload as a new emerging application, supporting Gx reference point on nodes is becoming even more important.

The Gx interface on the node encompasses the following functionality:

- Per subscriber host policy management
- Usage-Monitoring

Gx will be applicable to Enhanced Subscriber Management (ESM) as well as to AA.

15.5.1 Gx Protocol

The Gx application is defined as a vendor specific Diameter application, where the vendor is 3GPP and the Application-ID for Gx application is 16777238. The vendor identifier assigned to 3GPP by IANA is 10415.

When a Diameter protocol defined over the Gx interface, the node (PCEF) acts as a Diameter Client and the PCRF acts as a Diameter server. The Gx Diameter application uses existing Diameter command codes from the Diameter Base Protocol (RFC 6733) and Diameter Credit Control Application (RFC 4006), both of which are already implemented on the node.

Gx is using Attribute-Value Pairs (AVPs) for data representation within its messaging structures (command codes). AVPs in Gx come from various sources:

- Gx-specific AVPs defined in 3GPP Gx specification TS 29.212.
- Reused AVPs from other existing Diameter applications (RFC 4006, RFC 4005, and so on), other 3GPP specifications, ETSI, and so on.
- RADIUS reused attributes (AVP codes 0-255 are reserved for RADIUS re-used attributes)
- Vendor-specific AVPs

The initialization and maintenance of the connection between the node (PCEF) and the PCRF is defined by the underlying Diameter protocol as defined in RFC 3588/6733.

15.5.2 Policy Assignment Models

Subscriber and AA policies on the node (PCEF with integrated TDF) will be assigned via the Gx protocol from the policy server (PCRF).

There are two modes of operation:

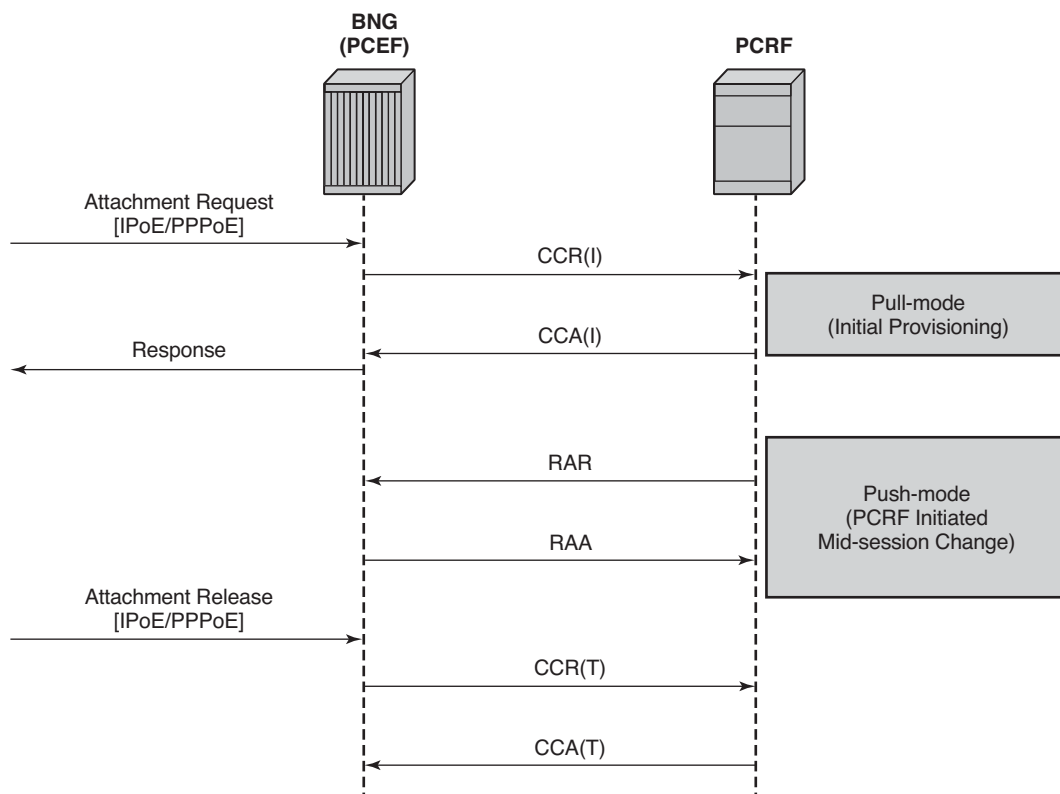

- Pull mode — The policy creation/modification is solicited by the node.
- Push mode — The policy change is unsolicited by the node.

In the pull mode, during the host creation process, a user is authenticated by the AAA server. This process is independent from PCRF. Once the user is authenticated and the IP address is allocated to it, the node sends a request for policies to the PCRF via CCR-i messages (initialization request message). This communication occurs via the Gx interface. The subscriber-host must be uniquely identified in this request towards the PCRF. This sub-identification over the Gx interface could be by means of IP address, username, SAP ID, and so on.

Based on the user identification, PCRF will submit policies to the node. Those policies can range from subscriber strings (sub/sla-profiles/AA-profiles) to QoS and filter-related parameters.

In the push mode, the PCRF initiates the mid-session policy change through the Re-Authentication Request (RAR) message.

Figure 200 Policy Assignment Models

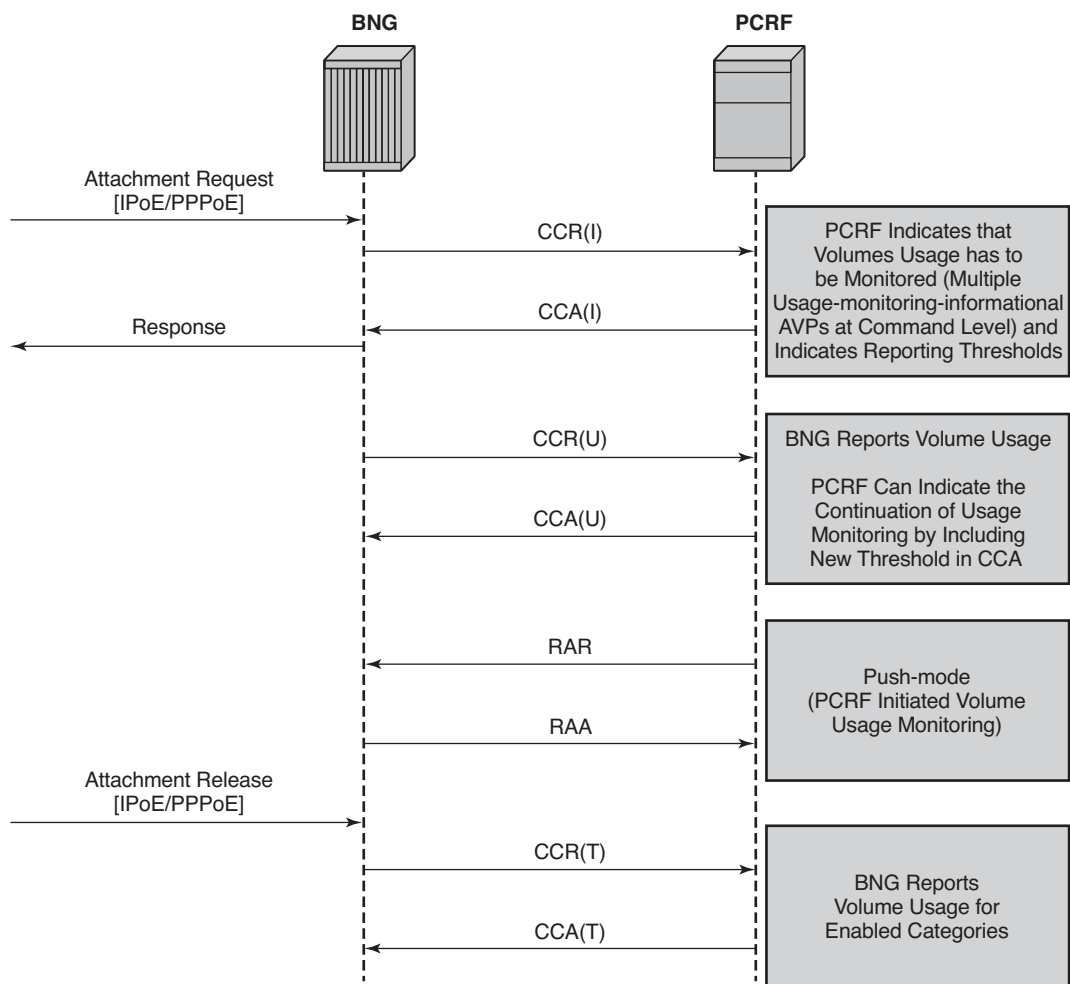

al_0465

If that Usage-Monitoring is requested, the PCRF submitted policy changes are triggered by the Credit Control Request (Update) messages. This is based on ESM or AA Usage-Monitoring. Once the specified usage threshold is reached on the session-level, credit-category level, pcc rule level or application level on the node, the Usage-Monitoring is reported from the node to the PCRF in the CCR-u message. Refer to the Multi-Service Integrated Services Adapter Guide for details on AA based Usage-Monitoring.

Alternatively, PCRF can request usage reporting on-demand via the **rar** command.

Figure 201 On-Demand Usage Reporting

al_0466

15.5.3 IP-CAN Session – Gx Session Identification

The IP Connectivity Access Network (IP-CAN) session is a concept that has roots in mobile applications. A policy rule via the Gx interface can be applied/modified to an entity that is identified as an IP-CAN session (in addition to individual bearers within the IP-CAN session, the bearer concept is currently not applicable to the BNG). For example, a UE (user interface or simply a mobile phone) can host several services, each of which appears as a separate IP-CAN session associated with the same IP address. For example, in mobile technologies, an IP-CAN session can be defined as <IP_address, APN, IMSI>, where:

- APN (Access Point Name) is the service identifier
- IMSI (International Mobile Subscriber Identification) is the UE identifier (SIM Card)

In a wireline environment (ESM deployments), an IP-CAN session will identify an entity to which the policy can be applied/modified, and currently, this is a subscriber-host instantiated on the node.

To identify the host on the node in all Gx-related transactions, the node will generate a unique, per-host (single or dual-stack) session-id AVP (RFC 6733, §8.8). The Gx session-id will in essence represent the IP-CAN session from the standpoint of the node. The Gx session-id AVP is not the same as the acct-session-id attribute used in RADIUS accounting.

15.5.3.1 User Identification in PCRF

The following identification related AVPs will be sent to the PCRF via Gx messages to aid in IP-CAN session identification:

- **subscription-id** AVP (RFC 4006, §8.46) — This can be used to identify the subscribers on the PCRF. For the supported fields within the subscription-id AVP, refer to the Gx AVPs Reference Guide.
- **NAS-Port-Id** AVP (RFC 2869 / §5.17; RFC 4005 / §4.3)
- **AN-GW-Address** AVP (3GPP 29.212 / § 5.3.49)
- **Calling-Station-ID** AVP (RFC 4005 / §4.6)
- **user-equipment-info** AVP (RFC 4006, §8.49)
- **logical-access-id** AVP (ETSI TS 283 034) — This will contain circuit-id from DHCPv4 Option (82,1) or interface-id from DHCPv6 option 18. The vendor-id will be set to ETSI (13019).

- **physical-access-id** AVP (ETSI TS 283 034) — This will contain remote-id from DHCPv4 option (82,2) or DHCPv6 option 37. The vendor-id will be set to ETSI (13019).

Physical and logical access IDs are also defined in BBF TR-134 (§7.1.4.1).

Table 111 PDP to PEP Direction Parameters

Parameter	Category	Type	Description
Logical access ID	User identification	Octet String	The identity of the logical access to which the user device is connected. It is stored temporarily in the AAA function connected to PDP. This corresponds to the Agent ID in case of IPv4 and to THR Interface Id of DHCP option 82 for IPv6
Physical Access ID	User identification	UTF8String	The identity of the physical access to which the user device is connected. It is stored temporarily in the AAA function connected to the PDP. This corresponds to the Agent Remote ID

A Subscription-id AVP is most commonly used to identify the subscriber but any combination of the above listed parameters can be used to uniquely identify the IP-CAN session on PCRF and consequently identify the subscriber.

In addition, NAS-Port, NAS-Port-Type, and Called-Station-ID AVPs from RFC 4005 (§4.2, §4.4, §4.5) can be passed to the PCRF.

15.5.3.2 NAS-Port-Id as Subscription-Id

The node allows the NAS-Port-Id to be carried within the Subscription-Id AVP. Since the NAS-Port-Id may not be unique network-wide (two independent nodes may use the same NAS-Port-Id), there is a need for another identifier in conjunction with NAS-Port-Id to make the Subscription-Id unique across the network. This additional identifier is a custom string that can be appended to the NAS-Port-Id. It is defined when the NAS-Port-Id is configured for inclusion in Gx messages. Refer to the RADIUS Attribute Reference Guide for information to format NAS-Port-Id AVP on the node.

The string can be used to identify the location of the node. For example:

```
@ALU-MOV-SITE-1
```

An example of the augmented NAS-Port-Id would look like:

```
NAS-Port-Id = lag-1.1/1/2:23.2000@ALU-MOV-SITE-1
```

where: 'lag-1.1/1/2:23.2000' is the part referencing the SAP on the node (port + vlan tags) and the '@ALU-MOV-SITE-1' is the node itself.

The NAS-Port-Id can be then inserted in the Subscription-Id AVP.

15.5.4 Gx Interface and ESM Subscriber Instantiation

Policy management via Gx enables operators to consolidate policy management systems used in wireline (mostly based on RADIUS/CoA) and wireless environment (PCRF/Gx) into a single system (PCRF/Gx).

The model for policy instantiation/modification via Gx is similar to the one using RADIUS CoA. The authentication and IP address assignment is provided outside of Gx while the policy management function is provided via Gx.

Some PCRFs may require that the IP address information is passed from the node in CCR-i. This assumes that the IP address assignment phase (via LUDB, RADIUS or DHCP Server) is completed before the PCRF is contacted via CCR-i. Message flow for various protocols (DHCP, AAA, Gx) related to IPv4 subscriber-host instantiation phase is shown in [Figure 202](#).

CCR-i message is sent to the PCRF once DHCP Ack is received from the DHCP server. Relaying DHCP Ack to the client in the final phase of the host instantiation process will depend on the answer from the PCRF and the configuration settings of the fallback function if the answer is not received.

This model allows the IP address of the host to be sent in the CCR-i message, even though the subscriber-host is not fully instantiated at the time when the CCR-i message is generated.

AAA/LUDB must still be used for authentication and assignment of parameters necessary to place the subscriber host in the proper routing context (service-id, grp-id, msap-policy).

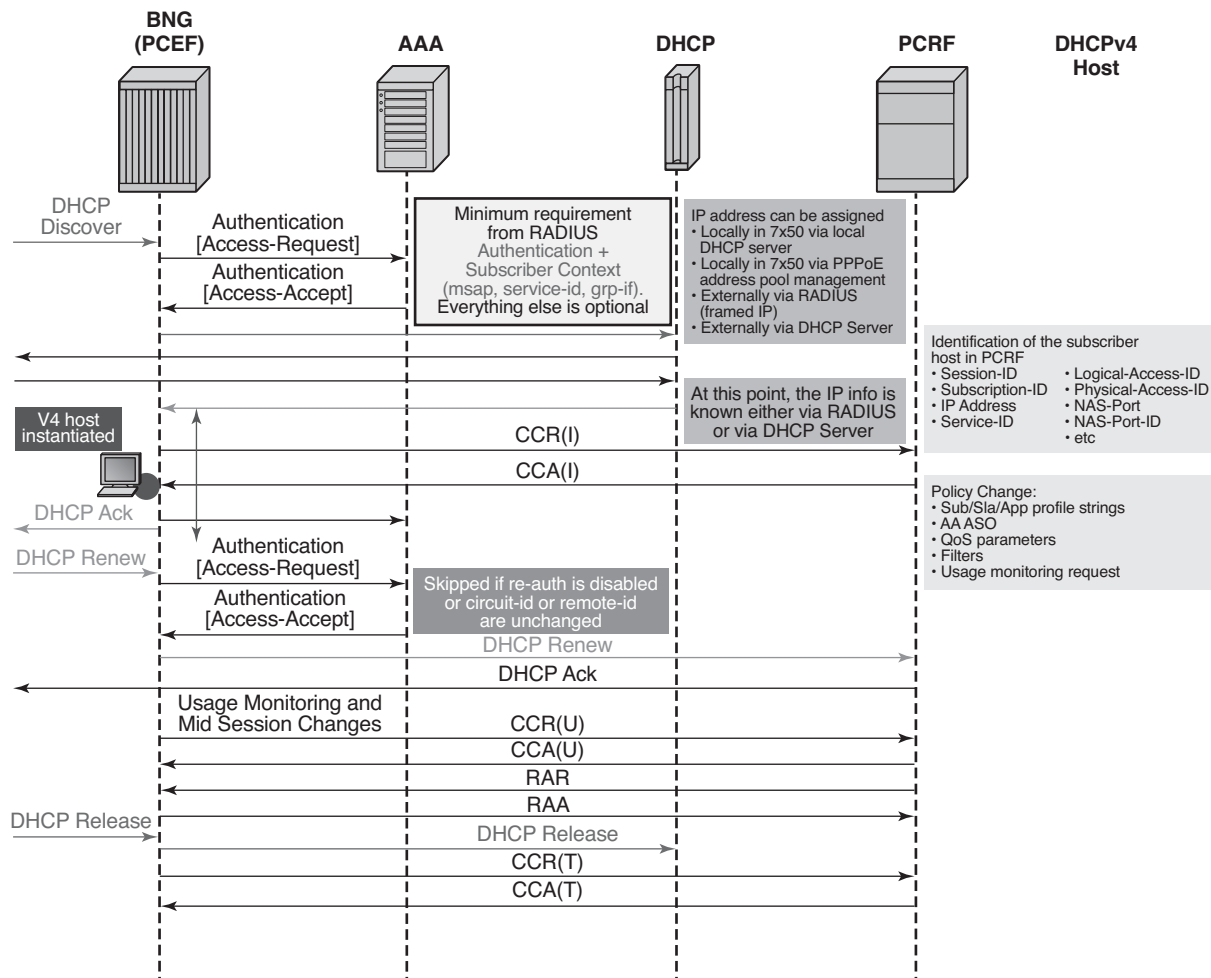

Start of the accounting process nicely fits into this model since the host is not instantiated until the policy information from all sources (Gx, AAA, defaults) is known. Once the final sub-profile (containing the acct-policy) is known, the host will be instantiated and accounting can consequently be activated.

The IP address itself cannot be assigned via Gx, and this functionality is outside of the Gx scope (3GPP TS 23.203 Rel12, Annex S, IP-CAN Session Establishment section).

The purpose of the CCR-i message is the following:

- To notify the PCRF that the sub-host was about to be instantiated on the node. Consequently, the PCRF will create a Gx session for the subscriber host if the CCR-i is successfully processed by PCRF.
- To identify the subscriber host in the PCRF, the PCRF will use the subscriber host identification information to identify the policy (for the subscriber host) that needs to be submitted to the node. The policy rules can be sent via CCA-i immediately following the initial CCR-i or they can be modified at any time during the subscriber-host lifetime via RAR messages.

Figure 202 Messages Flow During DHCPv4 Host Instantiation Phase

al_0467

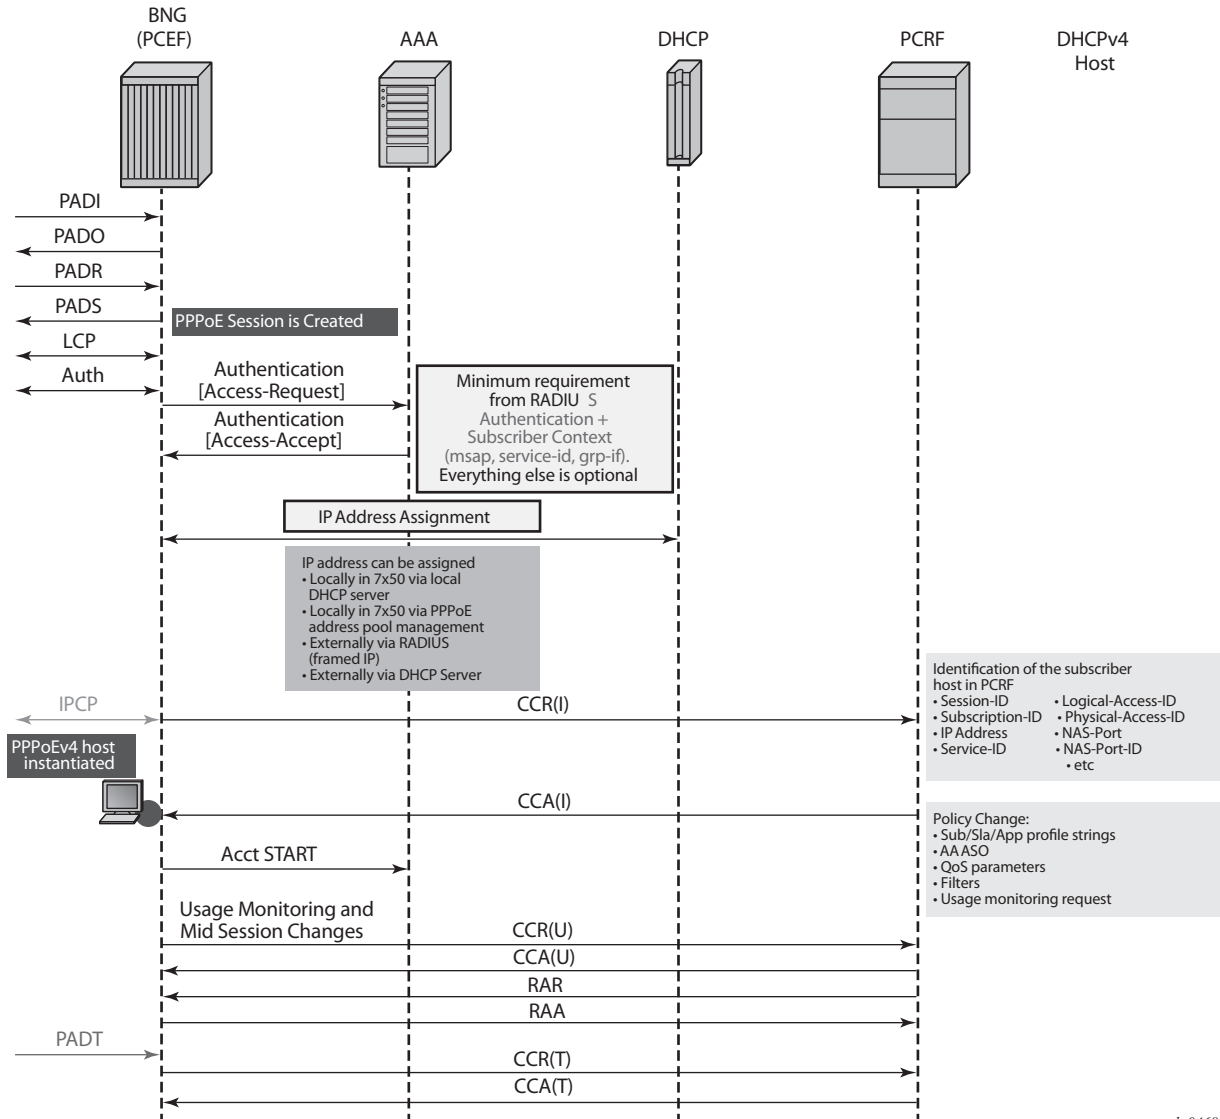

Message flow for PPPoEv4 host is similar. The host will be instantiated once the answer from PCRF is received.

However, IPCP negotiation and Gx negotiation (CCR/CCA) are performed in parallel, independently of each other, and therefore the node will not wait for the Gx session to be established before the last IPCP ConfAck is sent (as it is for DHCP ACK).

Once the host is instantiated on the node (after the CCA-i is received or as defined by the fallback action if the PCRF is not available), the Accounting-Start message will be sent by the node (assuming that accounting is enabled).

The message flow is shown in [Figure 203](#).

Figure 203 Message Flow During PPPoEv4 Host Instantiation Phase

al_0468

The host is created when the Gx session is established and therefore the subscriber host will transition into the traffic forwarding state once the Gx processing is completed. If the PCRF is unavailable or unresponsive, the host creation/termination will be driven by the fallback configuration.

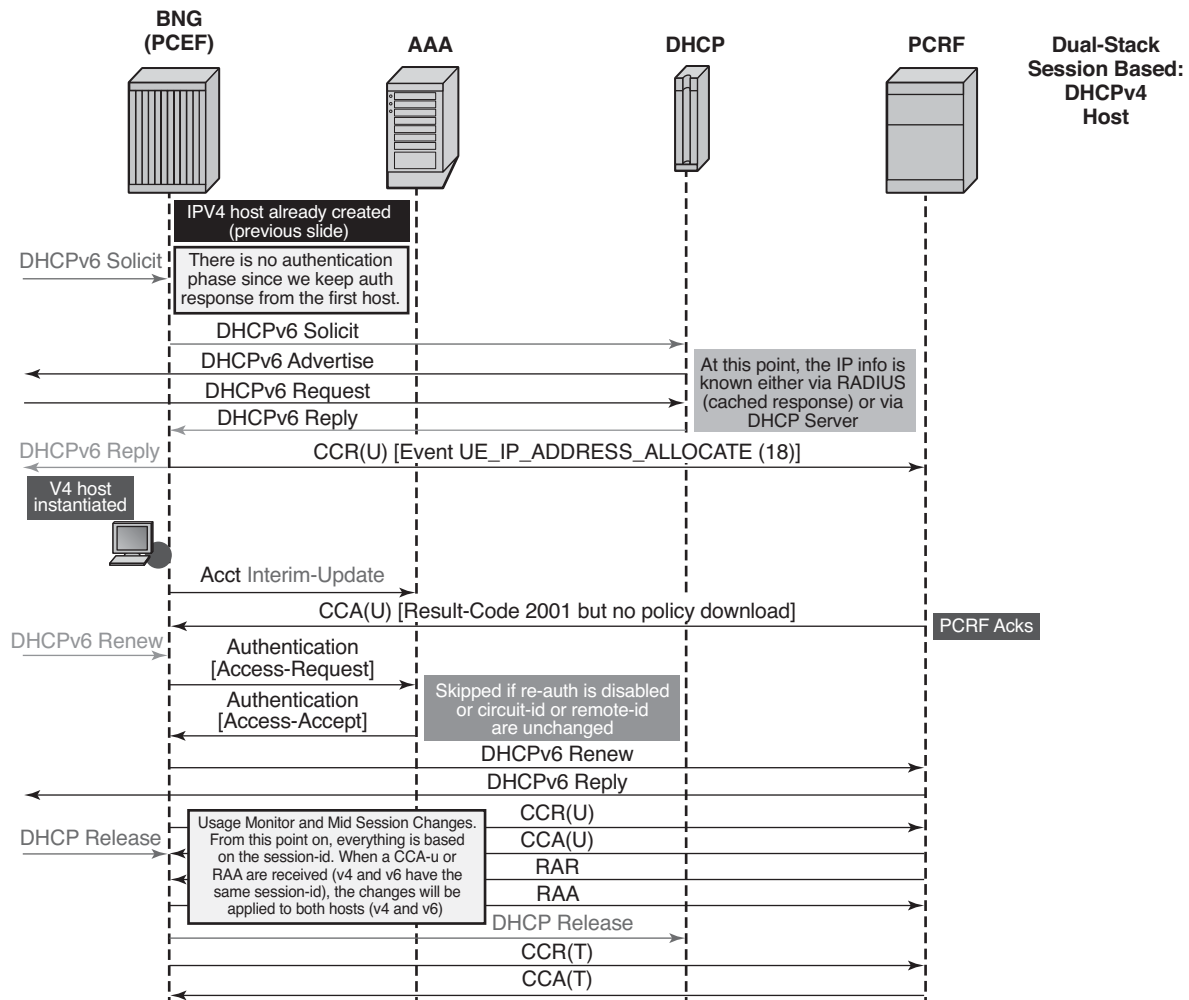

15.5.4.1 Gx and Dual-Stack Hosts

Dual-stack (DS) hosts are treated as a single session from the Gx perspective. The PCRF submits the policy rule that will be applied to DS host as a whole, regardless of the IP address (IPv4 or IPv6) that triggered the CCR-i message. DHCPv4 and DHCPv6 requests for DS host are linked by the same <SAP,MAC> combination which must be unique per system, while with PPPoE, the existing concept of the PPPoE session provides the v4/v6 linking natively.

The CCR-i will contain the IP address that was allocated first (the one that triggered the session creation). The request for the second IP address family will trigger (if enabled by configuration) an additional CCR-u that will carry the IP address allocation update to the PCRF along with the UE_IP_ADDRESS_ALLOCATE (18) event. Apart from that, the CCR-u content will mirror the content of the CCR-i with exception of already allocated IP address(es). There is a single Gx message (CCR-i or CCR-u) carrying the update for DHCPv6 IA-NA+IA-PD and DHCPv6/PPPoE NA+PD address/prefix, assuming that NA+PD is requested in a single DHCP message.

Similarly for the Gx session teardown, CCR-u messages will be sent carrying the UE_IP_ADDRESS_RELEASE event, followed by the CCR-t message.

The message flow is depicted in [Figure 204](#).

Figure 204 Gx and Dual Stack Session Instantiation

al_0469

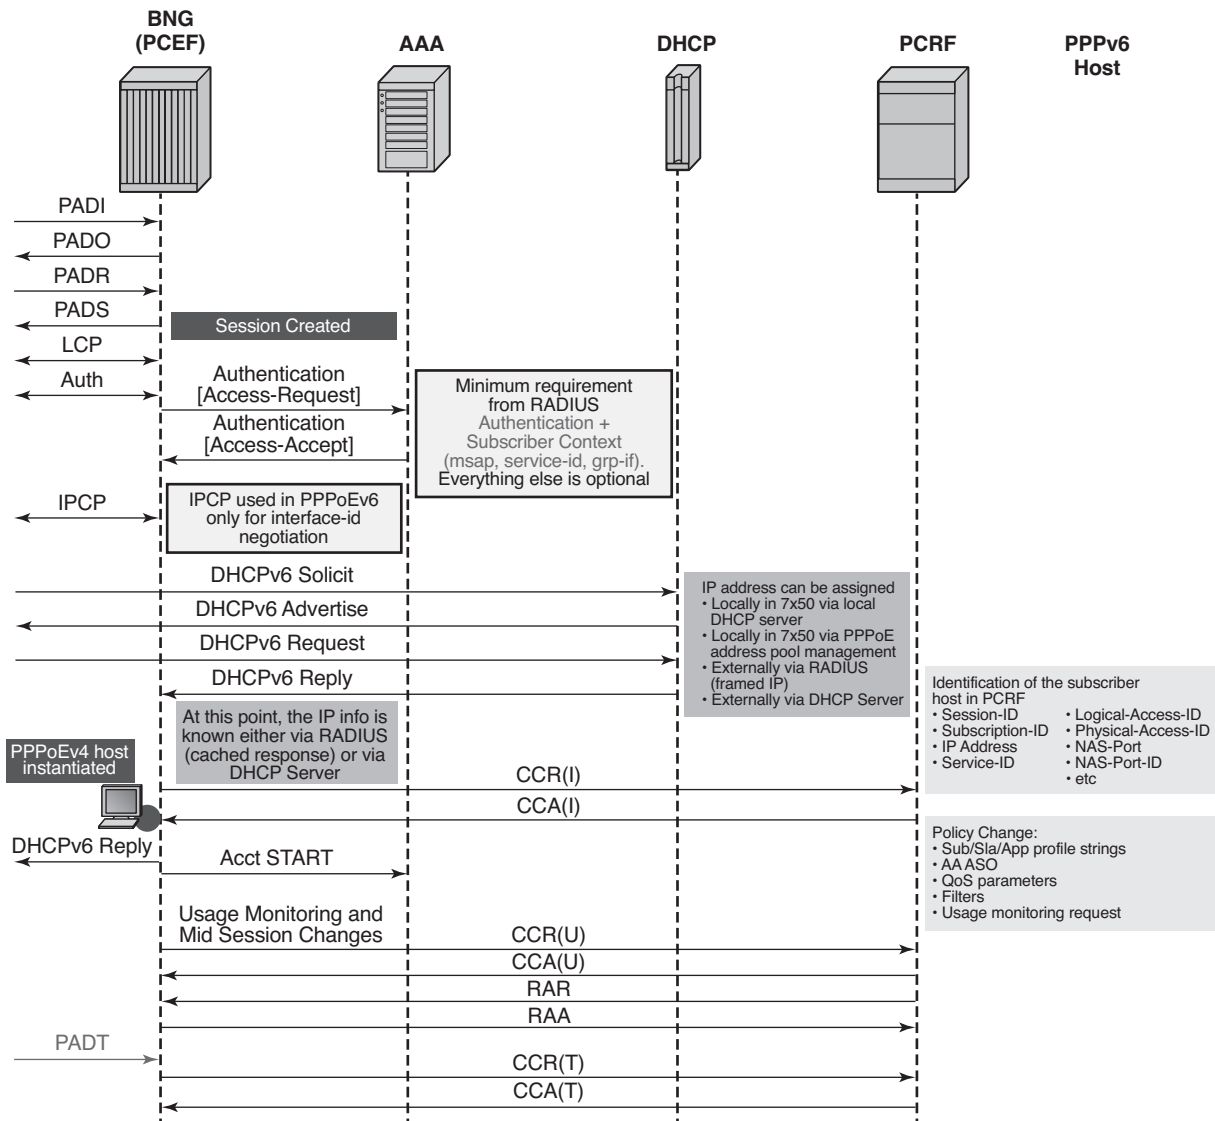

For Dual-Stack PPPoE host, the CCR-i is sent when the first IP address is assigned to the host. In the example in [Figure 204](#), processing of the DHCPv6 Replay and CCR-u messages is performed in parallel. In other words, sending the DHCPv6 Reply message to the client will not be delayed until the response from the PCRF is received. The reason being is that the Gx session is already established (triggered by the IPv4 host in our example) and all parameters for IPv4 and IPv6 are already known as received in CCA-i. Then, the CCR-u message is simply a notification message, informing the PCRF about the new IPv6 address/prefix being assigned to an existing client.

15.5.4.2 Gx and PPPoEv6-DHCP

For PPPoE v6 hosts, the IPv6 address is not obtained during the IPCP phase (only interface-id is negotiated). Then, the node will wait until the IPv6 address/prefix is allocated to the IPv6 hosts before it sends the CCR-I message. Otherwise, the IP address would not be available in CCR-i.

This is shown in [Figure 205](#).

Figure 205 Gx and PPPoEv6 Host Instantiation

al_0470

15.5.5 Gx Fallback Function

The Gx fallback functionality refers to the behavior related to the subscriber host instantiation in situations where the PCRF is unresponsive while peering connection(s) are up or the PCRF is unavailable with all peering connections down. This functionality affects only Gx session processing related to CCR-i messages on the node and has no effect on already established Gx sessions.

The fallback behavior can be controlled via local configuration on the node or can be controlled via certain AVPs provided by PCRF.

PCRF-provided AVPs that control fallback behavior are:

- CC-Session-Failover AVP with the following values:
 - FAILOVER_NOT_SUPPORTED
 - FAILOVER_SUPPORTED
- Credit-Control-Failure-Handling AVP with the following values:
 - TERMINATE
 - CONTINUE
 - RETRY_AND_TERMINATE

If the fallback-related AVPs are not provided via PCRF, the node can provide a local configuration option to define the fallback behavior. If the response from the PCRF cannot be obtained, the local configuration can allow the subscriber host to be instantiated with default parameters, or alternatively the local configuration can deny subscriber host instantiation.

PCRF provided AVPs will overrule local configuration.

The local configuration that defines Gx fallback behavior can be found under the following CLI hierarchy:

```
config
  subscr-mgmt
    diam-appl-plcy
      on-failure
        failover {enabled|disabled}
        handling {continue|retry-and-terminate|terminate}
```

The **failover** configuration option (equivalent to CC-Session-Failover AVP) controls whether the secondary peer will be used in if the primary peer is unresponsive. The unresponsiveness is determined by the timeout of the previously sent message.

The **handling** configuration option (equivalent to Credit-Control-Failure-Handling AVP) controls whether the subscriber will be terminated or instantiated with default parameters if the PCRF is unresponsive.

Table 112 Handling Options

	Handling: CONTINUE	Handling: RETRY-AND-TERMINATE	Handling: TERMINATE
Failover: ENABLED			
Once the message sent to the primary peer times out, the secondary peer (and consecutive peers after that) will be attempted. Once the message times out after it has been sent to all available peers, the HANDLING action will be examined in order to determine whether to terminate the host instantiation attempt or whether to use default parameters to instantiate the host.	Once the message times out after it has been sent to all available peers, the subscriber host will be instantiated with default parameters (if they are configured)	Once the message times out after it has been sent to all available peers, the subscriber host instantiation will be terminated.	Once the message sent to the primary peer times out, the subscriber host instantiation will be terminated.
Failover: DISABLED			
Once the message sent to the primary peer times out, the HANDLING action will be examined in order to determine whether to terminate the host instantiation attempt or whether to use default parameters to instantiate the host.	Once the message sent to the primary server times out, the subscriber host will be instantiated with default parameters (if they are configured)	Once the message sent to the primary peer times out, the subscriber host will be terminated.	Once the message sent to the primary peer times out, the subscriber host will be terminated.

The CCR retransmissions are controlled by the **tx-timer** command under **diameter-application-policy**. Refer to the [9.24](#) for the description of **retransmission** handling.

If all peers are down (no connections are open), the **handling** action will determine the behavior. If the action is set to **continue**, the subscriber-host will be immediately instantiated with the default-settings (provided that the defaults are available). In all other action cases, the host instantiation will be immediately terminated.

15.5.6 Gx CCR-I Replays

As described in the previous section, the subscriber host can optionally be (configuration controlled) established with default settings (sla-profile, sub-profile, app-profile) if the PCRF is not available to answer the CCR-i. This results in a subscriber-host state mismatch between the node and the PCRF, where the subscriber-host is established on the node but there is no corresponding Gx session established in the PCRF.

In order to resolve this situation, ESM periodically sends CCR-i for the Gx *orphaned subscriber-host* until the response from PCRF is received. The CCR-i is periodically retransmitted every 60 seconds.

15.5.7 Gx CCR-t Replays

Termination of the subscriber-host on the node without termination of the corresponding Gx session in PCRF will result in a state mismatch between the node and the PCRF, whereby the host Gx session is present in the PCRF while it is removed from the node

Some PCRFs can cope with such out-of-sync condition by periodically auditing all existing Gx sessions. For example, a **probing** RAR can be sent periodically for each active Gx session. The sole purpose of this probing RAR is to solicit a response from the PCEF (node) and provide indication on whether the corresponding Gx session is alive on the node or is vanished. The 'probing' RAR can contain an Event-Trigger that is already applied on the node, or if none is applied, then the Event-Trigger can contain NO_EVENT_TRIGGER. In either case the 'probing' RAR will not cause any specific action to be taken in the node and it is used only to solicit reply from PCRF.

To minimize the impact on performance, **probing** RARs are sent infrequently and thus it may take days to discover stale Gx session on the PCRF. The node offers a mechanism that can clear the stale session in the PCRF sooner. It does this by re-playing CCR-t messages until the proper response from the PCRF is received (CCA-t). The CCR-t messages will be re-played up to 24 hours. This period of 24 hours is not configurable. In case that 24-hour period expires before the proper answer is received, the CCR-t is deleted and a log is generated. The log contains Gx session-id.

The T-bit (retransmission bit) is set in all re-played CCR-t messages.

The following command will clear all orphaned sessions on the node for a given Diameter application policy:

```
clear subscriber-mgmt diameter-session CCR-t-replay diameter-application-policy <gx-policy-name>.
```

15.5.7.1 RAR and CCR-t Replay

Certain scenarios will make possible that the PCRF sends a RAR message to an orphaned Gx session running CCR-t replays on the node. The ESM host associated with the orphaned Gx session does not exist and therefore RAR cannot be applied.

In this scenario, the node will reply with RAA carrying Result-Code=DIAMETER_UNKNOWN_SESSION_ID (5002).

15.5.7.2 CCR-t Replay And Multi-Chassis Redundancy

The first CCR-t reply for each Gx session will be synchronized, but the consecutive CCR-t replays for the same Gx sessions will not be synchronized. Once the answer (CCA-t) is received, the CCR-t replay will be terminated and this event (deletion of CCR-t replay) will be synchronized to the other node.

CCR-t replays are sent from the node that was in SRRP active state at the time when the CCR-t was initiated. They will continue to be sent from the same node even if the SRRP is switched over in the meantime.

This entire process can be thought of as if the CCR-t initiating node (active SRRP) armed its MCS peer with CCR-t replay for a given Gx session. This occurs at the very beginning, when a CCR-t replay is first initiated for a given Gx session. The armed node will stay silent until the MCS peer that is actively sending CCR-t replays for a given Gx session, reboots. Only when the MCS peer reboots, the armed node will start sending CCR-t replays for a given Gx session in the following fashion: first message is sent with cleared T-bit, followed by replays at the configured replay interval and a fresh 24 hour lifetime.

15.5.7.3 CCR-t Replay And High Availability

On CPM switchover, the newly active CPM will immediately trigger a new CCR-t replay with T-bit set. From then onwards, CCR-t replays will be sent according to the configured replay interval. In other words, the replay interval will be reset on the CPM switchover. However, the lifetime is not reset when CPM switchover occurs, and is synchronized between CPMs.

15.5.8 Automatic Updates for IP Address Allocation/De-allocation

During the subscriber-host setup phase, the first allocated IP address is sent in the CCR-i message from the node to the PCRF.

Each subsequent IP address allocation/de-allocation for the same host can optionally trigger a CCR-u, notifying the PCRF of the IP address allocation/de-allocation event.

This behavior can be enabled via the following CLI command:

```
configure
  subscriber-mgmt
    diameter-application-policy <pol-name>
      gx
        [no] report-ip-addr-event
```

The IP address allocation/de-allocation event driven CCR-u message will carry the respective event code [UE_IP_ADDRESS_ALLOCATE(18) or UE_IP_ADDRESS_RELEASE(19)] along with the corresponding IP address.

The IP address allocation/de-allocation events are applicable to the following addresses:

- Framed-IP-Address (AVP Code 8) IPv4
- Framed-IPv6-Prefix (AVP Code 97) SLAAC
- Delegated-IPv6Prefix (AVP Code 123) IA-PD
- Alc-IPv6-Address (AVP Code 1023) IA-NA

These event-codes will only be sent in CCR-u messages and not in CCR-i and CCR-t messages (when the host is instantiated and terminated).

Examples:

- IPv6 attachment request arrives with two IP addresses: IA-NA and IA-PD. This is a new host. CCR-i will be generated with two IP addresses included (IA-NA and IA-PD, assuming that request for their allocation is carried in the same DHCPv6 message).
- Afterward, the attachment request for an IPv4 address arrives on the same host. CCR-u will be generated with the event `UI_IP_ADDRESS_ALLOCATE` and corresponding AVP (framed-address) will be sent to the PCRF. No IP address other than this new IPv4 address will be sent.
- RAR is received for the (any) policy change. The node will reply with RAA and it will contain all three IP addresses (AVPs) that have been allocated to the host.

If the IP address notification event is enabled, the node-originated Gx message will carry all known IP addresses/prefixes associated with the subscriber-host (Gx session), unless those messages contain one of the two event codes:

`UE_IP_ADDRESS_ALLOCATE(18)` or `UE_IP_ADDRESS_RELEASE(19)`.

If one of those two events is present in the Gx message, the IP address/prefix carried in that message will be only relevant to the event contained in the message (address/prefix allocated or released).

If the IP address notification event is disabled, the node will only send the IP address from the first host. This IP address will be included in all messages related to the Gx session. If this IP address is removed (de-allocated) mid-session from the dual-stack host, the node will stop advertising it, or any other address, from Gx messages for that particular session.

15.5.9 DHCPv4/v6 Re-Authentication and RADIUS CoA Interactions With Gx

If re-authentication for DHCPv4/v6 hosts is enabled, any policy changes that may be submitted during re-authentication (for example sla-profile update via Access-Accept) will overwrite the one previously applied, regardless of the source of the policy update. For example, if that the Gx policy is applied to a subscriber host via RAR (mid-session policy update) and then some time later an overlapping policy with different values is submitted via RADIUS or LUDB during the re-authentication phase, the RADIUS/LUDB submitted policy will overwrite the one applied via Gx. In other words, the origin of the current policy in effect is not maintained internally in the system and therefore the overlapping policy update cannot be prioritized according to the source of the policy.

The following guidelines should be followed if the policy is provided via Gx:

- If LUDB access is enabled, there should be no overlap between the LUDB provided parameters and Gx provided parameters. LUDB is accessed during every DHCP lease renew process and consequently parameters configured via LUDB would overwrite parameters provided by Gx.
- If LUDB access is enabled, there should be no overlap between the LUDB provided parameters and Gx provided parameters. LUDB is accessed during every DHCP lease renew process and consequently parameters configured via LUDB would overwrite parameters provided by Gx.
- If re-authentication is enabled, there should be no overlap between the RADIUS provided parameters and Gx provided parameters. With re-authentication enabled, RADIUS is contacted during every DHCP lease renew process and consequently parameters configured via RADIUS would overwrite parameters provided by Gx.

These guidelines are not applicable for PPPoE subscriber-hosts since re-authentication cannot be enabled for PPPoE hosts. Consequently, LUDB or RADIUS parameters cannot override Gx provided parameters.

Coexistence of RADIUS CoA and Gx for the same host is allowed. The two policy change mechanisms are independent of each other and as such they can override each other. For example, if the RADIUS CoA for policy change for the host is received, the policy will be updated but the PCRF (Gx) will not be notified of the change. If both policy management mechanisms are deployed simultaneously, then it is the operator's responsibility to synchronize the actions between the two.

15.5.10 Gx, ESM and AA

Although the ESM subscriber and the AA subscriber are two separate instantiations on the node, their policy management and Usage-Monitoring are handled uniformly through a single Gx session.

15.5.10.1 ESM Subscriber-host vs AA Subscriber

Since ESM and AA modules are part of integrated service offering (ESM with residential AA on the same node), they share the same subscriber-id string. However, Gx interface in ESM is primarily applicable to hosts (basic entity to which policy is applied) while AA has no awareness of hosts. AA is only aware of subscribers (which is, in broader terms, a collection of hosts within a residence). Refer to the Multiservice Integrated Service Adapter Guide for details on Application Assurance concepts.

15.5.10.2 AA Subscriber State

AA subscriber state must exist for App-profiles and ASO overrides to be applied.

The app-profile for the aa-sub is applied explicitly by a CCR-i or RAR message with an AVP AA-App-Profile-Name.

App-profiles interact with ASO characteristics in this way:

- The AA-App-Service-Options AVP within the app-profile assignment is optional at subscriber instantiation time and may be used later to modify the policy.
- The newly submitted AA-App-Profile-Name AVP will overwrite the one that is already applied. Any ASO AVPs that is received within the Gx message will be applied.

Note: If an app-prof AVP is present, even if it is the same app-profile as currently applied, all previous ASO override policies are removed for the sub.

The state of the subscriber policy attributes is modified by ASO AVPs in this way:

- The app profile can define one or more ASO characteristics attributed to a subscriber

- If there are multiple ASO AVPs for the same characteristic in the message, the first one will take effect.
- There is no explicit delete of ASO overrides (the PCRF can always resend or change the app-profile in order to delete all overrides).

15.5.11 Policy Management via Gx

A policy change can be implicitly requested by the node at IP-Can session establishment time via the CCR-i command. The node will supply user identification attributes to the PCRF so that the PCRF can identify rules to be applied. However, the node will not explicitly request specific policy update, for example via Event-Trigger = RESOURCE_MODIFICATION_REQUEST.

Another way to request a policy update on the node is via the **rar** command in a PUSH model.

Gx policies on the node can be enforced via these three mechanisms:

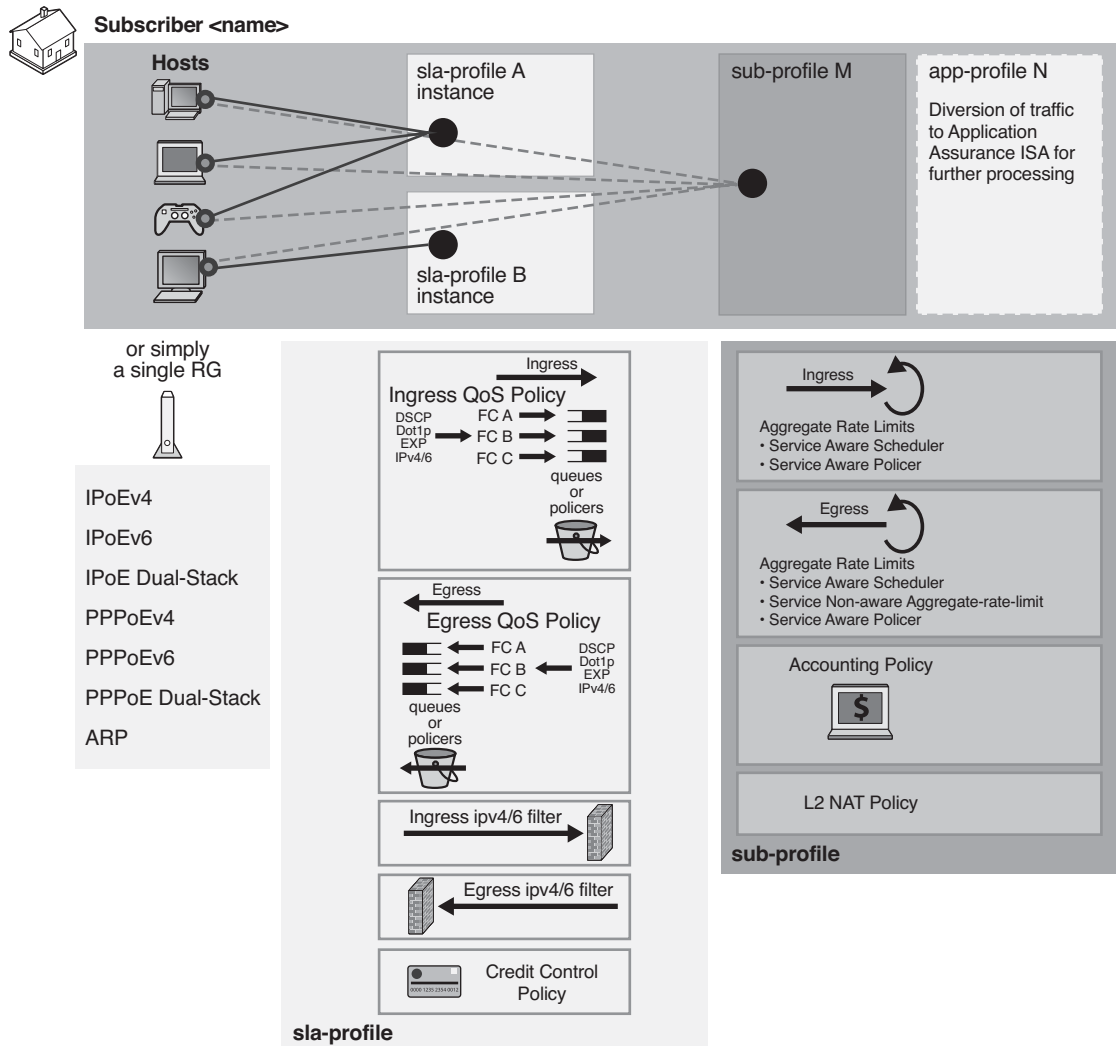

- Gx-based overrides — this refers to subscriber related overrides (sub/sla/aa-profile, subscriber-id, QoS, filter, category-map, etc.).
- PCC rules or IP-criterion based rules which are fully constructed Policy and Charging Control (PCC) rules with multiple qos/filter actions per rule and its own traffic classification.
- NAS filter entry inserts via Gx — basic permit/deny entries, akin to ACL filter entries.

15.5.12 Gx-Based Overrides

Gx-based overrides refer to activation or modification of the existing subscriber-host related objects on the node.

Subscriber-host related objects are shown in [Figure 206](#). A subscriber represents a residence or home and it is identified by Subscriber-Id string on the node. A subscriber on the node can consist of multiple hosts in a bridged home environment or a single host in a routed home environment.

Figure 206 ESM Objects Managed via Various Policies and Profiles

al_0471

The two basic concepts in ESM context are sla-profile with its associated objects and sub-profile with its associated objects.

- Sla-profile defines a service level (rates, queues, filters) for a group of hosts sharing the same sla-profile instance within the subscriber. There can be multiple sla-profile instances per subscriber.
- Sub-profile defines aggregate rate of the subscriber along with accounting policy. There is only one sub-profile per subscriber.

15.5.12.1 Instantiation of Gx Overrides

For a list of Gx related AVPs supported on the node, refer to the Gx AVPs Reference Guide.

Gx overrides are installed via Charging-Rule-Install AVP (for ESM or AA) or ADC-Rule-Install AVP (for AA only – 3GPP Release 11) sent from the PCRF towards the node.

AVP Format:

```
Charging-Rule-Install ::=      < AVP Header: 1001 >
                                * [ Charging-Rule-Definition ]
                                * [ Charging-Rule-Name ]
                                * [ AVP ]

ADC-Rule-Install ::=          < AVP Header: 1092 >
                                * [ ADC-Rule-Definition ]
                                * [ ADC-Rule-Name ]
                                * [ AVP ]
```

Every Gx override must have a Charging-Rule-Name (ESM) or ADC-Rule-Name (AA - 3GPP Release 11 and Release 12) associated with it. This is important in order to return the override status from the node to the PCRF upon the override instantiation.

The objects (subscriber-hosts) to which the new overrides are applied must exist on the node; otherwise, the override installation will fail.

The parameters defining a new override will simply replace the existing parameters that are already applied to the subscriber-host, without the need to remove the previously installed parameters.

There are four types of overrides that are currently supported via Gx:

- ESM string overrides (sla/sub/app-profiles, subscriber-id, etc.)
- Update of subscriber host QoS information (queue rate change, etc.)
- Filter override for the subscriber host (including one-time http redirect)
- Category-map installation/override
- HTTP redirect override within the filter.

A Charging-Rule-Name AVP within the Charging-Rule-Install grouped AVP can have several meanings.

- It can directly reference a preconfigured filter in the system.
- It can directly reference a preconfigured subscriber profile (sla and sub).
- It can directly reference a preconfigured category map.

- It can directly reference an ESM string (such as an inter-destination-string used to associate the subscriber host with a vPort construct).
- Or, if there is an HTTP redirect override, it serves as a special container within which the HTTP redirect URL is defined. Note that HTTP redirect override is not to be confused with PCC rule-based HTTP redirect.

In all of the above cases, the existing objects applied to the subscriber-host will be replaced with the referenced object.

It is important to distinguish two locations for invoking the Charging-Rule-Name AVP for overrides:

1. Directly under the Charging-Rule-Install AVP – Then, the Charging-Rule-Name will reference the predefined structures (profiles, filter-ids, cat-maps, and so on) on the node. The type of the structure is contained within the Charging-Rule-Name AVP in the form of a reserved keyword that has to be prepended to the identifier of structure:

Filter installation/overrides:

- Charging-Rule-Name = Ingr-v4:<id>
- Charging-Rule-Name = Ingr-v6:<id>
- Charging-Rule-Name = Egr-v4:<id>
- Charging-Rule-Name = Egr-v6:<id>
- Charging-Rule-Name = In-Othr-v4:<id> (othr - one-time-http-redirect)
- Charging-Rule-Name = In-Othr-v6:<id> (othr - one-time-http-redirect)

Subscriber-Id override:

- Charging-Rule-Name = Sub-Id:sub-id-string

Profile installation/overrides:

- Charging-Rule-Name = Sla-Profile:sla-profile-name
- Charging-Rule-Name = Sub-Profile:sub-profile-name

Inter-destination string override:

- Charging-Rule-Name = Inter-Dest:inter-dest-string

Usage-Monitoring:

- Charging-Rule-Name = Cat-Map:category-map-name

AA:

- Charging-Rule-Name = AA-UM:<string-name>
- Charging-Rule-Name=AA-Functions:<string-name>

In summary, the reserved prefixes “ingr-v4:”, “ingr-v6:”, “egr-v4:”, “egr-v6:”, “in-othr-v4:”, “in-othr-v6:”, “sub-id:”, “sla-profile:”, “sub-profile:”, “inter-dest:”, “cat-map:”, “aa-um:” and “aa-functions:” have special meaning within the Charging-Rule-Name AVP on the node.

One exception to this is HTTP redirect override, which is described separately.

2. Under the Charging-Rule-Install — Charging-Rule-Definition AVP. In this case, the override itself is not pre-provisioned on the node but instead, directly defined in the Charging-Rule-Definition. Part of the override definition is the name assignment via Charging-Rule-Name AVP. The Charging-Rule-Name AVP is used to report on the override status.

For example, the Charging-Rule-Name AVP for QoS overrides is an arbitrary name. This AVP is part of Charging-Rule-Definition AVP in which QoS-Information is provided. Such Charging-Rule-Name is used to report errors related to instantiation of the override.

Another example of the override defined within the Charging-Rule-Definition AVP is HTTP redirect override:

```
Charging-Rule-Name = v4-http-url:<name>
Redirect-Information ::= < AVP Header: 1085 >
```

```
[ Redirect-Address-Type ]
[ Redirect-Server-Address ]
```

and

```
Charging-Rule-Name = v6-http-url:<name>
Redirect-Information ::= < AVP Header: 1085 >
[ Redirect-Address-Type ]
[ Redirect-Server-Address ]
```

The ADC-Rule-Name AVP within the ADC-Rule-Install grouped AVP handles application policy related processing (AA). This AVP is applicable under the ADC-Rule-Install—ADC-Rule-Definition AVP. In this case the ADC rule itself is not pre-provisioned on the node but instead directly defined in the ADC-Rule-Definition. In AA, such rule definition can define AA overrides that will be applied to the subscriber. In other words, the existing objects for the subscriber will be replaced with the ones referenced in the rule. Part of the ADC rule definition is the ADC rule name assignment via ADC-Rule-Name AVP. The ADC-Rule-Name defined in such manner is used to report on the rule status.

The AA-Functions: prefix in the ADC rule name is reserved for ADC rule definitions applicable to AA-functions (namely, app-profile and ASOs):

ADC-Rule-Name = AA-Functions:aa-rule-name

Then the aa-rule-name is an arbitrary name that will be used in rule status reporting.

If that ADC-Rule-Name is used in AA Usage-Monitoring, the “AA-Functions:” prefix must not be present (Usage-Monitoring in AA is covered in details in the 7450 ESS and 7750 SR Multiservice Integrated Service Adapter Guide).

Note: AA-Function AVP and AA-Usage-Monitoring cannot co-exist in the same ADC rule.

The Charging-Rule-Definition AVP (AVP code 1003, 3GPP 29.212 §5.3.4) is of type Grouped, and it defines the override sent by the PCRF to the node.

The Charging-Rule-Name in this AVP can be arbitrarily set and it is used to uniquely identify the override in error reporting.

```
Charging-Rule-Definition ::= < AVP Header: 1003 >
    { Charging-Rule-Name }
    [ QoS-Information ]
    [ Nas-Filter-Rule]
    [ Alc-NAS-Filter-Rule-Shared]
    *[ AVP ]
```

The ADC-Rule-Definition AVP (AVP code 1094, 3GPP 29.212 §5.3.87) is of type Grouped, and it defines the ADC override sent by the PCRF to the node. The ADC-Rule-Name AVP within the ADC-Rule-Definition AVP uniquely identifies the ADC policy rule and it is used to reference to a policy rule in communication between the node and the PCRF within one IP CAN session.

```
ADC-Rule-Definition ::= < AVP Header: 1094 >
    { ADC-Rule-Name }
    [AA-Functions]
    *[ AVP ]
```

15.5.12.2 HTTP Redirect Override

HTTP redirect override submitted via the Gx interface will override the current URL string defined in the filter that is currently applied to the subscriber-host.

The override is implemented through the standard Redirect-Information AVP nested within the Charging-Rule-Definition (CRD) AVP.

IPv4

```
Charging-Rule-Install
  Charging-Rule-Definition
    Charging-Rule-Name = v4-http-url:<name>
    Redirect-Information ::= < AVP Header: 1085 >
      [ [ Redirect-Address-Type ]
        [ [ Redirect-Server-Address ]
```

IPv6

```
Charging-Rule-Install
  Charging-Rule-Definition
    Charging-Rule-Name = v6-http-url:<name>
    Redirect-Information ::= < AVP Header: 1085 >
      [ Redirect-Address-Type ]
      [ Redirect-Server-Address ]
```

The keywords **v4-http-url** and **v6-http-url** are special keywords that must be part of the CRN AVP. These keywords can be followed by an arbitrary string *name*.

The purpose of the <name> string in the Charging-Rule-Name (CRN) AVP is for the PCRF to differentiate between different HTTP redirect overrides. However, the *name* string in the context of the **http url host override** command in a filter has no meaning on the node, and therefore it is ignored. This means that there can be only one HTTP redirect override per host and per address family on a node.

The outcome of this Gx directive (Redirect-Information AVP without the Flow-Information AVP within the Charging-Rule-Definition AVP) is the override of the HTTP redirect URL in the currently applied subscriber-host filter. The filter definition must explicitly allow overrides via the **allow-radius-override** keyword.

As long as the override rule is present in the system (meaning, it has been submitted via the Gx and has not been explicitly removed since), the override will try to enforce itself when both of the following two conditions are met:

- A filter with the action **http-redirect** is applied to the subscriber-host. This is valid whether the filter was there when the rule was submitted, or whether the filter was applied after the rule was submitted.

- The filter definition allows **http-redirect** overrides (filter with the **allow-radius-override** keyword).

If the above conditions are not met, the override will be accepted (the node will respond with RAA=OK) and stored by the system, although it will not be applied until the above conditions are met.

For the HTTP URL host, the CRD directive must not contain any flow information or any other action besides the Redirect-Information AVP. Otherwise, the Diameter encoding will fail and an error response will be generated for RAR while CCR-I will be silently dropped.

15.5.12.3 Removal of Overrides

With the exception of HTTP redirect override, overrides cannot be removed by the Charging-Rule-Remove AVP. They can only be overridden, and consequently the Charging-Rule-Remove AVP is ignored. It is ignored only for regular overrides and not for PCC rules (see [PCC Rules](#)) or for HTTP redirect override.

An HTTP redirect override can be removed whether it is active (a filter with HTTP redirect action is applied) or inactive (a filter without HTTP redirection is applied).

```
Charging-Rule-Remove ::= < AVP Header: 1002 >  
    Charging-Rule-Name = v4-http-url:<name>  
    Charging-Rule-Name = v6-http-url:<name>
```

The *name* string in the CRN AVP is ignored in the context of HTTP redirect override. This means that the removal of HTTP redirect override with any name will remove the currently installed HTTP redirect override.

Similarly, the installation of the HTTP redirect override will replace any currently installed HTTP redirect override, regardless of the *name* string (implicit removal of the current HTTP redirect override, followed by the installation of the new one).

The node will reply with RAA=OK if a properly formatted Charging-Rule-Remove directive with any name is received for HTTP redirect override.

15.5.12.4 Examples of Gx Overrides

The instantiation of HTTP redirect overrides via the Gx can be summarized as:

- The Central AVP for the Gx overrides in SR OS is the Charging-Rule-Install AVP. Multiple overrides can be submitted to a node via a single Charging-Rule-Install AVP, or each Gx override can be submitted via its own Charging-Rule-Install AVP.
- Gx override is identified by the Charging-Rule-Name AVP. This AVP is also used to report on the status of Gx override. The Charging-Rule-Name can reference a pre-configured construct on the node (profiles, cat-maps, filters) or it can be assigned by PCRF to identify the PCRF defined override (QoS policy modifications, HTTP redirect AA ASO modifications, and so on).
- With the exception of the HTTP redirect override, overrides cannot be removed by the Charging-Rule-Remove AVP. They can only be overridden. The Charging-Rule-Remove AVP is ignored for Gx overrides.

The following is an example of Gx override instantiation where all Gx overrides are submitted under a single Charging-Rule-Install AVP. The AVPs in this example can be included in the CCA-i, CCA-u or RAR messages sent from the PCRF.

The outcome of the override is the following:

- The subscriber-id will be overridden with the new name 'residence-1'.
- New ingress v4 and egress v6 filters will be installed.
- New sub-profiles and sla-profiles will be applied to the subscriber host.
- The subscriber host will be associated with the vPort named *vport-AN-1*.
- The existing HTTP redirect URL will be overwritten with a new one.
- Characteristics for queue 5 and 7 will be overridden.
- The egress rate limit for the subscriber will be overridden.
- ASOs will be overridden.

```
Charging-Rule-Install ::= <AVP Header: 1001>
Charging-Rule-Name <AVP Header: 1005> = "sub-id:residence-1"
Charging-Rule-Name <AVP Header: 1005> = "ingr-v4:7"
Charging-Rule-Name <AVP Header: 1005> = "eggr-v6:5"
Charging-Rule-Name <AVP Header: 1005> = "Sub-Profile:prem"
Charging-Rule-Name <AVP Header: 1005> = "Sla-Profile:voip+data"
Charging-Rule-Name <AVP Header: 1005> = "Inter-Dest:vport-AN-1"

Charging-Rule-Definition <AVP Header: 1003>
Charging-Rule-Name <AVP Header: 1005> "v4-http-url:http-redir-1"
Redirect-Information < AVP Header: 1085 >
  Redirect-Address-Type < AVP Header: 433 > = 2 -> URL type
```

```

Redirect-Server-Address < AVP Header: 435 > =
"http://www.operator.com/portal.php?mac=$MAC"

Charging-Rule-Definition <AVP Header: 1003>
Charging-Rule-Name <AVP Header: 1005> = "premium-service"
QoS-Information <AVP Header: 1016>
Alc-Queue <AVP Header; vnd ALU; 1016>
Alc-Queue-id <AVP Header; vnd ALU; 1007> = 5
Max-Requested-Bandwidth-UL <AVP Header: 516> = 10000
    Max-Requested-Bandwidth-DL <AVP Header: 515> = 100000
    Guaranteed-Bitrate-UL <AVP Header: 1026> = 5000
    Guaranteed-Bitrate-DL <AVP Header: 1027> = 50000
Alc-Committed-Burst-Size-UL <AVP Header; vnd ALU; 1008> = 1000
Alc-Maximum-Burst-Size-UL <AVP Header; vnd ALU; 1009> = 2000
Alc-Committed-Burst-Size-DL <AVP Header; vnd ALU; 1010> = 1000
Alc-Maximum-Burst-Size-DL <AVP Header; vnd ALU; 1011> = 2000

Alc-Queue <AVP Header; vnd ALU; 1006>
Alc-Queue-id <AVP Header; vnd ALU; 1007> = 7
Max-Requested-Bandwidth-UL <AVP Header: 516> = 10000
    Max-Requested-Bandwidth-DL <AVP Header: 515> = 100000
    Guaranteed-Bitrate-UL <AVP Header: 1026> = 5000
    Guaranteed-Bitrate-DL <AVP Header: 1027> = 50000
Alc-Committed-Burst-Size-UL <AVP Header; vnd ALU; 1008> = 1000
Alc-Maximum-Burst-Size-UL <AVP Header; vnd ALU; 1009> = 2000
Alc-Committed-Burst-Size-DL <AVP Header; vnd ALU; 1010> = 1000
Alc-Maximum-Burst-Size-DL <AVP Header; vnd ALU; 1011> = 2000

Alc-Sub-Egress-Rate-Limit <AVP Header; vnd ALU; 1016> = 10000

ADC-Rule-Install ::= <AVP Header: 1092>
ADC-Rule-Definition <AVP Header: 1094>
ADC-Rule-Name <AVP Header: 1096> = "AA-Functions:apps"
AA-Functions
AA-App-Profile-Name = "apps-prof"
AA-App-Service-Options
AA-App-Serv-Options-Name = "bittorrent"
AA-App-Serv-Options-Value = "low-prio-1mbps"
AA-App-Service-Options
AA-App-Service-Options-Name = "ftp"
AA-App-Service-Options-Value = "hi-prio"

```

In the following example, all Gx overrides are submitted via a separate Charging-Rule-Install AVP:

```

Charging-Rule-Install ::= <AVP Header: 1001>
    Charging-Rule-Name <AVP Header: 1005> = "sub-id:residence-1"

Charging-Rule-Install ::= <AVP Header: 1001>
    Charging-Rule-Name <AVP Header: 1005> = "ingr-v4:7"

Charging-Rule-Install ::= <AVP Header: 1001>
    Charging-Rule-Name <AVP Header: 1005> = "eggr-v6:5"

```

```

Charging-Rule-Install ::= <AVP Header: 1001>
    Charging-Rule-Name <AVP Header: 1005> = "Sub-Profile:prem"

Charging-Rule-Install ::= <AVP Header: 1001>
    Charging-Rule-Name <AVP Header: 1005> = "Sla-Profile:voip+data"

Charging-Rule-Install ::= <AVP Header: 1001>
    Charging-Rule-Name <AVP Header: 1005> = "Inter-Dest:Gx-inserted-string"

Charging-Rule-Install ::= <AVP Header: 1001>
    Charging-Rule-Definition <AVP Header: 1003>
        Charging-Rule-Name <AVP Header: 1005> = "v4-http-url:http-redir-1"
        Redirect-Information < AVP Header: 1085 >
            Redirect-Address-Type < AVP Header: 433 > = 2 ? URL type
            Redirect-Server-Address < AVP Header: 435 > =
                "http://www.operator.com/portal.php?mac=$MAC"
Charging-Rule-Install ::= <AVP Header: 1001>
    Charging-Rule-Definition <AVP Header: 1003>
        Charging-Rule-Name <AVP Header: 1005> = "premium-service"
        QoS-Information <AVP Header: 1016>
            Alc-Queue <AVP Header; vnd ALU; 1016>
                Alc-Queue-id <AVP Header; vnd ALU; 1007> = 5
                Max-Requested-Bandwidth-UL <AVP Header: 516> = 10000
                Max-Requested-Bandwidth-DL <AVP Header: 515> = 100000
            Guaranteed-Bitrate-UL <AVP Header: 1026> = 5000
            Guaranteed-Bitrate-DL <AVP Header: 1027> = 50000
            Alc-Committed-Burst-Size-
                UL <AVP Header; vnd ALU; 1008> = 1000
                Alc-Maximum-Burst-Size-UL <AVP Header; vnd ALU; 1009> = 2000
                Alc-Committed-Burst-Size-DL <AVP Header; vnd ALU; 1010> = 1000
                Alc-Maximum-Burst-Size-DL <AVP Header; vnd ALU; 1011> = 2000

                Alc-Queue <AVP Header; vnd ALU; 1006>
                    Alc-Queue-id <AVP Header; vnd ALU; 1007> = 7
                    Max-Requested-Bandwidth-UL <AVP Header: 516> = 10000
                    Max-Requested-Bandwidth-DL <AVP Header: 515> = 100000
                    Guaranteed-Bitrate-UL <AVP Header: 1026> = 5000
                    Guaranteed-Bitrate-DL <AVP Header: 1027> = 50000
                    Alc-Committed-Burst-Size-
                        UL <AVP Header; vnd ALU; 1008> = 1000
                        Alc-Maximum-Burst-Size-UL <AVP Header; vnd ALU; 1009> = 2000
                        Alc-Committed-Burst-Size-DL <AVP Header; vnd ALU; 1010> = 1000
                        Alc-Maximum-Burst-Size-DL <AVP Header; vnd ALU; 1011> = 2000

                        Alc-Sub-Egress-Rate-Limit <AVP Header; vnd ALU; 1016> = 10000

ADC-Rule-Install ::= <AVP Header: 1092>
    ADC-Rule-Definition <AVP Header: 1094>
        ADC-Rule-Name <AVP Header: 1096> = "AA-Functions:apps"
        AA-Functions
            AA-App-Profile-Name = "apps-prof"
            AA-App-Service-Options
                AA-App-Service-Options-Name = "bittorrent"
                AA-App-Service-Options-Value = "low-prio-1mbps"
            AA-App-Service-Options
                AA-App-Service-Options-Name = "ftp"
                AA-App-Service-Options-Value = "hi-prio"

```

Gx overrides (QoS rates, sub/sla-profiles, filters, etc.) can be examined individually with subscriber specific operational commands. In the example below, fields in bold can be overridden.

15.5.13 PCC Rules

A generic use case for flow-based dynamic policy is related to customized network level treatment of on-demand services. Such services can represent a wide range of applications, such as video-on-demand or access to a specific application in the network. The service can be identified by traffic destination parameters or DSCP bits. Once the service is identified, a set of actions can be applied to the service (rate change, forwarding-class change, Usage-Monitoring, and so on).

Figure 207 Generic Use Case For IP Criterion-Based Policy Change via Gx

al_0778

Typical flow of events for service activation is shown in [Figure 207](#):

1) An established user subscribes to a service in the network via a Web portal at any given time.

2) Once the authentication/payment is accepted, the back end (for example, the Web portal integrated in OSS) identifies the service and submits the parameters defining the network delivery of the offered service to the PCRF.

3) The PCRF converts those parameters into rules and submits those rules to the subscriber-host on the BNG via the Gx. The rules identify the service on the network level (destination IP@ and port) along with the desired action.

4) [and 5) and 6)] Before the service can be started, the action of individual policy management elements must be acknowledged to ensure that the resources for the service delivery are available and instantiated before the service is delivered to the subscriber.

7) The service traffic can be started from the subscriber side. Network requirements for the successful service delivery will be enforced on a per flow/DSCP basis as defined by the PCC rule.

15.5.13.1 PCC Rule Concept

A PCC rule consists of traffic classifiers (Flow-Information AVPs) required for traffic identification, and one or more actions associated with such classified traffic. PCC rules are unidirectional, which means that each rule is applied on ingress or egress. They are provisioned from PCRF via Gx interface.

Traffic classification is based on:

- 5 Tuple (IPv4 and IPv6)
- DSCP bits. When the content hosting device cannot be identified by the IP address, port and protocol, the DSCP marking can be used instead. Then, the DSCP marking will be set by the client application and the markings should be preserved throughout the network until they reach the BNG.

Supported actions are:

- Rate limiting (in | out)
- Forwarding Class (FC) change (in | out)
- QoS forward (in | out)
- Next-hop redirect (in)
- Service-Id redirect (in)
- HTTP redirect (in)
- Service gating function (in | out)
- Filter forward/drop (in | out)

- Usage-Monitoring (in | out)

15.5.13.2 PCC Rule Instantiation

A PCC rule that is submitted to the node via PCRF is internally instantiated using two basic policy constructs, QoS policy and filter policy (ACL). This internal division is transparent to the operator at the time of the rule provisioning. The operator perceives Gx as a unified method for provisioning policy rules, whether the rule is QoS-related or filter-related.

The type of action within the PCC rule will determine whether the PCC rule is split between the QoS policy and the filter policy.

Rules with actions:

- Rate limit
- Forwarding class change
- QoS forward — Matching traffic is forwarded without QoS actions and will not match on the next entry (match and exit behavior). This is equivalent to a *white-list* entry.
- Usage-Monitoring

will be converted into a **qos-policy** while the rules with actions:

- Next hop redirect
- Service ID redirect
- HTTP redirect
- Gate Function (enable/drop)
- Filter forward/drop

will be converted into **filter** rules.

The operator should be aware of this division for dimensioning (scaling) purposes. Operational commands can be utilized to reveal resource consumption on the node.

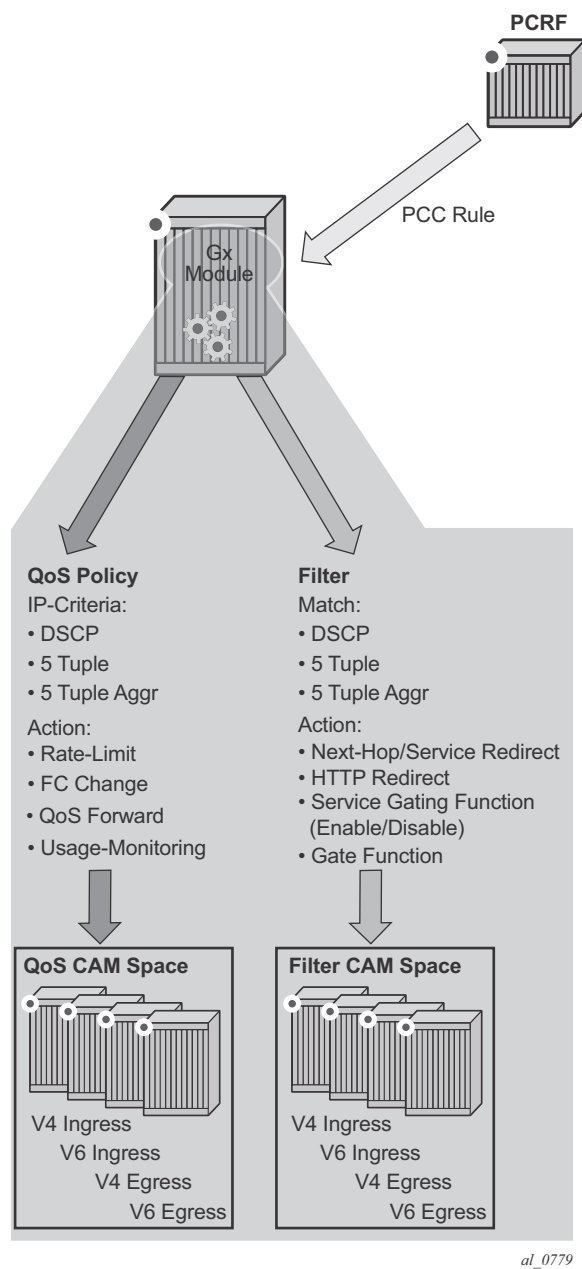

A PCC rule is addressed to a subscriber-host (single stack or dual stack) via the diameter session-id. However, qos-policy-related entries are applied per sla-profile instance since the qos resources are allocated per sla-instance. An sla-profile instance and sla-profile are two distinct concepts. An sla-profile instance is an instantiation of the sla-profile which is a configuration concept in which parameters are defined. An sla-profile is instantiated per a subscriber-host, or multiple subscriber-hosts can share an sla-profile instance as long as they belong to the same SAP and have the same subscriber ID.

This means that all hosts sharing the same sla-profile instance will inherit the change. The **sla-profile instance** and **sla-profile** are two distinct concepts. The **sla-profile instance** is an instantiation of the **sla-profile** which is a configuration concept in which parameters are defined. The **sla-profile** is instantiated per a subscriber-host, or multiple subscriber-hosts can share an **sla-profile instance** as long as they belong to the same SAP and have the same subscriber-id.

Filter-related entries are applied per each subscriber-host, whether the hosts are sharing or not sharing an sla-profile instance.

The concept of splitting the rules is shown in [Figure 208](#).

Figure 208 PCC Rule Conversion on the Node

The PCC rule instantiation will fail if a PCC rule contains only actions without any classification, or if it contains only classification without any actions.

15.5.13.3 Base QoS-Policy and Base Filter

Subscriber host must have an explicit static (or base) filter or qos-policy before any dynamic entries can be inserted via Gx. For example, a base filter/qos-policy can be referenced by a sla-profile when the subscriber is instantiated. However, the parameters in the base qos-policy and base filter cannot be modified via Gx.

In the absence of explicitly defined qos-policy for the subscriber host, the default **qos-policy 1** will be in effect. Then, PCC rules with qos related action cannot be applied.

PCC rule entries can be inserted in specifically allocated range in the base filter or qos-policy. The insertion point is controlled by the operator. This is shown in [Figure 209](#). The entries reserved for PCC rules start at the beginning of the range specified by the following CLI command:

```
sub-insert-shared-pccrule start-entry <entry-id> count <count>
```

under the following CLI hierarchy:

```
configure>filter>ip-filter>  
configure>filter>ipv6-filter  
configure>qos>sap-ingress>  
configure>qos>sap-egress>
```

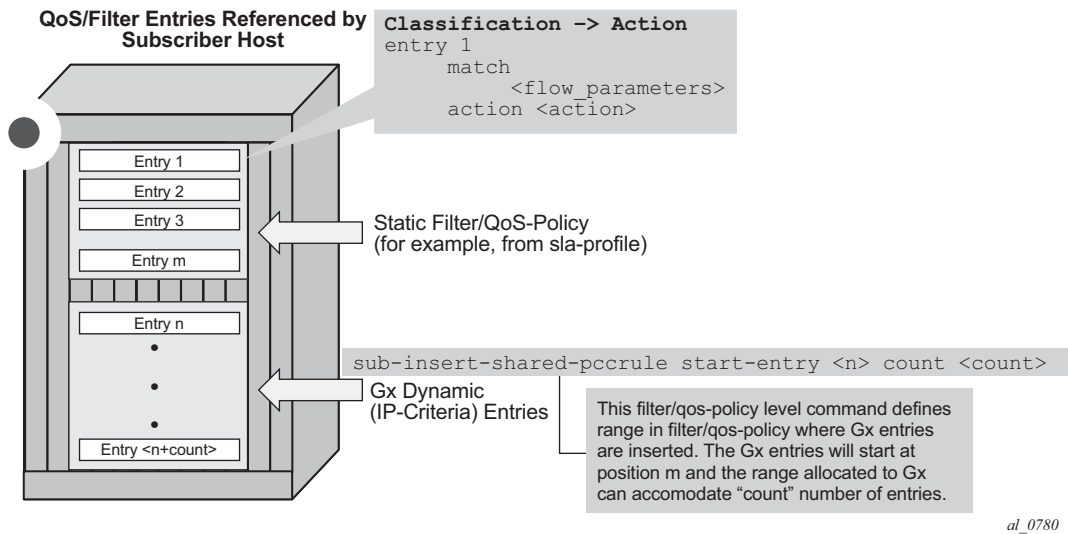

An entry corresponds to a Flow-Information AVP and is equivalent to a match condition defined as any combination of the following parameters under a filter or **qos-policy ip-criteria**:

- source IP address
- destination IP address
- source port or port range
- destination port or port range
- protocol
- DSCP

Such defined entry will map into a single CAM entry with exception of port range configured as match criteria whereby a single port range command can expand into multiple CAM entries.

Static entries in filter/qos-policy can be inserted before and after the range reserved for PCC rules.

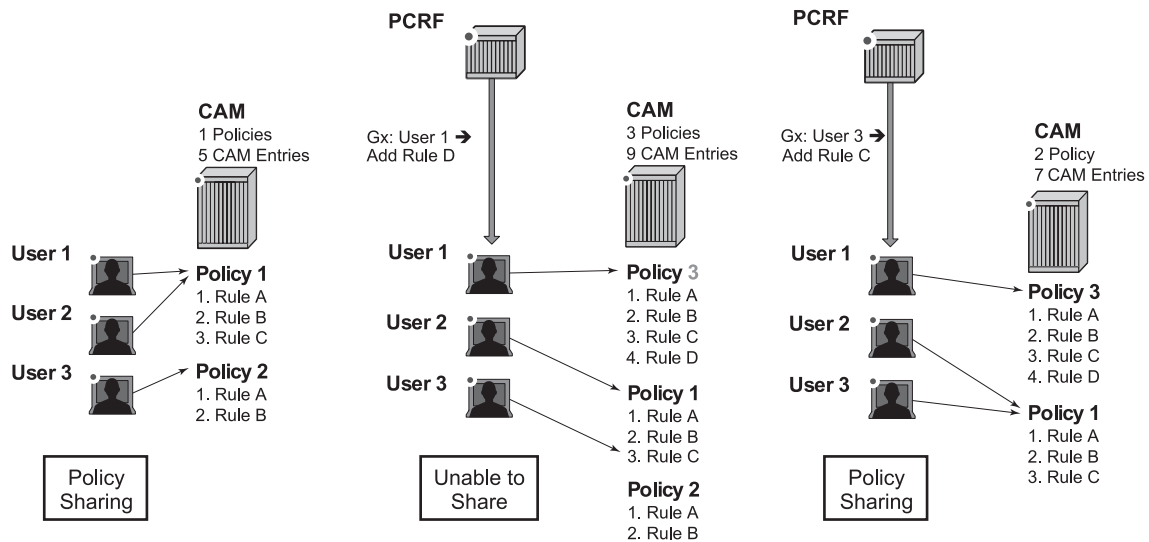

Figure 209 Static and Dynamic QoS-Policy/Filter Entries

15.5.13.4 Generic Policy Sharing and Rule Sharing

Policy (defined in this context as a collection of static and dynamic rules) sharing between the subscriber hosts is depicted in [Figure 210](#). In order to simplify CAM scaling explanations, the examples in this section assume that one rule within the policy occupies exactly one CAM entry. For simplicity, only PCC rules are shown but in reality a subscriber-host policy consist of PCC rules together with the base qos-policy/filter.

A policy, as a set of rules, can be shared amongst the subscriber-hosts. However, when a new rule is added to one of the subscriber-host, the newly created set of rules for this host becomes unique. Hence, a new policy for the subscriber-host will be instantiated. This new policy will consume additional resources for all the old rules (clone of the old policy) along with the new rule. Figure below shows that a new policy (3) is instantiated when rule D is added to User 1, even though the rules A, B and C remain the same for Users 1 and 2. Policy 3 is a newly cloned with the same rules as Policy 1, and then Rule D is added onto it. On the other hand, when the rule C is applied to User 3, the set of rules becomes identical to the set of rules for User 2. Thus the two can start sharing rules and therefore the resources are freed.

Figure 210 Policy Cloning

al_0788

15.5.13.5 PCC Rule Name and PCC Rule Removal

Each PCC rule has a subscriber-host scope and it is referred to it by its name which is assigned by the operator on PCRF. The rules with exactly the same content but different rule names are evaluated into separate rules. To optimize performance and maximize scale, it is recommended that the rules sharing the same content have the same name (as provisioned in the PCRF).

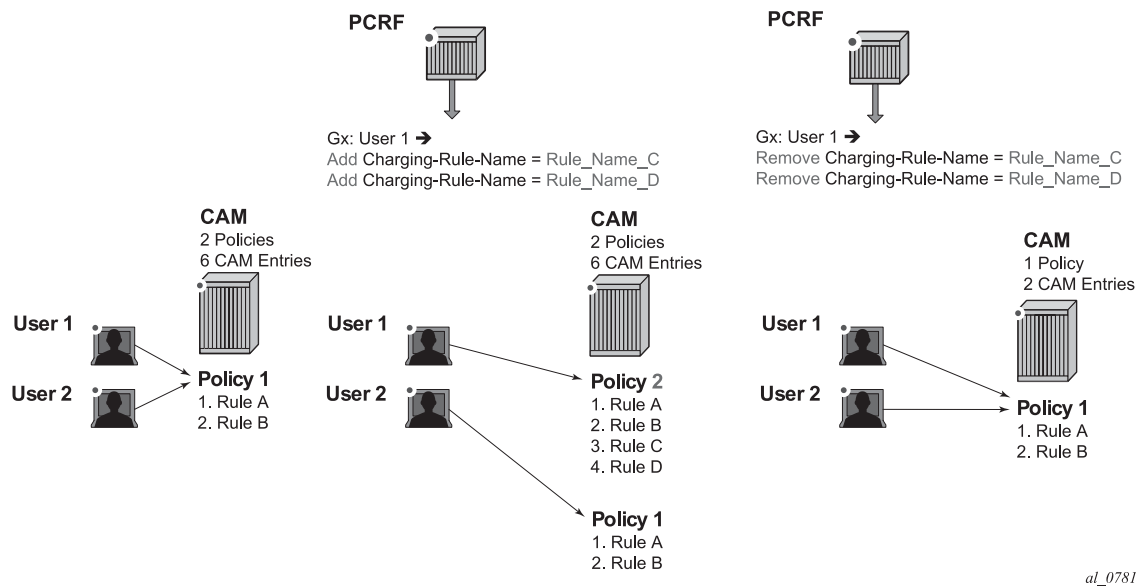

PCC rules can be removed from the node via a Gx directive by referencing the PCC rule name. The rule name is supplied via the Charging-Rule-Name AVP at the time of the rule submission to the node by the PCRF. There is no Gx mechanism that would remove all PCC rules at once. Each PCC rule must be removed individually.

The AVP used to remove the rule from the node is:

```
Charging-Rule-Remove ::= < AVP Header: 1002 >
                        *[ Charging-Rule-Name ]
```

An example of rule instantiation and rule removal is shown in [Figure 211](#).

Figure 211 Policy Removal by Name

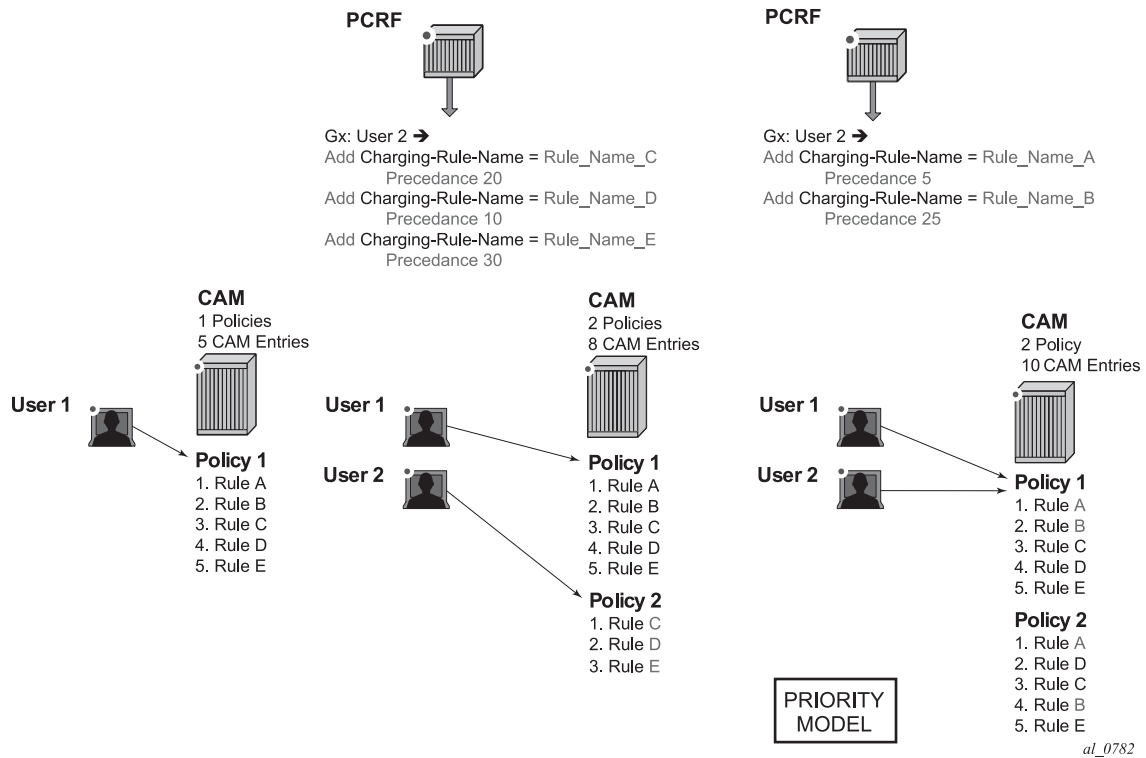

15.5.13.6 Gx Rule Ordering

Entries in IPv4/v6 filter and QoS policy created via CLI are ordered according to the numerical value associated with each entry command (which corresponds to the match condition) within the policy. CLI rules can be re-ordered with the **renum** command (in filters and QoS policies).

On the other hand, the PCC rules are ordered in one of the two ways. The difference between ordering of the entries with the rules, and the ordering of the rules themselves is:

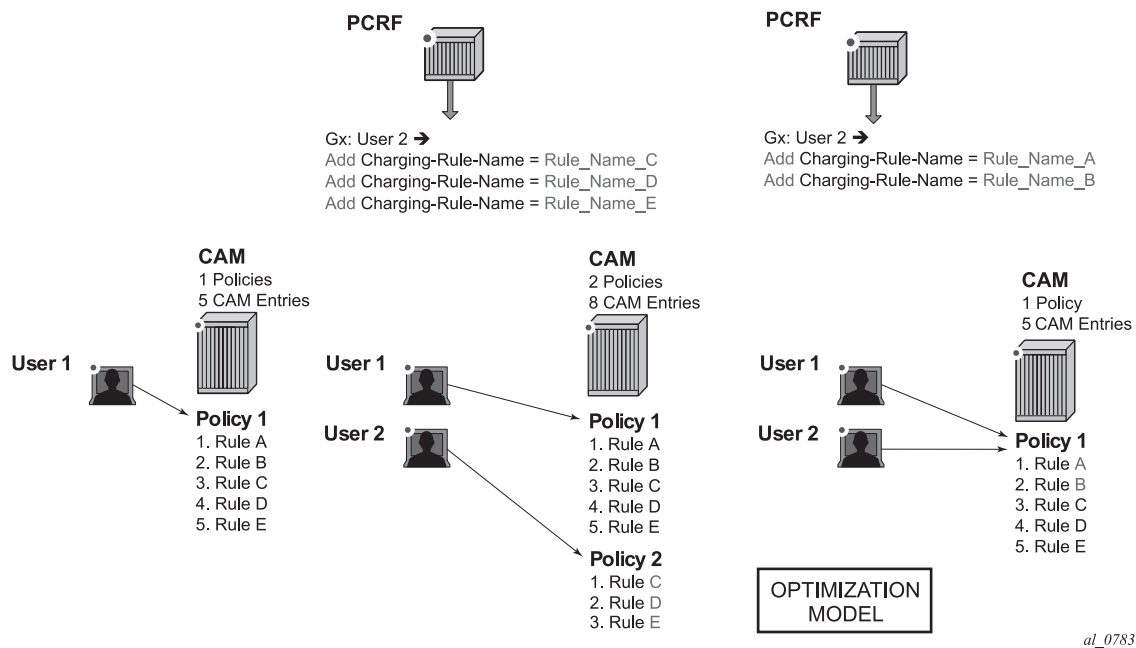

- PCC rules are prioritized according to the Precedence AVP within the Charging-Rule-Definition AVP. They are inserted within the subscriber-host policy, according to the Precedence AVP relative to the other PCC rules already applied to the subscriber-host. A PCC rule with a lower Precedence value will be applied before a rule with a higher Precedence value.

The ordering behavior according to the Precedence is shown in [Figure 212](#).

Figure 212 PCC Rule Ordering - Priority Model

- Automatic optimization of PCC rules. Automatic optimization is used in cases where the PCC rule order is not important to the operator. Then, the node will optimize the rule ordering to achieve the best possible scale by maximizing rule sharing. This optimization (or internal rule ordering) is performed for PCC rules without the Precedence AVP, or for PCC rules with the same Precedence value. The premise of the automatic rule optimization is shown in [Figure 212](#).

Figure 213 Rule Ordering - Optimization Model

The ordering of PCC rules has no effect on the ordering of the static entries in the base qos-policy or filter.

Mixing of the PCC rules with the Precedence AVP and without Precedence AVP is allowed for the same subscriber-host. PCC rules without the Precedence AVP will be inserted at the end of all PCC rules that do have the Precedence value set explicitly. In other words, the Precedence value for PCC rules without the explicitly configured Precedence AVP is assumed to be the highest. The PCC rules without the Precedence value are automatically inserted at the bottom of the PCC rule range.

A distinction should be made between the order of PCC rules in a PCC rule set and the order between the entries within each PCC rule. A PCC rule contains a group of classifiers that are all associated with the same actions. Therefore, the order of the entries (equivalent to match conditions) within any given PCC rule does not matter (all entries result in the same action). For this reason, PCC rules with identical name and identical entries but different order of the entries are automatically ordered in a way that would allow more optimal sharing of the rules between different subscribers.

15.5.13.7 PCC Rule Override

A PCC rule applied to a subscriber-host on the node can be overridden by re-submitting the PCC rule with the same name but different contents.

If at least 1 new flow is sent in the PCC rule update, then the existing flows are removed and replaced with the new flow. If no new flows are submitted, then the existing flows stay in place.

If there are conflicting parameters between the existing rule and the modified rule (for example the combination of the unsupported actions), the PCC rule override will fail.

15.5.13.8 Aggregation of IP-Criterion

An action with a PCC rule can be applied for a set of IP-criterion.

For example, a single policer can be instantiated for a set of flows for rate-limiting purposes.

A pseudo Gx directive would look like this:

```
Charging-Rule-Install – Directive to install the rule in 7750 SR
    Charging-Rule-Definition – PCC rule definition created on PCRF
        Charging-Rule-Name = Rule-1 – PCC rule name
            Flow1          – match-criteria for flow 1
            Flow2          – match-criteria for flow 2
            Flow 2         – match-criteria for flow 3
            Rate-limit      – rate-
limiting action applicable as an aggregate action for all 3 flows
```

All three flows will be fed into the same rate limiter (policer).

15.5.13.9 Combining IPv4 and IPv6 Entries within the Rule

IPv4 flow entries and IPv6 flows entries can be combined within the same PCC rule. The actions that carry the IP address are address-type-specific (for example **next-hop-redirect**). All other actions (rate-limit, FC change, and so on) are universal and it will be applied to both flow types (IPv4 and IPv6). The node will automatically sort out flow types (IPv4 and IPv6) within the rule and apply corresponding actions.

If the rule contains a mismatching flow type and actions (for example, IPv4 flows and IPv6 specific actions), the rule will be rejected. It is the operator's responsibility to ensure that the address-type-specific actions in the rule have corresponding flows to which they can be applied.

15.5.13.10 Gx Rules with Multiple Actions and Action Sharing

PCC rules can contain multiple actions. For the list of support action combinations, refer to the [PCC Rules](#).

15.5.13.11 Alc-NAS-Filter-Rule-Shared AVP vs Flow-Information AVP

A Gx rule (as defined in a single Charging-Rule-Definition AVP) can contain either Flow-Information AVP or Alc-NAS-Filter-Rule-Shared AVP, but not both simultaneously.

Presence of either AVP within the Charging-Rule-Definition AVP determines the mode of operation for the rule:

Alc-NAS-Filter-Rule-Shared AVP indicates the mode of operation in which the permit or deny action is part of the flow definition itself (Alc-NAS-Filter-Rule-Shared AVP). This mode of operation is referred as NAS filter inserts. The basic format of the AVP is the following (RFC 4849 and 4005; AVP Code 400):

```
<action> <direction> <protocol> from <source> to <destination> <options>.
```

There can be multiple ip-criteria definitions within the rule per subscriber-host, and each ip-criteria carries its own permit/deny action. There can be only one such rule (Charging-Rule-Definition) per subscriber-host. The rule entries are installed within the filter range defined by the following command:

```
sub-insert-shared-radius start-entry <entry-id> count <count>  
under the following CLI hierarchy:  
configure>filter>ip-filter>  
configure>filter>ipv6-filter
```

Such rule cannot be removed by the Charging-Rule-Remove directive referencing the rule name. Instead, each such Gx rule will overwrite the previous one.

Flow-Information AVP indicates the mode of operation whereby all the flows in the rule share the same actions carried in separate AVPs. This mode of operation is referred to as PCC rule inserts. The rule entries are installed within the filter or qos-policy range defined by the following command:

```
sub-insert-shared-pccrule start-entry <entry-id> count <count>  
under the following CLI hierarchy:  
configure>filter>ip-filter>  
configure>filter>ipv6-filter>  
configure>qos>sap-ingress>  
configure>qos>sap-egress>
```

There can be multiple flow based rules present in an orderly fashion and each rule can be individually removed by referencing its name.

Both modes of operation are supported simultaneously for the subscriber host.

15.5.13.12 RADIUS and Gx Interaction

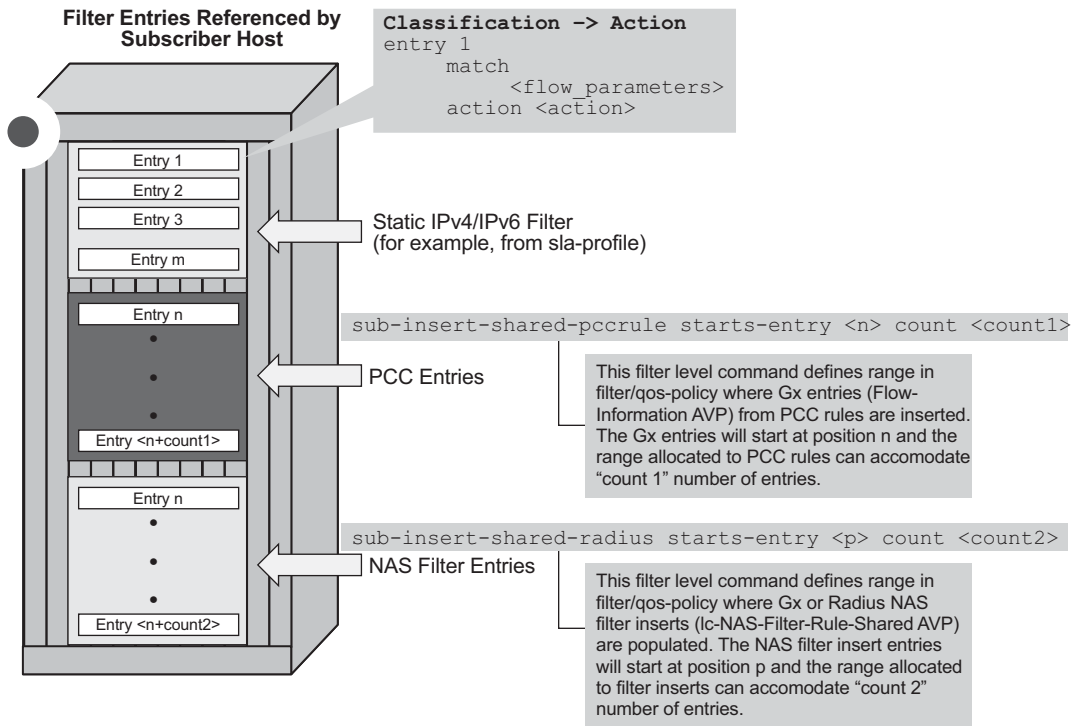

Gx and RADIUS (CoA) policy management interfaces are simultaneously supported for the same subscriber-host.

RADIUS and Gx share the same entries for filter entry inserts (NAS-Filter-Rules and Alc-NAS-Filter-Rule-Shared) and therefore the most recent insert will override the previous one. Similar logic applies to subscriber-string overrides and QoS overrides, where the most recent source, overrides the previous one.

However, PCC rules (IP-criteria based Gx rules) are provisioned in a separate filter 'entry' space from RADIUS and Gx filter inserts and therefore the PCC rules and RADIUS/Gx based filter inserts can independently coexist.

Filter/QoS-policy entry order is shown in [Figure 214](#). The order of configuration blocks (static, PCC rules or NAS filter inserts) is configurable. For example, an operator can specify that static filter entries are populated before PCC rules which are then populated before NAS filter inserts.

Figure 214 CAM Table Population

al_0784

15.5.13.13 Bulk Changes via CLI while Gx Rules are Active

Once PCC rules are applied to a subscriber-host, the operator is allowed to modify via CLI some of the parameters in the base filter/qos-policy. For example, the operator is allowed to add/remove terms in the base ACL filter.

The list of the parameters in the QoS policy that can be changed is shown in Table 3. Adding/removing queue/policer, re-mapping of FC, modifying dscp-map or modifying static ip-criteria is not allowed.

Modified parameters in the base-policy/filter referenced in the sla-profile will affect all subscribers using this sla-profile. Replacing the base qos-policy/filter in sla-profile is not allowed for any subscriber-host if a clone of the base qos-policy/filter exist anywhere in the system.

However, replacing the base filter-id for a host via CoA or Gx override is allowed. Then, only the targeted host will be affected and all existing PCC rules for this host will be merged with the new filter.

Table 113 CLI Modifiable Parameters in Base QoS-Policy that Contains Clones

CLI
config>qos>sap-ingress>queue
[no] cbs - Specify CBS

[no] parent - Specify the scheduler to which this policer feeds
[no] percent-rate - Specify percent rates (CIR and PIR)
[no] rate - Specify rates (CIR and PIR)

15.5.13.14 PCC Rule Direction

PCC rules are unidirectional. The PCC rule direction is determined based on the value of the Flow-Direction AVP within the Flow-Information AVP. In the absence of the Flow-Direction AVP, the PCC rule direction is determined based on the Flow-Description AVP (as part of IPFilterRule direction field). Both of these AVPs (Flow-Direction and Flow-Description) are part of the PCC rule definition.

If the action within the PCC rule is in conflict with the direction of the flow, the PCC rule instantiation will fail. For example, an error will be raised if the flow direction is UPSTREAM, while the action is ‘Max-Requested-Bandwidth-DL’ (downstream bandwidth limit).

15.5.13.15 Action

A PCC rule may contain multiple actions. Each action is carried in a separate, action specific AVP. The action specified in the **flow-description->ipfilterrule** data type is ignored. If rule contains multiple instances of the same action, each with a different value, the last occurrence of the action value will be in effect.

Not all of the action types can be applied at the same time. The allowed combination of the actions per direction is given in [Table 113](#) and [Table 114](#).

15.5.13.16 Rate-Limiting Action (Ingress, Egress)

Rate-limiting action is implemented via policers. The policer is dynamically created at the PCC rule instantiation time. The rate can be enforced based on Layer 2 rates or Layer 3 rates.

Dynamically instantiated policers have their own policer id range to avoid the conflict with static policers.

The dynamically created policers will share common properties configured under the dynamic-policer CLI hierarchy:

```
configure
  qos
    sap-ingress/egress
      dynamic-policer
        stat-mode <stat_mode>
        parent <arbiter-name> [weight <weight-level>] [level <level>]
        mbs <size> [bytes | kilobytes]
        cbs <size> [bytes | kilobytes]
        packet-byte-offset {add <add-bytes> | subtract <sub-bytes>}
        range start-entry <entry-id> count <count>
```

The policer rates are part of PCC rule itself and are not part of static configuration.

The generic Gx directive for rate-limiting action is:

```
Charging-Rule-Install ::=          <AVP Header: 1001>
  Charging-Rule-Definition <AVP Header: 1003>
    Charging-Rule-Name <AVP Header: 1005>
    QoS-Information <AVP Header: 1016>
      Max-Requested-Bandwidth-
        UL <AVP Header: 516> [bps] 3GPP 29.214 §5.3.15
          Max-Requested-Bandwidth-DL <AVP Header: 515> [bps] 3GPP 29.214 §5.3.14
          Guaranteed-Bitrate-UL <AVP Header: 1026> [bps] 3GPP 29.214 §5.3.26
          Guaranteed-Bitrate-DL <AVP Header: 1027> [bps] 3GPP 29.214 §5.3.25
```

The above rate limits refer to PIR and CIR rates of the dynamic policer in the respective direction.

15.5.13.16.1 Dynamic Policers and Queue Mappings

Once traffic is processed by the dynamic policers on **ingress**, the traffic will flow through the policer-output-queues shared queues. Traffic through dynamic policers will always bypass subscriber queues or policers on **ingress** that are statically configured in the base qos-policy.

Similar behavior is exhibited when static policers are configured on **egress**. Traffic outputting dynamic policer is never mapped to another static policer. Instead, such traffic will be mapped to the corresponding shared queue in a queue-group. By default, this queue-group is the policer-output-queue group. However, the selection of the queue-group is configurable.

In contrast to the above, traffic processed by dynamic policers can be fed into statically configured **subscriber (local) queues on egress**. Dynamic policers and subscriber queues are tied through the forwarding-class.

The policer to local queue mapping and inheritance of the forwarding-class is shown in Figure 15. In this example, the mapping of traffic —> forwarding-class in rule 2 (flow 2) will depend on the DSCP bits in the traffic flow. If the DSCP value in this traffic flow are different from the explicitly configured DSCP values in the static (base) QoS policy, then traffic will be mapped to the default forwarding-class.

Figure 215 FC Inheritance for Dynamically Instantiated Policers on Egress

15.5.13.16.2 Dynamic Policer Rates and Accounting Statistics

By default, policer rates are configured based on Layer 2 frame length (for example, the Ethernet header plus the IP packet). This can be changed by the **packet-byte-offset** (PBO) command under the policer. If the policer is fed into a local queue, the PBO of the policer will not affect the PBO of the local queue it is feeding.

The rates for local subscriber queues can be independently measured based on Layer 2 or Layer 1 frame length and the queue statistics can be measured based on Layer 1, Layer 2 or Layer 3 (IP-only) frame length. The IP-only stats for queues can be configured in the **sub-profil>volume-stats-type {ip|default}**.

Dynamic policer (instantiated due to rate limiting or usage-monitoring action in PCC rules) statistics are not reported in RADIUS-based accounting. On egress, this will have no effect on volume counters in RADIUS-based accounting, since the dynamic policers are normally fed into local queues whose statistics are reported in RADIUS-based accounting. However, on ingress, the dynamic policers are always fed into the queue-group queues which are excluded from RADIUS based accounting. The consequence is that the ingress RADIUS-based accounting will lack statistics for the traffic that is flowing via dynamic policers.

If the dynamic policer is feeding a local queue, the aggregate statistics in show commands for such queue are not reported in order to avoid double counting (since the traffic statistics in **show** commands are already reported for the dynamic policer). However, the per-queue statistics are reported in **show** commands, irrespective of whether the policer is mapped to the local queue or not.

To avoid losing aggregate SAP or subscriber stats in show commands, the recommendation is to have policers feed into local queues which are not already mapped to an FC. For example:

```
queue 4 create //Not counted since policer 2 is feeding it
exit
policer 2 create
exit
fc be create
    queue 4 //Not counted
exit
fc l1 create
    queue 4 //Not counted
exit
fc ef create
    policer 2 queue 4
exit
```

FC BE, FC2 L1 —> queue 4

FC EF —> policer 2, queue 4

Then, traffic from queue 4 will not be counted in aggregate stats at all and consequently the aggregate accounting information will be lost for FC BE and FC L1.

15.5.13.17 Forwarding-Class Change (Ingress, Egress)

Traffic can be re-prioritized via PCC rule by re-classification into a different forwarding class. The forwarding-class can be changed in several cases.

The original static mapping between traffic type, forwarding-class and the queue/policer in the base qos-policy is configured outside of ip-criteria CLI hierarchy.

For example:

```
configure>qos>sap-egress#
      dscp af11 fc "af"
```

Such mapping is configured outside of CAM and as such it has lower evaluation priority than the mapping configured via PCC rule which is installed in CAM.

The original static mapping is provisioned in the base qos-policy via ip-criteria CLI hierarchy.

For example:

```
config>qos>sap-egress>#
      ip-criteria
        entry 40000 create
          match
            dscp af11
          exit
        action fc "af"
      exit
    exit
```

Then, the configured entry range for PCC rules **must** precede the static entry (match criteria) in which the original forwarding-class is configured. The insertion point (entry) is controlled via configuration: **sub-insert-shared-pccrule start-entry <entry-id> count <count>** command under the qos-policy.

In both of the above cases, the following PCC rule would override forwarding-class for traffic with DSCP value of 10 ('af11' traffic class) from value 'af' to 'h2'.

```
Charging-Rule-Install
  Charging-Rule-Definition
    Charging-Rule-Name = fc-change
    Flow-Information
      ToS-Traffic-Class = 00101000 11111100
      Flow-Direction = 1
    QoS-Information
      QoS-Class-Identifier = 2
```

The eight forwarding classes are mapped to QCI (3GPP TS 23.203 §6.1.7.2) in the following manner:

BE → QCI 8

L2 → QCI 7

AF → QCI 6

L1 → QCI 4

H2 → QCI 2

EF → QCI 3

H1 → QCI 1

NC → QCI 5

The generic Gx directive for forwarding-class change:

```
Charging-Rule-Install ::=          <AVP Header: 1001>
    Charging-Rule-Definition <AVP Header: 1003>
        Charging-Rule-Name <AVP Header: 1005>
            QoS-Information <AVP Header: 1016>          3GPP 29.212 §5.3.16
                QoS-Class-Identifier <AVP Header: 1028> 3GPP 29.212 §5.3.17
```

15.5.13.18 QoS Forward (Ingress and Egress)

Create an **ip-criteria** and/or **ipv6-criteria** entry with no action specified. Matching traffic is forwarded without a QoS action and will not match on a next entry (match and exit behavior). This is equivalent to a *white-list* entry.

CLI equivalent:.

```
config>qos
  sap-ingress | sap-egress <id> create
    ip-criteria | ipv6-criteria
      entry <id> create
        match
          <5-tuple | dscp>
        exit
      action
    exit
  exit
```

The generic Gx directive for QoS forwarding:

```
Charging-Rule-Install ::= <AVP Header: 1001>
  Charging-Rule-Definition <AVP Header: 1003>
    Charging-Rule-Name <AVP Header: 1005>
      Alc-QoS-Action = Forward (1) <AVP Header: 1028>
```

15.5.13.19 Next-Hop Redirect (Ingress)

The next hop redirection will explicitly or implicitly change the next-hop for the traffic flow within the same service ID (routing context) or a different service ID (routing context).

If the next hop is not explicitly provided, the next hop will be selected automatically, according to the routing lookup in the referenced service ID.

The generic Gx directive:

```
Charging-Rule-Install <AVP Header: 1001>
  Charging-Rule-Definition <AVP Header: 1003>
    Charging-Rule-Name <AVP Header: 1005>
      Alc-Next-Hop :: <AVP Header: 1023>
        Alc-Next-Hop-IP <AVP Header: 1024>
      Alc-V4-Next-Hop-Service-id <AVP Header: 1025>
        Alc-V6-Next-Hop-Service-id <AVP Header: 1026>
```

This action overwrites the routing table lookup based on the destination IP and sets the next hop to the:

- IPv4/6 address within the same service id
- IPv4/6 address within a different service id

The next-hop search is indirect, which means that if the explicitly provided next-hop in the PCC rule cannot be found in the routing table, then an additional routing table lookup will be performed to find the path (next-hop) to the indirect next hop from the PCC rule.

If only the service-id is specified in PCC rule (without the next-hop), then the next-hop will be selected from the specified service-id based on the destination IP address of the packet.

15.5.13.20 HTTP Redirect (Ingress)

HTTP redirect utilizes Redirect-Information AVP from 3GPP 29.212, §5.3.82.

The generic Gx directive:

```
Redirect-Information < AVP Header: 1085 >  
  Redirect-Support < AVP Header: 1086 >  
  Redirect-Address-Type < AVP Header: 433 >  
  Redirect-Server-Address < AVP Header: 435 >
```

15.5.13.21 Filter Forward/Drop (Ingress and Egress)

This action is used to control traffic flow within a PCC rule by using ALU specific AVP. PCC rules are utilizing filters and QoS policies as distinct building blocks. This action within a PCC rule will create an IP or IPv6 filter entry with an action **forward** or **drop**.

The CLI equivalent follows:

```
config>filter  
  ip-filter | ipv6-filter <id> create  
    entry <id> create  
      match  
        <5-tuple | dscp>  
      exit  
      action  
        forward | drop  
      exit  
    exit  
  exit
```

The generic Gx directive for filter forward/drop is implemented through ALU specific AVP:

```

Charging-Rule-Install ::= <AVP Header: 1001>
  Charging-Rule-Definition <AVP Header: 1003>
    Charging-Rule-Name <AVP Header: 1005>
      Alc-Filter-Action = Forward (1) <AVP Header: 1027>
      Alc-Filter-Action = Drop (2)

```

15.5.13.22 Service Gating Function

The service gating function is used to enable or disable the service that is represented by the PCC rule. This action is enforced through a Flow-Status AVP (AVP code 511) - 3GPP 29.214, §5.3.11.

The system supports the following values (actions) for the Flow-Status:

- enabled (2) — Enables all actions specified within the PCC rule.
Note that although Flow-Status (service gating function) is considered an action, in this context it is used to enable all other actions that are explicitly set within the PCC rule.
- disabled (2) — Disable all action specified within the PCC rule and drops the traffic.

The service gating function is applicable in the direction that is associated with the rule (PCC rules in the system are unidirectional).

Flow-Status is by default 'enabled (2)' (if the Flow-Status AVP is not explicitly specified within the PCC rule). Flow-Status=Enabled must be accompanied by one or more additional actions in the same PCC rule (refer to [15.5.13.10](#) for a list of allowed simultaneous actions), otherwise the PCC rule instantiation in the node will fail.

If the Flow-Status is set to 'disabled (3)', all other actions within the same rule will lose their meaning since the packet will be dropped. Basically, the 'disabled' directive will disable the flow of packet through the system. A disabled Flow-Status is equivalent to the Alc-Filter-Action = Drop (2).

This AVP will be carried inside of Charging-Rule-Definition (3GPP 29.212, §5.3.5):

```

Charging-Rule-Definition ::= < AVP Header: 1003 >
  { Charging-Rule-Name }
  * [ Flow-Information ]
  [ Flow-Status ]
  [ QoS-Information ]
  [ Precedence ]
  * [ Flows ]
  [ Monitoring-Key ]
  [ Redirect-Information ]
  * [ AVP ]

```

15.5.13.23 PCC Rule Provisioning Example

The following is an example of PCC rule provisioning in a CCA-I message:

```
<CC-Answer> ::= < Diameter Header: 272, PXY >
    < Session-Id >
    { Auth-Application-Id }
    { Origin-Host }
    { Origin-Realm }
    [ Result-Code ]
    [ Experimental-Result ]
    { CC-Request-Type }
    { CC-Request-Number }
    *[ Supported-Features ]
    *[ Event-Trigger ]
    [ Origin-State-Id ]

Charging-Rule-Install ::= <AVP Header: 1001> -> host instantiation
    Charging-Rule-Name = "ingr-v4:7"
    Charging-Rule-Name = "eggr-v6:5"
    Charging-Rule-Name = "Sub-Profile:prem"
    Charging-Rule-Name = "Sla-Profile:voip+data"
    Charging-Rule-Name = "Inter-Dest:vport-AN-1"

Charging-Rule-Install -> service instantiation
    Charging-Rule-Definition
        Charging-Rule-Name = "service-1" -
> should be able to remove the rule by name later on
        Flow-Information -> traffic flow definition
        Flow-Description = "permit in 6(TCP) from any to ip 10.10.10.10/
32 40000-40010"
        ToS-Traffic-Class = 00101000 11111100] -
> DSCP definition (value mask). In case of the DSCP, Flow-
Direction (1080) AVP must be included.
        Flow-Direction = UPSTREAM -> traffic flow direction
        QoS-Information <AVP Header: 1016>
            Max-Requested-Bandwidth-UL = 100000000 -
> UPSTREAM rate definition (not downstream, since the traffic flow direction is IN)
            QoS-Class-Identifier = 3 -
> EF forwarding class; in general one of 8 forwarding-classes (FC) in 7450 ESS and
7750 SR (be|l2|af|l1|h2|ef|h1|nc). This is used for re-
prioritization of the traffic.
```

In this example the host is instantiated using the two Charging-Rule-Install AVPs. The first one is used to instantiate the host. The second one is used to instantiate the IP-criterion based service named service-1. Service-1 is defined as the upstream traffic flow with traffic class AF11, destined to the TCP port range 40000-40010 on the node with IP address 10.10.10.10/32.

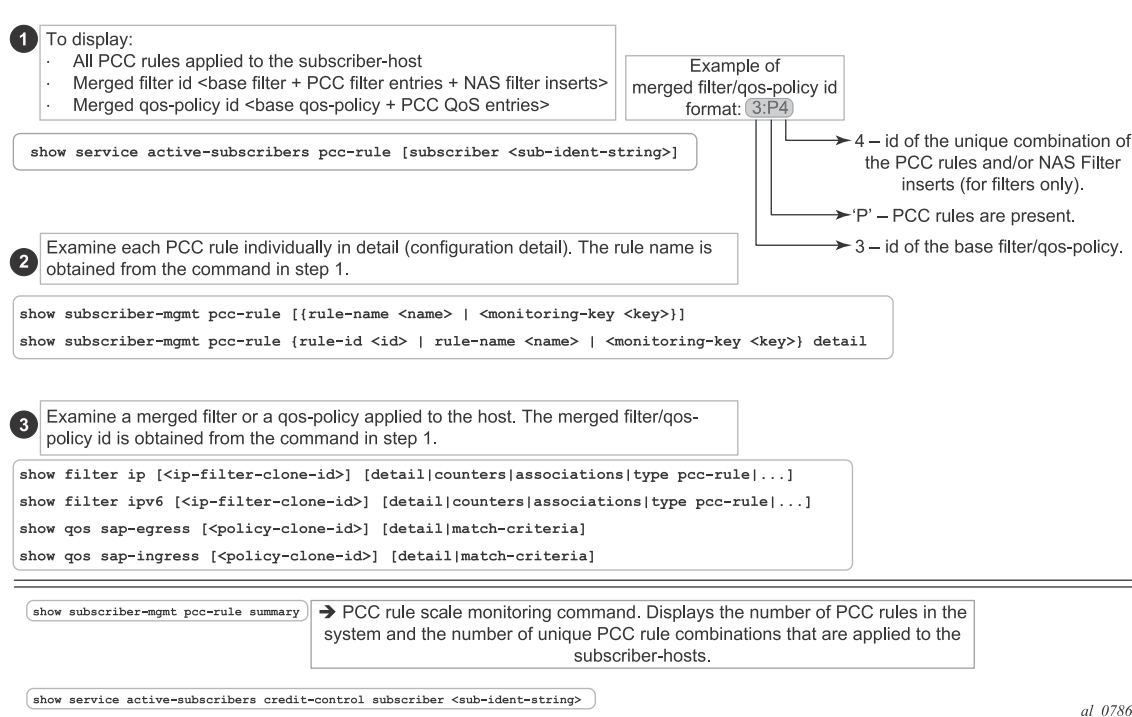

The actions for this traffic flow are:

- Rate-limit of 10M
- Change forwarding-class to AF11.

15.5.13.24 Operational Aspects

The commands used to examine dynamic rules and NAS filter inserts associated with the subscriber hosts are shown in [Figure 216](#).

Figure 216 Overview of PCC Rule-Related Operational Commands

15.5.13.25 PCC Rules and Capacity Planning

One of the most important factors to be considered for capacity planning with PCC rules is the number of unique policies that are applied to subscribers.

A unique policy constitutes a base a QoS policy or filter ID along with all PCC rules that are applied to a subscriber or a set of subscribers.

Now examine an example where there are 'n' PCC rules in the system ('n' qos rules and 'n' ACL filter rules). Those rules are applied to IPv4 traffic in ingress direction. Further, assume that the PCC rules do not have defined Precedence AVP, which means that the system can optimize their order for maximum sharing and maximized scale. Then, 'n' PCC rules can be combined by various permutation into $2^n - 1$ unique combinations. Next assumption is that there are five possible base qos-policies for IPv4 traffic in ingress direction and five possible base filters for IPv4 traffic in the ingress direction.

Given the above, the unique PCC rule combinations ($2^n - 1$) together with five base qos-policies will produce $5 * (2^n - 1)$ unique qos-policies per ingress IPv4. Same logic can be applied for ingress IPv4 filters.

This exercise must be repeated for egress direction as well as for IPv6 type traffic, by taking into consideration the number of respective base qos-policies/filters and the number of PCC rules.

Once the number of unique policy combinations is determined and ensured that it is within the system limits, each policy must be further evaluated to determine the number of entries it will take in CAM.

15.5.13.26 PCC Rule Scaling Example

[Figure 217](#) depicts an example relevant to capacity planning with focusing on understanding the scaling limits pertaining to the number of PCC rules and their mutual combinations when they are applied to the subscriber hosts.

This example is focuses on an IPv4 filter applied in ingress direction but similar logic can be used in understanding other policy types (QoS, egress, IPv6).

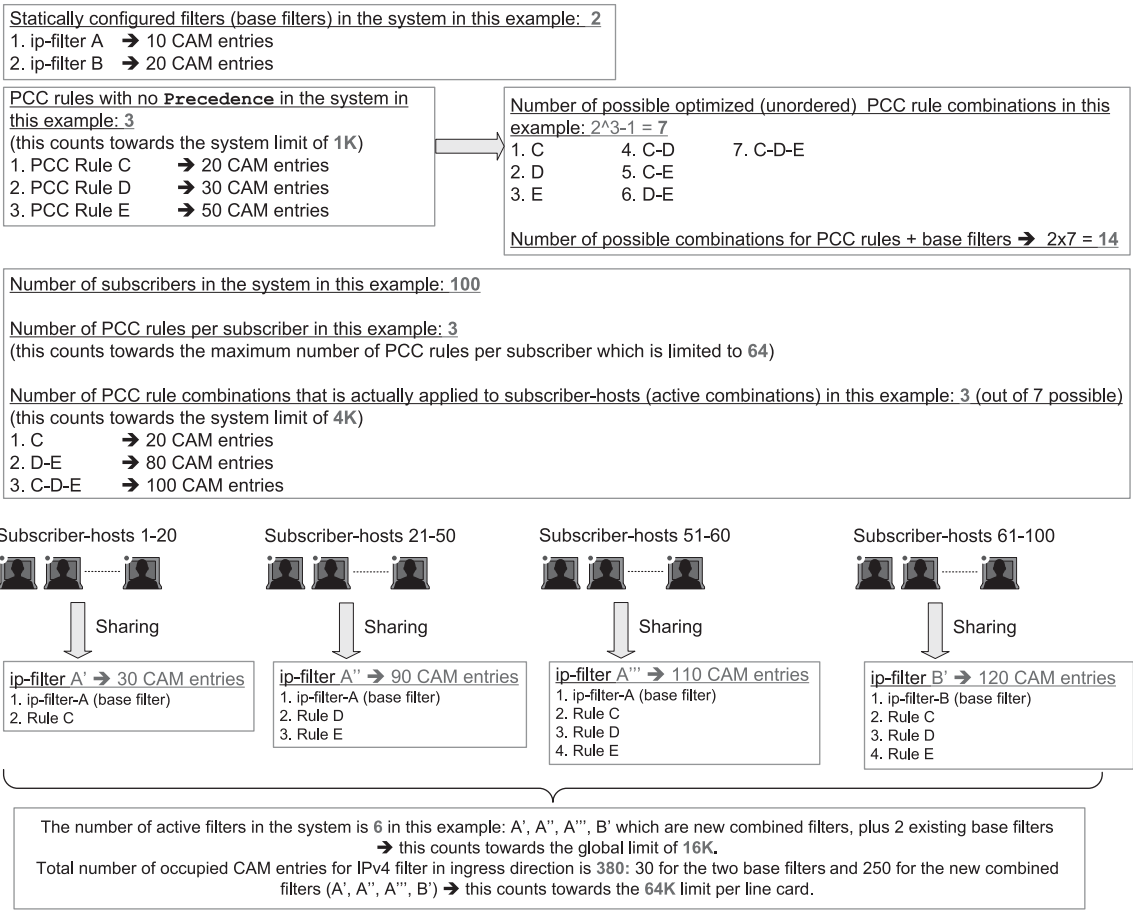

The system/line card limits in this example are set to the following values for illustration purposes only:

- Number of PCC rules per system: 1K
- Max number of rules per subscriber host: 64
- Max number of combinations of the PCC rules (or services) that are active (applied to the subscriber-hosts) per system: 4K
- Max ingress IPv4 filter CAM entries per FP2/FP3: 64k
- Max filters per system: 16k

Note: The actual CAM limits vary per policy type (filter/QoS), direction and IP address type (v4 vs v6). The actual scaling limits can be found in the Scaling Guides for the relevant software release.

Figure 217 Example of the Scaling Limits for PCC Rules

al_0787

15.5.14 NAS Filter Inserts

Gx filter entries inserted via the NAS-Filter-Rule are subscriber-host-specific entries. This means that in the upstream direction, the source IP address in the NAS-Filter-Rule will always be internally set by the node to the IP address of the subscriber host itself. Similarly, in the downstream direction, the destination IP address in the NAS-Filter-Rule will be set by the node to be the IP address of the subscriber-host itself.

On the other hand, the entries in the Alc-NAS-Filter-Rule-**Shared** AVP are processed as received without any modifications. This means that such entries can be shared with all the hosts that have the same Alc-NAS-Filter-Rule-Shared applied.

Similar to QoS overrides, NAS filter entries are not predefined on the node but instead they are defined under the Charging-Rule-Install — Charging-Rule-Definition AVP.

The Charging-Rule-Name AVP for NAS filter inserts is an arbitrary name that is part of Charging-Rule-Definition AVP in which NAS-Filter-Rule AVP or Alc-NAS-Filter-Rule-Shared is provided. Such Charging-Rule-Name will be used to report errors related to instantiation of the inserts.

15.5.14.1 Examples of NAS Entry Inserts

The following AVPs will identify NAS filter inserts that will be applied to a subscriber host. Those AVPs can be included in CCA-i, CCA-u or RAR message sent from the PCRF.

```
Charging-Rule-Install ::= <AVP Header: 1001>
Charging-Rule-Definition <AVP Header: 1003>
    Charging-Rule-Name <AVP Header: 1005> = "allow-all"
    Alc-NAS-Filter-Rule-
Shared <AVP Header: 158> = "permit in ip from any to any "ASCII NUL" permit out ip f
rom any to any"
```

In this example, the filter entry defined in Alc-NAS-Filter-Rule-Shared AVP will be inserted in the clone of the existing base filter for the subscriber(s).

15.5.15 Error Handling and Rule Failure Reporting in ESM

The Gx rule (overrides, PCC rules or NAS filter inserts) instantiation failure can occur on two levels:

- AVP Decoding level in the Diameter — The Gx message contains an unrecognized AVP with the M-bit set. Then, all Gx rules (ESM, UM and AA) in the message will be rejected and the CCR-u with the Charging-Rule-Report AVP (rule status) and Error-Message AVP (failure description) or an RAA message with the appropriate Result-Code AVP (fail – 5xxx), Error-Message AVP (description) and the Failed-AVP AVP will be sent to the PCRF.

Invalid content of a supported AVP with the M-bit set will also trigger the same response. Invalid content of an AVP refers to the malformed syntax of an AVP that carries the type of the AVP value implicitly embedded in the AVP value itself. Consider sla-profile:rule-name-1 string. then, the sla-profile: refers to the type of the value carried in the Charging-Rule-Name AVP. The value that the Charging-Rule-Name carries is rule-name-1 and this value represents the sla-profile name already configured on the node (as opposed to filter, sub-profile, category-map, and so on). If the sla-profile is misspelled (type is unrecognized), the whole AVP will be un-decodable.

- Gx rule instantiation level in ESM, UM or AA – Then each module (ESM, UM or AA) would fail all rules destined for it. The failure of a Gx rule within a module can be caused by referencing non-existing profile (for example sla-profile:unknown-name) or a lack of resources on the node. Then, a CCR-u message from the respective module will be sent with the Rule-Report-Status AVP listing all the rules destined for this module and the corresponding Error-Message AVP describing the cause for the failure.

Another example that can cause all rules with the ESM module to fail would be invalid combination of actions within the rule.

15.5.15.1 AVP Decoding Failure in Gx

Reporting an AVP decoding problem in Gx is described in the following example:

A Gx directive is received to install two overrides on the node. The two overrides are supposed to change the sla-profiles and sub-profiles for the subscriber host. The AVP that is used to change the sla-profile is miss-formatted. The predefined sla-profile keyword in the Charging-Rule-Install AVP is misspelled as spa-profile instead of sla-profile.

```
Charging-Rule-Install ::= <AVP Header: 1001>
  Charging-Rule-Name <AVP Header: 1005> = "Sub-Profile:prem"
  Charging-Rule-Name <AVP Header: 1005> = "Spa-Profile:voip+data"
```

Since the Charging-Rule-Name AVP has the M-bit set, the whole message will fail and an error will be reported. No rules within this Gx message will be installed (not even the valid ones, then this would be the Charging-Rule-Name = “**Sub-Profile:prem**”).

Note: If the M-bit was clear in the Charging-Rule-Name AVP, the erroneous AVP would be simply ignored and proceed with installation of the remaining, ‘correctly formatted’ rules.

The nature of the error will depend on the original directive sent by the PCRF (RAR or CCA – push or pull model).

If the directive from the PCRF is passed via CCA command, the response will be CCR-u command with the following error related AVPs:

```
[ Error-Message ] – “Invalid value spa-profile:voip+data”
```

```
Charging-Rule-Report ::= < AVP Header: 1018 >  
  * [ Charging-Rule-Name ] – Spa-Profile:voip+data  
  [ PCC-Rule-Status ] – INACTIVE (1)  
  [ Rule-Failure-Code ] – GW/PCEF_MALFUNCTION (4)
```

```
Charging-Rule-Report ::= < AVP Header: 1018 >  
  * [ Charging-Rule-Name ] – Sub-Profile:prem  
  [ PCC-Rule-Status ] – INACTIVE (1)  
  [ Rule-Failure-Code ] – GW/PCEF_MALFUNCTION (4)
```

```
Failed-AVP ::= < AVP Header: 279 >  
  Charging-Rule-Name = Spa-Profile:voip+data
```

- If the directive is passed to the node via RAR, the node will respond with the following RAA message:

```
Failed-AVP ::= < AVP Header: 279 >  
  Charging-Rule-Name = Spa-Profile:voip+data
```

```
Result-Code ::= < AVP Header: 268 > = DIAMETER_INVALID_AVP_VALUE (5004)
```

Similarly, if the number of filter entries for each entry type (NAS-Filter-Rule — host-specific or Alc-NAS-Filter-Rule-Shared — shared) exceeds the maximum supported number (see the Gx AVPs Reference Guide), the whole message will fail the decoding phase.

The reason that the Result-Code AVP is present in the RAA message and not in the CCR-u message is that this code is only allowed to be present in the answer messages, according to the standard.

15.5.15.2 ESM Rule-Installation Failure

This assumes that the rule installation directives are successfully passed from the Gx module to the ESM module and the failure to install rules occurs in the ESM module.

In the Gx override example below, the referenced sla-profile is unknown. Then, all directives passed to the ESM module will fail and consequently no rules/overrides will be installed. The sub-profile change will fail as well although the prem sub-profile is known in the system.

```
Charging-Rule-Install ::= <AVP Header: 1001>
  Charging-Rule-Name <AVP Header: 1005> = "Sub-Profile:prem"
  Charging-Rule-Name <AVP Header: 1005> = "Sla-Profile:unknown"
```

The error reporting flow will be the following:

- If the directives are passed via CCA command, the response will be CCR-u command with the following error related AVPs:

```
[ Error-Message ]                - "sla-profile 'unknown' lookup failed"
```

```
Charging-Rule-Report ::= < AVP Header: 1018 >
  *[ Charging-Rule-Name ]          - Sla-Profile:unknown
  [ PCC-Rule-Status ]              - INACTIVE (1)
  [ Rule-Failure-Code ]            - GW/PCEF_MALFUNCTION (4)
```

```
Charging-Rule-Report ::= < AVP Header: 1018 >
  *[ Charging-Rule-Name ]          - Sub-Profile:prem
  [ PCC-Rule-Status ]              - INACTIVE (1)
  [ Rule-Failure-Code ]            - GW/PCEF_MALFUNCTION (4)
```

- If the directive is passed to the node via RAR, the node will respond with the following messages:

RAA = OK since the Gx module successfully processed the AVP parsing.

The RAA will be followed by CCR-u, triggered by the rule instantiation failure in ESM module. CCR-u will contain the following AVP related to the rule status:

```
[ Error-Message ]                - "sla-profile 'unknown' lookup failed"
```

```
Charging-Rule-Report ::= < AVP Header: 1018 >
  *[ Charging-Rule-Name ]          - Sla-Profile:unknown
  [ PCC-Rule-Status ]              - INACTIVE (1)
  [ Rule-Failure-Code ]            - GW/PCEF_MALFUNCTION (4)
```

```
Charging-Rule-Report ::= < AVP Header: 1018 >
  *[ Charging-Rule-Name ]          - Sub-Profile:prem
  [ PCC-Rule-Status ]              - INACTIVE (1)
  [ Rule-Failure-Code ]            - GW/PCEF_MALFUNCTION (4)
```

Similar behavior would be exhibited if the directive is sent to the UM or AA modules. However, ESM, UM and AA are separate modules and failure to install rule in one module will not affect rule installation in another.

15.5.15.3 Failure Reporting in AA

Failure reporting in AA is performed in similar fashion as in ESM.

Instead of Charging-Rule-Report AVP, the ADC-Rule-Report will be used:

```
ADC-Rule-Report ::= < AVP Header: 1097 >
    * [ ADC-Rule-Name ]
    [ PCC-Rule-Status ]
    [ Rule-Failure-Code ]
    * [ AVP ]
```

15.5.15.4 Summary of Failure Reporting

Table 114 summarizes Gx failure reporting on the node.

Table 114 Failure Reporting

Failure Event	Gx Message Received via CCA (Pull Model)	Gx Message Received via RAR (Push Model)
AVP decoding/ interpreting failure; M-bit cleared	Ignore AVP	Ignore AVP
AVP decoding/ interpreting failure; M-bit set	<p>CCR-u will be sent by the node. CCR-u will contain:</p> <ul style="list-style-type: none">• Charging-Rule-Report AVP for all rules (all rules inactive)• First failed AVP in Failed-AVP AVP• Error-Message AVP at the top level describing the reason for the failure. <p>No rules within the message will be instantiated on the node.</p>	<p>RAA will be sent by the node. RAA will contain:</p> <ul style="list-style-type: none">• Result-Code AVP [DIAMETER_INVALID_AVP_VALUE (5004), DIAMETER_AVP_UNSUPPORTED (5001), DIAMETER_UNABLE_TO_COMPLY (5012)• First failed AVP in Failed-AVP AVP <p>No rules within the message will be instantiated on the node.</p>

Table 114 Failure Reporting (Continued)

Failure Event	Gx Message Received via CCA (Pull Model)	Gx Message Received via RAR (Push Model)
Rule failure in ESM	<p>CCR-U will be sent by the node. CCR-u will contain:</p> <ul style="list-style-type: none"> Charging-Rule-Report AVP for all rules (all rules inactive) Error-Message AVP at the top level describing the reason for the failure. <p>No rules will be instantiated in the ESM module.</p>	<p>RAA with the Result-Code AVP 'success' (2001) will be sent by the node, followed by a CCR-u. CCR-u will contain:</p> <ul style="list-style-type: none"> Charging-Rule-Report AVP for all rules (all rules inactive) Error-Message AVP at the top level describing the reason for the failure. <p>No rules will be instantiated in the ESM module.</p>
Rule failure in Usage-Monitoring (UM)	<p>CCR-U will be sent by the node. CCR-u will contain:</p> <ul style="list-style-type: none"> Charging-Rule-Report AVP for all rules (all rules inactive) Error-Message AVP at the top level describing the reason for the failure. <p>No rules will be instantiated in the UM module.</p>	<p>RAA with the Result-Code AVP 'success' (2001) will be sent by the node, followed by a CCR-u. CCR-u will contain:</p> <ul style="list-style-type: none"> Charging-Rule-Report AVP for all rules (all rules inactive) Error-Message AVP at the top level describing the reason for the failure. <p>No rules will be instantiated in the UM module.</p>
Rule failure in AA	<p>CCR-U will be sent by node. CCR-u will contain:</p> <ul style="list-style-type: none"> ADC-Rule-Report AVP for all rules (all rules inactive) Error-Message AVP at the top level describing the reason for the failure. <p>No AA rules will be instantiated in the AA module.</p>	<p>RAA with the Result-Code AVP 'success' (2001) will be sent by the node, followed by CCR-u. CCR-u will contain:</p> <ul style="list-style-type: none"> ADC-Rule-Report AVP for all rules (all rules inactive) Error-Message AVP at the top level describing the reason for the failure. <p>No rules will be instantiated in the AA module.</p>

15.5.16 Usage-Monitoring and Reporting

Usage-Monitoring and reporting refers to the collection and reporting of octets (volume) that a service or application on the node has consumed during a certain period. The usage on the node is reported via the Gx interface to the PCRF. Based on this information, the PCRF can apply a specific action (policy change) to the entity being monitored. For example, QoS can be modified, or the service can be blocked when specific thresholds are reached.

Usage-Monitoring and reporting is performed over a single Gx session for the ESM/AA subscriber. In other words, there is only a single session for an ESM subscriber-host and corresponding AA subscriber. Via this single Gx session, Usage-Monitoring can be requested simultaneously in ESM context (PCC rule level, credit-category and/or IP-CAN session) and AA context (application based Usage-Monitoring).

15.5.16.1 ESM Usage-Monitoring - What is Being Monitored

In the ESM context, volume consumption (octets - 3GPP 23.203 §4.4) can be monitored on three levels:

- per entire IP-CAN session
- per credit-category
- per PCC rule

Usage-Monitoring can be monitored simultaneously on all three levels.

An IP-CAN session on the node represents a subscriber-host whose service types are determined by the sla-profile instance. In per IP-CAN session volume monitoring, the aggregated queue/policer counters will be reported per direction (in | out). This includes dynamic policers that are instantiated as a result of a Gx action; for example, rate-limiting.

The following configuration is necessary to allow per IP-CAN session level Usage-Monitoring to be enabled for sessions associated with the category map:

```
configure
  subscriber-mgmt
    category-map <category-map-name> [create]
      gx-session-level-usage
```

If the sla-profile instance changes mid-session, the counters will be reset.

One obvious difference between regular RADIUS accounting and Gx Usage-Monitoring is that in RADIUS accounting the cumulative byte number for sla-profile instance is presented in each report (interim-updates or stop acct messages), while in Usage-Monitoring this count is reset between the two reports (when the quota is reached, the usage report is triggered).

Per credit-category monitoring refers to volume monitoring of a single queue/policer or a set of queues/policers within the sla-profile instance. Each queue/policer (or set of queues/policers as a subset of the sla-profile instance) represents a service for which the Usage-Monitoring is required. Those queues/policers (services) are organized on the node in credit categories.

```
*A:7750>config>subscr-mgmt>cat-map# info
-----
activity-threshold 1
credit-exhaust-threshold 50
category "queue1" create

    queue 7 egress-only
    queue 8 egress-only
exit
-----
```

Each service category has a name that is used to reference the category in Usage-Monitoring and reporting.

The category-map (predefined on the node) that is used in Usage-Monitoring can be associated with the subscriber-host through the following methods (in the order of priority):

- PCRF — Charging-Rule-Install AVP that references the category map in Charging-Rule-Name = cat-map:<cat-map-name>
- LUDB
- RADIUS
- Python script

PCC rule Usage-Monitoring reports volume usage per flow or set of flows. PCC rule Usage-Monitoring is described in a separate section below.

Usage-Monitoring for the subscriber host can be configured on the node, but it will not be active until it is turned on by the PCRF either via CCA-i, CCA-u or RAR.

Usage-Monitoring can be enabled per ingress and/or egress direction or as total count. However monitoring the total count is mutually exclusive with per direction count. For example, total Usage-Monitoring cannot be enabled simultaneously with ingress (or egress) Usage-Monitoring for the same monitoring entity (session or category).

15.5.16.2 AA Usage-Monitoring – What is Being Monitored

In AA, charging groups (CG), application groups (AG) and applications are monitored. Refer to the Multi-Service Integrated Services Adapter Guide for details.

15.5.16.3 Requesting Usage-Monitoring in ESM

Gx Usage-Monitoring is activated explicitly from the PCRF via CCA-I, CCA-U or RAR. It is triggered via the Usage-Monitoring-Information AVP along with the event-trigger = usage-report (33). The Usage-Monitoring-Information AVP contains the following AVPs:

```
Usage-Monitoring-Information ::= < AVP Header: 1067 >
                                [ Monitoring-Key ]
                                0,2 [ Granted-Service-Unit ]
                                0,2 [ Used-Service-Unit ]
                                [ Usage-Monitoring-Level ]
                                [ Usage-Monitoring-Report ]
                                [ Usage-Monitoring-Support ]
```

There could be multiple instances of Usage-Monitoring-Information AVP present in a single CCA or RAR messages. For example, simultaneous Usage-Monitoring for IP-CAN session level, credit-category level or pcc rule level can be requested.

Usage-Monitoring-Level for IP-CAN session is set to SESSION_LEVEL (0)

Usage-Monitoring-Level for category-map is set to PCC_RULE_LEVEL (1)

Usage-Monitoring-Level for PCC rules is set to PCC_RULE_LEVEL (1)

15.5.16.4 Reporting Accumulated Usage

The node reports usage information to the PCRF under the following conditions:

- When a usage threshold is reached
- When all pcc rules associated with the monitoring are removed or deactivated
- When Usage-Monitoring is explicitly disabled by PCRF
- When a session is terminated
- When requested by PCRF (on demand)

To report accumulated usage for a specific monitoring-key, the node sends a CCR with the Usage-Monitoring-Information AVP containing the accumulated usage information since the last report. For each of the enabled monitoring-keys, the Usage-Monitoring-Information AVP will include the Monitoring-Key AVP and the accumulated volume usage in the Used-Service-Unit AVP.

A usage report on the node can be triggered by reaching the usage threshold communicated to the node by the PCRF in the CCR-u message carrying accumulated usage for that monitoring entity along with the Event-Trigger AVP set to USAGE_REPORT.

In response to the CCR-u message, the PCRF will communicate to the node via a CCA-u message whether the Usage-Monitoring should continue:

- If the new thresholds for the currently monitored entity/levels are provided in Granted-Service-Units AVP, the Usage-Monitoring will continue
- If the thresholds are not included in Granted-Service-Units AVP, the Usage-Monitoring will stop.

Thresholds are incremental. For example, if the quota of 100 MB is submitted to the node, the usage should be reported when that quota is reached. At that point, the user can be granted another 100 MB. The new usage report on the node will be triggered when another 100 MB are accumulated. Absence of the threshold for a given entity in the CCA-u message is an indication that the Usage-Monitoring should stop.

When the PCRF informs the node that Usage-Monitoring should stop (by not including thresholds in CCA-u), the node will not report usage which has accumulated between sending the CCR and receiving the CCA.

Another possibility of usage reporting is on-demand. In this scenario, usage for one or more monitoring keys will be reported whether the usage threshold has been reached. This is achieved by sending the node the Usage-Monitoring-Report AVP (within the Usage-Monitoring-Information AVP) set to USAGE-MONITORING_REPORT_REQUIRED. If the Monitoring-Key AVP is omitted in such a request, Usage-Monitoring for all enabled entities will be reported to the PCRF.

If that the credit-category is removed from the subscriber host (the sla-profile instance referencing the category-map is changed for the subscriber host), the node will report the outstanding usage in a CCR-u message with the Event-Trigger set to USAGE_REPORT.

15.5.16.5 Disabling Usage-Monitoring

When the PCRF explicitly disables Usage-Monitoring on the node, the node will report the accumulated usage which has occurred while Usage-Monitoring was enabled.

To disable Usage-Monitoring for an entity, the PCRF sends the Usage-Monitoring-Information AVP referencing only the applicable monitoring entity with the Monitoring-Key AVP and the Usage-Monitoring-Support AVP set to USAGE_MONITORING_DISABLED.

When the PCRF disables Usage-Monitoring in a RAR or CCA command, the node sends new a CCR-U with the Event-Trigger AVP set to "USAGE_REPORT" to report the accumulated usage for the disabled Usage-Monitoring entities.

15.5.16.6 Usage-Monitoring for PCC Rules

Each PCC rule for which Usage-Monitoring is required, contains Monitoring-Key AVP.

```
Charging-Rule-Definition ::= < AVP Header: 1003 >
    { Charging-Rule-Name }
    * [ Flow-Information ]
    [ Flow-Status ]
    [ QoS-Information ]
    [ Precedence ]
    [ Monitoring-Key ]
    * [ AVP ]
```

Usage-Monitoring for PCC rules is implemented through a dynamic policer. The policer is instantiated at the time when the PCC rule with Monitoring-Key AVP is installed.

The same monitoring-key can be used in multiple PCC rules assuming that these rules are for the same direction. In other words, the charging rule will be rejected if the same monitoring-key is used for ingress and egress.

15.5.16.7 Session Termination

At IP-CAN session termination, the node sends the accumulated usage information for all entities for which Usage-Monitoring is enabled in the CCR-t.

15.5.16.8 Usage-Monitoring Examples

For the description of the specific AVP, refer to the Gx AVPs Reference Guide.

IP-CAN session Usage-Monitoring

A **category-map** with **gx-session-level-usage-monitoring** must be associated with the subscriber host or session:

```
configure
  subscriber-mgmt
    category-map cat-map-1 create
      gx-session-level-usage
```

PCRF in RAR sends the following AVPs (among all the other mandatory ones: session-id, etc.)

```
Usage-Monitoring-Information
  Monitoring-Key = "any-string"
  Granted-Service-Unit
    CC-Input-Octets = 1000000
    CC-Output-Octets = 1000000
  Usage-Monitoring-Level = session_level(0)

Event-Trigger = USAGE_REPORT
```

The node reports usage when the thresholds are reached some time later in the CCR-U. The usage is monitored internally on the node based on the current sla-profile instance.

```
Usage-Monitoring-Information
  Monitoring-Key = "any-string"
  Used-Service-Unit
    CC-Input-Octets = 1000000
    CC-Output-Octets = 1000000
```

The PCRF instructs the node to continue Usage-Monitoring with the new thresholds in the CCA-U:

```
Usage-Monitoring-Information
  Monitoring-Key = "any-string"
  Granted-Service-Unit
    CC-Input-Octets = 1000000
    CC-Output-Octets = 1000000
  Usage-Monitoring-Level = session_level(0)
```

Category Usage-Monitoring

Assume that the following category-map is associated with the subscriber host:

```
*A:7750>config>subscr-mgmt>cat-map# info
-----
      activity-threshold 1
      credit-exhaust-threshold 50
      category "queue1" create
        queue 1 ingress-egress
      exit
      category "queue3-5" create
        queue 3 ingress-egress
        queue 5 ingress-egress
      exit
      category "rest-queues" create
        queue 2 egress-only
        queue 4 egress-only
        queue 6 egress-only
        queue 7 egress-only
        queue 8 egress-only
      exit
```

The PCRF will send the following AVPs in the RAR message (among all the other mandatory ones: session-id, etc.)

```
Charging-Rule-Install
  Charging-Rule-Name = Cat-Map:cat1 - cat-map rule install

Usage-Monitoring-Information
  Monitoring-Key = "queue-1"
  Granted-Service-Unit
    CC-Input-Octets = 1000000
    CC-Output-Octets = 1000000
    Usage-Monitoring-Level = PCC_RULE_LEVEL (1)
Usage-Monitoring-Information
  Monitoring-Key = "queue-3-5"
  Granted-Service-Unit
    CC-Input-Octets = 2000000
    CC-Output-Octets = 2000000
    Usage-Monitoring-Level = PCC_RULE_LEVEL (1)
Event-Trigger = USAGE_REPORT
```

The node reports usage when the thresholds are reached some time later in the CCR-U:

```
Usage-Monitoring-Information
  Monitoring-Key = "queue-1"
  Used-Service-Unit
    CC-Input-Octets = 1000000
    CC-Output-Octets = 1000000
Usage-Monitoring-Information
  Monitoring-Key = "queue-3-5"
  Used-Service-Unit
    CC-Input-Octets = 2000000
    CC-Output-Octets = 2000000
```

The PCRF instructs the node to continue Usage-Monitoring with the new thresholds in the CCA-U:

```
Usage-Monitoring-Information
  Monitoring-Key = "queue-1"
  Granted-Service-Unit
    CC-Input-Octets = 1000000
    CC-Output-Octets = 1000000
    Usage-Monitoring-Level = PCC_RULE_LEVEL (1)
Usage-Monitoring-Information
  Monitoring-Key = "queue-3-5"
  Granted-Service-Unit
    CC-Input-Octets = 2000000
    CC-Output-Octets = 2000000
    Usage-Monitoring-Level = PCC_RULE_LEVEL (1)
```

15.5.17 Event Triggers

The PCRF may subscribe to an event trigger on the node. The PCRF subscribes to new event triggers or removes armed event triggers unsolicited at any time. When an event matching the event trigger occurs, the node reports the event to the PCRF. The event triggers that are required in procedures will be unconditionally reported (for example, IP address allocation/de-allocation) from the node, while the PCRF may subscribe to the remaining events (for example Usage-Monitoring).

When sent from the PCRF to the node, the Event Trigger AVP indicates an event that will trigger an action in the node. When sent from the node to the PCRF, the Event Trigger AVP indicates that the corresponding event has occurred. If no Event Trigger AVP is included in a CCA or RAR operation, any previously provisioned event trigger will still be applicable.

The PCRF may remove all previously provided event triggers by providing the Event-Trigger AVP set to the value NO_EVENT_TRIGGERS. When an Event-Trigger AVP is provided with this value, no other Event-Trigger AVP will be provided in the **cca** or **rar** command. Upon reception of an Event-Trigger AVP with this value, the node will not inform the PCRF of any event except for those events that are always reported and do not require provisioning from the PCRF.

When the PCRF subscribes to one or more event triggers by using the **rar** command, the node will send the corresponding currently applicable values to the PCRF in the RAA if available, and in this case, the Event-Trigger AVPs will not be included.

For a list of the supported events on the node, refer to the Gx AVPs Reference Guide.

15.5.18 Subscriber Verification

At any time, the PCRF can query the node for the presence of the subscriber-host via a RAR message.

The node will respond with the following result-codes in RAA:

- DIAMETER_SUCCEES (2001) — subscriber active
- DIAMETER_UNKNOWN_SESSION_ID (5002) — subscriber does not exist

15.5.19 Subscriber Termination

The PCRF can request IP-CAN session termination on the node via two messages:

- a RAR directive with the Session-Release-Cause AVP to the node
- ASR

Upon the arrival of either of those messages, the node will start the IP-CAN session termination procedure (CCR-t with corresponding Termination-Cause AVP will be sent to the PCRF). This is described in the 3GPP 29.212 document, §4.5.9.

For a list of the supported Termination-Cause AVP values on the node, refer to the Gx AVPs Reference Guide.

15.5.20 Mobility Support in WiFi

When a WiFi subscriber moves between the access points (APs), a CCR-u message is triggered on the node, carrying the Called-Station-Id AVP. The Called-Station-Id AVP carries the MAC IP address of the new AP. This functionality allows the PCRF to make a location-based policy decision.

This functionality is enabled via event trigger USER_LOCATION_CHANGE (13) [3GPP 29.212, §5.3.7] sent to the node by a PCRF in a CCA or RAR message.

The same event will be reported back from the node to the PCRF in a CCR-u message when the user location changes.

15.5.20.1 Redundancy

Redundancy in Gx relies on the Diameter redundancy mechanisms described in the [Diameter Redundancy](#).

15.5.21 Persistency and Origin-State-ID AVP

Persistency and Origin-State-ID AVP (RFC 6733, §8.6 and §8.16).

Persistency (saving the state of IPoE hosts on the compact flash) for Gx sessions is not supported. This means that, on reboot, the node will restore the subscriber-hosts from the persistency but the Gx session awareness for the recovered hosts is lost. Any previously applied QoS or filter overrides will be lost. However, subscriber-strings (subscriber-id, sub-profile, sla-profile, aa-profile) can be made persistent and can be preserved across reboots.

The Origin-State-Id (OSI) AVP is not stored in persistency. If the node reboots, the Origin-State-ID AVP is set to boot time (UTC).

The Origin-State-Id AVP is contained in the CER messages and application messages that are sent from the node to the PCRF/DRA. In the other direction, sent by the PCRF to the node, the OSI is ignored.

To restore a lost session after the reboot, the node will initiate a CCR-i message for every host that has recovered from persistency. The CCR-i will contain the new session-id and origin-state-id. Based on this CCR-i, it is expected that the PCRF will return the most current policy for the host.

15.5.22 Overload Protection

The node has a receiving queue per Gx application (ESM, UM, AA). Each queue can hold 10K messages. While the queue is in the overloaded state, the node replies to every new RAR message with the RAA message that contains the Result-Code AVP set to the DIAMETER_TOO_BUSY (3004) value. This can be considered as explicit signaling towards the PCRF notifying it of the condition on the node.

If the messages in the overwhelmed the node queue do not require sending an answer (if the overwhelmed queue contains CCA-i/u messages), the TCP window will fill up, TCP ACKs will not be sent, and consequently this will be an implicit notification to the PCRF to slow down.

If the node receives a response from an overloaded PCRF (Result-Code = DIAMETER_TOO_BUSY), the node will time out (**tx-timer**) the originally sent message. Once the message is timed out, the configuration settings (on-failure) will determine whether to trigger the peer-failover procedure or not (peer-failover based on DIAMETER_TOO_BUSY Result-Code is recommended in RFC6733, §7.1.3).

15.6 Diameter NASREQ Application

The Diameter NASREQ application is used for Authentication, Authorization, and Accounting services in the Network Access Server (NAS) environment. The SR OS supports a stateless operation of NASREQ authentication and authorization, interacting with a NASREQ server that does not maintain session state.

Subscriber host or session authentication results in an AA-Request (AAR) message being sent to the Diameter NASREQ server. An Auth-Session-State AVP with value equal to 1 (No State Maintained) is included in the AAR to inform the server of the stateless mode. The server responds with an AA-Answer (AAA) message and must include the Auth-Session-State AVP with value equal to 1 (No State Maintained), together with the authorization AVPs.

Diameter NASREQ accounting is not supported.

[Table 115](#) lists the supported Diameter NASREQ messages. Vendor-specific AVP's are shown as: v-<vendor-id>-<AVP id>.

Table 115 Supported Diameter NASREQ Messages

Diameter Message		Code
AAR	AA-Request	265
AAA	AA-Answer	265

Diameter NASREQ authentication is supported for IPoE hosts and sessions, PPPoE PTA PAP/CHAP authentication. Diameter NASREQ authentication is not supported for L2TP LAC/LNS.

NASREQ and RADIUS authentication cannot be configured simultaneously on a capture-sap, local-user-database, or group-interface. They have the same priority in the hierarchy of different sources (such as local user database, Gx, defaults, etc.) for obtaining the subscriber host or session authorization parameters.

Multi-chassis redundancy is supported via separate Diameter NASREQ peers on each redundant node. Each node of the multi-chassis redundancy pair has its own Diameter Identity (origin host/realm). The subscriber host or session is authenticated on the BNG where it is initially connected. Due to the stateless operation, there is no need to synchronize NASREQ session state. Alternatively, the Diameter proxy can be used if it is required to have a single Diameter Identity (origin host/realm) per pair of multi-chassis redundant nodes.

There is no NASREQ re-authentication for active subscriber hosts or sessions, except for a forced re-authentication when the circuit ID/interface ID or remote ID of a DHCP host is changed.

Stateless NASREQ authentication can be complemented with Diameter Gx policy management for policy control and mid-session changes. Diameter NASREQ and Gx applications are supported simultaneously on a single Diameter peer.

Figure 218 shows a sample call flow for a subscriber using Diameter NASREQ for authentication and Diameter Gx for policy management.

Figure 218 Sample Diameter NASREQ Call Flow

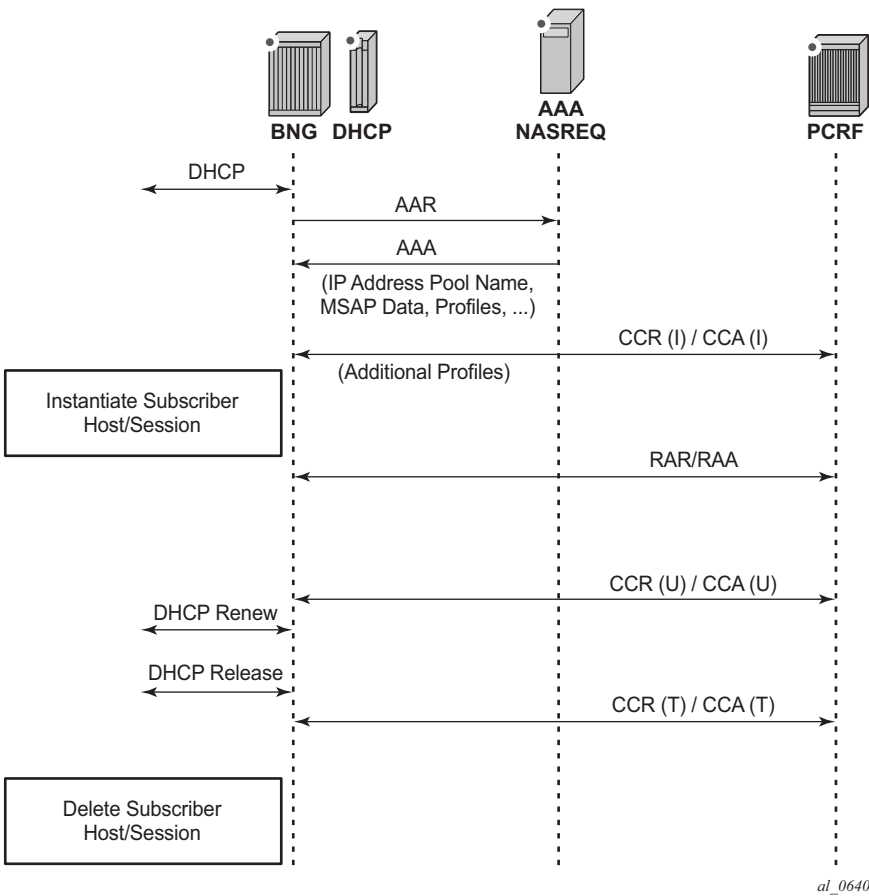

Table 115 lists the authorization AVPs that are accepted in a Diameter NASREQ AA-Answer message. Vendor-specific AVPs are shown in the table as: v-<vendor-id>-<AVP-id>.

Table 116 AA-Answer Message — Accepted Authorization AVPs

AVP ID	AVP Name	Description
1	User-Name	Overrides the “Radius User-Name”.
8	Framed-IP-Address	The IPv4 address of the subscriber host.
9	Framed-IP-Netmask	The IPv4 netmask of the subscriber host.
22	Framed-Route	IPv4 managed route to be configured on the NAS for a routed subscriber host.
25	Class	Opaque value; echoed in RADIUS accounting.
88	Framed-Pool	The name of an IPv4 address pool.
97	Framed-IPv6-Prefix	SLAAC IPv6 prefix (wan-host).
99	Framed-IPv6-Route	IPv6 managed route to be configured on the NAS for a v6 routed subscriber host..
100	Framed-IPv6-Pool	The name of an IPv6 IA-NA address pool (wan-host).
123	Delegated-IPv6-Prefix	DHCPv6 IA-PD IPv6 prefix (pd-host).
v-6527-9	Alc-Primary-Dns	The IPv4 address of the primary DNS server.
v-6527-10	Alc-Secondary-Dns	The IPv4 address of the secondary DNS server.
v-6527-11	Alc-Subsc-ID-Str	Unique subscriber ID string.
v-6527-12	Alc-Subsc-Prof-Str	Subscriber profile string.
v-6527-13	Alc-SLA-Prof-Str	SLA profile string.
v-6527-16	Alc-ANCP-Str	ACNP string.
v-6527-17	Alc-Retail-Serv-Id	The service-id of the retailer to which this subscriber host belongs.
v-6527-18	Alc-Default-Router	The default gateway for the user (DHCP option [3] default-router for a DHCPv4 proxy)
v-6527-28	Alc-Inc-Dest-Id-Str	Intermediate destination ID string.
v-6527-29	Alc-Primary-Nbns	The IPv4 address of the primary NetBios Name Server (NBNS).
v-6527-30	Alc-Secondary-Nbns	The IPv4 address of the secondary NetBios Name Server (NBNS).
v-6527-31	Alc-MSAP-Serv-Id	Service ID where the managed SAP is to be created.
v-6527-32	Alc-MSAP-Policy	Managed SAP policy used to create the MSAP.

Table 116 **AA-Answer Message — Accepted Authorization AVPs (Continued)**

AVP ID	AVP Name	Description
v-6527-33	Alc-MSAP-Interface	Group-interface name where the managed SAP is to be created.
v-6527-45	Alc-App-Prof-Str	Application profile string.
v-6527-99	Alc-Ipv6-Address	DHCPv6 IA-NA IPv6 address (wan-host).
v-6527-105	Alc-Ipv6-Primary-Dns	The IPv6 address of the primary DNSv6 server.
v-6527-106	Alc-Ipv6-Secondary-Dns	The IPv6 address of the secondary DNSv6 server.
v-6527-131	Alc-Delegated-Ipv6-Pool	The name of an IPv6 IA-PD prefix pool (pd-host).
v-6527-161	Alc-Delegated-Ipv6-Prefix-Length	DHCPv6 IA-PD prefix length (pd-host).
v-6527-174	Alc-Lease-Time	The lease-time for proxy, in seconds.
v-6527-181	Alc-SLAAC-IPv6-Pool	The name of an IPv6 SLAAC prefix pool (wan-host).

15.6.1 Sample Configuration Steps

To specify the peers to reach the Diameter NASREQ server in a diameter peer policy:

```
configure
aaa
    diameter-peer-policy "diameter-peer-policy-1" create
        description "Diameter NASREQ peer policy"
        applications nasreq
        origin-host "bng@nokia.com"
        origin-realm "nokia.com"
        peer "peer-1" create
            address 172.16.3.1
            destination-realm "myDSCRealm.com"
            no shutdown
        exit
    exit
exit
```

To specify the Diameter NASREQ application specific parameters, such as AVP format and values, in a Diameter application policy:

```
configure
subscriber-mgmt
    diameter-application-policy "diameter-nasreq-policy-1" create
        description "Diameter NASREQ application policy"
        application nasreq
        diameter-peer-policy "diameter-peer-policy-1"
        nasreq
            user-name-format mac
            include-avp
                circuit-id
                nas-port-id
                nas-port-type
                remote-id
            exit
        exit
    exit
exit
```

To apply the Diameter NASREQ application policy as Diameter authentication policy at a VPLS capture SAP, at an IES/VRPN group-interface and/or at a local user database:

Note: A Diameter authentication policy cannot be configured simultaneously with a RADIUS authentication policy on the same group-interface or capture SAP, nor for the same host in a local user database.

```
configure
service
```

```

vpls 10 customer 1 create
  sap 1/1/4:*. * capture-sap create
  ---snip---
  diameter-auth-policy "diameter-nasreq-policy-1"
ies 1000 customer 1 create
  subscriber-interface "sub-int-1" create
  ---snip---
  group-interface "group-int-1-1" create
  ---snip---
  diameter-auth-policy "diameter-nasreq-policy-1"
vprn 2000 customer 1 create
  subscriber-interface "sub-int-1" create
  ---snip---
  group-interface "group-int-1-1" create
  ---snip---
  diameter-auth-policy "diameter-nasreq-policy-1"

configure
  subscriber-mgmt
    local-user-db "ludb-1" create
    ipoe
      host "ipoe-host-1" create
      ---snip---
      diameter-auth-policy "diameter-nasreq-policy-1"
    ppp
      host "ppp-host-1" create
      diameter-auth-policy "diameter-nasreq-policy-1"

```

If no AA-Answer message is received from the primary or secondary Diameter peer, then the host or session can be instantiated with the configured defaults. This is achieved by the following NASREQ application policy configuration:

```

configure
  subscriber-mgmt
    diameter-application-policy "diameter-nasreq-policy-1" create
    on-failure failover enabled handling continue

```

To enable flexible integration with different NASREQ servers, a Python policy can be configured on the Diameter peer policy. The Python script can interact on the AVPs present in the AA-Request and AA-Answer messages.

```

configure
  python
    python-policy "py-policy-nasreq-1" create
    diameter aar direction egress script "NasreqAar"
    diameter aaa direction ingress script "NasreqAaa"
configure
  aaa
    diameter-peer-policy "diameter-peer-policy-1" create
    ---snip---
    python-policy "py-policy-nasreq-1"

```

15.7 Diameter Redundancy

Diameter redundancy is supported on multiple levels:

- **Diameter Peer Level Redundancy:** A Diameter client on the node supports up to five open peers, two of which (primary and secondary) can actively participate in Diameter transactions. The purpose of the secondary peer is to protect the primary peer, should the primary peer experience problems.
- **Diameter Multi-Chassis Redundancy:** Diameter sessions are synchronized on the application level (via ESM in case of Gx and NASREQ) between two redundant nodes. Only one of the nodes open up a peering connection on behalf of the redundant node pair towards the DRA/PCRF.
- **High Availability (HA):** This refers to control plane redundancy with dual Control Plane Modules (CPMs) in a single chassis configuration. Diameter transactions are fully synchronized between CPMs and the peering connection towards DRA/PCRF remains uninterrupted if one of the control plane modules fails.

15.7.1 Diameter Peer Level Redundancy

Once the peer in the Diameter policy (maximum five peers per policy) is administratively enabled (**no-shutdown**), the node starts connecting to it. If the establishment of the TCP connection fails, the node periodically retries to connect.

If creation of the TCP connection succeeds, the peer is placed in the **peer table**, and in that table the “preference” defines the **current usability** of the peers. All administratively enabled peers that are in the open state have keepalives (DWR/DWA) enabled to check the liveliness of the connection, but only the two open peers with the highest preference are considered as primary and secondary. In this fashion, the application messages (for example, DCCA or Gx) are sent only to the primary and/or the secondary peer.

Initially all messages are sent to the primary peer. If a session-failover occurs (timeout or primary peer closes), the messages are sent to the secondary peer (which could have become primary by that time). Once an (application) session has switched, the consecutive messages are sent to the peer where it had its last success request/answer (it sticks to the peer).

The status of primary and secondary peer is constantly re-evaluated, if an error condition occurs at the primary or secondary peer.

The following example shows how DCCA messages are treated:

1. There are ten sessions that have been created; the primary peer at that moment is peer-a, secondary peer is peer-b, and peer-c, peer-d and peer-e are in state open (being kept alive with diameter watchdog request/watchdog-answer messages). Consequently, all CCR-i messages are sent to peer-a since this is the **preferred** peer at the time of handling CCA-i.
2. All ten sessions start requesting credit updates (CCR-u), but only six of them are successfully completed (CCR-u/CCA-u) by the peer-a. Their **preferred** peer will remain peer-a. Then, the connection to the peer-a fails (connection is closed). Peer-b becomes the primary, peer-c becomes the secondary. The remaining four CCR-u sessions that were pending will now be redirected to the peer-b with the retransmission bit (T) set in the diameter header. When these four outstanding transactions successfully complete (CCA-u received), they will have the peer-b as the **preferred** peer.
3. In the meantime, peer-a recovers, and the cooldown sequence is deactivated (by three successful DWR/DWAs). Peer-a becomes primary again and peer-b becomes secondary.
4. Now, the sessions need a new credit. Six of them will ask peer-a and four will ask peer-b.

If peer-a did not become alive in time, peer-c would be used for re-transmissions. At some point later, when peer-a and peer-b become the primary and the secondary peers again, those sessions with the **preferred** peer-c will be redirected back to peer-a (as we only use peer-a and peer-b to send application messages).

So in essence, a **revertive** mode is used for the peer recovery, where the sessions are reverted back to the peer on which the session was originally setup, as long as this peer is one of the two active peers (primary and secondary).

15.7.2 Diameter Multi-Chassis Redundancy

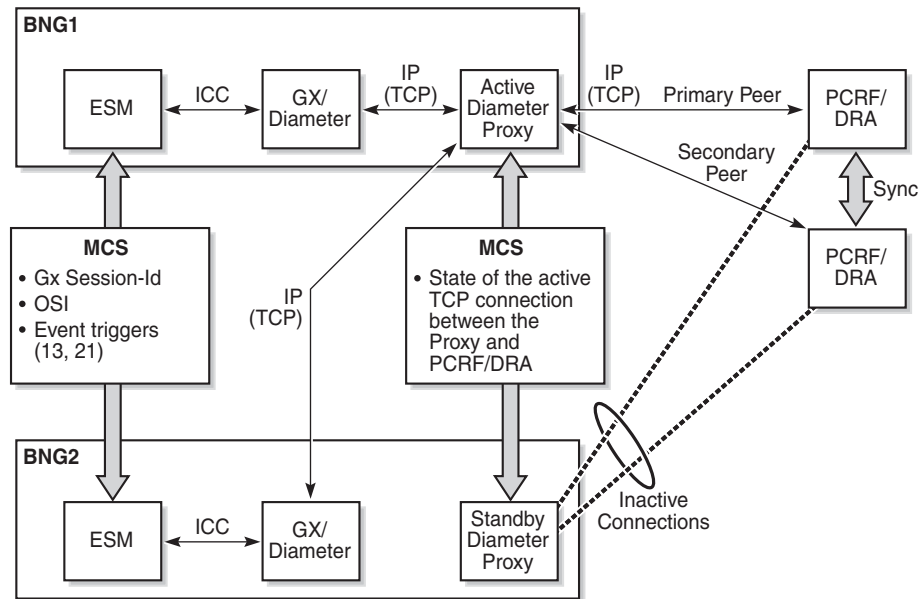

The Diameter Multi-Chassis Redundancy solution on the node is based on the model where communication with the PCRF/DRA occurs over a single Diameter peering connection for the redundant pair of nodes; that is, an active Diameter proxy module running on the node is front-ending the communication with the PCRF/DRA, and is relaying messages between the Diameter clients (in redundant nodes) and the DRA/PCRF. Both nodes run the Diameter proxy module, but only the active one opens the TCP peering connection towards the DRA/PCRF.

The benefits of the Diameter proxy model are:

- The redundant pair of nodes appear as a single node to the PCRF/DRA.
- Diameter Identity is uniform across the pair of redundant nodes; that is, both nodes share the same origin-host/realm, a property that carries operational benefits.
- There is a robust and predictable failover of a single connection, as opposed to having separate diameter peering sessions per node.

The goal of this redundancy model is to provide a predictable and quick recovery after a node failure, PCRF failure, or relevant components within those two entities (such as line cards, MDAs, and physical ports).

[Figure 219](#) illustrates the basic concept for Diameter Multi-Chassis Redundancy for a Gx application. The model shows two nodes (BNGs). Each BNG contains an ESM module and a Gx/Diameter module which have a peering connection to the active Diameter proxy module. The peering connections are IP connections. Both nodes communicate with the PCRF/DRA through the active Diameter proxy which maintains a peering connection with the PCRF/DRA.

Figure 219 Proxy Gx Model

24874

15.7.2.1 Diameter Proxy Model General Operational Principles

The fundamental principles of the Diameter proxy-based redundant solution are described below (also refer to [Figure 219](#)):

1. There can be only one active Diameter proxy per redundant pair of nodes. This active Diameter proxy maintains peering connections (primary/secondary) towards the PCRF/DRA at any given time. There are no peering connections open on the standby Diameter proxy. The active Diameter proxy accepts the connections from the client side, while the standby does not. The standby Diameter proxy ignores, without any reply, requests from the clients to open peering connections.
2. The activity selection is based on the system MAC address of each node and the current state of the Diameter proxy (Init, Active, Standby, Active-Wait, Standby-Wait and the Proxy-Switchover-Reg) in each node. This information is exchanged between the nodes via MCS. The system MAC address is unique per node. The activity selection is automatic and cannot be influenced via CLI, other than shutting down peers on the currently active Diameter proxy.

Application level information (Gx session, NASREQ session, etc.) is not synchronized between Diameter proxies. Instead, synchronization of session level information is performed on the application level; for example, Gx session information is performed through subscriber management (ESM) synchronization.

3. Preemption is not supported if a node coming up from a boot-up sequence would cause the MCS peer to transition from active to standby state. Only in the case where the two nodes are booting simultaneously, or are recovering from the MCS synchronization loss (both nodes are joining MCS while in the active state), would the node with a higher system MAC address transition into the active state (during the simultaneous node boot-up) or remain in the active state (after isolation re-synchronization).
4. When the Diameter proxy transitions from an active to standby state, the newly-transitioned standby Diameter proxy closes the TCP connections towards the Diameter clients. The clients then initiate a new connection towards the secondary peer, but only after the current connection-timer expires (30 s by default). For example, assume that the connection timer is set for 30 s. If the TCP RST is received when the running connection-timer is at 15th s, then the secondary peer is not initiated for another 15 s.
5. In the case where the active Diameter proxy receives messages from the client while it does not have any peers on the server side open, the Diameter proxy sends a `DIAMETER_UNABLE_TO_DELIVER` (3002) message to the client. The client then retransmits the message to the same peer since it has only one peer that is in the UP state. Upon receipt of the `DIAMETER_UNABLE_TO_DELIVER` (3002) message, the client leaves the original message to time out, and then retransmits it (that is, the message is NOT retransmitted from the client side immediately upon the arrival of the `DIAMETER_UNABLE_TO_DELIVER` (3002) message).
6. The TCP protocol handles retransmissions on the transport layer to the same peer. This is valid on the Diameter client side and on the Diameter proxy side. A TCP retransmission normally occurs at the intervals driven by an exponential back-off. The initial timeout depends on the implementation, but for the most common case, it can be assumed to be 1.5 s, followed by an exponential back-off capped at 64 s (1.5 s, 3 s, 6 s, 12 s, 24 s, 48 s, 64 s).
7. The Diameter client handles retransmissions on the Diameter level. The Diameter client will be able to retransmit on the same socket since it only has a single socket (to the active Diameter proxy). The T-bit in the Diameter header will be set for every retransmitted message. The watchdog interval should be set to 1 s, so that the dead TCP connection (dead proxy) can be quickly identified. The Diameter client will retransmit when:
 - The original request times out.

- It receives a reply with the E-bit set. Such retransmissions will not be triggered immediately upon the arrival of the response with E-bit set. Instead, the original messages that need to be retransmitted will be left in the pending queue to time out and will be retransmitted after the timeout period, which is controlled by the tx-timer command.
 - The primary peer is closed and the secondary peer is available.
8. The Diameter proxy never retransmits a message on the Diameter level since it does not perform any buffering (Tx/Pending queue). However, it does retransmit on the TCP level (hop-by-hop).
 9. The Diameter proxy only relays messages between the client (application) and the server side (DRA/PCRF). The two bits in the Diameter header that the proxy is reacting on are the T-bit and the E-bit.

If the T-bit is set in the message coming from the client side, the Diameter proxy sends the message to the secondary peer (invokes the peer failover procedure). That is, the application level retransmissions is performed by the Diameter client (which is peering with the Diameter proxy). The client sets the T-bit (retransmission bit) in the Diameter header and this signals to the Diameter proxy that it needs to failover the message to the alternate peer. This operation is performed on a per message basis and not on a per session basis.

The Diameter proxy initiates a failover procedure to the secondary peer when the primary peer on Diameter proxy is closed, or the watchdog timer on the primary peer expires.

All messages in the DRA/PCRF-to client direction with the E-bit set (the E-bit can be present only in answer messages) are dropped in the proxy. Consequently, the client retransmits the request, upon timeout.

The messages with the E-bit set that are traveling in the opposite direction are not dropped; they are transparently passed to the DRA/PCRF.
 10. On an SRRP Switchover, the AN-GW-IP of the newly-transitioned Master can be reported in CCR-u as an indication of the switchover. This functionality is enabled by arming the node with the event-trigger id 13 (USER_LOCATION_CHANGE) from PCRF.
 11. On a Diameter proxy switchover, a SNMP Log/Trap is generated.
 12. The standby client (SRRP standby) discards all messages received by the Diameter proxy.

15.7.2.2 Diameter Proxy Activity Selection

The Diameter proxy with the highest system MAC address assumes the controller role. The controller node decides which proxy becomes ACTIVE or STANDBY. Activity election information is processed by the controller node and then the controller node delegates the actual ACTIVE/STANDBY roles to Diameter proxies. The ACTIVE proxy may not necessarily be the same node as the controller node.

The activity selection (by the controller node) in the Diameter proxy is based on the current states of both Diameter Proxies (local and remote) and the system MAC.

Preemption is not supported, which means that newly brought up Diameter proxy does not overtake the activity state from the existing active Diameter proxy, regardless of the system MAC addresses.

Once the node becomes active, it advertises the new state to the MCS Diameter proxy peer and tries to open a DRA/PCRF peering connections and at the same time accept the client connections. The active Diameter proxy replies to the client with a DIAMETER_UNABLE_TO_DELIVER error-code when server side peers cannot be opened.

15.7.2.3 Synchronization and MCS

All application level (Gx or NASREQ) sessions related parameters are synchronized on the ESM level via MCS.

The parameters synchronized on the ESM level are:

- Session-Id
- Event-Triggers
- CC-Request-Number

The Diameter proxy module is synchronized via MCS; the information passed between the two nodes is:

- System MAC address: this address plays a role in the Diameter proxy state selection
- Controller MAC address: the System MAC address of the node that is performing the Diameter proxy state selection. The node with the highest system MAC address assumes the controller role. Once the controller makes the state selection for both nodes, it delegates those states to Diameter proxies. The controller role is collocated with one of the Diameter proxy nodes.
- Origin-State-Id (OSI)

- Diameter proxy States

The above information is used to determine the activity of the Diameter proxy at each node.

If an MCS link fails, the nodes become isolated. Each node acts independently and tries to become active. This scenario is described in [Isolated Chassis](#).

15.7.2.4 Retransmissions

The handling of Diameter retransmissions is crucial for the Diameter Multi-Chassis Redundancy operation. Retransmissions provide the means to recover a Diameter session that was left in an unacknowledged state due to failure of the path between the node and the DRA/PCRF.

Retransmissions of Diameter messages are handled on two levels by a pair of redundant nodes:

1. At the TCP level: request and answer messages are retransmitted by TCP. These types of retransmissions are only significant between two directly connected peers, hop-by-hop retransmissions. For example, if the failure occurs beyond two directly connected peers, these type of retransmissions will not help.
2. At the application (Gx, Gy, NASREQ) level: only request messages are retransmitted. These types of retransmissions extend beyond two directly connected peers and can cover end-to-end failure cases.

A more detailed explanation of the processing that occurs on each level for a Gx application is given below.

1. The first level of retransmissions occurs at the TCP level. The Gx message is handed over to the TCP socket Base Diameter module. TCP tries to deliver this message in a connection-oriented (reliable) fashion. If a TCP ACK for the transmitted message is not received, the message, in the most common case, is retransmitted in intervals of 1.5 s, 3 s, 6 s, up to 64 s. After 10 s of trying to retransmit the message to the same peer at the TCP level, the Base Diameter tries to retransmit (configuration dependent) the message to the next TCP socket (secondary peer). The assumption is that the primary peer is unavailable (busy, failed, or the network path to it is broken) after 10 s of trying. The TCP retransmissions are peer oriented and very localized (to the particular TCP connection on the particular BNG node). If a network fails, TCP retransmissions cannot re-route the traffic to an alternate destination. As such, they cannot

protect against the peer (PCRF) failure or the BNG node failure. They can, however, indirectly provide a clue that something is happening at the peer level, so that the upper layers can take adequate actions. Watchdogs are also used to detect peer failure and they can provide faster detection of the peer failure (after 2 s).

2. Re-routing of the traffic occurs at the Application/Diameter level. Once the peer is considered unavailable, or the original requests message times out, the Diameter has the ability to re-route the retransmitted message to an alternate (secondary) peer. The Diameter level retransmissions can protect against a PCRF/DRA failure. Traffic can be switched to the secondary peer (this functionality must be enabled via configuration).

Since the Diameter proxy only relays the messages between the client and the DRA/PCRF, it never buffers and retransmits the Diameter message.

Retransmissions are the responsibility of the Diameter peer (Diameter client) that sits behind the Diameter proxy. Retransmitting Diameter client sets the T-bit in the Diameter header of the retransmitted message (CC-req-num is kept the same in the original and retransmitted message). The T-bit in the message triggers the Diameter proxy to re-route the messages to the secondary peer while the primary peer is still active. This means that the Gx client has already retransmitted the message, and the Diameter proxy re-route its.

With single peer, the Diameter **client** retransmits the message to the same peer and it sets the T-bit in the Diameter header.

With a single peer, the Diameter **proxy** sends the message with the T-bit set to the same peer.

The Gx client typically re-routes the message to the secondary peer in the following cases:

- The primary peer is closed and the secondary peer is available.
- The Diameter message times out due to no response.
- The Diameter message times out due to a received answer with E-bit set in the Diameter header (E-bit can be only set in the answer messages and it indicates protocol errors with Result-Code from the 3xxx range). Once the reply with E-bit set is received, the corresponding request message is left on the pending queue where it times out after the interval controlled by the tx-timer statement in the diameter-application-policy. Upon message timeout, the node retransmits the message to the secondary peer if the secondary peer is available. If not, the message will be retransmitted to the same (primary) peer.

In summary:

- TCP handles retransmissions towards the peer (hop-by-hop retransmissions).

- Diameter and Diameter applications (Gx, Gy, NASREQ) retransmit to the secondary peer in cases where the application level message times out, a protocol error is received (Result-Code 3xxx) in the answer from the DRA/PCRF, or the primary peer is 'closed'. If there is only one peer available (primary), the Diameter application retransmits to that peer. The T-bit in retransmitted messages is always set. Diameter level retransmissions cover failure cases that extend beyond two directly connected hops.
- The Diameter proxy never retransmits (retransmissions are handled by the Diameter client that sits behind the proxy). However, the Diameter proxy sends messages with the T-bit set to the secondary peer.

These scenarios are shown in [Figure 220](#), [Figure 221](#), and [Figure 222](#).

Figure 220 Retransmissions with Two Peers and no Diameter Proxy

24879

Figure 221 Retransmissions with a Single Peer and no Diameter Proxy

- ① Req/Answ retransmissions governed by TCP (such as windowing and exp backoff).
- ② Request retransmissions handled at the Gx level (peer failover). T-bit is set.

24880

Figure 222 Redirection with Diameter Proxy (T-bit set)

- ② Diameter Proxy will use secondary peer only if T-bit is set, or the primary peer is closed.

24881

15.7.2.5 Retransmissions and the T-bit

Multi-chassis redundancy is less concerned with the retransmissions of the answer messages (RAA) since, if the answer is not received, the PCRF retransmits the request (RAR). Retransmission of the **answer** messages is performed only on the TCP level within a single node. It is not performed on the Diameter level.

When the **request** message is retransmitted by the Diameter application (due to the Tx timer timeout, primary peer failure - DWR timeout, or receipt of the answer message with E-bit set), the content of the message stays the same, including the CC-Request numbers but the T-bit in the Diameter header is set. The T-bit indicates to the PCRF that the message is retransmitted (mostly used for accounting purposes so that the counting records are not duplicated). It also signals to the Diameter proxy that the message rerouting to the secondary peer should be performed.

15.7.2.6 Diameter Proxy Role

The Diameter proxy is applied to an IPv4 or IPv6 address within a routing-context on a node. This IP address is a Diameter proxy listening IP address that is associated with an interface on a node, including the system interface (system IPv4 or IPv6 address) or loopback interface (loopback IPv4 or IPv6 address).

The number of Diameter Proxies per listening IP address is limited to one. That is, each proxy diameter-peer-policy requires a unique combination of source-ip (listening IP address) and the routing-context (node).

The number of Diameter-peer-policies on a node is limited to 32. This means that the combined number of Diameter clients and Proxies on a node cannot exceed 32.

The Diameter Proxy has the following role on a node:

1. The active Diameter proxy relays messages between the application (Gx and NASREQ) module on a node and the PCRF/DRA.
2. Only the active Diameter proxy allows peering connection with the client (the Diameter on a node). The standby Diameter proxy refuses the client connection.
3. The Diameter proxy with open peering connections is referred to as the active Diameter proxy (ADP). Its counterpart is called the standby Diameter proxy.
4. The Diameter proxy retransmits the message on the TCP level towards the same peer.

5. However, the Diameter proxy does not perform application level message retransmission and the peer failover procedure due to the timeout of the application level message. Instead, the application level retransmission is performed by the Diameter client (which is peering with the Diameter proxy). The client sets the T-bit (retransmission bit) in the Diameter header of the retransmitted message (same CC-Req_Number) and this signals to the Diameter proxy that it needs to failover the message to the alternate peer.

Note: This re-routing operation in the proxy is performed per message and not per sessions, as it is the case for a Diameter client.

6. When the primary peer is closed, or the watchdog timer on the primary peer expires, the Diameter proxy initiates failover procedure to the secondary peer.
7. The standby client (SRRP standby) discards received RAR messages.
8. The active Diameter proxy replies to the client with the error message UNABLE_TO_DELIVER if the peering connection towards the server cannot be open. The client retransmits the messages (since it has only one connection) after the timeout interval.

Table 117 summarizes the differences between the regular Diameter client and the Diameter proxy.

Table 117 Summary of Differences

Regular Diameter Client	Diameter Proxy
Initiates messages.	Transparently passes all messages between the client and the server. Never initiates the messages.
Buffering is implemented, thus retransmissions are supported.	Buffering is not implemented (pending queue), thus messages are never retransmitted.
When retransmitting, it sets the T-bit in the Diameter Header.	Never retransmits the messages.
Failover to the secondary peer is triggered by: <ul style="list-style-type: none">• Message timeout• Primary peer is down; immediate failover.• All messages with an E-bit set triggers failover after the message times out on the pending queue.	Failover to the secondary peer is triggered by: <ul style="list-style-type: none">• Messages with T-bit set; immediate failover per message.• Primary peer shutdown
Diameter client performs peer failover per session.	Diameter proxy performs peer failover per message (with the T-bit set).

15.7.2.7 Diameter Proxy and CC-Request-Number AVP

CC-Request-Number AVP (RFC 4006, 8.2) are typically used to match requests with answers. Session-id and CC-Req-Num are a unique per-message pair. CC Request Numbers along with the session-id uniquely identify a transaction (matching requests and answer messages) on a global level.

The Diameter proxy does not re-write the CC-Request-Number in the messages received by the client.

CC-Req-numbers are synchronized at the ESM level. This is needed so that operation with proper CC-Req-Num can resume after the switchover.

For example, the following CC-Req-Num sequence for the session is preserved across SRRP switch-overs:

- 1st host (e.g. IPv4) of a dual-stack host is setup
- CCR-I with CC-Req-Num = 1 is sent
- 2nd host (for example, IPv6 IA-NA) of the same dual-stack host is set up
- CCR-U with CC-Req-Num=2 is sent
- SRRP switchover occurs
- 2nd host in the dual-host is removed (DHPCv6 release)
- CCR-U with CC-Req-Num=3 is sent from the new SRRP Master

15.7.2.8 Stateless Diameter Proxy

The Diameter proxy does not maintain any session state. Forwarding is based on transactions which are short lived. Transactions are based on a pairing request/answer messages matched by the same hop-by-hop identifier and the peer from which the request was received. In this fashion, answer messages coming from the DRA/PCRF can be unambiguously forwarded to the proper Diameter client (from which the request was received).

Since the session state is not kept in Diameter proxy, RAR request are be flooded to both Diameter clients.

15.7.2.9 Switchover Scenarios

The following are four types of switchovers that are most likely to occur:

1. Switchover to a new DRA/PCRF peer at a Diameter proxy
2. Diameter proxy switchover due to failed peers on the server side
3. Diameter proxy switchover due to Diameter proxy node failure
4. SRRP switchover

Each switchover type for a Gx application is discussed in more detail below:

1. Switchover to a new PCRF/DRA peer is handled at the Diameter proxy level. This scenario is shown in [Figure 223](#).

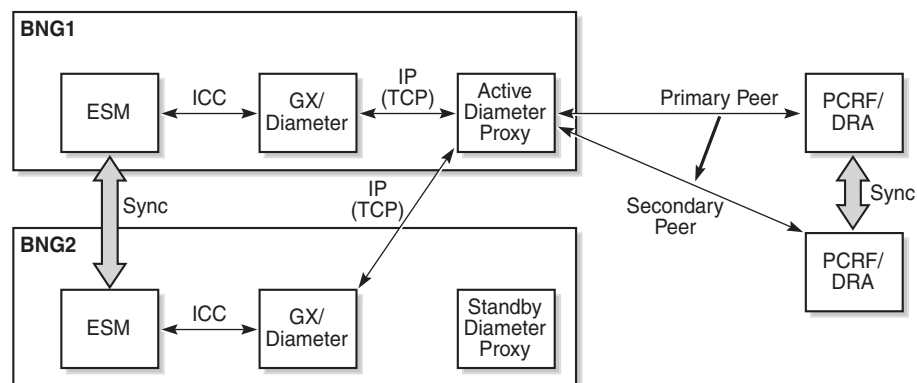

The Diameter proxy switches over to the new peer in the event of two cases:

- It receives a Diameter message with the T-bit set (retransmission bit in the Diameter header) from the Diameter client.

Retransmission due to the message timeout is performed at the Diameter **client** level, and setting the T-bit signals to the Diameter proxy that peer failover is needed for this particular message.

- The TCP connection to the primary peer is explicitly closed (for example, due to TCP RST or watchdog timeouts). Then, the Diameter proxy performs a fail-over of all sessions to the secondary peer immediately.

Figure 223 PCRF/DRA Peer Switchover

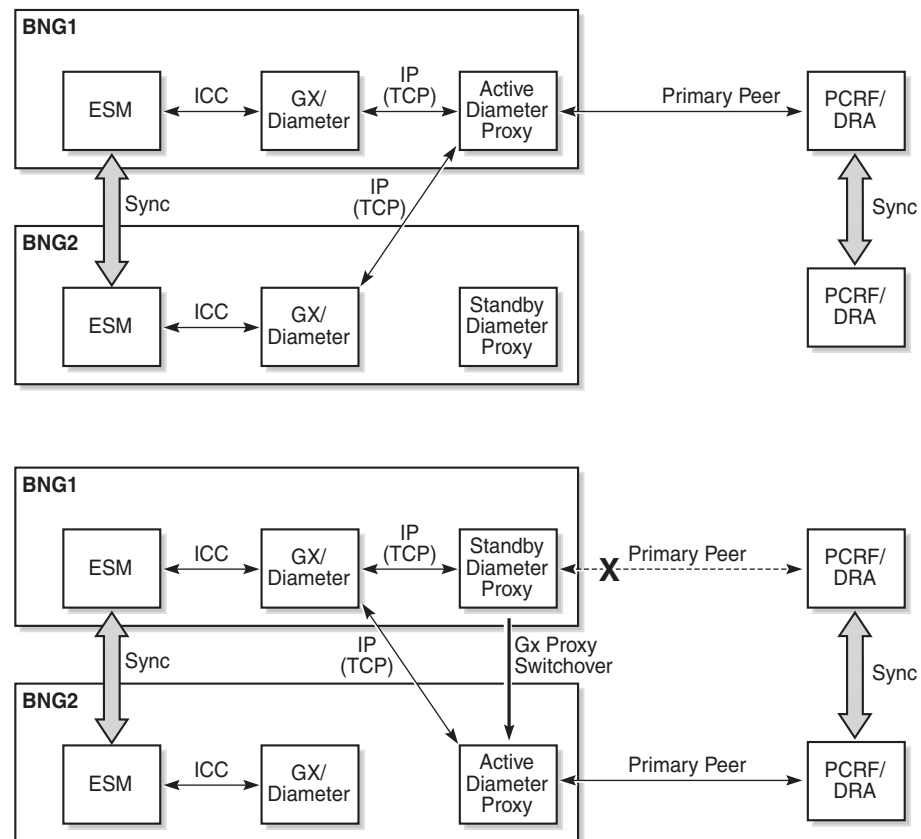

24875

2. Activity switchover between the Diameter proxies occurs when the active Diameter proxy loses all peering connections to the PCRFs/DRAs while both nodes (including MCS) are operational.

This type of switchover (without the node failure) is unlikely to occur. For example, a Diameter proxy switchover (without the node failure) would mean that all PCRFs/DRAs have failed, since normally the same pair of PCRF/DRA peers are configured in both Diameter proxy nodes. This would mean that all DRA/PCRFs are unavailable, which indicates a problem on the network side (either network paths to DRA/PCRFs are broken or all DRA/PCRFs have crashed).

Another example where this scenario could occur is poor redundancy design practices. For example, the active Diameter proxy has a single peering connection to one PCRF (no secondary peer), while the standby Diameter proxy is configured with a separate PCRF peer (the two PCRFs are still synch'd). This scenario is shown in [Figure 224](#).

Figure 224 Diameter Proxy Switchover

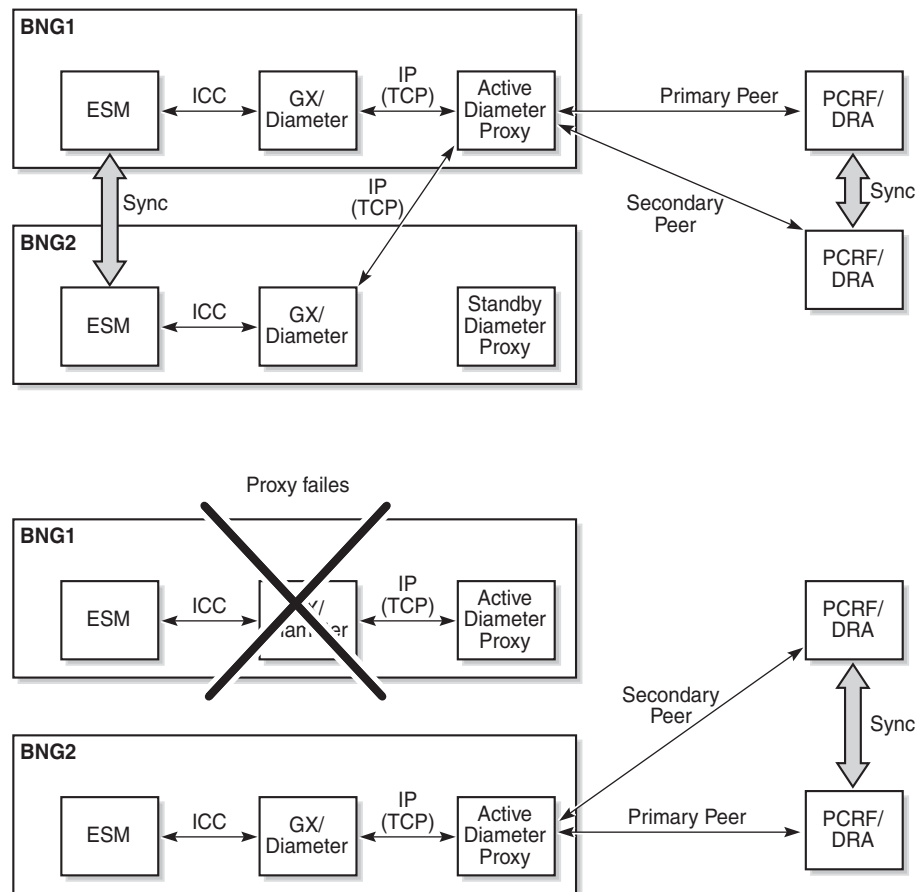

24876

As always, only the active Diameter proxy maintains an open TCP peering connection towards the PCRF/DRA. If this connection fails, the active proxy sends a TCP RST towards the client and transitions into standby state. The client then, upon expiry of connection-timer, open a new TCP connection towards the newly active Diameter proxy.

3. In this scenario, the entire proxy node fails, as shown in [Figure 225](#). The surviving node resumes operation.

Figure 225 Node Failure

24877

4. The last scenario is where the switchover occurs in the access and the SRRP switches activity. The new SRRP master resumes uninterrupted operation.

15.7.2.10 Log/Trap Generation Caused by Diameter Proxy State Change

In cases where the Diameter proxy changes its states (INIT, ACTIVE, STANDBY), a log/trap is generated. This log is enabled by default in log-event control. The notification name is tmnxDiamProxyStateChange.

15.7.2.11 Switchover Update Event (CCR-u)

The AN-GW-Address carried in the CCR-I message for the Diameter application session (for example, Gx) is the IP address of the node on which the underlying SRRP instance (for this Gx session) is in the SRRP master state.

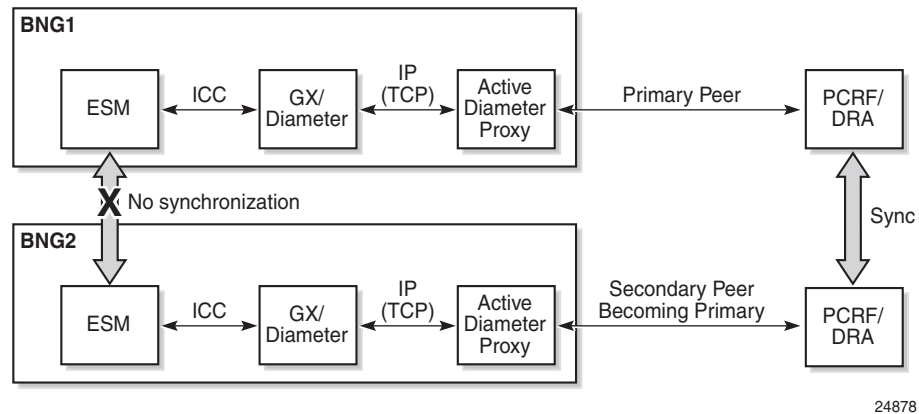

When the SRRP switches over due to the failure in the access part of the network (including the ports on a node), a CCR-U can be optionally (configuration dependent) sent with the AN-GW-Address AVP of the node on which an SRRP instance transitioned into the master state. This behavior is controlled via the event trigger id 13 (USER_LOCATION_CHANGE).

15.7.2.12 Isolated Chassis

In cases where the MCS connection is broken, the Diameter proxy on both nodes try to become active since they each consider that they are the only functional node. From the local point of view, the MCS peer is dead.

While in isolation scenario, both nodes are most likely able to open the TCP peering session with the PCRF/DRA (see [Figure 226](#)).

Figure 226 Isolated Nodes

Once the MCS is recovered, the states are re-synchronized.

15.7.2.13 Diameter Identities

Diameter identities (origin-host/realm) can be configured to be the same on both nodes. This ensures that the redundant pair of nodes appears as a single node at the Diameter level (Diameter Identities).

15.7.2.14 High Availability

A CPM switchover on the active Diameter proxy causes the peering connections between the client and the proxy to be lost. Consequently, the clients have to re-establish their peering connections. Peering connections on the active Diameter proxy towards the server remain uninterrupted.

15.7.3 Gx Specific Behavior

Gx specific behavior in a multi-chassis configuration is as follows:

1. A Gx client at a node attempts to open a TCP connections to both Diameter proxies, but only the active Diameter proxy accepts accept the TCP request (see [Diameter Multi-Chassis Redundancy](#)).

2. The standby Diameter proxy ignores the connection request and does not respond in any way (not even TCP RST).
3. The Gx client normally tries to reopen the configured connections (peers) every connection-timer interval (30 s by default).
4. Since the Gx client has only one peering connection open, retransmissions due to the application level message timeout occurs on that same peer. The T-bit is set and signals to the Diameter proxy that it needs to perform a peer failover procedure.
5. The Gx client discards/ignores all messages received on the standby node (standby SRRP).

15.8 Diameter Debugging

This section explains the debugging capabilities for troubleshooting a Diameter or Diameter application problem.

Debugging should be as specific as possible and limited to relevant messages only. Enabling detailed debugging for all diameter messages on a production node generates a flood of information and is not very helpful in isolating the problem; it can, however, be a valid scenario for lab testing.

Diameter debug output can be limited to:

- messages to a specified origin and/or destination realm

Messages that have no origin or destination realm AVP to match against will also be shown in this configuration.

```
debug
  diameter
    dest-realm dest.com
    origin-realm origin.com
  exit
exit
```

- messages of specified message types

```
debug
  diameter
    message-type ccr cca
  exit
exit
```

- messages sent or received on peers belonging to a specific Diameter peer policy. Up to eight diameter peer policies can be specified

```
debug
  diameter
```

```

        diameter-peer-policy "diameter-peer-policy-1"
        exit
        diameter-peer-policy "diameter-peer-policy-2"
        exit
    exit
exit

```

- messages sent or received on a specific Diameter peer

```

debug
    diameter
        diameter-peer "peer-1"
    exit
exit

```

Only messages that match all specified criteria will be shown in the debug output.

The **diameter debug detail-level** command can be set to

- Low (default): displays the Diameter message header
- Medium: displays the Diameter message header and AVPs
- High: displays the Diameter message header, AVPs, and a packet hex dump

```

debug
    diameter
        detail-level medium
    exit
exit

```

For a per-diameter peer policy additional criteria can be specified to further restrict the debug output to:

- messages sent or received on a specific Diameter peer
overrides the peer configuration at the debug diameter level

```

debug
    diameter
        diameter-peer-policy "diameter-peer-policy-1"
        diameter-peer "peer-1"
    exit
    exit
exit

```

- messages of specified message types
overrides the message type at the debug diameter level

```

debug
    diameter
        diameter-peer-policy "diameter-peer-policy-1"
        message-type ccr cca rar raa
    exit
    exit
exit

```

- messages from a diameter session where the diameter session is learned from Diameter application messages matching specified AVP values (avp-match criteria)

```
debug
  diameter
    diameter-peer-policy "diameter-peer-policy-1"
      avp-match 1
        avp 443.444 octetstring ascii value "1/1/1:10.20@bng1"
        message-type ccr
        no shutdown
      exit
    exit
  exit
exit
```

Only messages sent or received on a peer that belongs to the diameter peer policy and matches all specified criteria will be shown in the debug output.

To restrict debug output to messages from a given diameter session, AVP matching with session learning is required. AVP 263 Session-Id is the only Diameter AVP that is present in all messages of a Diameter session and is dynamically assigned when the Diameter session is initiated. The session ID is not useful to specify as criteria in debugging because its value is unknown upfront. Instead, using AVP matching, it is possible to learn the session ID from Diameter application messages (NASREQ, Gx, and Gy) matching a message type and one or multiple AVP values. All subsequent Diameter application messages that belong to the learned session ID are then included in the debug output, as shown in the following example:

```
debug
  diameter
    detail-level medium
    diameter-peer-policy "diam-pol-1"
      avp-match 1
        avp 25 octetstring ascii value "trace-me"
        avp 10415-1005 octetstring ascii value "sub-id:vip-1"
        message-type cca
        no shutdown
      exit
      avp-match 2
        avp 443.444 octetstring ascii value "1/1/1:10.20@bng1"
        message-type ccr
        no shutdown
      exit
      message-type ccr cca rar raa
    exit
  message-type all
  exit
exit
```

In this configuration, the debug output for Diameter messages is restricted to messages of type ccr, cca, rar, or raa that are sent or received on diameter peer policy “diam-pol-1” and that belong to Diameter sessions for which:

- a CCA message is received with Class AVP = "trace-me" and 3GPP Charging-Rule-Name AVP = "sub-id:vip-1". The session ID is learned from the message. All subsequent ccr, cca, rar, and raa messages with the same session ID are also shown until a relearning occurs: a new CCA message received matching the AVP criteria specified for this AVP match ID. If still available in the system, the corresponding CCR message is also shown.
- a CCR message is received with subscription-id-data AVP = "1/1/1:10.20@bng1" (grouped within the subscription-id AVP). Session ID learning occurs for this AVP match ID and all subsequent ccr, cca, rar, and raa messages with the same session ID are shown as described above.

The rules for Diameter debug AVP matching are summarized below:

- Diameter debug AVP match criteria are specified in an **avp-match id** command. Up to five AVP match IDs can be specified per diameter peer policy. For each AVP match ID, a unique Session ID is learned and the corresponding messages are logged in debug: OR function for all **debug diameter diameter-peer-policy policy avp-match id** commands.
- For each AVP match ID, a message-type and at least one AVP ID criteria must be specified. Up to five AVP ID criteria can be specified per each AVP match ID. Session ID learning or relearning occurs when all specified AVP ID criteria are matched in any of the specified application message types: AND function for all **debug diameter diameter-peer-policy policy avp-match id avp avp-id** commands
- For each AVP in an AVP match, the AVP ID, type, and value should be specified:
 - *avp-id* is specified as [*vendor-id*]*avp-code*[*.avp-id*] with nesting up to five levels deep. For example: “443.444” to indicate Subscription-Id.Subscription-Id-Data and “456.10415-871” to indicate Multiple-Services-Credit-Control.Quota-Holding-Time.
 - *type* corresponds to the type as defined in the standards or as defined in the *Diameter Interface Specification* document for vendor-specific AVPs. The following types are supported: octetstring (used for utf8string, octetstring and diameterid), integer32, integer64, unsigned32, unsigned64, and address. Any AVP can be specified as an octetstring in hex format.
 - *value* is the AVP value to be matched. Optionally the format in which the value is specified can be configured as ascii or hex. A hex string is specified as “0xaabbcc...” (starting with “0x” followed by the hex nibbles).
- The message type specified in an **avp-match id** command is only used as match criteria and does not limit the debug output:

```
debug
diameter
  diameter-peer-policy "diam-pol-1"
    avp-match 1
      avp 443.444 octetstring ascii value "1/1/1:10.20@bng1"
      message-type ccr
      no shutdown
    exit
    message-type ccr cca rar raa
  exit
exit
exit
```

In this configuration, the session ID is learned only from CCR messages with subscription-id data AVP = “1/1/1:10.20@bng1”. When the session ID is learned, all CCR, CCA, RAR and RAA messages from that session ID are shown in the debug output.

- When at least one AVP match ID is configured with the **debug diameter diameter-peer-policy policy avp-match id no shutdown** command, only the messages for learned session IDs for the specified diameter peer policy are shown in the debug output. An AVP match ID in shutdown state is not active (session ID learning disabled and no debug messages are logged for this AVP match ID).
- If the session ID learning happens based on a match in an Answer message, then the corresponding Request message is also logged in debug only if it was still available in the system.
- Relearning occurs when a message from a session ID different from the learned session ID matches all specified AVP ID criteria in any of the specified application message types. The learned session ID for the AVP match ID is overwritten.
- Messages from a learned session ID are no longer matched against the AVP match criteria. The same session ID is learned only once.
- Learning or relearning events are reported in the debug output:

```
174 2016/01/21 15:31:02.63 UTC MINOR: DEBUG #2001 Base DIAMETER
"DIAMETER: Session-Id learning
diameter-peer-policy diameter-peer-policy-1 avp-match 1 learned Session-
Id bng.origin.com;1453294062;8 (replacing Session-Id bng.origin.com;1453294062;7) "
```

- The learned session ID is deleted when the corresponding AVP match ID debug command is deleted or shutdown.
- The **tools>dump>debug>diameter>avp-match-learned-session-id** command displays the current learned Diameter session IDs for each Diameter application policy AVP match ID.

16 Python Script Support for ESM

16.1 In This Chapter

This section describes the Python script support for Enhanced Subscriber Management (ESM).

The following topics are included:

- [Python Script Support for ESM](#)
- [Python in SR OS Overview](#)
 - [Python Changes](#)
- [Python Support in sub-ident-policy](#)
 - [Configuration](#)
 - [Operator Debugging](#)
 - [Python Scripts](#)
 - [Sample Python Scripts](#)
 - [Limitations](#)
- [RADIUS Script Policy Overview](#)
 - [Python RADIUS API](#)
 - [Sample Script](#)
- [Python Policy Overview](#)
 - [Python Policy – RADIUS API](#)
 - [Python Policy – DHCPv4 API](#)
 - [Python Policy – DHCPv6 API](#)
 - [Python Policy – Diameter API](#)
 - [Python Policy – DHCP Transaction Cache API](#)
 - [Python for PPPoE API](#)
 - [Python API for PPP Packet](#)
 - [Python API for PPP PAP](#)
 - [Python API for PPP CHAP](#)
 - [Python ESM API](#)
 - [Applying a Python Policy](#)
 - [Python Script Protection](#)

- [Tips and Tricks](#)

16.2 Python Script Support for ESM

In order to provide programmable flexibility in ESM applications, the SR OS provides the following features with Python script support:

- sub-ident-policy
- radius-script-policy
- python-policy

16.3 Python in SR OS Overview

The SR-OS python script support is based on Python version 2.4.2. Python has a set of language features (such as functions, lists and dictionaries) and a very large set of packages which provide most of the Python functionality. By keeping the language features intact and drastically reducing the number of packages available, the operator is provided with a flexible, although small, scripting language.

The only feature removed from the Python language is unicode support. The only packages provided to the operator are:

- **alc** — The SR OS-provided packages provide access to various ESM objects such as DHCPv4, DHCPv6 or RADIUS packets
- **binascii** — Common ASCII decoding like base64
- **re** — Regular expression support
- **struct** — Parses and manipulates binary strings
- **md5** — MD5 message digest algorithm

16.3.1 Python Policy – GTPv1-C API

The system will provide a Python object for input GTPv1-C packet `alc.gtp1c`. The `alc.gtp1c` packet has following attributes to represent the GTPv1-C header fields as displayed in the following table.

Table 118 GTPv1-C Header Fields

Class Attrs	GTPv1-C Header Field	Access
alc.gtp1c.version	Integer, version field in the header	Read
alc.gtp1c.ptbit	boolean, true mean 1, false means 0; PT bit in the header	Read
alc.gtp1c.ebit	boolean, E bit in the header	Read
alc.gtp1c.sbit	boolean, S bit in the header	Read
alc.gtp1c.pnbit	boolean, PN bit in the header	Read
alc.gtp1c.type	Integer message type field in the header	Read
alc.gtp1c.len	Integer message length field in the header	Read
alc.gtp1c.teid	Unsigned integer, or None if TEID does not exist	Read
alc.gtp1c.seq	Integer sequence number in the header	Read
alc.gtp1c.npdu_number	Integer N-PDU Number field in the header	Read
alc.gtp1c.next_ext_type	Integer Next Extension Type field in the header	Read
alc.gtp1c.ext_list	Tuple, a tuple of extension headers; each element in the tuple represent one extension header: (ext_type, ext_content)	Read

The following is a list of `alc.gtp1c` functions:

- **`alc.gtp1c.drop()`**: The system will drop the resulting packet.
- **`alc.gtp1c.getIEList()`**: The system returns a tuple of ie-type, each element represent one IE instance in the packet.
- **`alc.gtp1c.get(ie_type)`**: The system returns a tuple of str, each str is the IE data of specified ie_type instances. If the specified IE doesn't exist, then return (); if the IE length=0, then return "" for this IE instance.
- **`alc.gtp1c.set(ie_type, ie_tuple)`**: This function will remove all instances of ie_type and insert a list of new IE instances. Each element in ie_tuple is a string, represent one instance of IE to be inserted. For each inserted IE instance, the type is ie_type. System will use TV format for type<128 and TLV format for type>=128.
- **`alc.gtp1c.clear(ie_type)`**: This function will remove all existing instances of ie_type.

16.3.2 Python Policy – GTPv2-C API

The system will provide a Python object for input GTPv2-C packet: `alc.gtp2c`.

The `alc.gtp2c` packet has following attributes to represent the GTPv2-C header fields:

Table 119 GTPv2-C API

Class Attrs	GTPv2-C Header Field	Access
<code>alc.gtp2c.version</code>	Integer version field in the header	Read
<code>alc.gtp2c.pbit</code>	boolean, true mean 1, false means 0; P bit in the header	Read
<code>alc.gtp2c.tbit</code>	boolean, T bit in the header	Read
<code>alc.gtp2c.type</code>	Integer message type field in the header	Read
<code>alc.gtp2c.len</code>	Integer message length field in the header	Read

Table 119 GTPv2-C API (Continued)

Class Attrs	GTPv2-C Header Field	Access
alc.gtp2c.teid	Unsigned integer, or None if TEID doesn't exist	Read
alc.gtp2c.seq	Integer sequence number in the header	Read

The following is a list of alc.gtp2c functions:

- **alc.gtp2c.drop()**: The system drops the resulting packet.
- **alc.gtp2c.getIEList()**: The system returns a tuple of 2-element tuple (ie-type, ie-instance). Each 2-element tuple represent one IE instance in the packet. For example: a packet with the following IEs:
 - type:2, instance: 1
 - type:2, instance: 1
 - type:74, instance: 0The system will return ((2,1),(2,1),(74,0))
- **alc.gtp2c.get(ie_type, instance_id)**: The system returns a tuple of str. Each str is the IE data of specified (ie-type, instance-id). If the IE is a grouped IE, then the str is also the content of whole grouped IE. If the specified (ie_type, instance_id) doesn't exist, then return (); if the IE length=0, then return "" for this IE instance.
- **alc.gtp2c.set(ie_type, instance_id, ie_tuple)**: This function removes all instances of (ie_type, instance_id) and inserts a list of new IE instances. Each element in an ie_tuple is a string, represent one instance of IE to be inserted. For each inserted IE instance, the type is ie_type, the instance is instance_id.
- **alc.gtp2c.clear(ie_type, instance_id)**: This function removes all existing instances of (ie_type, instance-id).
- **alc.gtp2c.str_to_groupedIE (parent_ie_str)**: Parses the parent_ie_str and return a tuple of embedded IEs. Parent_ie_str is a string of data field of parent IE; each element of returned tuple is a tuple of (ie_type, ie_instance, ie_data), which represent one embedded IE. For example, with the following code:
 - ie_str = alc.gtp2c.get(93,0)[0]
 - ie_tuple = alc.gtp2c.str_to_groupedie(ie_str)

The above code parses the first instance of the bearer context with an instance=0. Assume the bearer context looks like the following:

Figure 227 Bearer Context Example

```

⊞ Bearer Context : [Grouped IE]
  IE Type: Bearer Context (93)
  IE Length: 44
  0000 .... = CR flag: 0
  .... 0000 = Instance: 0
  ⊞ EPS Bearer ID (EBI) : 5
    IE Type: EPS Bearer ID (EBI) (73)
    IE Length: 1
    0000 .... = CR flag: 0
    .... 0000 = Instance: 0
    0000 .... = Spare bit(s): 0
    .... 0101 = EPS Bearer ID (EBI): 5
  ⊞ Fully Qualified Tunnel Endpoint Identifier (F-TEID) : S2b-U ePDG GTP-U interface, TEID/GRE Key: 0xfe500225, IPv4 10.190.172.254
    IE Type: Fully Qualified Tunnel Endpoint Identifier (F-TEID) (87)
    IE Length: 9
    0000 .... = CR flag: 0
    .... 0101 = Instance: 5
    1... .... = V4: IPv4 address present
    .0... .... = V6: IPv6 address not present
    ..01 1111 = Interface Type: s2b-u ePDG GTP-U interface (31)
    TEID/GRE Key: 0xfe500225
    F-TEID IPv4: 10.190.172.254 (10.190.172.254)
  ⊞ Bearer Level Quality of Service (Bearer QoS) :
    IE Type: Bearer Level Quality of Service (Bearer QoS) (80)
    IE Length: 22
    0000 .... = CR flag: 0
    .... 0000 = Instance: 0
    .... 0 = PVI (Pre-emption Vulnerability): Enabled
    ..00 01.. = PL (Priority Level): 1
    .0... .... = PCI (Pre-emption Capability): Enabled
    Label (QCI): 8
    Maximum Bit Rate for uplink: 0
    Maximum Bit Rate for Downlink: 0
    Guaranteed Bit Rate for uplink: 0
    Guaranteed Bit Rate for Downlink: 0

```

1043

Then, the `ie_tuple` is

```
((5,0,'x05'),(87,5'\x9f\xfe\x50\x02\x25\x0a\xbe\xac\xfe'),(80,0,'x04\x08\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00'))
```

An exception is raised if the system cannot parse the `parent_ie_str` into a `ie_tuple`.

- **`alc.gtp2c.groupedie_to_str(grouped_ie_tuple)`**: Converts the `grouped_ie_tuple` into a `str` and return the `str` (see the description of `alc.gtp2c.str_to_groupedie` for the format `grouped_ie_tuple`). An exception is raised if the conversion fails. The following is an example:

```

ie_str = alc.gtp2c.get(93,0)[0]
ie_tuple = alc.gtp2c.str_to_groupedie(ie_str)
fteid = list(ie_tuple[1])
fteid[1]=0
ie_str = alc.gtp2c.groupedie_to_str((ie_tuple[0],tuple(fteid),ie_tuple[2]))
alc.gtp2c.set(93,0,(ie_str))

```

With previous example packet, the code changes the instance of the embedded F-TEID to 0.

16.3.3 Python Changes

The following changes have been made to Python for it to run on an embedded system:

- No files or sockets can be opened from inside Python scripts.
- No system calls can be made from inside Python scripts nor is the posix package available.
- The maximum recursion depth is fixed to twenty.
- The total amount of dynamic memory available for Python itself and Python scripts (excluding the Python cache) is capped at 8 MB for 32-bit SR OS and 16 MB for 64-bit SR OS on a CPM.
- The size of the Python script source file should be less than 60 KB.

16.4 Python Support in sub-ident-policy

A Python script can be configured in sub-ident-policy to return following ESM attributes:

- sub-id
- sla-profile name
- sub-profile name
- ancp-string

The system will run the Python script configured in the sub-ident-policy against the received DHCPv4 ACK message. This is used as the input of the script. Within the script, the user can set the value with the above ESM attributes.

The alc package contains a DHCP object, and has the following members ([Table 120](#)).

Table 120 DHCP Object Members

Name	Read	Write	Class
htype	X		integer
hlen	X		integer
hops	X		integer
flags	X		integer
ciaddr	X		integer
yiaddr	X		integer
siaddr	X		integer
giaddr	X		integer
chaddr	X		string
sname	X		string
file	X		string
options	X		TLV
sub_ident		X	string
sub_profile_string		X	string

Table 120 DHCP Object Members (Continued)

Name	Read	Write	Class
sla_profile_string		X	string
ancp_string		X	string
app_profile_string		X	string
category_map_name		X	string
int_dest_id		X	string

The TLV type provides easy access to the value part of a stream of type-length-value variables, as is the case for the DHCP option field. In the example on [16.4.1](#), the circuit-ID is accessed as `alc.dhcp.options[82][1]`.

Some DHCP servers do not echo the relay agent option (option 82) when the DHCP message was snooped instead of relayed. For the convenience of the operator, the relay agent option from the request message is returned when `alc.dhcp.options[82]` is called.

16.4.1 Configuration

As an example consider script `us5.py` on [16.4.3](#) which sets the `sub_ident` variable based on the circuit ID of three different DSLAMs:

```
import re
import alc
import struct
# ASAM DSLAM circuit ID comes in three flavours:
#     FENT    string          "TLV1: ATM:3/0:100.33"
#     GELT    octet-stream    0x01010000A0A0A0A0000000640022
#     GENT    string          "ASAM11 atm 1/1/01:100.35"
#
# Script sets output ('subscriber') to 'sub-vpi.vci', e.g.: 'sub-100.33'. circuitid =
str(alc.dhcp.options[82][1])
m = re.search(r'(\d+\.\d+)$', circuitid)
if m:
# FENT and GENT
alc.dhcp.sub_ident = "sub-" + m.group()
elif len(circuitid) >= 3:
# GELT
# Note: what byte order does GELT use for the VCI?
# Assume network byte (big endian) order for now. vpi = struct.unpack('B', circuitid[-
3:-2])[0]
vci = struct.unpack('>H', circuitid[-2:])[0]
alc.dhcp.sub_ident = "sub-%d.%d" % (vpi, vci)
```

Configure the url to this script in a sub-ident-policy as follows:

```
-----
sub-ident-policy "DSLAM" create
description "Parse circuit IDs from different DSLAMs"
primary

    script-url "ftp://xxx.xxx.xxx.xx/py/us5.py"
    no shutdown
exit
exit
-----
```

And attach this sub-ident-policy to the sub-sla-mgmt from a SAP:

```
A:dut-A>config>service>vpls>sap# info
```

```
-----
dhcp
    description "client side"
    lease-populate 50

    no shutdown
exit
anti-spoof ip-mac
sub-sla-mgmt
    sub-ident-policy "DSLAM"
    no shutdown
exit
-----
```

Note: DHCP snooping/relaying should be configured properly in order for this to work.

16.4.2 Operator Debugging

Verbose debug output is sent to debug-trace on compile errors, execution errors, execution output and the exported result variables.

```
A:dut-A>config>subscr-mgmt>sub-ident-pol>primary# script-url "ftp://xxx.xxx.xx.xx/
py/
parsefail1.py"
A:dut-A>config>subscr-mgmt>sub-ident-pol>primary# no shutdown

```

Note: All the Python Result events are empty because none of the scripts set any of the output variables.

16.4.3 Python Scripts

Note: The scripts in this section are test scripts and not scripts which the operator would normally use.

dump.py — from alc import dhcp

```
def print_field(key, value):
    print '%-8s = %r' % (key, value)

def ipaddr2a(ipaddr):
```

```

return '%d.%d.%d.%d' % (
    (ipaddr & 0xFF000000) >> 24, (ipaddr & 0x00FF0000) >> 16, (ipaddr & 0x0000FF00) >> 8,
    (ipaddr & 0x000000FF))

print_field('htype',    dhcp.htype) print_field('hlen',    dhcp.hlen)
print_field('hops',    dhcp.hops) print_field('flags',    dhcp.flags)
print_field('ciaddr',  ipaddr2a(dhcp.ciaddr)) print_field('yiaddr',
ipaddr2a(dhcp.yiaddr)) print_field('siaddr',  ipaddr2a(dhcp.siaddr))
print_field('giaddr',  ipaddr2a(dhcp.giaddr)) print_field('chaddr',  dhcp.chaddr)
print_field('sname',   dhcp.sname) print_field('file',    dhcp.file)
print_field('options', str(dhcp.options))

```

us5.py — import re import alc import struct

```

# ASAM DSLAM circuit ID comes in three flavors:
#      FENT    string      "TLV1: ATM:3/0:100.33"
#      GELT    octet-stream 0x01010000A0A0A0A00000000640022
#      GENT    string      "ASAM11 atm 1/1/01:100.35"
#
# Script sets output ('subscriber') to 'sub-vpi.vci', e.g.: 'sub-100.33'. circuitid =
str(alc.dhcp.options[82][1])
m = re.search(r'(\d+\.\d+)$', circuitid)
if m:
    # FENT and GENT
    alc.dhcp.sub_ident = "sub-" + m.group()
    elif len(circuitid) >= 3:
    # GELT
    # Note: what byte order does GELT use for the VCI?
    # Assume network byte (big endian) order for now. vpi = struct.unpack('B', circuitid[-
3:-2])[0]
    vci = struct.unpack('>H', circuitid[-2:])[0]
    alc.dhcp.sub_ident = "sub-%d.%d" % (vpi, vci)

```

16.4.4 Sample Python Scripts

This section provides examples to show how the script can be used in the context of Enhanced Subscriber Management.

Note: These scripts are included for informational purposes only. The operator must customize the script to match their own network and processes.

16.4.4.1 Example

This script uses the IP address assigned by the DHCP server to derive both *sub_ident* and *sla_profile_string*.

Script:

```
1. import alc
2. yiaddr = alc.dhcp.yiaddr
3. # Subscriber ID equals full client IP address.
4. # Note: IP address 10.10.10.10 yields 'sub-168430090'
5. # and not 'sub-10.10.10.10'
6. alc.dhcp.sub_ident = 'sub-' + str(yiaddr)
7. # DHCP server is configured such that the third byte (field) of the IP
8. # address indicates the session Profile ID.
9. alc.dhcp.sla_profile_string = 'sp-' + str((yiaddr & 0x0000FF00) >> 8)
```

Explanation:

Line 1 — Imports the library “alc” – Library imports can reside anywhere in the script as long as the items are imported before they are used.

Line 2— Assigns the decimal value of the host’s IP address to a temporary variable “yiaddr”. Line 6: The text “sub_” followed by yiaddr is assigned to “sub_ident” string.

Line 9— The text “sp-” followed with the third byte of the IP address is assigned to the “sla_profile” string.

If this script is run, for example, with a DHCP-assigned IP address of:

```
yiaddr = 10.10.0.2
```

The following variables are returned:

```
sub_ident: sub-168427522(hex = A0A00002 = 10.10.0.2)
sla_ident: sp-0
```

16.4.4.2 Example

This script returns the *sub_profile_string* and *sla_profile_string*, which are coded directly in the Option 82 string.

Script:

```
1. import re
2. import alc
3. # option 82 formatted as follows:
4. # "<subscriber Profile>-<sla-profile>"
5. ident = str(alc.dhcp.options[82][1])
6. alc.dhcp.sub_ident = ident
7. tmp = re.match("(?P<sub>.+)-(P<sla>.+)", str(ident))
8. alc.dhcp.sub_profile_string = tmp.group("sub")
9. alc.dhcp.sla_profile_string = tmp.group("sla")
```

Explanation:

Line 1-2 — Import the libraries “re” and “alc”. Library imports can reside anywhere in the script as long as the items are imported before they are used.

Line 6 — Assigns the full contents of the DHCP Option 82 field to the “sub_ident” variable.

Line 7 — Splits the options 82 string into two parts, separated by “-”.

Line 8 — Assigns the first part of the string to the variable “sub_profile_string”.

Line 9 — Assigns the second part of the string to the variable “sla_profile_string”.

If this script is run, for example, with DHCP option field:

```
options = \x52\x0D\x01\0x0Bmydsl-video
```

The following variables are returned:

```
sub_ident: mydsl-video
sub_profile_string: mydsl
sla_profile_string: video
```

16.4.4.3 Example

This script parses the Option82 “circuit-id” info inserted in the DHCP packet by a DSLAM, and returns the *sub_ident* string.

Script:

```
1. import re
2. import alc
3. import struct
4. # Nokia 7300 ASAM circuit ID comes in three flavors:
5. #      FENT      string      "TLV1: ATM:3/0:100.33"
6. #      GELT      octet-stream 0x01010000A0A0A0A00000000640022
7. #      GENT      string      "ASAM11 atm 1/1/01:100.35"
8. #
9. # Script sets output ('subscriber') to 'sub-vpi.vci',
10. # e.g.: 'sub- 100.33'.
11. circuitid = str(alc.dhcp.options[82][1])
12. m = re.search(r'(\d+\.\d+)$', circuitid)
13. if m:
14.     # FENT and GENT
15.     alc.dhcp.sub_ident = "sub-" + m.group()
16. elif len(circuitid) >= 3:
17.     # GELT
18.     # Note: GELT uses network byte (big endian) order for the VCI
19.     vpi = struct.unpack('B', circuitid[-3:-2])[0]
20.     vci = struct.unpack('>H', circuitid[-2:])[0]
21.     alc.dhcp.sub_ident = "sub-%d.%d" % (vpi, vci)
```

Explanation:

Line 1-2 — Import the libraries “re” and “alc” – Library imports can reside anywhere in the script as long as the items are imported before they are used. Needed if regular expressions are used.

Line 3 — Imports the “struct” library, needed if regular expressions are used.

Line 11 — Assigns the contents of the DHCP Option 82 Circuit-ID field to a temporary variable called “circuitid”.

Line 12 — Parses the “circuitid” and checks for the existence of the regular expression “digit.digit” at the end of the string.

Line 15 — If found, a string containing the text “sub-” followed by these two digits is assigned to the variable “sub-ident”.

Line 16 — If not found, and the length of circuit-id is at least 3.

Line 19 — Parses the “circuitid” and assigns the third-last byte to the temporary variable “vpi”.

Line 20 — Parses the “circuitid” and assigns the last two bytes to the temporary variable “vci”.

Line 21 — Assigns a string containing the text “sub-” followed by vpi and vci to the variable “sub-ident”.

If this script is run, for example, with DHCP option field (assigned by an ASAM with FENT card) containing:

```
options = \x52\x16\x01\x14TLV1: ATM:3/0:100.33
```

(in decimal: 80, 22, 1, 20TLV...)

The following variables are returned:

```
sub_ident: sub-100.33
```

If the above script is run, for example, with a DHCP option field (assigned by an ASAM with GELT card) containing:

```
options = \x52\x10\x01\x0E\x01\x01\x00\x00\xA0\xA0\xA0\xA0\x00\x00\x00\x64 \x00\x22
```

(in decimal: 82, 16, 1, 15, 1, 1, 0, 0, 160, 160, 160, 160, 0, 0, 0, 100, 0, 34;
corresponding to VPI 100, VCI 34)

Python returns the following variables:

```
sub_ident: sub-100.34
```

If the above script is run, for example, with a DHCP option field (assigned by an ASAM with GENT card) containing:

```
options = \x52\x1A\x01\x18ASAM11 atm 1/1/01:100.35
```

The following variables are returned:

```
sub_ident: sub-100.35
```

16.4.5 Limitations

'%' operator — While %f is supported, %g and %e are not supported.

Floating Point Arithmetic — The floating point arithmetic precision on the box is less than the precision required by the regression suites of Python. For example, pow(2., 30) equals to

1024.*1024.*1024. until five numbers after the point instead of seven and sqrt(9) equals to 3. for the first seven numbers after the point.

Using the round operator fixes these problems. For example, round(pow(2., 30)) equals round(1024.*1024.*1024.) and round(sqrt(9)) equals 3.

16.5 RADIUS Script Policy Overview

Python scripts for RADIUS AAA packets support manipulation in subscriber management application. This feature is supported on the 7750 SR and 7450 ESS routers in mixed mode.

A Python script can be executed in following cases:

- Before the system sends an access-request packet.
- After the system receives an access-accept packet.
- After the system receives an CoA-request packet.
- Before the system sends an accounting-request packet.

The input of the script is the corresponding original packet; and the output of the packet will be used as the new corresponding packet for further ESM AAA process.

The **radius-script-policy** contains URLs of a primary and an optional secondary Python script, which could be a local CF file path or a FTP URL. The configured **radius-script-policy** could be used in different ESM policies like authentication-policy or radius-accounting-policy.

The following operations are supported within the script:

- Obtain the value of an existing attribute or VSA.
- Modify the value of an existing attribute or VSA.
- Add a new attribute or VSA.
- Remove an existing attribute or VSA.

Note: The following RADIUS attributes or VSA are read-only to Python script:

- Message-Authenticator
- Alc-LI-Action
- Alc-LI-Direction
- Alc-LI-Destination
- Alc-LI-FC
- Alc-LI-Intercept-Id
- Alc-LI-Session-Id

Since R12.0R1, users should use a Python policy (instead of a RADIUS script policy) for RADIUS packet manipulation.

16.5.1 Python RADIUS API

The following new Python objects, `alc.radius`, have the following methods:

- `drop()`: Drop the packet.
- `header()`: Return the dictionary object that includes RADIUS header information.

`alc.radius` also provides methods to manipulate radius attributes via `alc.radius.attributes`, which has the following methods:

- `get(type)`: Return the first attribute with specified type as a string.
- `getTuple(type)`: The same as above but returns a tuple of strings.
- `getVSA(vendor, type)`: Return the first VSA as a string.
- `getVSATuple(vendor, type)`: The same as above but returns a tuple of strings.
- `getExt(type, ext-type)`: Return a string containing the value of the first Extended Type attribute (RFC6929) matching the specified type and extended type.
- `getExtTuple(type, ext-type)`: Return a tuple of strings. For each occurrence of an Extended Type attribute (RFC6929) matching the specified type and extended type, the attribute value is included as a string entry in the tuple.
- `getExtVSA(type, vendor, vendor-type)`: Return a string containing the value of the first Extended Vendor Specific attribute (RFC6929) matching the specified type, vendor and vendor-type.

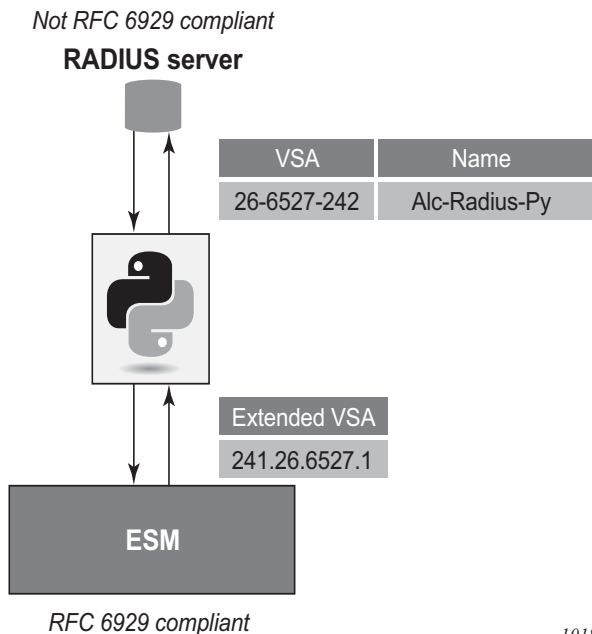

- `getExtVSATuple(type, vendor, vendor-type)`: Return a tuple of strings. For each occurrence of an Extended Vendor Specific attribute (RFC6929) matching the specified type, vendor and vendor-type, the attribute value is included as a string entry in the tuple.
- `getLongExtTuple(type, ext-type)`: Return a tuple of strings. For each occurrence of a Long Extended Type attribute (RFC6929) matching the specified type and extended type, the attribute value is included as a string entry in the tuple. The value of all fragments of the same Long Extended Type attribute are concatenated in a single string entry.
- `getLongExtVSATuple(type, vendor, vendor-type)`: Return a tuple of strings. For each occurrence of a Long Extended Vendor Specific attribute (RFC6929) matching the specified type, vendor and vendor-type, the attribute value is included as a string entry in the tuple. The value of all fragments of the same Long Extended Vendor Specific attribute are concatenated in a single string entry.
- `set(type, value)`: Set the specified attribute to the value. The value must be either a string or a tuple of strings.
- `setVSA(vendor, type, value)`: Set the specified VSA to the value. The value must be either a string or a tuple of strings.
- `setExt(type, ext-type, value)`: Set the specified Extended Type attribute value (RFC6929). The value can be specified as a string (single attribute) or a tuple of strings (multiple attributes).
- `setExtVSA(type, vendor, vendor-type, value)`: Set the specified Extended Vendor Specific attribute value (RFC 6929). The value can be specified as a string (single attribute) or a tuple of strings (multiple attributes).
- `setLongExt(type, ext-type, value)`: Set the specified Long Extended Type attribute value (RFC6929). The value can be specified as a string (single attribute) or a tuple of strings (multiple attributes). When the string value length is too long to fit in a single attribute (more than 251 octets), then the value field is fragmented across multiple attributes. The M-bit (more) is set in all but the last fragment.
- `setLongExtVSA(type, vendor, vendor-type, value)`: Set the specified Long Extended Vendor Specific attribute value (RFC 6929). The value can be specified as a string (single attribute) or a tuple of strings (multiple attributes). When the string value length is too long to fit in a single attribute (more than 246 octets), then the value field is fragmented across multiple attributes. The M-bit (more) is set in all but the last fragment.
- `clear(type)`: Remove the specified attribute.
- `clearVSA(vendor, type)`: Remove the specified VSA.
- `clearExt(type, ext-type)`: Remove all Extended Type or Long Extended Type attributes (RFC6929) matching the specified type and extended type.

- `clearExtVSA(type, vendor, vendor-type)`: Remove all Extended Vendor Specific or Long Extended Vendor Specific attributes (RFC6929) matching the specified type, vendor and vendor-type.
- `isSet(type)`: Return True if the specified attribute exists, False otherwise.
- `isVSASet(vendor, type)`: Return True if the specified VSA exists, False otherwise.
- `isExtSet(type, ext-type)`: Return True if an Extended Type or Long Extended Type attribute (RFC6929) matching the specified type and extended type is present. Else return False.
- `isExtVSASet(type, vendor, vendor-type)`: Return True if an Extended Vendor Specific or Long Extended Vendor Specific attribute (RFC6929) matching the specified type, vendor and vendor-type is present. Else return False.

Extended attribute type, Long Extended attribute type, and Extended Vendor Specific data type are specified in RFC 6929 RADIUS Protocol Extensions.

Both the RADIUS client and RADIUS server must support RFC6929 RADIUS Protocol Extensions to successfully use the Extended and Long Extended attribute types and the Extended Vendor Specific data type. Therefore it is recommended to check the RADIUS servers for RFC 6929 support and upgrade if needed. As shown in [Figure 228](#), RADIUS Python can be used as a workaround to interwork with a RADIUS server that does not support these extensions. You can use the general purpose [26-6527-242] Alc-Radius-Py VSA of type "octets" for this purpose.

Figure 228 RADIUS Python: Interworking with RADIUS Server with no RFC 6929 Support

1018

16.5.2 Sample Script

From alc import radius

#1. Get the value of an existing Attribute

```
Username=radius.attributes.get(1)
```

#2. Modify an existing attribute

```
radius.attributes.set(1, 'Tom')
```

#3. Remove an existing attribute

```
radius.attributes.clear(1)
```

#4. Add a new attribute

```
radius.attributes.set(126, "WIFI-operator")
```

16.6 Python Policy Overview

The Python policy represents a general framework to support all existing and new python features. A Python policy allows users to configure a Python script for a specified ESM packet type (such as DHCP and RADIUS) in a specified direction (ingress or egress). The system will execute the configured script when sending or receiving the specified type of packet.

The corresponding original packet will be used as input within the script. The user can use the system-provided API to manipulate the input packet (such as add, change, remove option or attribute). The changed packet is used as the output for further ESM processing. With a DHCP transaction cache, the script can return ESM attributes.

Python policies support the following ESM packet types and applications:

- DHCP Transaction Cache on CPM
- DHCPv4 on CPM
- DHCPv6 on CPM
- Diameter on CPM
- GTPv1-C/GTPv2-C
- Python cache on CPM
- RADIUS on CPM
- RADIUS on ISA

There are two types of Python policies:

- Centralized: Runs on the CPM and handles above protocol packets processed on the CPM.
- Distributed: Runs on the ISA and handles packets processed locally on the ISA (such as the DSM). Currently in RADIUS only.

The user must specify the type when creating the Python policy.

The following is an example configuration of a specified group interface. The system will execute `cf1:/dhcpv4.py` after receiving DHCPv4 discovery and before the system forwards a DHCPv4 request packet.

```
config>python# info
-----
python-script "dhcpv4" create
  primary-url "cf1:/dhcpv4.py"
  no shutdown
exit
python-policy "dhcp" create
```

```
        dhcp discover direction ingress script "dhcpv4"
        dhcp request direction egress script "dhcpv4"
    exit
-----
config>service>vprn>sub-if>grp-if>dhcp# info
-----
        python-policy "dhcp"
        server 9.9.9.9
        lease-populate 100
        gi-address 192.168.100.1
        no shutdown
-----
```

16.6.1 Python Policy – RADIUS API

The RADIUS API in Python policy uses the same API of the radius-script-policy.

16.6.2 Python Policy – DHCPv4 API

- The system will provide a Python object for input DHCPv4 packet: `alc.dhcpv4`.
- `alc.dhcpv4` has following attributes to represent the DHCPv4 header fields:

Table 121 **alc.dhcpv4 Attributes**

Class Attrs	DHCPv4 Header Field	Access
<code>alc.dhcpv4.pkt_len</code>	Integer Total length of original DHCPv4 packet (UDP/IP header excluded, including pad option) in bytes	read
<code>alc.dhcpv4.pkt_netlen</code>	Integer Total length of original DHCPv4 packet(UDP/IP header excluded, pad option in the “options” field excluded) in bytes	read
<code>alc.dhcpv4.op</code>	op	read
<code>alc.dhcpv4.htype</code>	htype	read/write
<code>alc.dhcpv4.hlen</code>	hlen	read/write
<code>alc.dhcpv4.hops</code>	hops	read/write
<code>alc.dhcpv4.xid</code>	xid	read
<code>alc.dhcpv4.secs</code>	secs	read/write

Table 121 **alc.dhcpv4 Attributes (Continued)**

Class Attrs	DHCPv4 Header Field	Access
alc.dhcpv4.flags	flags	read/write
alc.dhcpv4.ciaddr	ciaddr	read/write
alc.dhcpv4.yiaddr	yiaddr	read/write
alc.dhcpv4.siaddr	siaddr	read/write
alc.dhcpv4.giaddr	giaddr	read/write
alc.dhcpv4.chaddr	chaddr	read/write
alc.dhcpv4.sname	sname	read/write
alc.dhcpv4.file	file	read/write

All attributes, except `alc.dhcpv4.pkt_len` and `alc.dhcpv4.pkt_netlen`, are string with value of the actual bytes in the header.

The following is a list all functions of `alc.dhcpv4`:

- `alc.dhcpv4.drop()`
- `alc.dhcpv4.getOptionList()`
- `alc.dhcpv4.pad(min_size=300)`
- `alc.dhcpv4.get(op_code)`
- `alc.dhcpv4.set(op_code,valTuple)`
- `alc.dhcpv4.clear(op_code)`
- `alc.dhcpv4.get_relayagent() / alc.dhcpv4.set_relayagent(D4OL)`
- `alc.dhcpv4.get_vendorspecific() / alc.dhcpv4.set_vendorspecific (D4OL)`

DHCPv4 allows using `sname` and `file` fields to store options. However all DHCPv4 functions will only operate with the “options” field. If a customer wants to manipulate options in the `sname/file` field, they need to do the parsing work in the script. (extended `string.tlvxy` method could help here)

- `alc.dhcpv4.drop()`: The system will drop the result packet
- `alc.dhcpv4.getOptionList()`: Returns a tuple that includes the option-code of the existing top level DHCPv4 options in the packet.
 - The order of the element in the tuple is as same as the options that appear in the packet.
 - If there are multiple instances of the same option, then each instance is one element in the tuple.

-
- Pad option(0) is excluded.
 - End option(255) is included
 - Example: A DHCP discovery packet with msg-type/lease-time/request-addr/parameter-request-list/agent-info/end will return (53,51,50,55,82,255)
 - `alc.dhcpv4.pad(min_size=300)`: This function will pad the resulting DHCPv4 packet to the specified min_size with pad option(0) after executing the whole script. Padding will not be added if the result packet is already \geq min_size. The default value of min_size is 300. Although not defined in DHCPv4 RFC, many DHCPv4 implementation has a minimal length requirement of 300 bytes. So this function could pad the result packet to the specified min_size.
 - `alc.dhcpv4.get(op_code)`: Returns a tuple that includes all instances of the specified top level option as a string. The value of this string is the exact bytes of the option as it appears in packet(excludes option-code and option-len).
 - If the specified option does not exist, then the function will return ()
 - If the certain instance of specified option does not have the value (len=0 or doesn't have len and value part), then the function will return "" for that instance in the tuple.
 - Example: There is an address lease time option(51) in the packet, with value 60, then `alc.dhcpv4.get(51)` should return: ('x00\x00\x00\x3c',)
 - `alc.dhcpv4.set(op-code,valTuple)`: This function will in fact remove the all existing instances of specified top level option and insert a list of new options. Each element in valTuple is a string, representing one instance of the new option to be inserted; For each new option, the option-code is specified in op-code. The option-len is the length of the element. The rest of option is the element itself.
 - Example: To insert an address lease time option(51) in the packet, with the value 60; use `alc.dhcpv4.set(51, ('x00\x00\x00\x3c',))`
 - `alc.dhcpv4.clear(op-code)`: This function will remove the all existing instances of specified top level option.
 - Although `alc.dhcpv4.get()` and `alc.dhcpv4.set()` provide a generic way to manipulate DHCPv4 top level options, but some DHCPv4 options have a complex/hierarchical structure like option82 and option43. To provide a friendly access to these kinds of options, the system provides the following options' specific functions:
 - `alc.dhcpv4.get_relayagent()` / `alc.dhcpv4.set_relayagent(D4OL)`
 - `alc.dhcpv4.get_vendorspecific()` / `alc.dhcpv4.set_vendorspecific (D4OL)`
- All `alc.dhcpv4.get_XXX()` will return a data structure:"D4OL" (DHCPv4 Option List)

- D4OL is a list. Each element in the list represents an instance of that option. For example, if there are 3 option82 in the “options” field of packet, then get_relayagent() will return a list of 3 elements. Each element represents one instance of the option in the packet.
- Each element in D4OL is a dict (called dict as “D4O” in this example):
 - The key of D4O is the sub-option- code. The value is a list of strings of sub-option-value of all instance of the sub-option.

All alc.dhcpv4.set_XX(OPDL) will accept D4OL as the parameter. Remove all existing instances of the corresponding options and then insert the new options represented by specified D4OL.

Examples:

For a packet with an option82 like following

```
Option: (82) Agent Information Option
Length: 22
Option (82) Suboption: (1) Agent Circuit ID
Length: 8
Agent Circuit ID: 4a616e737656e73
Option 82 Suboption: (2) Agent Remote ID
Length: 10
Agent Remote ID 62617369632364617461
```

The option-data is (hex formatted)

“01:08:4a:61:6e:73:73:65:6e:73:02:0a:62:61:73:69:63:23:64:61:74:61”

The following is an example script:

```
import alc

option82_list=alc.dhcpv4.get_relayagent()
#option82_list will be
[{1:['\x4a\x61\x6e:73\x73\x65\x6e\x73'],2:['\x62\x61\x73\x69\x63\x23\x64\x61\x74\x61',]},]
Option82_list[0][2][0]='basic#video' #change remote-id to 'basic#video'
alc.dhcpv4.set_relayagent(option82_list)#update the option82
```

16.6.3 Python Policy – DHCPv6 API

- The system provides a Python object for input DHCPv6 packet: alc.dhcpv6
- alc.dhcpv6 has following attributes to represent the DHCPv6 header fields:

Table 122 DHCPv6 Header Fields

Class Attrs	DHCPv6 Header Field	Client/ Server Msg	Relay Msg	Access
alc.dhcpv6.pkt_len	Integer, Total length of original DHCPv4 packet(UDP/IP header excluded) in bytes	•	•	Read
alc.dhcpv6.msg_type	msg-type	•	•	Read
alc.dhcpv6.transaction_id	transaction-id	•		Read
alc.dhcpv6.hop_count	hop-count		•	read/write
alc.dhcpv6.link_addr	link-address		•	read/write
alc.dhcpv6.peer_addr	peer-address		•	read/write

All header fields (as the attribute of alc.dhcpv6 class) are strings(except pkt_len) with exact bytes as it appears in the packet.

If certain attribute does not exist in the given msg-type, for example if the link_attr does not exist in client/server message(C/S msg), then its value should be None.

- The following is a list of all functions in the class:
 - alc.dhcpv6.drop()
 - alc.dhcpv6. getOptionList()
 - alc.dhcpv6. get(op-code)
 - alc.dhcpv6. set(op-code,valTuple)
 - alc.dhcpv6. clear(op-code)
 - alc.dhcpv6.get_iana() / alc.dhcpv6.set_iana(OPDL)
 - alc.dhcpv6.get_iata() / alc.dhcpv6.set_iata(OPDL)
 - alc.dhcpv6.get_vendoropts() / alc.dhcpv6.set_vendoropts(OPDL)
 - alc.dhcpv6.get_iapd() / alc.dhcpv6.set_iapd(OPDL)
 - alc.dhcpv6.get_relaymsg()
 - alc.dhcpv6.set_relaymsg(packet)
- alc.dhcpv6. drop(): The system will drop the resulting packet.

- `alc.dhcpv6.getOptionList()`: Returns a tuple that includes the option-code of the existing top level DHCPv6 options in the packet. The order of the element in the tuple is as same as the options appear in the packet. If there are multiple instances of same option, then each instance is one element in the tuple. For example:
 - A C/S Msg with Elapsed Time/Client Identifier/IANA/FQDN/Vendor Class/Option Request will return (8,1,3,39,16,6).
 - A Relay Msg with Relay Message option only will return (9)
- `alc.dhcpv6.get(op-code)`: Returns a tuple that includes all instances of the specified top level option as string. The value of this string is the exact bytes of the option as it appears in packet(excludes option-code and option-len). If the specified option does not exist in the input packet, then it will return ().

Examples:

- If there is a Status Code option in the packet, status-code 0 and status-msg: "Address Assigned"; then `alc.dhcpv6.get(13)` should return: (`'\x00\x00Address Assigned'`),)
- `alc.dhcpv6.set(op-code, valTuple)`: This function will remove the all existing instances of the specified top level option and insert a list of new options. Each element in `valTuple` is a string, representing one instance of the new option to be inserted. For each new option, the option-code is specified in `op-code`, the option-len is the length of the element, reset of option is the element itself.
 - To insert a Status Code options with status-code 0 and status-msg: "Address Assigned"; use `alc.dhcpv6.set(13, ('\x00\x00Address Assigned',))`
- `alc.dhcpv6.clear(op-code)`: This function will remove the all existing instances of specified top level option.
- Although `alc.dhcpv6.get()` and `alc.dhcpv6.set()` provide a generic way to manipulate DHCPv6 top level options, but some DHCPv6 options have more complex/hierarchical structure like IA_NA/IA_TA, etc. To provide a friendly access to these kinds of options, the system provides the following options specific functions:
 - `alc.dhcpv6.get_iana()` / `alc.dhcpv6.set_iana(OPDL)`
 - `alc.dhcpv6.get_iata()` / `alc.dhcpv6.set_iata(OPDL)`
 - `alc.dhcpv6.get_vendoropts()` / `alc.dhcpv6.set_vendoropts(OPDL)`
 - `alc.dhcpv6.get_iapd()` / `alc.dhcpv6.set_iapd(OPDL)`

All `alc.dhcpv6.get_XXX()` will return a data structure: "OPDL" (Option Data structure List)

- OPDL is a list. Each element in the list represents an instance of that option. For example, if there are 3 IANA in the packet, then `get_iana()` will return a list of 3 elements, each element represent one instance of IANA option in the packet.
- Each element in OPDL is a list, referred to as “OPD” in this list.
 - Each element in OPD represent one field in the option(option-code and option-len are not included), the order of the element is as same as the fields appear in the option
 - For field that could be parsed into sub-option by RFC, then the element is a dict, the key of this dict is the sub-option type, if sub-option is one of following supported-sub-option, the value to the key is a sub-option_OPDL represent the list of that specific sub-option
 - IAADDR(5)
 - Status Code(13)
 - IAPREFIX(26)

Else, if the sub-option is **not** one of above, then the value to the key is a list of string of sub-option-data, each string represent one instance of the sub-option.

- The structure of sub-option_OPDL of IAADDR is:
[[v6_addr,prefer_lifetime, valid_lifetime,sub-option_OPDL], etc.]
- The structure of sub-option_OPDL of Status Code is: [[status-code,status-msg], etc.]
- The structure of sub-option_OPDL of IAPREFIX is:
[[prefer_lifetime,valid_lifetime,prefix-len,v6prefix,sub-option_OPDL],...]
- For the field (by RFC definition) could be parsed into sub-options, but it does not actually exist, then the dict will be empty {}
- For field that cannot be parsed into sub-option by RFC, the element is a string of exact bytes of that field

All `alc.dhcpv6.set_XX(OPDL)` will accept an OPDL as the parameter. Remove all existing instances of the corresponding options and then insert new options represented by the specified OPDL.

- `alc.dhcpv6.get_iana()/alc.dhcpv6.get_iana(OPDL)`
- The general OPDL structure for these two functions is:
[[IAID_val,T1_val,T2_val, sub-option_dict]]
- The structure of sub-option_dict is:{sub-option-type:sub-option_val}
- If sub-option is supported-sub-option, then sub-option_val is a sub-option_OPDL

- For all other sub-options, the sub-option_val is a list of string of sub-option-data

Examples: These two function are very similar with IANA, so the examples are skipped here.

- alc.dhcpv6.get_iapd()/alc.dhcpv6.get_iapd(OPDL)
- The general OPDL structure for these two functions is:
[[IAID_val,T1_val,T2_val, sub-option_dict]]
- The structure of sub-option_dict is:{sub-option-type:sub-option_val}
- If sub-option is supported-sub-option, then sub-option_val is a sub-option_OPDL
- For all other sub-options, the sub-option_val is a list of string of sub-option-data

Examples: For a packet with IA_PD like following:

```

❑ Identity Association for Prefix Delegation
  Option: Identity Association for Prefix Delegation (25)
  Length: 41
  Value: 000000010000070800000b40001a001900000e1000015180...
  IAID: 00000001
  T1: 1800
  T2: 2880
❑ IA Prefix
  Option: IA Prefix (26)
  Length: 25
  Value: 00000e10000151803820010db8000200000000000000000...
  Preferred lifetime: 3600
  Valid lifetime: 86400
  Prefix length: 56
  Prefix address: 2001:db8:2::

```

The option-data is (hex formatted)

```
"00:00:00:01:00:00:07:08:00:00:0b:40:00:1a:00:19:00:00:0e:10:00:01:51:80:38:20:01:0d:b8:00:02:00:00:00:00:00:00:00:00:00"
```

Following is an example script:

```

import alc

iapd_list=alc.dhcpv6.get_iapd()
#iapd_list will be
[['\x00\x00\x00\x01', '\x00\x00\x07\x08', '\x00\x00\x0b\x40', {26: [['\x00\x00\x0e\x10',
'\x00\x01\x51\x80', '\x38', '\x20\x01\x0d\xdb\x80\x02\x00\x00\x00\x00\x00', {}]]}]]
iapd_list[0][1]='\x00\x00\x04\xb0' #change T1 to 1200
alc.dhcpv6.set_iapd(iapd_list)#update the iapd

```

- `alc.dhcpv6.get_vendoropts()/alc.dhcpv6.get_vendoropts (OPDL)`
 - The general OPDL structure for these two functions is: `[[enterpriseid_val, sub-option_dict]]`
 - The structure of `sub-option_dict` is: `{sub-option-type:sub-option_val}`
 - If sub-option is supported-sub-option, then `sub-option_val` is a sub-option_OPDL
 - For all other sub-options, the `sub-option_val` is a list of string of sub-option-data

Examples: For a packet with vendor options like following:

```

❏ Vendor-specific Information
  Option: vendor-specific Information (17)
  Length: 40
  Value: 0000197f0001000969612d6e615f3030310002000969612d...
  Enterprise ID: Panthera Networks, Inc. (6527)
❏ option
  option code: 1
  option length: 9
  option-data
❏ option
  option code: 2
  option length: 9
  option-data
❏ option
  option code: 3
  option length: 1
  option-data
❏ option
  option code: 4
  option length: 1
  option-data

```

The option-data is (hex formatted)

```

"00:00:19:7f:00:01:00:09:69:61:2d:6e:61:5f:30:30:31:00:02:00:09:69:61:2d:70:64:5f:30:30:31:00:03:00:01:38:00:04:00:01:40"

```

The following is an example script:

```

import alc

vendoropts_list=alc.dhcpv6.get_vendoropts()
# vendoropts_list will be [['\x00\x00\x19\x7f',
{1: ['\x69\x61\x2d\x6e\x61\x5f\x30\x30\x31'], 2: [
'\x69\x61\x2d\x70\x64\x5f\x30\x30\x31'], 3: ['\x38'], 4: ['\x40']}]
iapd_list[0][1][4][0]='\x60' #change sub-option 4's value to 0x60
alc.dhcpv6.set_vendoropts(vendoropts_list)#update the vendor options

```

- For DHCPv6 relay message, the “Relay Message” option embedded a full DHCPv6 packet and the embedded packet could itself have a “Replay Message” option which embedded another DHCPv6 packet.

To provide direct access to embedded DHCPv6 packet, the system provides following functions:

- `alc.dhcpv6.get_relaymsg()`
- `alc.dhcpv6.set_relaymsg(packet)`
- `alc.dhcpv6.get_relaymsg()`: This function will return a populated `alc.dhcpv6` object, which means the returned object was initialized with the DHCPv6 packet embedded in “Relay Message” option as the input.
- `alc.dhcpv6.set_relaymsg(packet)`: This function will accept an `alc.dhcpv6` object as a parameter. This object will replace existing “Relay Message” option.

Example-1 script for single relay message:

```
import alc
#input packet is a relay-reply msg
embed_dhcpv6_packet=alc.dhcpv6.get_relaymsg()
iana_list=embed_dhcpv6_packet.get_iana()
iana_list[0][1]='\x00\x00\x04\xb0' #change T1 to 1200
embed_dhcpv6_packet.set_iana(iana_list)#update the iana of the embedded packet
alc.dhcpv6.set_relaymsg(embed_dhcpv6_packet)#update the Relay Message option
```

Example-2 script for double relay message (relay of relay):

```
import alc
#input packet is a relay-reply msg
embed_lv1_packet=alc.dhcpv6.get_relaymsg() #get the level=1 embedded packet
embed_lv2_packet= embed_lv1_packet.get_relaymsg()#get level-2 packet embedded in
level-1 packet
iana_list=embed_dhcpv6_packet.get_iana()
iana_list[0][1]='\x00\x00\x04\xb0' #change T1 to 1200
embed_dhcpv6_packet.set_iana(iana_list)#update the iana
embed_lv1_packet.set_relaymsg(embed_lv2_packet)#update the Relay Message option of
lv1 msg
alc.dhcpv6.set_relaymsg(embed_lv1_packet)#update the Relay Message option of the top
level msg
```

16.6.4 Python Policy – Diameter API

The `alc.diameter` Python module provides an API for Diameter message manipulation.

Terminology used in the API description:

- **top-level-AVP** — AVP appearing at the top level in a Diameter message, i.e. not embedded in the Data field of a grouped AVP
- **embedded-AVP** — AVP embedded in the Data field of a grouped AVP. An embedded AVP can be a grouped AVP. This is called nesting.
- **AVP-tuple** — Python tuple with following values:
(AVP code, vendor id, flags)
 - AVP code : integer, AVP header field
 - vendor id : integer, AVP header field
 - flags : string, AVP header field
- **AVP-value-tuple** — Python tuple with following values:
(flags, data)
 - flags: string, AVP header field
 - data: string, AVP data field
- **AVP-key-tuple** — Python tuple with following values:
(AVP code, vendor id)
 - AVP code: integer, AVP header field
 - vendor id : integer, AVP header field
- **grouped-AVP-value-tuple** — Python tuple with following values:
(flags, grouped-AVP-dictionary)
 - flags: string, AVP header field
- **grouped-AVP-dictionary** - Python dictionary with following key:value pairs:
{AVP-key-tuple : [AVP-value-tuple or grouped-AVP-value-tuple, ...], ... }
 - key = AVP-key-tuple
 - value = list of AVP-value-tuples or list of grouped-AVP-value-tuples
- **grouped-AVP-decode-tuple** — Python tuple with following values:
(AVP-key-tuple, ...)
 - tuple of AVP-key-tuples
- **AVP-order-tuple** — Python tuple with following values:
(AVP-key-tuple, ...)
 - tuple of AVP-key-tuples

[Table 123](#) displays attributes available in **alc.diameter** module providing access to the Diameter message header:

Table 123 Diameter Message Header alc.diameter Attributes

Attribute	Description	Type	Access
application_id	Diameter message header field	string	Read/Write
code	Diameter message header field	string	Read/Write
end_to_end_id	Diameter message header field	string	Read/Write
flags	Diameter message header field	string	Read/Write
hop_by_hop_id	Diameter message header field	string	Read/Write
msg_length	Diameter message header field. The value is the message length of the original diameter message.	string	Read
version	Diameter message header field	string	Read/Write

[Table 124](#) displays methods available in **alc.diameter** module providing message and AVP manipulation functionality:

Table 124 Message and AVP Manipulation Functionality alc.diameter Methods

Method	Description
clear_avps(AVP code, vendor id) AVP code, vendor id = top-level-AVP	Remove all instances of the specified AVP from the message. Applies to top-level-AVP's only. If the specified AVP is not present, no python error is generated. Vendor id value zero matches top-level-AVP's without Vendor Id field. Return value: None For example: diameter.clear_avps(256, 12645)

Table 124 Message and AVP Manipulation Functionality alc.diameter Methods (Continued)

Method	Description
drop()	Drop the Diameter message. Packet is consumed at TCP level (ack send). A drop will trigger retransmits on Diameter level. Return value: None For example: diameter.drop()
get_avps(AVP code, vendor id) AVP code, vendor id = top-level-AVP	Returns a list of AVP-value-tuples. Each AVP-value-tuple represents an instance of the specified AVP in the message. Applies to top-level-AVP's only. The position in the list corresponds with the position of the AVP instance in the message at that stage in the script. When executed before any clear or set AVP method, the list order corresponds with the AVP order in the received message. If the specified AVP is a grouped AVP, then the data will contain all the embedded-AVP's. An empty list is returned if the specified AVP is not present. Vendor id value zero matches top-level-AVP's without Vendor Id field. For example: diameter.get_avps(263, 0) [('@', 'bng.nokia.com;1398156449;28')]
get_avps_list()	Returns a list of AVP-tuples. Each AVP-tuple represents an instance of an AVP in the message. Applies to top-level-AVP's only. The position in the list corresponds with the position of the AVP in the message at that stage in the script. When executed before any clear or set AVP method, the list order corresponds with the AVP order in the received message. When multiple instances of an AVP are present in the message, then there will be multiple instances in the list. The Vendor Id has value zero when not present. Grouped AVPs cannot be distinguished from other AVPs in the list. For example: diameter.get_avps_list() [(263, 0, '@'), (264, 0, '@'), (296, 0, '@'), (258, 0, '@'), (416, 0, '@'), (415, 0, '@'), (268, 0, '@'), (55, 0, '@'), (456, 0, '@'), (456, 0, '@'), (456, 0, '@'), (293, 0, '@'), (256, 12645, '\x80')]

Table 124 Message and AVP Manipulation Functionality alc.diameter Methods (Continued)

Method	Description
<code>get_grouped_avps(AVP code, vendor id, grouped-AVP-decode-tuple)</code> AVP code, vendor id = top-level-AVP	<p>Returns a list of grouped-AVP-value-tuples with each grouped-AVP-dictionary entry representing an embedded AVP. Each grouped-AVP-value-tuple represents an instance of the specified AVP in the message. Applies to top-level-AVP's of type grouped only. The position in the list corresponds with the position of the grouped AVP instance in the message at that stage in the script. When executed before any clear or set AVP method, the list order corresponds with the AVP order in the received message.</p> <p>If the grouped-AVP-decode-tuple is empty, only the specified top-level-AVP is expanded in a grouped-AVP-value-tuple, with each grouped-AVP-dictionary entry representing an embedded AVP and all dictionary values of type "list of AVP-value-tuples"</p> <p>To expand nested AVPs (grouped AVPs embedded in a grouped AVP), the grouped top-level-AVP and grouped embedded-AVP to expand must be added to the grouped-AVP-decode-tuple. All grouped AVP's in the grouped-AVP-decode-tuple will be expanded in a list of grouped-AVP-value-tuples provided that their embedding AVP is also in the list.</p> <p>The position of the embedded AVPs in the grouped-AVP-dictionary does not correspond with the position in the grouped AVP.</p>

Table 124 Message and AVP Manipulation Functionality alc.diameter Methods (Continued)

Method	Description
	<p>If the specified top-level-AVP is not a grouped AVP, then a Python error is generated: 'ValueError: malformed diameter message'.</p> <p>For example:</p> <p>To expand the Multiple Services Credit Control (456) grouped top level AVP:</p> <pre>diameter.get_grouped_avps(456,0,())</pre> <pre>[('@', {(432, 0): [('@', '\x00\x00\x00\x01')], (431, 0): [('@', '\x00\x00\x01\xa4@\x00\x00\x0c\x00\x00\x00d')], (448, 0): [('@', '\x00\x00\x04\xb0')], (268, 0): [('@', '\x00\x00\x07\xd1')])}, ('@', {(432, 0): [('@', '\x00\x00\x00\x02')], (431, 0): [('@', '\x00\x00\x01\xa4@\x00\x00\x0c\x00\x00\x03\x84')], (448, 0): [('@', '\x00\x00\x04\xb0')], (268, 0): [('@', '\x00\x00\x07\xd1')])}, ('@', {(432, 0): [('@', '\x00\x00\x00\x03')], (431, 0): [('@', '\x00\x00\x01\xa4@\x00\x00\x0c\x00\x00\x00<')], (448, 0): [('@', '\x00\x00\x04\xb0')], (268, 0): [('@', '\x00\x00\x07\xd1')])})]</pre>
	<p>To expand the nested Granted-Service-Unit AVP (code 431) in the grouped Multiple Services Credit Control top level AVP (code 456):</p> <pre>diameter.get_grouped_avps(456,0,((456,0),(431,0)))</pre> <pre>[('@', {(432, 0): [('@', '\x00\x00\x00\x01')], (431, 0): [('@', {(420, 0): [('@', '\x00\x00\x00d')])], (448, 0): [('@', '\x00\x00\x04\xb0')], (268, 0): [('@', '\x00\x00\x07\xd1')])}, ('@', {(432, 0): [('@', '\x00\x00\x00\x02')], (431, 0): [('@', {(420, 0): [('@', '\x00\x00\x03\x84')])], (448, 0): [('@', '\x00\x00\x04\xb0')], (268, 0): [('@', '\x00\x00\x07\xd1')])}, ('@', {(432, 0): [('@', '\x00\x00\x00\x03')], (431, 0): [('@', {(420, 0): [('@', '\x00\x00\x00<')])], (448, 0): [('@', '\x00\x00\x04\xb0')], (268, 0): [('@', '\x00\x00\x07\xd1')])})]</pre>

Table 124 Message and AVP Manipulation Functionality alc.diameter Methods (Continued)

Method	Description
<p>set_avps(AVP code, vendor id, list of AVP-value-tuples)</p> <p>AVP code, vendor id = top-level-AVP</p>	<p>Remove all instances of the specified top-level-AVP from the message. For each entry in the AVP-value-tuple list, a top-level-AVP instance is inserted.</p> <p>If the specified vendor id value is zero, then no vendor id field is inserted and setting the Vendor-Specific bit in the flags field of the AVP value tuple will then result in a Python error: "ValueError: no vendor ID but vendor flag set".</p> <p>If the specified vendor id value is non-zero, then a vendor id field is inserted and not setting the Vendor-Specific bit in the flags field of the AVP value tuple will result in a Python error: "ValueError: vendor ID but vendor flag not set".</p> <p>Padding between AVPs, AVP length and Diameter message length are adapted accordingly by the system.</p> <p>Return value is None.</p> <p>For example:</p> <pre>diameter.set_avps(461,0,[('x40', 'Python-1'), ('x40', 'Python-2')])</pre>
<p>set_fixed_position_avps(AVP-order-tuple)</p>	<p>Put the specified top-level-AVPs at the beginning of the message in the order as specified in the AVP-order-tuple.</p> <p>This method overrides the order of the top-level-AVPs in the resulting Diameter message. If for example the session-id AVP must appear as first in the message, then the corresponding AVP-key-tuple must be included in the first position of the AVP-order-tuple.</p> <p>AVPs not present in the message but specified in the AVP-order-tuple are ignored.</p>
	<p>AVPs present in the message and not specified in the AVP-order-tuple will be included in the final message after the AVPs listed in the AVP-order-tuple. The order is deterministic but implementation specific.</p> <p>This method can appear at any point in the script. The last call will override the previous one.</p>

Table 124 Message and AVP Manipulation Functionality alc.diameter Methods (Continued)

Method	Description
	<p>From a black box viewpoint, this method is executed at the end of the script: the result of the call is not reflected in the list returned by a subsequent <code>get_avp_list()</code> call.</p> <p>Return value: None</p> <p>For example:</p> <pre>diameter.set_fixed_position_avps(((263,0), (264,0), (296,0), (268,0))</pre>
<p><code>set_grouped_avps(AVP code, vendor id, list of grouped-AVP-value-tuples)</code></p> <p>AVP code, vendor id = top-level-AVP</p>	<p>Remove all instances of the specified grouped top-level-AVP from the message. For each entry in the grouped-AVP-value-tuples list, a grouped top-level-AVP instance is inserted.</p> <p>The order of the embedded-AVPs in the grouped AVP cannot be specified. If the specified vendor id value is zero, then no vendor id field is inserted and setting the Vendor-Specific bit in the flags field of the AVP value tuple will then result in a Python error: "ValueError: no vendor ID but vendor flag set".</p> <p>If the specified vendor id value is non-zero, then a vendor id field is inserted and not setting the Vendor-Specific bit in the flags field of the AVP value tuple will result in a Python error: "ValueError: vendor ID but vendor flag not set".</p> <p>Padding between AVPs, AVP length and Diameter message length are adapted accordingly.</p> <p>Return value is None.</p> <p>For example:</p> <pre>diameter.set_grouped_avps(456,0,['@', {(432, 0): ['@', '\x00\x00\x00\x01')], (431, 0): ['@', {(420, 0): ['@', '\x00\x00\x00\x2b')}]}, (448, 0): ['@', '\x00\x00\x04\xb0')], (268, 0): ['@', '\x00\x00\x07\xd1')}]}, ('@', {(432, 0): ['@', '\x00\x00\x00\x03')], (431, 0): ['@', {(420, 0): ['@', '\x00\x00\x00\x53')}]}, (448, 0): ['@', '\x00\x00\x04\xb0')], (268, 0): ['@', '\x00\x00\x07\xd1')}]})</pre>

To enable Diameter message manipulation using Python, a python-policy must be configured in the diameter-peer-policy. For example:

```
configure
```

```
aaa
    diameter-peer-policy "diameter-peer-policy-1" create
        description "Diameter peer policy"
        applications gy
        origin-host "bng.nokia.com"
        origin-realm "nokia.com"
        python-policy "py-policy-diam-1"
        source-address 192.0.2.5
        peer "peer-1" create
            address 172.16.1.1
            destination-host "server.nokia.com"
            destination-realm "nokia.com"
            no shutdown
        exit
    exit
exit
```

The python-policy specifies the python-script to use for each Diameter message type received or transmitted on a Diameter peer. In the ingress direction, the Python script is executed when the corresponding packet type is received on the Diameter peer but prior to further processing in the system. In the egress direction, the Python script is executed prior to sending the corresponding packet type on the Diameter peer. For example:

```
configure
    python
        python-policy "py-policy-diam-1" create
            description "Python policy"
            diameter ccr direction egress script "diameter-1"
            diameter cca direction ingress script "diameter-2"
        exit
    exit
```

The python-script specifies the location of the script and optional protection mechanism. For example:

```
configure
    python
        python-script "diameter-1" create
            primary-url "ftp://usr:pwd@192.0.2.1/./py/diam-1.py"
            no shutdown
        exit
    exit
```

As an example, the diam-1.py script, clears the M-bit from the Event-Timestamp AVP (code 55):

```
from alc import diameter
avp55=diameter.get_avps(55,0)
diameter.set_avps(55,0,['\x00',avp55[0][1]])
```

16.6.5 Python Policy – DHCP Transaction Cache API

A DHCP transaction cache (DTC) is a short-lived cache during DHCPv4/v6 transaction. The cache could be used to store user-chosen information or return ESM attributes via a Python script. The DTC's lifetime is only during a single DHCP transaction (for example, only between discovery-offer, request-reply). This includes both `alc.dtc.store()` data and `alc.dtc.setESM()` data. DTC is also a transaction specific cache, which means the cached information could only be accessed by the Python script running in same DHCP transaction.

The following are the DTC APIs:

- `alc.dtc.derivedId`: A string used as a LUDB lookup key
- `alc.dtc.store(cache-key, cache-value)`: Store the value with the specified cache-key in DTC, both key and value are string.
- `alc.dtc.retrieve(cache-key)`: Returns the cached value string according to the specified cache-key, raise exception if specified key does not exist.
- `alc.dtc.setESM(ESM-key, value)`: Sets the specified ESM attribute, which could be used when system creating the ESM host.

Note: Due to the short-live nature of DTC, `setESM` should be used in final DHCP transaction before system create ESM host., such as DHCPv4 REQUEST-ACK.

- The following is a list of supported ESM-keys and corresponding Python type:
 - `alc.dtc.accountingPolicy:str`
 - `alc.dtc.ancpString:str`
 - `alc.dtc.appProfileString:str`
 - `alc.dtc.catMapString:str`
 - `alc.dtc.defGw:str`
 - `alc.dtc.dhcpv4GIAddr:str`
 - `alc.dtc.dhcpv4Pool:str`
 - `alc.dtc.dhcpv4ServerAddr:str`
 - `alc.dtc.dhcpv6LinkAddr:str`
 - `alc.dtc.dhcpv6PreferredLifetime`
 - `alc.dtc.dhcpv6RebindTimer`
 - `alc.dtc.dhcpv6RenewTimer`
 - `alc.dtc.dhcpv6ServerAddr:str`
 - `alc.dtc.dhcpv6ValidLifetime`

- alc.dtc.intDestId:str
- alc.dtc.ipAddress:str
- alc.dtc.ipv4LeaseTime:int
- alc.dtc.ipv4PrimDns:str
- alc.dtc.ipv4SecDns:str
- alc.dtc.ipv6Address:str
- alc.dtc.ipv6DelegatedPrefix:str
- alc.dtc.ipv6DelegatedPrefixLength:int
- alc.dtc.ipv6PrefixPool:str
- alc.dtc.ipv6PrimDns:str
- alc.dtc.ipv6SecDns:str
- alc.dtc.ipv6SlaacPrefix:str
- alc.dtc.ipv6WanPool:str
- alc.dtc.msapGroupInterface:str
- alc.dtc.msapPolicy:str
- alc.dtc.msapServiceId:str
- alc.dtc.primNbns:str
- alc.dtc.primNbns:str

16.6.6 Python for PPPoE API

The following are the system-provided Python API PPPoE packets:

- The system will provide a Python object for input PPPoE packet: `alc.pppoe`.
- `alc.pppoe` class is always available even when Python script is trigger by other type of packet that encapsulated in PPPoE, such as LCP/IPCP/PAP/CHAP, and so on.
- `alc.pppoe` has the following attributes to represent the PPPoE header fields.

Table 125 System Provided Python API PPPoE Packets

Class Attrs	PPPoE Header Field	Access
<code>alc.pppoe.dest_mac</code>	Str, destination MAC address; the format is "xx:xx:xx:xx:xx:xx"	Read
<code>alc.pppoe.src_mac</code>	Str, source MAC address; the format is "xx:xx:xx:xx:xx:xx"	Read
<code>alc.pppoe.port_id</code>	Str, the port id of the PPPoE session like "1/1/3"	Read
<code>alc.pppoe.vlan_tag</code>	Str, the vlan tag of the PPPoE session like "100" or "100.200"	Read
<code>alc.pppoe.ver</code>	Integer, ver field in PPPoE header	Read
<code>alc.pppoe.type</code>	Integer, type field in PPPoE header	Read
<code>alc.pppoe.code</code>	Integer, code field in PPPoE header	Read
<code>alc.pppoe.session_id</code>	Integer, session_id field in PPPoE header	Read
<code>alc.pppoe.len</code>	Integer, length field in PPPoE header	Read

The following is a list of functions of `alic.pppoe`:

-
- `alc.pppoe.drop()` — The system drops the resulting packet.
 - `alc.pppoe.getTagList()` — The system returns a tuple that includes tag-type of existing PPPoE tags in the packet. The order of the element in the tuple is as same as the tags appear in the packet. If there are multiple instances of same option, then each instance is one element in the tuple.
 - `alc.pppoe.get(tag-type)` — The system returns a tuple of strings, each string represent one instance of the specified tags, the value of this string is exact bytes of the tag_value as it appears in packet(excludes tag_type and tag_len); if tag does not exist, return (); if a specific instance's tag_length=0, return "" for this instance.
 - `alc.pppoe.set(tag-type,valTuple)` — This function removes the all existing instances of specified tags and insert a list of new tags. Each element in valTuple is a string, represent one instance of the new tag to be inserted. For each new option, the type is specified in tag-type, the option-len is the length of the element, reset of option is the element itself.
 - `alc.pppoe.clear(tag-type)` — This function removes the all existing instances of specified tags. In fact this function is a shortcut version of `alc.pppoe.set(tag-type,())`.
 - `alc.pppoe.getPPP()` — This function returns an `alc.ppp` object which represent the LCP/PCP/IP6CP packet encapsulated inside the PPPoE packet. It will return none if there is no such packet.
 - `alc.pppoe.getPAP()` — This function returns an `alc.pap` object which represents the PAP packet encapsulated inside the PPPoE packet. It will return none if there is no PAP packet;
 - `alc.pppoe.setPAP(pap_obj)` — This function accepts an `alc.pap` object as the parameter and replace the existing PAP packet that encapsulated in the PPPoE packet. An exception is raised when there is no existing PAP packet.
 - `alc.pppoe.getCHAP()` — This function returns an `alc.chap` object, which represent the CHAP packet encapsulated inside the PPPoE packet. It will return none if there is no CHAP packet.
 - `alc.pppoe.setCHAP(chap_obj)` — This function accepts an `alc.chap` object as the parameter and replace the existing CHAP packet that encapsulated in the PPPoE packet. An exception is raised when there is no existing CHAP packet.

16.6.7 Python API for PPP Packet

The system will provide a Python object for PPP packet encapsulated in PPPoE packets: `alc.ppp`.

- Use `alc.pppoe.getPPP()` to get the `alc.ppp` object in the input PPPoE packet. This class only supports following control level protocol:
 - LCP (read-only)
 - IPCP(read-only)
 - IP6CP(read-only)
 - `alc.ppp` has following attributes to represent the PPP header fields:

Table 126 PPP Header Field Attributes

Class Attrs	PPP Header Field	Access
<code>alc.ppp.protocol</code>	Integer, protocol field in ppp header	Read
<code>alc.ppp.code</code>	Integer, code field in ppp protocol header	Read
<code>alc.ppp.id</code>	Integer, identifier field in ppp protocol header	Read
<code>alc.ppp.len</code>	Integer, length field in ppp protocol header	Read

The following is a list of functions of `alc.ppp`:

- `alc.ppp.getOptionList()` — Returns a tuple that includes type of existing PPP options in the packet. The order of the element in the tuple is as same as the options appear in the packet. If there are multiple instances of same option, then each instance is one element in the tuple.
- `alc.ppp.get(op-type)` — Returns a tuple of strings, each string represent one instance of the specified option , the value of this string is exact bytes of the `option_data` as it appears in packet (excludes `option_type` and `option_len`); if the option does not exist, return `()`; if a specific instance's `option_length=0`, return `""` for this instance.

16.6.8 Python API for PPP PAP

The system will provide a python object for PAP packet encapsulated in the input PPPoE packets: `alc.pap`.

Use `alc.pppoe.getPAP()` to get the `alc.pap` object in the input PPPoE packet.

To apply changes to PAP packet, `alc.pppoe.setPAP(new_alc.pap_obj)` must be called.

`alc.pap` has following attributes to represent the PAP header fields:

Table 127 PAP Header Fields

Class Attrs	PAP Field	Access
<code>alc.pap.code</code>	Integer, code field in pap protocol header	Read
<code>alc.pap.id</code>	Integer, identifier field in pap protocol header	Read
<code>alc.pap.len</code>	Integer, length field in pap protocol header	Read

The following is a list of functions in the class:

- `alc.pap.getCred()` — Only apply to Authentication-Request packet. Returns a tuple: (peer-id, password), both are str. If either of them has 0 length, it will be ""; if the system failed to parse the packet, such as the length < 6 bytes or the packet is not an authentication-request, then the system raises an exception. If the packet has a wrong type it returns None (that is, no exception is raised).
- `alc.pap.setCred(cred_tuple)` — Only apply to Authentication-Request packet. Set the peer-id and password to `cred_tuple`; `cred_tuple` is a tuple:(peer-id, password) both are str. "" is allowed as the value for either of them. If the packet is not authentication-request, then system will raise an exception.
- `alc.pap.getMsg()` — Only apply to Authentication-Ack/Nak packet. Return the message in the packet as a str; return "" if len of message is 0; raise an exception for wrong type of packet (such as an auth-request). If the packet has a wrong type it returns None (that is, no exception is raised).
- `alc.pap.setMsg(msg)` — Only apply to Authentication-Ack/Nak packet. set the message in the packet to parameter `msg`; `msg` is a str; "" is allowed; raise an exception for wrong type of packet (such as an auth-request).

16.6.9 Python API for PPP CHAP

The system will provide a python object for CHAP packet encapsulated in the input PPPoE packets: `alc.chap`.

Use `alc.pppoe.getCHAP()` to get the `alc.chap` object in the input PPPoE packet.

To apply changes to PAP packet, `alc.pppoe.setCHAP(new_alc.pap_obj)` need to be called.

`alc.chap` has following attributes to represent the CHAP header fields:

Table 128 CHAP Header Fields

Class Attrs	PAP Field	Access
<code>alc.chap.code</code>	Integer, code field in chap protocol header	Read
<code>alc.chap.id</code>	Integer, identifier field in chap protocol header	Read
<code>alc.chap.len</code>	Integer, length field in chap protocol header	Read

The following is a list of functions in the class:

- `alc.chap.getCred()` — Only apply to challenge/response packet. Returns a tuple: (name, challenge, response), both are str. If either of them has 0 length, it will be ""; if system failed to parse the packet, such as the length < `minimal_length` or the packet is not challenge/response, then system raise an exception. If the packet has a wrong type it returns None (that is, no exception is raised). The second value in the returned tuple either contains the challenge (in a challenge packet) or the response (in a response packet) value.
- `alc.chap.setCred(chap_cred_tuple)` — Only apply to challenge/response packet. Set the name and challenge to `chap_cred_tuple`; `chap_cred_tuple` is a tuple: (name, challenge, response) both are str. "" is allowed as the value for either of them. If packet is not challenge/response, then system will raise an exception. The second value in the supplied tuple either contains the challenge (in a challenge packet) or the response (in a response packet) value.

- `alc.chap.getMsg()` — Only apply to Success/Failure packet. Return the message in the packet as a str; return "" if len of message is 0; raise an exception for wrong type of packet (such as challenge). If the packet has a wrong type it returns None (that is, no exception is raised).
- `alc.chap.setMsg(msg)` — Only apply to Success/Failure packet. set the message in the packet to parameter msg; msg is a str; "" is allowed; raise an exception for wrong type of packet(such as challenge).

16.6.10 Python ESM API

The system provides a python object: `alc.esm`, to provide flexible LUDB lookup and return ESM attributes directly from script.

`alc.esm` support both DHCPv4/v6 and PPPoE hosts.

`alc.esm` has following attribute and function:

- `alc.esm.derivedId`: A string used as LUDB lookup key
- `alc.esm.set(ESM-key, value)`: Set the value of specified ESM attribute, it will be used for ESM host creation.

`alc.esm.derivedId` should be set for all types of ingress packets that system used to access LUDB; for example PPPoE PADI and PADR, DHCP discovery and request.

The following is a list of supported ESM-key and its corresponding Python type:

- `alc.esm.accountingPolicy`:str
- `alc.esm.ancpString`:str
- `alc.esm.appProfileString`:str
- `alc.esm.catMapString`:str
- `alc.esm.defGw`:str
- `alc.esm.dhcpv4GwAddr`:str
- `alc.esm.dhcpv4Pool`:str
- `alc.esm.dhcpv4ServerAddr`:str
- `alc.esm.dhcpv6LinkAddr`:str
- `alc.esm.dhcpv6ServerAddr`:str
- `alc.esm.intDestId`:str
- `alc.esm.ipAddress`:str
- `alc.esm.ipv4LeaseTime`:int

-
- alc.esm.ipv4PrimDns:str
 - alc.esm.ipv4SecDns:str
 - alc.esm.ipv6Address:str
 - alc.esm.dhcpv6PreferredLifetime
 - alc.esm.dhcpv6RebindTimer
 - alc.esm.dhcpv6RenewTimer
 - alc.esm.dhcpv6ValidLifetime
 - alc.esm.ipv6DelegatedPrefix:str
 - alc.esm.ipv6DelegatedPrefixLength:int
 - alc.esm.ipv6PrefixPool:str
 - alc.esm.ipv6PrimDns:str
 - alc.esm.ipv6SecDns:str
 - alc.esm.ipv6SlaacPrefix:str
 - alc.esm.ipv6WanPool:str
 - alc.esm.msapGroupInterface:str
 - alc.esm.msapPolicy:str
 - alc.esm.msapServiceId:str
 - alc.esm.primNbns:str
 - alc.esm.retailServiceId:str
 - alc.esm.secNbns:str
 - alc.esm.slaProfileString:str
 - alc.esm.subIdent:str
 - alc.esm.subProfileString:str
 - alc.esm.subnetMask:str
 - alc.dtc.dhcpv6PreferredLifetime
 - alc.dtc.dhcpv6RebindTimer
 - alc.dtc.dhcpv6RenewTimer
 - alc.dtc.dhcpv6ValidLifetime

The following are PPPoE-specific keys:

- alc.esm.padoDelay: int
- alc.esm.pppAuthProtocol: str, {'pap'|'chap'|'pref-chap'|'pref-pap'}
- alc.esm.pppMTU: int

In case of PPPoE, `alc.esm.set()` could only be called ingress discovery (PADI, PADR) and authentication (PAP Authenticate, CHAP Response) packets. If it is called multiple times, the first one wins except the derived-id, while the `alc.esm.padoDelay` only applies when the system receives PADI. `alc.esm.pppAuthProtocol` and `alc.esm.pppMTU` can only be set when a PADR is received.

`alc.esm.set()` will be blocked during LCP/IPC/P/CP/IP6CP phase.

The system will raise an exception if `alc.esm.set()` is called at wrong time. Setting the ESM keys that do not apply to the host type are ignored; for example, setting PPP(oE) keys for DHCP hosts is ignored.

The value returned by `alc.esm.set()` take highest precedence than other sources like CLI/LUDB.

For `alc.esm.set(ESM-key, value)`

- PPPoE can only be called for ingress discovery (PADI, PADR) and authentication (PAP Authenticate, CHAP Response) packets. An exception is raised otherwise (for example, wrong time, including egress discovery PADO and PADS, and authentication PAP Ack/Nak & CHAP Success/Failure).
- The PPPoE key `alc.esm.padoDelay` can only be set when PADI is received (otherwise, it is too late).
- PPP keys `alc.esm.pppAuthProtocol` and `alc.esm.pppMTU` can only be set when PADR is received. It has no effect when PADI is received.
- Setting ESM-keys for a PPPoE host which do not apply is ignored (that is, no exception is raised).
- Setting PPP(oE) keys for a DHCP host is ignored.

16.6.11 Python Cache Support

Python cache support allows information to be shared across different run times of the same python script or even different python scripts in a programmatic way. It essentially provides a central memory cache and a set of APIs which let the user store and retrieve strings. For example, a DHCP python-script could store a DHCP option into cache and later a RADIUS python-script could retrieve stored string and add it into access-request.

Each cached entry in the cache is a tuple of (**key**, **val**). **key** is used as entry id. **val** is the string to be cached. Both **key** and **val** are strings. The max length of the key is 512 bytes. Future more, the combine length of key+val is limited by the configured value of **entry-size** *size* command in the python-policy.

The Python cache can be enabled per python-policy. Each python policy has its own cache memory which script in other python-policy cannot access. This also implies that the key of a cached entry in different a python policy could overlap.

The user can also specify the max number cache entry per python policy the command **max-entries** command. System has a global limit for python cache memory of 256MB.

The cached entries could be made persistent by saving it to CF card. This can be enabled with the **persistence** command in the python policy.

Note: From memory consumption point of view, with MCS enabled, each cached entry will have a corresponding MCS record, so each entry will consume twice amount of memory.

The system also supports syncing the python cache across chassis with MCS. This can be configured per python policy with the **mcs-peer** command in the python policy.

Each cached entry has a remaining lifetime. If it decreases over time, the system will remove the cached entry if its remaining lifetime is 0. The remaining lifetime can be changed using a system- provided API. The initial lifetime of a newly created cache entry is 600 seconds.

The following are the python cache APIs in a module `alc.cache`:

- `alc.cache.save(val,key)`: Saves the val identified by the key into the cache. If there is an existing cache entry with same key, then it will be overwritten with the new val. An exception will be raised if the save failed (for example, due to exceeding the max number of entries).
- `alc.cache.retrieve(key)`: Returns the stored entry's val identified by the key. A `KeyError` exception will be raised if the specified entry does not exist.
- `alc.cache.clear(key)`: Removes the cached entry identified by the key. Raise `KeyError` exception if the specified entry does not exist.
- `cache.get_lifetime(key)`: The system will return a integer as seconds of remaining lifetime of the specified entry. It will return none if the specified entry does not exist. An exception will be raised for any other error.

- `cache.set_lifetime(key,new_lifetime)`: The `new_lifetime` value is an integer. The system will set the remaining lifetime of the specified entry to the number of seconds of the `new_lifetime`. An exception will be raised for any error including specified entry does not exist. If the `new_lifetime` \geq `max_lifetime` (configurable using the **max-entry-life** command in the python policy), then the system will set the actual lifetime to the `max_lifetime`.

16.6.12 Applying a Python Policy

The following is a list of places that a Python policy could be applied:

- Under capture SAP — Apply to the DHCPv4/v6 packets sent/received on the capture SAP.
- Under group-interface — Apply to DHCPv4/v6 packets sent/received on the group-interface.
- Under subscriber-interface — Apply to DHCPv4 packets on the retail subscriber interface.
- In the radius-server-policy — Apply to the RADIUS packets sent/received to/from the RADIUS servers configured in the radius-server-policy.
- In the radius-proxy-server — Apply to the RADIUS packets on the client side of proxy.
- In the diameter-peer-policy — Apply to the Diameter packets send/received on the Diameter peers configured in the policy.

16.6.13 Python Script Protection

In order to protect the Python script from unintended changes, the SR-OS supports a new Python script file format:SRPY. Since 12.0R1, SRPY includes a key based hash(HMAC) of the original script content. When the system loads a script with SRPY format, a hash will be computed by using a configured key and script content. The result hash will be compared to the embedded hash. If it is the same, then this script is considered valid. Otherwise, the system will abort with a warning message.

Users can configure **protection hmac-sha256 key <key>** within a Python script. To mandate, all configured scripts must be in SRPY format.

The system provides a tools command (**tools perform python-script protect**) to convert a Python script into SRPY format.

16.7 Tips and Tricks

- Use xrange() instead of range().
- Avoid too many string operations. The following scripts provide the same output:

```
# This script takes 2.5 seconds. s = ""
for c in 'A'*50000:
    s += str(ord(c)) + ', '
print '[' + s[:-2] + ']'

# This script takes 0.1 seconds. print map(ord, 'A'*50000)
```

16.8.2 Command Descriptions

16.8.2.1 Python Configuration Commands

16.8.2.1.1 Global Commands

description

Syntax	description <i>description-string</i> no description
Context	config>python>py-policy config>python>python-script
Description	<p>This command creates a text description stored in the configuration file for a configuration context.</p> <p>The description command associates a text string with a configuration context to help identify the context in the configuration file.</p> <p>The no form of this command removes any description string from the context.</p>
Default	No description is associated with the configuration context.
Parameters	<i>description-string</i> — A text string describing the entity. Allowed values are any string up to 80 characters long composed of printable, 7-bit ASCII characters excluding double quotes. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

shutdown

Syntax	[no] shutdown
Context	config>python>py-policy>cache config>python>python-script
Description	<p>Shutting down a Python script triggers the system to load and compile the script from the configured location(s). Since the system supports three locations, the primary, secondary and tertiary, the system will try to load the Python script in that order.</p> <p>Shutting down a Python script will disable the Python script and cause the corresponding packet to pass through without any modification.</p>

Default no shutdown

python

Syntax **python**

Context config

Description This command enables the context to configure Python parameters.

16.8.2.1.2 Python Policy Commands

python-policy

Syntax **python-policy** *name* [**create**] [**wlan-gw-group** *wlan-gw-group-id*] [**nat-group** *nat-group-id*]
no python-policy *name*

Context config>python

Description This command creates a new Python policy or enables an existing Python policy configuration context.

There are two types of Python policies: centralized and distributed. A centralized Python policy runs on a CPM, while a distributed Python policy runs on an ISA. With the distributed Python policy, a **wlan-gw-group** *wlan-gw-group-id* or a **nat-group** *nat-group-id* command must specified.

The **no** form of the command removes the Python policy.

Parameters *name* — Specifies the Python policy name up to 32 characters in length.

create — This keyword is required when first creating the Python policy. Once the context is created, it is possible to navigate into the context without the **create** keyword

wlan-gw-group *wlan-gw-group-id* — Specifies the ID of the WLAN GW group that the distributed python-policy installs

nat-group *nat-group-id* — Specifies the ID of the NAT group that the distributed python-policy installs

python-policy

Syntax **python-policy** *policy-name*
no python-policy

Context	config>aaa>isa-radius-policy
Description	<p>This command specifies the Python policy for the ISA RADIUS proxy server. This is the python policy for RADIUS packets to/from the client.</p> <p>The no form of the command removes the Python policy.</p>
Parameters	<p><i>name</i> — Specifies the Python policy name up to 32 characters in length</p> <p>create — This keyword is required when first creating the Python policy. Once the context is created, it is possible to navigate into the context without the create keyword.</p>

cache

Syntax	cache [create] no cache
Context	config>python>py-policy
Description	This command enables the context to configure the limits of the caching API inside the Python scripts.
Parameters	create — This keyword is required when first creating the Python policy. Once the context is created, it is possible to navigate into the context without the create keyword.

entry-size

Syntax	entry-size <i>size</i> no entry-size
Context	config>python>py-policy>cache
Description	<p>This command configures the maximum size of the data structure that can be stored in a single Python cache entry which includes both a value and key.</p> <p>When requesting to store a data structure, the size of the serialized object is compared with the value specified. If larger, the object will not be stored and Python will return exception.</p> <p>The no form of the command reverts to the default value.</p>
Default	256
Parameters	<p><i>size</i> — Configures the maximum accepted size of a single cache entry.</p> <p>Values 32 to 2048</p>

max-entries

Syntax	max-entries <i>count</i> no max-entries
Context	config>python>py-pol>cache
Description	<p>This command configures the maximum number of Python cache entries that can be stored in the cache of this Python policy.</p> <p>If the limit has been reached, a Python exception will be thrown when requested to store another data structure.</p>
Default	128000
Parameters	<p><i>count</i> — Specifies the maximum number of cache entries allowed.</p> <p>Values 1 to 1000000</p>

max-entry-lifetime

Syntax	max-entry-lifetime [<i>days days</i>] [<i>hrs hours</i>] [<i>min minutes</i>] [<i>sec seconds</i>] no max-entry-lifetime
Context	config>python>py-pol>cache
Description	<p>This command configures the maximum allowed lifetime for each entry of the Python cache of this Python policy.</p> <p>When adding data to the Python cache the lifetime of the given object must always be specified. If the specified lifetime is bigger than the configured value, then the value of the max-entry-lifetime will be used instead of the lifetime that was specified.</p> <p>The no form of the command reverts to the default.</p>
Parameters	<p>days <i>days</i> — Specifies the maximum lifetime that can be set on a cache entry in days.</p> <p>Values 0 to 7</p> <p>Default 1</p> <p>hrs <i>hours</i> — Specifies the maximum lifetime that can be set on a cache entry in hours.</p> <p>Values 0 to 23</p> <p>min <i>minutes</i> — Specifies the maximum lifetime that can be set on a cache entry in minutes.</p> <p>Values 0 to 59</p> <p>sec <i>seconds</i> — Specifies the maximum lifetime that can be set on a cache entry in seconds.</p> <p>Values 0 to 59</p>

mcs-peer

Syntax	mcs-peer <i>ip-address</i> sync-tag [<i>sync-tag</i>] no mcs-peer
Context	config>python>py-pol>cache
Description	This command specifies the MCS peer's address and sync-tag for syncing the cached entries of the python-policy. The sync-tag must be match on both chassis.
Default	no mcs-peer
Parameters	<i>ip-address</i> — Specifies the IPv4 address of the MCS peer. <i>sync-tag</i> — Specifies the tag for sync up to 32 characters max.

minimum-lifetimes

Syntax	minimum-lifetimes
Context	config>python>py-pol>cache
Description	This command enables the context to configure minimum-lifetime of python cache information.
Default	N/A

high-availability

Syntax	high-availability <i>seconds</i> no high-availability
Context	config>python>py-pol>cache>min-lifetimes
Description	This command specifies the minimum lifetime of an entry that it could be synced across CPM.
Default	no high-availability
Parameters	<i>seconds</i> — Specifies the minimal lifetime in seconds. Values 1 to 600

multi-chassis-redundancy

Syntax	multi-chassis-redundancy <i>seconds</i> no multi-chassis-redundancy
Context	config>python>py-pol>cache>min-lifetimes

Description	This command specifies the minimum lifetime for a cache entry to be synchronized with the MCS peer.
Default	no multi-chassis-redundancy
Parameters	<i>seconds</i> — Specifies the multi-chassis redundancy time in seconds.
Values	1 to 600

persistence

Syntax	persistence <i>seconds</i> no persistence
Context	config>python>py-pol>cache>min-lifetimes
Description	This command configures the minimum lifetime for a cache entry to be made persistent.
Default	no persistence
Parameters	<i>persistence</i> — The minimum lifetime in seconds.
Values	1 to 600

persistence

Syntax	[no] persistence
Context	config>python>py-pol>cache
Description	This command enables persistency support for the cached entries of the python-policy.
Default	no persistence

dhcp

Syntax	dhcp <i>type</i> direction { ingress egress } script <i>script</i> no dhcp <i>type</i> direction { ingress egress }
Context	config>python>py-policy
Description	This command specifies the Python script for the specified DHCPv4 packet type in the specified direction. Multiple dhcp command configurations are allowed in the same Python policy. The no form of the command reverts to the default.
Default	N/A

Parameters	<i>type</i> — Specifies the message type of the event. Values discover, offer, request, decline, ack, nak, release, inform, force-renew, lease-query, lease-unassigned, lease-unknown, lease-active direction {ingress egress} — Specifies whether the packet is being received by the system or being sent by the system. script script — Specifies the name of the Python script up to 32 characters in length, that will be used to handle the specified message.
-------------------	--

dhcp6

Syntax	dhcp6 type direction {ingress egress} script script no dhcp6 type direction {ingress egress}
Context	config>python>py-policy
Description	<p>This command specifies the Python script for the specified DHCPv6 packet type in the specified direction.</p> <p>Multiple dhcps command configurations are allowed in the same Python policy.</p>
Default	N/A
Parameters	<i>type</i> — Specifies the message type of the event. Values solicit, advertise, request, confirm, renew, rebind, reply, release, decline, reconfigure, info-request, relay-forward, relay-reply direction {ingress egress} — Specifies whether the event is incoming or outgoing. script script — Specifies the name of the Python script up to 32 characters in length, that will be used to handle the specified message.

diameter

Syntax	diameter type direction {ingress egress} script script no diameter type direction {ingress egress}
Context	config>python>py-policy
Description	<p>This command specifies the Python script to use for the specified Diameter message type in the specified direction.</p> <p>Multiple diameter command configurations are allowed in the same Python policy.</p>
Default	N/A

Parameters *type* — Specifies the message type.

Message type	Application	Direction
aaa – AA Answer	Nasreq	ingress
aar – AA Request	Nasreq	egress
asa – Abort Session Answer	Gx, Gy	egress
asr – Abort Session Request	Gx, Gy	ingress
cca – Credit Control Answer	Gx, Gy	ingress
ccr – Credit Control Request	Gx, Gy	egress
cea – Capabilities Exchange Answer	Base	ingress
cer – Capabilities Exchange Request	Base	egress
dpa – Disconnect Peer Answer	Base	ingress/egress
dpr – Disconnect Peer Request	Base	ingress/egress
dwa – Device Watchdog Answer	Base	ingress/egress
dwr – Device Watchdog Request	Base	ingress/egress
raa – Re-Authentication Answer	Gx, Gy	egress
rar – Re-Authentication Request	Gx, Gy	ingress

direction {**ingress** | **egress**} — Specifies if the message is incoming or outgoing.

script *script* — Specifies the name of the Python script up to 32 characters in length, that will be used to handle the specified message.

gtpv1-c

Syntax	gtpv1-c <i>type</i> direction { ingress egress } script [<i>script</i>] no gtpv1-c <i>type</i> direction { ingress egress }
Context	config>python>py-policy
Description	This command configures a Python script for the specified GTPv1-C message type in the specified direction.
Default	N/A
Parameters	<i>type</i> — Specifies the message type. Values echo-request, echo-response, version-not-supported, create-pdp-context-request, create-pdp-context-response, delete-pdp-context-request, delete-pdp-context-response, error-indication direction { ingress egress } — Specifies if the message is incoming or outgoing.

script *script* — Specifies the name of the Python script up to 32 characters in length, that will be used to handle the specified message.

gtpv2-c

Syntax	gtpv2-c <i>type</i> direction { ingress egress } script [<i>script</i>] no gtpv2-c <i>type</i> direction { ingress egress }
Context	config>python>py-policy
Description	This command configures a Python script for the specified GTPv2-C message type in the specified direction.
Default	N/A
Parameters	<p><i>type</i> — Specifies the message type.</p> <p>Values echo-request, echo-response, version-not-supported, create-session-request, create-session-response, delete-session-request, delete-session-response, delete-bearer-request, delete-bearer-response</p> <p>direction {ingress egress} — Specifies if the message is incoming or outgoing.</p> <p>script <i>script</i> — Specifies the name of the Python script up to 32 characters in length, that will be used to handle the specified message.</p>

pppoe

Syntax	pppoe <i>type</i> direction { ingress egress } script <i>name</i> no pppoe <i>type</i> direction { ingress egress }
Context	config>python>py-policy
Description	<p>This command specifies the python-script for the specified PPPoE message type in the specified direction. Multiple pppoe command configuration are allowed in the same Python policy.</p> <p>The no form of the command reverts to the default.</p>
Default	N/A
Parameters	<p><i>type</i> — Specifies the message type.</p> <p>Values session-lcp, session-pap, session-chap, session-ipcp, session-ip6cp, pado, padi, padr, pads, padt</p> <p>direction {ingress egress} — Specifies whether the event is incoming or outgoing. The system will only invoke the configured script for the specified packet type in the specified direction</p>

script *script* — Specifies the name of the Python script up to 32 characters in length, that will be used to handle the specified message.

radius

Syntax	radius <i>type</i> direction { ingress egress } script <i>script</i> no radius <i>type</i> direction { ingress egress }
Context	config>python>py-policy
Description	This command specifies the Python script for the specified RADIUS packet type in the specified direction. Multiple radius command configurations are allowed in the same Python policy.
Parameters	<i>type</i> — Specifies the message type of the event. access-request, access-accept, access-reject, accounting-request, accounting-response, access-challenge, disconnect-request, change-of-authorization-request direction { ingress egress } — Specifies whether the event is incoming or outgoing. script <i>script</i> — Specifies the name of the Python script up to 32 characters in length, that will be used to handle the specified message.

vsd

Syntax	vsd script [32 chars max] no vsd
Context	config>python>py-policy
Description	This command configures scripts to handle VSD messages.
Default	N/A
Parameters	script <i>script</i> — Specifies the name of the Python script up to 32 characters in length, that will be used to handle the specified message.

16.8.2.1.3 Python Script Commands

python-script

Syntax	python-script <i>name</i> [create] no python-script <i>name</i>
---------------	---

Context	config>python
Description	<p>This command enables the context to configure Python scripts to modify messages of different protocols.</p> <p>The no form of the command removes the Python script name from the configuration.</p>
Parameters	<p>name — Specifies the name of this Python script policy.</p> <p>create — This keyword is required when first creating the Python script. Once the context is created, it is possible to navigate into the context without the create keyword.</p>

action-on-fail

Syntax	action-on-fail {drop passthrough} no action-on-fail
Context	config>python>python-script
Description	<p>This command specifies the action taken when Python fails to modify the given message.</p> <p>The no form of the command reverts to the default.</p>
Default	drop
Parameters	<p>drop — Specifies that the packet will be dropped.</p> <p>passthrough — Specifies that the packet will be sent out without any modifications.</p>

primary-url

Syntax	primary-url <i>url</i> no primary-url
Context	config>python>python-script
Description	<p>This command specifies the location of the primary Python script. The system supports three locations for each Python script. Users can store the script file on either a local CF card or an FTP server.</p> <p>The no form of the command removes the URL.</p>
Default	no primary-url
Parameters	<p>url — Specifies the primary URL of the Python script up to 180 characters in length, either a local CF card url or a FTP server URL.</p>

protection

Syntax	protection none protection hmac-sha256 key <i>key</i> [hash hash2] no protection
Context	config>python>python-script
Description	This command specifies the format of the Python script file(s) in this python-script. Unintentional changing of Python script file could be prevented by using protected format. The no form of this command equals to protection none .
Default	N/A
Parameters	none — Indicates the Python script is stored in plain-text, without any mechanism in place to ensure the integrity nor the confidentiality of the content of the Python script. hmac-sha256 — Indicates the first line of the Python script must consist of the hash value obtained by hashing the rest of the Python script using the hmac-sha256 hashing algorithm given the key specified in tmnxPythonScriptProtectionKey. key <i>key</i> — The specified key along with original Python script file content are used to compute the hash. The computed hash will be compared to the hash in the Python script file. If there is no match, then system will fail to load the script. hash — Specifies the key is entered in an encrypted form. If the hash or hash2 parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the hash or hash2 parameter specified hash2 — Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the hash2 encrypted variable cannot be copied and pasted. If the hash or hash2 parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the hash or hash2 parameter specified.

secondary-url

Syntax	secondary-url <i>url</i> no secondary-url
Context	config>python>python-script
Description	This command specifies the location of secondary Python script. The system supports three locations for each Python-script. Users can store scripts file on either a local CF card or a FTP server. The no form of the command removes the URL.
Default	no secondary-url

Parameters **url** — Specifies the secondary URL of the Python script up to 180 characters in length, either a local CF card URL or a FTP server URL.

tertiary-url

Syntax **tertiary-url** *url*
no tertiary-url

Context config>python>python-script

Description This command specifies the location of tertiary Python script. The system supports three locations for each Python-script. Users can store scripts file on either a local CF card or a FTP server.

 The **no** form of the command removes the URL.

Default no tertiary-url

Parameters **url** — Specifies the tertiary URL of the Python script up to 180 characters in length, either a local CF card URL or a FTP server URL.

16.8.2.1.4 Services Commands

dhcp-python-policy

Syntax **dhcp-python-policy** *policy-name*
no dhcp-python-policy

Context config>service>vpls>sap

Description This command specified the Python policy for DHCPv4 packets sent/received on the capture SAP.

 The **no** form of the command removes the policy name from the configuration.

Default N/A

Parameters *policy name* — Specifies an existing Python policy name.

dhcp6-python-policy

Syntax **dhcp6-python-policy** *policy-name*
no dhcp6-python-policy

Context config>service>vpls>sap

Description	This command specified the Python policy for DHCPv6 packets sent/received on the capture SAP. The no form of the command removes the policy name from the configuration.
Default	N/A
Parameters	<i>policy name</i> — Specifies an existing Python policy name.

pppoe-python-policy

Syntax	pppoe-python-policy <i>policy-name</i> no pppoe-python-policy
Context	config>service>vpls>sap
Description	This command specified the Python policy for PPPoE packets sent/received on the capture SAP. The no form of the command removes the policy name from the configuration.
Default	N/A
Parameters	<i>policy-name</i> — Specifies an existing Python policy name.

python-policy

Syntax	python-policy <i>name</i> no python-policy
Context	config>service>vprn>sub-if>grp-if>ipv4>dhcp4 config>service>ies>sub-if>grp-if>ipv4>dhcp4
Description	This command specified the python-policy for DHCPv4 packets sent/received on the group interface. The no form of the command removes the policy name from the configuration.
Default	N/A
Parameters	<i>name</i> — Specifies an existing Python policy name.

python-policy

Syntax	python-policy <i>name</i> no python-policy
---------------	---

Context	config>service>vprn>sub-if>grp-if>ipv6>dhcp6 config>service>ies>sub-if>grp-if>ipv6>dhcp6
Description	This command specified the python-policy for DHCPv6 packets sent/received on the group interface. The no form of the command removes the policy name from the configuration.
Default	N/A
Parameters	<i>name</i> — Specifies an existing Python policy name.

python-policy

Syntax	python-policy <i>policy-name</i> no python-policy
Context	config>service>ies>sub-if>grp-if>pppoe config>service>vprn>sub-if>grp-if>pppoe
Description	This command specifies the Python policy for PPPoE packets sent/received on the group interface. The no form of the command removes the policy name from the configuration.
Default	N/A
Parameters	<i>policy-name</i> — Specifies an existing Python policy name.

python-policy

Syntax	python-policy <i>name</i> no python-policy
Context	config>service>vprn>sub-if>dhcp config>service>ies>sub-if>dhcp
Description	This command specified the Python policy for DHCPv4 packets sent/received on the retail subscriber interface.
Default	N/A
Parameters	<i>name</i> — Specifies the name of the Python policy.

python-policy

Syntax	python-policy <i>name</i>
---------------	----------------------------------

no python-policy

Context	config>aaa>radius-srv-plcy
Description	This command specifies the python-policy for RADIUS packets to/from the RADIUS servers defined in the specified radius-server-policy .
Default	N/A
Parameters	<i>name</i> — Specifies the name of the Python policy

python-policy

Syntax	python-policy <i>name</i> no python-policy
Context	config>router>radius-proxy>server config>service>vpn>radius-proxy>server
Description	<p>This command specifies the python-policy for RADIUS packets sent/received on the client side of the RADIUS proxy server.</p> <p>This command supports RADIUS proxy on both CPMs and ISAs.</p>
Default	N/A
Parameters	<i>name</i> — Specifies the name of the Python policy

persistence

Syntax	[no] persistence
Context	config>system
Description	<p>This command enables the context to configure persistence parameters on the system.</p> <p>The persistence feature enables state on information learned through DHCP snooping across reboots to be retained. This information includes data such as the IP address and MAC binding information, lease-length information, and ingress SAP information (required for VPLS snooping to identify the ingress interface).</p> <p>If persistence is enabled when there are no DHCP relay or snooping commands enabled, an empty file is created.</p>
Default	no persistence

python-policy-cache

Syntax	python-policy-cache
Context	config>system>persistence
Description	This command configures Python policy cache persistency parameters.

python

Syntax	python
Context	config>redundancy>multi-chassis>peer>sync
Description	<p>This command enables syncing of python-policy cached entries to the peer.</p> <p>Use the mcs-peer command in the python-policy to enable syncing for a specific python-policy.</p>
Default	no python

location

Syntax	location <i>cflash-id</i> no location
Context	config>system>persistence>python
Description	<p>This command instructs the system where to write the file. The name of the file is: dhcp-persistence.db. On boot the system scans the file systems looking for dhcp-persistence.db, if it finds it starts to load it.</p> <p>In the subscriber management context, the location specifies the flash device on a CPMCFM card where the data for handling subscriber management persistency is stored.</p> <p>The no form of this command returns the system to the default. If there is a change in file location while persistence is running, a new file will be written on the new flash, and then the old file will be removed.</p>
Default	no location

16.8.2.1.5 Tools Commands

python-policy

Syntax	python-policy <i>name</i> cache python-policy <i>name</i> cache hex-key <i>hex-string</i> python-policy <i>name</i> cache string-key [<i>string-key</i>]
Context	tools>dump>python
Description	This command dumps all cached entries or a specified entry of a specified Python policy. The DDP key in the output is the python cache persistency record key.

Note: The DDP Key in the output could be used for the **tools>dump>persistence>python** command.

Parameters	<i>name</i> — Specifies the name of the Python policy. <i>string-key</i> — Specifies the key of the entry to be updated in ASCII strong format. <i>hex-key</i> — Specifies the key of the entry to be updated in hex string format.
-------------------	---

python-policy

Syntax	python-policy <i>name</i> cache hex-key <i>hex-string</i> set-lifetime [<i>lifetime</i>] python-policy <i>name</i> cache <i>string-key</i> [512 chars max] set-lifetime [<i>lifetime</i>]
Context	tools>perform
Description	This command set the lifetime of a specified python cache entry.
Parameters	<i>name</i> — Specifies the name of the Python policy. <i>string-key</i> — Specifies the key of the entry to be updated in ASCII strong format. hex-key <i>hex-string</i> — Specifies the key of the entry to be updated in hex string format. set-lifetime — Specifies the new lifetime of the entry. Values 1 to 2147483647

python-script protect

Syntax	python-script protect input <i>file-url</i> hmac-sha256 key <i>secret-key</i> output <i>file-url</i>
Context	tools>perform

Description	This command converts a normal (unprotected) Python script file into an SRPY format with specified key.
Parameters	input <i>file-url</i> — Specifies the URL of the input script file. key <i>secret-key</i> — Specifies the key used to compute the hash output <i>file-url</i> — Specifies the URL of the output script file

python-script reload

Syntax	python-script reload <i>name</i>
Context	tools>perform
Description	This command will try to reload/recompile the primary/secondary/tertiary scripts in the specified Python script in order. The system will use the first script that comes up.
Parameters	<i>name</i> — Specifies the name of the python-script to be reloaded.

16.8.2.2 Show Commands

Note: The command outputs in the following section are examples only; actual displays may differ depending on supported functionality and user configuration.

python

Syntax	python
Context	show
Description	This command enables the context to display Python information.

python-policy

Syntax	python-policy python-policy <i>policy-name</i> [association]
Context	show>python
Description	This command displays information about the currently configured Python policy. The system will display a list of currently configured Python policy names if no parameter is specified.
Parameters	<i>policy-name</i> — Specifies the Python policy name to display. association — Displays the associations of the specified Python policy.
Output	

Sample Output

```
show python python-policy "dhcp"
=====
Python policy "dhcp"
=====
Description   : (Not Specified)
-----
Messages
-----
Type                               Dir      Script
-----
dhcpDiscover                       egress   dhcpv4
dhcpRequest                        egress   dhcpv4
dhcpAck                            ingress   dtc
-----
No. of Messages: 3
```

```

-----
=====

show python python-policy "dhcp" association
=====
Python Policy Association
=====
Location
-----
Service: 500, GrpIf g1, dhcp
-----
No. of Python policy association: 1
=====

```

python-script

Syntax	python-script python-script <i>script-name</i> [association source-in-use]
Context	show>python
Description	This command displays information about the currently configured Python script. The system will display a list of currently configured Python script names if no parameter is specified.
Parameters	<i>script-name</i> — Specifies the Python script name to display information. association — Displays the associations of the specified Python script. source-in-use — Displays the Python source code in use.

Output

Sample Output

```

show python python-script "dhcpv4"
=====
Python script "dhcpv4"
=====
Description   : (Not Specified)
Admin state   : inService
Oper state    : inService
Action on fail: drop
Protection    : none
Primary URL   : cfl:/dhcpv4.py
Secondary URL : (Not Specified)
Tertiary URL  : (Not Specified)
Active URL    : primary
Last changed  : 01/26/2014 05:02:10
=====

```

```
show python python-script "dhcpv4" association
=====
Python Script Association
=====
Policy                                Type                                Dir
-----
dhcp                                  dhcpDiscover                        egress
dhcp                                  dhcpRequest                         egress
-----
No. of Python script association: 2
=====
```

16.8.2.3 Debug Commands

python-script

Syntax	python-script <i>script-name</i>
Context	debug>python
Description	This command enters the debug context the specified Python script
Parameters	<i>policy-name</i> — Specifies the Python script name.

script-all-info

Syntax	script-all-info
Context	debug>python>py-script
Description	This command enables the script-compile-error, script-export-variables, script-output, script-outputon-error, and script-runtime-error functionalities.

script-compile-error

Syntax	[no] script-compile-error
Context	debug>python>py-script
Description	This command sends the traceback of the compile error to the logger. The traceback contains detailed information about where and why the compilation fails. The compilation takes place when the CLI user changes the admin state of the Python script from shutdown to no-shutdown.

script-export-variables

Syntax	[no] script-export-variables
Context	debug>python>py-script
Description	This command sends the output variables of the Python script to the logger when the script ran successfully.

script-output

Syntax	[no] script-output
Context	debug>python>py-script
Description	This command sends the output (such as from 'print' statements) of the Python script to the logger.

script-output-on-error

Syntax	[no] script-output-on-error
Context	debug>python>py-script
Description	This command sends the output (such as traceback data) of the Python script to the logger, but only when the script fails.

script-runtime-error

Syntax	[no] script-runtime-error
Context	debug>python>py-script
Description	This command generates log information when detecting a script runtime error.

16.8.2.4 Clear Commands

python-policy

Syntax	python-policy <i>name</i> cache python-policy <i>name</i> cache hex-key <i>hex-string</i> python-policy <i>name</i> cache <i>string-key</i> [512 chars max]
Context	clear>python
Description	This command clears Python policy data.
Parameters	<i>name</i> — Specifies the name of the Python policy. <i>string-key</i> — Specifies the key of the entry to be updated in ASCII strong format. <i>hex-key</i> — Specifies the key of the entry to be updated in hex string format.

16.9 Python RADIUS Command Reference

16.9.1 Command Hierarchies

```

configure
  — aaa
    — radius-script-policy policy-name [create]
    — no radius-script-policy policy-name
      — action-on-fail {drop | passthrough}
      — no action-on-fail
      — description description
      — no description
      — primary
        — script-url primary-script-url
        — no script-url
        — [no] shutdown
      — secondary
        — script-url secondary-script-url
        — no script-url
        — [no] shutdown

configure
  — aaa
    — l2tp-accounting-policy policy-name [create]
    — no l2tp-accounting-policy policy-name
      — request-script-policy policy-name

16.9.2 Command Descriptions

16.9.2.1 Generic Commands

description

Syntax	description <i>description-string</i> no description
Context	confif>aaa>radius-script-policy
Description	<p>This command creates a text description stored in the configuration file for a configuration context.</p> <p>The description command associates a text string with a configuration context to help identify the context in the configuration file.</p> <p>The no form of this command removes any description string from the context.</p>
Default	No description is associated with the configuration context.
Parameters	<i>description-string</i> — A text string describing the entity. Allowed values are any string up to 80 characters long composed of printable, 7-bit ASCII characters excluding double quotes. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

shutdown

Syntax	[no] shutdown
Context	config>aaa>radius-scr-plcy>primary config>aaa>radius-scr-plcy>secondary
Description	<p>The shutdown command administratively disables the entity. When disabled, an entity does not change, reset, or remove any configuration settings or statistics. Many entities must be explicitly enabled using the no shutdown command.</p> <p>The shutdown command administratively disables an entity. The operational state of the entity is disabled as well as the operational state of any entities contained within. Many objects must be shut down before they can be deleted.</p> <p>Unlike other commands and parameters where the default state is not indicated in the configuration file, shutdown and no shutdown are always indicated in system generated configuration files.</p> <p>The no form of the command puts an entity into the administratively enabled state.</p>

Default no shutdown

16.9.2.2 Script Commands

radius-script-policy

Syntax	radius-script-policy <i>policy-name</i> [create] no radius-script-policy <i>policy-name</i>
Context	config>aaa
Description	This command configures a RADIUS script policy. The no form of the command removes the scrip policy from the configuration.
Default	none
Parameters	<i>policy-name</i> — Configures Python scripts to modify RADIUS messages. create — This keyword is required when first creating the configuration context. Once the context is created, it is possible to navigate into the context without the create keyword.

action-on-fail

Syntax	action-on-fail { drop passthrough } no action-on-fail
Context	config>aaa>radius-scr-plcy
Description	specifies the action taken when Python fails to modify the RADIUS message. The no form of the command reverts to the default.
Default	drop
Parameters	drop — Specifies that the packet will be dropped. passthrough — Specifies that the packet will be sent out without any modifications.

primary

Syntax	primary
Context	config>aaa>radius-scr-plcy

Description	This command enables the context to configure a primary script.
Default	none

script-url

Syntax	script-url <i>primary-script-url</i> no script-url
Context	config>aaa>radius-scr-plcy>primary
Description	This command configures the URL of the primary script. The no form of the command removes the URL from the configuration.
Default	no script-url
Parameters	<i>primary-script-url</i> — Specifies the URL of the secondary script to change RADIUS attributes of the RADIUS message.

secondary

Syntax	secondary
Context	config>aaa>radius-scr-plcy
Description	This command enables the context to configure a secondary script.
Default	none

script-url

Syntax	script-url <i>secondary-script-url</i> no script-url
Context	config>aaa>radius-scr-plcy>secondary
Description	Specifies the URL of the secondary script to change RADIUS attributes of the RADIUS message. The no form of the command removes the URL from the configuration.
Default	no script-url
Parameters	<i>secondary-script-url</i> — Specifies the URL of the secondary script to change RADIUS attributes of the RADIUS message.

l2tp-accounting-policy

Syntax	l2tp-accounting-policy <i>policy-name</i> [create] no l2tp-accounting-policy <i>policy-name</i>
Context	config>aaa
Description	This command configures an L2TP accounting policy. The no form of the command removes the policy-name from the configuration.
Default	none
Parameters	<i>policy-name</i> — Specifies a policy name create — This keyword is required when first creating the configuration context. Once the context is created, it is possible to navigate into the context without the create keyword.

request-script-policy

Syntax	request-script-policy <i>script-policy</i> no request-script-policy
Context	config>aaa>l2tp-accounting-policy config>aaa>radius-srv-plcy
Description	This command configures a Python script policy to modify Access-Request. The no form of the command removes the policy-name from the configuration.
Default	none
Parameters	<i>script-policy</i> — Specifies a the RADIUS script policy used to change the RADIUS attributes of the outgoing Access-Request messages.

radius-server-policy

Syntax	radius-server-policy <i>policy-name</i> [create] no radius-server-policy <i>policy-name</i>
Context	config>aaa
Description	This command configures the RADIUS script policy used to change the RADIUS attributes of the outgoing Access-Accept messages. The no form of the command removes the policy-name from the configuration.
Default	none

Parameters	<p><i>policy-name</i> — Specifies a the RADIUS script policy used to change the RADIUS attributes of the outgoing Access-Request messages.</p> <p>create — This keyword is required when first creating the configuration context. Once the context is created, it is possible to navigate into the context without the create keyword.</p>
-------------------	---

authentication-policy

Syntax	authentication-policy <i>name</i> [create] no authentication-policy
Context	config>subscr-mgmt
Description	<p>This command creates the context to configure RADIUS server parameters for session authentication.</p> <p>The no form of the command removes the RADIUS server configuration for session authentication.</p> <p>RADIUS servers can be configured for three different applications:</p> <ol style="list-style-type: none"> 1. For authentication of dynamic Triple Play subscriber sessions, under config>subscr-mgmt>authentication-plcy 2. For 802.1x port authentication, under config>system>security>dot1x>radius-plcy 3. For CLI login users, under config>system>radius
Default	none
Parameters	<i>name</i> — The name of the profile. The string is case sensitive and limited to 32 ASCII 7-bit printable characters with no spaces.

accept-script-policy

Syntax	accept-script-policy <i>policy-name</i> no accept-script-policy
Context	config>aaa>radius-srv-plcy
Description	<p>This command configures the the RADIUS script policy used to change the RADIUS attributes of the outgoing Access-Accept messages.</p> <p>The no form of the command removes the policy name from the configuration.</p>
Default	no accept-script-policy
Parameters	<i>policy-name</i> — Specifies the Python script policy to modify Access-Accept.

radius-accounting-policy

Syntax	radius-accounting-policy <i>name</i> [create] no radius-accounting-policy
Context	config>subscr-mgmt
Description	This command specifies a subscriber RADIUS based accounting policy.
Parameters	<i>name</i> — The name of the policy. The string is case sensitive and limited to 32 ASCII 7-bit printable characters with no spaces.

coa-script-policy

Syntax	coa-script-policy <i>policy-name</i> no coa-script-policy
Context	config>subscr-mgmt>auth-plcy
Description	This command configures the RADIUS script policy used to change the RADIUS attributes of the Change-of-Authorization messages. The no form of the command removes the policy name from the configuration.
Default	none
Parameters	<i>policy-name</i> — Specifies the Python script policy to modify the Change-of-Authorization messages.

request-script-policy

Syntax	request-script-policy <i>policy-name</i> no request-script-policy
Context	config>subscr-mgmt>auth-plcy
Description	This command configures the RADIUS script policy used to change the RADIUS attributes of the outgoing Access-Request messages. The no form of the command removes the policy name from the configuration.
Default	none
Parameters	<i>policy-name</i> — Specifies the Python script policy to modify Access-Request messages.

acct-request-script-policy

Syntax	acct-request-script-policy <i>policy-name</i> no acct-request-script-policy
Context	config>subscr-mgmt>acct-plcy#
Description	This command configures the Python script policy to modify Accounting-Request messages. The no form of the command removes the policy name from the configuration.
Default	none
Parameters	<i>policy-name</i> — Specifies the Python script policy to modify Accounting-Request messages.
