| Number of Bindings Found | The total number of SDP bindings that exist within the specified egress label range               |

## fdb-info

|                    |                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>fdb-info</b>                                                                                                        |
| <b>Context</b>     | show>service                                                                                                           |
| <b>Description</b> | This command displays global forwarding database (FDB) usage information.                                              |
| <b>Output</b>      | The following output is an example of global FDB usage information, and <a href="#">Table 65</a> describes the fields. |

### Output Example

```
*A:ALU-48>show>service# fdb-info

**Table 65 Service FDB-Info Field Descriptions**

| Label            | Description                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Service Id       | The value that identifies a service                                                                                                                                                                                                                                                                                                                                                                         |
| Mac Move         | Indicates the administrative state of the MAC movement feature associated with the service                                                                                                                                                                                                                                                                                                                  |
| Mac Move Rate    | The maximum rate at which MACs can be relearned in this TLS service, before the SAP where the moving MAC was last seen is automatically disabled in order to protect the system against undetected loops or duplicate MACs.<br><br>The rate is computed as the maximum number of relearns allowed in a 5-s interval. The default rate of 10 relearns per second corresponds to 50 relearns in a 5-s period. |
| Mac Move Timeout | Indicates the time, in seconds, to wait before a SAP that has been disabled after exceeding the maximum relearn rate is re-enabled. A value of 0 indicates that the SAP will not be automatically re-enabled after being disabled. If after the SAP is re-enabled it is disabled again, the effective retry timeout is doubled in order to avoid thrashing.                                                 |
| Table Size       | The maximum number of learned and static entries allowed in the FDB                                                                                                                                                                                                                                                                                                                                         |
| Total Count      | The current number of entries (both learned and static) in the FDB of this service                                                                                                                                                                                                                                                                                                                          |
| Learned Count    | The current number of learned entries in the FDB of this service                                                                                                                                                                                                                                                                                                                                            |
| Static Count     | The current number of static entries in the FDB of this service                                                                                                                                                                                                                                                                                                                                             |

**Table 65 Service FDB-Info Field Descriptions (Continued)**

| Label                          | Description                                                                                                                                                                                                                                           |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OAM-learned Count              | The current number of OAM-learned entries in the FDB of this service                                                                                                                                                                                  |
| DHCP-learned Count             | The current number of DHCP-learned entries in the FDB of this service                                                                                                                                                                                 |
| Host-learned Count             | The current number of host-learned entries in the FDB of this service                                                                                                                                                                                 |
| Remote Age                     | The number of seconds used to age out FDB entries learned on an SDP; these entries correspond to MAC addresses learned on remote SAPs                                                                                                                 |
| Local Age                      | The seconds used to age out FDB entries learned on local SAPs                                                                                                                                                                                         |
| High Watermark                 | The usage of the FDB table of this service at which a “table full” alarm is raised by the agent                                                                                                                                                       |
| Low Watermark                  | The usage of the FDB table of this service at which a “table full” alarm is cleared by the agent                                                                                                                                                      |
| Mac Learning                   | Specifies whether the MAC learning process is enabled in this service                                                                                                                                                                                 |
| Discard Unknown                | Specifies whether frames received with an unknown destination MAC are discarded in this service                                                                                                                                                       |
| MAC Aging                      | Specifies whether MAC aging is enabled                                                                                                                                                                                                                |
| MAC Pinning                    | Specifies whether MAC pinning is enabled                                                                                                                                                                                                              |
| Relearn Only                   | When enabled, indicates that either the FDB table of this service is full or that the maximum system-wide number of MACs supported by the agent has been reached, and thus MAC learning is temporarily disabled, and only MAC relearns can take place |
| Total Service FDB              | The current number of service FDBs configured on this node                                                                                                                                                                                            |
| Total FDB Configured Size      | The sum of configured FDBs                                                                                                                                                                                                                            |
| Total FDB Entries In Use       | The total number of entries (both learned and static) in use                                                                                                                                                                                          |
| PBB MAC Address Indices in Use | Not applicable                                                                                                                                                                                                                                        |

## fdb-mac

- Syntax** **fdb-mac** *ieee-address* [**expiry**]
- Context** show>service
- Description** This command displays the FDB entry for a given MAC address.
- Parameters** *ieee-address* — the 48-bit MAC address for which to display the FDB entry in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee and ff are hexadecimal numbers
- expiry** — shows the time until the MAC is aged out
- Output** The following output is an example of FDB information for a specific MAC address, and [Table 66](#) describes the fields.

### Output Example

```
*A:ALU-48>show>service# fdb-mac
=====
Service Forwarding Database
=====
ServId MAC Source-Identifier Type/Age Last Change

1 00:99:00:00:00:00 sap:1/2/7:0 Static 02/17/2007 13:58:41

No. of Entries: 1

Legend: L=Learned; P=MAC is protected
=====
*A:ALU-48>show>service#
```

**Table 66** Service FDB-MAC Field Descriptions

| Label             | Description                           |
|-------------------|---------------------------------------|
| ServId            | The service ID number                 |
| MAC               | The specified MAC address             |
| Source-Identifier | The location where the MAC is defined |

| <b>Description</b> | This command displays basic information about the service ID, including service type, description, SAPs, and SDPs. |

**Output** The following output is an example of basic information about a service, and [Table 68](#) describes the fields.

### Output Example

```
*A:ALU-48>show>service>id# base
=====
Service Basic Information
=====
Service Id : 5001
Service Type : VPLS
Name : VPLS5001
Description : (Not Specified)
Customer Id : 1
Last Status Change: 10/26/2010 20:13:08
Last Mgmt Change : 10/26/2010 20:13:09
Admin State : Down
MTU : 1514
SAP Count : 1
Snd Flush on Fail : Disabled
Propagate MacFlush: Disabled
Def. Gateway IP : None
Def. Gateway MAC : None
Oper State : Down
Def. Mesh VC Id : 5001
SDP Bind Count : 1
Host Conn Verify : Disabled

**Table 68 Service Service-ID (Base) Field Descriptions**

| Label              | Description                                                                       |
|--------------------|-----------------------------------------------------------------------------------|
| Service Id         | The service identifier                                                            |
| Service Type       | The type of service                                                               |
| Name               | The service name                                                                  |
| Description        | Generic information about the service                                             |
| Customer Id        | The customer identifier                                                           |
| Last Status Change | The date and time of the most recent status change to this customer               |
| Last Mgmt Change   | The date and time of the most recent management-initiated change to this customer |
| Admin State        | The administrative state of the service                                           |

**Table 68 Service Service-ID (Base) Field Descriptions (Continued)**

| Label                                        | Description                                                                                                                                                                   |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Oper State                                   | The operational state of the service                                                                                                                                          |
| MTU                                          | The largest frame size (in octets) that the service can handle                                                                                                                |
| Def. Mesh VC Id                              | This object is only valid in services that accept mesh SDP bindings. It is used to validate the VC ID portion of each mesh SDP binding defined in the service.                |
| SAP Count                                    | The number of SAPs defined on the service                                                                                                                                     |
| SDP Bind Count                               | The number of SDPs bound to the service                                                                                                                                       |
| Snd Flush on Fail                            | Specifies the state of sending a MAC flush on failure (enabled or disabled)                                                                                                   |
| Host Conn Verify                             | Specifies the state of verifying host connectivity (enabled or disabled)                                                                                                      |
| Propagate MacFlush                           | Specifies the state of propagating a MAC flush (enabled or disabled)                                                                                                          |
| Def. Gateway IP                              | Specifies the defined gateway IP address for the service                                                                                                                      |
| Def. Gateway MAC                             | Specifies the defined gateway MAC address for the service                                                                                                                     |
| <b>Service Access and Destination Points</b> |                                                                                                                                                                               |
| Identifier                                   | Specifies the service access (SAP) and destination (SDP) points                                                                                                               |
| Type                                         | Specifies the signaling protocol used to obtain the ingress and egress labels used in frames transmitted and received on the SDP                                              |
| AdmMTU                                       | Specifies the largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented            |
| OprMTU                                       | Specifies the actual largest service frame size (in octets) that can be transmitted through this service to the far-end router, without requiring the packet to be fragmented |
| Adm                                          | The administrative state of the service                                                                                                                                       |
| Opr                                          | The operational state of the service                                                                                                                                          |

# dhcp

|                    |                                                                                         |

| <b>Description</b> | This command displays DHCP statistics information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Parameters</b>  | <p><i>sap-id</i> — specifies the physical port identifier portion of the SAP definition. See <a href="#">Table 41</a> for a full list of SAP IDs.</p> <p><i>sdp-id</i> — the SDP identifier</p> <p><b>Values</b> 1 to 17407</p> <p><i>vc-id</i> — the virtual circuit ID on the SDP ID for which to display information</p> <p><b>Values</b> 1 to 4294967295</p> <p><i>ip-int-name</i> — the IP interface name for which to display information</p> <p><i>ip-address</i> — the IP address of the interface for which to display information</p> <p><b>Values</b> a.b.c.d (host bits must be 0)</p> |
| <b>Output</b>      | The following output is an example of DHCP statistics information for a SAP, an SDP, and an interface, and <a href="#">Table 69</a> describes the fields.                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Output Example

```
*A:ALU-48>show>service>id>dhcp# statistics

**Table 70 Service Service-ID (DHCP Summary) Field Descriptions**

| Label           | Description                                                                                                                                                                                                                                                                                                                  |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Sap/Sdp         | The SAP or SDP identifier of the router interface                                                                                                                                                                                                                                                                            |
| Snoop           | Specifies whether DHCP snooping is enabled                                                                                                                                                                                                                                                                                   |
| Used/Provided   | Used: the number of lease-states that are currently in use on a specific interface; that is, the number of clients on that interface who received an IP address via DHCP. This value is always less than or equal to the "Provided" field.<br>Provided: the lease-populate value that is configured for a specific interface |
| Arp Reply Agent | Specifies whether the ARP reply agent is enabled                                                                                                                                                                                                                                                                             |
| Info Option     | Indicates whether Option 82 processing is enabled on the interface                                                                                                                                                                                                                                                           |
| Admin State     | Indicates the administrative state                                                                                                                                                                                                                                                                                           |

## endpoint

**Syntax** **endpoint** [*endpoint-name*]

**Context** show>service>id

**Description** This command displays service endpoint information.

**Parameters** *endpoint-name* — specifies a name for the endpoint

**Values** any combination of ASCII characters up to 32 characters in length. If spaces are used in the string, enclose the entire string in quotation marks (" ").

**Output** The following output is an example of endpoint information, and [Table 71](#) describes the fields.

### Output Example

```
*A:ALU>show>service>id# endpoint

**Table 71 Service Service-ID (Endpoint) Field Descriptions**

| Label                      | Description                                                                                                                                           |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| Endpoint name              | The name of the endpoint                                                                                                                              |
| Description                | A description of the endpoint                                                                                                                         |
| Revert time                | The programmable time delay to switch back to the primary spoke SDP                                                                                   |
| Act Hold Delay             | Not applicable                                                                                                                                        |
| Ignore Standby Signaling   | Specifies whether ignore standby signaling is configured<br>True: standby signaling is ignored<br>False: standby signaling is not ignored             |
| Suppress Standby Signaling | Specifies whether suppress standby signaling is configured<br>True: standby signaling is suppressed<br>False: standby signaling is not suppressed     |
| Block On Mesh Fail         | Specifies whether to take down the spoke SDP when the mesh SDP is down<br>True: the spoke SDP is not taken down<br>False: the spoke SDP is taken down |
| Tx Active                  | The identifier of the active spoke SDP                                                                                                                |
| Tx Active Up Time          | The total amount of time that a spoke SDP remains the active spoke SDP                                                                                |
| Revert Time Count Down     | The amount of time remaining before active transmission reverts to the primary spoke SDP                                                              |
| Tx Active Change Count     | The number of times that the active spoke SDP has changed                                                                                             |
| Last Tx Active Change      | The timestamp of the last active spoke SDP change                                                                                                     |

**Table 71 Service Service-ID (Endpoint) Field Descriptions (Continued)**

| Label          | Description                                                                                                        |
|----------------|--------------------------------------------------------------------------------------------------------------------|
| <b>Members</b> |                                                                                                                    |
| Spoke-sdp      | Identifies the spoke SDP                                                                                           |
| Prec           | Specifies the precedence of this SDP binding when there are multiple SDP bindings attached to one service endpoint |
| Oper Status    | Indicates the operational status of the endpoint                                                                   |

## fdb

**Syntax** **fdb** [**sap** *sap-id* | **sdp** *sdp-id* | **mac** *ieee-address* | **endpoint** *endpoint* | **detail**] [**expiry**]

**Context** show>service>id

**Description** This command displays FDB entries for a specified entity associated with the service.

**Parameters** *sap-id* — specifies the physical port identifier portion of the SAP definition. See [Table 41](#) for a full list of SAP IDs.

*sdp-id* — specifies the SDP ID for the display

**Values** 1 to 17407

*ieee-address* — : xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx

*endpoint* — specifies an endpoint name

**Values** any combination of ASCII characters up to 32 characters in length. If spaces are used in the string, enclose the entire string in quotation marks (" ").

**detail** — displays detailed information

**expiry** — displays the time until entity is aged out

**Output** The following output is an example of FDB entries for a specific MAC address, and [Table 72](#) describes the fields.

**Output Example**

```
*A:ALU-48>show>service>id# fdb

**Table 72 Service Service-ID (FDB) Field Descriptions**

| Label             | Description                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ServID            | The service ID                                                                                                                                                                                                                                                                                                                                                                                                           |
| Mac Move          | The administrative state of the MAC movement feature associated with this service                                                                                                                                                                                                                                                                                                                                        |
| Primary Factor    | A factor for the primary ports defining how many MAC relearn periods should be used to measure the MAC relearn rate                                                                                                                                                                                                                                                                                                      |
| Secondary Factor  | A factor for the secondary ports defining how many MAC relearn periods should be used to measure the MAC relearn rate                                                                                                                                                                                                                                                                                                    |
| Mac Move Rate     | <p>The maximum rate at which MACs can be relearned in this service, before the SAP where the moving MAC was last seen is automatically disabled in order to protect the system against undetected loops or duplicate MACs</p> <p>The rate is computed as the maximum number of relearns allowed in a 5-s interval: for example, the default rate of 2 relearns per second corresponds to 10 relearns in a 5-s period</p> |
| Mac Move Timeout  | <p>The time, in seconds, to wait before a SAP that has been disabled after exceeding the maximum relearn rate is re-enabled.</p> <p>A value of 0 indicates that the SAP will not be automatically re-enabled after being disabled. If after the SAP is re-enabled it is disabled again, the effective retry timeout is doubled in order to avoid thrashing.</p>                                                          |
| Mac Move Retries  | The number of times retries are performed for re-enabling the SAP/SDP                                                                                                                                                                                                                                                                                                                                                    |
| Table Size        | The maximum number of learned and static entries allowed in the FDB of this service                                                                                                                                                                                                                                                                                                                                      |
| Total Count       | The total number of learned entries in the FDB of this service                                                                                                                                                                                                                                                                                                                                                           |
| Learned Count     | The current number of learned entries in the FDB of this service                                                                                                                                                                                                                                                                                                                                                         |
| Static Count      | The current number of static entries in the FDB of this service                                                                                                                                                                                                                                                                                                                                                          |
| OAM-learned Count | The current number of OAM entries in the FDB of this service                                                                                                                                                                                                                                                                                                                                                             |

**Table 72 Service Service-ID (FDB) Field Descriptions (Continued)**

| Label              | Description                                                                                                                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DHCP-learned Count | The current number of DHCP-learned entries in the FDB of this service                                                                                                                                                                          |
| Host-learned Count | The current number of host-learned entries in the FDB of this service                                                                                                                                                                          |
| Remote Age         | The number of seconds used to age out FDB entries learned on an SDP. These entries correspond to MAC addresses learned on remote SAPs.                                                                                                         |
| Local Age          | The number of seconds used to age out FDB entries learned on local SAPs                                                                                                                                                                        |
| High Watermark     | The usage of the FDB table of this service at which a table full alarm will be raised by the agent                                                                                                                                             |
| Low Watermark      | The usage of the FDB table of this service at which a table full alarm will be cleared by the agent                                                                                                                                            |
| Mac Learning       | Specifies whether MAC learning is enabled                                                                                                                                                                                                      |
| Discard Unknown    | Specifies whether frames received with an unknown destination MAC are discarded                                                                                                                                                                |
| Mac Aging          | Specifies whether MAC aging is enabled                                                                                                                                                                                                         |
| Relearn Only       | When enabled, displays that either the FDB table of this service is full or the maximum system-wide number of MACs supported by the agent has been reached, and thus MAC learning is temporarily disabled and only MAC relearns can take place |
| Mac Subnet Len     | The number of bits to be considered when performing MAC-learning or MAC-switching                                                                                                                                                              |
| Source-Identifier  | The location where the MAC is defined                                                                                                                                                                                                          |

**Table 72 Service Service-ID (FDB) Field Descriptions (Continued)**

| Label       | Description                                                                                                                                     |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| Type/Age    | Type: the number of seconds used to age out TLS FDB entries learned on local SAPs                                                               |
|             | Age: the number of seconds used to age out TLS FDB entries learned on an SDP. These entries correspond to MAC addresses learned on remote SAPs. |
|             | L: learned - dynamic entries created by the learning process<br>OAM: entries created by the OAM process                                         |
|             | H: host, the entry added by the system for a static configured subscriber host                                                                  |
|             | D or DHCP: DHCP-installed MAC. Learned addresses can be temporarily frozen by the DHCP snooping application for the duration of a DHCP lease.   |
|             | P: indicates the MAC is protected by the MAC protection feature                                                                                 |
|             | Static: statically configured                                                                                                                   |
| Last Change | Indicates the time of the most recent state changes                                                                                             |

**Table 74 Service Service-ID IGMP and MLD Snooping (Base) Field Descriptions**

| Label                     | Description                                                                                |
|---------------------------|--------------------------------------------------------------------------------------------|
| Admin State               | The administrative state of the IGMP or MLD instance                                       |
| Querier                   | The address of the IGMP or MLD querier on the IP subnet to which the interface is attached |
| Sap/Sdp Id                | The SAP IDs and SDP IDs for the service ID                                                 |
| Oper Stat                 | The operational state of the SAP IDs and SDP IDs of the service ID                         |
| MRtr Port                 | Specifies whether the port is a multicast router port                                      |
| Pim Port                  | (IGMP only)<br>Specifies whether the port is a PIM port                                    |
| Send Qrys<br>Send Queries | Specifies whether the <b>send-queries</b> command is enabled or disabled                   |

**Table 74 Service Service-ID IGMP and MLD Snooping (Base) Field Descriptions (Continued)**

| Label                  | Description                                                                                |
|------------------------|--------------------------------------------------------------------------------------------|
| Max Grps               | (IGMP only)<br>The maximum number of multicast groups for the entry                        |
| Max Srcs               | (IGMP only)<br>The maximum number of multicast sources for the entry                       |
| Max Grp Srcs           | (IGMP only)<br>The maximum number of multicast group sources for the entry                 |
| Max Num Groups         | (MLD only)<br>The maximum number of multicast groups that can be joined on this SAP or SDP |
| MVR From-VPLS          | Specifies MVR from VPLS                                                                    |
| Num Grps<br>Num Groups | The actual number of multicast groups that can be joined on this SAP or SDP                |

## port-db

**Syntax** **port-db sap** *sap-id* [**detail**]  
**port-db sap** *sap-id* **group** *grp-ip-address*  
**port-db sap** *sap-id* **group** *grp-ipv6-address*  
**port-db sdp** *sdp-id:vc-id* [**detail**]  
**port-db sdp** *sdp-id:vc-id* **group** *grp-ip-address*  
**port-db sdp** *sdp-id:vc-id* **group** *grp-ipv6-address*

**Context** show>service>id>igmp-snooping  
show>service>id>mld-snooping

**Description** This command displays information on the IGMP or MLD snooping port database for the VPLS service.

**Parameters** *grp-ip-address* — displays the IGMP snooping port database for the specified multicast group address

**Values** a.b.c.d

*grp-ipv6-address* — displays the MLD snooping port database for the specified multicast group address

**Values** x:x:x:x:x:x:x (eight 16-bit pieces)  
x:x:x:x:x:d.d.d.d

x: [0 to FFFF]H  
d: [0 to 255]D

*sap-id* — displays the IGMP or MLD snooping port database for the specified SAP. See [Table 41](#) for a full list of SAP IDs.

*sdp-id* — displays the IGMP or MLD snooping port database for the specified SDP. For a spoke SDP, the VC ID must be specified; for a mesh SDP, the VC ID is optional.

**Values** 1 to 17407

*vc-id* — the virtual circuit ID on the SDP ID for which to display information

**Values** 1 to 4294967295

**Output** The following outputs are examples of port database information for IGMP snooping and MLD snooping displays for the specified VPLS service, and [Table 75](#) describes the fields.

### Output Example (IGMP Snooping)

|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Compat Mode     | <p>The IGMP or MLD compatibility mode.</p> <p>This is used in order for routers to be compatible with older version routers. IGMPv3 hosts must operate in version 1 and version 2 compatibility modes; MLD must operate in version 1 mode. IGMPv3 and MLDv2 hosts must track the compatibility mode of each attached network on a per-local-interface basis.</p> <p>A host's compatibility mode is determined from the host compatibility mode variable, which can be in one of three states for IGMP (IGMPv1, IGMPv2, or IGMPv3) or one of two states for MLD (MLDv1 or MLDv2).</p> <p>The compatibility mode variable is kept on a per-interface basis and is dependent on the version of general queries heard on that interface and the older version querier present timers for the interface.</p> |
| V1 Host Expires | <p>The time remaining until the local router assumes that there are no longer any IGMPv1 members on the IP subnet attached to this interface. Upon receiving an IGMPv1 membership report, this value is reset to the setting of the group membership timer. While the time remaining on the timer is non-zero, the local router ignores any IGMPv3 leave messages for this group that are received on this interface.</p>                                                                                                                                                                                                                                                                                                                                                                               |
| V2 Host Expires | <p>The time remaining until the local router assumes that there are no longer any IGMPv2 members on the IP subnet attached to this interface. Upon receiving an IGMPv2 membership report, this value is reset to the setting of the group membership timer. While the time remaining on the timer is non-zero, the local router ignores any IGMPv3 leave messages for this group that are received on this interface.</p>                                                                                                                                                                                                                                                                                                                                                                               |

| Label              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IGMP Group Address | The IP multicast group address for which this entry contains information                                                                                                                                                                                                                                                                                                                                                                                        |
| Up Time            | The time since the source group entry was created                                                                                                                                                                                                                                                                                                                                                                                                               |
| Mode               | The type of membership reports received on the interface for the group: include or exclude<br>Include — reception of packets sent to the specified multicast address is requested only from those IP source addresses listed in the source-list parameter of the IGMP or MLD membership report<br>Exclude — reception of packets sent to the given multicast address is requested from all IP source addresses except those listed in the source-list parameter |
| Source Address     | The source address for which this entry contains information                                                                                                                                                                                                                                                                                                                                                                                                    |
| Num Sources        | Indicates the number of IGMP or MLD group and source specific queries received on this SAP                                                                                                                                                                                                                                                                                                                                                                      |
| Number of groups   | Indicates the number of groups configured for this SAP or SDP                                                                                                                                                                                                                                                                                                                                                                                                   |

## querier

**Syntax** **querier**

**Context** show>service>id>igmp-snooping  
show>service>id>mld-snooping

**Description** This command displays information on the current IGMP or MLD snooping querier for the VPLS service.

**Output** The following outputs are examples of querier information for IGMP snooping and MLD snooping displays for the specified VPLS service, and [Table 77](#) describes the fields.

### Output Example

```
*A:ALA-1>show>service>id>igmp-snooping# querier
=====
IGMP Snooping Querier info for service 10
=====
Sap Id : 1/1/1
IP Address : 10.10.10.1
```

```

Expires : 6s
Up Time : 0d 00:56:50
Version : 3
General Query Interval : 5s
Query Response Interval : 2.0s
Robust Count : 2
=====
*A:ALA-1>show>service>id>snooping#

```

**Table 77 Service Service-ID IGMP and MLD Snooping (Querier) Field Descriptions**

| Label                   | Description                                                                                                                                                                                                               |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SAP Id                  | The SAP ID of the service                                                                                                                                                                                                 |
| IP Address              | The IP address of the querier                                                                                                                                                                                             |
| Expires                 | The length of time remaining before this query ages out, in seconds                                                                                                                                                       |
| Up Time                 | The length of time that the query has been enabled                                                                                                                                                                        |
| Version                 | The configured version of IGMP or MLD                                                                                                                                                                                     |
| General Query Interval  | The frequency at which host-query packets are transmitted                                                                                                                                                                 |
| Query Response Interval | The time to wait to receive a response to the host-query message from the host                                                                                                                                            |
| Robust Count            | The number of IGMP or MLD message intervals that are used when there is expected packet loss on the SAP or SDP. Robust count is similar to a retry counter, where the number of retries is robust count minus one packet. |

## static

**Syntax** **static** [**sap** *sap-id* | **sdp** *sdp-id:vc-id*]

**Context** show>service>id>igmp-snooping  
show>service>id>mld-snooping

**Description** This command displays information on static IGMP or MLD snooping source group membership for the VPLS service.

**Parameters** *sap-id* — displays static IGMP or MLD snooping source groups for the specified SAP.  
See [Table 41](#) for a full list of SAP IDs.  
*sdp-id* — displays the IGMP or MLD snooping source groups for the specified SDP

**Values** 1 to 17407

*vc-id* — the virtual circuit ID on the SDP ID for which to display information

**Values** 1 to 4294967295

**Output** The following outputs are examples of static SAP or SDP multicast source and group information for IGMP snooping and MLD snooping displays for the specified VPLS service, and [Table 78](#) describes the fields.

### Output Example

```

**Table 78**      **Service Service-ID IGMP and MLD Snooping (Static) Field Descriptions**

| Label                      | Description                                       |
|----------------------------|---------------------------------------------------|
| Source                     | The source IP address of the static group         |
| Group                      | The group IP address of the static (S,G) or (*,G) |
| Static (*,G)/(S,G) entries | The number of static (S,G) or (*, G) entries      |

# statistics

**Syntax**      **statistics [sap sap-id | sdp sdp-id:vc-id]**

**Context**      show>service>id>igmp-snooping  
show>service>id>mld-snooping

**Description**      This command displays IGMP or MLD snooping statistics information for the specified VPLS SAP or SDP.

**Parameters**      *sap-id* — displays IGMP or MLD snooping statistics for the specified SAP. See [Table 41](#) for a full list of SAP IDs.

*sdp-id* — displays the IGMP or MLD snooping statistics for the specified SDP

**Values**      1 to 17407

*vc-id* — the virtual circuit ID on the SDP ID for which to display information

**Values**      1 to 4294967295

**Output** The following outputs are examples of multicast statistics for SAPs and SDPs for IGMP snooping and MLD snooping displays for the specified VPLS service, and [Table 79](#) describes the fields.

### Output Example

```

| Unknown Type                          | The number of unknown type messages received, transmitted, and forwarded                       |
| <b>Drop Statistics</b>                |                                                                                                |
| Bad Length                            | The number of packets dropped due to bad length                                                |
| Bad IP Checksum                       | (IGMP only)<br>The number of packets dropped due to a bad IP checksum                          |
| Bad IGMP Checksum<br>Bad MLD Checksum | The number of packets dropped due to a bad IGMP or MLD checksum                                |
| Bad Encoding                          | The number of packets dropped due to bad encoding                                              |
| No Router Alert                       | The number of packets dropped because there was no router alert                                |
| Zero Source IP                        | The number of packets dropped due to a source IP address of 0.0.0.0 or 00:00:00:00:00:00:00:00 |
| Wrong Version                         | The number of packets dropped due to a wrong version of IGMP or MLD                            |
| Lcl-Scope Packets                     | The number of local scope packets dropped                                                      |
| Rsvd-Scope Packets                    | The number of reserved scope packets dropped                                                   |
| Send Query Cfg Drops                  | The number of messages dropped because of send query configuration errors                      |
| Import Policy Drops                   | The number of messages dropped because of import policy                                        |
| Exceeded Max Num Groups               | The number of packets dropped because the maximum number of groups has been exceeded           |
| Exceeded Max Num Sources              | The number of packets dropped because the maximum number of sources has been exceeded          |

**Table 79 Service Service-ID IGMP and MLD Snooping (Statistics) Field Descriptions (Continued)**

| Label                     | Description                                                                                 |
|---------------------------|---------------------------------------------------------------------------------------------|
| Exceeded Max Num Grp Srcs | The number of packets dropped because the maximum number of group sources has been exceeded |
| MCAC Policy Drops         | The number of packets dropped due to multicast CAC                                          |
| MCS Failures              | The number of packets dropped due to multicast server (MCS) failures                        |
| MVR From VPLS Cfg Drops   | The number of packets dropped due to VPLS configuration multicast VPLS registration (MVR)   |
| MVR To SAP Cfg Drops      | The number of packets dropped due to SAP configuration                                      |

## labels

|                    |                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>labels</b>                                                                                                       |
| <b>Context</b>     | show>service>id                                                                                                     |
| <b>Description</b> | This command displays information about ingress and egress labels for the specified service.                        |
| <b>Output</b>      | The following output is an example of service label information, and <a href="#">Table 80</a> describes the fields. |

### Output Example

```
*A:ALU-48>show>service>id# labels
=====
Martini Service Labels
=====
Svc Id Sdp Binding Type I.Lbl E.Lbl

5001 5001:100 Spok 0 0

Number of Bound SDPs : 1

```

**Table 80 Service Service-ID (Labels) Field Descriptions**

| Label       | Description                                |
|-------------|--------------------------------------------|
| Svc Id      | The service identifier                     |
| Sdp Binding | The SDP binding identifier                 |
| Type        | Indicates whether the SDP is spoke or mesh |

**Table 80 Service Service-ID (Labels) Field Descriptions (Continued)**

| Label                | Description                                                                                            |
|----------------------|--------------------------------------------------------------------------------------------------------|
| I.Lbl                | The ingress label used by the far-end device to send packets to this device in this service by the SDP |
| E.Lbl                | The egress label used by this device to send packets to the far-end device in this service by the SDP  |
| Number of Bound SDPs | The number of SDP bindings                                                                             |

| Mac Move                         | The administrative state of the MAC movement feature associated with this service                                                                                                                                                                                                                                                                                                                                          |
| Primary Factor                   | A factor for the primary ports defining how many MAC relearn periods should be used to measure the MAC relearn rate                                                                                                                                                                                                                                                                                                        |
| Secondary Factor                 | A factor for the secondary ports defining how many MAC relearn periods should be used to measure the MAC relearn rate                                                                                                                                                                                                                                                                                                      |
| Mac Move Rate                    | <p>The maximum rate at which MACs can be relearned in this service, before the SAP where the moving MAC was last seen is automatically disabled in order to protect the system against undetected loops or duplicate MACs.</p> <p>The rate is computed as the maximum number of relearns allowed in a 5-s interval: for example, the default rate of 2 relearns per second corresponds to 10 relearns in a 5-s period.</p> |
| Mac Move Timeout                 | <p>The time, in seconds, to wait before a SAP that has been disabled after exceeding the maximum relearn rate is re-enabled.</p> <p>A value of 0 indicates that the SAP will not be automatically re-enabled after being disabled. If after the SAP is re-enabled it is disabled again, the effective retry timeout is doubled in order to avoid thrashing.</p>                                                            |
| Mac Move Retries                 | The number of times retries are performed for re-enabling the SAP or SDP                                                                                                                                                                                                                                                                                                                                                   |
| <b>SAP Mac Move Information:</b> |                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Admin State                      | The administrative state of the SAP                                                                                                                                                                                                                                                                                                                                                                                        |
| Oper State                       | The operational state of the SAP                                                                                                                                                                                                                                                                                                                                                                                           |
| Flags                            | Specifies the conditions that affect the operating status of this SAP. Display output includes: ServiceAdminDown, PortOperDown, L2OperDown.                                                                                                                                                                                                                                                                                |

**Table 81 Service Service-ID (MAC Move) Field Descriptions (Continued)**

| Label                            | Description                                                                                                                                                                                                                                                                                                                                              |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Time to RetryReset               | The time, in seconds, to wait before a SAP that has been disabled after exceeding the maximum relearn rate is re-enabled.<br><br>A value of 0 indicates that the SAP will not be automatically re-enabled after being disabled. If after the SAP is re-enabled it is disabled again, the effective retry timeout is doubled in order to avoid thrashing. |
| Retries Left                     | The number of remaining attempts to re-enable the SAP                                                                                                                                                                                                                                                                                                    |
| Mac Move                         | Specifies whether MAC move is configured as blockable or not blockable on the SAP                                                                                                                                                                                                                                                                        |
| Blockable Level                  | Specifies the level at which MAC move is blockable on the SAP (primary, secondary, or tertiary)                                                                                                                                                                                                                                                          |
| <b>SDP Mac Move Information:</b> |                                                                                                                                                                                                                                                                                                                                                          |
| Admin State                      | The administrative state of the SDP                                                                                                                                                                                                                                                                                                                      |
| Oper State                       | The operational state of the SDP                                                                                                                                                                                                                                                                                                                         |
| Flags                            | Specifies the conditions that affect the operating status of this SDP. Display output includes: SvcAdminDown, SdpOperDown, NoIngVCLabel, NoEgrVCLabel, PathMTUTooSmall.                                                                                                                                                                                  |
| Time to RetryReset               | The time, in seconds, to wait before a SDP that has been disabled after exceeding the maximum relearn rate is re-enabled.<br><br>A value of 0 indicates that the SDP will not be automatically re-enabled after being disabled. If after the SDP is re-enabled it is disabled again, the effective retry timeout is doubled in order to avoid thrashing. |
| Retries Left                     | The number of remaining attempts to re-enable the SDP                                                                                                                                                                                                                                                                                                    |
| Mac Move                         | Specifies whether MAC move is configured as blockable or not blockable on the SDP                                                                                                                                                                                                                                                                        |
| Blockable Level                  | Specifies the level at which MAC move is blockable on the SDP (primary, secondary, or tertiary)                                                                                                                                                                                                                                                          |

| <b>Description</b> | This command displays information about SAPs. When the <b>sap</b> command is used without specifying a <i>sap-id</i> , the display shows all the information for all SAPs in the service. Including the <i>sap-id</i> and a filtering keyword with the <b>sap</b> command displays information pertaining to the keyword.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <p><i>sap-id</i> — specifies the physical port identifier portion of the SAP definition. See <a href="#">Table 41</a> for a full list of SAP IDs.</p> <p><b>atm</b> — filters the command results to display ATM information for the specified SAP</p> <p><b>base</b> — filters the command results to display base information for the specified SAP</p> <p><b>detail</b> — displays detail information for the specified SAP</p> <p><b>qos</b> — filters the command results to display QoS information for the specified SAP</p> <p><b>sap-stats</b> — filters the command results to display SAP statistics information for the specified SAP</p> <p><b>stats</b> — filters the command results to display statistics information for the specified SAP</p> |
| <b>Output</b>      | The following output is an example of service SAP information, and <a href="#">Table 82</a> describes the fields.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| SAP                 | The SAP identifier                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Encap               | The encapsulation type of the SAP                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Admin State         | The administrative state of the SAP                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Oper State          | The operating state of the SAP                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Flags               | Specifies the conditions that affect the operating status of this SAP. Display output includes:<br>ServiceAdminDown, SapAdminDown,<br>InterfaceAdminDown, PortOperDown,<br>PortMTUTooSmall, L2OperDown,<br>SapIngressQoSMismatch,<br>SapEgressQoSMismatch, RelearnLimitExceeded,<br>RxProtSrcMac, ParentIfAdminDown,<br>NoSapPipeCelpAddr, TodResourceUnavail,<br>TodMssResourceUnavail, SapParamMismatch,<br>CemSapNoEcidOrMacAddr, StandByForMcRing,<br>ServiceMTUTooSmall,<br>SapIngressNamedPoolMismatch,<br>SapEgressNamedPoolMismatch,<br>NoSapEpipeRingNode. |
| Last Status Change  | The time of the most recent operating status change to this SAP                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Last Mgmt Change    | The time of the most recent management-initiated change to this SAP                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Sub Type            | The supported sub type: regular                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Split Horizon Group | Indicates the split horizon group that this SAP is a member of                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Admin MTU           | The desired largest service frame size (in octets) that can be transmitted through the SAP to the far-end router, without requiring the packet to be fragmented                                                                                                                                                                                                                                                                                                                                                                                                     |
| Oper MTU            | The actual largest service frame size (in octets) that can be transmitted through the SAP to the far-end router, without requiring the packet to be fragmented                                                                                                                                                                                                                                                                                                                                                                                                      |
| Ingr IP Fltr-Id     | The IPv4 ingress filter policy ID assigned to the SAP                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Egr IP Fltr-Id      | The IPv4 egress filter policy ID assigned to the SAP                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**Table 82 Service ID (SAP) Field Descriptions (Continued)**

| Label              | Description                                                                               |
|--------------------|-------------------------------------------------------------------------------------------|
| Ingr Mac Fltr-Id   | Not applicable                                                                            |
| Egr Mac Fltr-Id    | Not applicable                                                                            |
| Ingr IPv6 Fltr-Id  | The IPv6 ingress filter policy ID assigned to the SAP                                     |
| Egr IPv6 Fltr-Id   | The IPv6 egress filter policy ID assigned to the SAP                                      |
| tod-suite          | Indicates whether a time-based policy is applied to a multiservice site                   |
| qinq-pbit-marking  | Indicates the qinq P-bit marking for the service: both or top                             |
| Ing Scheduler Mode | The scheduler mode for the SAP in the access ingress direction: 4-priority or 16-priority |
| Egr Scheduler Mode | The scheduler mode for the SAP in the access egress direction: 4-priority or 16-priority  |
| Ing Agg Rate Limit | The PIR rate limit in the access ingress direction for the aggregate of the SAP queues    |
| Egr Agg Rate Limit | The PIR rate limit in the access egress direction for the aggregate of the SAP queues     |
| Ing Agg cir        | The CIR rate limit in the access ingress direction for the aggregate of the SAP queues    |
| Egr Agg cir        | The CIR rate limit in the access egress direction for the aggregate of the SAP queues     |
| Ing Shaper Group   | The ingress shaper group for the SAP                                                      |
| Egr Shaper Group   | The egress shaper group for the SAP                                                       |
| ARP Reply Agent    | Specifies whether the ARP reply agent is enabled                                          |
| Host Conn Verify   | Specifies the state of verifying host connectivity (enabled or disabled)                  |
| Mac Learning       | Specifies whether MAC learning is enabled                                                 |
| Discard Unkwn Srce | Specifies whether frames received with an unknown destination MAC are discarded           |
| Mac Aging          | Specifies whether MAC aging is enabled                                                    |
| Mac Pinning        | Specifies whether MAC pinning is enabled                                                  |
| Acct. Pol          | The accounting policy ID applied to the SAP                                               |

| For. InProf                              | The number of in-profile packets or octets (rate below CIR) forwarded                                                 |
| For. OutProf                             | The number of out-of-profile packets or octets (rate above CIR) forwarded                                             |
| Dro. InProf                              | The number of in-profile packets or octets dropped for the SAP                                                        |
| Dro. OutProf                             | The number of out-of-profile packets or octets discarded                                                              |
| <b>ATM SAP Configuration Information</b> |                                                                                                                       |
| Ingress TD Profile                       | The profile ID of the traffic descriptor applied to the ingress SAP                                                   |

**Table 82 Service ID (SAP) Field Descriptions (Continued)**

| Label               | Description                                                                         |
|---------------------|-------------------------------------------------------------------------------------|
| Egress TD Profile   | The profile ID of the traffic descriptor applied to the egress SAP                  |
| Alarm Cell Handling | Indicates that OAM cells are being processed                                        |
| OAM Termination     | Indicates whether this SAP is an OAM termination point                              |
| AAL-5 Encap         | Indicates the type of AAL5 encapsulation for this ATM SAP                           |
| OAM Termination     | Indicates the state of the OAM termination for this ATM SAP (enabled or disabled)   |
| Periodic Loopback   | Indicates the state of the periodic loopback for this ATM SAP (enabled or disabled) |

## sdp

**Syntax** **sdp** [*sdp-id*[:*vc-id*]] [**detail**]  
**sdp far-end** {*ip-address* | *ipv6-address*} [**detail**]

**Context** show>service>id

**Description** This command displays information about SDPs. When the **sdp** command is used without specifying a *sdp-id*, the display shows all the information for all SDPs in the service. Including the *sdp-id* and a filtering keyword with the **sdp** command displays information pertaining to the keyword.]

**Parameters** *sdp-id* — the SDP identifier

**Values** 1 to 17407

*vc-id* — the VC identifier

**Values** 1 to 4294967295

*ip-address* — displays information for the SDP having this as far-end IPv4 or IPv6 address

**Values** ip-address: a.b.c.d

**detail** — adds details to SDP information

**Output** The following output is an example of service SDP information, and [Table 83](#) describes the fields.

**Output Example**

```

**Table 83 Service ID (SDP) Field Descriptions**

| Label               | Description                                                                                                                                                      |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SDP Id              | The SDP identifier                                                                                                                                               |
| Type                | Indicates whether this service SDP binding is a spoke or a mesh                                                                                                  |
| Split Horizon Group | The name of the split horizon group                                                                                                                              |
| VC Type             | The VC type: ether or vlan                                                                                                                                       |
| VC Tag              | The explicit dot1q value used when encapsulating to the SDP far end                                                                                              |
| Admin Path MTU      | The desired largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented |
| Oper Path MTU       | The actual largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented  |
| Far End             | Specifies the IP address of the remote end of the GRE, MPLS, or IP tunnel defined by this SDP                                                                    |
| Delivery            | Specifies the type of delivery used by the SDP: GRE, MPLS, or IP                                                                                                 |
| Admin State         | The administrative state of this SDP                                                                                                                             |
| Oper State          | The operational state of this SDP                                                                                                                                |
| Acct. Pol           | The accounting policy applied to the SDP                                                                                                                         |

**Table 83 Service ID (SDP) Field Descriptions (Continued)**

| Label              | Description                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------------------|
| Collect Stats      | Specifies whether accounting statistics are collected on the SDP                                                        |
| Ingress Label      | The label used by the far-end device to send packets to this device in this service by this SDP                         |
| Egress Label       | The label used by this device to send packets to the far-end device in this service by this SDP                         |
| Ing mac Fltr       | Not applicable                                                                                                          |
| Egr mac Fltr       | Not applicable                                                                                                          |
| Ing ip Fltr        | The SDP ingress filter policy ID for IPv4                                                                               |
| Egr ip Fltr        | The SDP egress filter policy ID for IPv4                                                                                |
| Ing ipv6 Fltr      | Not applicable                                                                                                          |
| Egr ipv6 Fltr      | Not applicable                                                                                                          |
| Admin ControlWord  | The administrative state of the control word: Preferred (control word enabled) or Not Preferred (control word disabled) |
| Oper ControlWord   | The operational state of the control word: True (control word enabled) or False (control word disabled)                 |
| Last Status Change | The date and time of the most recent status change to this SDP                                                          |
| Signaling          | The signaling protocol used to obtain the ingress and egress labels used in frames transmitted and received on this SDP |
| Last Mgmt Change   | The date and time of the most recent management-initiated change to this SDP                                            |
| Endpoint           | The name of the service endpoint                                                                                        |
| Precedence         | Specifies the precedence of this SDP binding when there are multiple SDP bindings attached to one service endpoint      |
| PW Status Sig      | Specifies whether pseudowire status signaling for spoke SDPs is enabled or disabled                                     |

**Table 83 Service ID (SDP) Field Descriptions (Continued)**

| Label                        | Description                                                                                                                                                                                |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Flags                        | Specifies the conditions that affect the operating status of this SAP. Display output includes: ServiceAdminDown, SvcAdminDown, SdpOperDown, NoIngVCLLabel NoEgrVCLLabel, PathMTUTooSmall. |
| Retries Left                 | The number of remaining attempts to re-enable the SDP                                                                                                                                      |
| Mac Move                     | The administrative state of the MAC movement feature associated with the SDP                                                                                                               |
| Blockable Level              | Specifies the level at which MAC move is blockable on the SAP (primary, secondary, or tertiary)                                                                                            |
| MAC Learning                 | Specifies whether MAC learning is enabled                                                                                                                                                  |
| MAC Pinning                  | Specifies whether MAC pinning is enabled in this SDP                                                                                                                                       |
| Ignore Standby Sig           | Specifies whether ignore standby signaling is configured<br>True: standby signaling is ignored<br>False: standby signaling is not ignored                                                  |
| Block On Mesh Fail           | Specifies whether to take down the spoke SDP when the mesh SDP is down<br>True: the spoke SDP is not taken down<br>False: the spoke SDP is taken down                                      |
| <b>KeepAlive Information</b> |                                                                                                                                                                                            |
| Admin State                  | The operating status of the keepalive protocol                                                                                                                                             |
| Oper State                   | The current status of the keepalive protocol                                                                                                                                               |
| Hello Time                   | Specifies how often the SDP echo request messages are transmitted on this SDP                                                                                                              |
| Hello Msg Len                | The length of the SDP echo request messages transmitted on this SDP                                                                                                                        |
| Max Drop Count               | The maximum number of consecutive SDP Echo Request messages that can be unacknowledged before the keepalive protocol reports a fault                                                       |
| Hold Down Time               | The time to wait before the keepalive operating status is eligible to enter the alive state                                                                                                |

**Table 84 Service ID (Split Horizon Group) Field Descriptions**

| Label        | Description                                                                                                |
|--------------|------------------------------------------------------------------------------------------------------------|
| Name         | The name of the split horizon group. When preceded by "R", the group is a residential split horizon group. |
| Description  | A description of the split horizon group as configured by the user                                         |
| Associations | A list of SAPs and SDPs associated with the split horizon group                                            |

**stp**

|                    |                                                                                                                            |

| <b>Stp info, Service #</b> |                                                                                                                                                                                                                                                   |
| Bridge Id                  | The MAC address used to identify this bridge in the network                                                                                                                                                                                       |
| Top Change Count           | The total number of topology changes detected by the Spanning Tree Protocol instance associated with this service since the management entity was last reset or initialized                                                                       |
| Root Bridge                | The bridge identifier of the root of the spanning tree as determined by the Spanning Tree Protocol instance associated with this service. This value is used as the Root Identifier parameter in all Configuration BPDUs originated by this node. |
| Topology Change            | Specifies whether a topology change is currently in progress                                                                                                                                                                                      |
| Mode                       | Always RSTP                                                                                                                                                                                                                                       |
| Last Top. Change           | The time (in hundredths of a second) since the last time a topology change was detected by the Spanning Tree Protocol instance associated with this service                                                                                       |
| Root Port                  | The port number of the port that offers the lowest cost path from this bridge to the root bridge                                                                                                                                                  |
| <b>Stp port info</b>       |                                                                                                                                                                                                                                                   |
| Sap/Sdp/PIP Id             | The ID of the access port where the SAP or spoke SDP is defined                                                                                                                                                                                   |
| Oper-State                 | Indicates the operational state of the Rapid Spanning Tree Protocol instance associated with this service. This field is applicable only when STP is enabled on the router.                                                                       |
| Port-State                 | The port identifier of the port on the designated bridge for this port's segment                                                                                                                                                                  |

**Table 85 Service ID (STP) Field Descriptions (Continued)**

| Label                                 | Description                                                                                                                                                       |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Port-Num                              | The value of the port number field that is contained in the least significant 12 bits of the 16-bit port ID associated with the SAP or spoke SDP                  |
| Oper-Edge                             | The state of the oper-edge variable: true or false                                                                                                                |
| Link-Type                             | The link type (number of bridges that can exist behind the SAP or spoke SDP): pt-pt or shared                                                                     |
| <b>VPLS Spanning Tree Information</b> |                                                                                                                                                                   |
| VPLS oper state                       | The operational state of the Rapid Spanning Tree Protocol instance associated with this service. This field is applicable only when STP is enabled on the router. |
| Core Connectivity                     | The connectivity status to the core                                                                                                                               |
| Stp Admin State                       | The administrative state of the Rapid Spanning Tree Protocol instance associated with this service                                                                |
| Stp Oper State                        | The operational state of the Rapid Spanning Tree Protocol instance associated with this service. This field is applicable only when STP is enabled on the router. |
| Mode                                  | Always RSTP                                                                                                                                                       |
| Bridge Id                             | The MAC address used to identify this bridge in the network                                                                                                       |
| Bridge Priority                       | The priority of the Spanning Tree Protocol instance associated with this service                                                                                  |
| Tx Hold Count                         | The interval length during which no more than two Configuration BPDUs shall be transmitted by this bridge                                                         |
| Topology Change                       | Specifies whether a topology change is currently in progress                                                                                                      |
| Bridge Hello Time                     | The amount of time between the transmission of Configuration BPDUs                                                                                                |

**Table 85 Service ID (STP) Field Descriptions (Continued)**

| Label               | Description                                                                                                                                                                                                                                       |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Last Top. Change    | The time (in hundredths of a second) since the last time a topology change was detected by the Spanning Tree Protocol instance associated with this service                                                                                       |
| Bridge Max Age      | The maximum age of Spanning Tree Protocol information learned from the network on any port before it is discarded. This is the actual value that this bridge is currently using.                                                                  |
| Top. Change Count   | The total number of topology changes detected by the Spanning Tree Protocol instance associated with this service since the management entity was last reset or initialized                                                                       |
| Bridge Fwd Delay    | Specifies how fast a bridge changes its state when moving toward the forwarding state                                                                                                                                                             |
| MST region revision | Not applicable                                                                                                                                                                                                                                    |
| MST region name     | Not applicable                                                                                                                                                                                                                                    |
| Root Bridge         | The bridge identifier of the root of the spanning tree as determined by the Spanning Tree Protocol instance associated with this service. This value is used as the Root Identifier parameter in all Configuration BPDUs originated by this node. |
| Root Path Cost      | The cost of the path to the root bridge as seen from this bridge                                                                                                                                                                                  |
| Root Forward Delay  | Specifies how fast the root changes its state when moving toward the forwarding state                                                                                                                                                             |
| Rcvd Hello Time     | The amount of time between the transmission of configuration BPDUs                                                                                                                                                                                |
| Root Max Age        | The maximum age of Spanning Tree Protocol information learned from the network on any port before it is discarded                                                                                                                                 |
| Root Priority       | The priority of the bridge that is currently selected as root-bridge for the network                                                                                                                                                              |

**Table 85 Service ID (STP) Field Descriptions (Continued)**

| Label                                        | Description                                                                                                                                      |
|----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| Root Port                                    | The port number of the port that offers the lowest cost path from this bridge to the root bridge                                                 |
| <b>Spanning Tree Sap/Spoke SDP Specifics</b> |                                                                                                                                                  |
| SAP Identifier                               | The ID of the access port where this SAP is defined                                                                                              |
| SDP Identifier                               | The ID of the SDP and VC                                                                                                                         |
| Stp Admin State                              | The administrative state of the Rapid Spanning Tree Protocol instance associated with this service                                               |
| Port State                                   | The port identifier of the port on the designated bridge for this port's segment                                                                 |
| Port number                                  | The value of the port number field that is contained in the least significant 12 bits of the 16-bit port ID associated with the SAP or spoke SDP |
| Port Priority                                | The value of the port priority field that is contained in the most significant 4 bits of the 16-bit port ID associated with the SAP or spoke SDP |
| Port Path Cost                               | The contribution of this port to the path cost of paths towards the spanning tree root which include this port                                   |
| Auto Edge                                    | Specifies whether auto edge is enabled or disabled                                                                                               |
| Oper Edge                                    | The state of the oper-edge variable: true or false                                                                                               |
| Link Type                                    | The link type (number of bridges that can exist behind the SAP or spoke SDP): pt-pt or shared                                                    |
| BPDU Encap                                   | The type of encapsulation used on BPDUs sent out and received on this SAP or spoke SDP                                                           |
| Root Guard                                   | Specifies whether the port is allowed to become an STP root port                                                                                 |

**Table 85 Service ID (STP) Field Descriptions (Continued)**

| Label             | Description                                                                                                       |
|-------------------|-------------------------------------------------------------------------------------------------------------------|
| CIST Desig Bridge | The bridge identifier of the bridge which this port considers to be the designated bridge for this port's segment |
| Designated Port   | The port identifier of the port on the designated bridge for this port's segment                                  |

## ingress-label

**Syntax** `ingress-label start-label [end-label]`

**Context** `show>service`

**Description** This command displays services using a range of ingress labels.

If only the mandatory *start-label* parameter is specified, only services using the specified label are displayed.

If both *start-label* and *end-label* parameters are specified, the services using the range of labels are displayed.

Use the **show router ldp bindings** command to display dynamic labels.

**Parameters** *start-label* — the starting ingress label value for which to display services using the label range. If only *start-label* is specified, services only using *start-label* are displayed.

**Values** 0, 2048 to 131071

*end-label* — the ending ingress label value for which to display services using the label range

**Values** 2049 to 131071

**Default** the *start-label* value

**Output** The following output is an example of information about services using the specified range of ingress labels, and [Table 86](#) describes the fields.

### Output Example

```
*A:ALU-48>show>service# ingress-label 0
=====
Martini Service Labels
=====

```

**Table 86**      **Service Ingress-Label Field Descriptions**

| Label                    | Description                                                                                            |
|--------------------------|--------------------------------------------------------------------------------------------------------|
| Svc ID                   | The service identifier                                                                                 |
| SDP Binding              | The SDP binding identifier                                                                             |
| Type                     | Indicates whether the SDP is spoke or mesh                                                             |
| I.Lbl                    | The ingress label used by the far-end device to send packets to this device in this service by the SDP |
| E.Lbl                    | The egress label used by this device to send packets to the far-end device in this service by the SDP  |
| Number of Bindings Found | The number of SDP bindings within the label range specified                                            |

## pim-snooping

|                    |                                                                       |
|--------------------|-----------------------------------------------------------------------|
| <b>Syntax</b>      | <b>pim-snooping</b>                                                   |
| <b>Context</b>     | show>service>id                                                       |
| <b>Description</b> | This command enables the context to display PIM snooping information. |

## group

|                    |                                                                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>group</b> [ <i>grp-ip-address</i> ] [ <b>source</b> <i>ip-address</i> ] [ <b>type</b> { <b>starg</b>   <b>sg</b> }] [ <b>detail</b> ] [ <i>family</i> ]                                                                                               |
| <b>Context</b>     | show>service>id>pim-snooping                                                                                                                                                                                                                             |
| <b>Description</b> | This command displays the multicast group information.                                                                                                                                                                                                   |
| <b>Parameters</b>  | <i>grp-ip-address</i> — displays information for the multicast group address (IPv4 or IPv6)<br><i>ip-address</i> — displays information for the source address or the RP address (IPv4 or IPv6)<br><b>starg</b> — displays information for (*,G) entries |

**sg** — displays information for (S,G) entries

**detail** — displays detailed information

**family** — displays either IPv4 or IPv6 information

**Values**      ipv4 or ipv6

**Output**      The following output is an example of PIM snooping multicast group information, and [Table 87](#) describes the fields.

### Output Example

```
*A:ALU# show service id 1 pim-snooping group

| <b>PIM Snooping Groups</b> |                                                            |
| Group Address              | The IP address of the multicast group                      |
| Source Address             | The IP address of the multicast source                     |
| Type                       | The type of source-group pair: (S,G) or (*,G)              |
| Incoming Intf              | The interface identifier for the incoming multicast stream |
| Num Oifs                   | The number of outgoing interfaces                          |
| Groups                     | The number of groups displayed                             |

## neighbor

**Syntax**      **neighbor** [{**sap** *sap-id* | **sdp** *sdp-id:vc-id*} [**address** *ip-address*]] [**detail**] [*family*]

**Context**      show>service>id>pim-snooping

**Description**      This command displays PIM neighbor information.

- Parameters**
- sap-id* — displays information for the PIM neighbor associated with the specified SAP
  - sdp-id:vc-id* — displays information for the PIM neighbor associated with the specified SDP
  - ip-address* — displays information for the PIM neighbor with the specified IP address (IPv4 or IPv6)
  - detail** — displays detailed PIM neighbor information
  - family* — displays either IPv4 or IPv6 information for the specified neighbor
  - Values**      ipv4 or ipv6

**Output**      The following output is an example of PIM snooping neighbor information, and [Table 88](#) describes the fields.

### Output Example

```
*A:ALU# show service id 1 pim-snooping neighbor

| <b>PIM Snooping Neighbors</b> |                                                                        |
| Sap/Sdp Id<br>Nbr Address     | The SAP or SDP identifier and the IP address of the neighbor           |
| Nbr DR Prty                   | The neighbor designated router parity                                  |
| Up Time                       | The length of time that the multicast connection has been up           |
| Expiry Time                   | The length of time remaining before the multicast connection goes down |
| Hold Time                     | The length of time that PIM snooping checks for the PIM state          |
| Neighbors                     | The number of neighbors for the specified instance of PIM snooping     |

port

- Syntax

port [sap sap-id | sdp sdp-id:vc-id] [group grp-ip-address]] [detail] [family]
- Context

show>service>id>pim-snooping
- Description

This command displays PIM port information.
- Parameters

sap-id — displays port information for the specified SAP

sdp-id:vc-id — displays port information for the specified SDP

group — displays port information for multicast groups

grp-ip-address — displays port information for the specified multicast group address (IPv4 or IPv6)

detail — displays detailed port information

family — displays either IPv4 or IPv6 information for the specified port
- Values

ipv4 or ipv6
- Output

The following output is an example of PIM snooping port information, and [Table 89](#) describes the fields.

Output Example

```
*A:ALU# show service id 1 pim-snooping port
=====
PIM Snooping Ports ipv4
=====

|--------------------------------|---------------------------------------------------------------------------------------------------|
| Join Prune                     | The number of join-prune messages transmitted, received, and received with errors                 |
| Total Packets                  | The total number of hello and join-prune messages transmitted, received, and received with errors |
| <b>General Statistics</b>      |                                                                                                   |
| Rx Neighbor Unknown            | The number of packets received from an unknown neighbor                                           |
| Rx Bad Checksum Discard        | The number of packets received and discarded because of a bad checksum                            |
| Rx Bad Encoding                | The number of packets received with bad encoding                                                  |
| Rx Bad Version Discard         | The number of packets received and discarded because of a bad version                             |
| Join Policy Drops              | The number of join messages dropped due to the join policy actions                                |
| <b>Source Group Statistics</b> |                                                                                                   |
| (S,G)                          | The number of (S,G)s in the multicast                                                             |
| (* ,G)                         | The number of (* ,G)s in the multicast                                                            |

## status

**Syntax** **status** [*family*]

**Context** show>service>id>pim-snooping

**Description** This command displays PIM status information.

**Parameters** *family* — displays either IPv4 or IPv6 status information

**Values** ipv4 or ipv6

**Output** The following output is an example of PIM snooping status information, and [Table 91](#) describes the fields.

### Output Example

```
*A:ALU# show service id 1 pim-snooping status
=====
PIM Snooping Status ipv4
=====
Admin State : Up
```

```

Oper State : Up
Mode Admin : Proxy
Mode Oper : Proxy
Hold Time : 90
Designated Router : 10.0.1.2
J/P Tracking : Inactive
Up Time : 0d 00:08:43
Group Policy : None
=====

```

```
*A:ALU#
```

**Table 91 Service VPLS PIM Snooping Status Field Descriptions**

| Label             | Description                                                        |
|-------------------|--------------------------------------------------------------------|
| Admin State       | The administrative state of PIM snooping for the specified service |
| Oper State        | The operational state of PIM snooping for the specified service    |
| Mode Admin        | The administrative mode: snoop or proxy                            |
| Mode Oper         | The operational mode: snoop or proxy                               |
| Hold Time         | The length of time that PIM snooping checks for the PIM state      |
| Designated Router | The IP address of the designated router                            |
| J/P Tracking      | The join-prune status                                              |
| Up Time           | The length of time that the multicast connection has been up       |
| Group Policy      | The group policy name                                              |

## sap-using

**Syntax**

```

sap-using [sap sap-id]
sap-using interface [ip-address | ip-int-name]
sap-using description
sap-using authentication-policy auth-plcy-name
sap-using [ingress | egress] filter filter-id
sap-using [ingress | egress] atm-td-profile td-profile-id
sap-using [ingress | egress] qos-policy [qos-policy-id | qos-policy-name]
sap-using [ingress | egress] scheduler-mode {4-priority | 16-priority}
sap-using [ingress | egress] shaper-group shaper-group-name

```

**Context** show>service

**Description** This command displays SAP information.

If no optional parameters are specified, the command displays a summary of all defined SAPs.

The optional parameters restrict output to only SAPs matching the specified properties.

- Parameters**
- description** — displays a SAP summary table with description information
  - ingress** — specifies matching an ingress policy
  - egress** — specifies matching an egress policy
  - qos-policy-id** — the ingress or egress QoS policy ID for which to display matching SAPs  
**Values** 1 to 65535
  - qos-policy-name** — the ingress or egress QoS policy name for which to display matching SAPs  
**Values** up to 64 characters
  - td-profile-id** — displays SAPs using this traffic descriptor
  - filter-id** — the filter policy for which to display matching SAPs specifies. The filter ID or filter name must already exist.  
**Values** 1 to 65535 or *filter-name* (up to 64 characters)
  - auth-plcy-name** — the session authentication policy for which to display matching SAPs
  - sap-id** — specifies the physical port identifier portion of the SAP definition. See [Table 41](#) for a full list of SAP IDs.
  - interface** — specifies matching SAPs with the specified IP interface
  - ip-address** — the IP address of the interface for which to display matching SAPs  
**Values** 1.0.0.0 to 223.255.255.255
  - ip-int-name** — the IP interface name for which to display matching SAPs
  - scheduler-mode** — specifies the scheduler mode for which to display the SAPs
  - shaper-group** — specifies the shaper group for which to display matching SAPs

**Output** The following output is an example of information about SAPs matching the specified properties, and [Table 92](#) describes the fields.

### Output Example

**Table 92 Service SAP-Using Field Descriptions**

| Label     | Description                                                    |
|-----------|----------------------------------------------------------------|
| Port ID   | The ID of the access port where the SAP is defined             |
| SvcID     | The service identifier                                         |
| Ing.QoS   | The SAP ingress QoS policy number specified on the ingress SAP |
| Ing. Fltr | The filter policy ID applied to the ingress SAP                |

**Table 92 Service SAP-Using Field Descriptions (Continued)**

| Label          | Description                                                   |
|----------------|---------------------------------------------------------------|
| Egr.QoS        | The SAP egress QoS policy number specified on the egress SAP  |
| Egr. Fltr      | The filter policy ID applied to the egress SAP                |
| Scheduler Mode | The scheduler mode of the SAP: 4-priority or 16-priority      |
| Shaper Policy  | Identifies the shaper policy that the shaper group belongs to |
| Adm            | The administrative state of the SAP                           |
| Opr            | The actual state of the SAP                                   |
| Description    | The description of the SAP                                    |
| Number of SAPs | The total number of SAPs listed in the output                 |
| GroupName      | The group name of any aggregation groups                      |

### 5.21.2.4 VPLS Clear Commands

id

|                    |                                                               |
|--------------------|---------------------------------------------------------------|
| <b>Syntax</b>      | <b>id</b> <i>service-id</i>                                   |
| <b>Context</b>     | clear>service<br>clear>service>statistics                     |
| <b>Description</b> | This command clears commands for a specific service.          |
| <b>Parameters</b>  | <i>service-id</i> — the ID that uniquely identifies a service |
| <b>Values</b>      | 1 to 2147483647 or <i>service-name</i>                        |

statistics

|                    |                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>statistics</b> [ <b>sap</b> <i>sap-id</i>   <b>sdp</b> <i>sdp-id[:vc-id]</i>   <b>interface</b> [ <i>ip-address</i>   <i>ip-int-name</i> ]]            |
| <b>Context</b>     | clear>service>id>dhcp                                                                                                                                     |
| <b>Description</b> | This command clears DHCP statistics for this service.                                                                                                     |
| <b>Parameters</b>  | <i>sap-id</i> — clears the specified SAP statistics. See <a href="#">Table 41</a> for a full list of SAP IDs.<br><i>sdp-id</i> — the SDP ID to be cleared |
| <b>Values</b>      | 1 to 17407                                                                                                                                                |
|                    | <i>vc-id</i> — the virtual circuit ID on the SDP ID to be cleared                                                                                         |
| <b>Values</b>      | 1 to 4294967295                                                                                                                                           |
|                    | <i>ip-int-name</i> — clears the statistics for the IP interface with the specified name                                                                   |
|                    | <i>ip-addr</i> — clears the statistics for the IP interface with the specified IP address                                                                 |

fdb

|                    |                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| <b>Parameters</b> | <p><b>all</b> — clears all FDB entries</p> <p><i>ieee-address</i> — clears only FDB entries in the FDB table with the specified 48-bit MAC address. The MAC address can be expressed in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee and ff are hexadecimal numbers.</p> <p><i>sap-id</i> — specifies the physical port identifier portion of the SAP definition. See <a href="#">Table 41</a> for a full list of SAP IDs.</p> <p><i>mesh-sdp</i> — clears only service FDB entries associated with the specified mesh SDP ID. For a mesh SDP, the VC ID is optional.</p> <p><i>spoke-sdp</i> — clears only service FDB entries associated with the specified spoke SDP ID. For a spoke SDP, the VC ID must be specified.</p> <p><i>sdp-id</i> — the SDP ID for which to clear associated FDB entries</p> <p><b>Values</b> 1 to 17407</p> <p><i>vc-id</i> — the virtual circuit ID on the SDP ID for which to clear associated FDB entries</p> <p><b>Values</b> 1 to 4294967295</p> |

| <b>Description</b> | This command clears CEM statistics for this service. |

## counters

|                    |                                                                                |
|--------------------|--------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>counters</b>                                                                |
| <b>Context</b>     | clear>service>statistics>id                                                    |
| <b>Description</b> | This command clears all traffic queue counters associated with the service ID. |

## spoke-sdp

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>spoke-sdp</b> <i>sdp-id:vc-id</i> { <b>all</b>   <b>counters</b>   <b>l2pt</b>   <b>mrp</b> }                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Context</b>     | clear>service>statistics>id                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | This command clears statistics for the spoke SDP bound to the service.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <p><i>sdp-id</i> — the spoke SDP ID for which to clear statistics</p> <p><b>Values</b> 1 to 17407</p> <p><i>vc-id</i> — the virtual circuit ID on the SDP ID to be reset</p> <p><b>Values</b> 1 to 4294967295</p> <p><b>all</b> — clears all queue statistics associated with the SDP</p> <p><b>counters</b> — clears all queue counters associated with the SDP</p> <p><b>l2pt</b> — clears all L2PT statistics associated with the SDP</p> <p><b>mrp</b> — clears all MRP statistics associated with the SDP</p> |

## stp

|                    |                                                                      |
|--------------------|----------------------------------------------------------------------|
| <b>Syntax</b>      | <b>stp</b>                                                           |
| <b>Context</b>     | clear>service>statistics>id                                          |
| <b>Description</b> | This command clears all spanning tree statistics for the service ID. |

## sap

|                    |                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>sap</b> <i>sap-id</i> { <b>all</b>   <b>cem</b>   <b>counters</b>   <b>l2pt</b>   <b>stp</b>   <b>mrp</b> }                                 |
| <b>Context</b>     | clear>service>statistics                                                                                                                       |
| <b>Description</b> | This command clears statistics for the SAP bound to the service.                                                                               |
| <b>Parameters</b>  | <i>sap-id</i> — specifies the physical port identifier portion of the SAP definition. See <a href="#">Table 41</a> for a full list of SAP IDs. |

---

**all** — clears all queue statistics associated with the SAP  
**cem** — clears all CEM statistics associated with the SAP  
**counters** — clears all queue counters associated with the SAP  
**l2pt** — clears all L2PT statistics associated with the SAP  
**stp** — clears all STP statistics associated with the SAP  
**mrp** — clears all MRP statistics associated with the SAP

## sdp

**Syntax** **sdp** *sdp-id* **keep-alive**

**Context** clear>service>statistics

**Description** This command clears keepalive statistics associated with the SDP ID.

**Parameters** *sdp-id* — the SDP ID for which to clear statistics

**Values** 1 to 17407

**keep-alive** — clears the keep alive history associated with this SDP ID

## dhcp

**Syntax** **dhcp**

**Context** clear>router

**Description** This command enables the context to clear and reset DHCP entities.

## statistics

**Syntax** **statistics** [**interface** *ip-int-name* | *ip-address*]

**Context** clear>router>dhcp

**Description** This command clears DHCP statistics.

**Parameters** *ip-int-name* — clears the statistics for the IP interface with the specified name  
*ip-addr* — clears the statistics for the IP interface with the specified IP address

---

### 5.21.2.5 VPLS Debug Commands

#### id

|                    |                                                               |
|--------------------|---------------------------------------------------------------|
| <b>Syntax</b>      | <b>id</b> <i>service-id</i>                                   |
| <b>Context</b>     | debug>service                                                 |
| <b>Description</b> | This command debugs commands for a specific service.          |
| <b>Parameters</b>  | <i>service-id</i> — the ID that uniquely identifies a service |

#### igmp-snooping

|                    |                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] igmp-snooping</b>                                                                                                |
| <b>Context</b>     | debug>service>id                                                                                                         |
| <b>Description</b> | This command enables IGMP snooping debugging.<br><br>The <b>no</b> form of the command disables IGMP snooping debugging. |

#### mld-snooping

|                    |                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] mld-snooping</b>                                                                                               |
| <b>Context</b>     | debug>service>id                                                                                                       |
| <b>Description</b> | This command enables MLD snooping debugging.<br><br>The <b>no</b> form of the command disables MLD snooping debugging. |

#### detail-level

|                    |                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>detail-level {low   medium   high}</b><br><b>no detail-level</b>                                                                                                            |
| <b>Context</b>     | debug>service>id>igmp-snooping<br>debug>service>id>mld-snooping                                                                                                                |
| <b>Description</b> | This command enables debugging for the IGMP or MLD tracing detail level.<br><br>The <b>no</b> form of the command disables debugging for the IGMP or MLD tracing detail level. |

| <b>Context</b>     | debug>service>id>stp                               |
| <b>Description</b> | This command enables STP debugging for all events. |

## bpdu

|                    |                                                                        |
|--------------------|------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] bpdu</b>                                                       |
| <b>Context</b>     | debug>service>id>stp                                                   |
| <b>Description</b> | This command enables STP debugging for received and transmitted BPDUs. |

## core-connectivity

|                    |                                                           |
|--------------------|-----------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] core-connectivity</b>                             |
| <b>Context</b>     | debug>service>id>stp                                      |
| <b>Description</b> | This command enables STP debugging for core connectivity. |

## exception

|                    |                                                    |
|--------------------|----------------------------------------------------|
| <b>Syntax</b>      | <b>[no] exception</b>                              |
| <b>Context</b>     | debug>service>id>stp                               |
| <b>Description</b> | This command enables STP debugging for exceptions. |

## fsm-state-changes

|                    |                                                           |
|--------------------|-----------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] fsm-state-changes</b>                             |
| <b>Context</b>     | debug>service>id>stp                                      |
| <b>Description</b> | This command enables STP debugging for FSM state changes. |

## fsm-timers

|                    |                                                           |
|--------------------|-----------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] fsm-timers</b>                                    |
| <b>Context</b>     | debug>service>id>stp                                      |
| <b>Description</b> | This command enables STP debugging for FSM timer changes. |

## port-role

|                    |                                                               |
|--------------------|---------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] port-role</b>                                         |
| <b>Context</b>     | debug>service>id>stp                                          |
| <b>Description</b> | This command enables STP debugging for changes in port roles. |

## port-state

|                    |                                                     |
|--------------------|-----------------------------------------------------|
| <b>Syntax</b>      | <b>[no] port-state</b>                              |
| <b>Context</b>     | debug>service>id>stp                                |
| <b>Description</b> | This command enables STP debugging for port states. |

## sap

|                    |                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] sap</b> <i>sap-id</i>                                                                                                                  |
| <b>Context</b>     | debug>service>id>stp                                                                                                                           |
| <b>Description</b> | This command enables STP debugging for a specific SAP.                                                                                         |
| <b>Parameters</b>  | <i>sap-id</i> — specifies the physical port identifier portion of the SAP definition. See <a href="#">Table 41</a> for a full list of SAP IDs. |

---

## 6 Internet Enhanced Service

This chapter provides information about Internet Enhanced Service (IES), used to provide IP routing services; that is, direct forwarding of IP traffic between CE devices, and also to facilitate the transport of in-band management datagrams of the 7705 SAR over ATM links.

Internet Enhanced Services can coexist with IES management SAP services on the same 7705 SAR node. IP over ATM is used exclusively for in-band management of the 7705 SAR. Up to two IPoATM SAPs can be bound to IES along with many other SAPs with other (non-ATM) supported SAP encapsulation types. Traffic from IPoATM SAPs is extracted to the CSM for further processing. Traffic received from other IES SAPs is forwarded as per the forwarding table (FIB).

Topics in this chapter include:

- [IES for In-band Management](#)
- [IES for Customer Traffic](#)
- [Configuring IES with CLI](#)
- [IES Command Reference](#)

---

## 6.1 IES for In-band Management

Topics in this section include:

- [Setting Up Connections Between the NSP NFM-P and the 7705 SAR](#)
- [Encapsulation](#)
- [Layer 2 and Layer 3 Traffic Management](#)
- [Troubleshooting and Fault Detection Services](#)
- [IP ECMP Load Balancing](#)

In the HSDPA offload application (see [HSDPA Offload](#)), the main uplink out of a typical cell site is over the ATM network using leased lines. Mission-critical traffic such as voice, signaling, and synchronization traffic is carried over the ATM network.

Internet Enhanced Service (IES) provides a reliable means of diverting the node management IP packets from the DSL IP network to the more reliable Layer 2 ATM network. To do this, IES provides an IP address and interworking function between the Layer 3 IP network and the Layer 2 ATM network. Without this capability, the in-band IP management traffic for the 7705 SAR could only be connected to an IP network.

IES can be used for in-band management of the 7705 SAR over the ATM network. IP over an ATM SAP bound to IES is for in-band management purposes only, and IP traffic from the ATM SAP is only extracted to the CSM; it is not forwarded.

IES management service is supported on the following cards for the 7705 SAR-8 and 7705 SAR-18:

- 16-port T1/E1 ASAP Adapter card
- 32-port T1/E1 ASAP Adapter card

IES management service is also supported on the T1/E1 ports on the following:

- 7705 SAR-M (variants with T1/E1 ports)
- 7705 SAR-A (variants with T1/E1 ports)
- 7705 SAR-X
- 4-port T1/E1 and RS-232 Combination module

The service can be created on an ATM port or on an IMA group.

In the 7705 SAR, all traffic received over IES management SAPs is extracted directly to the control plane (CSM) in the same way as management traffic received over the CSM console port or Ethernet management port, or management traffic destined for the 7705 SAR over an Ethernet or MLPPP encapsulated network port. With IES management, the traffic transported is always IP packets. At the termination point of the ATM link, the IP packets are extracted to the CSM for further processing.

### 6.1.1 Setting Up Connections Between the NSP NFM-P and the 7705 SAR

IP over ATM is used for in-band management of the 7705 SAR. This requires the use of IP addresses so that the packets can be routed through the network using a routing table to indicate the next hop. Because Apipe interfaces (SAPs) do not have IP addresses, Apipes cannot be used to carry the management traffic.

With IES, the ATM SAP can be used for the forwarding of management IP packets. To set up a connection, IES is enabled on an interface on the 7705 SAR and the IP address for the interface is defined. A PVCC connection is then set up between the 7705 SAR and the remote router (SR) attached to the network manager (NSP NFM-P).

The IP datagrams are encapsulated into AAL5 for transport over the ATM network.

At the remote SR end, the SAP is bound to a VPRN instance to ensure that LDP signaling to the system IP address of the 7705 SAR flows through the IP/GRE link and not over the ATM link. Within the VPRN, an IP address is assigned at the termination SAP. The IP datagram is extracted from the ATM cell at this termination point and is routed to the NSP NFM-P.

Alternatively, manually configured connections can be used instead of signaled pseudowires.

**Note:** The remote IP address must be manually configured and a static route must be set up between the two connections. This configuration is beyond the scope of this document; refer to the 7705 SAR Router Configuration Guide for information.

For redundancy, it is recommended that two VCs be configured per ATM port or IMA group. This requires the configuration of two static routes. ECMP must be enabled to allow duplicate routes in the routing table, and BFD can be enabled to trigger a faster handoff to the other route in case of route failure.

## 6.1.2 Encapsulation

To run IP traffic over ATM links, the system uses routed VC-mux encapsulation as specified in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*. Since the only supported Layer 3 protocol over the management VC is IP, the VC mux encapsulation method is implemented to reduce complexity and overhead; likewise, routing mode is preferred over bridged mode.

The maximum MTU size supported is 2048 bytes.

## 6.1.3 Layer 2 and Layer 3 Traffic Management

ATM traffic descriptors can be applied at the ingress (policing) and egress (shaping and service category scheduling and prioritization) of the IES SAP in order to provide traffic management functions at Layer 2.

Management IP traffic that is destined for the CSM is classified at Layer 3 and is forwarded into the fabric from one of three of the adapter card control queues:

- high priority
- low priority
- FTP priority

The high-priority and low-priority queues are limited to 1 Mb/s and the FTP queue is rate-limited to 3 Mb/s ingress to the fabric toward the control plane.

**Note:** Proper configuration of the traffic descriptor profiles is essential for proper operation of the IES SAP. If no profile is assigned, the default UBR service category is assumed. All IES 7705 SAR traffic is scheduled; no shaping is supported in this mode. To ensure that IP traffic transported over the IES SAP is prioritized fairly, ATM layer traffic descriptors should be assigned. See [IES Management SAP Commands](#) in the [IES Command Reference](#) section for information.

## 6.1.4 Troubleshooting and Fault Detection Services

The IES in-band management service supports ATM OAM F4 (VP level) and F5 (VC level) cell generation and termination. For more information on OAM, refer to the 7705 SAR OAM and Diagnostics Guide, “OAM and SAA”.

Bidirectional forwarding detection (BFD) can also be configured on the IES interface. BFD is a simple protocol for detecting failures in a network. BFD uses a “hello” mechanism that sends control messages periodically to the far end and receives periodic control messages from the far end. BFD is implemented for IGP and BGP protocols, including static routes, in asynchronous mode only, meaning that neither end responds to control messages; rather, the messages are sent in the time period configured at each end.

To support redundancy, ECMP must be enabled to allow duplicate routes in the routing table, and BFD must be enabled to trigger the handoff to the other route in case of failure.

Due to the lightweight nature of BFD, it can detect failures faster than other detection protocols, making it ideal for use in applications such as mobile transport.

If the configured number of consecutive missed BFD messages is reached, the route to the peer is declared not active.

**Note:** Layer 2 AIS/RDI cells that are received on the IES SAP will disable the IP interface. Link failures detected by BFD will also disable the IP interface.

## 6.1.5 IP ECMP Load Balancing

IP ECMP allows the configuration of load balancing across all IP interfaces at the system level or interface level on the network side. Layer 4 port attributes and the TEID attribute in the hashing algorithm can be configured with the **l4-load-balancing** and **teid-load-balancing** commands in the **config>service>ies> interface** context. Configuration of the **l4-load-balancing** command at the interface level overrides the system-level settings for the specific interface. The **teid-load-balancing** command can only be configured at the interface level.

The system IP address can be included in or excluded from the hashing algorithm with the system-level **system-ip-load-balancing** command.

For more information on IP ECMP, refer to the 7705 SAR Router Configuration Guide, “Static Routes, Dynamic Routes, and ECMP”.

---

## 6.2 IES for Customer Traffic

Topics in this section include:

- [DHCP Relay and DHCPv6 Relay](#)
- [IPCP](#)
- [IPSec Support](#)
- [Security Zones and IES](#)
- [Proxy ARP](#)
- [Configurable ARP Retry Timer](#)
- [Unnumbered Interfaces](#)
- [Troubleshooting and Fault Detection Services](#)
- [VRRP on IES Interfaces](#)
- [SAPs](#)
- [Spoke SDP Termination to IES](#)
- [Bandwidth Optimization for Low-speed Links](#)

IES provides IP connectivity between customer access points. From the customer's perspective, IES provides a direct IP connection and can be used for Internet connectivity, as shown in [Figure 105](#). The customer is assigned an IP interface and a SAP is associated with the IP interface to designate a customer access point to the service—one SAP per interface. SAPs can be MC-MLPPP, PPP/MLPPP, LAG, or null/dot1q/qinq Ethernet. SDPs are not required, because traffic is routed rather than being encapsulated in a tunnel.

**Figure 105 IES for Customer Access to the Internet**

20720

IES supports static routes on customer IP interfaces (that is, SAPs). These routes are redistributed into the global routing table of the 7705 SAR.

IES is supported on the following:

- the 16-port T1/E1 ASAP Adapter card
- the 32-port T1/E1 ASAP Adapter card
- the Packet Microwave Adapter card
- any T1/E1 port on the 7705 SAR-M (variants with T1/E1 ports)
- any T1/E1 port on the 7705 SAR-A (variants with T1/E1 ports)
- any T1/E1 port on the 4-port T1/E1 and RS-232 Combination module
- any port on the 8-port Ethernet Adapter card
- any port on the 6-port Ethernet 10Gbps Adapter card
- any port on the 8-port Gigabit Ethernet Adapter card
- any port on the 10-port 1GigE/1-port 10GigE X-Adapter card (10-port 1GigE mode)
- any port on the 4-port SAR-H Fast Ethernet module
- any port on the 6-port SAR-M Ethernet module
- any Ethernet port on the 7705 SAR-M (all variants)
- any Ethernet port on the 7705 SAR-A (both variants)
- any Ethernet port on the 7705 SAR-Ax

- 
- any Ethernet port on the 7705 SAR-W
  - any Ethernet port on the 7705 SAR-Wx (all variants)
  - any Ethernet port on the 7705 SAR-H
  - any Ethernet port on the 7705 SAR-Hc
  - any Ethernet port on the 7705 SAR-X
  - GPON module ports and DSL module ports when the module is installed in the 7705 SAR-M (variants with module slots)

Ports must be in access mode.

The encapsulation type for Ethernet ports must be null, dot1q, or qinq. The encapsulation type for DSL and GPON module ports on the 7705 SAR-M must be null or dot1q; however, the encapsulation type on a DSL port on the 7705 SAR-Wx can be null, dot1q, or qinq.

IES IPv6 SAPs are supported on the following cards, modules, and ports:

- the 8-port Ethernet Adapter card (version 2 only)
- the 6-port Ethernet 10Gbps Adapter card
- the 8-port Gigabit Ethernet Adapter card
- the 10-port 1GigE/1-port 10GigE X-Adapter card (10-port 1GigE mode)
- the Packet Microwave Adapter card
- the 4-port SAR-H Fast Ethernet module
- the 6-port SAR-M Ethernet module
- any Ethernet port on the 7705 SAR-M (all variants)
- any Ethernet port on the 7705 SAR-A (both variants)
- any Ethernet port of the 7705 SAR-Ax
- the 7705 SAR-W
- any Ethernet port on the 7705 SAR-Wx (all variants)
- the 7705 SAR-H
- any Ethernet port on the 7705 SAR-Hc
- any Ethernet port of the 7705 SAR-X
- GPON module ports and DSL module ports when the module is installed in the 7705 SAR-M (variants with module slots)

For more information on IPv6 addressing, refer to the 7705 SAR Router Configuration Guide, “Internet Protocol Versions”.

More than one Internet Enhanced Service can be created for a single customer ID, and more than one IP interface can be created within a single IES. All IP interfaces created within an IES belong to the same customer.

The service provider applies billing, ingress/egress shaping and policing to the customer.

**Note:**

- Internet Enhanced Services require that the fabric mode be set to aggregate mode rather than per-destination mode. IES is only supported with aggregate-mode fabric profiles. If the fabric mode is set to per-destination mode, creation of the Internet Enhanced Service is blocked through the CLI. The fabric mode must be changed to aggregate mode before IES can be configured. As well, if IES is configured, alteration of the fabric mode is blocked.
- For information on configuring fabric mode, refer to the 7705 SAR Quality of Service Guide, “Configurable Ingress Shaping to Fabric (Access and Network)”.

## 6.2.1 DHCP Relay and DHCPv6 Relay

The 7705 SAR provides DHCP/BOOTP Relay agent services and DHCPv6 Relay agent services for DHCP clients. DHCP is used for IPv4 network addresses and DHCPv6 is used for IPv6 network addresses. Both DHCP and DHCPv6 are known as stateful protocols because they use dedicated servers to maintain parameter information.

Unless stated otherwise, DHCP is equivalent to “DHCP for IPv4”, or DHCPv4.

In the stateful autoconfiguration model, hosts obtain interface addresses and/or configuration information and parameters from a server. The server maintains a database that keeps track of which addresses have been assigned to which hosts.

The 7705 SAR supports DHCP Relay on access IP interfaces associated with IES and VPRN and on network interfaces. Each DHCP instance supports up to eight DHCP servers.

The 7705 SAR supports DHCPv6 Relay on access IP interfaces associated with IES and VPRN. Each DHCPv6 instance supports up to eight DHCPv6 servers.

**Note:**

- The 7705 SAR acts as a Relay agent for DHCP and DHCPv6 requests and responses, and can also be configured to function as a DHCP or DHCPv6 server. DHCPv6 functionality is only supported on network interfaces and on access IP interfaces associated with VPRN.
- When used as a CPE, the 7705 SAR can act as a DHCP client to learn the IP address of the network interface. Dynamic IP address allocation is supported on both network and system interfaces.
- For more information on DHCP and DHCPv6, refer to the 7705 SAR Router Configuration Guide, “DHCP and DHCPv6”.

### 6.2.1.1 DHCP Relay

The 7705 SAR provides DHCP/BOOTP Relay agent services for DHCP clients. DHCP is a configuration protocol used to communicate network information and configuration parameters from a DHCP server to a DHCP-aware client. DHCP is based on the BOOTP protocol, with additional configuration options and the added capability of allocating dynamic network addresses. DHCP-capable devices are also capable of handling BOOTP messages.

A DHCP client is an IP-capable device (typically a computer or base station) that uses DHCP to obtain configuration parameters such as a network address. A DHCP server is an Internet host or router that returns configuration parameters to DHCP clients. A DHCP/BOOTP Relay agent is a host or router that passes DHCP messages between clients and servers.

Home computers in a residential high-speed Internet application typically use the DHCP protocol to have their IP address assigned by their Internet service provider.

The DHCP protocol requires the client to transmit a request packet with a destination broadcast address of 255.255.255.255 that is processed by the DHCP server. Since IP routers do not forward broadcast packets, this would suggest that the DHCP client and server must reside on the same network segment. However, for various reasons, it is sometimes impractical to have the server and client reside in the same IP network. When the 7705 SAR is acting as a DHCP Relay agent, it processes these DHCP broadcast packets and relays them to a preconfigured DHCP server. Therefore, DHCP clients and servers do not need to reside on the same network segment.

DHCP OFFER messages are not dropped if they contain a yiaddr that does not match the local configured subnets on the DHCP relay interface. This applies only to regular IES and VPRN interfaces with **no lease-populate** configured on the DHCP relay interface.

### 6.2.1.1.1 DHCP Options

DHCP options are codes that the 7705 SAR inserts in packets being forwarded from a DHCP client to a DHCP server. Some options have additional information stored in suboptions.

The 7705 SAR supports the Relay Agent Information Option 82 as specified in RFC 3046. The following suboptions are supported:

- circuit ID
- remote ID
- vendor-specific options

### 6.2.1.2 DHCPv6 Relay

DHCPv6 Relay operation is similar to DHCP in that servers send configuration parameters such as IPv6 network addresses to IPv6 nodes, but DHCPv6 Relay is not based on the DHCP or BOOTP protocol. DHCPv6 can be used instead of stateless autoconfiguration (refer to the 7705 SAR Router Configuration Guide, “Neighbor Discovery”) or in conjunction with it.

DHCPv6 is also oriented around IPv6 methods of addressing, especially the use of reserved, link-local scoped multicast addresses. DHCPv6 clients transmit messages to these reserved addresses, allowing messages to be sent without the client knowing the address of any DHCP server. This transmission allows efficient communication even before a client has been assigned an IP address. When a client has an address and knows the identity of a server, it can communicate with the server directly using unicast addressing.

The DHCPv6 protocol requires the client to transmit a request packet with a destination multicast address of ff02::1:2 (all DHCP servers and relay agents on the local network segment) that is processed by the DHCP server.

Similar to DHCP address allocation, if a client needs to obtain an IPv6 address and other configuration parameters, it sends a Solicit message to locate a DHCPv6 server, then requests an address assignment and other configuration information from the server. Any server that can meet the client’s requirements responds with an Advertise message. The client chooses one of the servers and sends a Request message, and the server sends back a Reply message with the confirmed IPv6 address and configuration information.

If the client already has an IPv6 address, either assigned manually or obtained in some other way, it only needs to obtain configuration information. In this case, exchanges are done using a two-message process. The client sends an Information Request message, requesting only configuration information. A DHCPv6 server that has configuration information for the client sends back a Reply message with the information.

The 7705 SAR supports the DHCPv6 Relay Agent option in the same way that it supports the DHCP Relay Agent option. This means that when the 7705 SAR is acting as a DHCPv6 Relay Agent, it relays messages between clients and servers that are not connected to the same link.

#### 6.2.1.2.1 DHCPv6 Options

DHCPv6 options are codes that the 7705 SAR inserts in packets being forwarded from a DHCPv6 client to a DHCPv6 server. DHCPv6 supports interface ID and remote ID options as defined in RFC 3315, *Dynamic Host Configuration Protocol for IPv6 (DHCPv6)* and RFC 4649, *DHCPv6 Relay Agent Remote-ID Option*.

### 6.2.2 IPCP

Similar to DHCP over Ethernet interfaces, Internet Protocol Control Protocol (IPCP) extensions to push IP information over PPP/MLPPP IES SAPs are supported. Within this protocol, extensions can be configured to define the remote IP address and DNS IP address to be signaled via IPCP on the associated PPP interface. The IPCP-based IP and DNS assignment process is similar to DHCP behavior; IPCP-based IP/DNS assignment uses PPP/MLPPP IP layer protocol handshake procedures. PPP/MLPPP connected devices hooked up to IES can benefit from this feature for the assignment of IP and DNS to the associated interface.

### 6.2.3 IPSec Support

The 7705 SAR supports IPSec and IPSec tunnels, where IES or VPRN is used as a public (untrusted) network-facing service and VPRN is used as a private (trusted) network-facing service. IES interfaces support the provisioning of tunnel SAPs as part of IPSec provisioning. The *sap-id* for a public-side IPSec tunnel SAP is **tunnel-1.public:tag**.

For more information, see the [IPSec](#) chapter in this guide.

## 6.2.4 Security Zones and IES

The 7705 SAR supports a number of mechanisms for node security, including Access Control Lists (ACLs), Network Address Translation (NAT), and stateful, zone-based firewalls. For information about ACLs, NAT, and firewalls, refer to the 7705 SAR Router Configuration Guide, “Configuring Security Parameters”.

NAT and firewall security configurations are both based on zones. Zones segment a network, making it easier to control and organize traffic. A zone consists of a group of Layer 3 interfaces with common criteria, bundled together. Security policies, which define a set of rules that determine how NAT or firewall should direct traffic, can be applied to the entire zone or to multiple zones. To enable NAT or firewall functionality, security policy and profile parameters must be configured under the **config>security** context in the CLI, and a security zone must be configured under one or more of the following contexts:

- **config>router>zone**
- **config>service>vprn>zone**
- **config>service>ies>zone**

A zone is created by adding at least one Layer 3 interface to the zone configuration. Multiple zones can be created within each service or within the router context. Layer 3 interfaces from different services cannot be grouped into a single common zone. [Table 93](#) lists the supported interfaces that can be added to zones in each CLI context for NAT or firewall.

**Table 93 Security Zone Interfaces per Context**

| CLI Context | Interface Type        | NAT | Firewall |
|-------------|-----------------------|-----|----------|
| Router      | Layer 3               | ✓   | ✓        |
| VPRN        | SAP                   | ✓   | ✓        |
|             | Spoke-SDP termination | ✓   | ✓        |
|             | IPSec private         | ✓   | ✓        |
|             | IPSec public          | ✓   |          |
|             | Routed VPLS           | ✓   | ✓        |

**Table 93 Security Zone Interfaces per Context (Continued)**

| CLI Context | Interface Type        | NAT | Firewall |
|-------------|-----------------------|-----|----------|
| IES         | SAP                   | ✓   | ✓        |
|             | Spoke-SDP termination | ✓   | ✓        |
|             | IPSec public          | ✓   |          |
|             | Routed VPLS           | ✓   | ✓        |

## 6.2.5 Proxy ARP

Proxy ARP is supported on IES interfaces.

Proxy ARP is a technique by which a router on one network responds to ARP requests intended for another node that is physically located on another network. The router effectively pretends to be the destination node by sending an ARP response to the originating node that associates the router's MAC address with the destination node's IP address (acts as a proxy for the destination node). The router then takes responsibility for routing traffic to the real destination.

For more information on proxy ARP, refer to the 7705 SAR Router Configuration Guide, "Proxy ARP".

## 6.2.6 Configurable ARP Retry Timer

A timer is available to configure a shorter retry interval when an ARP request fails. An ARP request may fail for a number of reasons, such as network connectivity issues. By default, the 7705 SAR waits 5000 ms before retrying an ARP request. The configurable retry timer makes it possible to shorten the retry interval to between 100 and 30 000 ms.

**Note:** The ARP retry default value of 5000 ms is intended to protect CPU cycles on the 7705 SAR, especially when it has a large number of interfaces. Configuring the ARP retry timer to a value shorter than the default should be done only on mission-critical links, such as uplinks or aggregate spoke SDPs transporting mobile traffic; otherwise, the retry interval should be left at the default value.

---

The configurable ARP retry timer is supported on VPRN and IES service interfaces, as well on the router interface.

## 6.2.7 Unnumbered Interfaces

Unnumbered interfaces are supported on IES and VPRN services for IPv4. Unnumbered interfaces are point-to-point interfaces that are not explicitly configured with a dedicated IP address and subnet; instead, they borrow (or link to) an IP address from another interface on the system (the system IP address, another loopback interface, or any other numbered interface) and use it as the source IP address for packets originating from the interface.

This feature is supported via both dynamic and static ARP for unnumbered interfaces to allow interworking with unnumbered interfaces that may not support dynamic ARP.

The use of unnumbered interfaces has no effect on IPv6 routes; however, the **unnumbered** command must only be used in cases where IPv4 is active (IPv4 only and mixed IPv4/IPv6 environments). When using an unnumbered interface for IPv4, the loopback address used for the unnumbered interface must have an IPv4 address. The interface type for the unnumbered interface is automatically point-to-point.

## 6.2.8 Troubleshooting and Fault Detection Services

Bidirectional forwarding detection (BFD) can be configured on the IES interface. BFD is a simple protocol for detecting failures in a network. BFD uses a “hello” mechanism that sends control messages periodically to the far end and expects to receive periodic control messages from the far end. On the 7705 SAR, BFD is implemented for IGP and BGP protocols, including static routes, in asynchronous mode only, meaning that neither end responds to control messages; rather, the messages are sent periodically from each end.

To support redundancy with fast switchover, BFD must be enabled to trigger the handoff to the other route in case of failure.

Due to the lightweight nature of BFD, it can detect failures faster than other detection protocols, making it ideal for use in applications such as mobile transport.

If BFD packets are not received in the configured amount of time, the associated route is declared “not active”, causing a reroute to an alternative path, if any.

**Note:** Link failures detected by BFD will disable the IP interface.

The 7705 SAR also supports Internet Control Message Protocol (ICMP and ICMPv6). ICMP is a message control and error reporting protocol that also provides information relevant to IP packet processing. For more information on ICMP and ICMPv6, refer to the 7705 SAR Router Configuration Guide, “ICMP and ICMPv6”.

## 6.2.9 VRRP on IES Interfaces

VRRP can be implemented on IES service interfaces to participate as part of a virtual router instance. This implementation prevents a single point of failure by ensuring access to the gateway address, which is configured on all IES service interfaces in the VRRP. VRRPv3 can also be implemented on IES service interfaces, including r-VPLS interfaces for IES.

The 7705 SAR supports VRRPv3 for IPv4 and IPv6 as described in RFC 5798. Within a VRRP router, the virtual routers in each of the IPv4 and IPv6 address families are in separate domains and do not overlap.

**Note:**

- VRRPv3 for IPv6 is not support on a Layer 3 spoke SDP termination.
- VRRP is not supported on an IPSec public interface.

For information on VRRP and VRRP IES service interface parameters, as well as the configuration parameters of VRRP policies, refer to the “VRRP” section in the 7705 SAR Router Configuration Guide. CLI command descriptions for VRRP policies are also given in the 7705 SAR Router Configuration Guide.

For CLI command descriptions related to IES service interfaces, see [IES Command Reference](#).

## 6.2.10 SAPs

Topics in this section include:

- [Encapsulations](#)
- [Routing Protocols](#)
- [QoS Policies](#)
- [QinQ \(IES\)](#)
- [IP Filter Policies on an IES SAP](#)

### 6.2.10.1 Encapsulations

The following SAP encapsulations are supported on the 7705 SAR Internet Enhanced Service:

- Ethernet null
- Ethernet dot1q
- Ethernet qinq
- PPP/MLPPP/MC-MLPPP

### 6.2.10.2 Routing Protocols

OSPFv2, RIP, and PIM routing protocols are supported on IES SAPs (that is, access IP interfaces).

The SAP for the IES IP interface is created at the IES service level, but the routing protocol for the IES IP interface is configured at the routing protocol level for the main router instance in the global context.

Refer to the chapters on “OSPF” and “RIP” in the 7705 SAR Routing Protocols Guide for information on configuring these routing protocols.

IPv4 in IES supports PIM-SM and PIM-SSM. IPv6 in IES supports PIM-SSM. Refer to the “IP Multicast” chapter in the 7705 SAR Routing Protocols Guide for information on configuring these routing protocols.

---

### 6.2.10.3 QoS Policies

When applied to an Internet Enhanced Service SAP, service ingress QoS policies only create the unicast queues defined in the policy.

Service egress QoS policies function in the same way as Ethernet and IP pseudowire services, where class-based queues are created based on the QoS policy. Multiple queues are supported. Refer to the 7705 SAR Quality of Service Guide, “Creating a Service Egress QoS Policy”.

Both Layer 2 and Layer 3 match criteria can be used in the QoS policies for traffic classification in an IES.

### 6.2.10.4 QinQ (IES)

IES supports QinQ functionality. For details, see [QinQ Support](#).

### 6.2.10.5 IP Filter Policies on an IES SAP

IPv4 filter policies can be applied to ingress IES management SAPs.

IPv4 and IPv6 filter policies can be applied to both ingress and egress IES SAPs (null, dot1q, or qinq interfaces).

Configuration and assignment of IP filter policies is similar for all services. Refer to the 7705 SAR Router Configuration Guide, “Filter Policies”, for information on configuring IP filters.

## 6.2.11 Spoke SDP Termination to IES

This feature enables a customer to exchange traffic between a VLL or VPLS (Layer 2) service and an IES or VPRN (Layer 3) service. Customer premises traffic coming in from a VLL or VPLS service (SAP to spoke SDP) is forwarded over the IP/MPLS network to the IES or VPRN service, and vice versa. Network QoS policies can be applied to the spoke SDP to control traffic forwarding to the Layer 3 service.

In a Layer 3 spoke SDP termination to an IES or VPRN service, where the destination IP address resides within the IES or VPRN network, CE device-generated ARP frames must be processed by the Layer 3 interface. When an ARP frame is received over the spoke SDP at the Layer 3 interface endpoint, the 7705 SAR responds to the ARP frame with its own MAC address. When an ARP request is received from the routed network and the ARP entry for the CE device that is connected to the spoke SDP is not known, the 7705 SAR initiates an ARP frame to resolve the MAC address of the next hop or CE device.

Figure 106 shows traffic terminating on a specific IES or VPRN service that is identified by the SDP ID and VC label present in the service packet.

**Figure 106 SDP ID and VC Label Service Identifiers (Conceptual View of the Service)**

21510

Figure 107 shows a spoke SDP terminating directly into an IES. In this case, a spoke SDP could be tied to an Epipe or a hierarchical VPLS service. There is no configuration required on the PE connected to the CE.

**Figure 107 IES Spoke SDP Termination**

21511

---

Ethernet spoke SDP termination for IES is supported over the following network uplinks:

- Ethernet network ports (null or dot1q encapsulation)
- PPP/MLPPP network ports. For information on PPP/MLPPP ports, refer to the 7705 SAR Interface Configuration Guide, “Access, Network, and Hybrid Ports”
- GPON module ports and DSL module ports when the module is installed in the 7705 SAR-M (variants with module slots)
- POS ports

Spoke SDP termination for IES supports the following:

- Ethernet PW to VRF
- interface shutdown based on PW standby signaling
- spoke SDP ingress IP filtering with filter logging
- label withdrawal for spoke SDPs terminated on IES
- statistics collection
- VCCV ping (type 2)

A spoke SDP on an IES interface can be connected to the following entities:

- Epipe spoke SDP
- Epipe spoke SDP redundancy with standby-signal-master enabled
- IES interface
- VPRN interface
- VPLS spoke SDP
- VPLS spoke SDP redundancy with suppress-standby-signaling disabled

[Figure 108](#) shows an example of backhauling from a given site that uses PW and IES on the 7705 SAR. An individual PW is configured on a per-CE device or a per-service basis. For routing services, this PW can be terminated to an IES at the 7750 SR end. This scenario offers per-service OAM and redundancy capabilities. Because there is no local communication on the remote 7705 SAR, traffic between any two devices connected to the 7705 SAR must traverse through the 7750 SR at the MTSO/CO.

**Figure 108 Pseudowire-Based Backhaul (Spoke SDP Termination at 7750 SR)**

21522

## 6.2.12 Bandwidth Optimization for Low-speed Links

The 7705 SAR can be used in deployments where the uplink bandwidth capacity and requirements are considerably less than if the router is used for fixed or mobile backhaul applications. For example, the 7705 SAR can be used to direct traffic from multiple individual homes for applications such as smart meter aggregation or relay connectivity. Connecting to end systems such as smart meters or relays requires uplink bandwidth capacity in terms of hundreds of kilobits per second, rather than hundreds of megabits per second.

One way to optimize operation in lower-bandwidth applications is to minimize head-of-line (HoL) blocking caused by large packets. HoL blocking occurs when transmission of a large non-mission-critical packet delays a mission-critical packet beyond acceptable limits. The propagation delay of large packets over a slow link is fairly significant. For example, the propagation delay when transmitting a 1500-byte packet over a 100 kb/s link is 120 ms. If a mission-critical packet is queued immediately after the first bit of a non-mission-critical 1500-byte packet begins transmission, the mission-critical packet must wait 120 ms before the uplink is available again.

To minimize HoL blocking, the 7705 SAR now supports a lower MTU of 128 bytes (from the original 512-byte minimum) so that large IP packets can be fragmented into 128-byte chunks. In the preceding example, transmitting a 128-byte packet over a 100 kb/s link will only delay the next packet by 10.24 ms.

This lower MTU is supported on IES and VPRN interfaces (access interfaces) and on network interfaces. The IP MTU is derived from the port MTU, unless specifically configured with the **ip-mtu** command. This command is supported on access interfaces only.

The following must be considered when using a lower IP MTU:

- applicability – the lower IP MTU is only applicable for IP forwarded traffic and cannot be applied to pseudowire or VPLS traffic
- reassembly – the far-end/destination node must reassemble the packet before it can process the data, which may impact the performance of the end system and/or may require different hardware to perform the reassembly
- extra overhead – each fragment must have an IPv4 header so that all fragments of the packet can be forwarded to the destination. Care must be taken to ensure that the extra IP overhead for each fragment does not offset the gain achieved by using the lower MTU. As an example, for a 128-byte packet, the IPv4 header, which is 20 bytes in length, constitutes approximately 15% of the total packet size.

**Note:**

- Lower IP MTU applies to IPv4 applications only. As per RFC 2640, IPv6 interfaces or dual-stack interfaces should not be configured to a value lower than 1280 bytes.
- Lower IP MTU is supported only on Ethernet encapsulated ports.
- Most routing and signaling protocols, such as OSPF, IS-IS, and RSVP-TE, cannot be supported with port MTUs lower than 512 bytes due to the protocol layer requirements and restrictions.
- Special care must be taken with routing protocols that use TCP, such as BGP and LDP. The minimum TCP MSS value supported on the 7705 SAR is 384 bytes; therefore, these protocols should only be enabled on links that can transport 384-byte IP packets without fragmentation. If there is a mismatch in TCP MSS in the network, this mismatch can potentially cause severe network performance issues due to the overhead caused by fragmentation and retransmissions, it can cause multi-vendor interoperability issues, and it can potentially cause the protocols to continuously flap.
- Not all OAM diagnostics are supported with lower port MTUs. Detailed information is provided in [OAM Diagnostics Restrictions with Lower IP MTU](#).

### 6.2.12.1 OAM Diagnostics Restrictions with Lower IP MTU

OAM tests require a minimum network port MTU in order to run; this value depends on the test. If the port MTU is set to a value lower than the minimum requirement, the test will fail.

If the port MTU is set to a value that meets the minimum requirement, the packet size parameter can be configured for the test (for example, **oam sdp-ping 1 size 102**).

If the **size** parameter is not specified, the system builds the packet based on the default payload size. If the **size** parameter is configured and is greater than the default payload size, padding bytes are added to equal the configured value.

The packet size is dependent on the port MTU value; that is, if the minimum port MTU value is used, there are restrictions on the packet size. If the configured size is greater than the maximum value supported with the minimum port MTU, the test will fail.

[Table 94](#) and [Table 95](#) list the minimum port MTU required for each OAM test and the maximum size of the OAM packet that can be configured when the minimum port MTU is used, based on SDP tunnel type.

**Note:** RSVP LSPs will not come up if the network port MTU value is lower than 302 bytes.

**Table 94** Port MTU Requirements for OAM Diagnostics (GRE Tunnels)

| SDP Type: GRE |                                                                                |                             |
|---------------|--------------------------------------------------------------------------------|-----------------------------|
| Test Type     | Minimum Network Port MTU Requirement over Ethernet Dot1q Encapsulation (Bytes) | OAM Test Size Range (Bytes) |
| sdp-ping      | 128                                                                            | 72 to 82                    |
| svc-ping      | 196                                                                            | N/A <sup>1</sup>            |
| vccv-ping     | 143                                                                            | 1 to 93                     |
| vccv-trace    | 143                                                                            | 1 to 93                     |
| vprn-ping     | 182                                                                            | 1 to 136                    |
| vprn-trace    | 302                                                                            | 1 to 256                    |
| mac-ping      | 188                                                                            | 1 to 142                    |

**Table 94 Port MTU Requirements for OAM Diagnostics (GRE Tunnels)**

| SDP Type: GRE |                                                                                |                             |
|---------------|--------------------------------------------------------------------------------|-----------------------------|
| Test Type     | Minimum Network Port MTU Requirement over Ethernet Dot1q Encapsulation (Bytes) | OAM Test Size Range (Bytes) |
| mac-trace     | 240                                                                            | 1 to 194                    |
| cpe-ping      | 186                                                                            | N/A <sup>1</sup>            |

**Note:**

1. Size is not configurable

**Table 95 Port MTU Requirements for OAM Diagnostics (LDP Tunnels)**

| SDP Type: LDP |                                                                                |                             |
|---------------|--------------------------------------------------------------------------------|-----------------------------|
| Test Type     | Minimum Network Port MTU Requirement over Ethernet Dot1q Encapsulation (Bytes) | OAM Test Size Range (Bytes) |
| lsp-ping      | 128                                                                            | 1 to 106                    |
| lsp-trace     | 128                                                                            | 1 to 104                    |
| sdp-ping      | 128                                                                            | 72 to 102                   |
| svc-ping      | 176                                                                            | N/A <sup>1</sup>            |
| vccv-ping     | 128                                                                            | 1 to 98                     |
| vccv-trace    | 128                                                                            | 1 to 98                     |
| vprn-ping     | 182                                                                            | 1 to 156                    |
| vprn-trace    | 302                                                                            | 1 to 276                    |
| mac-ping      | 168                                                                            | 1 to 142                    |
| mac-trace     | 220                                                                            | 1 to 194                    |
| cpe-ping      | 166                                                                            | N/A <sup>1</sup>            |

**Note:**

1. Size is not configurable

For information on OAM diagnostics, refer to the 7705 SAR OAM and Diagnostics Guide.

## 6.3 Configuring IES with CLI

This section provides the information required to configure IP routing services; that is, direct forwarding of IP traffic between CE devices, and to configure IES for in-band management of the 7705 SAR over ATM links.

Topics in this section include:

- [Common Configuration Tasks](#)
- [Configuring IES Components](#)
- [Service Management Tasks](#)

---

## 6.4 Common Configuration Tasks

The following list provides a brief overview of the tasks that must be performed to configure IES.

- Associate the IES service with a customer ID.
- Create an IP interface on the 7705 SAR.
- Specify the IP address of the interface.
- Define interface parameters.
- Define SAP parameters.
- For IES spoke SDP applications only — define spoke SDP parameters.
- For IES applications only — configure VRRP (optional).
- For IES management service only—manually configure the remote address of the far-end router to which the NSP NFM-P is connected (far-end router must be enabled for IES service).\*
- For IES management service only—create a static route to the remote router and to the NSP NFM-P.\*
- Enable the service.

**Note:** \*Remote address and static route configuration is beyond the scope of this document. For information, refer to the 7705 SAR Router Configuration Guide.

## 6.5 Configuring IES Components

This section provides configuration examples for components of the IES service. Each component includes some or all of the following: introductory information, CLI syntax, a specific CLI example, and an example of the CLI display output.

Topics in this section include:

- [Creating an IES Service](#)
- [Configuring IES Interface Parameters](#)
- [Configuring IES SAP Parameters](#)
- [Configuring IES Spoke SDP Parameters](#)
- [Configuring VRRP](#)
- [Configuring a Security Zone Within IES](#)
- [Configuring Serial Raw Socket Transport Within IES](#)

### 6.5.1 Creating an IES Service

Use the following CLI syntax to create an IES service.

**CLI Syntax:**

```
config>service# ies service-id [customer customer-id]
[create] [vpn vpn-id]
description description-string
interface ip-int-name [create]
no shutdown
```

**Example:**

```
A:ALU-41>config>service# ies 5 customer 1 create
A:ALU-41>config>service>ies# description "IES for
in-band management"
A:ALU-41>config>service>ies# interface "ATMoIP
Management" create
A:ALU-41>config>service>ies# no shutdown
A:ALU-41>config>service>ies#
```

The following example displays the IES service creation output.

```
A:ALU-41>config>service# info

...
ies 5 customer 1 create
description "IES for in-band management"
interface "ATMoIP Management"
no shutdown
```

```

 exit
 ...

```

## 6.5.2 Configuring IES Interface Parameters

Configure interface parameters for:

- [IES Management Service](#)
- [IES Service](#)
- [IES IPv6 Service](#)

### 6.5.2.1 IES Management Service

Use the following CLI syntax to configure interface parameters for the IES management service.

**CLI Syntax:**

```

config>service# ies service-id [customer customer-id]
[create] [vpn vpn-id]
 interface ip-int-name
 address if-ip-address
 bfd transmit-interval [receive receive-
 interval] [multiplier multiplier] [type np]
 description description-string
 ip-mtu octets
 no shutdown

```

**Example:**

```

A:ALU-41>config>service# ies 5
A:ALU-41>config>service>ies# interface "ATMoIP
Management"
A:ALU-41>config>service>ies>if# address 10.1.1.1/8
A:ALU-41>config>service>ies>if# ip-mtu 1524
A:ALU-41>config>service>ies>if# no shutdown
A:ALU-41>config>service>ies>if#

```

The following example displays the IES interface creation output for the IES management service.

```

A:ALU-41>config>service>ies>if# info detail

...
 no description
 address 10.1.1.1/8
 ip-mtu 1524
 no bfd

```

```

exit
no shutdown
...

```

### 6.5.2.2 IES Service

Use the following CLI syntax to configure interface parameters for the IES service.

**Note:** The IES interface can be configured as a loopback interface by issuing the **loopback** command instead of the **sap** command. The loopback flag cannot be set on an interface where a SAP is already defined, and a SAP cannot be defined on a loopback interface.

**CLI Syntax:**

```

config>service# ies service-id [customer customer-id]
[create] [vpn vpn-id]
 interface ip-int-name
 address if-ip-address
 allow-directed-broadcasts
 arp-timeout
 bfd transmit-interval [receive receive-
 interval] [multiplier multiplier] [type np]
 description description-string
 dhcp
 description description-string
 option
 action {replace | drop | keep}
 circuit-id [ascii-tuple | ifindex |
 sap-id | vlan-ascii-tuple]
 remote-id [mac | string string]
 vendor-specific option
 client-mac-address
 sap-id
 service-id
 string text
 system-id
 server server1 [server2...(up to 8
 max)]
 no shutdown
 trusted
 icmp
 mask-reply
 ttl-expired [number seconds]
 unreachableables
 ip-mtu octets
 ipcp
 dns ip-address [secondary ip-address]

```

```

 dns secondary ip-address
 peer-ip-address ip-address
 14-load-balancing hashing-algorithm
 local proxy-arp
 loopback
 mac ieee-address
 proxy-arp-policy policy-name [policy-
 name...(up to 5 max)]
 remote-proxy-arp
 secondary {ip-address/mask | ip-address
 netmask} [broadcast all-ones | host-ones]
 [igmp-inhibit]
 no shutdown
 static-arp ip-address ieee-mac-address
 static-arp ieee-mac-address unnumbered
 teid-load-balancing
 unnumbered {ip-int-name | ip-address}
 no shutdown

```

**Example:**

```

A:ALU-41>config>service# ies 4
A:ALU-41>config>service>ies$ interface "to Internet"
A:ALU-41>config>service>ies>if$ address 192.168.0.0/16
A:ALU-41>config>service>ies>if$ dhcp option
A:ALU-41>config>service>ies>if>dhcp>option$ circuit-id
 ifindex
A:ALU-41>config>service>ies>if>dhcp>option$ exit
A:ALU-41>config>service>ies>if$ ip-mtu 1524

```

The following example displays the IES interface creation output for the IES service.

```

A:ALU-41>config>service>ies>if# info detail

...
 no description
 address 192.168.0.0/16 broadcast host-ones
 no mac
 arp-timeout 14400
 no allow-directed-broadcasts
 icmp
 mask-reply
 unreachable 100 10
 ttl-expired 100 10
 exit
 dhcp
 shutdown
 no description
 option
 action keep
 circuit-id ifindex
 no remote-id
 no vendor-specific-option
 exit
 no server

```

```

 no trusted
 exit
 ip-mtu 1524
 no bfd
 ipcp
 no peer-ip-address
 no dns
 exit
 proxy-arp policy "proxyARPolicy"
 local proxy-arp
 remote proxy-arp
 no shutdown...

```

### 6.5.2.3 IES IPv6 Service

Use the following CLI syntax to configure interface parameters for the IES IPv6 service.

**CLI Syntax:**

```

config>service# ies service-id [customer customer-id]
 [create] [vpn vpn-id]
 interface ip-int-name
 ipv6
 address ipv6-address/prefix-length
 [eui-64]
 dhcp6-relay
 description description-string
 option
 interface-id
 interface-id ascii-tuple
 interface-id ifindex
 interface-id sap-id
 interface-id string
 remote-id
 server ipv6-address
 [ipv6-address...(up to 8 max)]
 no shutdown
 icmp6
 packet-too-big [number seconds]
 param-problem [number seconds]
 time-exceeded [number seconds]
 unreachablees [number seconds]
 neighbor ipv6-address mac-address
 reachable-time seconds
 stale-time seconds

```

**Example:**

```

config>service# ies 9
config>service>ies$ interface "ies_interface"
config>service>ies>if$ ipv6

```

```

config>service>ies>if>ipv6$ address
2001:db8:0:1:1:1:1:1/24
config>service>ies>if>ipv6$ dhcp6-relay
config>service>ies>if>ipv6>dhcp6-relay$ server
2001:db8::1
config>service>ies>if>ipv6>dhcp6-relay$ option
config>service>ies>if>ipv6>dhcp6-relay>option$
interface-id ascii-tuple
config>service>ies>if>ipv6>dhcp6-relay>option$ exit
config>service>ies>if>ipv6$ icmp
config>service>ies>if>ipv6>icmp6$ packet-too-big 80 10
config>service>ies>if>ipv6>icmp6$ exit
config>service>ies>>if>ipv6# neighbor 2001:db8::2
config>service>ies>>if>ipv6>neighbor# exit
config>service>ies>>if>ipv6# reachable-time 30
config>service>ies>>if>ipv6# stale-time 14400
config>service>ies>>if>ipv6# exit

```

The following example displays the IES interface IPv6 output.

```

A:ALU-41>config>service>ies>if># info detail

...
no description
address 2001:db8:0:1:1:1:1:1/24
dhcp6-relay
no description
option
interface-id ascii-tuple
no remote-id
server 2001:db8:0:1:1:1:1:1
exit
icmp6
packet-too-big 80 10
param-problem 100 10
time-exceeded 100 10
unreachables 100 10
exit
exit
...
reachable-time 30
stale-time 14400
exit
...

```

## 6.5.3 Configuring IES SAP Parameters

Configure IES SAP parameters for:

- [IES Management SAP](#)
- [IES Service SAP](#)

### 6.5.3.1 IES Management SAP

Use the following CLI syntax to configure IES management SAP parameters.

**Note:** The encapsulation type is always aal5mux-ip.

**CLI Syntax:**

```
config>service# ies service-id [customer customer-id]
[create] [vpn vpn-id]
 interface ip-int-name
 sap sap-id [create]
 atm
 encapsulation encap-type
 egress
 traffic-desc traffic-desc-
 profile-id
 ingress
 traffic-desc traffic-desc-
 profile-id
 oam
 alarm-cells
 description description-string
 ingress
 filter ip ip-filter-id
 no shutdown
```

**Example:**

```
A:ALU-41>config>service# ies 5
A:ALU-41>config>service>ies# interface "ATMoIP
Management"
A:ALU-41>config>service>ies>if# sap 1/1/1.1:0/32 create
A:ALU-41>config>service>ies>if>sap# ingress
A:ALU-41>config>service>ies>if>sap>ingress# filter ip 3
A:ALU-41>config>service>ies>if>sap>ingress# exit
A:ALU-41>config>service>ies>if>sap# atm
A:ALU-41>config>service>ies>if>sap>atm# encapsulation
aal5mux-ip
```

```

A:ALU-41>config>service>ies>if>sap>atm# egress
A:ALU-41>config>service>ies>if>sap>atm>egress# traffic-
desc 3
A:ALU-41>config>service>ies>if>sap>atm>egress# exit
A:ALU-41>config>service>ies>if>sap>atm# ingress
A:ALU-41>config>service>ies>if>sap>atm>ingress#
traffic-desc 2
A:ALU-41>config>service>ies>if>sap>atm>ingress# exit
A:ALU-41>config>service>ies>if>sap>atm# oam
A:ALU-41>config>service>ies>if>sap>atm>oam# alarm-cells
A:ALU-41>config>service>ies>if>sap>atm>oam# exit
A:ALU-41>config>service>ies>if>sap>atm# exit
A:ALU-41>config>service>ies>if>sap# exit
A:ALU-41>config>service>ies>if# exit
A:ALU-41>config>service>ies#

```

The following example displays the IES SAP creation output.

```

A:ALU-41>config>service>ies>if>sap# info detail

...
 no description
 ingress
 filter ip 3
 exit
 atm
 encapsulation aal5mux-ip
 ingress
 traffic-desc 2
 exit
 egress
 traffic-desc 3
 exit
 oam
 alarm-cells
 exit
 exit
 no shutdown

```

### 6.5.3.2 IES Service SAP

Use the following CLI syntax to configure SAP parameters for the IES service.

**Note:** A SAP cannot be defined if the **loopback** command is enabled on the interface.

**CLI Syntax:**

```
config>service# ies service-id [customer customer-id]
[create] [vpn vpn-id]
 interface ip-int-name
 sap sap-id [create]
 accounting policy acct-policy-id
 collect stats
 description description-string
 egress
 filter ip ip-filter-id
 filter ipv6 ipv6-filter-id
 qos policy-id
 ingress
 filter ip ip-filter-id
 filter ipv6 ipv6-filter-id
 qos policy-id
 no shutdown
```

**Example:**

```
A:ALU-41>config>service# ies 4
A:ALU-41>config>service>ies$ interface "to Internet"
A:ALU-41>config>service>ies>if$ sap 1/4/1 create
A:ALU-41>config>service>ies>if>sap$ egress
A:ALU-41>config>service>ies>if>sap>egress$ qos 3
A:ALU-41>config>service>ies>if>sap$ ingress
A:ALU-41>config>service>ies>if>sap>ingress$ filter ip 3
```

The following example displays the IES SAP creation output.

```
A:ALU-41>config>service>ies>if>sap# info detail

...
 no description
 egress
 qos 3
 ingress
 filter ip 3
 exit
 no shutdown

```

## 6.5.4 Configuring IES Spoke SDP Parameters

Use the following CLI syntax to configure spoke SDP parameters for the IES service.

**CLI Syntax:**

```
config>service# ies service-id [customer customer-id]
[create] [vpn vpn-id]
 interface ip-int-name
 spoke-sdp sdp-id:vc-id [create]
 egress
 vc-label egress-vc-label
 ingress
 filter ip ip-filter-id
 vc-label ingress-vc-label
 [no] shutdown
```

**Example:**

```
A:ALU-41>config>service# ies 6
A:ALU-41>config>service>ies$ interface "ies6_interface"
A:ALU-41>config>service>ies>if$ spoke-sdp 5:6 create
A:ALU-41>config>service>ies>if>spoke-sdp$ ingress
A:ALU-41>config>service>ies>if>spoke-sdp>ingress$
 filter ip 56
A:ALU-41>config>service>ies>if>spoke-sdp>ingress$ vc-
 label 5566
```

The following example displays the IES spoke SDP creation output.

```
A:ALU-41>config>service>ies>if>spoke SDP# info detail

...
 no description
 egress
 no vc-label
 ingress
 filter ip 56
 vc-label 5566
 exit
 no shutdown

```

## 6.5.5 Configuring VRRP

Configuring VRRP policies and instances on service interfaces is optional. The basic owner and non-owner VRRP configurations on an IES interface must specify the backup **ip-address** parameter.

VRRP helps eliminate the single point of failure in a routed environment by using virtual router IP addresses shared between two or more routers connecting the common domain. VRRP provides dynamic failover of the forwarding responsibility to the backup router if the master becomes unavailable.

The VRRP implementation allows one master per IP subnet. All other VRRP instances in the same domain must be in backup mode.

For further information about VRRP CLI syntax and command descriptions for an IES service interface, see [IES Command Reference](#). For overview information on VRRP and VRRP IES interface parameters, refer to the “VRRP” chapter in the 7705 SAR Router Configuration Guide.

The following displays an IES interface VRRP owner configuration:

```
config>service>ies> info
#-----
...
 interface "vrrpowner"
 address 10.10.10.23/16
 vrrp 1 owner
 backup 10.10.10.24
 authentication-key "testabc"
 exit
 exit
...
#-----
config>service>ies#

config>service>ies>if># info

...
 ipv6
 address 2001:db8:0:1:1:1:1:1/16
 vrrp 1 owner
 backup 2001:db8:0:1:1:1:1:2
 exit
 exit
 exit
...

```

## 6.5.6 Configuring a Security Zone Within IES

To configure NAT or firewall security, you must:

- configure a NAT or firewall security profile and policy in the **config>security** context
  - in the **config>security>profile** context, specify the timeouts for the TCP/UDP/ICMP protocols and configure logging and application assurance parameters. This step is optional. If you do not configure the profile, a default profile is assigned.
  - in the **config>security>policy** context, configure a security policy, specify the match criteria and the action to be applied to a packet if a match is found.
- configure a security zone and apply the policy ID to the zone, as shown in the CLI syntax below

**CLI Syntax:**

```

config>service
 ies service-id [customer customer-id] [create]
 abort
 begin
 commit
 zone zone-id [create]
 description description-string
 interface ip-int-name [create]
 name zone-name
 nat
 pool pool-id [create]
 description description-string
 direction {zone-outbound | zone-
 inbound | both}
 entry entry-id [create]
 ip-address ip-address [to ip-
 address] interface ip-int-
 name
 port port [to port] interface
 ip-int-name
 name pool-name
 policy policy-id | policy-name
 shutdown

```

The following example displays a NAT zone configuration output.

```

A:ALU-B>config>service>ies# info

configure
 service ies 10 create
 zone 1 create

```

```

begin
 name "IES zone"
 description "uplink zone from private"
 interface ies-100-10.30.10.1
 exit
 nat
 pool 1 create
 description "pool 1"
 direction zone-inbound
 exit
 entry 1 create
 ip-addr interface ies-100-198.51.100.0/24
 exit
 exit
 exit
 policy 1 nat pool 1
 commit
exit
no-shutdown

A:ALU-B>config>service>ies#

```

## 6.5.7 Configuring Serial Raw Socket Transport Within IES

Configure an IP transport subservice within an IES service in order to enable the transport of serial data using raw sockets.

**CLI Syntax:**

```

config>service
 ies service-id [customer customer-id] [create]
 ip-transport ipt-id [create]
 description description-string
 filter-unknown-host
 local-host ip-addr ip-addr port-num port-
 num] protocol {tcp|udp}
 remote-host host-id [ip-addr ip-
 addr] [port-num port-num] [create]
 description description-string
 name host-name
 exit
 fc fc-name profile {in |out}
 shutdown
 tcp
 inactivity-timeout number
 max-retries seconds
 retry-interval seconds
 exit
 exit
 exit
exit

```

---

The following example displays an IP transport subservice configuration output.

```
A:ALU-B>config>service>ies# info

configure
 service ies 20 create
 ip-transport 1/2/4.1 create
 description "ip-transport one"
 filter-unknown-host
 local-host ip-address 192.168.1.1 port-number 4000 protocol udp
 exit
 remote-host 1 ip-address 192.168.1.7 port-number 4001 create
 exit
 exit
 no-shutdown

A:ALU-B>config>service>ies#
```

---

## 6.6 Service Management Tasks

This section discusses the following service management tasks:

- [Modifying IES Service Parameters](#)
- [Disabling an IES Service](#)
- [Re-enabling an IES Service](#)
- [Deleting an IES Service](#)

### 6.6.1 Modifying IES Service Parameters

Existing IES service parameters can be modified, added, removed, enabled, or disabled.

To display a list of customer IDs, use the **show>service>customer** command.

Enter the parameters (such as description, interface information, or SAP information), and then enter the new information.

The following is an example of changing the IP MTU size.

**Example:**

```
A:ALU-41>config>service# ies 5
A:ALU-41>config>service>ies# interface "testname"
A:ALU-41>config>service>ies>if# ip-mtu 1517
A:ALU-41>config>service>ies>if# exit
```

### 6.6.2 Disabling an IES Service

An IES service can be shut down without deleting the service parameters.

Use the **shutdown** command to shut down an IES service.

**CLI Syntax:**

```
config>service# ies service-id
shutdown
```

**Example:**

```
A:ALU-41>config>service# ies 5
A:ALU-41>config>service>ies# shutdown
A:ALU-41>config>service>ies# exit
```

---

### 6.6.3 Re-enabling an IES Service

Use the **no shutdown** command to re-enable a previously disabled IES service.

**CLI Syntax:**     `config>service# ies service-id  
                  no shutdown`

**Example:**       `A:ALU-41>config>service# ies 5  
A:ALU-41>config>service>ies# no shutdown  
A:ALU-41>config>service>ies# exit`

### 6.6.4 Deleting an IES Service

An IES service cannot be deleted until SAPs, spoke SDPs, and interfaces are shut down and deleted and the service is shut down on the service level.

Use the following CLI syntax to delete an IES service:

**CLI Syntax:**     `config>service#  
                  ies service-id  
                  interface ip-int-name  
                  sap sap-id  
                  shutdown  
                  exit  
                  no sap sap-id  
                  spoke-sdp sdp-id:vc-id  
                  shutdown  
                  exit  
                  no spoke-sdp sdp-id:vc-id  
                  interface ip-int-name  
                  shutdown  
                  exit  
                  no interface ip-int-name  
                  shutdown  
                  exit  
                  no ies service-id`

## 6.7 IES Command Reference

### 6.7.1 Command Hierarchies

- [Configuration Commands](#)
  - [IES Management Configuration Commands](#)
  - [IES Service Configuration Commands](#)
  - [Routed VPLS Commands](#)
  - [VRRP Commands](#)
  - [IES Security Zone Configuration Commands](#)
  - [IES Raw Socket IP Transport Configuration Commands](#)
- [Show Commands](#)
- [Clear Commands](#)

## 6.7.1.1 Configuration Commands

### 6.7.1.1.1 IES Management Configuration Commands

```

config
— service
— ies service-id [customer customer-id] [create] [vpn vpn-id]
— no ies service-id
— description description-string
— no description
— interface ip-int-name [create]
— no interface ip-int-name
— address {ip-address/mask | ip-address netmask}
— no address
— bfd transmit-interval [receive receive-interval] [multiplier multiplier]
 [type np]
— no bfd
— description description-string
— no description
— ip-mtu octets
— no ip-mtu
— sap sap-id [create]
— no sap sap-id
— atm
— encapsulation atm-encap-type
— egress
— traffic-desc traffic-desc-profile-id
— no traffic-desc
— ingress
— traffic-desc traffic-desc-profile-id
— no traffic-desc
— oam
— [no] alarm-cells
— description description-string
— no description
— ingress
— filter ip ip-filter-id
— no filter ip
— no filter ip [ip ip-filter-id]
— [no] shutdown
— [no] shutdown
— service-name service-name
— no service-name
— [no] shutdown

```

### 6.7.1.1.2 IES Service Configuration Commands

```

config
 — service
 — ies service-id [customer customer-id] [create] [vpn vpn-id]
 — description description-string
 — no description
 — [no] interface ip-int-name [create]
 — address {ip-address/mask | ip-address netmask} [broadcast {all-ones
 | host-ones}]
 — no address {ip-address/mask | ip-address netmask}
 — [no] allow-directed broadcasts
 — arp-retry-timer ms-timer
 — no arp-retry-timer
 — arp-timeout seconds
 — no arp-timeout
 — bfd transmit-interval [receive receive-interval] [multiplier multiplier]
 [type np]
 — no bfd
 — cflowd-parameters
 — sampling {unicast | multicast} type {interface} [direction
 {ingress-only | egress-only | both}]
 — no sampling {unicast | multicast}
 — description description-string
 — no description
 — dhcp
 — description description-string
 — no description
 — gi-address ip-address [src-ip-addr]
 — no gi-address
 — [no] option
 — action {replace | drop | keep}
 — no action
 — circuit-id [ascii-tuple | ifindex | sap-id |
 vlan-ascii-tuple]
 — no circuit-id
 — remote-id [mac | string string]
 — no remote-id
 — [no] vendor-specific option
 — [no] client-mac-address
 — [no] sap-id
 — [no] service-id
 — string text
 — no string
 — [no] system-id
 — server server1 [server2...(up to 8 max)]
 — no server
 — [no] shutdown
 — [no] trusted
 — icmp
 — [no] mask-reply
 — ttl-expired [number seconds]
 — no ttl-expired

```

### 6.7.1.1.3 Routed VPLS Commands

- ```

config
  — service
    — ies service-id
      — interface ip-interface-name [create]
      — no interface ip-interface-name
        — vpls service-name
        — no vpls
          — ingress
            — v4-routed-override-filter ip-filter-id
            — no v4-routed-override-filter
            — v6-routed-override-filter ipv6-filter-id
            — no v6-routed-override-filter

```

6.7.1.1.4 VRRP Commands

- ```

config
 — service
 — ies service-id [customer customer-id] [create] [vpn vpn-id]
 — [no] interface ip-int-name
 — [no] ipv6
 — vrrp virtual-router-id [owner]
 — no vrrp virtual-router-id
 — [no] backup ipv6-address
 — [no] bfd-enable service-id interface interface-name
 dst-ip ip-address
 — [no] bfd-enable interface interface-name dst-ip
 ip-address
 — init-delay seconds
 — no init-delay
 — mac mac-address
 — no mac
 — [no] master-int-inherit
 — message-interval {[seconds] [milliseconds]}
 — no message-interval
 — [no] ping-reply
 — policy vrrp-policy-id
 — no policy

```

---

— no vrrp virtual-router-id
— authentication-key [authentication-key | hash-key] [hash |
 hash2]
— no authentication-key
— [no] backup ip-address
— [no] bfd-enable service-id interface interface-name dst-ip
 ip-address
— [no] bfd-enable interface interface-name dst-ip ip-address
— init-delay seconds
— no init-delay
— mac mac-address
— no mac
— [no] master-int-inherit
— message-interval {[seconds] [milliseconds milliseconds]}
— no message-interval
— [no] ping-reply
— policy vrrp-policy-id
— no policy
— [no] preempt
— priority priority
— no priority
— [no] shutdown
— [no] ssh-reply
— [no] standby-forwarding
— [no] telnet-reply
— [no] traceroute-reply

```

#### 6.7.1.1.5 IES Security Zone Configuration Commands

```

config
— service
— ies service-id [customer customer-id] [create]
— no ies service-id
— zone {zone-id | zone-name} [create]
— no zone {zone-id | zone-name}
— abort
— begin
— commit
— description description-string
— no description
— inbound
— limit
— concurrent-sessions {tcp | udp | icmp | other} sessions

```

---

```

— no concurrent-sessions {tcp | udp | icmp | other}
— [no] interface interface-name
— [no] shutdown
— log {log-id | name}
— no log
— name zone-name
— no name
— nat
— pool pool-id [create]
— no pool pool-id
— description description-string
— no description
— direction {zone-outbound | zone-inbound | both}
— no direction
— entry entry-id [create]
— no entry entry-id
— ip-address ip-address [to ip-address] interface
ip-int-name
— no ip-address
— port port [to port]
— no port
— name pool-name
— no name
— outbound
— limit
— concurrent-sessions {tcp | udp | icmp | other} sessions
— no concurrent-sessions {tcp | udp | icmp | other}
— policy {policy-id | policy-name}
— no policy
— [no] shutdown

```

#### 6.7.1.1.6 IES Raw Socket IP Transport Configuration Commands

```

config
— service
— ies service-id [customer customer-id] [create]
— no ies service-id
— ip-transport ipt-id [create]
— no ip-transport ipt-id
— description description-string
— no description
— dscp dscp-name
— fc fc-name profile {in | out}
— [no] filter-unknown-host
— local-host ip-addr ip-addr port-num port-num protocol {tcp | udp}
— no local-host
— remote-host host-id [ip-addr ip-addr] [port-num port-num] [create]
— no remote-host host-id
— description description-string
— no description
— name host-name

```

- **no name**
- **[no] shutdown**
- **tcp**
  - **inactivity-timeout** *seconds*
  - **max-retries** *number*
  - **retry-interval** *seconds*

| <b>Syntax</b>      | <b>[no] shutdown</b>                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Context</b>     | config>service>ies<br>config>service>ies>interface<br>config>service>ies>if>dhcp<br>config>service>ies>if>ipv6>dhcp6-relay<br>config>service>ies>if>sap<br>config>service>ies>if>vrrp<br>config>service>ies>if>ipv6>vrrp<br>config>service>ies>ip-transport                                                                                                                                                                |
| <b>Description</b> | <p>This command administratively disables an entity. The operational state of the entity is disabled as well as the operational state of any entities contained within. When disabled, an entity does not change, reset, or remove any configuration settings or statistics. Many objects must be shut down before they may be deleted. Many entities must be explicitly enabled using the <b>no shutdown</b> command.</p> |

The **no** form of this command places the entity into an administratively enabled state.

The **dhcp** and **dhcp6-relay** commands do not apply to IES when used for in-band management.

Services are created in the administratively down (**shutdown**) state. When a **no shutdown** command is entered, the service becomes administratively up and tries to enter the operationally up state. Default administrative states for services and service entities are described in the following Special Cases.

**Special Cases**    **IES** — the default administrative status of an IES service is down. While the service is down, its associated interface is operationally down.

For example, if:

- 1) An IES service is operational and its associated interface is shut down
- 2) The IES service is administratively shut down and brought back up
- 3) The interface that is shut down remains in the administrative shutdown state

A service is regarded as operational provided that one IP interface is operational.

**IES IP Interfaces** — when the IP interface is shut down, it enters the administratively and operationally down states. For a SAP bound to the IP interface, no packets are transmitted out of the SAP and all packets received on the SAP are dropped and the packet discard counter is incremented.

**IES IP transport subservice** — when an IP transport subservice within an IES service is shut down, all TCP/UDP packets received from remote hosts are dropped and any serial data received from the serial port is dropped. Any TCP connections that were up are closed and no new TCP connection requests are accepted.

It is not possible to make configuration changes to an IP transport subservice without performing a **shutdown** first.

The operational state of an IP transport subservice is relative to the operational state of the serial port for which the IP transport subservice is defined. When a serial port is shut down, the IP transport subservice associated with the serial port becomes operationally down.

When the **no shutdown** command is executed for an IP transport subservice, it becomes operationally up, serial data from the serial port is encapsulated in TCP/UDP packets destined for remote hosts, and TCP/UDP packets can be received by the local host, where raw serial data is then sent out the serial port.

### 6.7.2.1.2 IES Global Commands

#### ies

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Description</b> | <p>This command enables Internet Enhanced Service (IES). On the 7705 SAR, IES is used for direct IP connectivity between customer access points as well as in-band management of the 7705 SAR over ATM links.</p> <p>The <b>no</b> form of this command deletes the IES service instance with the specified <i>service-id</i>.</p> <p>The service cannot be deleted until all the IP interfaces defined within the service ID have been shut down and deleted.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <p><i>service-id</i> — uniquely identifies a service in the service domain. This ID must be unique to this service and may not be used for any other service of any type. The <i>service-id</i> must be the same number or name used for every 7705 SAR on which this service is defined.</p> <p><b>Values</b> 1 to 2147483647 or <i>service-name</i></p> <p><i>customer-id</i> — specifies the customer ID number to be associated with the service. This parameter is required on service creation and is optional for service editing or deleting.</p> <p><b>Values</b> 1 to 2147483647</p> <p><i>vpn-id</i> — specifies the VPN ID number, which allows you to identify virtual private networks (VPNs) by a VPN identification number. If this parameter is not specified, the VPN ID uses the service ID number. This parameter is not the same as the VRF ID used with VPRN services.</p> <p><b>Values</b> 1 to 2147483647</p> |

#### service-name

|                    |                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>service-name</b> <i>service-name</i><br><b>no service-name</b>                                                                     |
| <b>Context</b>     | config>service>ies                                                                                                                    |
| <b>Description</b> | This command configures a service name that can be used in other configuration commands and show commands that reference the service. |
| <b>Parameters</b>  | <i>service-name</i> — up to 64 characters                                                                                             |

### 6.7.2.1.3 IES Management Interface Commands

#### interface

| <b>Context</b>     | config>service>ies                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b> | <p>This command creates a logical IP routing interface for an Internet Enhanced Service (IES). Once created, attributes like an IP address and service access point (SAP) can be associated with the IP interface.</p> <p>The <b>interface</b> command, under the context of services, creates and maintains IP routing interfaces within IES service IDs. The interface command can be executed in the context of an IES service ID. Two SAPs can be assigned to a single group interface.</p> <p>Interface names are case-sensitive and must be unique within the group of IP interfaces defined for <b>config router interface</b> and <b>config service ies interface</b> (that is, the network core router instance). Interface names cannot be in the dotted-decimal notation of an IP address. For example, the name “1.1.1.1” is not allowed, but “int-1.1.1.1” is allowed. Show commands for router interfaces use either interface names or the IP addresses. Use unique IP address values and IP address names to maintain clarity. It could be unclear to the user if the same IP address and IP address name values are used. Although not recommended, duplicate interface names can exist in different router instances.</p> <p>When a new name is entered, a new logical router interface is created. When an existing interface name is entered, the user enters the router interface context for editing and configuration.</p> <p>There are no default IP interface names defined within the system. All IES IP interfaces must be explicitly defined. Interfaces are created in an enabled state.</p> <p>The <b>no</b> form of this command removes the IP interface and all the associated configurations. The interface must be administratively shut down before issuing the no interface command. The IP interface must be shut down before the SAP on that interface can be removed.</p> |
| <b>Default</b>     | no interface                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <p><i>ip-int-name</i> — the name of the IP interface. Interface names must be unique within the group of IP interfaces defined for the network core router instance. An interface name cannot be in the form of an IP address. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.</p> <p><b>Values</b> 1 to 32 characters (must start with a letter)</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

If the *ip-int-name* already exists, the context is changed to maintain that IP interface. If the *ip-int-name* already exists as an IP interface defined within the **config router** command, an error will occur and the context will not be changed to that IP interface. If the *ip-int-name* does not exist, the interface is created and the context is changed to that interface for further command processing.

| <b>Context</b>     | config>service>ies>interface                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b> | <p>This command assigns an IP address and IP subnet to an IES IP interface. Only one IP address can be associated with an IP interface.</p> <p>An IP address must be assigned to each IP interface. An IP address and a mask combine to create a local IP prefix. The defined IP prefix must be unique within the context of the routing instance. The IP prefix cannot overlap with other existing IP prefixes defined as local subnets on other IP interfaces in the same routing context within the 7705 SAR.</p> <p>The IP address for the interface can be entered in either CIDR (classless inter-domain routing) notation or traditional dotted-decimal notation. <b>Show</b> commands display CIDR notation and are stored in configuration files.</p> <p>By default, no IP address or subnet association exists on an IP interface until it is explicitly created.</p> <p>The <b>no</b> form of the command removes the IP address assignment from the IP interface. The <b>no</b> form of this command can only be performed when the IP interface is administratively shut down. Shutting down the IP interface brings the interface operationally down.</p> |
| <b>Default</b>     | no address                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b>  | <p><i>ip-address</i> — the IP address of the IP interface. The <i>ip-address</i> portion of the <b>address</b> command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted-decimal notation.</p> <p><b>Values</b> 1.0.0.0 to 223.255.255.255</p> <p><i>/</i> — the forward slash is a parameter delimiter that separates the <i>ip-address</i> portion of the IP address from the mask that defines the scope of the local subnet. No spaces are allowed between the <i>ip-address</i>, the “/”, and the <i>mask</i> parameter. If a forward slash does not immediately follow the <i>ip-address</i>, a dotted-decimal mask must follow the prefix.</p>                                                                                                                                                                                                                                                                                                                                                                                                        |

*mask* — the subnet mask length when the IP prefix is specified in CIDR notation. When the IP prefix is specified in CIDR notation, a forward slash (/) separates the *ip-address* from the *mask* parameter. The *mask* parameter indicates the number of bits used for the network portion of the IP address; the remainder of the IP address determines the host portion of the IP address.

**Values** 1 to 32 (mask length of 32 is reserved for system IP addresses)

*netmask* — the subnet mask in dotted-decimal notation

**Values** 0.0.0.0 to 255.255.255.255 (network bits all 1 and host bits all 0)

## bfd

| <b>Description</b> | This command configures the time interval in which BFD control messages are transmitted and received on the interface. The <i>multiplier</i> parameter specifies the number of consecutive BFD messages that must be missed by the peer node before the BFD session closes and the upper layer protocols (OSPF, IS-IS, BGP, PIM) are notified of the fault.                                                                                                                                                      |
| <b>Default</b>     | no bfd                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <p><i>transmit-interval</i> — the number of milliseconds between consecutive BFD sent messages</p> <p><b>Values</b> 10 to 100000</p> <p><b>Default</b> 100</p> <p><i>receive-interval</i> — the number of milliseconds between consecutive BFD received messages</p> <p><b>Values</b> 10 to 100000</p> <p><b>Default</b> 100</p> <p><i>multiplier</i> — the number of consecutive BFD messages that must be missed before the interface is brought down</p> <p><b>Values</b> 3 to 20</p> <p><b>Default</b> 3</p> |

*type np* — controls the value range of the *transmit-interval* and *receive-interval* parameters. If the **type np** option is not specified, the range of the *transmit-interval* and *receive-interval* parameter values is from 100 ms to 100000 ms. If the **type np** option is specified, the range of the *transmit-interval* and *receive-interval* parameter values is from 10 ms to 1000 ms, with the restriction that the maximum receiving detection time for the missing BFD packets must be less than or equal to 3000 ms. The maximum receiving detection time is the *receive-interval* parameter multiplied by the *multiplier* parameter.

**Note:** The BFD session must be disabled before the **type np** parameter can be changed.

| <b>Description</b> | <p>This command creates a SAP within an IES service. Each SAP must be unique.</p> <p>All SAPs must be explicitly created with the <b>create</b> keyword. If no SAPs are created within a service or on an IP interface, a SAP will not exist on that object.</p> <p>Enter an existing SAP without the <b>create</b> keyword to edit SAP parameters.</p> <p>A SAP can only be associated with a single service. The SAP is owned by the service in which it was created. An IES SAP can only be defined on an ATM port or IMA group that has been configured as an access port in the <b>config&gt;port</b> <i>port-id</i> context using the <b>mode access</b> command. Fractional TDM ports are always access ports. Refer to the 7705 SAR Interface Configuration Guide for information on access ports.</p> <p>If a port is shut down, all SAPs on that port become operationally down. When a service is shut down, SAPs for the service are not displayed as operationally down although all traffic traversing the service will be discarded. The operational state of a SAP is relative to the operational state of the port on which the SAP is defined.</p> <p>The <b>no</b> form of this command deletes the SAP with the specified port. When a SAP is deleted, all configuration parameters for the SAP will also be deleted.</p> |
| <b>Default</b>     | no sap                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <p><i>sap-id</i> — specifies the physical port identifier portion of the SAP definition. See <a href="#">Table 41</a> for a full list of SAP IDs.</p> <p><b>create</b> — keyword used to create a SAP instance. The create keyword requirement can be enabled/disabled in the <b>environment&gt;create</b> context.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Description</b> | <p>This command associates an IP filter policy with an ingress SAP. Filter policies control the forwarding and dropping of packets based on the IP match criteria. Only one filter ID can be specified.</p> <p>The filter policy must already be defined before the filter command is executed. If the filter policy does not exist, the operation fails and an error message is returned. Filters applied to the ingress SAP apply to all IP packets on the SAP.</p> <p>The <b>no</b> form of this command removes any configured filter ID association with the SAP.</p> |
| <b>Default</b>     | no filter                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Parameters</b>  | <i>ip-filter-id</i> — specifies the IP filter policy. The filter ID or filter name must already exist within the created IP filters.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Values</b>      | 1 to 65535 or <i>filter-name</i> (up to 64 characters)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

**Note:** For information on configuring IP filter IDs, refer to the 7705 SAR Router Configuration Guide, “Filter Policies”.

atm

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Context</b>     | config>service>ies>if>sap                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | <p>This command enables access to the context to configure ATM-related attributes. This command can only be used when a given context (for example, a channel or SAP) supports ATM functionality such as:</p> <ul style="list-style-type: none"><li>• configuring ATM port or ATM port-related functionality on T1/E1 ASAP Adapter cards on a 7705 SAR-8 or 7705 SAR-18, or on T1/E1 ports on a 7705 SAR-M (variants with T1/E1 ports)</li><li>• configuring ATM-related configuration for ATM-based SAPs that exist on T1/E1 ASAP Adapter cards or T1/E1 ports on a 7705 SAR-8 or 7705 SAR-18, or on T1/E1 ports on a 7705 SAR-M (variants with T1/E1 ports)</li></ul> |

If ATM functionality is not supported for a given context, the command returns an error.

---

## encapsulation

|                    |                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>encapsulation</b> <i>atm-encap-type</i>                                                                                                                                                                                                                                                                                                                                        |
| <b>Context</b>     | config>service>ies>if>sap>atm                                                                                                                                                                                                                                                                                                                                                     |
| <b>Description</b> | <p>This command configures an ATM VC SAP for encapsulation in accordance with RFC 2684, <i>Multiprotocol Encapsulation over ATM Adaptation Layer 5</i>. This command is only supported in the IP over ATM management context.</p> <p>The only supported encapsulation type is aal5mux-ip.</p> <p>Ingress traffic that does not match the configured encapsulation is dropped.</p> |
| <b>Default</b>     | aal5mux-ip                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <i>atm-encap-type</i> — aal5mux-ip (routed IP encapsulation for a VC multiplexed circuit as defined in RFC 2684)                                                                                                                                                                                                                                                                  |

## egress

|                    |                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>egress</b>                                                                                     |
| <b>Context</b>     | config>service>ies>if>sap>atm                                                                     |
| <b>Description</b> | This command provides access to the context to configure egress ATM traffic policies for the SAP. |

## ingress

|                    |                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ingress</b>                                                                                     |
| <b>Context</b>     | config>service>ies>if>sap>atm                                                                      |
| <b>Description</b> | This command provides access to the context to configure ingress ATM traffic policies for the SAP. |

## traffic-desc

|                    |                                                                                     |
|--------------------|-------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>traffic-desc</b> <i>traffic-desc-profile-id</i><br><b>no traffic-desc</b>        |
| <b>Context</b>     | config>service>ies>if>sap>atm>egress<br>config>service>ies>if>sap>atm>ingress       |
| <b>Description</b> | This command assigns an ATM traffic descriptor profile to an egress or ingress SAP. |

When configured under the ingress context, the specified traffic descriptor profile defines the traffic contract in the forward direction.

When configured under the egress context, the specified traffic descriptor profile defines the traffic contract in the backward direction.

**Note:** Proper configuration of the traffic descriptor profiles is essential for proper operation of the IES SAP. If no profile is assigned, the default UBR service category is assumed. All IES 7705 SAR traffic is scheduled; no shaping is supported in this mode. To ensure that IP traffic transported over the IES SAP is prioritized fairly, ATM layer traffic descriptors should be assigned.

The **no** form of the command reverts to the default traffic descriptor profile.

**Default** The default traffic descriptor (trafficDescProfileId. = 1) is associated with newly created ATM VC SAPs.

**Parameters** *traffic-desc-profile-id* — specifies a defined traffic descriptor profile (for information on defining traffic descriptor profiles, see the 7705 SAR Quality of Service Guide)

**Values** 1 to 1000

oam

**Syntax** oam

**Context** config>service>ies>if>sap>atm

**Description** This command enables the context to configure OAM functionality for an IES SAP.

The T1/E1 ASAP Adapter cards support F4 and F5 end-to-end OAM functionality (AIS, RDI, Loopback).

alarm-cells

**Syntax** [no] alarm-cells

**Context** config>service>ies>if>sap>atm>oam

**Description** This command configures AIS/RDI fault management on a PVCC. Fault management allows PVCC terminations to monitor and report the status of their connection by propagating fault information through the network and by driving the PVCC operational status.

Layer 2 OAM AIS/RDI cells that are received on the IES SAP will cause the IP interface to be disabled.

---

The **no** command disables alarm-cells functionality for the SAP. When alarm-cells functionality is disabled, OAM cells are not generated as result of the SAP going into the operationally down state.

**Default**    enabled

---

| <b>Description</b> | <p>This command creates a logical IP routing interface for Internet Enhanced Service (IES). When created, attributes like an IP address and service access point (SAP) can be associated with the IP interface.</p> <p>The interface command, under the context of services, creates and maintains IP routing interfaces within IES service IDs. The interface command can be executed in the context of an IES service ID. The IP interface created is associated with the service core network routing instance and the default routing table. Two SAPs can be assigned to a single group interface.</p> <p>Interface names are case-sensitive and must be unique within the group of IP interfaces defined for <b>config router interface</b> and <b>config service ies interface</b> (that is, the network core router instance). Interface names cannot be in the dotted-decimal format of an IP address. For example, the name “1.1.1.1” is not allowed, but “int-1.1.1.1” is allowed. Show commands for router interfaces use either interface names or the IP addresses. Use unique IP address values and IP address names to maintain clarity. It could be unclear to the user if the same IP address and IP address name values are used. Although not recommended, duplicate interface names can exist in different router instances.</p> <p>When a new name is entered, a new logical router interface is created. When an existing interface name is entered, the user enters the router interface context for editing and configuration.</p> <p>There are no default IP interface names defined within the system. All IES IP interfaces must be explicitly defined. Interfaces are created in an enabled state.</p> <p>The <b>no</b> form of this command removes the IP interface and all the associated configurations. The interface must be administratively shut down before issuing the no interface command. The IP interface must be shut down before the SAP on that interface can be removed.</p> |
| <b>Default</b>     | no interface                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <p><i>ip-int-name</i> — the name of the IP interface. Interface names must be unique within the group of IP interfaces defined for the network core router instance. An interface name cannot be in the form of an IP address. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.</p> <p><b>Values</b> 1 to 32 characters (must start with a letter)</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

If the *ip-int-name* already exists, the context is changed to maintain that IP interface. If the *ip-int-name* already exists as an IP interface defined within the **config router** command, an error will occur and the context will not be changed to that IP interface. If the *ip-int-name* does not exist, the interface is created and the context is changed to that interface for further command processing.

| <b>Description</b> | <p>This command assigns an IP address, IP subnet, and broadcast address format to an IES IP interface.</p> <p>An IP address must be assigned to each IES IP interface. An IP address and a mask combine to create a local IP prefix. The defined IP prefix must be unique within the context of the routing instance. The IP prefix cannot overlap with other existing IP prefixes defined as local subnets on other IP interfaces in the same routing context within the 7705 SAR.</p> <p>The IP address for the interface can be entered in either CIDR (classless inter-domain routing) notation or traditional dotted-decimal notation. Show commands display CIDR notation and are stored in configuration files.</p> <p>By default, no IP address or subnet association exists on an IP interface until it is explicitly created.</p> <p>The <b>no</b> form of the command removes the IP address assignment from the IP interface. The <b>no</b> form of this command can only be performed when the IP interface is administratively shut down. Shutting down the IP interface brings the interface operationally down.</p> |
| <b>Default</b>     | no address                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Parameters</b>  | <p><i>ip-address</i> — the IP address of the IP interface. The <i>ip-address</i> portion of the <b>address</b> command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted-decimal notation.</p> <p><b>Values</b> 1.0.0.0 to 223.255.255.255</p> <p><i>/</i> — the forward slash is a parameter delimiter that separates the <i>ip-address</i> portion of the IP address from the mask that defines the scope of the local subnet. No spaces are allowed between the <i>ip-address</i>, the “/”, and the <i>mask</i> parameter. If a forward slash does not immediately follow the <i>ip-address</i>, a dotted-decimal mask must follow the prefix.</p>                                                                                                                                                                                                                                                                                                                                                                    |

*mask* — the subnet mask length when the IP prefix is specified in CIDR notation. When the IP prefix is specified in CIDR notation, a forward slash (/) separates the *ip-address* from the *mask* parameter. The *mask* parameter indicates the number of bits used for the network portion of the IP address; the remainder of the IP address determines the host portion of the IP address.

**Values** 1 to 32 (mask length of 32 is reserved for system IP addresses)

*netmask* — the subnet mask in dotted-decimal notation

**Values** 0.0.0.0 to 255.255.255.255 (network bits all 1 and host bits all 0)

**broadcast** — overrides the default broadcast address used by the IP interface when sourcing IP broadcasts on the IP interface. If no broadcast format is specified for the IP address, the default value is **host-ones**, which indicates a subnet broadcast address. Use this parameter to change the broadcast address to **all-ones** or revert to the default broadcast address of **host-ones**.

The broadcast format on an IP interface can be specified when the IP address is assigned or changed.

This parameter does not affect the type of broadcasts that can be received by the IP interface. A host sending either the local broadcast (all-ones) or the valid subnet broadcast address (host-ones) will be received by the IP interface.

**all-ones** — specifies that the broadcast address used by the IP interface for this IP address is 255.255.255.255 (also known as the local broadcast)

**host-ones** — specifies that the broadcast address used by the IP interface for this IP address is the subnet broadcast address. This is an IP address that corresponds to the local subnet described by the IP address and mask with all host bits set to 1. This IP address is the default broadcast address used by an IP interface.

allow-directed broadcasts

|                    |                                                                                     |
|--------------------|-------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] <b>allow-directed broadcasts</b>                                               |
| <b>Context</b>     | config>service>ies>interface                                                        |
| <b>Description</b> | This command enables the forwarding of directed broadcasts out of the IP interface. |

A directed broadcast is a packet received on a local router interface destined for the subnet broadcast address of another IP interface. The **allow-directed-broadcasts** command on an IP interface enables or disables the transmission of packets destined for the subnet broadcast address of the egress IP interface.

When enabled, a frame destined for the local subnet on this IP interface is sent as a subnet broadcast out this interface.

**Note:** Allowing directed broadcasts is a well-known mechanism used for denial-of-service attacks.

By default, directed broadcasts are not allowed and are discarded at this egress IP interface.

The **no** form of the command disables directed broadcasts forwarding out of the IP interface.

**Default** no allow-directed broadcasts

## arp-retry-timer

**Syntax** **arp-retry-timer** *ms-timer*  
**no arp-retry-timer**

**Context** config>service>ies>interface

**Description** This command specifies the length of time, in 100s of milliseconds, that the system waits before reissuing a failed ARP request.

The **no** form of the command resets the interval to the default value.

**Note:** The ARP retry default value of 5000 ms is intended to protect CPU cycles on the 7705 SAR, especially when it has a large number of interfaces. Configuring the ARP retry timer to a value shorter than the default should be done only on mission-critical links, such as uplinks or aggregate spoke SDPs transporting mobile traffic; otherwise, the retry interval should be left at the default value.

**Default** 50 (in 100s of ms)

**Parameters** *ms-timer* — the time interval, in 100s of milliseconds, the system waits before retrying a failed ARP request

**Values** 1 to 300

## arp-timeout

**Syntax** **arp-timeout** *seconds*  
**no arp-timeout**

**Context** config>service>ies>interface

**Description** This command configures the minimum interval, in seconds, that an ARP entry learned on the IP interface is stored in the ARP table. ARP entries are automatically refreshed when an ARP request or gratuitous ARP is seen from an IP host. Otherwise, the ARP entry is aged from the ARP table.

If the **arp-timeout** value is set to 0 s, ARP aging is disabled.

The **no** form of the command reverts to the default value.

**Note:** The 7705 SAR will attempt to refresh an ARP entry 30 s prior to its expiry. This refresh attempt occurs only if the ARP timeout is set to 45 s or more.

**Default** no arp-timeout

**Parameters** *seconds* — the minimum number of seconds a learned ARP entry is stored in the ARP table, expressed as a decimal integer. A value of 0 specifies that the timer is inoperative and learned ARP entries will not be aged.

**Values** 0 to 65535

**Default** 14400 s (4 h)

bfd

**Syntax** **bfd** [*transmit-interval*] [**receive** *receive-interval*] [**multiplier** *multiplier*] [**type np**]  
**no bfd**

**Context** config>service>ies>interface  
config>service>ies>if>ipv6

**Description** This command configures the time interval in which BFD control messages are transmitted and received on the interface. The *multiplier* parameter specifies the number of consecutive BFD messages that must be missed by the peer node before the BFD session closes and the upper layer protocols (OSPF, IS-IS, BGP, PIM) are notified of the fault.

**Default** no bfd

**Parameters** *transmit-interval* — the number of milliseconds between consecutive BFD sent messages

**Values** 10 to 100000

**Default** 100

*receive-interval* — the number of milliseconds between consecutive BFD received messages

**Values** 10 to 100000

**Default** 100

*multiplier* — the number of consecutive BFD messages that must be missed before the interface is brought down

**Values** 3 to 20

**Default** 3

*type np* — controls the value range of the *transmit-interval* and *receive-interval* parameters. If the **type np** option is not specified, the range of the *transmit-interval* and *receive-interval* parameter values is from 100 ms to 100000 ms. If the **type np** option is specified, the range of the *transmit-interval* and *receive-interval* parameter values is from 10 ms to 1000 ms, with the restriction that the maximum receiving detection time for the missing BFD packets must be less than or equal to 3000 ms. The maximum receiving detection time is the *receive-interval* parameter multiplied by the *multiplier* parameter.

**Note:** The BFD session must be disabled before the **type np** parameter can be changed.

### dhcp

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <b>Syntax</b>      | <b>dhcp</b>                                                    |
| <b>Context</b>     | config>service>ies>interface                                   |
| <b>Description</b> | This command enables the context to configure DHCP parameters. |

### gi-address

|                    |                                                                                                                                                                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>gi-address</b> <i>ip-address</i> [ <b>src-ip-addr</b> ]<br><b>no gi-address</b>                                                                                                                                                                              |
| <b>Context</b>     | config>service>ies>if>dhcp                                                                                                                                                                                                                                      |
| <b>Description</b> | This command configures the gateway interface address for the DHCP Relay Agent. By default, the GIADDR used in the relayed DHCP packet is the primary address of an interface. Specifying the GIADDR allows the user to choose a secondary address.             |
| <b>Default</b>     | no gi-address                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <i>ip-address</i> — the IP address of the gateway interface in dotted-decimal notation<br><div> <b>Values</b> a.b.c.d (host bits must be 0) </div> <b>src-ip-addr</b> — specifies that the GIADDR is to be used as the source IP address for DHCP relay packets |

### option

|                |                            |
|----------------|----------------------------|
| <b>Syntax</b>  | [no] <b>option</b>         |
| <b>Context</b> | config>service>ies>if>dhcp |

**Description** This command enables DHCP Option 82 (Relay Agent Information Option) parameters processing and enters the context for configuring Option 82 suboptions.

The **no** form of this command returns the system to the default.

**Default** no option

## action

**Syntax** **action** {**replace** | **drop** | **keep**}  
**no action**

**Context** config>service>ies>if>dhcp>option

**Description** This command configures the Relay Agent Information Option (Option 82) processing.

The **no** form of this command returns the system to the default value.

**Default** keep

**Parameters** **replace** — in the upstream direction (from the user), the Option 82 field from the router is inserted in the packet (overwriting any existing Option 82 field). In the downstream direction (toward the user), the Option 82 field is stripped (in accordance with RFC 3046).

**drop** — the DHCP packet is dropped if an Option 82 field is present, and a counter is incremented

**keep** — the existing information is kept in the packet and the router does not add any additional information. In the downstream direction, the Option 82 field is not stripped and is forwarded toward the client.

The behavior is slightly different in the case of Vendor Specific Options (VSOs). When the **keep** parameter is specified, the router will insert its own VSO into the Option 82 field. This will only be done if the incoming message already has an Option 82 field.

If no Option 82 field is present, the router will not create the Option 82 field. In this case, no VSO will be added to the message.

## circuit-id

**Syntax** **circuit-id** [**ascii-tuple** | **ifindex** | **sap-id** | **vlan-ascii-tuple**]  
**no circuit-id**

**Context** config>service>ies>if>dhcp>option

**Description** This command sends either an ASCII tuple or the interface index (If Index) on the specified SAP ID in the **circuit-id** suboption of the DHCP packet.

If disabled, the **circuit-id** suboption of the DHCP packet is left empty.

The **no** form of the command returns the system to the default.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | ascii-tuple                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b> | <p><b>ascii-tuple</b> — specifies that the ASCII-encoded concatenated tuple, which consists of the access node identifier, service ID, and interface name, separated by "/", will be used</p> <p><b>ifindex</b> — specifies that the interface index will be used. The If Index of a router interface can be displayed using the command <b>show&gt;router&gt;if&gt;detail</b>.</p> <p><b>sap-id</b> — specifies that the SAP ID will be used</p> <p><b>vlan-ascii-tuple</b> — specifies that the format will include VLAN ID and dot1p bits in addition to what is already included in <b>ascii-tuple</b>. The format is supported on dot1q and qinq ports only. Therefore, when the Option 82 bits are stripped, dot1p bits will be copied to the Ethernet header of an outgoing packet.</p> |

## remote-id

|                    |                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| <b>Context</b>     | config>service>ies>if>dhcp>option                                                                                                                                                                                                                                                                                                                                                 |
| <b>Description</b> | <p>This command sends the MAC address of the remote end (typically the DHCP client) in the <b>remote-id</b> suboption of the DHCP packet. This command identifies the host at the other end of the circuit.</p> <p>If disabled, the <b>remote-id</b> suboption of the DHCP packet is left empty.</p> <p>The <b>no</b> form of this command returns the system to the default.</p> |
| <b>Default</b>     | remote-id                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <p><b>mac</b> — specifies that the MAC address of the remote end is encoded in the suboption</p> <p><i>string</i> — the remote ID</p>                                                                                                                                                                                                                                             |

## vendor-specific option

|                    |                                                                                        |
|--------------------|----------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] vendor-specific-option</b>                                                     |
| <b>Context</b>     | config>service>ies>if>dhcp>option                                                      |
| <b>Description</b> | This command configures the <b>vendor-specific</b> suboption of the DHCP relay packet. |

## client-mac-address

|                    |                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] client-mac-address</b>                                                                                                                                                                          |
| <b>Context</b>     | config>service>ies>if>dhcp>option>vendor-specific-option                                                                                                                                                |
| <b>Description</b> | <p>This command enables the sending of the MAC address in the vendor-specific suboption of the DHCP relay packet.</p> <p>The <b>no</b> form of the command disables the sending of the MAC address.</p> |

## sap-id

|                    |                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] sap-id</b>                                                                                                                                                                            |
| <b>Context</b>     | config>service>ies>if>dhcp>option>vendor-specific-option                                                                                                                                      |
| <b>Description</b> | <p>This command enables the sending of the SAP ID in the vendor-specific suboption of the DHCP relay packet.</p> <p>The <b>no</b> form of the command disables the sending of the SAP ID.</p> |

## service-id

|                    |                                                                                                                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] service-id</b>                                                                                                                                                                                |
| <b>Context</b>     | config>service>ies>if>dhcp>option>vendor-specific-option                                                                                                                                              |
| <b>Description</b> | <p>This command enables the sending of the service ID in the vendor-specific suboption of the DHCP relay packet.</p> <p>The <b>no</b> form of the command disables the sending of the service ID.</p> |

## string

|                    |                                                                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>string</b> <i>text</i><br><b>no string</b>                                                                                                                              |
| <b>Context</b>     | config>service>ies>if>dhcp>option>vendor-specific-option                                                                                                                   |
| <b>Description</b> | <p>This command specifies the string in the vendor-specific suboption of the DHCP relay packet.</p> <p>The <b>no</b> form of the command reverts to the default value.</p> |
| <b>Default</b>     | no string                                                                                                                                                                  |

---

**Parameters**     *text* — any combination of ASCII characters up to 32 characters in length. If spaces are used in the string, the entire string must be enclosed within double quotes.

## system-id

**Syntax**     **[no] system-id**

**Context**     config>service>ies>if>dhcp>option>vendor-specific-option

**Description**     This command specifies whether the system ID is encoded in the vendor-specific suboption of the DHCP relay packet.

## server

**Syntax**     **server** *server1* [*server2*...(up to 8 max)]  
**no server**

**Context**     config>service>ies>if>dhcp>option

**Description**     This command specifies a list of servers where requests will be forwarded. The list of servers can be entered either as IP addresses or fully qualified domain names. There must be at least one server specified for DHCP relay to work. If there are multiple servers, the request is forwarded to all of the servers in the list.

There can be a maximum of 8 DHCP servers configured.

**Default**     no server

**Parameters**     *server* — the DHCP server IP address

## trusted

**Syntax**     **[no] trusted**

**Context**     config>service>ies>if>dhcp>option

**Description**     As specified in RFC 3046, *DHCP Relay Agent Information Option*, a DHCP request where the giaddr is 0.0.0.0 and that contains a Option 82 field in the packet, should be discarded unless it arrives on a “trusted” circuit. If **trusted** mode is enabled on an IP interface, the Relay Agent (the router) will modify the request giaddr to be equal to the ingress interface and forward the request.

This behavior only applies when the action in the Relay Agent Information Option is “**keep**”. In the case where the Option 82 field is being replaced by the Relay Agent (action = “**replace**”), the original Option 82 information is lost, and therefore there is no reason to enable the **trusted** option.

---

The **no** form of this command returns the system to the default.

**Default** not enabled

## icmp

**Syntax** **icmp**

**Context** config>service>ies>interface

**Description** This command enables access to the context to configure Internet Control Message Protocol (ICMP) parameters on a network IP interface. ICMP is a message control and error reporting protocol that also provides information relevant to IP packet processing.

## mask-reply

**Syntax** [**no**] **mask-reply**

**Context** config>service>ies>if>icmp

**Description** This command enables or disables responses to ICMP mask requests on the router interface.

If a local node sends an ICMP mask request to the router interface, the **mask-reply** command configures the router interface to reply to the request.

The **no** form of the command disables replies to ICMP mask requests on the router interface.

**Default** mask-reply

## ttl-expired

**Syntax** **ttl-expired** [*number seconds*]  
**no ttl-expired**

**Context** config>service>ies>if>icmp

**Description** This command configures the rate that ICMP Time To Live (TTL) expired messages are issued by the IP interface.

By default, generation of ICMP TTL expired messages is enabled at a maximum rate of 100 per 10-s time interval.

The **no** form of the command disables the generation of TTL expired messages.

**Default** ttl-expired 100 10—maximum of 100 TTL expired message in 10 s

---

|                   |                                                                                                                                                               |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>number</i> — the maximum number of ICMP TTL expired messages to send, expressed as a decimal integer. The <i>seconds</i> parameter must also be specified. |
| <b>Values</b>     | 10 to 100                                                                                                                                                     |
|                   | <i>seconds</i> — the time frame, in seconds, used to limit the number of ICMP TTL expired messages that can be issued, expressed as a decimal integer         |
| <b>Values</b>     | 1 to 60                                                                                                                                                       |

## unreachables

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Description</b> | <p>This command enables and configures the rate for ICMP host and network destination unreachable messages issued on the router interface.</p> <p>The <b>unreachables</b> command enables the generation of ICMP destination unreachable messages on the router interface. The rate at which ICMP unreachable messages are issued can be controlled with the optional <i>number</i> and <i>seconds</i> parameters by indicating the maximum number of destination unreachable messages that can be issued on the interface for a specified time interval.</p> <p>By default, generation of ICMP destination unreachable messages is enabled at a maximum rate of 100 per 10-s time interval.</p> <p>The <b>no</b> form of the command disables the generation of ICMP destination unreachable messages on the router interface.</p> |
| <b>Default</b>     | unreachables 100 10—maximum of 100 unreachable messages in 10 s                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <p><i>number</i> — the maximum number of ICMP unreachable messages to send, expressed as a decimal integer. The <i>seconds</i> parameter must also be specified.</p> <p><b>Values</b> 10 to 100</p> <p><i>seconds</i> — the time frame, in seconds, used to limit the <i>number</i> of ICMP unreachable messages that can be issued, expressed as a decimal integer</p> <p><b>Values</b> 1 to 60</p>                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Context</b>     | config>service>ies>interface                                                                                                                                                                                                                                                          |
| <b>Description</b> | This command enables the context to configure IPCP. Within this context, IPCP extensions can be used to signal the remote IP address and DNS IP address to the PPP peer over the PPP/MLPPP interface. This command is only applicable if the associated SAP is a PPP/MLPPP interface. |

| <b>Description</b> | <p>This command defines the remote IP address to be assigned to the far end of the associated PPP/MLPPP link via IPCP extensions. This command is only applicable if the associated SAP or port is a PPP/MLPPP interface with an IPCP encapsulation.</p> <p>The <b>no</b> form of the command deletes the IPCP extension peer-ip-address configuration.</p> |
| <b>Default</b>     | no peer-ip-address (0.0.0.0)                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <i>ip-address</i> — a unicast IPv4 address to be signaled to the far end of the associated PPP/MLPPP link by IPCP extensions                                                                                                                                                                                                                                |

## load-balancing

|                    |                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>load-balancing</b>                                                                                                                                                                            |
| <b>Context</b>     | config>service>ies>interface                                                                                                                                                                     |
| <b>Description</b> | <p>This command enables the context to configure load balancing hashing options on the interface. The options enabled at the interface level overwrite parallel system-level configurations.</p> |
| <b>Default</b>     | n/a                                                                                                                                                                                              |

## l4-load-balancing

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Context</b>     | config>service>ies>interface>load-balancing                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | <p>This command configures Layer 4 load balancing at the interface level. Configuration must be done on the ingress network interface (that is, the interface on the node that the packet is received on). When enabled, Layer 4 source and destination port fields of incoming TCP/UDP packets are included in the hashing calculation to determine the distribution of packets.</p> <p>You can add additional fields to generate more randomness and more equal distribution of packets with the <a href="#">teid-load-balancing</a> command.</p> |

The default configuration on the interface is to match the Layer 4 load-balancing configuration in the **config>system** context. Using this command to modify Layer 4 load-balancing configuration on an interface overrides the system-wide load-balancing settings for that interface.

|                   |                                                                                                                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>hashing-algorithm</i> — specifies that Layer 4 source and destination port fields are included in or excluded from the hashing calculation                                                                                                |
| <b>Values</b>     | <b>includeL4</b> : include Layer 4 source and destination port fields in the hashing calculation for TCP/UDP packets<br><b>excludeL4</b> : exclude Layer 4 source and destination port fields in the hashing calculation for TCP/UDP packets |
| <b>Default</b>    | the system configuration setting (under the <b>config&gt;system</b> context)                                                                                                                                                                 |

| <b>Context</b>     | config>service>ies>interface                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | <p>This command enables local proxy ARP on the interface.</p> <p>Local proxy ARP allows the 7705 SAR to respond to ARP requests received on an interface for an IP address that is part of a subnet assigned to the interface. The router responds to all requests for IP addresses within the subnet with its own MAC address and forwards all traffic between the hosts in the subnet.</p> <p>Local proxy ARP is used on subnets where hosts are prevented from communicating directly.</p> <p>When <b>local-proxy-arp</b> is enabled, ICMP redirects on the ports associated with the service are automatically blocked.</p> |
| <b>Default</b>     | no local-proxy-arp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## loopback

|                    |                                                                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] loopback</b>                                                                                                                                                               |
| <b>Context</b>     | config>service>ies>interface                                                                                                                                                       |
| <b>Description</b> | This command specifies that the interface is a loopback interface that has no associated physical interface. If this command is enabled, a SAP cannot be defined on the interface. |
| <b>Default</b>     | no loopback                                                                                                                                                                        |

| <b>Description</b> | This command enables proxy ARP on the interface and specifies an existing policy statement that controls the flow of routing information by analyzing match and action criteria. The policy statement is configured in the <b>config&gt;router&gt;policy-options</b> context (refer to the 7705 SAR Router Configuration Guide, "Route Policy Command Reference, Route Policy Options"). When proxy ARP is enabled, the 7705 SAR responds to ARP requests on behalf of another device. |
| <b>Default</b>     | no proxy-arp-policy                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <i>policy-name</i> — the route policy statement name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes. The policy statement must already be defined.                                                                                                                                                    |

|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | This command enables remote proxy ARP on the interface, allowing a router on one network to respond to ARP requests intended for another node that is physically located on another network. The router effectively pretends to be the destination node by sending an ARP response to the originating node that associates the router's MAC address with the destination node's IP address (acts as a proxy for the destination node). The router then takes responsibility for routing traffic to the real destination. |
| <b>Default</b>     | no remote-proxy-arp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Parameters</b>  | <p><i>ip-address</i> — the IP address of the IP interface. The <i>ip-address</i> portion of the <b>secondary</b> command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted-decimal notation.</p> <p><b>Values</b>      a.b.c.d<br/>                  (1.0.0.0 to 223.255.255.255 (with support of /31 subnets))</p> <p>The “/” (forward slash) is a parameter delimiter that separates the <i>ip-address</i> portion of the IP address from the <i>mask</i>, which defines the scope of the local subnet. No spaces are allowed between the <i>ip-address</i>, the “/”, and the <i>mask</i>. If a forward slash does not immediately follow the <i>ip-address</i>, a dotted-decimal <i>mask</i> must follow the prefix.</p> <p><i>mask</i> — the subnet mask length when the IP prefix is specified in CIDR notation. When the IP prefix is specified in CIDR notation, a forward slash separates the <i>ip-address</i> from the <i>mask</i>. The <i>mask</i> indicates the number of bits used for the network portion of the IP address; the remainder of the IP address is used to determine the host portion of the IP address.</p> <p><b>Values</b>      0 to 32</p> <p><i>netmask</i> — the subnet mask, in dotted-decimal notation. When the IP prefix is not specified in CIDR notation, a space separates the <i>ip-address</i> from a traditional dotted-decimal mask. The <i>netmask</i> parameter indicates the complete mask that will be used in a logical “AND” function to derive the local subnet of the IP address.</p> |

**Values** 128.0.0.0 to 255.255.255.252  
 (network bits all 1 and host bits all 0)  
 (255.255.255.255 is reserved for system IP addresses)

**broadcast** — the optional **broadcast** parameter overrides the default broadcast address used by the IP interface when sourcing IP broadcasts on the IP interface. If no broadcast format is specified for the IP address, the default value is **host-ones**, which indicates a subnet broadcast address. Use this parameter to change the broadcast address to **all-ones** or revert to a broadcast address of **host-ones**.

The broadcast format on an IP interface can be specified when the IP address is assigned or changed.

This parameter does not affect the type of broadcasts that can be received by the IP interface. A host sending either the local broadcast (**all-ones**) or the valid subnet broadcast address (**host-ones**) will be received by the IP interface.

**Default** host-ones

**all-ones** — specifies that the broadcast address used by the IP interface for this IP address will be 255.255.255.255, also known as the local broadcast

**host-ones** — specifies that the broadcast address used by the IP interface for this IP address will be the subnet broadcast address. This is an IP address that corresponds to the local subnet described by the *ip-address* and the *mask*, or the *mask* with all the host bits set to binary one. This is the default broadcast address used by an IP interface.

The **broadcast** parameter within the **secondary** command does not have a negation feature, which is usually used to revert a parameter to the default value. To change the broadcast type to **host-ones** after being changed to **all-ones**, the **secondary** command must be executed with the **broadcast** parameter defined.

**igp-inhibit** — specifies that this secondary IP interface should not be recognized as a local interface by the running IGP. For OSPF and IS-IS, this means that the secondary IP interface will not be injected and used as a passive interface and will not be advertised as an internal IP interface into the IGP link state database. For RIP, this means that the secondary IP interface will not source RIP updates.

| <b>Description</b> | This command configures a static ARP entry associating an IP address with a MAC address for the core router instance. This static ARP appears in the core routing ARP table. A static ARP can only be configured if it exists on the network attached to the IP interface. |

If an entry for a particular IP address already exists and a new MAC address is configured for the IP address, the existing MAC address is replaced by the new MAC address.

A router interface can only have one static ARP entry configured for it.

Static ARP is used when a 7705 SAR needs to know about a device on an interface that cannot or does not respond to ARP requests. Therefore, the 7705 SAR configuration can specify to send a packet with a particular IP address to the corresponding ARP address.

The **no** form of the command removes a static ARP entry.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | no static-arp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b> | <p><i>ip-address</i> — the IP address for the static ARP in dotted-decimal notation</p> <p><i>ieee-mac-address</i> — the 48-bit MAC address for the static ARP in the form <i>aa:bb:cc:dd:ee:ff</i> or <i>aa-bb-cc-dd-ee-ff</i>, where <i>aa</i>, <i>bb</i>, <i>cc</i>, <i>dd</i>, <i>ee</i>, and <i>ff</i> are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC, and non-IEEE reserved MAC addresses.</p> <p><b>unnumbered</b> — specifies the static ARP MAC addresses for an unnumbered interface. Unnumbered interfaces also support dynamic ARP. If this parameter is configured, it overrides any dynamic ARP.</p> |

|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command configures the maximum segment size (MSS) in a TCP SYN or SYN-ACK packet during the establishment of a TCP connection. A <b>tcp-mss</b> value can be specified on an ingress interface, egress interface, or both. When configured on two interfaces, the smaller of the two values is used. If the TCP SYN packet has no TCP MSS field, the 7705 SAR assigns it the MSS value configured on the interface and recalculates the IP checksum. If the TCP SYN or SYN-ACK packet has an MSS field and the value is greater than the value configured on the interface, the 7705 SAR overwrites the packet MSS value with the lower value. If the MSS value is less than the value configured on the interface, the packet MSS value does not change.</p> <p>This command is supported on interfaces with IPv4 and IPv6 traffic, and a different MSS value can be configured for the IPv4 and IPv6 interfaces. This command is not supported on IPsec public interfaces in IES.</p> |
| <b>Default</b>     | no tcp-mss                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <i>value</i> — the MSS, in bytes, to be used in a TCP SYN or SYN-ACK packet                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Values</b>      | 384 to 9732                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Description</b> | <p>This command configures an IP interface as an unnumbered interface and specifies an IP address or interface name to be used for the interface. Unnumbered interfaces are point-to-point interfaces that are not explicitly configured with a dedicated IP address and subnet; instead, they borrow (or link to) an IP address from another interface on the system (the system IP address, another loopback interface, or any other numbered interface) and use it as the source IP address for packets originating from the interface.</p> <p>By default, no IP address exists on an IP interface until it is explicitly created.</p> <p>The <b>no</b> form of the command removes the IP address assignment from the IP interface.</p> |
| <b>Default</b>     | no unnumbered                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <i>ip-int-name</i>   <i>ip-address</i> — the IP interface name or address to associate with the unnumbered IP interface                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Values</b>      | <i>ip-int-name</i> : 1 to 32 characters (must start with a letter)<br><i>ip-address</i> : a.b.c.d                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

### 6.7.2.2.2 IES Service IPv6 Commands

#### ipv6

|                    |                                                                          |
|--------------------|--------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] ipv6</b>                                                         |
| <b>Context</b>     | config>service>ies>interface                                             |
| <b>Description</b> | This command enables the context to configure IPv6 for an IES interface. |

#### address

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                                                                                                                         |                      |                                                                                                                         |  |                       |          |

| <b>Description</b> | This command enables the sending of interface ID options in the DHCPv6 Relay packet.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Default</b>     | ascii-tuple                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <p><b>ascii-tuple</b> — specifies that the ASCII-encoded concatenated tuple, which consists of the access node identifier, service ID, and interface name, separated by "/", will be used</p> <p><b>ifindex</b> — specifies that the interface index will be used. The If Index of a router interface can be displayed using the command <b>show&gt;router&gt;if&gt;detail</b>.</p> <p><b>sap-id</b> — specifies that the SAP ID will be used</p> <p><b>string</b> — specifies that a string of up to 32 printable, 7-bit ASCII characters, will be used. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.</p> |

## remote-id

|                    |                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] remote-id</b>                                                                                                                                   |
| <b>Context</b>     | config>service>ies>if>ipv6>dhcp6-relay>option                                                                                                           |
| <b>Description</b> | This command enables the sending of the remote ID option in the DHCPv6 Relay packet. The client DHCP Unique Identifier (DUID) is used as the remote ID. |

| <b>Context</b>     | config>service>ies>if>ipv6>dhcp6-relay                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | This command specifies a list of servers where DHCPv6 requests will be forwarded. The list of servers can be entered either as IP addresses or fully qualified domain names. At least one server must be specified in order for DHCPv6 Relay to work. If there are multiple servers, the request is forwarded to all of them. A maximum of eight servers can be configured. |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <i>ipv6-address</i> — the IPv6 addresses of the DHCP servers                                                                                                                                                                                                                                                                                                                |
| <b>Values</b>      | x:x:x:x:x:x:x (eight 16-bit pieces)<br>x:x:x:x:x:d.d.d.d<br>x: [0 to FFFF]H<br>d: [0 to 255]D                                                                                                                                                                                                                                                                               |

## icmp6

|                    |                                                                                       |
|--------------------|---------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>icmp6</b>                                                                          |
| <b>Context</b>     | config>service>ies>if>ipv6                                                            |
| <b>Description</b> | This command enables the context to configure ICMPv6 parameters on the IES interface. |

## packet-too-big

|                    |                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>packet-too-big</b> [ <i>number seconds</i> ]<br><b>no packet-too-big</b>                                                                                           |
| <b>Context</b>     | config>service>ies>if>ipv6>icmp6                                                                                                                                      |
| <b>Description</b> | This command configures the rate for ICMPv6 packet-too-big messages.<br><br>The <b>no</b> form of the command disables the sending of ICMPv6 packet-too-big messages. |
| <b>Default</b>     | 100 10                                                                                                                                                                |
| <b>Parameters</b>  | <i>number</i> — the maximum number of packet-too-big messages to send, expressed as a decimal integer, in the time frame specified by the <i>seconds</i> parameter    |
| <b>Values</b>      | 10 to 1000                                                                                                                                                            |

*seconds* — the time frame, in seconds, used to limit the number of packet-too-big messages that can be issued, expressed as a decimal integer

**Values** 1 to 60

## param-problem

**Syntax** **param-problem** [*number seconds*]  
**no param-problem**

**Context** config>service>ies>if>ipv6>icmp6

**Description** This command configures the rate for ICMPv6 param-problem messages.  
The **no** form of the command disables the sending of ICMPv6 param-problem messages.

**Default** 100 10

**Parameters** *number* — the maximum number of param-problem messages to send, expressed as a decimal integer, in the time frame specified by the *seconds* parameter

**Values** 10 to 1000

*seconds* — the time frame, in seconds, used to limit the number of param-problem messages that can be issued, expressed as a decimal integer

**Values** 1 to 60

## time-exceeded

**Syntax** **time-exceeded** [*number seconds*]  
**no time-exceeded**

**Context** config>service>ies>if>ipv6>icmp6

**Description** This command configures the rate for ICMPv6 time-exceeded messages.  
The **no** form of the command disables the sending of ICMPv6 time-exceeded messages.

**Default** 100 10

**Parameters** *number* — the maximum number of time-exceeded messages to send, expressed as a decimal integer, in the time frame specified by the *seconds* parameter

**Values** 10 to 1000

*seconds* — the time frame, in seconds, used to limit the number of time-exceeded messages that can be issued, expressed as a decimal integer

**Values** 1 to 60

## unreachables

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Syntax</b>      | <b>unreachables</b> [ <i>number seconds</i> ]<br><b>no unreachableables</b>                                                                                                                                                                                                                                                                                                                                         |
| <b>Context</b>     | config>service>ies>if>ipv6>icmp6                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | <p>This command enables and configures the rate for ICMPv6 host and network destination unreachable messages issued on the router interface.</p> <p>The <b>no</b> form of the command disables the generation of ICMPv6 destination unreachableables on the router interface.</p>                                                                                                                                   |
| <b>Default</b>     | 100 10                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b>  | <p><i>number</i> — the maximum number of destination unreachable messages to send, expressed as a decimal integer, in the time frame specified by the <i>seconds</i> parameter</p> <p><b>Values</b> 10 to 1000</p> <p><i>seconds</i> — the time frame, in seconds, used to limit the number of destination unreachable messages that can be issued, expressed as a decimal integer</p> <p><b>Values</b> 1 to 60</p> |

## link-local-address

|                    |                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>link-local-address</b> <i>ipv6-address</i> [ <b>preferred</b> ]<br><b>no link-local-address</b>                                                                                                                                                                                                                                                 |
| <b>Context</b>     | config>service>ies>if>ipv6                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | <p>This command configures the IPv6 link-local address.</p> <p>The <b>no</b> form of the command removes the configured link-local address, and the router automatically generates a default link-local address.</p> <p>Removing a manually configured link-local address may impact routing protocols that have a dependency on that address.</p> |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <p><i>ipv6-address</i> — the IPv6 address</p> <p><b>Values</b> <i>ipv6-address</i> x:x:x:x:x:x:x (eight 16-bit pieces)<br/>x:x:x:x:x:d.d.d.d<br/>x: [0 to FFFF]H<br/>d: [0 to 255]D</p>                                                                                                                                                            |

---

**preferred** — specifies that the IPv6 address is the preferred IPv6 address for this interface. A preferred address is an address assigned to an interface whose use by upper layer protocols is unrestricted. A preferred address may be used as the source or destination address of packets sent from or to the interface.

## neighbor

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>neighbor</b> <i>ipv6-address mac-address</i><br><b>no neighbor</b> <i>ipv6-address</i>                                                                                                                                                                                                                                                                                                                        |
| <b>Context</b>     | config>service>ies>if>ipv6                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b> | This command configures an IPv6-to-MAC address mapping on the IES interface. Use this command if a directly attached IPv6 node does not support ICMPv6 neighbor discovery or a static address must be used. This command can only be used on Ethernet interfaces. The <i>ipv6-address</i> must be on the subnet that was configured from the IPv6 address command or a link-local address.                       |
| <b>Parameters</b>  | <i>ipv6-address</i> — the IPv6 address on the interface<br><div style="margin-left: 40px;"> <b>Values</b>    x:x:x:x:x:x:x (eight 16-bit pieces)<br/>                        x:x:x:x:x:d.d.d.d<br/>                        x: [0 to FFFF]H<br/>                        d: [0 to 255]D         </div> <i>mac-address</i> — the MAC address for the neighbor in the form of xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx |

## reachable-time

|                    |                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] reachable-time</b> <i>seconds</i>                                                                                                                                                                  |
| <b>Context</b>     | config>service>ies>if>ipv6                                                                                                                                                                                 |
| <b>Description</b> | This command specifies the time an IPv6 neighbor remains in reachable state.                                                                                                                               |
| <b>Default</b>     | no reachable-time                                                                                                                                                                                          |
| <b>Parameters</b>  | <i>seconds</i> — specifies the number of seconds that an IPv6 neighbor remains in reachable state<br><div style="margin-left: 40px;"> <b>Values</b>    30 to 3600<br/> <b>Default</b>    30         </div> |

## stale-time

|                    |                                                                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] stale-time</b> <i>seconds</i>                                                                                                                                   |
| <b>Context</b>     | config>service>ies>if>ipv6                                                                                                                                              |
| <b>Description</b> | This command specifies the time that an IPv6 neighbor cache entry remains in stale state. When the specified time elapses, the system removes the neighbor cache entry. |
| <b>Default</b>     | no stale-time                                                                                                                                                           |
| <b>Parameters</b>  | <i>seconds</i> — specifies the number of seconds that an IPv6 neighbor remains in stale state                                                                           |
| <b>Values</b>      | 60 to 65535                                                                                                                                                             |
| <b>Default</b>     | 14400                                                                                                                                                                   |

### 6.7.2.2.3 IES Service VRRP Commands

#### vrrp

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Context</b>     | config>service>ies>interface<br>config>service>ies>if>ipv6                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | <p>This command creates or edits a virtual router ID on the service IP interface. A virtual router ID is internally represented in conjunction with the IP interface name. This allows the virtual router ID to be used on multiple IP interfaces while representing different virtual router instances.</p> <p>Two VRIDs can be defined on an IP interface. One, both, or none may be defined as <b>owner</b>.</p> <p>The <b>no</b> form of this command removes the specified virtual router ID from the IP interface. This terminates VRRP participation for the virtual router and deletes all references to the virtual router ID. The virtual router ID does not need to be shut down in order to remove the virtual router instance.</p> |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <p><i>virtual-router-id</i> — specifies a new virtual router ID or one that can be modified on the IP interface</p> <p><b>Values</b> 1 to 255</p> <p><b>owner</b> — defines the virtual router instance as an owner</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

#### authentication-key

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>authentication-key</b> [ <i>authentication-key</i>   <i>hash-key</i> ] [ <b>hash</b>   <b>hash2</b> ]<br><b>no authentication-key</b>                                                                                                                                                                                                                                                                                                                                              |
| <b>Context</b>     | config>service>ies>if>vrrp                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b> | <p>This command assigns a simple text password authentication key to generate master VRRP advertisement messages and validate received VRRP advertisement messages.</p> <p>If the command is re-executed with a different password key defined, the new key will be used immediately. If a <b>no authentication-key</b> command is executed, the password authentication key is restored to the default value. The <b>authentication-key</b> command may be executed at any time.</p> |

To change the current in-use password key on multiple virtual router instances:

- identify the current master
- shut down the virtual router instance on all backups
- execute the **authentication-key** command on the master to change the password key
- execute the **authentication-key** command and **no shutdown** command on each backup

The **no** form of this command restores the default value of the key.

**Default** The authentication data field contains the value 0 in all octets.

**Parameters** *authentication-key* — identifies the simple text password used when VRRP Authentication Type 1 is enabled on the virtual router instance. Type 1 uses a string 8 octets long that is inserted into all transmitted VRRP advertisement messages and compared against all received VRRP advertisement messages. The authentication data fields are used to transmit the key.

The *authentication-key* parameter is expressed as a string consisting up to eight alphanumeric characters. Spaces must be contained in quotation marks ( " "). The quotation marks are not considered part of the string.

The string is case-sensitive and is left-justified in the VRRP advertisement message authentication data fields. The first field contains the first four characters with the first octet containing the first character. The second field holds the fifth through eighth characters. Any unspecified portion of the authentication data field is padded with the value 0 in the corresponding octet.

|               |                                     |          |
|---------------|-------------------------------------|----------|
| <b>Values</b> | any 7-bit printable ASCII character |          |
| exceptions:   | double quote                        | ASCII 34 |
|               | carriage return                     | ASCII 13 |
|               | line feed                           | ASCII 10 |
|               | tab                                 | ASCII 9  |
|               | backspace                           | ASCII 8  |

*hash-key* — can be any combination of ASCII characters up to 11 characters in length (encrypted) for a hash key or up to 110 characters for a hash2 key. If spaces are used in the string, the entire string must be enclosed in quotation marks ( " ").

This option is useful when a user must configure the parameter, but for security purposes, the actual unencrypted key value is not provided.

**hash** — specifies that the key is entered in an encrypted form. If the **hash** keyword is not used, the key is assumed to be in a non-encrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** keyword specified.

**hash2** — specifies that the key is entered in a more complex encrypted form. If the **hash2** keyword is not used, the less-encrypted hash form is assumed.

## backup

|                    |                                                                                                                                                                                                                                  |

| <b>Description</b> | <p>This command assigns a BFD session that provides a heartbeat mechanism for a VRRP instance. Only one BFD session can be assigned to a VRRP instance, but multiple VRRP instances can use the same BFD session.</p> <p>BFD controls the state of the associated interface. By enabling BFD on a protocol interface, the state of the protocol interface is tied to the state of the BFD session between the local node and the remote node. The parameters used for the BFD session are set with the <b>bfd-enable</b> command under the IP interface specified in this command.</p> <p>The <b>no</b> form of this command removes BFD from the configuration.</p> |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Parameters</b>  | <i>service-id</i> — specifies the service ID of the interface running BFD<br><b>Values</b> 1 to 2147483690 or <i>service-name</i><br><i>interface-name</i> — specifies the name of the interface running BFD                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

---

*ip-address* — specifies the destination address to be used for the BFD session

**Values**

|                      |                                     |
|----------------------|-------------------------------------|
| <i>ipv4-address:</i> | a.b.c.d                             |
| <i>ipv6-address:</i> | x:x:x:x:x:x:x (eight 16-bit pieces) |
|                      | x:x:x:x:x:d.d.d.d                   |
|                      | x - [0..FFFF]H                      |
|                      | d - [0..255]D                       |

## init-delay

|                    |                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>init-delay</b> <i>seconds</i><br><b>no init-delay</b>                                     |

| <b>Description</b> | <p>This command allows the master instance to dictate the master down timer (non-owner context only).</p> <p>The master down interval is the time that the master router can be down before the backup router takes over. The master down interval is used to specify the master down timer. If the master down timer expires, the backup virtual router enters the master state. Refer to "Master Down Interval" in the "VRRP" chapter of the 7705 SAR Router Configuration Guide for details.</p> |
| <b>Default</b>     | no master-int-inherit                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Description</b> | <p>This command sets the advertisement timer and indirectly sets the master down timer on the virtual router instance. The message-interval setting must be the same for all virtual routers with the same VRID. Any VRRP advertisement message received with an advertisement interval field different from the virtual router instance configured message-interval value will be silently discarded.</p> <p>Configuring the message interval value can be done in three ways: using only the milliseconds value, using only the seconds value, or using a combination of the two values. <a href="#">Table 96</a> shows the ranges for each way of configuring the message interval.</p> |

**Table 96 Message Interval Configuration Ranges**

| Configuration                                     | IPv4                                             | IPv6                                           |
|---------------------------------------------------|--------------------------------------------------|------------------------------------------------|
| Using milliseconds value only                     | 100 to 900 ms                                    | 10 to 990 ms                                   |
| Using seconds value only                          | 1 to 255 s                                       | 1 to 40 s                                      |
| Using combination milliseconds and seconds values | 1 s 100 ms to 255 s 900 ms<br>(1.1 s to 255.9 s) | 1 s 10 ms to 40s 990 ms<br>(1.01 s to 40.99 s) |
| Default setting                                   | 1 s                                              | 1 s                                            |

The **message-interval** command is available for both non-owner and owner virtual routers. If the **message-interval** command is not executed, the default message interval is 1 s.

The **no** form of this command restores the default message-interval value of 1 s to the virtual router instance.

|                   |                                                                                                                                                             |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | 1 s                                                                                                                                                         |
| <b>Parameters</b> | <i>seconds</i> — the time interval, in seconds, between sending advertisement messages.                                                                     |
| <b>Values</b>     | IPv4: 1 to 255<br>IPv6: 1 to 40                                                                                                                             |
|                   | <i>milliseconds</i> — the time interval, in milliseconds, between sending advertisement messages. This parameter is not supported on non-redundant chassis. |
| <b>Values</b>     | IPv4: 100 to 900<br>IPv6: 10 to 990                                                                                                                         |

## ping-reply

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Description</b> | <p>This command enables the non-owner master to reply to ICMP echo requests directed to the virtual router instance IP addresses. The ping request can be received on any routed interface.</p> <p>Ping must not have been disabled at the management security level (either on the parent IP interface or based on the ping source host address). When ping reply is not enabled, ICMP echo requests to non-owner master virtual IP addresses are silently discarded.</p> <p>Non-owner backup virtual routers never respond to ICMP echo requests regardless of the setting of the ping reply configuration.</p> <p>The <b>ping-reply</b> command is only available for non-owner virtual routers.</p> <p>The <b>no</b> form of this command restores the default operation of discarding all ICMP echo request messages destined for the non-owner virtual router instance IP addresses.</p> |
| <b>Default</b>     | no ping-reply                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Description</b> | This command associates a VRRP priority control policy with the virtual router instance (non-owner context only). VRRP policies are defined under the <b>config&gt;vrrp&gt;policy</b> context. For details, refer to the “VRRP” chapter in the 7705 SAR Router Configuration Guide. |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                 |
| <b>Parameters</b>  | <i>vrrp-policy-id</i> — specifies a VRRP priority control policy. The VRRP policy ID must already exist in the system for the <b>policy</b> command to be successful.                                                                                                               |
| <b>Values</b>      | 1 to 9999                                                                                                                                                                                                                                                                           |

## preempt

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Description</b> | <p>This command provides the ability to override an existing non-owner master with a virtual router backup that has a higher priority. Enabling preempt mode enhances the operation of the base priority and VRRP policy ID definitions on the virtual router instance. If the virtual router cannot preempt an existing non-owner master, the effect of the dynamic changing of the in-use priority is greatly diminished.</p> <p>The <b>preempt</b> command is only available for non-owner VRRP virtual routers. The owner cannot be preempted because the priority of non-owners can never be higher than the owner. The owner will always preempt all other virtual routers when it is available.</p> <p>Non-owner backup virtual router instances will only preempt when preempt is set and the current master has an in-use message priority value less than the backup virtual router instance in-use priority.</p> <p>A master non-owner virtual router will only allow itself to be preempted when the incoming VRRP advertisement message priority field value is one of the following:</p> <ul style="list-style-type: none"> <li>• greater than its in-use priority value</li> <li>• equal to the in-use priority value, and the source IP address (primary IP address) is greater than its primary IP address</li> </ul> <p>The <b>no</b> form of this command prevents a non-owner virtual router instance from preempting another, less-desirable, virtual router.</p> |
| <b>Default</b>     | preempt                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Description</b> | <p>This command configures a specific priority value for the virtual router instance. In conjunction with the optional <b>policy</b> command, the base priority derives the in-use priority of the virtual router instance.</p> <p>The <b>priority</b> command is only available for non-owner VRRP virtual routers. The priority of owner virtual router instances is permanently set to 255 and cannot be changed. For non-owner virtual router instances, if the priority command is not executed, the base priority is set to 100.</p> <p>The <b>no</b> form of this command restores the default value of 100.</p> |               |          |                |     |
| <b>Parameters</b>  | <p><i>priority</i> — specifies the priority used by the virtual router instance. If a VRRP priority control policy is not defined, the base priority will be the in-use priority for the virtual router instance.</p> <table> <tr> <td><b>Values</b></td><td>1 to 254</td></tr> <tr> <td><b>Default</b></td><td>100</td></tr> </table>                                                                                                                                                                                                                                                                                  | <b>Values</b> | 1 to 254 | <b>Default</b> | 100 |

| <b>Description</b> | <p>This command enables the non-owner master to reply to SSH requests directed at the IP addresses of the virtual router instances. The SSH request can be received on any routed interface. SSH must not have been disabled at the management security level (either on the parent IP interface or based on the SSH source host address). Proper login and CLI command authentication are enforced.</p> <p>When the <b>ssh-reply</b> command is not enabled, SSH packets to non-owner master virtual IP addresses are silently discarded.</p> <p>Non-owner backup virtual routers never respond to SSH requests regardless of the SSH reply configuration.</p> <p>The <b>ssh-reply</b> command is only available for non-owner VRRP virtual routers.</p> <p>The <b>no</b> form of this command restores the default operation of discarding all SSH packets destined for the non-owner virtual router instance IP addresses.</p> |
| <b>Default</b>     | no ssh-reply                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Description</b> | <p>This command enables the non-owner master to reply to TCP port 23 Telnet requests directed at the IP addresses of the virtual router instance. The Telnet request can be received on any routed interface. Telnet must not have been disabled at the management security level (either on the parent IP interface or based on the Telnet source host address). Proper login and CLI command authentication are enforced.</p> <p>If the <b>telnet-reply</b> command is not enabled, TCP port 23 Telnet packets to non-owner master virtual IP addresses are silently discarded.</p> <p>Non-owner backup virtual routers never respond to Telnet requests regardless of the Telnet reply configuration.</p> <p>The <b>telnet-reply</b> command is only available for non-owner VRRP virtual routers.</p> <p>The <b>no</b> form of this command restores the default operation of discarding all Telnet packets destined for the non-owner virtual router instance IP addresses.</p> |
| <b>Default</b>     | no telnet-reply                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Context</b>     | config>service>ies>if>vrrp<br>config>service>ies>if>ipv6>vrrp                                                                                                                                                                                                                                                                                             |
| <b>Description</b> | This command enables a non-owner master to reply to traceroute requests directed to the virtual router instance IP addresses. The command is valid only if the VRRP virtual router instance associated with this entry is a non-owner. A non-owner backup virtual router never responds to traceroute requests regardless of the traceroute reply status. |
| <b>Default</b>     | no traceroute-reply                                                                                                                                                                                                                                                                                                                                       |

| <b>Description</b> | <p>This command creates a SAP within an IES service. Each SAP must be unique.</p> <p>All SAPs must be explicitly created with the <b>create</b> keyword. If no SAPs are created within a service or an IP interface, a SAP will not exist on that object.</p> <p>To edit SAP parameters, enter an existing SAP without the <b>create</b> keyword.</p> <p>A SAP can only be associated with a single service. The SAP is owned by the service in which it was created. A SAP can only be defined on a port that has been configured as an access port in the <b>config&gt;port</b> <i>port-id</i> context using the <b>mode access</b> command. Refer to the 7705 SAR Interface Configuration Guide, “Access Ports”.</p> <p>If a port is shut down, all SAPs on that port become operationally down. When a service is shut down, SAPs for the service are not displayed as operationally down although all traffic traversing the service will be discarded. The operational state of a SAP is relative to the operational state of the port on which the SAP is defined.</p> <p>The following SAP types are supported:</p> <ul style="list-style-type: none"><li>• PPP IPCP encapsulation of an IPv4 packet for IES (RFC 1332)</li><li>• MLPPP bundle</li><li>• LAG</li><li>• Ethernet SAPs supporting null, dot1q, and qinq</li></ul> <p>To configure an IES interface SAP that is used for a public IPsec tunnel interface, see <a href="#">sap</a> in <a href="#">Service Interface Tunnel Commands</a>.</p> <p>If the IES interface has been configured as a loopback interface with the <a href="#">loopback</a> command, a SAP cannot be defined on the interface.</p> <p>The <b>no</b> form of this command deletes the SAP with the specified port. When a SAP is deleted, all configuration parameters for the SAP will also be deleted.</p> |
| <b>Default</b>     | no sap                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Parameters</b>  | <p><i>sap-id</i> — specifies the physical port identifier portion of the SAP definition. See <a href="#">Table 41</a> for a full list of SAP IDs.</p> <p><b>create</b> — keyword used to create a SAP instance. The <b>create</b> keyword requirement can be enabled/disabled in the <b>environment&gt;create</b> context.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Context</b>     | config>service>ies>if>sap                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Description</b> | <p>This command creates the accounting policy context that can be applied to a SAP. An accounting policy must be defined before it can be associated with a SAP. If the policy ID does not exist, an error message is generated.</p> <p>A maximum of one accounting policy can be associated with a SAP at one time. Accounting policies are configured in the <b>config&gt;log&gt;accounting-policy</b> context.</p> <p>The <b>no</b> form of this command removes the accounting policy association from the SAP, and the accounting policy reverts to the default.</p> |
| <b>Default</b>     | no accounting-policy                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <i>acct-policy-id</i> — the accounting <i>policy ID</i> as configured in the <b>config&gt;log&gt;accounting-policy</b> context                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Values</b>      | 1 to 99                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Description</b> | <p>This command enables accounting and statistical data collection for the SAP. When applying accounting policies, the data, by default, is collected in the appropriate records and written to the designated billing file.</p> <p>When the <b>no collect-stats</b> command is issued, the statistics are still accumulated by the CSM. However, the CPU will not obtain the results and write them to the billing file. If a subsequent <b>collect-stats</b> command is issued, the counters written to the billing file include all the traffic while the <b>no collect-stats</b> command was in effect.</p> |
| <b>Default</b>     | collect-stats                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|                    |                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>egress</b>                                                                                 |
| <b>Context</b>     | config>service>ies>if>sap                                                                     |
| <b>Description</b> | This command enables the context to configure egress SAP QoS policies and IP filter policies. |

If no sap-egress QoS policy is defined, the system default sap-egress QoS policy is used for egress processing. If no egress IP filter policy is defined, no filtering is performed.

## ingress

|                    |                                                                                                                                                                                                                                                                                                       |

| <b>Description</b> | <p>This command sets the aggregate rate limits (PIR and CIR) for the SAP. The <i>agg-rate</i> sets the PIR value. The <i>cir-rate</i> sets the CIR value. When aggregate rate limits are configured on a second-generation (Gen-2) Ethernet adapter card, the scheduler mode must be set to 16-priority. On a third-generation (Gen-3) Ethernet adapter card, the scheduler mode is always 4-priority. For information on adapter card generations, refer to the “Evolution of Ethernet Adapter Cards, Modules, and Platforms” section in the 7705 SAR Interface Configuration Guide.</p> <p>Configuring the <i>cir-rate</i> is optional. If a <i>cir-rate</i> is not entered, then the <i>cir-rate</i> is set to its default value (0 kb/s). If a <i>cir-rate</i> has been set and the <i>agg-rate</i> is changed without re-entering the <i>cir-rate</i>, the <i>cir-rate</i> automatically resets to 0 kb/s. For example, to change the <i>agg-rate</i> from 2000 to 1500 while maintaining a <i>cir-rate</i> of 500, use the command <b>agg-rate-limit 1500 cir 500</b>.</p> <p>If the specified SAP is a LAG SAP, then <i>agg-rate</i> and <i>cir-rate</i> can be configured regardless of the scheduler mode setting on Gen-2 or Gen-3 hardware—it is not configurable if one of the ports configured in the LAG SAP is on Gen-1 hardware. If the active port is on a Gen-3 card or platform, then <i>agg-rate</i> and <i>cir-rate</i> are applicable. If the active port is on a Gen-2 card or platform, then <i>agg-rate</i> and <i>cir-rate</i> apply when the scheduler mode is set to 16-priority. If the active port is on a Gen-1 card, then <i>agg-rate</i> and <i>cir-rate</i> are not applicable. For details on the behavior of a mix-and-match LAG SAP, refer to the “LAG Support on Third-Generation Ethernet Adapter Cards, Ports, and Platforms” and “Network LAG Traffic Management” sections in the 7705 SAR Interface Configuration Guide.</p> |

**Note:** Starting with Release 7.0.R6, schedulers on Gen-3 adapter cards and platforms have been updated to better align with the scheduling behavior supported on the other 7705 SAR adapter cards and platforms. The updated scheduler mode is called "4-priority" scheduler-mode throughout the CLI. Prior to Release 7.0.R6, the CLI designation was "4-priority-hqos". In the updated mode of operation, arbitration among different flows at the second-tier aggregate (per-SAP or per-VLAN) and third-tier aggregate (per-customer (MSS)) levels are carried out in a round-robin manner, scheduling *cir-rate* first from the shapers, followed by the *pir-rate*.

**Caution:** Any Gen-3 adapter card or platform running Release 7.0.R6 or later software uses 4-priority scheduling instead of 4-priority-hqos scheduling, which was supported previously. The migration of scheduler mode is automatic with an upgrade and there is no operator action required. As part of the migration, all CIR values at second-tier (per-SAP and per-VLAN) and third-tier (per-customer (MSS)) aggregate shaper levels are set to zero. Operators must exercise caution when performing an upgrade to Release 7.0.R6 or later from a previous Release 7.0 version, and must adjust the affected CIR values in accordance with the needs of their applications as soon as possible.

The **no** form of the command sets the *agg-rate* to the maximum and the *cir-rate* to 0 kb/s.

**Default** no agg-rate-limit

**Parameters** *agg-rate* — sets the PIR for the aggregate of all the queues on the SAP. The **max** keyword applies the maximum physical port rate possible.

**Values** 1 to 10000000 kb/s, or **max**

**Default** max

*cir-rate* — sets the CIR for the aggregate of all the queues on the SAP

**Values** 0 to 10000000 kb/s, or **max**

**Default** 0 kb/s

filter

**Syntax** **filter ip** *ip-filter-id*  
**filter ipv6** *ipv6-filter-id*  
**no filter** [**ip** *ip-filter-id* | **ipv6** *ipv6-filter-id*]

**Context** config>service>ies>if>sap>egress  
config>service>ies>if>sap>ingress

**Description** This command associates an IPv4 or IPv6 filter policy with an egress or ingress IES SAP.

Filter policies control the forwarding and dropping of packets based on IP matching criteria. Only one filter can be applied to a SAP at a time.

The *ip-filter-id* or *ipv6-filter-id* must already be defined before the **filter** command is executed. If the filter policy does not exist, the operation will fail and an error message will be displayed.

The **no** form of the command removes any configured filter ID association with the SAP. The filter policy cannot be deleted until it is removed from all SAPs where it is applied.

**Default** no filter

**Parameters** *ip-filter-id* — specifies the IPv4 filter policy. The filter ID or filter name must already exist within the created IP filters.

**Values** 1 to 65535 or *filter-name* (up to 64 characters)

*ipv6-filter-id* — specifies the IPv6 filter policy. The filter ID or filter name must already exist within the created IP filters.

**Values** 1 to 65535 or *filter-name* (up to 64 characters)

**Note:** For information on configuring IP filter IDs, refer to the 7705 SAR Router Configuration Guide, “Filter Policies”.

match-qinq-dot1p

**Syntax** **match-qinq-dot1p** {**top** | **bottom**}  
**no match-qinq-dot1p**

**Context** config>service>ies>if>sap>ingress

**Description** This command specifies which dot1q tag position (top or bottom) in a qinq-encapsulated packet should be used when QoS evaluates dot1p classification.

The **no** form of the command restores the default dot1p evaluation behavior for the SAP, which means that the inner (bottom) tag (second tag) dot1p bits are used for classification.

By default, the dot1p bits from the inner tag service-delineating dot1q tag are used.

Table 97 shows which set of dot1p bits are used for QoS purposes when **match-qinq-dot1p** is configured. To use the table, find the row that represents the settings for **Port/SAP Type** and **Match-QinQ-Dot1q Setting**. Use the **Existing Packet Tags** column to identify which dot1q tags are available in the packet. Then use the **P-bits Used for Match** column to identify which dot1q tag contains the dot1p bits that are used for QoS dot1p classification.

**Default** no match-qinq-dot1p

**Parameters** **top** — the **top** parameter and **bottom** parameter are mutually exclusive. When the **top** parameter is specified, the outer tag's dot1p bits (topmost P-bits) are used (if existing) to match any **dot1p** *dot1p-value* entries.

**bottom** — the **bottom** parameter and **top** parameter are mutually exclusive. When the **bottom** parameter is specified, the bottommost P-bits (second tag's P-bits) are used (if existing) to match any **dot1p** *dot1p-value* entries.

**Table 97 Match-QinQ-Dot1p Matching Behavior**

| Port/ SAP Type | Match-QinQ-Dot1p Setting <sup>1</sup> | Existing Packet Tags          | P-bits Used for Match |
|----------------|---------------------------------------|-------------------------------|-----------------------|
| Null           | n/a                                   | None                          | None                  |
| Null           | n/a                                   | Dot1p (VLAN ID 0)             | None <sup>2</sup>     |
| Null           | n/a                                   | Dot1q                         | None <sup>2</sup>     |
| Null           | n/a                                   | TopQ BottomQ                  | None <sup>2</sup>     |

| QinQ/ X.0      | Top                                   | TopQ BottomQ                  | TopQ P-bits           |
| QinQ/ X.0      | Default or Bottom                     | TopQ BottomQ                  | BottomQ P-bits        |
| QinQ/ X.*      | Top                                   | TopQ                          | TopQ P-bits           |
| QinQ/ X.*      | Default or Bottom                     | TopQ                          | TopQ P-bits           |
| QinQ/ X.*      | Top                                   | TopQ BottomQ                  | TopQ P-bits           |
| QinQ/ X.*      | Default or Bottom                     | TopQ BottomQ                  | BottomQ P-bits        |
| QinQ/ 0.*      | Top                                   | None                          | None                  |
| QinQ/ 0.*      | Default or Bottom                     | None                          | None                  |
| QinQ/ 0.*      | Top                                   | TopQ                          | TopQ P-bits           |
| QinQ/ 0.*      | Default or Bottom                     | TopQ                          | TopQ P-bits           |

**Table 97 Match-QinQ-Dot1p Matching Behavior (Continued)**

| Port/ SAP Type | Match-QinQ-Dot1p Setting <sup>1</sup> | Existing Packet Tags | P-bits Used for Match |
|----------------|---------------------------------------|----------------------|-----------------------|
| QinQ/ 0.*      | Top                                   | TopQ BottomQ         | TopQ P-bits           |
| QinQ/ 0.*      | Default or Bottom                     | TopQ BottomQ         | BottomQ P-bits        |
| QinQ/ *.*      | Top                                   | None                 | None                  |
| QinQ/ *.*      | Default or Bottom                     | None                 | None                  |
| QinQ/ *.*      | Top                                   | TopQ                 | TopQ P-bits           |
| QinQ/ *.*      | Default or Bottom                     | TopQ                 | TopQ P-bits           |
| QinQ/ *.*      | Top                                   | TopQ BottomQ         | TopQ P-bits           |
| QinQ/ *.*      | Default or Bottom                     | TopQ BottomQ         | BottomQ P-bits        |

**Notes:**

1. "Default" in this column refers to the **no** form of **match-qinq-dot1p** command.
2. For null encapsulation, the 7705 SAR does not process dot1p bits.

**qinq-mark-top-only**

**Syntax** [no] **qinq-mark-top-only**

**Context** config>service>ies>if>sap>egress

**Description** When enabled, the **qinq-mark-top-only** command specifies which P-bits to mark during packet egress. When disabled, both sets of P-bits are marked. When enabled, only the P-bits in the top Q-tag are marked. The **no** form of the command is the default state (disabled).

[Table 98](#) shows the dot1p re-marking behavior for different egress port type/SAP type combinations and **qinq-mark-top-only** state, where "False" represents the default (disabled) state.

If a new tag is pushed, the dot1p bits of the new tag will be zero (unless the new tag is re-marked by the egress policy. The dot1p bits are configured using the **dot1p** parameter under the **config>qos** context.

**Table 98 Dot1P Re-marking Behavior for the QinQ-mark-top-only Command**

| Egress Port Type/SAP Type | QinQ-mark-top-only State | Egress P-Bits Marked or Re-marked |
|---------------------------|--------------------------|-----------------------------------|
| Null <sup>1</sup>         | n/a                      | None                              |

**Table 98** Dot1P Re-marking Behavior for the QinQ-mark-top-only Command (Continued)

| Egress Port Type/SAP Type | QinQ-mark-top-only State | Egress P-Bits Marked or Re-marked |
|---------------------------|--------------------------|-----------------------------------|
| Dot1q/ X <sup>1</sup>     | n/a                      | Outer tag                         |
| Dot1q/ * <sup>2</sup>     | n/a                      | None                              |
| Dot1q/ 0 <sup>2</sup>     | n/a                      | Outer tag                         |
| QinQ/ X.Y <sup>1</sup>    | False                    | Two outer tags <sup>3</sup>       |
|                           | True                     | Outer tag <sup>3</sup>            |
| QinQ/ X.* <sup>1</sup>    | True or False            | Outer tag                         |
| QinQ/ X.0 <sup>1</sup>    | True or False            | Outer tag                         |
| QinQ/ 0.* <sup>1</sup>    | True or False            | None                              |
| QinQ/ *.* <sup>2</sup>    | True or False            | None                              |

**Notes:**

1. This port type/SAP type is supported by the following services: Epipe, Ipipe, VPLS, IES, and VPRN.
2. This port type/SAP type is supported by the following services: Epipe and VPLS.
3. Normally, when a new tag is pushed, the dot1p bits of the new tag will be zero, unless the P-bits are remarked by the egress policy. However, an exception to this occurs when the egress SAP type is X.Y and only one new outer tag must be pushed. In this case, the new outer tag will have its dot1p bits set to the inner tag's dot1p bits.

**Default** no qinq-mark-top-only

**qos**

**Syntax** **qos** *policy-id*  
**no qos**

**Context** config>service>ies>if>sap>egress  
config>service>ies>if>sap>ingress

**Description** This command associates a QoS policy with an ingress or egress IES SAP.

QoS ingress and egress policies are important for the enforcement of SLA agreements. The policy ID must be defined prior to associating the policy with a SAP. If the *policy-id* does not exist, an error will be returned.

The **qos** command associates both ingress and egress QoS policies. The **qos** command allows only ingress policies to be associated on the SAP ingress and only egress policies to be associated on the SAP egress. Attempts to associate a QoS policy of the wrong type returns an error.

Only one ingress and one egress QoS policy can be associated with an IES SAP at one time. Attempts to associate a second QoS policy of a given type returns an error.

By default, no specific QoS policy is associated with the SAP for ingress or egress; therefore, the default QoS policy is used.

The **no** form of this command removes the QoS policy association from the SAP, and the QoS policy reverts to the default.

**Parameters** *policy-id* — associates the ingress or egress policy ID with the SAP. The policy ID or name must already exist.

**Values** 1 to 65535, or *policy-name* (up to 64 characters)

## scheduler-mode

**Syntax** **scheduler-mode {4-priority | 16-priority}**

**Context** config>service>ies>if>sap>egress  
config>service>ies>if>sap>ingress

**Description** This command sets the scheduler mode for the SAP and is part of the hierarchical QoS (H-QoS) feature on the 7705 SAR.

If the mode is 4-priority, then the SAP is considered an unshaped 4-priority SAP and the [agg-rate-limit](#) cannot be changed from its default values.

If the mode is 16-priority and the **agg-rate limit** parameters are configured to be non-default values, then the SAP is considered a shaped SAP. If the **agg-rate limit** parameters are left in their default settings, the SAP is considered an unshaped, 16-priority SAP.

This command is blocked on third-generation (Gen-3) Ethernet adapter cards and platforms, such as the 6-port Ethernet 10Gbps Adapter card and the 7705 SAR-X, which only support 4-priority scheduling mode.

If the specified SAP is a LAG SAP, **scheduler-mode** can be configured but is not applied to Gen-3 adapter cards and platforms. If one of the ports in the LAG is on a Gen-1 adapter card, then **scheduler-mode** cannot be configured.

**Default** 4-priority

**Parameters** **4-priority** — sets the scheduler mode for the SAP to be 4-priority mode  
**16-priority** — sets the scheduler mode for the SAP to be 16-priority mode

---

## shaper-group

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Context</b>     | config>service>ies>if>sap>egress<br>config>service>ies>if>sap>ingress                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | <p>This command applies a shaper group to a SAP. The shaper group must already be created and must be within the shaper policy assigned to the Ethernet MDA (for ingress) or port (for egress). A shaper group is a dual-rate aggregate shaper used to shape aggregate access ingress or egress SAPs at a shaper group rate. Multiple aggregate shaper groups ensure fair sharing of available bandwidth among different aggregate shapers.</p> <p>The default shaper group cannot be deleted.</p> <p>The <b>no</b> form of this command removes the configured <b>shaper-group</b>.</p> |
| <b>Default</b>     | shaper-group "default"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <p><i>shaper-group-name</i> — the name of the shaper group. To access the default shaper group, enter "default".</p> <p><b>create</b> — keyword used to create a shaper group</p>                                                                                                                                                                                                                                                                                                                                                                                                        |

### 6.7.2.2.5 IES Service Spoke SDP Commands

| <b>Description</b>   | <p>This command binds a service to an existing Service Distribution Point (SDP).</p> <p>A spoke SDP is treated like the equivalent of a traditional bridge “port”, where flooded traffic received on the spoke SDP is replicated on all other “ports” (other spoke SDPs or SAPs) and not transmitted on the port it was received on.</p> <p>The SDP has an operational state that determines the operational state of the SDP within the service. For example, if the SDP is administratively or operationally down, the SDP for the service is down.</p> <p>The SDP must already be defined in the <b>config&gt;service&gt;sdp</b> context in order to associate it with a service. If the <b>sdp</b> <i>sdp-id</i> is not already configured, an error message is generated. If the <i>sdp-id</i> does exist, a binding between that <i>sdp-id</i> and the service is created.</p> <p>SDPs must be explicitly associated and bound to a service. If an SDP is not bound to a service, no far-end devices can participate in the service.</p> <p>Class-based forwarding is not supported on a spoke SDP used for termination on an IES or VPRN service. All packets are forwarded over the default LSP.</p> <p>The <b>no</b> form of this command removes the SDP binding from the service. The SDP configuration is not affected; only the binding of the SDP to the service. Once the binding is removed, no packets are forwarded to the far-end router. The spoke SDP must be shut down first before it can be deleted from the configuration.</p> |
| <b>Default</b>       | no sdp-id is bound to a service                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Special Cases</b> | <b>IES</b> — only one <i>sdp-id</i> can be bound to an IES                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Description</b> | <p>This command associates an IP filter policy with an ingress spoke SDP. Filter policies control the forwarding and dropping of packets based on IP or MAC matching criteria.</p> <p>The filter policy must already be defined before the filter command is executed. If the filter policy does not exist, the operation will fail and an error message will be returned.</p> <p>In general, filters applied to ingress spoke SDPs apply to all packets on the spoke SDP. One exception is that non-IP packets are not applied to IP match criteria, so the default action in the filter policy applies to these packets.</p> |

The **no** form of this command removes any configured filter ID association with the spoke SDP.

**Parameters**    *ip-filter-id* — specifies the IP filter policy. The filter ID or filter name must already exist within the created IP filters.

**Values**        1 to 65535 or *filter-name* (up to 64 characters)

## vc-label

**Syntax**        **vc-label** *ingress-vc-label*  
**no vc-label** [*ingress-vc-label*]

**Context**        config>service>ies>if>spoke-sdp>ingress

**Description**    This command configures the static MPLS VC label used by the far-end device to send packets to the 7705 SAR in this service via this SDP.

**Parameters**    *ingress-vc-label* — a VC ingress value that indicates a specific connection

**Values**        2048 to 18431

### 6.7.2.2.6 Routed VPLS Commands

#### vpls

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>vpls</b> <i>service-name</i><br><b>no vpls</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Context</b>     | config>service>ies>if                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b> | <p>This command within the IP interface context binds the IP interface to the specified VPLS service name.</p> <p>The system does not attempt to resolve the service name until the IP interface is placed into the administratively up state (<b>no shutdown</b>). Once the IP interface is administratively up, the system scans the available VPLS services that have the allow-ip-int-binding flag set for a VPLS service associated with the service name. If the IP interface is already in the administratively up state, the system immediately attempts to resolve the given service name.</p> |
| <b>Parameters</b>  | <i>service-name</i> — specifies the service name that the system attempts to resolve to an <b>allow-ip-int-binding</b> enabled VPLS service associated with the service name. The specified service name is an ASCII string of up to 32 characters.                                                                                                                                                                                                                                                                                                                                                     |

#### ingress

|                    |                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ingress</b>                                                                                 |
| <b>Context</b>     | config>service>ies>if>vpls                                                                     |
| <b>Description</b> | This command within the VPLS binding context defines the routed IPv4 optional filter override. |

#### v4-routed-override-filter

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>v4-routed-override-filter</b> <i>ip-filter-id</i><br><b>no v4-routed-override-filter</b>                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Context</b>     | config>service>ies>if>vpls>ingress                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b> | <p>This command specifies an IPv4 filter ID applied to all ingress packets entering the VPLS service. The filter overrides the existing ingress IPv4 filter applied to SAPs or SDP bindings for packets associated with the routing IP interface. The override filter is optional, and if not defined or removed, the IPv4 routed packets use the existing ingress IPv4 filter on the VPLS virtual ports.</p> <p>The <b>no</b> form of the command removes the IPv4 routed override filter from the ingress IP interface.</p> |

### 6.7.2.2.7 IES Service Security Zone Configuration Commands

#### zone

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>zone</b> { <i>zone-id</i>   <i>zone-name</i> } [ <b>create</b> ]<br><b>no zone</b> { <i>zone-id</i>   <i>zone-name</i> }                                                                                                                                                                                                                                                                                                           |
| <b>Context</b>     | config>service>ies                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | <p>This command creates or specifies a security zone within an IES context. Each zone must have a unique ID.</p> <p>All zones must be explicitly created with the <b>create</b> keyword.</p> <p>Enter an existing zone without the <b>create</b> keyword to edit zone parameters.</p> <p>The <b>no</b> form of this command deletes the zone. When a zone is deleted, all configuration parameters for the zone are also deleted.</p> |
| <b>Parameters</b>  | <i>zone-id</i> — the zone ID number. The zone ID must be unique within the system.                                                                                                                                                                                                                                                                                                                                                    |
| <b>Values</b>      | 1 to 65534                                                                                                                                                                                                                                                                                                                                                                                                                            |

#### abort

|                    |                                                           |
|--------------------|-----------------------------------------------------------|
| <b>Syntax</b>      | <b>abort</b>                                              |
| <b>Context</b>     | config>service>ies>zone                                   |
| <b>Description</b> | This command discards changes made to a security feature. |
| <b>Default</b>     | n/a                                                       |

#### begin

|                    |                                                                   |
|--------------------|-------------------------------------------------------------------|
| <b>Syntax</b>      | <b>begin</b>                                                      |
| <b>Context</b>     | config>service>ies>zone                                           |
| <b>Description</b> | This command enters the mode to create or edit security features. |
| <b>Default</b>     | n/a                                                               |

## commit

|                    |                                                       |
|--------------------|-------------------------------------------------------|
| <b>Syntax</b>      | <b>commit</b>                                         |
| <b>Context</b>     | config>service>ies>zone                               |
| <b>Description</b> | This command saves changes made to security features. |
| <b>Default</b>     | n/a                                                   |

## inbound

|                    |                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>inbound</b>                                                                               |
| <b>Context</b>     | config>service>ies>zone                                                                      |
| <b>Description</b> | This command enables the context to configure limit parameters on inbound firewall sessions. |
| <b>Default</b>     | n/a                                                                                          |

## outbound

|                    |                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>outbound</b>                                                                                           |
| <b>Context</b>     | config>service>ies>zone                                                                                   |
| <b>Description</b> | This command enables the context to configure limit parameters for outbound firewall sessions on the CSM. |
| <b>Default</b>     | n/a                                                                                                       |

## limit

|                    |                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>limit</b>                                                                                                                      |
| <b>Context</b>     | config>service>ies>zone>inbound<br>config>service>ies>zone>outbound                                                               |
| <b>Description</b> | This command enables the context to configure limits on concurrent sessions for inbound or outbound firewall sessions on the CSM. |
| <b>Default</b>     | n/a                                                                                                                               |

## concurrent-sessions

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>concurrent-sessions</b> { <b>tcp</b>   <b>udp</b>   <b>icmp</b>   <b>other</b> } <i>sessions</i><br><b>no concurrent-sessions</b> { <b>tcp</b>   <b>udp</b>   <b>icmp</b>   <b>other</b> }                                                                                                                                                                                                                                                                                                          |
| <b>Context</b>     | config>service>ies>zone>inbound>limit<br>config>service>ies>zone>outbound>limit                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | This command configures the maximum number of concurrent firewall sessions that can be established per zone, in either the inbound or outbound direction.                                                                                                                                                                                                                                                                                                                                              |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <b>tcp</b> — specifies that TCP connection traffic is to be firewalled<br><b>udp</b> — specifies that UDP connection traffic is to be firewalled<br><b>icmp</b> — specifies that ICMP connection traffic is to be firewalled<br><b>other</b> — specifies that the traffic to be firewalled is other than TCP, UDP, or ICMP<br><i>sessions</i> — the maximum number of concurrent firewall sessions that can be created in a zone for the configured direction and protocol<br><b>Values</b> 1 to 16383 |

## interface

|                    |                                                                                                                                                                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [ <b>no</b> ] <b>interface</b> <i>ip-int-name</i>                                                                                                                                                                                                                                                                  |
| <b>Context</b>     | config>service>ies>zone                                                                                                                                                                                                                                                                                            |
| <b>Description</b> | This command creates a logical IP routing interface for a zone. Once created, attributes such as an IP address can be associated with the IP interface. Multiple interfaces can be configured on a zone.<br><br>The <b>no</b> form of this command removes the IP interface and all the associated configurations. |
| <b>Parameters</b>  | <i>ip-int-name</i> — the name of the interface to be configured within the zone<br><b>Values</b> 1 to 32 characters (must start with a letter)                                                                                                                                                                     |

## log

|                    |                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>log</b> { <i>log-id</i>   <i>name</i> }<br><b>no log</b>                                                                                                                                             |
| <b>Context</b>     | config>service>ies>zone                                                                                                                                                                                 |
| <b>Description</b> | This command configures a log identifier for the specified zone. A log identifier can be configured in the <b>config&gt;router&gt;zone</b> context and the <b>config&gt;security&gt;policy</b> context. |

---

The **no** form of this command removes logging for the zone.

**Parameters** *log-id* — the identifier for the log  
**Values** 1 to 32 characters

## name

**Syntax** **name** *zone-name*  
**no name**

**Context** config>service>ies>zone

**Description** This command configures a zone name. The zone name is unique within the system. It can be used to refer to the zone under configure, show, and clear commands.

**Parameters** *zone-name* — the name of the zone  
**Values** 1 to 32 characters (must start with a letter). If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

## nat

**Syntax** **nat**

**Context** config>service>ies>zone

**Description** This command enters the context to configure NAT parameters for a zone.

## pool

**Syntax** **pool** *pool-id* [**create**]  
**no pool** *pool-id*

**Context** config>service>ies>zone>nat

**Description** This command configures the NAT pool for the security zone within an IES service. Each pool must have a unique ID.

All pools must be explicitly created with the **create** keyword.

Enter an existing pool without the **create** keyword to edit pool parameters.

The **no** form of this command deletes the specified NAT pool. When a pool is deleted, all configuration parameters for the pool will also be deleted.

---

|                   |                                     |
|-------------------|-------------------------------------|
| <b>Parameters</b> | <i>pool-id</i> — the pool ID number |
| <b>Values</b>     | 1 to 100                            |

## direction

|                    |                                                                                                                                                                                                                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>direction</b> { <b>zone-outbound</b>   <b>zone-inbound</b>   <b>both</b> }<br><b>no direction</b>                                                                                                                                                                                                              |
| <b>Context</b>     | config>service>ies>zone>nat>pool                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | This command configures the NAT pool direction for the security zone. A specific NAT pool can be configured for different directions while using the same policy. For example, if the security policy entry direction is set to <b>both</b> , separate inbound and outbound pools can be created for that policy. |
| <b>Parameters</b>  | <b>zone-outbound</b> — configures a pool for the policy outbound traffic<br><b>zone-inbound</b> — configures a pool for the policy inbound traffic<br><b>both</b> — configures a pool for policy inbound and outbound traffic                                                                                     |

## entry

|                    |                                                                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>entry</b> <i>entry-id</i> [ <b>create</b> ]<br><b>no entry</b> <i>entry-id</i>                                                                                                                                                             |
| <b>Context</b>     | config>service>ies>zone>nat>pool                                                                                                                                                                                                              |
| <b>Description</b> | This command configures a NAT pool entry within an IES service.<br><br>The <b>no</b> form of this command deletes the entry with the specified ID. When an entry is deleted, all configuration parameters for the entry will also be deleted. |
| <b>Parameters</b>  | <i>entry-id</i> — the entry ID number<br><b>Values</b> 1 to 65535                                                                                                                                                                             |

## ip-address

|                |                                                                                                                                 |
|----------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>ip-address</b> <i>ip-address</i> [ <b>to</b> <i>ip-address</i> ] <b>interface</b> <i>ip-int-name</i><br><b>no ip-address</b> |
| <b>Context</b> | config>service>ies>zone>nat>pool>entry                                                                                          |

**Description** This command configures the source IP address or IP address range to which packets that match NAT policy are routed using NAT. An interface can also be configured, in which case all packets that match NAT policy are routed to the interface IP address. If the interface IP address is changed dynamically, NAT is updated accordingly. Only one IP address can be associated with an IP interface. Source IP addresses and interfaces cannot be used together in a single NAT pool.

The IP address for the interface must be entered in dotted-decimal notation. The maximum IP address range limit is 255.

The **no** form of the command removes the IP address assignment. The **no** form of this command can only be performed when the IP interface is administratively shut down. Shutting down the IP interface brings the interface operationally down.

**Parameters** *ip-address* — the source IP address to be used by NAT. The *ip-address* portion of the **ip-address** command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted-decimal notation.

**Values** 1.0.0.0 to 223.255.255.255

*ip-int-name* — the name of the interface to be used by NAT

## port

**Syntax** **port** *port* [**to** *port*]  
**no port**

**Context** config>service>ies>zone>nat>pool>entry

**Description** This command configures the UDP/TCP port or port range. Packets that match NAT policy undergo network port address translation (NPAT) and are routed to their source UDP/TCP port. Configuring a UDP/TCP port pool requires an IP-address pool because the 7705 SAR does not support port address translation (PAT) alone.

The **no** form of this command deletes the port or port range.

**Parameters** *port* — the UDP/TCP port or range of ports to which NPAT is applied

## name

**Syntax** **name** *pool-name*  
**no name**

**Context** config>service>ies>zone>nat>pool

**Description** This command configures a zone pool name. Pool names must be unique within the group of pools defined for a zone. It can be used to refer to the pool under configure, show, and clear commands.

**Parameters**    *pool-name* — the name of the pool. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

**Values**        1 to 32 characters (must start with a letter).

## policy

**Syntax**        **policy** {*policy-id* | *policy-name*}  
**no policy**

**Context**        config>service>ies>zone

**Description**    This command sets the policy to be used by the security zone to build its matching criteria for incoming packets.

The **no** form of this command deletes the specified policy.

**Parameters**    *policy-id* — the number of the referenced policy

**Values**        1 to 65535

*policy-name* — the name of the referenced policy

### 6.7.2.2.8 IES Raw Socket IP Transport Configuration Commands

#### ip-transport

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Context</b>     | config>service>ies                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Description</b> | <p>This command creates an IP transport subservice within an IES service. An IP transport subservice is used to transmit serial raw socket data to and from a local host and remote host.</p> <p>All IP transport subservices must be explicitly created using the <b>create</b> keyword. An IP transport subservice is owned by the service within which it is created. An IP transport subservice can only be associated with a single service. The <b>create</b> keyword is not needed when editing parameters for an existing IP transport subservice. An IP transport subservice must be first shut down before changes can be made to the configured parameters.</p> <p>The <b>no</b> form of this command deletes the IP transport subservice with the specified <i>ipt-id</i>. When an IP transport subservice is deleted, all configured parameters for the IP transport subservice are also deleted.</p> |
| <b>Default</b>     | no ip-transport                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <p><i>ipt-id</i> — the IP transport subservice physical port identifier. The <i>ipt-id</i> must reference an RS-232 serial port that has been configured as a <b>socket</b> and has its encapsulation type set to <b>raw</b>. Refer to the 7705 SAR Interface Configuration Guide, “Serial Commands”, for more information.</p> <p><b>Values</b>      value in the format <i>slot/mda/port.channel</i></p> <p><b>create</b> — creates this IP transport subservice</p>                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>remote-host</b> <i>host-id ip-addr ip-addr</i> <b>port-num</b> <i>port-num</i> [ <b>create</b> ]<br><b>no remote-host</b> <i>host-id</i>                                                                                                                                                                                                       |
| <b>Context</b>     | config>service>ies>ip-transport                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b> | <p>This command creates a remote host within the IP transport subservice. Multiple remote hosts may be created in order to send serial raw socket IP transport data to multiple destinations. The <b>create</b> keyword must be used for each remote host that is created.</p> <p>The <b>no</b> form of this command deletes the remote host.</p> |
| <b>Default</b>     | no remote-host                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <p><i>host-id</i> — the remote host identifier</p> <p><b>Values</b>      1 to 2147483647 or a name string up to 64 characters</p>                                                                                                                                                                                                                 |

*ip-addr* — the IP address that is used to reach the remote host in order to route IP transport packets to that remote host

**Values** a.b.c.d (IPv4 address)

*port-num* — the destination port number that is used to reach the serial port socket on the remote host

**Values** 1 to 65535

**create** — creates this remote host

## name

|                    |                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>name</b> <i>host-name</i><br><b>no name</b>                                                                                      |
| <b>Context</b>     | config>service>ies>ip-transport>remote-host                                                                                         |
| <b>Description</b> | This command configures a unique name for this remote host.<br><br>The <b>no</b> form of this command deletes the remote host name. |
| <b>Default</b>     | n/a                                                                                                                                 |
| <b>Parameters</b>  | <i>host-name</i> — a unique name for this remote host, up to 64 characters long                                                     |

## tcp

|                    |                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>tcp</b>                                                                                        |
| <b>Context</b>     | config>service>ies>ip-transport                                                                   |
| <b>Description</b> | This command enables the context to configure TCP parameters within this IP transport subservice. |
| <b>Default</b>     | n/a                                                                                               |

## inactivity-timeout

|                    |                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>inactivity-timeout</b> <i>seconds</i>                                                                                     |
| <b>Context</b>     | config>service>ies>ip-transport>tcp                                                                                          |
| <b>Description</b> | This command specifies how long to wait before disconnecting a TCP connection due to traffic inactivity over the connection. |
| <b>Default</b>     | 30 s                                                                                                                         |

---

|                   |                                                                                      |
|-------------------|--------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>seconds</i> — how long to wait, in seconds, before disconnecting a TCP connection |
| <b>Values</b>     | 1 to 65535                                                                           |

## max-retries

|                    |                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>max-retries</b> <i>number</i>                                                                                                                        |
| <b>Context</b>     | config>service>ies>ip-transport>tcp                                                                                                                     |
| <b>Description</b> | This command specifies the number of times that a remote host, acting as a client, tries to establish a TCP connection after the initial attempt fails. |
| <b>Default</b>     | 5                                                                                                                                                       |
| <b>Parameters</b>  | <i>number</i> — the number of attempts to establish a TCP connection after the initial attempt fails                                                    |
| <b>Values</b>      | 0 to 10                                                                                                                                                 |

## retry-interval

|                    |                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>retry-interval</b> <i>seconds</i>                                                      |
| <b>Context</b>     | config>service>ies>ip-transport>tcp                                                       |
| <b>Description</b> | This command specifies how long to wait before each TCP <b>max-retries</b> attempt.       |
| <b>Default</b>     | 5 s                                                                                       |
| <b>Parameters</b>  | <i>seconds</i> — how long to wait, in seconds, before each TCP <b>max-retries</b> attempt |
| <b>Values</b>      | 1 to 300                                                                                  |

### 6.7.2.3 Show Commands

**Note:** The following command outputs are examples only; actual displays may differ depending on supported functionality and user configuration.

#### customer

- Syntax** `customer [customer-id]`
- Context** show>service
- Description** This command displays service customer information.
- Parameters** *customer-id* — specifies the customer ID number to be displayed  
**Values** 1 to 2147483647
- Output** The following output is an example of service customer information, and [Table 100](#) describes the fields.

**Output Example**

```
A:ALU-2# show service customer 1
=====
Customer 1
=====
Customer-ID : 1
Contact : Tech Support
Description : Default customer
Phone : (613) 555-1122
=====
```

**Table 100**      **Service Customer Field Descriptions**

| Label       | Description                                       |
|-------------|---------------------------------------------------|
| Customer-ID | ID that uniquely identifies the customer          |
| Contact     | Name or title of the primary contact person       |
| Description | Generic information about the customer            |
| Phone       | Phone number by which to reach the contact person |

## egress-label

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>egress-label</b> <i>start-label</i> [ <i>end-label</i> ]                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Context</b>     | show>service                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Description</b> | <p>This command displays service information using the range of egress labels.</p> <p>If only the mandatory <i>start-label</i> parameter is specified, only services using the specified label are displayed.</p> <p>If both <i>start-label</i> and <i>end-label</i> parameters are specified, the services using the labels in the specified range are displayed.</p> <p>Use the <b>show router ldp bindings</b> command to display dynamic labels.</p>     |
| <b>Parameters</b>  | <p><i>end-label</i> — the ending egress label value for which to display services using the label range</p> <p><b>Values</b> 2049 to 131071</p> <p><b>Default</b> the <i>start-label</i> value</p> <p><i>start-label</i> — the starting egress label value for which to display services using the label range. If only <i>start-label</i> is specified, only services using <i>start-label</i> are displayed.</p> <p><b>Values</b> 0, or 2048 to 131071</p> |
| <b>Output</b>      | The following output is an example of service egress label information, and <a href="#">Table 101</a> describes the fields.                                                                                                                                                                                                                                                                                                                                  |

### Output Example

In the example below, services 3, 5 and 6 are IES, and services 5000 and 5001 are VPLS services.

```
*A:ALU-12>show>service# egress-label 0 131071

**Table 101 Service Egress Field Descriptions**

| Label                    | Description                                                                                    |
|--------------------------|------------------------------------------------------------------------------------------------|
| Svc Id                   | The ID that identifies a service                                                               |
| Sdp Binding              | The ID that identifies an SDP                                                                  |
| Type                     | Indicates whether the SDP binding is a spoke or a mesh                                         |
| I. Lbl                   | The VC label used by the far-end device to send packets to 7705 SAR in this service by the SDP |
| E. Lbl                   | The VC label used by 7705 SAR to send packets to the far-end device in this service by the SDP |
| Number of Bindings Found | The total number of SDP bindings that exist within the specified label range                   |

id

**Syntax** `id service-id`

**Context** `show>service`

**Description** This command displays information for a particular service ID

**Parameters** *service-id* — identifies the service in the domain by service number or name

all

**Syntax** `all`

**Context** `show>service>id`

**Description** This command displays detailed information for all aspects of the service.

**Output** The following output is an example of service ID all information, and [Table 102](#) describes the fields.

**Output Example (IES Management Service)**

```
A:ALU-2# show service id 751 all
=====

| <b>Service Detailed Information</b> |                                                                                                                             |
| Service Id                          | Service ID number                                                                                                           |
| Service Type                        | Type of service (IES)                                                                                                       |
| Name                                | The service name                                                                                                            |
| Description                         | Generic information about the service                                                                                       |
| Customer Id                         | Customer ID number                                                                                                          |
| Last Status Change                  | Date and time of the most recent status change to this service                                                              |
| Last Mgmt Change                    | Date and time of the most recent management-initiated change to this service                                                |
| Admin State                         | Desired state of the service                                                                                                |
| Oper State                          | Operating state of the service                                                                                              |
| MTU                                 | Service MTU                                                                                                                 |
| SAP Count                           | Number of SAPs specified for this service                                                                                   |
| <b>Service Access Points</b>        |                                                                                                                             |
| Service Id                          | Service Identifier                                                                                                          |
| SAP                                 | ID of the access port where this SAP is defined                                                                             |
| Encap                               | Encapsulation type for this SAP on the access port                                                                          |
| Admin State                         | Desired state of the SAP                                                                                                    |
| Oper State                          | Operating state of the SAP                                                                                                  |
| Flags                               | Conditions that affect the operating status of this SAP. Display output includes ServiceAdminDown, PortOperDown, and so on. |
| Multi Svc Site                      | Indicates the multiservice site that the SAP is a member of                                                                 |
| Last Status Change                  | Date and time of the most recent status change to this SAP                                                                  |
| Last Mgmt Change                    | Date and time of the most recent management-initiated change to this SAP                                                    |

**Table 102 Service ID All Field Descriptions (Continued)**

| Label              | Description                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Admin MTU          | Desired largest service frame size (in octets) that can be transmitted through this SAP to the far-end router, without requiring the packet to be fragmented |
| Oper MTU           | Actual largest service frame size (in octets) that can be transmitted through this SAP to the far-end router, without requiring the packet to be fragmented  |
| Ingr IP Fltr-Id    | Ingress IP filter policy ID assigned to the SAP                                                                                                              |
| Egr IP Fltr-Id     | Egress IP filter policy ID assigned to the SAP                                                                                                               |
| Ingr Mac Fltr-Id   | Ingress MAC filter policy ID assigned to the SAP (not applicable)                                                                                            |
| Egr Mac Fltr-Id    | Egress MAC filter policy ID assigned to the SAP (not applicable)                                                                                             |
| Ingr IPv6 Fltr-Id  | Specifies the ingress IPv6 filter policy ID assigned to the SAP                                                                                              |
| Egr IPv6 Fltr-Id   | Specifies the egress IPv6 filter policy ID assigned to the SAP                                                                                               |
| tod-suite          | n/a                                                                                                                                                          |
| qinq-pbit-marking  | Indicates the qinq P-bit marking for the SAP: both or top                                                                                                    |
| Ing Scheduler Mode | Indicates the ingress scheduler mode for the SAP                                                                                                             |
| Egr Scheduler Mode | Indicates the egress scheduler mode for the SAP                                                                                                              |
| Ing Agg Rate Limit | Indicates the PIR rate limit in the access ingress direction for the aggregate of the SAP queues                                                             |
| Egr Agg Rate Limit | Indicates the PIR rate limit in the access egress direction for the aggregate of the SAP queues                                                              |
| Ing Agg cir        | Indicates the CIR rate limit in the access ingress direction for the aggregate of the SAP queues                                                             |
| Egr Agg cir        | Indicates the CIR rate limit in the access egress direction for the aggregate of the SAP queues                                                              |
| Ing Shaper Group   | Indicates the ingress shaper group for the SAP                                                                                                               |
| Egr Shaper Group   | Indicates the egress shaper group for the SAP                                                                                                                |
| Acct. Pol          | Accounting policy applied to the SAP                                                                                                                         |
| Collect Stats      | Specifies whether accounting statistics are collected on the SAP                                                                                             |

**Table 102 Service ID All Field Descriptions (Continued)**

| Label                                      | Description                                                                                                        |
|--------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>QOS</b>                                 |                                                                                                                    |
| Ingress qos-policy                         | SAP ingress QoS policy ID                                                                                          |
| Egress qos-policy                          | SAP egress QoS policy ID                                                                                           |
| <b>Sap Statistics</b>                      |                                                                                                                    |
| Last Cleared Time                          | Date and time that a clear command was issued on statistics                                                        |
| <b>Forwarding Engine Stats (Ingress)</b>   |                                                                                                                    |
| Dropped                                    | Number of packets or octets dropped by the forwarding engine                                                       |
| Off. HiPrio                                | Number of high-priority packets or octets offered to the forwarding engine                                         |
| Off. LowPrio                               | Number of low-priority packets offered to the forwarding engine                                                    |
| <b>Queueing Stats (Ingress QoS Policy)</b> |                                                                                                                    |
| Dro. HiPrio                                | Number of high-priority packets or octets discarded, as determined by the SAP ingress QoS policy                   |
| Dro. LowPrio                               | Number of low-priority packets discarded, as determined by the SAP ingress QoS policy                              |
| For. InProf                                | Number of in-profile packets or octets (rate below CIR) forwarded, as determined by the SAP ingress QoS policy     |
| For. OutProf                               | Number of out-of-profile packets or octets (rate above CIR) forwarded, as determined by the SAP ingress QoS policy |
| <b>Queueing Stats (Egress QoS Policy)</b>  |                                                                                                                    |
| Dro. InProf                                | Number of in-profile packets or octets discarded, as determined by the SAP egress QoS policy                       |
| Dro. OutProf                               | Number of out-of-profile packets or octets discarded, as determined by the SAP egress QoS policy                   |
| For. InProf                                | Number of in-profile packets or octets (rate below CIR) forwarded, as determined by the SAP egress QoS policy      |
| For. OutProf                               | Number of out-of-profile packets or octets (rate above CIR) forwarded, as determined by the SAP egress QoS policy  |

| <b>ATM SAP Configuration Information</b> |                                                                                 |
| Ingress TD Profile                       | Profile ID of the traffic descriptor applied to the ingress SAP                 |
| Egress TD Profile                        | Profile ID of the traffic descriptor applied to the egress SAP                  |
| Alarm Cell Handling                      | Indicates that OAM cells are being processed                                    |
| AAL-5 Encap                              | AAL-5 encapsulation type—this is always mux-ip                                  |
| OAM Termination                          | Indicates whether this SAP is an OAM termination point                          |
| <b>Services Interfaces</b>               |                                                                                 |
| If Name                                  | Name used to refer to the IES interface                                         |

**Table 102 Service ID All Field Descriptions (Continued)**

| Label                    | Description                                                                                                                      |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| Admin State              | Administrative state of the interface                                                                                            |
| Oper State               | Operational state of the interface                                                                                               |
| IP Addr/mask             | IP address and subnet mask length of the interface                                                                               |
| Address Type             | Specifies whether the IP address for the interface is the primary or secondary address on the interface (this is always primary) |
| Broadcast Address        | Broadcast address of the interface                                                                                               |
| If Index                 | Interface index corresponding to the IES interface                                                                               |
| Virt. If Index           | Virtual interface index of the IES interface                                                                                     |
| Last Oper Chg            | Date and time of the last operating state change on the interface                                                                |
| Global IF Index          | Global interface index of the IES interface                                                                                      |
| SAP Id                   | SAP identifier                                                                                                                   |
| TOS Marking              | Specifies whether the ToS marking state is trusted or untrusted for the IP interface                                             |
| If Type                  | Type of interface: IES                                                                                                           |
| IES ID                   | Service identifier                                                                                                               |
| MAC Address              | IEEE 802.3 MAC address                                                                                                           |
| Arp Timeout              | Timeout for an ARP entry learned on the interface                                                                                |
| IP MTU                   | IP maximum transmit unit for the interface                                                                                       |
| ICMP Mask Reply          | Specifies whether the IP interface replies to a received ICMP mask request                                                       |
| ARP Populate             | Indicates if ARP is enabled or disabled                                                                                          |
| <b>Proxy ARP Details</b> |                                                                                                                                  |
| Rem Proxy ARP            | Indicates whether remote proxy ARP is enabled or disabled                                                                        |
| Local Proxy ARP          | Indicates whether local proxy ARP is enabled or disabled                                                                         |
| Policies                 | Specifies the policy statements applied to proxy ARP                                                                             |

**Table 102 Service ID All Field Descriptions (Continued)**

| Label               | Description                                                                                                                                                                                                                            |

| Unreachables        | Maximum number of ICMP destination unreachable messages that the IP interface will issue in a given period of time, in seconds<br><br>Disabled—indicates that the IP interface will not generate ICMP destination unreachable messages |
| TTL Expired         | Maximum number of ICMP TTL expired messages that the IP interface will issue in a given period of time, in seconds<br><br>Disabled—indicates that the IP interface will not generate ICMP TTL expired messages                         |

## arp

**Syntax** **arp** [*ip-address*] | [**mac** *ieee-address*] | **sap** *sap-id*] | [**interface** *ip-int-name*]

**Context** show>service>id

**Description** This command displays the ARP table for the IES instance.

**Parameters** *ip-address* — the IP address for which ARP entries will be displayed

**Default** all IP addresses

*ieee-address* — the 48-bit MAC address for which ARP entries will be displayed. The MAC address can be expressed in the form *aa:bb:cc:dd:ee:ff* or *aa-bb-cc-dd-ee-ff*, where *aa*, *bb*, *cc*, *dd*, *ee*, and *ff* are hexadecimal numbers.

**Default** all MAC addresses

*sap-id* — the SAP ID for which ARP entries will be displayed. See [Table 41](#) for a full list of SAP IDs.

*ip-int-name* — the interface name for which ARP entries will be displayed

**Output** The following output is an example of service ID ARP information, and [Table 103](#) describes the fields.

**Output Example**

```
*A:ALU-2# show service id 4 arp
=====
ARP Table
=====
IP Address MAC Address Type Expiry Interface SAP

```

```
10.2.3.3 Other 00h00m00s to Internet n/a

```

**Table 103**      **Service ID ARP Field Descriptions**

| Label            | Description                                             |
|------------------|---------------------------------------------------------|
| <b>ARP Table</b> |                                                         |
| IP Address       | Specified IP address                                    |
| MAC Address      | Specified MAC address                                   |
| Type             | Static—FDB entries created by management                |
|                  | Learned—dynamic entries created by the learning process |
|                  | OAM—entries created by the OAM process                  |
|                  | Other—local entries created for the IP interfaces       |
| Expiry           | Age of the ARP entry                                    |
| Interface        | Interface applied to the service                        |
| SAP              | SAP ID                                                  |

base

**Syntax**      **base**

**Context**      show>service>id

**Description**      This command displays basic information about the service specified by the ID.

**Output**      The following output is an example of service ID base information, and [Table 104](#) describes the fields.

**Output Example**

```
*A:ALU-2# show service id 4 base

| Interface Name<br>SapID/Sdp    | Name of the interface                                                                                                                                                                                                               |
| Arp Populate                   | Specifies whether ARP populate is enabled                                                                                                                                                                                           |
| Used/Provided:                 | Used—number of lease-states that are currently in use on the specified interface; that is, the number of clients on the interface that got an IP address by DHCP. This number is always less than or equal to the “Provided” field. |
|                                | Provided—lease-populate value configured for the specified interface                                                                                                                                                                |
| Info Option                    | Specifies whether Option 82 processing is enabled on the interface                                                                                                                                                                  |
| Admin State                    | Administrative state                                                                                                                                                                                                                |

## interface

**Syntax** **interface** [{*ip-address* | *ip-int-name*] [*interface-type*] [**detail**] [*family*] | **summary**

**Context** show>service>id

**Description** This command displays information for the IP interfaces associated with the IES service.

**Parameters** *ip-address* — only displays the interface information associated with the specified IP address

**Values**

- ipv4-address*: a.b.c.d (host bits must be 0)
- ipv6-address*: x:x:x:x:x:x:x (eight 16-bit pieces)
- x:x:x:x:x:x.d.d.d.d
- x: [0 to FFFF]H
- d: [0 to 255]D

*ip-int-name* — the IP interface name for which to display information

*interface-type* — displays either group or subscriber interfaces

**detail** — displays detailed IP interface information

*family* — displays the specified router IP interface family

**Values**

- ipv4*—displays only those peers that have the IPv4 family enabled
- ipv6*—displays the peers that are IPv6-capable

**summary** — displays summary IP interface information

**Output** The following output is an example of service ID interface information, and [Table 107](#) describes the fields.

### Output Example

```
*A:ALU-2 show service id 4 interface
=====
Interface Table
=====
Interface-Name Adm Opr (v4/v6) Type Port/SapId
IP-Address PfxState

to Internet Up Down/Down IES n/a
10.2.3.3/24 n/a

Interfaces : 1
=====
*A:ALU-2
```

**Table 107 Service ID Interface Field Descriptions**

|------------------------|-------------------------------------------|
| <b>Interface Table</b> |                                           |
| Interface-Name         | Name of the interface                     |
| IP-Address             | IP address of the interface               |
| Adm                    | Administrative state of the interface     |
| Opr (v4/v6)            | Operational state of the interface        |
| Type                   | Service type                              |
| Port/SapId PfxState    | Port or SAP associated with the interface |

## ip-transport

**Syntax** **ip-transport** *ipt-id* [**detail** | **statistics**]

**Context** show>service>id

**Description** This command displays information for a specified IP transport subservice within this IES service. If no IP transport subservice is specified, summary information is displayed for all IP transport subservices associated with the IES service.

**Parameters** *ipt-id* — the physical port associated with the IP transport subservice, in the format *slot/mda/port.channel*

**detail** — displays detailed information for the specified IP transport subservice

**statistics** — displays statistical information for the specified IP transport subservice

**Output** The following output is an example of IP transport subservice summary information for a specified service, and [Table 108](#) describes the fields.

### Output Example

```
*A:ALU-12# show service id 100 ip-transport

| Label                                    | Description                                                                                                    |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------|
| <b>IP Transport (Summary), Service x</b> |                                                                                                                |
| IptId                                    | The IP transport subservice physical port identifier                                                           |
| LocalIP                                  | The IP address (IPv4) that is used for the local host                                                          |
| LocalPort                                | The port number that is used by remote hosts to establish TCP/UDP sessions to the local host                   |
| Proto                                    | The protocol type that is used for all sessions to and from the local host (either TCP or UDP)                 |
| RemHost                                  | The number of remote hosts associated with the IP transport subservice                                         |
| DSCP                                     | The DSCP name used to mark the DSCP field in IP transport packets                                              |
| FC                                       | The FC name used for IP transport packets                                                                      |
| FltrUnkn                                 | Indicates whether the <b>filter-unknown-host</b> command is enabled or disabled on the IP transport subservice |
| Adm                                      | The administrative state of the IP transport subservice                                                        |
| Opr                                      | The operational state of the IP transport subservice                                                           |
| Entries found:                           | The number of IP transport subservices associated with this service                                            |

The following output is an example of detailed information for a specified IP transport subservice within a specified service, and [Table 109](#) describes the fields.

### Output Example

**Table 109 Service IP Transport Detailed Field Descriptions**

| Label               | Description                                                                                                      |
|---------------------|------------------------------------------------------------------------------------------------------------------|
| <b>IP Transport</b> |                                                                                                                  |
| Service Id          | The ID that identifies the service (the service type is shown in brackets)                                       |
| IP Transport Id     | The physical port identifier for this IP transport subservice                                                    |
| Description         | The description associated with this IP transport subservice                                                     |
| Admin State         | The administrative state of this IP transport subservice                                                         |
| Oper State          | The operational state of this IP transport subservice                                                            |
| Oper Flags          | The operational flags associated with this IP transport subservice                                               |
| Local IP Address    | The IP address (IPv4) that is used for the local host                                                            |
| Local Port Number   | The port number that is used by remote hosts to establish TCP/UDP sessions to the local host                     |
| Local IP Protocol   | The protocol type that is used for all sessions to/from the local host (either TCP or UDP)                       |
| DSCP                | The DSCP name used to mark the DSCP field in IP transport packets                                                |
| Filter Unknown Host | Indicates whether the <b>filter-unknown-host</b> command is enabled or disabled for this IP transport subservice |
| FC                  | The FC name used for IP transport packets                                                                        |
| Profile             | The profile marking for the IP transport packets (in or out)                                                     |
| TCP Inact Timeout   | The configured inactivity timeout value for TCP connections                                                      |
| TCP Max Retries     | The configured maximum retry value for TCP connections                                                           |
| TCP Retry Interval  | The configured retry interval value for TCP connections                                                          |
| Num Remote Hosts    | The number of remote hosts associated with this IP transport subservice                                          |
| Last Mgmt Change    | The date and time of the most recent management-initiated change to this IP transport subservice                 |
| Last Oper Change    | The date and time of the most recent operational status change for this IP transport subservice                  |

**Table 109 Service IP Transport Detailed Field Descriptions (Continued)**

| Label                                      | Description                                                                                                          |
|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------|
| <b>IP Transport Accumulated Statistics</b> |                                                                                                                      |
| <b>Known Remote Hosts</b>                  |                                                                                                                      |
| Packets sent                               | The number of packets sent to the host                                                                               |
| Characters sent                            | The number of data characters sent to the host                                                                       |
| Packets received                           | The number of packets received from the host                                                                         |
| Characters received                        | The number of data characters received from the host                                                                 |
| Connections<br>To<br>From                  | The number of connections to and from the host                                                                       |
| Connection retries                         | The number of connection retries to the host                                                                         |
| Connection failures                        | The number of connection failures to the host                                                                        |
| Currently connected                        | The number of hosts currently connected                                                                              |
| <b>Unknown Remote Hosts</b>                |                                                                                                                      |
| Packets sent                               | The number of packets sent to the host                                                                               |
| Characters sent                            | The number of data characters sent to the host                                                                       |
| Packets received                           | The number of packets received from the host                                                                         |
| Characters received                        | The number of data characters received from the host                                                                 |
| Successful connections from                | The number of successful connections from the host                                                                   |
| Rejected due to unknown host filter        | The number of rejected connection attempts from the host due to the <b>filter-unknown-host</b> command being enabled |
| Rejected due to out of resource            | The number of connection attempts from the host that were rejected due to the unavailability of resources            |
| Inactivity timeouts                        | The number of connections from the host that timed out due to inactivity                                             |
| Last RemIp:RemPort                         | The IP address (IPv4) and port number used by the host for the last connection                                       |
| Currently connected                        | The number of hosts that are currently connected                                                                     |
| Dropped packets due to no remote hosts     | The number of packets dropped due to no hosts being connected                                                        |

## remote-host

|                    |                                                                                                                                                                                                                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| <b>Description</b> | This command displays information for a specified remote host within this IP transport subservice within this service. If no remote host is specified, summary information is displayed for all remote hosts within this IP transport subservice.                                                      |
| <b>Parameters</b>  | <p><i>host-id</i> — the remote host identifier</p> <p><b>Values</b> 1 to 2147483647 or a name string up to 64 characters long</p> <p><b>detail</b> — displays detailed information for a specified remote host</p> <p><b>statistics</b> — displays summary information for a specified remote host</p> |
| <b>Output</b>      | The following output is an example of IP transport subservice remote host summary information when no remote host is specified, and <a href="#">Table 110</a> describes the fields.                                                                                                                    |

|--------------------------------|-------------------------------------------------------------------------------------|
| Sent Chars                     | The number of data characters sent to the remote host                               |
| Drop Chars                     | The number of data characters destined for the remote host that were dropped        |
| State                          | The operational state of the packet transport session connection to the remote host |
| Rcvd Pkts                      | The number of packets received from the remote host                                 |
| Sent Pkts                      | The number of packets sent to the remote host                                       |
| Drop Pkts                      | The number of packets destined for the remote host that were dropped                |
| Up Time                        | The amount of time that the remote host has been connected                          |
| Number of known remote hosts   | The number of known remote hosts associated with the IP transport subservice        |
| Number of unknown remote hosts | The number of unknown remote hosts associated with the IP transport subservice      |
| Total entries found            | The total number of hosts associated with the IP-Transport subservice               |

The following output is an example of IP transport subservice detailed information for a specified remote host, and [Table 111](#) describes the fields.

### Output Example

```

| Label                      | Description                                                     |
|----------------------------|-----------------------------------------------------------------|
| Rcvd Pkts                  | The number of packets received from this remote host            |
| Rcvd Chars                 | The number of data characters received from this remote host    |
| <b>Session information</b> |                                                                 |
| Connections<br>To<br>From  | The number of connections to and from the host                  |
| Connection retries         | The number of connection retries to the host                    |
| Connection failures        | The number of connection failures to this host                  |
| Closed by far end          | The number of connections closed by the far end                 |
| Inactivity timeouts        | The number of connections that were timed out due to inactivity |

## sap

**Syntax** **sap** [*sap-id*] [*detail*]

**Context** show>service>id

**Description** This command displays information for the SAP associated with the IES service.

**Parameters** *sap-id* — the SAP ID for which SAP information will be displayed. See [Table 41](#) for a full list of SAP IDs.

**detail** — displays detailed SAP information

**Output** The following output is an example of IES service SAP information. See [Table 52](#) in [VLL Services Command Reference](#) for field descriptions.

### Output Example

## ingress-label

- Syntax** **ingress-label** *start-label* [*end-label*]
- Context** show>service
- Description** This command displays service information using the range of ingress labels.
- If only the mandatory *start-label* parameter is specified, only services using the specified label are displayed.
- If both *start-label* and *end-label* parameters are specified, the services using the labels in the specified range are displayed.
- Use the **show router ldp bindings** command to display dynamic labels.
- Parameters** *end-label* — the ending ingress label value for which to display services using the label range
- Values** 2049 to 131071
- Default** the *start-label* value
- start-label* — the starting ingress label value for which to display services using the label range. If only *start-label* is specified, only services using *start-label* are displayed.
- Values** 0, or 2048 to 131071
- Output** The following output is an example of service ingress label information, and [Table 112](#) describes the fields.

### Output Example

In the example below, services 3, 5 and 6 are IES, and services 5000 and 5001 are VPLS services.

```

*A:ALU-12>show>service# ingress-label 0 131071
=====
Martini Service Labels
=====
Svc Id Sdp Binding Type I.Lbl E.Lbl

3 15:15 Spok 0 0
5 5:5 Spok 0 0
6 5:6 Spok 0 0

```

```

5000 15:5000 Mesh 0 0
5000 15:5001 Spok 0 0
5001 5001:100 Spok 0 0

```

```

Number of Bindings Found : 6

```
*A:ALU-12#
```

**Table 112 Service Ingress Output Fields**

| Label                    | Description                                                                                        |
|--------------------------|----------------------------------------------------------------------------------------------------|
| Svc Id                   | The ID that identifies a service                                                                   |
| Sdp Binding              | The ID that identifies an SDP                                                                      |
| Type                     | Indicates whether the SDP binding is a spoke or a mesh                                             |
| I. Lbl                   | The VC label used by the far-end device to send packets to the 7705 SAR in this service by the SDP |
| E. Lbl                   | The VC label used by the 7705 SAR to send packets to the far-end device in this service by the SDP |
| Number of Bindings Found | The total number of SDP bindings that exist within the specified label range                       |

## ip-transport-using

- Syntax** `ip-transport-using [ip-transport ipt-id]`
- Context** `show>service`
- Description** This command displays IP transport subservice information for a specified port. If no port is specified, the command displays a summary of all IP transport subservices defined for the IES service.
- Parameters** *ipt-id* — the physical port associated with the IP transport subservice, in the format *slot/mda/port.channel*
- Output** The following output is an example of **ip-transport-using** information, and [Table 113](#) describes the fields.

### Output Example

```

*A:ALU-48# show service ip-transport-using
=====

**Table 113** IP-Transport-Using Field Descriptions

| Label                | Description                                               |
|----------------------|-----------------------------------------------------------|
| <b>IP Transports</b> |                                                           |
| IptId                | The IP transport subservice physical port identifier      |
| SvcID                | The service identifier                                    |
| Type                 | The type of service                                       |
| Adm                  | The administrative state of the IP transport subservice   |
| Opr                  | The operational state of the IP transport subservice      |
| Entries found        | The number of IP transport subservices using this service |

## sap-using

**Syntax** **sap-using** [sap *sap-id*]  
**sap-using interface** [*ip-address* | *ip-int-name*]  
**sap-using description**  
**sap-using** [ingress | egress] atm-td-profile *td-profile-id*  
**sap-using** [ingress | egress] filter *filter-id*  
**sap-using** [ingress | egress] qos-policy [*qos-policy-id* | *qos-policy-name*]  
**sap-using** [ingress | egress] scheduler-mode {4-priority | 16-priority}  
**sap-using** [ingress | egress] shaper-group *shaper-group-name*

**Context** show>service

**Description** This command displays SAP information.

If no optional parameters are specified, the command displays a summary of all defined SAPs.

The atm-td-profile command applies only to HSDPA offload (that is, IES management service).

**Parameters** *sap-id* — the SAP ID for which SAP information will be displayed. See [Table 41](#) for a full list of SAP IDs.

*ip-address* — only displays the interface information associated with the specified IP address

**Values**

- ipv4-address:* a.b.c.d (host bits must be 0)
- ipv6-address:* x:x:x:x:x:x:x (eight 16-bit pieces)  
x:x:x:x:x:x:d.d.d.d  
x: [0 to FFFF]H  
d: [0 to 255]D

*ip-int-name* — the IP interface name for which to display information

**description** — displays a SAP summary table with description information

**ingress** — specifies matching an ingress policy

**egress** — specifies matching an egress policy

*td-profile-id* — displays SAPs using this traffic description

*filter-id* — specifies the ingress filter policy for which to display matching SAP specifies. The filter ID or filter name must already exist within the created IP filters.

**Values** 1 to 65535 or filter-name (up to 64 characters)

*qos-policy-id* — the ingress or egress QoS policy ID for which to display matching SAPs

**Values** 1 to 65535

*qos-policy-name* — the ingress or egress QoS policy name for which to display matching SAPs

**Values** up to 64 characters

**scheduler-mode** — specifies the scheduler mode for which to display the SAPs

**shaper-group** — specifies the shaper group for which to display matching SAPs

**Output** The following output is an example of service SAP-using information, and [Table 114](#) describes the fields.

### Output Example

```
*A:ALU-48# show service sap-using
=====

## service-using

**Syntax** `service-using [ies] [customer customer-id]`

**Context** `show>service`

**Description** This command displays the services matching certain usage properties. If no optional parameters are specified, all services defined on the system are displayed.

**Parameters** **ies** — displays matching IES services

*customer-id* — displays only those services associated with the specified customer ID

**Values** 1 to 2147483647

**Output** The following output is an example of service-using information, and [Table 115](#) describes the fields.

### Output Example

```
*A:ALU-2# show service service-using ies
=====
Services [ies]
=====
ServiceId Type Adm Opr CustomerId Last Mgmt Change

4 IES Down Down 1 01/07/2010 22:14:40
23 IES Down Down 1 01/07/2010 21:58:44

Matching Services : 2

=====
*A:ALU-2#
```

**Table 115 Service Service-Using Field Descriptions**

| Label             | Description                                                                  |
|-------------------|------------------------------------------------------------------------------|
| ServiceID         | ID that defines the service                                                  |
| Type              | Service type configured for the service ID                                   |
| Adm               | Administrative state of the service                                          |
| Opr               | Operational state of the service                                             |
| CustomerId        | ID of the customer owning the service                                        |
| Last Mgmt Change  | Date and time of the most recent management-initiated change to this service |
| Matching Services | Number of services of the same type                                          |

### 6.7.2.4 Clear Commands

#### id

|                    |                                                                             |
|--------------------|-----------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>id</b> <i>service-id</i>                                                 |
| <b>Context</b>     | clear>service                                                               |
| <b>Description</b> | This command clears commands for a specific service.                        |
| <b>Parameters</b>  | <i>service-id</i> — uniquely identifies a service by service number or name |

#### dhcp

|                    |                                                            |
|--------------------|------------------------------------------------------------|
| <b>Syntax</b>      | <b>dhcp</b>                                                |
| <b>Context</b>     | clear>service>id                                           |
| <b>Description</b> | This command enables the context to clear DHCP parameters. |

#### dhcp6

|                    |                                                              |
|--------------------|--------------------------------------------------------------|
| <b>Syntax</b>      | <b>dhcp6</b>                                                 |
| <b>Context</b>     | clear>service>id                                             |
| <b>Description</b> | This command enables the context to clear DHCPv6 parameters. |

#### statistics

|                    |                                                                                                                                                                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>statistics</b> [ <i>ip-int-name</i>   <i>ip-address</i> ]                                                                                                                                                                                                                           |
| <b>Context</b>     | clear>service>id>dhcp<br>clear>service>id>dhcp6                                                                                                                                                                                                                                        |
| <b>Description</b> | <p>This command clears statistics for DHCP and DHCPv6 Relay.</p> <p>If no interface name or IP address is specified, statistics are cleared for all configured interfaces.</p> <p>If an interface name or IP address is specified, statistics are cleared only for that interface.</p> |

---

|                   |                                                            |
|-------------------|------------------------------------------------------------|
| <b>Parameters</b> | <i>ip-int-name</i> — 32 characters maximum                 |
|                   | <i>ip-address</i> — IPv4 or IPv6 address                   |
| <b>Values</b>     | <i>ipv4-address:</i> a.b.c.d                               |
|                   | <i>ipv6-address:</i> x:x:x:x:x:x:x:x (eight 16-bit pieces) |
|                   | x:x:x:x:x:x:d.d.d.d                                        |
|                   | x: [0 to FFFF]H                                            |
|                   | d: [0 to 255]D                                             |

ip-transport

|                    |                                                                                                                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ip-transport</b> <i>ipt-id</i>                                                                                                                                                                 |
| <b>Context</b>     | clear>service>id                                                                                                                                                                                  |
| <b>Description</b> | This command clears configured information pertaining to a specified IP transport subservice.<br><br>If no port identifier is specified, information is cleared for all IP transport subservices. |
| <b>Parameters</b>  | <i>ipt-id</i> — the IP transport subservice physical port identifier, in the format <i>slot/mda/port.channel</i>                                                                                  |

remote-host

|                    |                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>remote-host</b> <i>host-id</i>                                                                                          |
| <b>Context</b>     | clear>service>id>ip-transport                                                                                              |
| <b>Description</b> | This command clears configured information pertaining to a specified remote host assigned to this IP transport subservice. |
| <b>Parameters</b>  | <i>host-id</i> — the remote host identifier                                                                                |
| <b>Values</b>      | 1 to 2147483647 or a name string up to 64 characters long                                                                  |

statistics

|                    |                                                                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>statistics</b>                                                                                                                                                                   |
| <b>Context</b>     | clear>service>id>ip-transport<br>clear>service>id>ip-transport>remote-host                                                                                                          |
| <b>Description</b> | This command clears statistics-related information pertaining to all configured IP transport subservices or to all configured remote hosts for a specified IP transport subservice. |

### 6.7.2.5 Debug Commands

id

|                    |                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>id</b> <i>service-id</i>                                                                                |
| <b>Context</b>     | debug>service                                                                                              |
| <b>Description</b> | This command debugs commands for a specific service. The <b>no</b> form of the command disables debugging. |
| <b>Parameters</b>  | <i>service-id</i> — the ID that uniquely identifies an IES service by service number or name               |

---

## 7 VPRN Services

This chapter provides information about the Virtual Private Routed Network (VPRN) service and implementation notes.

Topics in this chapter include:

- [VPRN Service Overview](#)
- [VPRN Features](#)
- [Configuring a VPRN Service with CLI](#)
- [VPRN Services Command Reference](#)

---

## 7.1 VPRN Service Overview

Topics in this section include:

- [Routing Prerequisites](#)
- [BGP Support](#)
- [IPSec Support](#)
- [Security Zones and VPRN](#)
- [Static One-to-One NAT and VPRN](#)
- [Route Distinguishers](#)
- [Route Target Constraint](#)
- [In-Band Management using a VPRN](#)

RFC 2547bis, an extension of RFC 2547, details a method of distributing routing information and forwarding data to provide a Layer 3 Virtual Private Network (VPN) service to end customers.

Each Virtual Private Routed Network (VPRN) consists of a set of customer sites connected to one or more PE routers. Each associated PE router maintains a separate IP forwarding table for each VPRN. Additionally, the PE routers exchange the routing information configured or learned from all customer sites via MP-BGP peering. Each route exchanged via the MP-BGP protocol includes a route distinguisher (RD), which identifies the VPRN association.

The service provider uses BGP to exchange the routes of a particular VPN among the PE routers that are attached to that VPN. This is done in a way that ensures that routes from different VPNs remain distinct and separate, even if two VPNs have an overlapping address space. Within a particular VPN, the PE routers distribute route information from and to the CE routers. Since the CE routers do not peer with each other, there is no overlay visible to the VPN routing algorithm.

When BGP distributes a VPN route, it also distributes an MPLS label for that route. On an individual 7705 SAR, a single label is assigned to (advertised for) all routes in a VPN. A VRF lookup is used to determine the egress interface for a packet.

Before a customer data packet travels across the service provider's backbone network, it is encapsulated with the MPLS label that corresponds, in the customer's VPN, to the route that best matches the packet's destination address. That label (called the inner label) is the label that was advertised from the destination 7705 SAR, as described in the previous paragraph. The MPLS packet is further encapsulated with either another MPLS label or GRE tunnel header, so that it gets tunneled across the backbone to the proper PE router.

Each route exchanged by the MP-BGP protocol includes a route distinguisher (RD), which identifies its VPRN association. Thus, the backbone core routers do not need to know the VPN routes.

Figure 109 shows an example of a VPRN network diagram, showing two VPNs (labeled “Red” and “Green”) attached to PEs. The core routers are labeled “P”.

**Figure 109 Virtual Private Routed Network**

20949

## 7.1.1 Routing Prerequisites

RFC 2547bis requires the following features:

- multiprotocol extensions
- LDP support
- extended BGP community support
- BGP capability negotiation
- parameters defined in RFC 2918, *BGP Route Refresh*, and RFC 2796, *Route Reflector*
- a 4-byte autonomous system (AS) number

Tunneling protocol requirements are as follows:

- RFC 2547bis, *BGP/MPLS VPNs*, recommends implementing Label Distribution Protocol (LDP) to set up a full mesh of LSPs based on the IGP
- MPLS RSVP-TE tunnels can be used instead of LDP
- BGP route tunnels can be used as defined in RFC 3107
- alternatively, Generic Routing Encapsulation (GRE) tunnels can also be used

## 7.1.2 BGP Support

BGP is used with BGP extensions, as mentioned in [Routing Prerequisites](#), to distribute VPRN routing information across the service provider's network.

BGP was initially designed to distribute IPv4 routing information. Therefore, multiprotocol extensions and the use of a VPN-IPv4 address were created to extend the ability of BGP to carry overlapping routing information. A VPN-IPv4 address is a 12-byte value consisting of the 8-byte route distinguisher (RD) and the 4-byte IPv4 IP address prefix. The RD must be unique within the scope of the VPRN. This allows the IP address prefixes within different VRFs to overlap. In addition, 128-bit VPN-IPv6 addresses extend the capability to distribute VPRN routing information.

BGP route tunnels can be used to distribute label mapping information for a particular route, as defined in RFC 3107. For more information on BGP route tunnels, refer to the 7705 SAR Routing Protocols Guide, "BGP Route Tunnel".

**Note:** The 7705 SAR supports 4-byte AS numbers, as defined in RFC 4893, *BGP Support for Four-octet AS Number Space*. This allows up to 4 294 967 295 unique AS numbers.

VPRN BGP is configured through the **config>service>vprn>bgp** context. Global BGP is configured through the **config>router>bgp** context.

### 7.1.2.1 BGP Fast Reroute with Prefix-Independent Convergence in a VPRN

BGP Fast Reroute (FRR) creates an alternate path to support fast rerouting of BGP traffic around failed or unreachable next hops. When BGP FRR is enabled, the system switches to a precalculated alternate path as soon as a failure is detected.

BGP Prefix-Independent Convergence (PIC) is supported on the 7705 SAR and is automatically enabled when a BGP backup path is enabled. With BGP FRR and PIC, alternate paths are precalculated and the FIB is updated with all alternate next hops. When a prefix has a backup path, and its primary paths fail, the affected traffic is rapidly diverted to the backup path without waiting for control plane reconvergence to occur. When many prefixes share the same primary paths, and in some cases also share the same backup path, the time to switch traffic to the backup path can be very fast and is independent of the number of prefixes.

In the VPRN context, BGP FRR is supported using unlabeled IPv4 /IPv6 and VPN-IPv4/VPN-IPv6 routes. The supported VPRN scenarios are outlined in [Table 116](#).

**Table 116 BGP FRR Scenarios**

| Ingress Packet    | Primary Route                                                              | Backup Route                                                               | PIC |
|-------------------|----------------------------------------------------------------------------|----------------------------------------------------------------------------|-----|
| IPv4 (ingress PE) | IPv4 route with next hop A resolved by an IPv4 route                       | IPv4 route with next hop B resolved by an IPv4 route                       | Yes |
| IPv4 (ingress PE) | VPN-IPv4 route with next hop A resolved by a GRE, LDP, RSVP or BGP tunnel  | VPN-IPv4 route with next hop B resolved by a GRE, LDP, RSVP or BGP tunnel  | Yes |
| IPv6 (ingress PE) | VPN-IPv6 route with next hop A resolved by a GRE, LDP, RSVP, or BGP tunnel | VPN-IPv6 route with next hop B resolved by a GRE, LDP, RSVP, or BGP tunnel | Yes |
| MPLS (egress PE)  | IPv4 route with next hop A resolved by an IPv4 route                       | IPv4 route with next hop B resolved by an IPv4 route                       | Yes |
| MPLS (egress PE)  | IPv4 route with next hop A resolved by an IPv4 route                       | VPN-IPv4 route with next hop B resolved by a GRE, LDP, RSVP or BGP tunnel  | Yes |
| MPLS (egress PE)  | IPv6 route with next hop A resolved by an IPv6 route                       | VPN-IPv6 route with next hop B resolved by a GRE, LDP, RSVP or BGP tunnel  | Yes |

If all IP prefixes require backup path protection, use a combination of the BGP context **backup-path** command and the VPRN context **enable-bgp-vpn-backup** command. If only specific IP prefixes require backup path protection, use route policies to apply the install backup path action to the best paths of the IP prefixes requiring protection.

For information about BGP FRR specific to the BGP context, refer to the 7705 SAR Routing Protocols Guide, “BGP FRR with Prefix-Independent Convergence”.

---

### 7.1.2.2 BGP Next-Hop Resolution and Peer Tracking

The 7705 SAR can attach a route policy to the BGP next-hop resolution process and can allow a route policy to be associated with the optional BGP peer-tracking function. These two features are supported for VPRN BGP service.

BGP next-hop resolution determines the best matching route (or tunnel) for the BGP next-hop address and uses information about this resolving route when running the best-path selection algorithm and programming the forwarding table. Attaching a policy to BGP next-hop resolution provides additional control over which IP routes in the routing table can become resolving routes. Similar flexibility and control is available for BGP peer tracking, which is an optional feature that allows a session with a BGP neighbor to be taken down if there is no IP route to the neighbor address or if the best matching IP route is rejected by the policy.

Use the following CLI syntax to configure next-hop resolution and peer-tracking policies:

**CLI Syntax:**

```
config>service>vprn>bgp
 next-hop-resolution
 policy policy-name
 no policy
 peer-tracking-policy policy-name
 no peer-tracking-policy
```

For details, refer to the “Route Policies for BGP Next-Hop Resolution and Peer Tracking” section in the 7705 SAR Router Configuration Guide.

### 7.1.3 IPSec Support

The 7705 SAR supports IPSec and IPSec tunnels, where VPRN or IES is used as a public (untrusted) network-facing service and VPRN is used as a private (trusted) network-facing service. VPRN interfaces support provisioning of tunnel SAPs as part of IPSec provisioning. The *sap-id* for a public-side IPSec tunnel SAP is **tunnel-1.public:tag**. The *sap-id* for a private-side IPSec tunnel SAP is **tunnel-1.private:tag**.

For more information, see the [IPSec](#) chapter in this guide.

---

## 7.1.4 Security Zones and VPRN

The 7705 SAR supports a number of mechanisms for node security, including Access Control Lists (ACLs), Network Address Translation (NAT), and stateful, zone-based firewalls. For information about ACLs, NAT, and firewalls, refer to the 7705 SAR Router Configuration Guide, “Configuring Security Parameters”.

NAT and firewall security configurations are both based on zones. Zones segment a network, making it easier to control and organize traffic. A zone consists of a group of Layer 3 interfaces with common criteria, bundled together. Security policies, which define a set of rules that determine how NAT or firewall should direct traffic, can be applied to the entire zone or to multiple zones. To enable NAT or firewall functionality, security policy, application group, host group, and profile parameters must be configured under the **config>security** context in the CLI, and a security zone must be configured under one or more of the following contexts:

- **config>router>zone**
- **config>service>vprn>zone**
- **config>service>ies>zone**

A zone is created by adding at least one Layer 3 interface to the zone configuration. Multiple zones can be created within each service context or within the router context. Layer 3 interfaces from different services cannot be grouped into a single common zone. [Table 117](#) lists the supported interfaces that can be added to zones in each CLI context for NAT or firewall.

**Table 117 Security Zone Interfaces per Context**

| CLI Context | Interface Type        | NAT | Firewall |
|-------------|-----------------------|-----|----------|
| Router      | Layer 3               | ✓   | ✓        |
| VPRN        | SAP                   | ✓   | ✓        |
|             | Spoke-SDP termination | ✓   | ✓        |
|             | IPSec private         | ✓   | ✓        |
|             | IPSec public          | ✓   |          |
|             | Routed VPLS           | ✓   | ✓        |
|             | MP-BGP                | ✓   | ✓        |
| IES         | SAP                   | ✓   | ✓        |
|             | Spoke-SDP termination | ✓   | ✓        |
|             | IPSec public          | ✓   |          |
|             | Routed VPLS           | ✓   | ✓        |

A zone configured in the VPRN context could be used to create border security for Layer 3 service traffic traversing from the secure edge VPRN into the network core.

[Figure 110](#) shows a firewall on a VPRN, where the core of the network is protected from access devices and from any traffic entering the VPRN through the transport tunnel. A VPRN configured with access security policies can also protect access networks or LANs from each other.

**Figure 110 Firewall Protection for the Network Core**

25129

A security zone can also be created with spoke SDPs or auto-bind tunnels that have been configured for a VPRN service using MP-BGP. For auto-bind tunnels, the **auto-bind-tunnel resolution-filter** type can be set to gre, ldp, rsvp, sr-isis, sr-ospf, or sr-te. When a zone contains spoke SDPs or auto-bind MPLS tunnels, it cannot contain any other type of interface. A zone configured with spoke SDPs or auto-bind MPLS tunnels will firewall traffic arriving from the access side to this zone for any MP-BGP transport tunnel residing in that Layer 3 service. Once a security zone is created for MP-BGP transport tunnels, all MP-BGP transport tunnels going to far-end peers are part of this zone. Traffic entering or exiting the zone is firewalled; however, traffic traveling from one auto-bind tunnel to another within the same zone is not firewalled.

---

## 7.1.5 Static One-to-One NAT and VPRN

With static one-to-one NAT, NAT is performed on packets traveling from an inside (private) interface to an outside (public) interface or from an outside interface to an inside interface. Static one-to-one NAT can be applied to a single IP address or a subnet of IP addresses and is performed on the IP header of a packet, not on the UDP/TCP port.

Mapping statements, or entries, can be configured to map an IP address range to a specific IP address. The direction of the NAT mapping entry dictates whether NAT is performed on a packet source IP address or subnet or on a packet destination IP address or subnet. The 7705 SAR supports inside mapping entries that map an inside IP address range to an outside IP address range sequentially.

With an inside mapping entry, the following points apply.

- Packets that originate from an inside interface and are destined for an inside interface are forwarded without any NAT being applied.
- If there is a matching one-to-one NAT mapping entry, packets that originate from an inside interface and are destined for an outside interface undergo static one-to-one NAT where NAT changes the source IP address of the packet IP header. The packet is forwarded whether or not a NAT mapping entry is found unless the **drop-packets-without-nat-entry** command is enabled. When a mapping entry is not found and the **drop-packets-without-nat-entry** command is enabled, the packet is not forwarded.
- If there is a matching one-to-one NAT mapping entry, packets that originate from an outside interface and are destined for an inside interface undergo static one-to-one NAT where NAT changes the destination IP address of the packet IP header. The packet is forwarded whether or not a NAT mapping entry is found unless the **drop-packets-without-nat-entry** command is enabled. When a mapping entry is not found and the **drop-packets-without-nat-entry** command is enabled, the packet is not forwarded.
- Packets that originate from an outside interface and are destined for an outside interface are forwarded without any NAT being applied.

Static one-to-one NAT is supported in the GRT and in VPRNs. For more information about static one-to-one NAT, refer to the 7705 SAR Router Configuration Guide, “Static One-to-One NAT”.

For VPRNs, one-to-one NAT can be configured between an inside interface and a outside MP-BGP MPLS transport tunnel interface. Policies should be used to not leak the inside interface/IP address via MP-BGP to the peer. Policies should be used to leak the NAT routes to the MP-BGP peer.

---

[Table 118](#) lists the types of outside and inside interfaces that are supported in a VPRN for one-to-one NAT.

**Table 118 VPRN Interfaces Supported for Static One-to-One NAT**

| VPRN Interface Type                                                             | Outside | Inside |
|---------------------------------------------------------------------------------|---------|--------|
| SAP interface                                                                   | Yes     | Yes    |
| R-VPLS interface                                                                | Yes     | Yes    |
| Layer 3 spoke SDP interface                                                     | Yes     | Yes    |
| IPSec private interface                                                         | Yes     | Yes    |
| Auto-bind GRE/MPLS (MP-BGP), where MPLS includes segment routing, LDP, and RSVP | Yes     | No     |

### 7.1.6 Route Distinguishers

The route distinguisher (RD) is an 8-byte value consisting of two major fields: the Type field and Value field. The Type field determines how the value field should be interpreted. The 7705 SAR implementation supports the three (3) Type-Value combinations, as defined in RFC 2547bis. [Figure 111](#) illustrates the RD structure.

**Figure 111**     **Route Distinguisher Structure**

20950

The three Type-Value combinations supported are described in [Table 119](#).

**Table 119**     **Route Distinguisher Type-Value Fields**

| Type Field | Value Field                        | Notes                                                                                              |
|------------|------------------------------------|----------------------------------------------------------------------------------------------------|
| Type 0     | Administrator subfield (2 bytes)   | The Administrator field must contain an AS number (using private AS numbers is discouraged)        |
|            | Assigned number subfield (4 bytes) | The Assigned field contains a number assigned by the service provider                              |
| Type 1     | Administrator subfield (4 bytes)   | The Administrator field must contain an IP address (using private IP address space is discouraged) |
|            | Assigned number subfield (2 bytes) | The Assigned field contains a number assigned by the service provider                              |
| Type 2     | Administrator subfield (4 bytes)   | The Administrator field must contain a 4-byte AS number (using private AS numbers is discouraged)  |
|            | Assigned number subfield (2 bytes) | The Assigned field contains a number assigned by the service provider                              |

---

### 7.1.6.1 PE-to-CE Route Exchange

Routing information between the Provider Edge (PE) and Customer Edge (CE) can be exchanged by the following methods:

- EBGp (for IPv4 and IPv6 address families)
- OSPF
- OSPFv3
- RIP
- static routes

Each protocol provides controls to limit the number of routes learned from each CE router.

#### 7.1.6.1.1 Route Redistribution

Routing information learned from the PE-to-CE routing protocols and configured static routes is injected into the associated local virtual routing and forwarding table (VRF). In the case of the dynamic routing protocols, there may be protocol-specific route policies that modify or reject certain routes before they are injected into the local VRF.

Route redistribution from the local VRF to the PE-to-CE routing protocols is controlled via the route policies in each routing protocol instance, in the same manner that is used by the base router instance.

The advertisement or redistribution of routing information from the local VRF to or from the MP-BGP instance is specified per VRF and is controlled by VRF route target associations or by VRF route policies.

A route belonging to a VPRN must use the protocol owner, VPN-IPv4, to denote that it is a VPRN route. This can be used within the route policy match criteria.

#### 7.1.6.1.2 CPE Connectivity Check

Static routes are used within many IES and VPRN services. Unlike dynamic routing protocols, there is no way to change the state of routes based on availability information for the associated CPE. CPE connectivity check adds flexibility so that unavailable destinations are removed from the service provider's routing tables dynamically, and wasted bandwidth is minimized.

Figure 112 and Figure 113 illustrate the use of CPE connectivity check in directly connected and multiple-hop connected routes.

**Figure 112 Directly Connected IP Target**

20951

**Figure 113 Multiple Hops to IP Target**

20952

The availability of the far-end static route is monitored through periodic polling. The polling period is configured. If the poll fails a specified number of sequential polls, the static route is marked as inactive.

Either ICMP ping or unicast ARP mechanism can be used to test the connectivity. ICMP ping is preferred.

If the connectivity check fails and the static route is deactivated, the 7705 SAR router will continue to send polls and reactivate any routes that are restored.

## 7.1.7 Route Target Constraint

Route Target Constraint (RTC) is a mechanism that allows a router to advertise route target membership information to its BGP peers to indicate interest in receiving only VPN routes tagged with specific route target extended communities. Upon receiving RTC route information, peers restrict the advertised VPN routes to only those requested, minimizing control plane load in terms of protocol traffic and potentially reducing RIB memory usage.

The route target membership information is carried using MP-BGP, using an AFI value of 1 and SAFI value of 132. The NLRI of an RTC route encodes an Origin AS and a route target extended community using prefix type encoding with host bits after the prefix-length set to zero.

In order for two routers to exchange route target membership NLRI, they must advertise the corresponding AFI and SAFI to each other during capability negotiation. The use of MP-BGP means route target membership NLRI are propagated, loop-free, within an autonomous system and between autonomous systems, using well-known BGP route selection and advertisement rules.

Route target constrained route distribution and outbound route filtering (ORF) both allow routers to advertise which route target extended communities they want to receive in VPN routes from peers. RTC, however, is more widely supported, is simpler to configure, and its distribution scope is not limited to a direct peer.

### 7.1.7.1 Configuring the Route Target Address Family

RTC is supported only by the base router BGP instance. When the **family** command in the BGP router group or neighbor CLI context includes the **route-target** keyword, the RTC capability is negotiated with the associated set of EBGP and IBGP peers.

ORF and RTC are mutually exclusive for a particular BGP session. The CLI does not attempt to block the configuration of both ORF and RTC, but if both capabilities are enabled for a session, the ORF capability will not be included in the OPEN message sent to the peer.

---

### 7.1.7.2 Originating RTC Routes

When the base router has one or more RTC peers (BGP peers with which the RTC capability has been successfully negotiated), one RTC route is created for each route target extended community imported into a locally configured Layer 3 VPN service. These imported route targets are configured in the following contexts:

- **config>service>vpn**
- **config>service>vpn>mvpn**

By default, RTC routes are automatically advertised to all RTC peers without the need for an export policy to explicitly accept them. Each RTC route has a prefix, a prefix length, and path attributes. The prefix value is the concatenation of the origin AS (a 4-byte value representing the 2-octet or 4-octet AS of the originating router, as configured using the **config>router>autonomous-system** command) and 0 or 16 to 64 bits of a route target extended community encoded in one of the following formats: 2-octet AS specific extended community, IPv4 address specific extended community, or 4-octet AS specific extended community.

A router may be configured to send the default RTC route to a group or neighbor with the **default-route-target** CLI command. The default RTC route is a special route that has a prefix length of zero. Sending the default RTC route to a peer conveys a request to receive all VPN routes from that peer, whether they match the route target extended community. The default RTC route is typically advertised by a route reflector to PE clients. Advertising the default RTC route to a peer does not suppress other more specific RTC routes from being sent to that peer. A received default RTC route is never propagated to other routers.

### 7.1.7.3 Receiving and Readvertising RTC Routes

All received RTC routes that are considered valid are stored in the RIB-In. RTC routes are considered invalid and treated as withdrawn if the prefix length is configured to be any of the following:

- 1 to 31
- 33 to 47
- 48 to 96 and the 16 most-significant bits are not 0x0002, 0x0102, or 0x0202

If multiple RTC routes are received for the same prefix value (same NLRI), then standard BGP best-path selection procedures are used to determine the best route. The propagation of the best path installs RIB-Out filter rules as it travels from one router to the next, and this process creates an optimal VPN route distribution tree rooted at the source of the RTC route.

The best RTC route per prefix is readvertised to RTC peers based on the following rules.

- The best path for a default RTC route (prefix length 0, origin AS only with prefix length 32, or origin AS plus 16 bits of a route target type with prefix-length 48) is never propagated to another peer.
- A PE with only IBGP RTC peers that is not a route reflector or an ASBR does not readvertise the best RTC route to any RTC peer, due to standard IBGP split-horizon rules.
- A route reflector that receives its best RTC route for a prefix from a client peer readvertises that route (subject to export policies) to all its client and non-client IBGP peers (including the originator), per standard route reflector operation. When the route is readvertised to client peers, the route reflector sets the `ORIGINATOR_ID` to its own router ID and modifies the `NEXT_HOP` to be its local address for the sessions (for example, system IP).
- A route reflector that receives its best RTC route for a prefix from a non-client peer readvertises that route (subject to export policies) to all its client peers, per standard route reflector operation. If the route reflector has a non-best path for the prefix from any of its clients, it advertises the best of the client-advertised paths to all non-client peers.
- An ASBR that is not a PE or a route reflector, that receives its best RTC route for a prefix from an IBGP peer, readvertises that route (subject to export policies) to its EBGp peers. The `NEXT_HOP` and `AS_PATH` of the re-advertised route are modified per standard BGP rules. No aggregation of RTC routes is supported.
- An ASBR that is not a PE or a route reflector, that receives its best RTC route for a prefix from an EBGp peer, readvertises that route (subject to export policies) to its EBGp and IBGP peers. The `NEXT_HOP` and `AS_PATH` of the re-advertised route are modified per standard BGP rules. No aggregation of RTC routes is supported.

**Note:** These advertisement rules do not handle hierarchical route reflector topologies properly. This is a limitation of the current RTC standard.

#### 7.1.7.4 Using RTC Routes

In general, the best VPN route for every prefix or NLRI in the RIB is sent to every peer supporting the VPN address family. Export policies may be used to prevent some prefixes or NLRIs from being advertised to specific peers. These export policies may be configured statically, or created dynamically by using ORF or RTC with a peer. ORF and RTC are mutually exclusive for a session.

When RTC is configured on a session that also supports VPN address families using route targets (VPN-IPv4, VPN-IPv6, or MVPN-IPv4), the advertisement of the VPN routes is affected as follows.

- When the session comes up, the advertisement of the VPN routes is delayed for a short while to allow RTC routes to be received from the peer.
- After the initial delay, the received RTC routes are analyzed and acted upon. If S1 is the set of routes previously advertised to the peer and S2 is the set of routes that should be advertised based on the most recent received RTC routes, then:
  - the set of routes in S1 but not in S2 are withdrawn immediately (subject to the minimum route advertisement interval (MRAI))
  - the set of routes in S2 but not in S1 are advertised immediately (subject to the MRAI)
- If a default RTC route is received from a peer P1, the set of VPN routes that are advertised to P1 are routes that:
  - are eligible for advertisement to P1 per BGP route advertisement rules
  - have not been rejected by manually configured export policies
  - have not been advertised to the peer

This applies whether or not P1 advertised the best route for the default RTC prefix.

A default RTC route is a route with any of the following:

- NLRI length = zero
- NLRI value = origin AS and NLRI length = 32
- NLRI value = {origin AS+0x0002 | origin AS+0x0102 | origin AS+0x0202} and NLRI length = 48
- If an RTC route for prefix A (origin-AS = A1, RT = A2/n,  $n > 48$ ) is received from an IBGP peer I1 in autonomous system A1, the set of VPN routes that are advertised to I1 are the routes that:
  - are eligible for advertisement to I1 per BGP route advertisement rules
  - have not been rejected by manually configured export policies
  - carry at least one route target extended community with value A2 in the  $n$  most significant bits
  - have not been advertised to the peer

This applies whether or not I1 advertised the best route for A.

- If the best RTC route for a prefix A (origin-AS = A1, RT = A2/n,  $n > 48$ ) is received from an IBGP peer I1 in autonomous system B, the set of VPN routes that are advertised to I1 are routes that:
  - are eligible for advertisement to I1 per BGP route advertisement rules

- have not been rejected by manually configured export policies
- carry at least one route target extended community with value A2 in the  $n$  most significant bits
- have not been advertised to the peer

This applies only if I1 advertised the best route for A.

- If the best RTC route for a prefix A (origin-AS = A1, RT = A2/ $n$ ,  $n > 48$ ) is received from an EBGp peer E1, the set of VPN routes that are advertised to E1 are the routes that:
  - are eligible for advertisement to E1 per BGP route advertisement rules
  - have not been rejected by manually configured export policies
  - carry at least one route target extended community with value A2 in the  $n$  most significant bits
  - have not been advertised to the peer

This applies only if E1 advertised the best route for A.

## 7.1.8 In-Band Management using a VPRN

VPRN in-band management is supported on the 7705 SAR. In-band management of the 7705 SAR is performed using the global routing table (GRT) to perform a lookup on the system IP address of the 7705 SAR.

On network ingress, when a packet arrives from the transport tunnel to the VPRN, a lookup is performed within the VPRN on the inner customer packet IP header. If a destination IP address in the packet header matches any system IP address configured under **grt-lookup** with a GRT **static-route-entry** set to the system IP address specified under **vprn>static-route-entry>grt**, the packet is extracted to the CSM for processing. If the **vprn>grt-lookup>enable-grt>allow-local-management** command is not enabled, the packet is routed using the 7705 SAR VRF FIB.

If the 7705 SAR system IP address is the same as any local IP address within the VPRN and the arriving packet destination IP matches this address, the packet is extracted to the CSM for processing only if the **allow-local-management** command is enabled. Any ICMP packet destined for local interfaces will be processed by the system IP. If the local interface is operationally down, the system IP will still reply to ICMP packets successfully. Having a single IP address shared by the system IP and VPRN local interface is not recommended because some GRT-supported management protocols, such as Telnet and SSH, will not function with this configuration.

For MP-BGP VPRNs, the system IP address can be advertised to the far-end node using a static route configured under **vprn>static-route-entry>grt**. If the command **allow-local-management** is enabled under the VPRN instance, a packet arriving on a transport tunnel will be extracted to the CSM before hitting the blackhole route. In this case, the only effect of the blackhole route will be to advertise the system IP address to the far-end peer. If the command **allow-local-management** is not enabled, packet forwarding will be the default forwarding mode; that is, all packets destined for the system IP address will be blackholed because of the static route configuration.

For MP-BGP VPRNs, when the command **allow-local-management** is enabled, at least one interface (such as a loopback interface) must be configured on the VPRN and have an operational status of Up.

On network egress, the packets generated from the CSM with a source IP address that matches the local IP address and destination IP address of either the far-end NSP NFM-P or other management entity must perform a GRT route lookup in order to be resolved. A route policy can be configured with an IP address prefix of the far-end management entity and with the action to accept. This policy is configured for the GRT under the **config>router>policy-options** context and is installed in the GRT FIB using the **export-grt** command. The route installed in the GRT FIB will have a next hop of the corresponding VRF tunnel. This prevents any user data traffic in the GRT data path from leaking into the VPRN, and ensures that only the management traffic originating from the system IP address and the CSM gets transported through the VPRN. This forces the management packet to get routed by the corresponding VPRN transport tunnel, which means the VPRN route is leaked into the GRT so the GRT resolves the route using the corresponding VPRN.

[Table 120](#) lists the management protocols supported by IPv4 and IPv6 GRT in the reverse and forward directions.

**Table 120 IPv4 and IPv6 GRT-Supported Management Protocols**

| Protocol                  | Reverse Direction<br>(Towards the 7705 SAR) | Forward Direction<br>(From the 7705 SAR) |
|---------------------------|---------------------------------------------|------------------------------------------|
| FTP<br>Passive and Active | Yes <sup>1</sup>                            | Yes <sup>2</sup>                         |
| SFTP                      | Yes <sup>1</sup>                            | —                                        |
| NTP                       | —                                           | Yes <sup>3</sup>                         |
| RADIUS                    | Yes                                         | —                                        |
| SCP                       | Yes <sup>1</sup>                            | Yes <sup>3</sup>                         |
| SNMP                      | Yes                                         | —                                        |

**Table 120 IPv4 and IPv6 GRT-Supported Management Protocols**

| Protocol           | Reverse Direction<br>(Towards the 7705 SAR) | Forward Direction<br>(From the 7705 SAR) |
|--------------------|---------------------------------------------|------------------------------------------|
| SNMP Trap          | —                                           | Yes                                      |
| SSH                | Yes <sup>1</sup>                            | Yes <sup>3</sup>                         |
| TACACS+            | Yes                                         | —                                        |
| Telnet             | Yes <sup>1</sup>                            | Yes <sup>3</sup>                         |
| TWAMP <sup>4</sup> | Yes <sup>5</sup>                            | Yes <sup>6</sup>                         |
| TWAMP Light        | Yes <sup>5</sup>                            | Yes <sup>6</sup>                         |

**Notes:**

1. Supported, if the 7705 SAR is acting as a server
2. Supported, if the 7705 SAR is acting as an active client
3. Supported, if the 7705 SAR is acting as a client
4. Supported on IPv4 only
5. Supported, if the 7705 SAR is acting as a server (control packets)
6. Supported, if the 7705 SAR is acting as a session reflector (test packets)

Figure 114 shows an example of IPv4 in-band management of the 7705 SAR and the switches behind it by the NSP NFM-P and a TACACS+ server. In the example, an IPsec tunnel is being used as the VPRN in order to transport the management traffic via a secure and encrypted medium over the public internet.

**Figure 114 IPv4 In-Band Management Using a VPRN Configured with GRT Lookup**

In this example, the 7705 SAR system IP address is in the same subnet as the local interface; that is, subnet 192.168.0.x.

On network ingress in the above example, when **allow-local-management** is configured for the VPRN, packets arriving on the 192.168.0 subnet are treated as follows.

- If the packet destination IP address is 192.168.0.2, the packet is extracted to the CSM to be processed as management traffic.
- If the packet is destined for subnet 192.168.0.x/29, it is forwarded out of interface 192.168.0.1.

On network egress in the above example, routing is as follows.

- A static route can be installed in the 7705 SAR VPRN for subnet 192.168.1.0/24 with a next hop to IPSecTunnel\_1.
- A route policy can be created with an IP address prefix of 192.168.1.0/24 and an action to accept. This route policy is configured under the **config>router>policy-options** context, and can be exported to the GRT FIB using the **export-grt** command.
- The above configuration will add route 192.168.1.0/24 to the GRT FIB with the next hop being the corresponding VPRN IPSec tunnel. This entry will force the CSM-generated packets destined for the 192.168.1.x subnet to be resolved by the VPRN IPSec tunnel.

Figure 115 shows an example of IPv6 in-band management of the 7705 SAR and the switches behind it by the NSP NFM-P and a TACACS+ server.

**Figure 115 IPv6 In-Band Management Using a VPRN Configured with GRT Lookup**

25381

---

On network ingress in the above example, the 7705 SAR system IP address is in the same subnet as the local interface IPv6 VPRN address. When **allow-local-management** is configured for the IPv6 VPRN, packets arriving on the fd00:1:1:1 subnet are treated as follows.

- If the packet destination IP address is fd00:1:1:1::2, then the packet is extracted to the CSM to be processed as management traffic.
- If the packet is destined for subnet fd00:1:1:1::/64, it is forwarded out of interface fd00:1:1:1.

On network egress in the above example, routing is as follows.

- A static route can be installed at the 7705 SAR VPRN for subnet fd00:1:129:1::/64 with a next hop to IPSecTunnel\_1.
- A route policy can be created with an IP address prefix of fd00:1:129:1::/64 and an action to accept. This route policy is configured under the **config>router>policy-options** context, and can be exported to the GRT FIB using the **export-grt** command.

The above configuration adds route fd00:1:129:1::/64 to the GRT FIB with the next hop being the corresponding VPRN IPSec tunnel. This entry forces the CSM-generated packets destined for the fd00:1:129:1::x subnet to be resolved by the VPRN IPSec tunnel.

---

## 7.2 VPRN Features

This section describes the 7705 SAR service features and any special capabilities or considerations as they relate to VPRN services:

- [IP Interfaces](#)
- [SAPs](#)
- [PE-to-CE Routing Protocols](#)
- [PE-to-PE Tunneling Mechanisms](#)
- [Per-VRF Route Limiting](#)
- [RIP Metric Propagation in VPRNs](#)
- [Multicast VPN \(MVPN\)](#)
- [VPRN Auto-binding Tunnels](#)
- [Spoke SDPs](#)
- [Spoke SDP Termination to VPRN](#)
- [IPv6 on Virtual Private Edge Router](#)
- [IPv6 over IPv4 LAN-to-LAN IPSec Tunnels](#)
- [Bandwidth Optimization for Low-speed Links](#)

### 7.2.1 IP Interfaces

VPRN customer IP interfaces can be configured with most of the same options found on the core IP interfaces. The advanced configuration options supported are:

- Unnumbered interfaces (see [Unnumbered Interfaces](#))
- DHCP options (see [DHCP and DHCPv6](#))
- Local DHCP server options (see [Local DHCP and DHCPv6 Server](#))
- IPSec tunnel interfaces (see [IPSec Support](#))
- IPCP options (see [IPCP](#))
- ICMP options (see [Troubleshooting and Fault Detection Services](#))
- VRRP options (see [VRRP on VPRN Interfaces](#))

Configuration options found on core IP interfaces not supported on VPRN IP interfaces are:

- NTP broadcast receipt

### 7.2.1.1 Unnumbered Interfaces

Unnumbered interfaces are supported on VPRN and IES services for IPv4. Unnumbered interfaces are point-to-point interfaces that are not explicitly configured with a dedicated IP address and subnet; instead, they borrow (or link to) an IP address from another interface on the system (the system IP address, another loopback interface, or any other numbered interface) and use it as the source IP address for packets originating from the interface.

This feature is supported via both dynamic and static ARP for unnumbered interfaces to allow interworking with unnumbered interfaces that may not support dynamic ARP.

The use of unnumbered interfaces has no effect on IPv6 routes; however, the **unnumbered** command must only be used in cases where IPv4 is active (IPv4 only and mixed IPv4/IPv6 environments). When using an unnumbered interface for IPv4, the loopback address used for the unnumbered interface must have an IPv4 address. The interface type for the unnumbered interface is automatically point-to-point.

### 7.2.1.2 DHCP and DHCPv6

DHCP is a configuration protocol used to communicate network information and configuration parameters from a DHCP server to a DHCP-aware client. DHCP is based on the BOOTP protocol, with additional configuration options and the added capability of allocating dynamic network addresses. DHCP-capable devices are also capable of handling BOOTP messages.

A DHCP client is an IP-capable device (typically a computer or base station) that uses DHCP to obtain configuration parameters such as a network address. A DHCP server is an Internet host or router that returns configuration parameters to DHCP clients. A DHCP/BOOTP Relay agent is a host or router that passes DHCP messages between clients and servers.

DHCPv6 is not based on, and does not use, the BOOTP protocol.

The 7705 SAR can act as a DHCP client, a DHCP or DHCPv6 Relay agent, or a local DHCP or DHCPv6 server.

Home computers in a residential high-speed Internet application typically use the DHCP protocol to have their IP address assigned by their Internet service provider.

Since IP routers do not forward broadcast or multicast packets, this would suggest that the DHCP client and server must reside on the same network segment. However, for various reasons, it is sometimes impractical to have the server and client reside in the same IP network.

When the 7705 SAR is acting as a DHCP Relay agent, it processes these DHCP broadcast or multicast packets and relays them to a preconfigured DHCP server. Therefore, DHCP clients and servers do not need to reside on the same network segment.

When the 7705 SAR is acting as a local DHCP server, it processes these DHCP broadcast or multicast packets and allocates IP addresses for the DHCP client as needed.

The 7705 SAR supports a maximum of 16 servers per node on the 7705 SAR-A, 7705 SAR-Ax, 7705 SAR-H, 7705 SAR-Hc, 7705 SAR-M, 7705 SAR-W, 7705 SAR-Wx, and 7705 SAR-X. The 7705 SAR supports a maximum of 62 servers per node on the 7705 SAR-8 with a CSMv2 and on the 7705 SAR-18. Any Layer 3 interface configured using the global routing table or Layer 3 services supports up to 8 servers.

#### **7.2.1.2.1 DHCP Relay and DHCPv6 Relay**

The 7705 SAR provides DHCP/BOOTP Relay agent services and DHCPv6 Relay agent services for DHCP clients. DHCP is used for IPv4 network addresses and DHCPv6 is used for IPv6 network addresses. Both DHCP and DHCPv6 are known as stateful protocols because they use dedicated servers to maintain parameter information.

Unless stated otherwise, DHCP is equivalent to “DHCP for IPv4”, or DHCPv4.

In the stateful autoconfiguration model, hosts obtain interface addresses and/or configuration information and parameters from a server. The server maintains a database that keeps track of which addresses have been assigned to which hosts.

The 7705 SAR supports DHCP Relay on access IP interfaces associated with IES and VPRN and on network interfaces. Each DHCP instance supports up to eight DHCP servers.

The 7705 SAR supports DHCPv6 Relay on access IP interfaces associated with IES and VPRN. Each DHCPv6 instance supports up to eight DHCPv6 servers.

**Note:**

- The 7705 SAR acts as a Relay agent for DHCP and DHCPv6 requests and responses, and can also be configured to function as a DHCP or DHCPv6 server. DHCPv6 functionality is only supported on network interfaces and on access IP interfaces associated with VPRN.
- When used as a CPE, the 7705 SAR can act as a DHCP client to learn the IP address of the network interface. Dynamic IP address allocation is supported on both network and system interfaces.
- For more information on DHCP and DHCPv6, refer to the 7705 SAR Router Configuration Guide, “DHCP and DHCPv6”.

## DHCP Relay

The 7705 SAR provides DHCP/BOOTP Relay agent services for DHCP clients. DHCP is a configuration protocol used to communicate network information and configuration parameters from a DHCP server to a DHCP-aware client. DHCP is based on the BOOTP protocol, with additional configuration options and the added capability of allocating dynamic network addresses. DHCP-capable devices are also capable of handling BOOTP messages.

A DHCP client is an IP-capable device (typically a computer or base station) that uses DHCP to obtain configuration parameters such as a network address. A DHCP server is an Internet host or router that returns configuration parameters to DHCP clients. A DHCP/BOOTP Relay agent is a host or router that passes DHCP messages between clients and servers.

Home computers in a residential high-speed Internet application typically use the DHCP protocol to have their IP address assigned by their Internet service provider.

The DHCP protocol requires the client to transmit a request packet with a destination broadcast address of 255.255.255.255 that is processed by the DHCP server. Since IP routers do not forward broadcast packets, this would suggest that the DHCP client and server must reside on the same network segment. However, for various reasons, it is sometimes impractical to have the server and client reside in the same IP network. When the 7705 SAR is acting as a DHCP Relay agent, it processes these DHCP broadcast packets and relays them to a preconfigured DHCP server. Therefore, DHCP clients and servers do not need to reside on the same network segment.

DHCP OFFER messages are not dropped if they contain a yiaddr that does not match the local configured subnets on the DHCP relay interface. This applies only to regular IES and VPRN interfaces with **no lease-populate** configured on the DHCP relay interface.

### DHCP Options

DHCP options are codes that the 7705 SAR inserts in packets being forwarded from a DHCP client to a DHCP server. Some options have additional information stored in suboptions.

The 7705 SAR supports the Relay Agent Information Option 82 as specified in RFC 3046. The following suboptions are supported:

- circuit ID
- remote ID
- vendor-specific options

### DHCPv6 Relay

DHCPv6 Relay operation is similar to DHCP in that servers send configuration parameters such as IPv6 network addresses to IPv6 nodes, but DHCPv6 Relay is not based on the DHCP or BOOTP protocol. DHCPv6 can be used instead of stateless autoconfiguration (refer to the 7705 SAR Router Configuration Guide, “Neighbor Discovery”) or in conjunction with it.

DHCPv6 is also oriented around IPv6 methods of addressing, especially the use of reserved, link-local scoped multicast addresses. DHCPv6 clients transmit messages to these reserved addresses, allowing messages to be sent without the client knowing the address of any DHCP server. This transmission allows efficient communication even before a client has been assigned an IP address. When a client has an address and knows the identity of a server, it can communicate with the server directly using unicast addressing.

The DHCPv6 protocol requires the client to transmit a request packet with a destination multicast address of ff02::1:2 (all DHCP servers and relay agents on the local network segment) that is processed by the DHCP server.

Similar to DHCP address allocation, if a client needs to obtain an IPv6 address and other configuration parameters, it sends a Solicit message to locate a DHCPv6 server, then requests an address assignment and other configuration information from the server. Any server that can meet the client’s requirements responds with an Advertise message. The client chooses one of the servers and sends a Request message, and the server sends back a Reply message with the confirmed IPv6 address and configuration information.

If the client already has an IPv6 address, either assigned manually or obtained in some other way, it only needs to obtain configuration information. In this case, exchanges are done using a two-message process. The client sends an Information Request message, requesting only configuration information. A DHCPv6 server that has configuration information for the client sends back a Reply message with the information.

The 7705 SAR supports the DHCPv6 Relay Agent option in the same way that it supports the DHCP Relay Agent option. This means that when the 7705 SAR is acting as a DHCPv6 Relay Agent, it relays messages between clients and servers that are not connected to the same link.

### DHCPv6 Options

DHCPv6 options are codes that the 7705 SAR inserts in packets being forwarded from a DHCPv6 client to a DHCPv6 server. DHCPv6 supports interface ID and remote ID options as defined in RFC 3315, *Dynamic Host Configuration Protocol for IPv6 (DHCPV6)* and RFC 4649, *DHCPv6 Relay Agent Remote-ID Option*.

#### 7.2.1.2.2 Local DHCP and DHCPv6 Server

The 7705 SAR supports local DHCP server functionality on the base router and on access IP interfaces associated with VPRN, by dynamically assigning IPv4 or IPv6 addresses to access devices that request them. This standards-based, full DHCP server implementation allows a service provider the option to decentralize IP address management into the network. The 7705 SAR can support public and private addressing in the same router, including overlapped private addressing in the form of VPRNs in the same router.

The 7705 SAR can act as a DHCP server or a DHCPv6 server.

An administrator creates pools of addresses that are available for assigned hosts. Locally attached hosts can obtain an address directly from the server. Routed hosts receive addresses through a relay point in the customer's network.

When a DHCP server receives a DHCP message from a DHCP Relay agent, the server looks for a subnet to use for assigning an IP address. If configured with the **use-pool-from-client** command, the server searches Option 82 information for a pool name. If a pool name is found, an available address from any subnet of the pool is offered to the client. If configured with the **use-gi-address** command, the server uses the gateway IP address (GIADDR) supplied by the Relay agent to find a matching subnet. If a subnet is found, an address from the subnet is offered to the client. If no pool or subnet is found, then no IP address is offered to the client.

When a DHCPv6 server receives a DHCP message from a DHCPv6 Relay agent, the server looks for a subnet to use for assigning an IP address. If configured with the **use-pool-from-client** command, the server searches Option 17 information for a pool name. If a pool name is found, an available address from any subnet of the pool is offered to the client. If configured with the **use-link-address** command, the server uses the address supplied by the Relay agent to find a matching subnet prefix. If a prefix is found, an address from the subnet is offered to the client. If no pool or prefix is found, then no IP address is offered to the client.

IPv4 and IPv6 address assignments are temporary and expire when the configured lease time is up. The server can reassign addresses after the lease expires.

If both the **no use-pool-from-client** command and the **no use-gi-address** command or **no use-link-address** command are specified, the server does not act.

### DHCP and DHCPv6 Server Options

Options and identification strings can be configured on several levels.

DHCPv4 servers support the following options, as defined in RFC 2132:

- Option 1—Subnet Mask
- Option 3—Default Routers
- Option 6—DNS Name Servers
- Option 12—Host Name
- Option 15—Domain Name
- Option 44—Netbios Name Server
- Option 46—Netbios Node Type Option
- Option 50—IP Address
- Option 51—IP Address Lease Time
- Option 53—DHCP Message Type
- Option 54—DHCP Server IP Address
- Option 55—Parameter Request List
- Option 58—Renew (T1) Timer
- Option 59—Renew (T2) Timer

DHCPv4 servers also support Suboption 13 Relay Agent Information Option 82 as specified in RFC 3046, to enable the use of a pool indicated by the DHCP client.

DHCPv6 servers support the following options, as defined in RFC 3315:

- Option 1—OPTION\_CLIENTID
- Option 2—OPTION\_SERVERID
- Option 3—OPTION\_IA\_NA
- Option 4—OPTION\_IA\_TA
- Option 5—OPTION\_IAADDR
- Option 6—OPTION\_ORO
- Option 7—OPTION\_PREFERENCE
- Option 8—OPTION\_ELAPSED\_TIME
- Option 9—OPTION\_RELAY\_MSG
- Option 11—OPTION\_AUTH
- Option 12—OPTION\_UNICAST
- Option 13—OPTION\_STATUS\_CODE
- Option 14—OPTION\_RAPID\_COMMIT
- Option 15—OPTION\_USER\_CLASS
- Option 16—OPTION\_VENDOR\_CLASS
- Option 17—OPTION\_VENDOR\_OPTS
- Option 18—OPTION\_INTERFACE\_ID
- Option 19—OPTION\_RECONF\_MSG
- Option 20—OPTION\_RECONF\_ACCEPT

These options are copied into the DHCP reply message, but if the same option is defined several times, the following order of priority is used:

1. subnet options
2. pool options
3. options from the DHCP client request

A local DHCP server must be bound to a specified interface by referencing the server from that interface. The DHCP server will then be addressable by the IP address of that interface. A normal interface or a loopback interface can be used.

A DHCP client is defined by the MAC address and the circuit identifier. This implies that for a certain combination of MAC and circuit identifier, only one IP address can be returned; if more than one request is made, the same address will be returned.

---

### 7.2.1.3 IPCP

Similar to DHCP over Ethernet interfaces, Internet Protocol Control Protocol (IPCP) extensions to push IP information over PPP/MLPPP VPRN (and IES) SAPs are supported. Within this protocol, extensions can be configured to define the remote IP address and DNS IP address to be signaled via IPCP on the associated PPP interface. The IPCP-based IP and DNS assignment process is similar to DHCP behavior; IPCP-based IP/DNS assignment is a natural use of PPP/MLPPP IP layer protocol handshake procedures. PPP/MLPPP connected devices hooked up to VPRN (and IES) can benefit from this feature for the assignment of IP and DNS to the associated interface.

### 7.2.1.4 Troubleshooting and Fault Detection Services

Bidirectional forwarding detection (BFD) can be configured on the VPRN interface. BFD is a simple protocol for detecting failures in a network. BFD uses a “hello” mechanism that sends control messages periodically to the far end and expects to receive periodic control messages from the far end. On the 7705 SAR, BFD is implemented for IGP and BGP protocols, including static routes, in asynchronous mode only, meaning that neither end responds to control messages; rather, the messages are sent periodically from each end.

To support redundancy with fast switchover, BFD must be enabled to trigger the handoff to the other route in case of failure.

Due to the lightweight nature of BFD, it can detect failures faster than other detection protocols, making it ideal for use in applications such as mobile transport.

If BFD packets are not received in the configured amount of time, the associated route is declared “not active”, causing a reroute to an alternative path, if any.

**Note:** Link failures detected by BFD will disable the IP interface.

The 7705 SAR also supports Internet Control Message Protocol (ICMP). ICMP is a message control and error reporting protocol that also provides information relevant to IP packet processing.

### 7.2.1.5 VRRP on VPRN Interfaces

VRRP can be implemented on VPRN service interfaces to participate as part of a virtual router instance. This implementation prevents a single point of failure by ensuring access to the gateway address, which is configured on all VPRN service interfaces in the VRRP. VRRPv3 can also be implemented on VPRN service interfaces, including r-VPLS interfaces for VPRN.

The 7705 SAR supports VRRPv3 for IPv4 and IPv6 as described in RFC 5798. Within a VRRP router, the virtual routers in each of the IPv4 and IPv6 address families are a domain unto themselves and do not overlap.

**Note:** VRRPv3 for IPv6 is not supported on a Layer 3 spoke-SDP termination.

For information on VRRP and VRRP VPRN service interface parameters, as well as the configuration parameters of VRRP policies, refer to the “VRRP” section in the 7705 SAR Router Configuration Guide. CLI command descriptions for VRRP policies are also given in the 7705 SAR Router Configuration Guide.

For CLI command descriptions related to VPRN service interfaces, see [VPRN Services Command Reference](#).

### 7.2.1.6 IP ECMP Load Balancing

IP ECMP allows the configuration of load balancing across all IP interfaces at the system level or interface level on the network side. Layer 4 port attributes and the TEID attribute in the hashing algorithm can be configured with the **l4-load-balancing** and **teid-load-balancing** commands in the **config>service>vprn> interface** context. Configuration of the **l4-load-balancing** command at the interface level overrides the system-level settings for the specific interface. The **teid-load-balancing** command can only be configured at the interface level.

The system IP address can be included in or excluded from the hashing algorithm with the system-level **system-ip-load-balancing** command.

For more information on IP ECMP, refer to the 7705 SAR Router Configuration Guide, “Static Routes, Dynamic Routes, and ECMP”.

---

### 7.2.1.7 Proxy ARP

Proxy ARP is supported on VPRN interfaces.

Proxy ARP is a technique by which a router on one network responds to ARP requests intended for another node that is physically located on another network. The router effectively pretends to be the destination node by sending an ARP response to the originating node that associates the router's MAC address with the destination node's IP address (acts as a proxy for the destination node). The router then takes responsibility for routing traffic to the real destination.

For more information on proxy ARP, refer to the 7705 SAR Router Configuration Guide, "Proxy ARP".

### 7.2.1.8 Configurable ARP Retry Timer

A timer is available to configure a shorter retry interval when an ARP request fails. An ARP request may fail for a number of reasons, such as network connectivity issues. By default, the 7705 SAR waits 5000 ms before retrying an ARP request. The configurable retry timer makes it possible to shorten the retry interval to between 100 and 30 000 ms.

**Note:** The ARP retry default value of 5000 ms is intended to protect CPU cycles on the 7705 SAR, especially when it has a large number of interfaces. Configuring the ARP retry timer to a value shorter than the default should be done only on mission-critical links, such as uplinks or aggregate spoke SDPs transporting mobile traffic; otherwise, the retry interval should be left at the default value.

The configurable ARP retry timer is supported on VPRN and IES service interfaces, as well on the router interface.

---

## 7.2.2 SAPs

Topics in this section include:

- [Encapsulations](#)
- [QoS Policies](#)
- [QinQ \(VPRN\)](#)
- [Filter Policies on a VPRN SAP](#)

VPRN service also supports SAPs for IPSec tunnels (see [IPSec Support](#)).

### 7.2.2.1 Encapsulations

The following SAP encapsulations are supported on the 7705 SAR VPRN service:

- Ethernet null
- Ethernet dot1q
- Ethernet qinq
- PPP
- MLPPP
- MC-MLPPP
- LAG

**Note:** When gathering statistics on VPRN SAPs and ports, the SAP ingress counters might be different from the port counters as the SAP takes into account encapsulation headers. For Ethernet-encapsulated SAPs, counters can be adjusted by configuring the packet byte offset, which adjusts the packet size that schedulers, shapers, and the SAP counters take into account by offsetting the configured number of bytes. For information on packet byte offset, refer to the 7705 SAR Quality of Service Guide, “Packet Byte Offset (PBO)”.

---

### 7.2.2.2 QoS Policies

For each instance of VPRN service, QoS policies can be applied to the ingress and egress VPRN interface SAPs.

At VPRN access ingress, traffic can be classified as unicast or multicast traffic types. In a VPRN access ingress QoS policy, users can create queues that map to forwarding classes. For each forwarding class, traffic can be assigned to a queue that is configured to support unicast, multicast, or both. As shown in the following example, for fc "af", both unicast and multicast traffic use queue 2, and for fc "l2", only multicast traffic uses queue 3.

```
configure qos sap-ingress qos 2 create
 queue 1 create
 exit
 queue 2 create
 exit
 queue 3 create
 exit
 fc "af" create
 queue 2
 multicast-queue 2
 exit
 fc "l2" create
 multicast-queue 3
 exit
```

VPRN service egress QoS policies function in the same way as they do for other services, where the class-based queues are created as defined in the policy.

Both the Layer 2 and Layer 3 criteria can be used in the QoS policies for traffic classification in a VPRN.

For VPRN services, the fabric mode needs to be set to aggregate mode as opposed to per-destination mode. VPRN services are only supported with aggregate-mode fabric profiles. When the fabric mode is set to per-destination mode, creation of VPRN service is blocked through the CLI. The user must change the fabric mode to aggregate mode before being able to configure VPRN services. As well, when a VPRN service is configured, changing from aggregate mode is blocked. The fabric mode is configured under the **config>qos>fabric-profile** context. For more information, refer to the 7705 SAR Quality of Service Guide.

---

#### 7.2.2.2.1 CoS Marking for Self-generated Traffic

For each instance of VPRN service, DSCP marking and dot1p marking for self-generated traffic QoS can be configured for the applications supported by the 7705 SAR.

For VPRN service, DSCP marking is configured in the **vprn>sgt-qos>application** context. For more information about DSCP marking and self-generated QoS traffic, see “CoS Marking for Self-generated Traffic” in the 7705 SAR Quality of Service Guide.

#### 7.2.2.3 QinQ (VPRN)

VPRN supports QinQ functionality. For details, see [QinQ Support](#).

#### 7.2.2.4 Filter Policies on a VPRN SAP

IPv4 and IPv6 filter policies can be applied to ingress and egress VPRN SAPs.

Refer to the 7705 SAR Router Configuration Guide, “Filter Policies”, for information on configuring IP filters.

### 7.2.3 PE-to-CE Routing Protocols

The 7705 SAR supports the following PE-to-CE routing protocols for VPRN service:

- EBGp (for IPv4 and IPv6 address families)
- OSPF
- OSPFv3
- RIP
- static routes

EBGP is supported within both the router context and VPRN service context. Both OSPF and OSPFv3 are supported within the router context as well as within the VPRN service context; however, there are some minor differences in the command sets depending on the context.

---

### 7.2.3.1 Using OSPF or OSPFv3 in IP VPNs

Using OSPF or OSPFv3 as a PE-to-CE routing protocol allows the version of OSPF that is currently running as the IGP routing protocol to migrate to an IP-VPN backbone without changing the IGP routing protocol, introducing BGP as the PE-CE, or relying on static routes for the distribution of routes into the service provider's IP-VPN.

The following features are supported:

- transportation of OSPF/OSPFv3 learned routes as OSPF/OSPFv3 externals  
This feature uses OSPF or OSPFv3 as the protocol between the PE and CE routers; however, instead of transporting the OSPF/OSPFv3 LSA information across the IP-VPN, the OSPF/OSPFv3 routes are "imported" into MP-BGP as AS externals. As a result, other OSPF- or OSPFv3-attached VPRN sites on remote PEs receive these via type 5 LSAs.
- advertisement/redistribution of BGP-VPN routes as summary (type 3) LSAs flooded to CE neighbors of the VPRN OSPF/OSPFv3 instance  
This occurs if the OSPF or OSPFv3 route type (in the OSPF/OSPFv3 route type BGP extended community attribute carried with the VPN route) is not external (or NSSA) and the locally configured domain ID matches the domain ID carried in the OSPF/OSPFv3 domain ID BGP extended community attribute carried with the VPN route.

#### 7.2.3.1.1 DN Bit

When a type 3 LSA is sent from a PE router to a CE router, the DN bit in the LSA options field is set. This ensures that if any CE router sends this type 3 LSA to a PE router, the PE router will not redistribute it further.

When a PE router needs to distribute to a CE router a route that comes from a site outside the CE router's OSPF/OSPFv3 domain, the PE router presents itself as an autonomous system boundary router (ASBR) and distributes the route in a type 5 LSA. The DN bit must be set in these LSAs to ensure that they will be ignored by any other PE routers that receive them.

DN bit loop avoidance is also supported.

---

### 7.2.3.2 TTL Security

TTL security provides protection for EBGp peering sessions against CPU utilization-based attacks such as denial of service (DoS) attacks. This feature is supported for directly connected peering sessions and for multihop EBGp peering sessions. The BGP session can be over spoke-SDP terminated VPRN interfaces, SAP interfaces, and loopback interfaces, as well as over router interfaces and IPSec interface tunnels.

TTL security is most important for EBGp PE-CE sessions because CE devices can be multiple hops away, which adds a higher level of risk. TTL security provides a mechanism to better ensure the validity of BGP sessions from the CE device.

For more information on TTL security, refer to the 7705 SAR Routing Protocols Guide, “TTL Security”.

## 7.2.4 PE-to-PE Tunneling Mechanisms

The 7705 SAR supports multiple mechanisms to provide transport tunnels for the forwarding of traffic between PE routers within the RFC 2547bis network.

The 7705 SAR VPRN implementation supports the use of:

- RSVP-TE protocol to create tunnel LSPs between PE routers
- LDP protocol to create tunnel LSPs between PE routers
- GRE tunnels between PE routers

These transport tunnel mechanisms provide the flexibility of using dynamically created LSPs, where the service tunnels are automatically bound (the “auto-bind” feature) and there is the ability to provide certain VPN services with their own transport tunnels by explicitly binding SDPs, if desired. When the **auto-bind-tunnel** command is used, all services traverse the same LSPs and do not allow alternate tunneling mechanisms (such as GRE) or the ability to configure sets of LSPs with bandwidth reservations for specific customers, as is available with explicit SDPs for the service.

## 7.2.5 Per-VRF Route Limiting

The 7705 SAR allows setting the maximum number of routes that can be accepted in the VRF for a VPRN service. There are options to specify a percentage threshold at which to generate an event that the VRF is nearly full and an option to disable additional route learning when the VRF is full or only generate an event.

## 7.2.6 RIP Metric Propagation in VPRNs

When RIP is used as the PE-CE protocol for VPRNs (IP-VPNs), the RIP metric is used only by the local node running RIP with the Customer Equipment (CE). The metric is not used with the MP-BGP path attributes that are exchanged between PE routers. [Figure 116](#) shows an example of RIP metric propagation in a VPRN across two autonomous systems.

**Figure 116 RIP Metric Propagation in VPRNs**

The RIP metric can also be used to exchange routing information between PE routers if a customer network is dual homed to separate PEs. The RIP metric learned from the CE router can be used to choose the best route to the destination subnet. The RIP metric sets the BGP MED attribute, which allows remote PEs to choose the lowest MED and the PE with the lowest advertised RIP metric as the preferred egress point for the VPRN.

---

## 7.2.7 Multicast VPN (MVPN)

The two main multicast VPN (MVPN) service implementations are the *draft-rosen-vpn-mcast* and the Next-Generation Multicast VPN (NG-MVPN).

The 7705 SAR supports NG-MVPNs, which use BGP for customer-multicast (C-multicast) signaling.

The 7705 SAR conforms to the relevant sections of the following RFCs related to MVPNs:

- RFC 6388, *Label Distribution Protocol Extensions for Point-to-Multipoint and Multipoint-to-Multipoint Label Switched Paths*
- RFC 6512, *Using Multipoint LDP When the Backbone Has No Route to the Root (only as source router)*
- RFC 6513, *Multicast in MPLS/BGP IP VPNs*

This section includes information on the following topics:

- [Multicast in IP-VPN Applications](#)
- [MVPN Building Blocks](#)
- [Provider Tunnel Support](#)
- [Inter-AS and Intra-AS Solutions](#)
- [Mrinfo and Mtrace](#)
- [Multicast-only Fast Reroute \(MoFRR\)](#)
- [mLDP Point-to-Multipoint Support](#)
- [mLDP Fast Upstream Switchover](#)
- [Multicast Source Discovery Protocol](#)

### 7.2.7.1 Multicast in IP-VPN Applications

This section focuses on IP-VPN multicast functionality. As a prerequisite for MVPN, readers should be familiar with the “IP Multicast” material in the 7705 SAR Routing Protocols Guide, where multicast protocols (PIM, IGMP, and MLD) are described.

Applications for this feature include enterprise customers implementing a VPRN solution for their WAN networking needs, video delivery systems, and customer applications that include stock-ticker information as well as financial institutions for stock and other types of trading data.

Implementation of next-generation VPRN (NG-VPRN) requires the separation of the provider's core multicast domain from customer multicast domains, and the customer multicast domains from each other.

Figure 117 shows an example of multicast in an IP-VPN application and shows the following domains:

- provider's domain
  - core routers (1 through 4)
  - edge routers (5 through 10)
- customers' IP-VPNs, each having their own multicast domain
  - VPN-1 (CE routers 12, 13, and 16)
  - VPN-2 (CE routers 11, 14, 15, 17, and 18)

In this VPRN multicast example, VPN-1 data generated by the customer behind router 16 is multicast by PE router 9 to PE routers 6 and 7 for delivery to CE routers 12 and 13, respectively. VPN-2 data generated by the customer behind router 15 is forwarded by PE router 8 to PE routers 5, 7, and 10 for delivery to CE routers 11 and 18, 14, and 17, respectively.

The demarcation points for these domains are in the PEs (routers 5 through 10). The PE routers participate in both the customer multicast domain and the provider multicast domain. The customer CEs are limited to a multicast adjacency with the multicast instance on the PE, where the PE multicast instance is specifically created to support that specific customer IP-VPN. As a result, customers are isolated from the provider core multicast domain and other customer multicast domains, while the provider core routers only participate in the provider multicast domain and are isolated from all customer multicast domains.

The PE for a customer's multicast domain becomes adjacent to the CE routers attached to that PE and to all other PEs that participate in the IP-VPN (customer) multicast domain. The adjacencies are set up by the PE that encapsulates the customer multicast control data and the multicast streams inside the provider's multicast packets. The encapsulated packets are forwarded only to the PE nodes that are attached to the same customer's edge routers as the originating stream and are part of the same customer VPRN. This process prunes the distribution of the multicast control and data traffic to the PEs that participate in the customer's multicast domain.

## 7.2.7.2 MVPN Building Blocks

This section includes information on the following topics:

- [PMSI](#)
- [MVPN Using BGP Control Plane](#)
- [Auto-Discovery](#)
- [PE-CE Multicast Protocols and Services](#)
- [PE-PE Transmission of C-Multicast Routing Using BGP](#)
- [PE-PE Multicast Protocols](#)
- [PE-PE Multicast Data Transmission](#)

### 7.2.7.2.1 PMSI

A provider-multicast (P-multicast) service interface (PMSI), described in RFC 6513, refers to an abstract service in the service provider's core network that can take a packet from one PE, belonging to one MVPN, and deliver a copy of the packet to some or all of the other PEs supporting that MVPN.

The most common PMSI uses a multicast distribution tree (MDT). An MDT is a point-to-multipoint traffic path that is instantiated using forwarding table entries that support packet replication. For example, an MDT forwarding entry would specify the incoming interface—where the node expects to receive a packet flowing up or down the MDT—and the set of outgoing interfaces that each receive a copy of the packet. The MDT forwarding state can be set up using an IP multicast signaling protocol such as PIM, or an MPLS protocol such as multicast LDP (mLDP) or RSVP-TE.

The 7705 SAR supports only mLDP PMSI.

This section includes information on the following topics:

- [PMSI Types](#)
- [Creating a PMSI](#)

---

## PMSI Types

There are two types of PMSIs: inclusive and selective.

An inclusive PMSI (I-PMSI) includes all of the PEs supporting an MVPN. A selective PMSI (S-PMSI) includes a subset of the PEs supporting an MVPN (that is, an S-PMSI is a subset of an I-PMSI). An MVPN can have more than one S-PMSI.

### Inclusive PMSIs (I-PMSIs)

An MVPN has one I-PMSI. The I-PMSI carries MVPN-specific control information between the PEs of the MVPN. In the 7705 SAR implementation, by default, all C-multicast flows use the I-PMSI. This minimizes the number of PE router states in the service provider core, but wastes bandwidth because a C-multicast flow on an I-PMSI is delivered to all PEs in the MVPN, even when only a subset of the PEs have receivers for the flow. To reduce wasted bandwidth, a service provider can migrate the C-multicast flow from the I-PMSI to an S-PMSI that includes only the PEs with receivers interested in that (S,G) flow.

On a 7705 SAR, migration of a C-multicast-flow from I-PMSI to S-PMSI can be configured to be initiated automatically by the PE closest to the source of the C-multicast-flow, where the migration trigger is based on the data rate of the flow. Migration occurs when the data rate exceeds the configured threshold.

### Selective PMSIs (S-PMSIs)

A selective PMSI is one that includes a subset of the PEs supporting an MVPN. Each MVPN can have zero or more S-PMSIs. As stated above, the transition from I-PMSI to S-PMSI is triggered when the data rate exceeds the user-configured threshold.

### I-PMSI versus S-PMSI

[Figure 118](#) illustrates the difference between an I-PMSI and an S-PMSI. In the figure, the arrowheads indicate send and receive capabilities supported by the PMSI. Two-way arrows imply sender and receiver transmissions, and one-way arrows imply sender-only or receiver-only transmission.

In [Figure 118](#), all the VRFs that are part of the MVPN domain receive PDUs from the I-PMSI MDT entries, whether or not the VRFs are configured to receive the PDUs. When the traffic for an (S,G) exceeds the configured data rate threshold, the multicast tree for that (S,G) switches from an I-PMSI to an S-PMSI. Each (S,G) has its own S-PMSI tree built when the threshold for that (S,G) has been exceeded.

**Figure 118 I-PMSI and S-PMSI**

25927

### Creating a PMSI

The 7705 SAR supports only multicast LDP (mLDP) as the mechanism to build a PMSI tunnel.

When the C-multicast protocol for a leaf node in an MVPN initiates a multicast request, it triggers mLDP to generate an LSP. The C-multicast protocol can be IGMP or PIM, which is configured under the VPRN service.

Multicast LDP tries to resolve the source address of (S,G) by looking up the source (S) in the routing table manager (RTM). If there is a resolution, mLDP generates a FEC toward the source (S). The mLDP FEC, as described in RFC 6388, contains the root node's system IP address and an opaque value. The opaque value contains a point-to-multipoint LSP ID, which uniquely identifies the point-to-multipoint LSP in the context of the root node. [Figure 119](#) illustrates a point-to-multipoint FEC element and an opaque value.

The P2MP ID is generated on the root node and is advertised to the leaf node via a BGP MVPN address family route update (see [Figure 120](#)).

In [Figure 119](#), the point-to-multipoint FEC element contains of the address of the root of the point-to-multipoint LSP and an opaque value. The opaque value consists of one or more LDP multiprotocol (MP) opaque value elements. The opaque value is unique within the context of the root node, and for the 7705 SAR it is the P2MP ID. The combination of “Root Node Address Type”, “Root Node Address”, and “Opaque Value” uniquely identifies a point-to-multipoint LSP within the MPLS network.

**Figure 119     P2MP FEC and MP LDP Opaque Value as per RFC 6388**

Figure 120 shows the following items:

- the BGP MVPN address family update (#1), which contains the unique P2MP ID
- the LDP FEC (#2), which is generated when the C-multicast IGMP or PIMv4 prompts the LDP to generate the mLDP FEC from the leaf to the root node
- the opaque value (basic type) (#3), which is encoded into the mLDP FEC and contains the P2MP ID

**Figure 120 BGP MVPN Address Family Updates**

25929

### 7.2.7.2.2 MVPN Using BGP Control Plane

To communicate auto-discovery routes and C-multicast signaling, add the **mvpn-ipv4** address family to the BGP address family configuration. For more information, refer to the “Configuring BGP Address Families” section in the 7705 SAR Routing Protocols Guide.

---

The 7705 SAR MVPN implementation is based on NG-VPRN standards and supports the following features:

- auto-discovery
- PE-PE transmission of C-multicast routing using BGP
- IPv4
- use of mLDP for S-PMSIs used as PMSIs
- inter-AS with direct VRF connect
- inter-AS as root router only (source connect) (options B and C)

### 7.2.7.2.3 Auto-Discovery

Auto-discovery for multicast VPN refers to the process by which a PE with a multicast MVPN service dynamically learns about the other PEs supporting the same MVPN.

The basic auto-discovery function is to discover the identity of all other PEs in the MVPN. This information is essential for setting up the I-PMSI.

Advanced auto-discovery functions are:

- discovering the subsets of PEs in the MVPN that are interested in receiving a specific multicast flow
- discovering Autonomous System Border Routers (ASBRs) in other ASs that are interested in receiving a specific multicast flow
- discovering C-multicast sources that are actively sending traffic across the service provider backbone (in a PMSI)
- discovering bindings between multicast flows and PMSIs

The MVPN standards define two different options for MVPN auto-discovery, BGP and PIM. The 7705 SAR only uses MP-BGP for auto-discovery and S-PMSI signaling.

With BGP auto-discovery, MVPN PEs advertise special auto-discovery routes to their peers using multiprotocol extensions to BGP.

Using BGP for auto-discovery does not imply that BGP must be used for C-multicast signaling, nor does it impose any restrictions about the technology used to tunnel MVPN packets between PEs in the service provider backbone.

---

### **MVPN Membership Auto-Discovery Using BGP**

BGP-based auto-discovery is performed by referring to a multicast VPN address family (for example, **mvpn-ipv4**). Any PE that attaches to an MVPN must issue a BGP update message containing an NLRI in the address family, along with a specific set of attributes.

The PE router uses route targets to specify an MVPN route import and export policy. The route target may be the same target as the one used for the corresponding unicast VPN, or it may be a different target. For a given MVPN, the PE router can specify separate import route targets for sender sites and receiver sites.

The route distinguisher (RD) that is used for the corresponding unicast VPN can also be used for the MVPN.

In addition, the bindings of C-trees to P-tunnels are discovered using BGP S-PMSI auto-discovery routes.

#### **7.2.7.2.4 PE-CE Multicast Protocols and Services**

A PE with an MVPN service must learn about the networks and multicast receivers located beyond the CE devices at the MVPN customer site. Typically, IGMP or a PIM protocol is used by the CE to inform the PE that it (the CE) wants to receive a particular multicast flow because it has downstream receivers of that flow. The 7705 SAR supports both IGMP (versions 1, 2, and 3) and PIM Source Specific Multicast (SSM) as the CE-to-PE protocol.

The use of PIM as the CE-to-PE protocol requires that the PE learn about networks beyond the CE so that the PE can appropriately select the correct upstream next hop for sending PIM join and prune messages. The join and prune messages normally follow the reverse path of unicast data traffic and establish the required multicast forwarding state in the PE, CE, and other PIM routers at the customer site. The reachability of networks beyond the CE can be learned through a routing protocol such as OSPF, RIP, or BGP, or it can be configured statically when static routes or multiprotocol BGP are used between the CE and a 7705 SAR PE.

Layer 2 services, such as routed VPLS, can be used to snoop IGMP from the VPLS access interface and translate IGMP to PIM on the PE-CE Layer 3 interface.

The 7705 SAR supports IPv4 PE-CE protocols (for example, IGMP and PIM).

---

### 7.2.7.2.5 PE-PE Transmission of C-Multicast Routing Using BGP

MVPN C-multicast routing information is exchanged between PEs by using C-multicast routes that are carried by the MVPN NLRI.

### 7.2.7.2.6 PE-PE Multicast Protocols

When a PE gets a request for a multicast flow from a connected CE in an MVPN, it must convey that request to the PE closest to the source of the multicast traffic. In order for a PE to know that another PE is closer to a source, unicast routes must be exchanged between the PEs. This is done by exchanging VPN-IP routes using multiprotocol BGP (MP-BGP). The VPN-IP routes exchanged for this purpose may carry additional information as compared to VPN-IP routes used only for unicast routing. In particular, when NG-MVPN signaling is used, as per RFC 6513, a route that is a candidate for upstream multicast hop (UMH) selection carries two additional BGP extended communities: a source-AS extended community and a VRF route import extended community.

C-multicast signaling is the signaling of joins and prunes from a PE that is connected to a site with receivers of a multicast flow to another PE that is closest to a sender of the multicast flow. Similar to auto-discovery, the MVPN standards allow either PIM or BGP to be used for C-multicast signaling.

The 7705 SAR uses only BGP for C-multicast signaling and multicast route advertisement between PEs.

When BGP is used for C-multicast signaling, a PE announces its desire to join a source C-tree by announcing a special source-join BGP NLRI using BGP multiprotocol extensions. The source-join BGP NLRI has the same AFI and SAFI as the BGP auto-discovery routes (described in RFC 6513). When a PE wants to leave an inter-site source tree, it withdraws the source-join BGP NLRI that it had previously advertised. A PE directs a source-join BGP NLRI to a specific upstream PE—the one it determines to be closest to the source—by including the VRF route import extended community associated with that upstream PE; other PEs may receive the source-join BGP NLRI, but do not import and use it.

Using C-multicast signaling protocols with BGP means that each MVPN PE typically has a small number of BGP sessions (for example, two interior border gateway protocol (IBGP) sessions with two route reflectors in the local AS).

The use of BGP minimizes the control plane load, but may lead to slightly longer join and leave latencies than is the case for the faster recovery of lost BGP messages by the TCP layer underlying the BGP sessions. This is due to the route reflector propagating join and prune messages from downstream PEs to upstream PEs.

---

### 7.2.7.2.7 PE-PE Multicast Data Transmission

A PMSI can be built on one or more point-to-point, point-to-multipoint, or multipoint-to-multipoint tunnels that carry customer multicast packets transparently through the service provider core network. The MVPN standards provide several technology options for PMSI tunnels:

- RSVP-TE LSP (point-to-point and point-to-multipoint)
- mLDP LSP (point-to-point, point-to-multipoint, and multipoint-to-multipoint)
- GRE tunnel (point-to-point and point-to-multipoint)

Only point-to-multipoint mLDP as a PMSI tunnel is supported.

The 7705 SAR platforms support the following transport options:

- I-PMSI – mLDP point-to-multipoint LSPs
- S-PMSI – mLDP point-to-multipoint LSPs

### 7.2.7.3 Provider Tunnel Support

The following provider tunnel features are supported:

- I-PMSI
- S-PMSI

Topics in this section include:

- [Point-to-Multipoint I-PMSI and S-PMSI](#)
- [Point-to-Multipoint LDP I-PMSI and S-PMSI](#)
- [Point-to-Multipoint LSP S-PMSI](#)
- [MVPN Sender-only and Receiver-only](#)

#### 7.2.7.3.1 Point-to-Multipoint I-PMSI and S-PMSI

BGP C-multicast signaling must be enabled for an MVPN instance to use point-to-multipoint mLDP to create an I-PMSI or S-PMSI.

By default, all PE nodes participating in MVPN receive data traffic over an I-PMSI. Optionally, for efficient data traffic distribution, S-PMSIs can be used to send traffic to PE nodes that have at least one active receiver connected.

Only one unique multicast flow is supported over each mLDP point-to-multipoint LSP S-PMSI.

The number of S-PMSIs that can be initiated per MVPN instance is set by the **maximum-p2mp-spmsi** command. A point-to-multipoint LSP S-PMSI cannot be used for more than one (S,G) stream once the maximum number of S-PMSIs per MVPN is reached. Multicast flows that cannot switch to an S-PMSI remain on the I-PMSI.

### 7.2.7.3.2 Point-to-Multipoint LDP I-PMSI and S-PMSI

A point-to-multipoint LDP LSP as an inclusive or selective provider tunnel is available with BGP NG-MVPN only. A point-to-multipoint LDP LSP is set up dynamically from leaf nodes upon auto-discovery of leaf PE nodes that are participating in multicast VPN. Each LDP I-PMSI or S-PMSI LSP can be used with a single MVPN instance only.

The **multicast-traffic** command (under **config>router>ldp>interface-parameters>interface**) must be configured on a per-LDP interface basis to enable a point-to-multipoint LDP setup. Point-to-multipoint LDP must also be configured as an inclusive or selective provider tunnel on a per-MVPN basis. Use the **mldp** command (under **provider-tunnel>inclusive** or **>selective**) to dynamically initiate a point-to-multipoint LDP LSP to leaf PE nodes learned via NG-MVPN auto-discovery signaling. S-PMSI is for efficient data distribution and is optional.

### 7.2.7.3.3 Point-to-Multipoint LSP S-PMSI

NG-MVPN allows the use of a point-to-multipoint LDP LSP as the S-PMSI. An S-PMSI is generated dynamically, based on the user-configured traffic bandwidth threshold for a number of multicast flows. Use the **data-threshold** command (under **provider-tunnel>selective**) to set the bandwidth threshold.

In MVPN, the root node PE discovers all the leaf PEs via I-PMSI auto-discovery routes. All multicast PDUs traverse through the I-PMSI until the configured threshold is reached on the root node. When the configured threshold is reached on the root node, the root node signals the desire to switch to an S-PMSI via BGP signaling of the S-PMSI auto-discovery NLRI.

Because of the way that LDP normally works, mLDP point-to-multipoint LSPs are set up (unsolicited) from the leaf PEs towards the root node PE. The leaf PE discovers the root node PE via auto-discovery routes (I-PMSI or S-PMSI). The tunnel identifier carried in the PMSI attribute is used as the point-to-multipoint FEC element.

The tunnel identifier consists of the root node PE address, along with a point-to-multipoint LSP ID. The generic LSP identifier value is automatically generated by the root node PE.

#### 7.2.7.3.4 MVPN Sender-only and Receiver-only

The I-PMSI can be optimized by configuring PE nodes that behave as a sender-only or receiver-only node. By default, PE nodes are both sender and receiver nodes (sender-receiver).

In MVPN, by default, if multiple PE nodes form a peering within a common MVPN instance, then each PE node originates a local multicast tree towards the other PE nodes in this MVPN instance. This behavior creates an I-PMSI mesh across all PE nodes in the MVPN. Typically, a VPN has many sites that host multicast receivers only, and has a few sites that host sources only or host both receivers and sources.

MVPN **sender-only** and **receiver-only** commands allow the optimization of control-plane and data-plane resources by preventing unnecessary I-PMSI mesh setups when a PE device hosts only multicast sources or only multicast receivers for an MVPN.

For PE nodes that host only multicast sources for a VPN, operators can configure the MVPN to block those PE nodes from joining I-PMSIs that belong to other PEs in the MVPN. For PE nodes that host only multicast receivers for a VPN, operators can block those PE nodes in order to set up a local I-PMSI to other PEs in this MVPN.

MVPN **sender-only** and **receiver-only** commands are supported with NG-MVPN using IPv4 LDP provider tunnels for both IPv4 and IPv6 customer multicast.

[Figure 121](#) shows a four-site MVPN with sender-only, receiver-only, and sender-receiver (default) sites.

**Note:** Attention needs to be paid to the physical location of the BSR and RP nodes when sender-only or receiver-only is enabled. Since the source DR sends unicast-encapsulated traffic towards RP, the RP needs to be at a sender-receiver or sender-only site, so that (\*,G) traffic can be sent over the tunnel. The BSR needs to be deployed at the sender-receiver site. The BSR can be at a sender-only site if the RPs are at the same site. The BSR needs to receive packets from other candidate-BSR and candidate-RP nodes and also needs to send BSM packets to all other BSR and RP nodes.

**Figure 121 I-PMSI Sender-Receiver, Sender-Only, and Receiver-Only: Optimized I-PMSI Mesh**

25931

### 7.2.7.4 Inter-AS and Intra-AS Solutions

An MVPN service that spans more than one AS is called an inter-AS MVPN. As is the case with unicast-only IP VPN services, there are different approaches for supporting inter-AS MVPNs. Generally, the approaches belong to one of two categories:

- all P-tunnels and P-multicast trees start and end on PEs and ASBRs in the same AS
- P-tunnels and P-multicast trees extend across multiple ASs

In the first category, the P-tunnels and P-multicast trees start on PEs and ASBRs of an AS, and end on PEs and ASBRs in that same AS (extending no further). In this scenario, C-multicast traffic that must cross an AS boundary is handed off natively between the ASBRs on each side of the AS boundary.

From the perspective of each ASBR, the other ASBR is simply a collection of CEs, each reachable through separate logical connections (for example, VPRN SAPs). In this type of deployment, no auto-discovery signaling is required between the different ASs, and the exchange of C-multicast routes and C-multicast signaling uses the same protocols and procedures as described in [PE-CE Multicast Protocols and Services](#) for PE-CE interfaces.

In the second category, P-tunnels and P-multicast trees extend across the boundaries between different ASs. In this scenario, the PMSI extends end-to-end between the PEs of the MVPN, even when those PEs are in different ASs. ASBRs need to exchange auto-discovery information in order to determine whether, for a given MVPN:

- the neighbor AS has PEs with sites in the MVPN
- the neighbor AS is a transit node on the best path to a remote AS that has sites of the MVPN

If a P-multicast tree is used to transport the PMSI, there are two options for extending the P-tree across multiple ASs:

- non-segmented inter-AS MDT

The end-to-end P-tree is end-to-end between all the PEs supporting the MVPN, passing through ASBRs as necessary.

- segmented inter-AS MDT (see [Figure 122](#))

The end-to-end P-tree is formed by stitching together a sub-tree from each AS. A sub-tree of an AS connects only the PEs and ASBRs of that AS. A point-to-point tunnel between ASBRs on each side of an AS boundary is typically used to stitch the sub-trees together.

**Note:** The 7705 SAR supports non-segmented inter-AS trees only as a root node.

Constructing and using a non-segmented inter-AS MDT is similar to constructing and using an intra-AS MDT, except that BGP auto-discovery messages are propagated by ASBRs across AS boundaries, where the BGP auto-discovery messages are I-PMSI intra-AS auto-discovery routes, despite the reference to intra-AS.

When segmented inter-AS tunnels are used for an NG-MVPN, the ASBRs configured to support that MVPN will originate inter-AS I-PMSI auto-discovery routes for that MVPN toward their external peers after having received intra-AS I-PMSI auto-discovery routes for the MVPN from one or more PEs in their own AS. The inter-AS I-PMSI auto-discovery messages are propagated through all ASs that support the MVPN (that is, through all ASs that have PEs or ASBRs for the MVPN).

When an ASBR receives an inter-AS I-PMSI auto-discovery route, and it is the best route for the NLRI, the ASBR sends a leaf auto-discovery route to the exterior Border Gateway Protocol (EBGP) peer that advertised the route. The leaf auto-discovery route is used to set up a point-to-point, one-hop MPLS LSP that stitches together the P-multicast trees of each AS.

The 7705 SAR supports inter-AS and intra-AS option A.

The 7705 SAR does not support non-segmented inter-AS and intra-AS options B and C as an ABR or ASBR router or as a leaf router. However, the 7705 SAR can be part of non-segmented inter-AS and intra-AS options B and C as a root node.

#### 7.2.7.4.1 7705 SAR as Source of Non-Segmented Inter-AS or Intra-AS Network

The 7705 SAR can be the source of a non-segmented inter-AS or intra-AS network, as per RFC 6512 and RFC 6513.

[Figure 122](#) shows inter-AS option B connectivity via non-segmented mLDP, and [Figure 123](#) shows inter-AS option C. In inter-AS solutions, the leaf and ABR/ASBR nodes need recursive opaque FEC to route the mLDP FEC through the network.

**Note:** Currently, the 7705 SAR does not support recursive opaque FEC. Therefore, the 7705 SAR only can be positioned as a root node in inter-AS option B and C solutions.

**Figure 122 Inter-AS Option B: Non-Segmented Solution**

25933

**Figure 123 Inter-AS Option C: Non-Segmented Solution**

25934

### 7.2.7.5 Mrinfo and Mtrace

When using **mrinfo** and **mtrace** in a Layer 3 VPN context, the configuration for the VPRN should have a loopback address configured that has the same address as the core VPRN instance's system address (that is, the BGP next hop).

For more information, refer to the “IP Multicast Debugging Tools” section in the 7705 SAR OAM and Diagnostics Guide.

### 7.2.7.6 Multicast-only Fast Reroute (MoFRR)

The 7705 SAR supports MoFRR in the context of GRT for mLDP. The multicast traffic is duplicated on a primary mLDP multicast tree and a secondary mLDP multicast tree.

---

For more information, refer to the “Multicast-only Fast Reroute (MoFRR)” section in the 7705 SAR Routing Protocols Guide.

### **7.2.7.7 mLDP Point-to-Multipoint Support**

The 7705 SAR supports mLDP point-to-multipoint traffic.

For more information, refer to the “LDP Point-to-Multipoint Support” section in the 7705 SAR MPLS Guide.

### **7.2.7.8 mLDP Fast Upstream Switchover**

This feature allows a downstream LSR of an mLDP FEC to perform a fast switchover in order to source the traffic from another upstream LSR while IGP and LDP are converging due to a failure of the upstream LSR, where the upstream LSR is the primary next hop of the root LSR for the point-to-multipoint FEC.

For more information, refer to the “Multicast LDP Fast Upstream Switchover” section in the 7705 SAR MPLS Guide.

### **7.2.7.9 Multicast Source Discovery Protocol**

7705 SAR supports Multicast Source Discovery Protocol (MSDP) for MVPNs.

MSDP is a mechanism that allows rendezvous points (RPs) to share information about active sources. When RPs in remote domains hear about the active sources, they can pass on that information to the local receivers and multicast data can be forwarded between the domains. MSDP allows each domain to maintain an independent RP that does not rely on other domains, but it also enables RPs to forward traffic between domains. PIM-SM is used to forward the traffic between the multicast domains.

In addition to supporting MSDP on MVPNs in the VPRN service context, the 7705 SAR supports MSDP in the base router context. For information about MSDP, refer to the 7705 SAR Routing Protocols Guide.

In an MVPN, a PE node can act as an RP and run the MSDP functionality.

To interconnect multicast domains and to learn about source in other domains, MSDP peering is maintained between RP nodes. MSDP peering occurs over a TCP connection and control information is exchanged between peers to learn about multicast sources in other domains and to distribute information about multicast sources in the local domain.

When MSDP is configured in a service provider MVPN for a given IP VPN customer, at least one of the PEs that are part of that MVPN becomes an MSDP peer to customer-instance RPs. MSDP groups are configured on PEs to limit source-active (SA) advertisements to routers within a group. As the PE RP learns about multicast sources within its domain via PIM-SM, it encapsulates the first data packet in an MSDP SA message and distributes it to all of its peer RP nodes. Based on the RPF check, each peer node sends the control message to other peers to distribute information about the active source. If there is an existing entry for the multicast group, the RP node joins the shortest path tree towards the source.

## 7.2.8 VPRN Auto-binding Tunnels

The 7705 SAR supports auto-binding for selecting tunnels in the tunnel table manager (TTM) in the following resolution contexts:

- resolution of RFC 3107 BGP label route prefix using tunnels to a BGP next hop
- resolution of a VPN-IPv4 or VPN-IPv6 prefix to a BGP next hop

The command to auto-bind tunnels is **config>service>vprn>auto-bind-tunnel**, which has **resolution** and **resolution-filter** options.

The user configures the **resolution** option to enable auto-bind resolution to tunnels in the TTM. If the **resolution** option is explicitly set to **disabled**, the auto-binding to the tunnel is removed.

If **resolution** is set to **any**, any supported tunnel type in the resolution context will be selected following the TTM preference. The following tunnel types are selected in order of preference: RSVP, LDP, segment routing, and GRE. The user can configure the preference of the segment routing tunnel type in the TTM for a specific IGP instance.

If **resolution** is set to **filter**, one or more explicit tunnel types are specified using the **resolution-filter** option, and only these specified tunnel types will be selected according to the TTM preference.

**Note:**

- Prior to Release 9.0 of the 7705 SAR, the command for auto-binding is **config>service>vprn>auto-bind {ldp | gre | rsvp-te | mpls}**. When a router is upgraded to Release 9.0 or later, the commands are automatically converted to the new format **config>service>vprn>auto-bind-tunnel>resolution** and **>resolution-filter** with **gre**, **ldp**, **rsvp**, **sr-isis**, **sr-ospf**, and **sr-te** options. The pre-Release 9.0 **mpls** option converts to “**ldp** and **rsvp**”.
- If a VPRN is configured with **auto-bind-tunnel** using GRE and the BGP next hop of a VPN route matches a static blackhole route, all traffic matching that VPN route will be blackholed even if the static blackhole route is later removed. Similarly, if a static blackhole route is added after **auto-bind-tunnel** GRE has been enabled, the blackholing of traffic will not be performed optimally. In general, static blackhole routes that match VPN route next hops should be configured first, before the **auto-bind-tunnel** GRE command is applied.
- An SDP specified by **vprn>spoke-sdp** is always preferred over auto-bind tunnel, regardless of the tunnel table manager (TTM) preference.
- In Release 9.0, BGP-VPN next hops can no longer be improperly bound to a GRE tunnel resolved by IPv4 BGP; therefore, the BGP-VPN next hop will remain unresolved if GRE is the only **auto-bind-tunnel** option.

## 7.2.9 Spoke SDPs

For VPRN service, spoke SDPs can be used only for providing network connectivity between the PE routers.

## 7.2.10 Spoke SDP Termination to VPRN

This feature enables a customer to exchange traffic between a VLL or VPLS (Layer 2) service and an IES or VPRN (Layer 3) service. Customer premises traffic coming in from a VLL or VPLS service (SAP to spoke SDP) is forwarded over the IP/MPLS network to the IES or VPRN service, and vice versa. Network QoS policies can be applied to the spoke SDP to control traffic forwarding to the Layer 3 service.

In a Layer 3 spoke SDP termination to an IES or VPRN service, where the destination IP address resides within the IES or VPRN network, CE device-generated ARP frames must be processed by the Layer 3 interface. When an ARP frame is received over the spoke SDP at the Layer 3 interface endpoint, the 7705 SAR responds to the ARP frame with its own MAC address. When an ARP request is received from the routed network and the ARP entry for the CE device that is connected to the spoke SDP is not known, the 7705 SAR initiates an ARP frame to resolve the MAC address of the next hop or CE device.

Figure 124 shows traffic terminating on a specific IES or VPRN service that is identified by the SDP ID and VC label present in the service packet.

**Figure 124 SDP ID and VC Label Service Identifiers (Conceptual View of the Service)**

21510

Figure 125 shows a spoke SDP terminating directly into a VPRN. In this case, a spoke SDP could be tied to an Epipe or a hierarchical VPLS service. There is no configuration required on the PE connected to the CE.

**Figure 125 VPRN Spoke SDP Termination**

22726

---

Ethernet spoke SDP termination for VPRN service is supported over the following network uplinks:

- Ethernet network ports (null or dot1q encapsulation)
- PPP/MLPPP network ports. For information on PPP/MLPPP ports, refer to the 7705 SAR Interface Configuration Guide, “Access, Network, and Hybrid Ports”
- GPON module ports and DSL module ports when the module is installed in the 7705 SAR-M (variants with module slots)
- POS ports

Spoke SDP termination for VPRN supports the following:

- Ethernet PW to VRF
- interface shutdown based on PW standby signaling
- spoke SDP ingress IP filtering with filter logging
- label withdrawal for spoke SDPs terminated on VPRN
- statistics collection
- VCCV ping (type 2)

A spoke SDP on a VPRN interface service can be connected to the following entities:

- Epipe spoke SDP
- Epipe spoke SDP redundancy with standby-signal-master enabled
- IES interface
- VPRN interface
- VPLS spoke SDP
- VPLS spoke SDP redundancy with suppress-standby-signaling disabled

There are three scenarios to backhaul traffic from a given site that uses PWs and VPRN on a 7705 SAR.

- Scenario 1 ([Figure 126](#)): An individual PW is configured on a per-CE device or a per-service basis. For routing services, this PW can be terminated to a VPRN at the 7750 SR end. This scenario offers per-service OAM and redundancy capabilities. Also, because there is no local communication on the remote 7705 SAR, traffic between any two devices connected to the 7705 SAR must traverse through the 7750 SR at the MTSO/CO.

**Figure 126 Pseudowire-Based Backhaul (Spoke SDP Termination at 7750 SR)**

21512

- Scenario 2 (Figure 127): An MP-BGP-based solution can provide a fully routed scenario.

**Figure 127 VPRN in Mobile Backhaul Application**

21513

- Scenario 3 ([Figure 128](#)): In the hybrid scenario, IP forwarding among locally connected devices is handled by the 7750 SR directly, but instead of using MP-BGP to backhaul traffic, a PW is used to backhaul traffic to the MTSO/CO 7750 SR or possibly to a 7705 SAR node.

**Figure 128 Spoke-SDP Termination to VPRN**

21514

## 7.2.11 IPv6 on Virtual Private Edge Router

The IPv6 on Virtual Private Edge Router (6VPE) feature allows customers that are migrating from an IPv4 to an IPv6 environment to use their existing IPv4 core infrastructure for transporting IPv6 traffic. Customers can migrate their access network to IPv6, including the eNodeBs, and keep the IPv4 core. The IPv4 core can be used for transporting eNodeB IPv6 traffic over MPLS or GRE tunnels. See [IPv6 over IPv4 LAN-to-LAN IPsec Tunnels](#) for a description of how the 6VPE functionality is achieved.

**Note:** The 6VPE feature is not supported on the 16-port T1/E1 ASAP Adapter card or the 32-port T1/E1 ASAP Adapter card. This applies to both the access side (VPRN interfaces) and network side (MPLS/GRE tunnels).

On the network side, 6VPE is not supported on DS3/OC3 network interfaces, but is supported on SAR-A, SAR-M, SAR-H, and SAR-X T1/E1 ASAP network interfaces.

On the access side, 6VPE (VPRN SAP interfaces) is not supported on any T1/E1 ASAP adapter cards/blocks. VPRN spoke-SDP interfaces (spoke-SDP termination) are supported on SAR-A, SAR-M, SAR-H, and SAR-X T1/E1 ASAP blocks but not on T1/E1 adapter cards.

The classification of packets on a 6VPE access network is based on a customer packet Transaction Code (TC) field. The TC field is one byte long, but only the first six bits are used for the classification process. The use of six bits offers 64 different classes. The marking of the network outer tunnel DSCP/EXP bits is based on this access classification.

The supported protocols for 6VPE are listed in [Table 120](#). The Access Control Lists for 6VPE are provided by [Table 121](#), [Table 122](#), and [Table 123](#).

**Table 121 6VPE Access Control List, SAP**

| Service | IngV4 | IngV6 | IngMac | EgrV4 | EgrV6 | EgrMac |
|---------|-------|-------|--------|-------|-------|--------|
| Network | Yes   | Yes   | No     | Yes   | Yes   | No     |
| Epipe   | Yes   | No    | No     | No    | No    | No     |
| IES     | Yes   | Yes   | No     | Yes   | Yes   | No     |
| Ipipe   | Yes   | No    | No     | No    | No    | No     |
| VPLS    | Yes   | Yes   | Yes    | Yes   | Yes   | No     |
| VPRN    | Yes   | Yes   | No     | Yes   | Yes   | No     |

**Table 122 6VPE Access Control List, SDP**

| Service | IngV4 | IngV6 | IngMac | EgrV4 | EgrV6 | EgrMac |
|---------|-------|-------|--------|-------|-------|--------|
| Epipe   | No    | No    | No     | No    | No    | No     |

**Table 123 6VPE Access Control List, r-VPLS Override**

| Service | Ingress Override-v4 | Ingress Override-v6 |
|---------|---------------------|---------------------|
| IES     | Yes                 | Yes                 |
| VPRN    | Yes                 | Yes                 |

## 7.2.12 IPv6 over IPv4 LAN-to-LAN IPsec Tunnels

In order to support the 6VPE functionality described in [IPv6 on Virtual Private Edge Router](#), access (customer) IPv6 traffic is aggregated using a service VPRN and encrypted via an IPsec IPv4 static LAN-to-LAN tunnel, as shown in [Figure 129](#). BGPv4 or BGPv6 can be configured over the IPsec IPv4 static LAN-to-LAN tunnel with an IPv6 address family to advertise the IPv6 VPRN routes to the peer VPRN.

The management IP addresses of all customer switches are migrated to IPv6. The system IP address of the 7705 SAR is configured as an IPv6 address and also migrated to IPv6. The OAM customer traffic is aggregated via an r-VPLS (IPv6 r-VPLS) into a 6VPE OAM VPRN. An IPv6 static route carries the IPv6 OAM traffic to an IPv4 static LAN-to-LAN tunnel, where the traffic is encrypted and encapsulated in an IPsec IPv4 transport tunnel. The IPsec IPv4 transport tunnel uses a NAT-to-single public IP address method, that is, NAT-T.

**Figure 129 Access IPv6 Traffic Aggregation and Encryption**

---

## 7.2.13 Bandwidth Optimization for Low-speed Links

The 7705 SAR can be used in deployments where the uplink bandwidth capacity and requirements are considerably less than if the router is used for fixed or mobile backhaul applications. For example, the 7705 SAR can be used to direct traffic from multiple individual homes for applications such as smart meter aggregation or relay connectivity. Connecting to end systems such as smart meters or relays requires uplink bandwidth capacity in terms of hundreds of kilobits per second, rather than hundreds of megabits per second.

The 7705 SAR is optimized to operate in environments with megabits per second of uplink capacity for network operations. Therefore, many of the software timers are designed to ensure the fastest possible detection of failures, without considering bandwidth limitations. In deployments with very low bandwidth constraints, the system must also be optimized for effective operation of the routers without any interruption to mission-critical customer traffic. This can be achieved by:

- minimizing head-of-line (HoL) blocking by supporting a lower MTU
- redirecting self-generated traffic (SGT) to data queues (refer to the 7705 SAR Quality of Service Guide, “SGT Redirection”, for information)

One way to optimize operation in lower-bandwidth applications is to minimize HoL blocking caused by large packets. HoL blocking occurs when transmission of a large non-mission-critical packet delays a mission-critical packet beyond acceptable limits. The propagation delay of large packets over a slow link is fairly significant. For example, the propagation delay when transmitting a 1500-byte packet over a 100 kb/s link is 120 ms. If a mission-critical packet is queued immediately after the first bit of a non-mission-critical 1500-byte packet begins transmission, the mission-critical packet must wait 120 ms before the uplink is available again.

To minimize HoL blocking, the 7705 SAR now supports a lower MTU of 128 bytes (from the original 512-byte minimum) so that large IP packets can be fragmented into 128-byte chunks. In the preceding example, transmitting a 128-byte packet over a 100 kb/s link will only delay the next packet by 10.24 ms.

This lower MTU is supported on IES and VPRN interfaces (access interfaces) and on network interfaces. The IP MTU is derived from the port MTU, unless specifically configured with the **ip-mtu** command. This command is supported on access interfaces only.

---

The following must be considered when using a lower IP MTU:

- applicability – the lower IP MTU is only applicable for IP forwarded traffic and cannot be applied to pseudowire or VPLS traffic
- reassembly – the far-end/destination node must reassemble the packet before it can process the data, which may impact the performance of the end system and/or may require different hardware to perform the reassembly
- extra overhead – each fragment must have an IPv4 header so that all fragments of the packet can be forwarded to the destination. Care must be taken to ensure that the extra IP overhead for each fragment does not offset the gain achieved by using the lower MTU. As an example, for a 128-byte packet, the IPv4 header, which is 20 bytes in length, constitutes approximately 15% of the total packet size.

**Note:**

- Lower IP MTU applies to IPv4 applications only. As per RFC 2640, IPv6 interfaces or dual-stack interfaces should not be configured to a value lower than 1280 bytes.
- Lower IP MTU is supported only on Ethernet encapsulated ports.
- Most routing and signaling protocols, such as OSPF, IS-IS, and RSVP-TE, cannot be supported with port MTUs lower than 512 bytes due to the protocol layer requirements and restrictions.
- Special care must be taken with routing protocols that use TCP, such as BGP and LDP. The minimum TCP MSS value supported on the 7705 SAR is 384 bytes; therefore, these protocols should only be enabled on links that can transport 384-byte IP packets without fragmentation. If there is a mismatch in TCP MSS in the network, this mismatch can potentially cause severe network performance issues due to the overhead caused by fragmentation and retransmissions, it can cause multi-vendor interoperability issues, and it can potentially cause the protocols to continuously flap.
- Not all OAM diagnostics are supported with lower port MTUs. Detailed information is provided in [OAM Diagnostics Restrictions with Lower IP MTU](#).

### 7.2.13.1 OAM Diagnostics Restrictions with Lower IP MTU

OAM tests require a minimum network port MTU in order to run; this value depends on the test. If the port MTU is set to a value lower than the minimum requirement, the test will fail.

If the port MTU is set to a value that meets the minimum requirement, the packet size parameter can be configured for the test (for example, **oam sdp-ping 1 size 102**).

If the **size** parameter is not specified, the system builds the packet based on the default payload size. If the **size** parameter is configured and is greater than the default payload size, padding bytes are added to equal the configured value.

The packet size is dependent on the port MTU value; that is, if the minimum port MTU value is used, there are restrictions on the packet size. If the configured size is greater than the maximum value supported with the minimum port MTU, the test will fail.

[Table 124](#) and [Table 125](#) list the minimum port MTU required for each OAM test and the maximum size of the OAM packet that can be configured when the minimum port MTU is used, based on SDP tunnel type.

**Note:** RSVP LSPs will not come up if the network port MTU value is lower than 302 bytes.

**Table 124 Port MTU Requirements for OAM Diagnostics (GRE Tunnels)**

| SDP Type: GRE |                                                                                |                             |
|---------------|--------------------------------------------------------------------------------|-----------------------------|
| Test Type     | Minimum Network Port MTU Requirement over Ethernet Dot1q Encapsulation (Bytes) | OAM Test Size Range (Bytes) |
| sdp-ping      | 128                                                                            | 72 to 82                    |
| svc-ping      | 196                                                                            | N/A <sup>1</sup>            |
| vccv-ping     | 143                                                                            | 1 to 93                     |
| vccv-trace    | 143                                                                            | 1 to 93                     |
| vprn-ping     | 182                                                                            | 1 to 136                    |
| vprn-trace    | 302                                                                            | 1 to 256                    |
| mac-ping      | 188                                                                            | 1 to 142                    |

**Table 124 Port MTU Requirements for OAM Diagnostics (GRE Tunnels)**

| SDP Type: GRE |                                                                                |                             |

**Note:**

1. Size is not configurable

**Table 125 Port MTU Requirements for OAM Diagnostics (LDP Tunnels)**

| SDP Type: LDP |                                                                                |                             |
|---------------|--------------------------------------------------------------------------------|-----------------------------|
| Test Type     | Minimum Network Port MTU Requirement over Ethernet Dot1q Encapsulation (Bytes) | OAM Test Size Range (Bytes) |
| lsp-ping      | 128                                                                            | 1 to 106                    |
| lsp-trace     | 128                                                                            | 1 to 104                    |
| sdp-ping      | 128                                                                            | 72 to 102                   |
| svc-ping      | 176                                                                            | N/A <sup>1</sup>            |
| vccv-ping     | 128                                                                            | 1 to 98                     |
| vccv-trace    | 128                                                                            | 1 to 98                     |
| vprn-ping     | 182                                                                            | 1 to 156                    |
| vprn-trace    | 302                                                                            | 1 to 276                    |
| mac-ping      | 168                                                                            | 1 to 142                    |
| mac-trace     | 220                                                                            | 1 to 194                    |
| cpe-ping      | 166                                                                            | N/A <sup>1</sup>            |

**Note:**

1. Size is not configurable

For information on OAM diagnostics, refer to the 7705 SAR OAM and Diagnostics Guide.

---

## 7.3 Configuring a VPRN Service with CLI

This section provides information to configure Virtual Private Routed Network (VPRN) services using the command line interface.

Topics in this section include:

- [Basic Configuration](#)
- [Common Configuration Tasks](#)
- [Configuring VPRN Components](#)
- [Service Management Tasks](#)

---

## 7.4 Basic Configuration

The following fields require specific input (there are no defaults) to configure a basic VPRN service:

- customer ID (refer to [Configuring Customer Accounts](#))
- interface parameters
- spoke SDP parameters (at VPRN service level)

The following example displays a VPRN service configuration.

```
*A:ALU-1>config>service>vprn# info

vrf-import "vrfImpPolCust1"
vrf-export "vrfExpPolCust1"
autonomous-system 10000
route-distinguisher 10001:1
auto-bind-tunnel
 resolution-filter
 ldp
 exit
 resolution filter
exit
vrf-target target:10001:1
interface "to-cel" create
 address 172.16.0.0/12
 exit
 sap 1/1/10:1 create
 ingress
 qos 100
 filter ip 10
 exit
 egress
 qos 1010
 exit
 exit
 dhcp
 description "DHCP test"
 exit
exit
exit
static-route-entry 10.1.1.1/8
 next-hop 10.1.1.2
 no shutdown
 exit
exit

*A:ALU-1>config>service>vprn#
```

---

## 7.5 Common Configuration Tasks

This section provides a brief overview of the tasks that must be performed to configure a VPRN service and provides the CLI commands.

1. Enabling BGP in the global routing context is needed in some configurations; for example, MVPN in PIM-SM.

To configure BGP for the router, refer to the 7705 SAR Routing Protocols Guide, “BGP”

2. Associate a VPRN service with a customer ID.
3. Define a route distinguisher (RD) (mandatory).
4. Set the **auto-bind-tunnel** parameter. Alternatively, define a VPRN spoke SDP. When using the **vprn>spoke-sdp** command, you must enter the command for each peer PE router.
5. Define VRF route-target associations or VRF import/export policies.
6. Define PIM parameters (optional).
7. Define OSPF parameters (optional).
8. Create a VPRN interface.
9. Define SAP parameters on the VPRN interface:
  - select nodes and ports
  - optional—select QoS policies other than the default (configured in the **config>qos** context)
  - optional—select filter policies (configured in the **config>filter** context)
  - optional—select accounting policy (configured in the **config>log** context)
  - optional—configure DHCP features
10. Define BGP parameters for the VPRN (**config>service>vprn>bgp**) (optional).
11. Define RIP parameters (optional).
12. Define spoke SDP parameters on the VPRN interface.
13. Configure VRRP (optional).
14. Enable the service.

---

## 7.6 Configuring VPRN Components

Topics in this section include:

- [Creating a VPRN Service](#)
- [Configuring Global VPRN Parameters](#)
- [Configuring Router Interfaces](#)
- [Configuring Static Route Entries for VPRN](#)
- [Configuring BGP for VPRN](#)
- [Configuring IPv6 Parameters for VPRN BGP](#)
- [Configuring VPRN IPv6 Neighbor Discovery Parameters](#)
- [Configuring OSPF or OSPFv3 for VPRN](#)
- [Configuring RIP for VPRN](#)
- [Configuring IGMP for VPRN](#)
- [Configuring PIM for VPRN](#)
- [Configuring MVPN for VPRN](#)
- [Configuring a VPRN Interface](#)
- [Configuring a VPRN IPv6 Interface](#)
- [Configuring VPRN Interface Routed VPLS IPv6 Parameters](#)
- [Configuring VPRN Interface SAP Parameters](#)
- [Configuring VPRN Interface SAP IPv6 Parameters](#)
- [Configuring VPRN Interface Spoke SDP Parameters](#)
- [Configuring VPRN Interface Spoke SDP IPv6 Parameters](#)
- [Configuring VRRP](#)
- [Configuring a Security Zone Within a VPRN](#)
- [Configuring Serial Raw Socket Transport Within VPRN](#)
- [Configuring VPRN Router Advertisement](#)

## 7.6.1 Creating a VPRN Service

Use the following CLI syntax to create a VPRN service. A route distinguisher must be defined in order for VPRN to be operationally active.

**CLI Syntax:**

```
config>service# vprn service-id [customer customer-id]
 route-distinguisher rd
 description description-string
 no shutdown
```

The following example displays a VPRN service configuration.

```
*A:ALU-1>config>service# info

...
 vprn 1 customer 1 create
 route-distinguisher 10001:0
 no shutdown
 exit
...

*A:ALU-1>config>service>vprn#
```

## 7.6.2 Configuring Global VPRN Parameters

The autonomous system (AS) number for a VPRN service is configured in the **config>service>vprn** context. Local AS numbers can be set at the VPRN BGP global, group, and neighbor levels.

A spoke SDP can be bound to the VPRN service using the **auto-bind-tunnel** command or the **spoke-sdp sdp-id** command. However, when using the **spoke-sdp** command, you must create a spoke SDP for each peer PE router.

A VPRN spoke SDP can be any of the supported SDPs, except the IP SDP.

The following example displays a VPRN service with configured parameters.

```
*A:ALU-1>config>service# info

...
 vprn 1 customer 1 create
 vrf-import "vrfImpPolCust1"
 vrf-export "vrfExpPolCust1"
 autonomous-system 10000
 router-id 2000
 route-distinguisher 10001:0
 spoke-sdp 2 create
 exit
```

```

 no shutdown
 exit
...

*A:ALU-1>config>service#

```

### 7.6.3 Configuring Router Interfaces

Refer to the 7705 SAR Router Configuration Guide for command descriptions and syntax information to configure router interfaces.

The following example displays a router interface configuration:

```

ALU48>config>router# info
#-----
echo "IP Configuration"
#-----
...
 interface "if1"
 address 10.0.0.0/8
 port 1/1/33
 exit
 interface "if2"
 address 10.0.0.1/8
 port 1/1/34
 exit
 interface "if3"
 address 10.0.0.2/8
 port 1/1/35
 exit
...
#-----
ALU48>config>router#

```

### 7.6.4 Configuring Static Route Entries for VPRN

The 7705 SAR VPRN service supports static routes to next-hop addresses.

Only one next-hop IP address can be specified per IP interface for static routes.

Use the following CLI syntax to create a VPRN static route entry. Multiple types of static routes (**black-hole**, **grt**, **indirect**, **ipsec-tunnel**, and **next-hop**) can be applied to the same entry. Unless **no shutdown** is specified, the **static-route-entry** will be created in a **shutdown** state.

**CLI Syntax:**    `config>service>vprn>`  
                   `static-route-entry {ip-prefix/prefix-length}`

```

black-hole {ip-int-name | ip-address | ipv6-
address}
 description description-string
 metric metric
 preference preference
 prefix-list prefix-list-name [all | none]
 no shutdown
 tag tag
grt
 description description-string
 metric metric
 preference preference
 no shutdown
indirect ip-address
 cpe-check cpe-ip-address
 drop-count count
 interval seconds
 log
 description description-string
 metric metric
 preference preference
 prefix-list prefix-list-name {all | none}
 no shutdown
 tag tag
ipsec-tunnel [ipsec-tunnel-name]
 description description-string
 metric metric
 preference preference
 no shutdown
 tag tag
next-hop {ip-int-name | ip-address | ipv6-
address}
 bfd-enable
 cpe-check cpe-ip-address
 drop-count count
 interval interval
 log
 description description-string
 metric metric
 preference preference
 prefix-list prefix-list-name [all | none]
 no shutdown
 tag tag

```

**Example:**

```

config>service>vprn# static-route-entry 10.5.5.5/8
static-route-entry# next-hop 10.1.1.2
next-hop# metric 1
next-hop# preference 5
next-hop# tag 20

```

---

```
next-hop# no shutdown
```

## 7.6.5 Configuring BGP for VPRN

Configuring BGP between the PE routers allows the PE routers to exchange information about routes originating and terminating in the VPRN. The PE routers use the information to determine which labels are used for traffic intended for remote sites.

The minimal parameters that should be configured for a VPRN BGP instance are:

- an autonomous system number

For an example of a VPRN service with a configured autonomous system number, refer to [Configuring Global VPRN Parameters](#).

- a router ID

For an example of a VPRN service with a configured router ID, refer to [Configuring Global VPRN Parameters](#).

- a VPRN BGP peer group
- a VPRN BGP neighbor with which to peer
- a VPRN BGP peer-AS that is associated with the above peer

VPRN BGP is administratively enabled upon creation. Minimally, to enable VPRN BGP in a VPRN instance, you must associate an autonomous system number and router ID for the VPRN service, create a peer group, neighbor, and associate a peer AS number. There are no default VPRN BGP groups or neighbors. Each VPRN BGP group and neighbor must be explicitly configured.

All parameters configured for VPRN BGP are applied to the group and are inherited by each peer, but a group parameter can be overridden on a specific basis. The VPRN BGP command hierarchy consists of three levels:

- global level
- group level
- neighbor level

Use the following CLI syntax to configure these three levels:

**CLI Syntax:**

```
config>service>vprn>bgp#
 group
 neighbor
```

**Note:** The **local-address** command must be explicitly configured if two systems have multiple BGP peer sessions between them.

BGP for MP-BGP purposes is configured under the **config>router>bgp** context. For more information about the BGP protocol, refer to the 7705 SAR Routing Protocols Guide, “BGP”.

### 7.6.5.1 Configuring VPRN BGP Group and Neighbor Parameters

A group is a collection of related VPRN BGP peers. The group name should be a descriptive name for the group. Follow your group, name, and ID naming conventions for consistency and to help when troubleshooting faults.

After a group name is created and options are configured, neighbors can be added in different autonomous systems, creating EBGP peers. All parameters configured for the peer group are inherited by each peer (neighbor), but a group parameter can be overridden on a specific neighbor-level basis.

### 7.6.5.2 Configuring Route Reflection

Route reflection can be implemented in autonomous systems with a large internal BGP mesh to reduce the number of IBGP sessions required. One or more routers can be selected to act as focal points for internal BGP sessions. Several BGP-speaking routers can peer with a route reflector. A route reflector forms peer connections to other route reflectors. A router assumes the role as a route reflector by configuring the **cluster** *cluster-id* command. No other command is required unless disabling reflection to specific peers is desired.

If you configure the **cluster** command at the global level, then all subordinate groups and neighbors are members of the cluster. The route reflector cluster ID is expressed in dotted decimal notation. The ID should be a significant topology-specific value. No other command is required unless disabling reflection to specific peers is desired.

If a route reflector client is fully meshed, the **disable-client-reflect** command can be enabled to stop the route reflector from reflecting redundant route updates to a client.

### 7.6.5.3 VPRN BGP CLI Syntax

The following example displays a VPRN BGP configuration. The example includes two BGP groups: one group has a static (configured) neighbor and the other group has dynamic neighbors.

```
*A:ALU-1>config>service# info

...
vprn 1 customer 1 create
 vrf-import "vrfImpPolCust1"
 vrf-export "vrfExpPolCust1"
 autonomous-system 10000
 route-distinguisher 10001:1
 auto-bind-tunnel
 resolution-filter
 ldp
 exit
 resolution filter
 exit
vrf-target target:10001:1
interface "to-cel" create
 address 172.16.0.0/12
 sap 1/1/10:1 create
 ingress
 qos 100
 filter ip 6
 exit
 egress
 qos 1010
 exit
 exit
exit
static-route-entry 10.1.1.1/8
 next-hop 10.1.1.2
 no shutdown
 exit
exit
bgp
 router-id 10.0.0.1
 group "to-cel"
 export "vprnBgpExpPolCust1"
 multihop 3
 peer-as 65101
 ttl-security 10
 neighbor 172.16.0.10
 exit
 group "dynamic"
 peer-as 100
 dynamic-neighbor
 prefix 10.100.0.0/16
 dynamic-neighbor-limit 75
 exit
 exit
exit
spoke-sdp 2 create
exit
```

```

 no shutdown
 exit
 ...

*A:ALU-1>config>service#

```

## 7.6.6 Configuring IPv6 Parameters for VPRN BGP

Use the following CLI syntax to configure IPv6 parameters for VPRN BGP:

**CLI Syntax:**

```

config>service# vprn service-id [customer customer-id]
 bgp
 family ipv6
 group name
 family ipv6
 neighbor ipv6-address
 family ipv6

```

**Example:**

```

A:ALU>config>service# vprn 20
A:ALU>config>service>vprn$ bgp
A:ALU>config>service>vprn>bgp$ family ipv6
A:ALU>config>service>vprn>bgp>family$ group BGP1
A:ALU>config>service>vprn>bgp>family>group$ family ipv6
A:ALU>config>service>vprn>bgp>family>group>family$
 neighbor 2001:db8:a::123
A:ALU>config>service>vprn>bgp>family>group>family>
 neighbor$ family ipv6
A:ALU>config>service>vprn>bgp>family>group>family>
 neighbor$ exit
A:ALU>config>service>vprn>bgp>family>group>family$ exit
A:ALU>config>service>vprn>bgp>family>group$ exit
A:ALU>config>service>vprn>bgp>family$ exit
A:ALU>config>service>vprn>bgp$ exit

```

## 7.6.7 Configuring VPRN IPv6 Neighbor Discovery Parameters

Use the following CLI syntax to configure IPv6 neighbor discovery parameters for a VPRN service:

**CLI Syntax:**

```

config# config>service# vprn service-id [customer
 customer-id]
 ipv6

```

```
reachable-time seconds
stale-time seconds
```

**Example:**

```
config# service vprn 20
config>service>vprn# ipv6
config>service>vprn>ipv6# reachable-time 30
config>service>vprn>ipv6# stale-time 14400
config>service>vprn>ipv6# exit
config>service>vprn# exit
```

The following example displays IPv6 neighbor discovery parameters output.

```
A:ALU-A>config>service>vprn 20# info
#-----
...
 reachable-time 30
 stale-time 14400
exit
...
```

## 7.6.8 Configuring OSPF or OSPFv3 for VPRN

Each VPN routing instance is isolated from any other VPN routing instance and from the routing used across the backbone. OSPF or OSPFv3 can be run with any VPRN, independently of the routing protocols used in other VPRNs, or in the backbone. For more information on the OSPF and OSPFv3 protocols and for the commands used to run OSPF or OSPFv3 over the backbone (router context), refer to the 7705 SAR Routing Protocols Guide.

Use the following CLI syntax to configure OSPF or OSPFv3 in the VPRN context:

**CLI Syntax:**    config>service>vprn>ospf#

**CLI Syntax:**    config>service>vprn>ospf3#

The following example displays a VPRN OSPF configuration:

```
*A:ALU-1>config>service# info

vprn 2 customer 1 create
 interface "ospf_interface" create
 exit
 ospf
 area 0.0.0.0
 interface "ospf_interface"
 no shutdown
 exit
 exit
```

```
exit

*A:ALU-1>config>service#
```

## 7.6.9 Configuring RIP for VPRN

PE routers need to advertise reachability information for each CE that is attached to a VRF. RIP can be used to exchange reachability information between PE and CE routers by establishing adjacency with a CPE router that supports RIP. Via this adjacency, RIP learns the subnet or subnets for the customer site and will advertise any routes learned from other CEs. The routing table is updated to reflect the new information.

RIP can be used to distribute routes between PE and CE routers. When PE and CE routers are RIP peers, the CE router can use RIP to transmit to the PE router the set of address prefixes that are reachable via the CE router. When RIP is configured on the CE, care must be taken to ensure that address prefixes from other sites, that is, address prefixes learned by the CE router from the PE router, are never advertised to the PE. Specifically, if a PE router receives a VPN-IPv4 route and distributes it to a CE, that route must never be distributed from the CE site to, either the originating PE router, or any other PE router.

The parameters configured at the VPRN RIP global level are inherited by the group and neighbor levels. Parameters can be modified and overridden on a level-specific basis. The VPRN RIP command hierarchy consists of three levels:

- global
- group
- neighbor

Hierarchical VPRN RIP commands can be modified on different levels. The most specific value is used. A group-specific command takes precedence over a global command. A neighbor-specific command takes precedence over a global or group-specific command.

**Note:** Careful planning is essential to implement commands that can affect the behavior of global, group, and neighbor levels. Because the RIP commands are hierarchical, analyze the values that can disable features on a particular level.

To enable a VPRN RIP instance, the RIP protocol must be enabled in the **config>service>vprn>rip** context of the VPRN. VPRN RIP is administratively enabled upon creation. Configuring other RIP commands and parameters is optional.

The minimum RIP configuration for a VPRN instance must define:

- one VPRN RIP peer group
- one VPRN RIP neighbor peer
- one VPRN RIP peer-AS associated with the neighbor peer

The following example displays a VPRN RIP configuration:

```
*A:ALU-1>config>service# info

...
 vprn 1 customer 1 create
 vrf-import "vrfImpPolCust1"
 vrf-export "vrfExpPolCust1"
 ecmp 8
 autonomous-system 10000
 route-distinguisher 10001:1
 auto-bind-tunnel
 resolution-filter
 ldp
 exit
 resolution filter
 exit
 vrf-target target:10001:1
 interface "to-cel" create
 address 172.16.0.0/12
 sap 1/1/10:1 create
 ingress
 qos 100
 exit
 egress
 qos 1010
 filter ip 6
 exit
 exit
 rip
 export "vprnRipExpPolCust1"
 group "cel"
 neighbor "to-cel"
 exit
 exit
 spoke-sdp 2 create
 exit
 no shutdown
 exit
...

```

For more information about the RIP protocol, refer to the 7705 SAR Routing Protocols Guide.

## 7.6.10 Configuring IGMP for VPRN

When using the **ssm-translate** command, the group range is not created until the source is specified.

The following example displays multicast IGMP parameters under a VPRN configuration:

```
*A:Sar18 Dut-B>config>service>vprn>igmp# info detail

 interface "mvpn_if"
 no import
 version 3
 subnet-check
 no max-groups
 no max-grp-sources
 no disable-router-alert-check
 ssm-translate

 exit
 no non-dr-attract-traffic
 no ssm-default-range-disable ipv4
 no shutdown
 no ipv4-multicast-disable

A:ALU-1>config>service>vprn>pim#

```

## 7.6.12 Configuring MVPN for VPRN

For selective PMSI provider tunnels, mLDP must be configured prior to setting a **maximum-p2mp-spmsi**. Also, the **data-threshold** *c-grp-ip-addr* must be a valid multicast address.

The following example displays the MVPN parameters for VPRN configuration:

```

*A:ALU>config>service>vprn>mvpn# info detail

 auto-discovery default
 c-mcast-signaling bgp
 umh-selection highest-ip
 mdt-type sender-receiver
 provider-tunnel
 inclusive
 mldp
 shutdown
 exit
 exit
 selective
 mldp
 shutdown

```

```

 exit
 maximum-p2mp-spmsi 4
 no data-delay-interval
 data-threshold 239.255.0.0/6 10
 exit
exit
vrf-target unicast
exit

*A:ALU>config>service>vprn>mvpn#

```

The following example displays a VPRN service with MVPN. The MVPN in this example supports inclusive PMSI and selective PMSI. The **data-threshold** that forces a group C(S,G) to switch from I-PMSI to S-PMSI in this example is 1 kb/s.

```

vprn 1 customer 1 create

 no shutdown

```

```

 exit
 exit
exit
no shutdown
exit

```

## 7.6.13 Configuring a VPRN Interface

Interface names associate an IP address with the interface, and then associate the IP interface with a physical port. The logical interface can associate attributes such as an IP address, port, or Link Aggregation Group (LAG). There are no default interfaces.

### Note:

- The VPRN interface can be configured as a loopback interface by issuing the **loopback** command instead of the **sap** command. The loopback flag cannot be set on an interface where a SAP is already defined, and a SAP cannot be defined on a loopback interface.
- See [Configuring a VPRN IPv6 Interface](#) for the CLI required to configure VPRN IPv6 interface parameters.

When using **mrinfo** and **mtrace** in a Layer 3 VPN context, the configuration for the VPRN should have a loopback address configured that has the same address as the core VPRN instance's system address (that is, the BGP next hop).

See [VPRN Services Command Reference](#) for CLI commands and syntax.

The following example displays a VPRN interface configuration:

```

*A:ALU-1>config>service>vprn# info

...
vprn 1 customer 1 create
 vrf-import "vrfImpPolCust1"
 vrf-export "vrfExpPolCust1"
 autonomous-system 10000
 route-distinguisher 10001:1
 auto-bind-tunnel
 resolution-filter
 ldp
 exit
 resolution filter
 exit
vrf-target target:10001:1
interface "to-cel" create
 address 172.16.0.1/12
 proxy-arp policy "proxyARPolicy"

```

```

 local proxy-arp
 remote proxy-arp
 exit
exit
static-route-entry 10.1.1.1/8
 next-hop 10.1.1.2
 no shutdown
 exit
exit
spoke-sdp 2 create
exit
no shutdown
exit
...

*A:ALU-1>config>service#

```

Use the following CLI syntax to configure interface parameters for the VPRN service.

**CLI Syntax:** `config>service# vprn service-id [customer customer-id]`  
`[create]`  
`interface ip-int-name`  
`address if-ip-address`  
`allow-directed-broadcasts`  
`arp-timeout`  
`bfd transmit-interval [receive receive-`  
`interval] [multiplier multiplier] [type np]`  
`description description-string`  
`dhcp`  
`description description-string`  
`option`  
`action {replace | drop | keep}`  
`circuit-id [ascii-tuple | ifindex |`  
`sap-id | vlan-ascii-tuple]`  
`remote-id [mac | string string]`  
`vendor-specific-option`  
`client-mac-address`  
`sap-id`  
`service-id`  
`string text`  
`system-id`  
`server server1 [server2... (up to 8 max)]`  
`no shutdown`  
`trusted`  
`icmp`  
`mask-reply`  
`ttl-expired [number seconds]`  
`unreachables`  
`if-attribute`  
`admin-group group-name [group-name... (up`  
`to 5 max)]`

```

 srlg-group group-name [group-name...(up
 to 5 max)]
 ip-mtu octets
 ipcp
 dns ip-address [secondary ip-address]
 dns secondary ip-address
 peer-ip-address ip-address
 14-load-balancing hashing-algorithm
 local-dhcp-service local-server-name
 local-proxy-arp
 loopback
 mac ieee-address
 proxy-arp-policy policy-name [policy-
 name...(up to 5 max)]
 remote-proxy-arp
 secondary {ip-address/mask | ip-address
 netmask} [broadcast all-ones | host-ones]
 [igp-inhibit]
 no shutdown
 static-arp ip-address ieee-mac-address
 static-arp ieee-mac-address unnumbered
 tcp-mss mss-value
 teid-load-balancing
 unnumbered {ip-int-name | ip-address}
no shutdown

```

**Example:**

```

A:ALU-41>config>service# vprn 4
A:ALU-41>config>service>vprn$ interface "vprn_interface"
A:ALU-41>config>service>vprn>if$ address 192.168.0.0/16
A:ALU-41>config>service>vprn>if$ dhcp option
A:ALU-41>config>service>vprn>if>dhcp>option$ circuit-id
 ifindex
A:ALU-41>config>service>vprn>if>dhcp>option$ exit
A:ALU-41>config>service>vprn>if$ ip-mtu 1524

```

The following example displays the VPRN interface creation output.

```

A:ALU-41>config>service>vprn>if# info detail

...
 no description
 address 192.168.0.0/16 broadcast host-ones

remote proxy-arp
no shutdown...

```

## 7.6.14 Configuring a VPRN IPv6 Interface

Use the following CLI syntax to create a VPRN IPv6 interface and to configure optional VPRN IPv6 interface parameters:

**CLI Syntax:**

```

config>service
 vprn service-id
 interface ip-int-name
 ipv6
 address ipv6-address/prefix-length
 [eui-64] [preferred]
 bfd transmit-interval [receive
 receive-interval] [multiplier
 multiplier]
 dhcp6-relay
 description description-string
 option
 interface-id
 interface-id ascii-
 tuple
 interface-id ifindex
 interface-id sap-id
 interface-id string
 remote-id
 server ipv6-address...(upto 8
 max)
 shutdown
 source-address ipv6-address

```

```

dhcp6-server
 max-nbr-of-leases max-nbr-of-leases
 prefix-delegation
 prefix ipv6-address/
 prefix-length
 duid duid [iaid iaid]
 preferred-lifetime
 seconds
 preferred-lifetime
 infinite
 valid-lifetime seconds
 valid-lifetime
 infinite
 no shutdown
icmp6
 packet-too-big number seconds
 param-problem number seconds
 time-exceeded number seconds
 unreachableables number seconds
link-local-address ipv6-address
 [preferred]
local-dhcp-server server-name
 [create]
neighbor ipv6-address mac-address
reachable-time seconds
stale-time seconds

```

(The example below shows only some of the CLI VPRN IPv6 interface commands).

**Example:**

```

config>service# vprn 20
config>service>vprn# interface "int1"
config>service>vprn>if>ipv6#
config>service>vprn>if>ipv6>address# 2001:db8:a::123
config>service>vprn>if>ipv6>icmp6# packet-too-big 100 10
config>service>vprn>if>ipv6>icmp6# param-problem 100 10
config>service>vprn>if>ipv6>icmp6# time-exceeded 100 10
config>service>vprn>if>ipv6>icmp6# unreachableables 100 10
config>service>vprn>if>ipv6>icmp6# exit
config>service>vprn>if>ipv6>neighbor# 2001:db8:a::124
config>service>vprn>if>ipv6>reachable-time# 30
config>service>vprn>if>ipv6>stale-time# 14400
config>service>vprn>if>ipv6># exit
config>service>vprn>if># exit

```

The following example displays a VPRN IPv6 interface configuration:

```
A:ALU-B>config>service>vprn 20# info detail

.....
 ipv6
 icmp6
 packet-too-big 100 10
 param-problem 100 10
 time-exceeded 100 10
 unreachablees 100 10
 exit
 address 2001:db8:a::123
 reachable-time 30
 stale-time 14400
 no dhcp6-relay
 no local-dhcp-server
 neighbor 2001:db8:a::124
 no bfd
 exit
.....
```

## 7.6.15 Configuring VPRN Interface Routed VPLS IPv6 Parameters

Use the following CLI syntax to configure VPRN interface routed VPLS IPv6 parameters:

**CLI Syntax:**

```
config>service# vprn service-id [customer customer-id]
[create]
 interface ip-int-name
 vpls service-name create
 ingress
 v6-routed-override-filter ipv6-
 filter-id
 [no] shutdown
```

**Example:**

```
A:ALU-41>config>service# vprn 20
A:ALU-41>config>service>vprn$ interface
 "vprn20_interface"
A:ALU-41>config>service>vprn>if$ vpls 2/2/2:1 create
A:ALU-41>config>service>vprn>if>vpls$ ingress
A:ALU-41>config>service>vprn>if>vpls>ingress$ v6-
 routed-override-filter 44
A:ALU-41>config>service>vprn>if>vpls>ingress$ exit
A:ALU-41>config>service>vprn>if>vpls$ exit
A:ALU-41>config>service>vprn>if$ exit
```

---

## 7.6.16 Configuring VPRN Interface SAP Parameters

A SAP is a combination of a port and encapsulation parameters that identify the service access point on the interface and within the 7705 SAR. Each SAP must be unique within a router. A SAP cannot be defined if the **loopback** command is enabled on the interface.

When configuring VPRN interface SAP parameters, a default QoS policy is applied to each ingress and egress SAP. Additional QoS policies must be configured in the **config>qos** context. Filter policies are configured in the **config>filter** context and must be explicitly applied to a SAP. There are no default filter policies.

A VPRN interface SAP is supported on the following ports and adapter cards:

- port in access mode with PPP or MLPPP encapsulation (by setting the port's channel-group **encap-type** to be **ipcp**):
  - any T1/E1 ASAP port or bundle on a 16-port T1/E1 ASAP Adapter card or on a 32-port T1/E1 ASAP Adapter card on a 7705 SAR-8 or 7705 SAR-18:
    - fractional T1/E1
    - clear channel T1/E1
  - any T1/E1 ASAP port or bundle on a 7705 SAR-X, or on a 7705 SAR-M or 7705 SAR-A (variants with T1/E1 ports):
    - fractional T1/E1
    - clear channel T1/E1
- port in access mode:
  - any Ethernet port (null, dot1q, or qinq) on:
    - an 8-port Ethernet Adapter card, version 1 or version 2, or an 8-port Gigabit Ethernet Adapter card on a 7705 SAR-8
    - a 6-port Ethernet 10Gbps Adapter card on a 7705 SAR-8 Shelf V2 with CSMv2
    - a 6-port Ethernet 10Gbps Adapter card, 8-port Ethernet Adapter card, version 2, or an 8-port Gigabit Ethernet Adapter card, or a 10-port 1GigE/1-port 10GigE X-Adapter card on a 7705 SAR-18
  - any Ethernet port (null, dot1q, or qinq) on a 7705 SAR-M (all variants), 7705 SAR-H, 7705 SAR-Hc, 7705 SAR-A (both variants), 7705 SAR-Ax, 7705 SAR-W, 7705 SAR-Wx (all variants), or 7705 SAR-X
  - DSL module ports (null, dot1q, or qinq) on a 7705 SAR-Wx
  - GPON module ports and DSL module ports (null or dot1q) when the module is installed in a 7705 SAR-M (variants with module slots)

**Note:** The 10-port 1GigE/1-port 10GigE X-Adapter card supports qinq only when it is in 10-port 1GigE mode.

See [VPRN Services Command Reference](#) for CLI commands and syntax.

The following examples show the configuration of a VPRN interface SAP for:

- an access port on a 16-port T1/E1 ASAP Adapter card
- an MLPPP bundle on an access port on a 16-port T1/E1 ASAP Adapter card

```
*A:ALU-1>config>service# info

```

## 7.6.17 Configuring VPRN Interface SAP IPv6 Parameters

Use the following CLI syntax to configure VPRN interface SAP IPv6 parameters:

**CLI Syntax:**

```
config>service# vprn service-id [customer customer-id]
[create]
 interface ip-int-name
 sap sap-id create
 ingress
 filter ipv6 ipv6-filter-id
 [no] shutdown
```

**Example:**

```
A:ALU-41>config>service# vprn 20
A:ALU-41>config>service>vprn$ interface
 "vprn20_interface"
A:ALU-41>config>service>vprn>if$ sap 1/1/10:1 create
A:ALU-41>config>service>vprn>if>sap$ ingress
A:ALU-41>config>service>vprn>if>sap>ingress$ filter ipv6
 78
A:ALU-41>config>service>vprn>if>sap>ingress$ exit
A:ALU-41>config>service>vprn>if>sap$ exit
```

## 7.6.18 Configuring VPRN Interface Spoke SDP Parameters

Use the following CLI syntax to configure VPRN interface spoke SDP parameters:

**CLI Syntax:**

```
config>service# vprn service-id [customer customer-id]
[create]
 interface ip-int-name
 spoke-sdp sdp-id:vc-id [create]
 egress
 vc-label egress-vc-label
 ingress
 filter ip ip-filter-id
 vc-label ingress-vc-label
 [no] shutdown
```

**Example:**

```
A:ALU-41>config>service# vprn 6
A:ALU-41>config>service>vprn$ interface
 "vprn6_interface"
A:ALU-41>config>service>vprn>if$ spoke-sdp 7:8 create
A:ALU-41>config>service>vprn>if>spoke-sdp$ ingress
A:ALU-41>config>service>vprn>if>spoke-sdp>ingress$
 filter ip 78
```

```
A:ALU-41>config>service>vprn>if>spoke-sdp>ingress$ vc-
label 7788
```

The following example displays the VPRN interface spoke SDP creation output.

```
A:ALU-41>config>service>vprn>if>spoke SDP# info detail

...
 no description
 egress
 no vc-label
 ingress
 filter ip 78
 vc-label 7788
 exit
 no shutdown
```

## 7.6.19 Configuring VPRN Interface Spoke SDP IPv6 Parameters

Use the following CLI syntax to configure VPRN interface spoke SDP IPv6 parameters:

**CLI Syntax:**

```
config>service# vprn service-id [customer customer-id]
[create]
 interface ip-int-name
 spoke-sdp sdp-id:vc-id [create]
 egress
 filter ipv6 ipv6-filter-id
 ingress
 filter ipv6 ipv6-filter-id
 [no] shutdown
```

**Example:**

```
A:ALU-41>config>service# vprn 10
A:ALU-41>config>service>vprn$ interface
"vprn10_interface"
A:ALU-41>config>service>vprn>if$ spoke-sdp 8:9 create
A:ALU-41>config>service>vprn>if>spoke-sdp$ egress
A:ALU-41>config>service>vprn>if>spoke-sdp>egress$
 filter ipv6 88
A:ALU-41>config>service>vprn>if>spoke-sdp>egress$ exit
A:ALU-41>config>service>vprn>if>spoke-sdp$ ingress
A:ALU-41>config>service>vprn>if>spoke-sdp>ingress$
 filter ipv6 89
A:ALU-41>config>service>vprn>if>spoke-sdp>ingress$ exit
A:ALU-41>config>service>vprn>if>spoke-sdp$ exit
```

## 7.6.20 Configuring VRRP

Configuring VRRP policies and instances on service interfaces is optional. The basic owner and non-owner VRRP configurations on a VPRN interface must specify the backup **ip-address** parameter.

VRRP helps eliminate the single point of failure in a routed environment by using virtual router IP addresses shared between two or more routers connecting the common domain. VRRP provides dynamic failover of the forwarding responsibility to the backup router if the master becomes unavailable.

The VRRP implementation allows one master per IP subnet. All other VRRP instances in the same domain must be in backup mode.

For overview information on VRRP and VRRP VPRN interface parameters, refer to the “VRRP” chapter in the 7705 SAR Router Configuration Guide.

The following displays a VPRN interface VRRP owner configuration:

```
config>service>vprn> info
#-----
...
 interface "vrrpowner"
 address 10.10.10.24
 vrrp 1 owner
 backup 10.10.10.23
 authentication-key "testabc"
 exit
 exit
...
#-----
config>service>vprn#

config>service>vprn>if># info

...
 ipv6
 address 2001:db8:a::123
 vrrp 1 owner
 backup 2001:db8:a::124
 exit
 exit
 exit
...

```

## 7.6.21 Configuring a Security Zone Within a VPRN

To configure NAT or firewall security functionality, you must:

- configure a NAT or firewall security profile and policy in the **config>security** context
  - in the **config>security>profile** context, specify the timeouts for the TCP/UDP/ICMP protocols and configure logging and application assurance parameters. This step is optional. If you do not configure the profile, a default profile is assigned.
  - in the **config>security>policy** context, configure a security policy, specify the match criteria and the action to be applied to a packet if a match is found.
- configure a security zone and apply the policy ID to the zone, as shown in the following CLI syntax

**CLI Syntax:**

```

config>service
 vprn service-id [customer customer-id] [create]
 abort
 begin
 commit
 zone zone-id [create]
 description description-string
 interface ip-int-name [create]
 name zone-name
 nat
 pool pool-id [create]
 description description-string
 direction {zone-outbound | zone-
 inbound | both}
 entry entry-id [create]
 ip-address ip-address [to ip-
 address] interface ip-int-
 name
 port port [to port] interface
 ip-int-name
 name pool-name
 policy policy-id | policy-name
 shutdown

```

The following example displays a NAT zone configuration output.

```
A:ALU-B>config>service>vprn# info

configure
 service vprn 1 create
 zone 1 create
 begin
 name "VPRN zone"
 description "uplink zone from private"
 interface vprn-100-192.168.0.0
 exit
 nat
 pool 1 create
 description "pool 1"
 direction zone-inbound
 exit
 entry 1 create
 ip-addr interface vprn-100-203.0.113.0
 exit
 exit
 exit
 policy 1 nat pool 1
 commit
 exit
no-shutdown

A:ALU-B>config>service>ies#
```

## 7.6.22 Configuring Serial Raw Socket Transport Within VPRN

Configure an IP transport subservice within a VPRN service in order to enable the transport of serial data using raw sockets.

**CLI Syntax:**

```
config>service
 vprn service-id [customer customer-id] [create]
 ip-transport ipt-id [create]
 description description-string
 filter-unknown-host
 local-host ip-addr ip-addr port-num port-num protocol {tcp | udp}
 remote-host host-id [ip-addr ip-addr]
 [port-num port-num] [create]
 description description-string
 name host-name
 exit
 fc fc-name profile {in | out}
 shutdown
 tcp
```

```

 inactivity-timeout seconds
 max-retries number
 retry-interval seconds
 exit
 exit
 exit
 exit

```

The following example displays an IP transport subservice configuration output.

```

A:ALU-B>config>service>vprn# info

configure
service vprn 100 create
 ip-transport 1/2/4.1 create
 description "ip-transport vprn"
 filter-unknown-host
 local-host ip-address 192.168.0.0 port-number 4000 protocol udp
 exit
 remote-host 1 ip-address 192.168.0.1 port-number 4001 create
 exit
 exit
 no-shutdown

A:ALU-B>config>service>vprn

```

## 7.6.23 Configuring VPRN Router Advertisement

Use the following CLI syntax to enable VPRN router advertisement on all IPv6-enabled interfaces and to configure optional router advertisement parameters:

**CLI Syntax:**

```

config>service
 vprn service-id
 router-advertisement
 interface ip-int-name
 current-hop-limit number
 managed-configuration
 max-advertisement-interval seconds
 min-advertisement-interval seconds
 mtu mtu-bytes
 other-stateful-configuration
 prefix ipv6-prefix/prefix-length
 autonomous
 on-link
 preferred-lifetime {seconds |
 infinite}
 valid-lifetime {seconds |
 infinite}
 reachable-time milli-seconds

```

```

retransmit-time milli-seconds
router-lifetime seconds
no shutdown

```

**Example:**

```

config>service# vprn 1
config>service>vprn# router-advertisement
config>service>vprn>router-advert# interface "int1"
config>service>vprn>router-advert>if# prefix
2001:db8:a::123
config>router>router-advert>if>prefix# autonomous
config>router>router-advert>if>prefix# on-link
config>router>router-advert>if>prefix# preferred-
lifetime 206800
config>router>router-advert>if>prefix# valid-lifetime
1502000
config>router>router-advert>if>prefix# exit
config>router>router-advert>if# exit
config>router>router-advert# exit

```

The following example displays a VPRN router advertisement configuration:

```

A:ALU-A>config>service# info detail

 interface "n1"
 prefix 3::/64
 exit
 no shutdown

A:ALU-A>config>router>router-advert# interface n1
A:ALU-A>config>router>router-advert>if# prefix 2001:db8:a::123
A:ALU-A>config>router>router-advert>if>prefix# into detail

 autonomous
 on-link
 preferred-lifetime 604800
 valid-lifetime 2592000

A:ALU-A>config>router>router-advert>if>prefix#

```

---

## 7.7 Service Management Tasks

This section discusses the following service management tasks:

- [Modifying VPRN Service Parameters](#)
- [Deleting a VPRN Service](#)
- [Disabling a VPRN Service](#)
- [Re-enabling a VPRN Service](#)

### 7.7.1 Modifying VPRN Service Parameters

Use the CLI syntax to modify VPRN parameters.

The following example displays the VPRN service creation output.

```
*A:ALU-1>config>service# info

...
 vprn 1 customer 1 create
 shutdown
 vrf-import "vrfImpPolCust1"
 vrf-export "vrfExpPolCust1"
 maximum-routes 2000
 autonomous-system 10000
 route-distinguisher 10001:1
 interface "to-cel" create
 address 172.16.0.0/12
 sap 1/1/10:1 create
 exit
 exit
 static-route-entry 192.168.255.255/16
 next-hop 192.168.0.0
 no shutdown
 exit
 exit
 spoke-sdp 2 create
 exit
exit
...

*A:ALU-1>config>service>vprn#
```

## 7.7.2 Deleting a VPRN Service

A VPRN service cannot be deleted until SAPs, interface spoke SDPs, and interfaces are shut down and deleted. If protocols and/or a service spoke SDP are defined, they must be shut down and removed from the configuration as well.

Use the following CLI syntax to delete a VPRN service:

**CLI Syntax:**

```
config>service#
[no] vprn service-id [customer customer-id]
shutdown
[no] interface ip-int-name
[no] sap sap-id
[no] spoke-sdp sdp-id:vc-id
shutdown
[no] spoke-sdp sdp-id
[no] shutdown
```

## 7.7.3 Disabling a VPRN Service

A VPRN service can be shut down without deleting any service parameters.

**CLI Syntax:**

```
config>service#
vprn service-id [customer customer-id]
shutdown
```

**Example:**

```
config>service# vprn 1
config>service>vprn# shutdown
config>service>vprn# exit
```

```
*A:ALU-1>config>service# info

...
vprn 1 customer 1 create
shutdown
vrf-import "vrfImpPolCust1"
vrf-export "vrfExpPolCust1"
autonomous-system 10000
route-distinguisher 10001:1
auto-bind-tunnel
resolution-filter
ldp
exit
resolution filter
exit
vrf-target target:10001:1
interface "to-cel" create
address 172.16.0.0/12
```

```
 sap 1/1/10:1 create
 ingress
 qos 100
 filter ip 6
 exit
 egress
 qos 1010
 exit
 exit
exit
static-route-entry 192.168.0.0/16
 next-hop 192.168.0.1
 no shutdown
exit
exit
spoke-sdp 2 create
exit
exit
...

*A:ALU-1>config>service#
```

## 7.7.4 Re-enabling a VPRN Service

To re-enable a VPRN service that was shut down:

**CLI Syntax:**    config>service#  
                  vprn *service-id* [customer *customer-id*]  
                  no shutdown

---

## 7.8 VPRN Services Command Reference

### 7.8.1 Command Hierarchies

- Configuration Commands
  - VPRN Service Configuration Commands
  - BGP Commands
  - OSPF Commands
  - OSPFv3 Commands
  - IGMP Commands
  - PIM Commands
  - RIP Commands
  - VPRN Security Zone Configuration Commands
  - VPRN Raw Socket IP Transport Configuration Commands
  - Multicast VPN Commands
  - MSDP Commands
  - Router Advertisement Commands
  - Local DHCP and DHCPv6 Server Commands
  - Interface Commands
  - IPv6 Interface Commands
  - Interface DHCP Commands
  - Interface ICMP Commands
  - Interface SAP IPSec-Tunnel Commands
  - Routed VPLS Commands
  - Interface VRRP Commands
  - VPRN Static One-to-One NAT Configuration Commands
  - TWAMP Light Commands
- Show Commands
- Clear Commands
- Debug Commands

## 7.8.1.1 Configuration Commands

### 7.8.1.1.1 VPRN Service Configuration Commands

```

config
 — service
 — vprn service-id [customer customer-id] [create]
 — no vprn service-id
 — aggregate ip-prefix/ip-prefix-length [summary-only] [as-set] [aggregator as-number:ip-address]
 — no aggregate ip-prefix/ip-prefix-length
 — auto-bind-tunnel
 — resolution {any | filter | disabled}
 — resolution-filter
 — [no] gre
 — [no] ldp
 — [no] rsvp
 — [no] sr-isis
 — [no] sr-ospf
 — [no] sr-te
 — autonomous-system as-number
 — no autonomous-system
 — [no] bgp
 — description description-string
 — no description
 — dhcp (refer to the 7705 SAR Router Configuration Guide, “Local DHCP Server Commands”)
 — dhcp6 (see Local DHCP and DHCPv6 Server Commands)
 — ecmp max-ecmp-routes
 — no ecmp
 — encryption-keygroup keygroup-id direction {inbound | outbound}
 — no encryption-keygroup direction {inbound | outbound}
 — [no] entropy-label
 — grt-lookup
 — [no] enable-grt
 — [no] allow-local-management
 — export-grt policy-name [policy-name...(up to 5 max)]
 — no export-grt
 — export-limit num-routes
 — no export-limit
 — export-v6-limit num-routes
 — no export-v6-limit
 — interface ip-int-name
 — [no] entropy-label
 — interface ip-int-name tunnel create (see Service Interface Tunnel Commands)
 — no interface ip-int-name
 — ipsec (see the IPSec Command Reference)
 — maximum-ipv6-routes number [log-only] [threshold percent]
 — no maximum-ipv6-routes

```

- 
- **maximum-routes** *number* [**log-only**] [**threshold percent**]
  - **no maximum-routes**
  - **[no] ospf**
  - **route-distinguisher** *[rd]*
  - **no route-distinguisher**
  - **router-id** *ip-address*
  - **no router-id**
  - **service-name** *service-name*
  - **no service-name**
  - **sgt-qos**
    - **application** *dscp-app-name* **dscp** {*dscp-value* | *dscp-name*} [**fc-queue** *fc-name* **profile** {**in** | **out**}]
    - **application** *dot1p-app-name* **dot1p** {*dot1p-priority*} [**fc-queue** *fc-name* **profile** {**in** | **out**}]
    - **no application** {*dscp-app-name* | *dot1p-app-name*}
    - **dscp** *dscp-name* **fc** *fc-name*
    - **no dscp** *dscp-name*
  - **[no] shutdown**
  - **snmp-community** *community-name* [**hash** | **hash2**] [**version** *SNMP-version*]
  - **no snmp-community** *community-name* [**hash** | **hash2**]
  - **source-address**
    - **application** {**app** [**ping** | **ptp** | **ssh** | **telnet** | **traceroute**]} | {[*ip-int-name* | *ip-address*]}
    - **no application** **app** {[**ping** | **ptp** | **ssh** | **telnet** | **traceroute**]}
    - **application6** **app** {[*ping* | *telnet* | *ssh* | *traceroute*]} | *ipv6-address*
    - **no application6** **app** {[**ping** | **telnet** | **ssh** | **traceroute**]}
  - **[no] spoke-sdp** *sdp-id*
    - **[no] shutdown**
  - **[no] static-route-entry** *ip-prefix/prefix-length*
    - **[no] black-hole**
      - **[no] description** *description-string*
      - **[no] metric** *metric*
      - **preference** *preference*
      - **no preference**
      - **[no] prefix-list** *prefix-list-name* {**all** | **none**}
      - **[no] shutdown**
      - **[no] tag** *tag*
    - **[no] grt**
      - **[no] description** *description-string*
      - **[no] metric** *metric*
      - **preference** *preference*
      - **no preference**
      - **[no] shutdown**
    - **[no] indirect** *ip-address*
      - **[no] cpe-check** *cpe-ip-address*
        - **drop-count** *count*
        - **no drop-count**
        - **interval** *seconds*
        - **no interval**
        - **[no] log**
      - **[no] description** *description-string*
      - **[no] metric** *metric*
      - **preference** *preference*
      - **no preference**

7.8.2.1.1 Generic Commands

description

Syntax	description <i>description-string</i> no description
Context	<pre> config>service>vpn config>service>vpn>bgp config>service>vpn>bgp>group config>service>vpn>bgp>group>neighbor config>service>vpn>dhcp>local-dhcp-server config>service>vpn>dhcp>local-dhcp-server>pool config>service>vpn>interface config>service>vpn>if>dhcp config>service>vpn>if>ipv6>dhcp6-relay config>service>vpn>if>sap config>service>vpn>ip-transport config>service>vpn>ip-transport>remote-host config>service>vpn>rip config>service>vpn>rip>group config>service>vpn>rip>group>neighbor config>service>vpn>static-route-entry>black-hole config>service>vpn>static-route-entry>grt config>service>vpn>static-route-entry>indirect config>service>vpn>static-route-entry>ipsec-tunnel config>service>vpn>static-route-entry>next-hop config>service>vpn>twamp-light>reflector config>service>vpn>twamp-light>reflector>prefix config>service>vpn>zone config>service>vpn>zone>nat>pool </pre>
Description	This command creates a text description that is stored in the configuration file for a configuration context. The description command associates a text string with a configuration context to help identify the contents in the configuration file. The no form of this command removes the string from the configuration.
Default	no description
Parameters	<i>description-string</i> — the description character string. Allowed values are any string up to 80 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

shutdown

Syntax	[no] shutdown
Context	<pre> config>service>vprn config>service>vprn>bgp config>service>vprn>bgp>group config>service>vprn>bgp>group>neighbor config>service>vprn>interface config>service>vprn>if>dhcp config>service>vprn>if>ipv6>dhcp6-relay config>service>vprn>if>ipv6>dhcp6-server>prefix-delegation config>service>vprn>if>spoke-sdp config>service>vprn>if>sap config>service>vprn>if>vrrp config>service>vprn>ip-transport config>service>vprn>msdp config>service>vprn>msdp>group config>service>vprn>msdp>group>peer config>service>vprn>msdp>peer config>service>vprn>ospf config>service>vprn>ospf>area>interface config>service>vprn>ospf>area>virtual-link config>service>vprn>ospf3 config>service>vprn>ospf3>area>interface config>service>vprn>ospf3>area>virtual-link config>service>vprn>pim config>service>vprn>pim>interface config>service>vprn>rip config>service>vprn>rip>group config>service>vprn>rip>group>neighbor config>service>vprn>router-advertisement>interface config>service>vprn>pim>rp>bsr-candidate config>service>vprn>pim>rp>rp-candidate config>service>vprn>spoke-sdp config>service>vprn>static-route-entry>black-hole config>service>vprn>static-route-entry>grt config>service>vprn>static-route-entry>indirect config>service>vprn>static-route-entry>ipsec-tunnel config>service>vprn>static-route-entry>next-hop config>service>vprn>twamp-light>reflector config>service>vprn>zone config>service>vprn>zone>interface </pre>
Description	This command administratively disables an entity. When disabled, an entity does not change, reset, or remove any configuration settings or statistics. The operational state of the entity is disabled as well as the operational state of any entities contained within. Many objects must be shut down before they can be deleted.

Services are created in the administratively down (**shutdown**) state. When a **no shutdown** command is entered, the service becomes administratively up and then tries to enter the operationally up state. Default administrative states for services and service entities are described below in **Special Cases**.

The **no** form of this command places the entity into an administratively enabled state.

Special Cases

Service Admin State — bindings to an SDP within the service will be put into the out-of-service state when the service is shut down. While the service is shut down, all customer packets are dropped and counted as discards for billing and debugging purposes.

A service is regarded as operational providing that one IP Interface SAP and one SDP is operational.

VPRN IP transport subservice — when an IP transport subservice within a VPRN service is shut down, all TCP/UDP packets received from remote hosts are dropped and any serial data received from the serial port is dropped. Any TCP connections that were up are closed and no new TCP connection requests are accepted.

It is not possible to make configuration changes to an IP transport subservice without performing a **shutdown** first.

The operational state of an IP transport subservice is relative to the operational state of the serial port for which the IP transport subservice is defined. When a serial port is shut down, the IP transport subservice associated with the serial port becomes operationally down.

When the **no shutdown** command is executed for an IP transport subservice, it becomes operationally up, serial data from the serial port is encapsulated in TCP/UDP packets destined for remote hosts, and TCP/UDP packets can be received by the local host, where raw serial data is then sent out the serial port.

7.8.2.1.2 Global Commands

vprn

Syntax	vprn <i>service-id</i> [customer <i>customer-id</i>] [create] no vprn <i>service-id</i>
Context	config>service
Description	This command creates or edits a Virtual Private Routed Network (VPRN) service instance. If the <i>service-id</i> does not exist, a context for the service is created. If the <i>service-id</i> exists, the context for editing the service is entered. VPRN services allow the creation of customer-facing IP interfaces in a separate routing instance from the one used for service network core routing connectivity. VPRN services allow the IP addressing scheme used by the subscriber to overlap with other addressing schemes used by other VPRN services or by the provider and, potentially, the entire Internet. IP interfaces defined within the context of a VPRN service ID must have a SAP created as the access point to the subscriber network. When a service is created, the customer keyword and <i>customer-id</i> must be specified, which associates the service with a customer. The <i>customer-id</i> must already exist, having been created using the customer command in the service context. When a service is created with a customer association, it is not possible to edit the customer association. To change the association between service and customer, the service must be deleted and recreated with a new customer association. Once a service is created, the use of customer <i>customer-id</i> is optional to navigate into the service configuration context. Attempting to edit a service with an incorrect <i>customer-id</i> results in an error. Multiple VPRN services are created in order to separate customer-owned IP interfaces. More than one VPRN service can be created for a single customer ID. More than one IP interface can be created within a single VPRN service ID. All IP interfaces created within a VPRN service ID belong to the same customer. The no form of the command deletes the VPRN service instance with the specified <i>service-id</i>. The service cannot be deleted until all the IP interfaces and all routing protocol configurations defined within the service ID have been shut down and deleted.
Default	n/a

Parameters	<i>service-id</i> — the unique service identification number or name that identifies the service in the service domain. The ID must be unique to this service and cannot be used for any other service of any type (such as Epipe, Cpipe, IES). However, a VPRN instance in the service provider network can include different <i>service-ids</i> on the routers in the network. Values 1 to 2147483647 or <i>service-name</i> <i>customer-id</i> — an existing customer identification number to be associated with the service. This parameter is required during service creation and is optional for service editing or deleting. Values 1 to 2147483647 create — keyword is mandatory when creating a VPRN service

aggregate

Syntax	aggregate <i>ip-prefix/ip-prefix-length</i> [summary-only] [as-set] [aggregator <i>as-number:ip-address</i>] [description <i>description-text</i>] no aggregate <i>ip-prefix/ip-prefix-length</i>		
Context	config>service>vprn		
Description	This command creates an aggregate route. Use this command to group a number of routes with common prefixes into a single entry in the routing table. This reduces the number of routes that need to be advertised by this router and reduces the number of routes in the routing tables of downstream routers. Both the original components and the aggregated route (source protocol aggregate) are offered to the Routing Table Manager (RTM). Subsequent policies can be configured to assign protocol-specific characteristics, such as the OSPF tag, to aggregate routes. Multiple entries with the same prefix but a different mask can be configured; routes are aggregated to the longest mask. If one aggregate is configured as 10.0/16 and another as 10.0.0/24, then route 10.0.128/17 would be aggregated into 10.0/16 and route 10.0.0.128/25 would be aggregated into 10.0.0/24. If multiple entries are made with the same prefix and the same mask, the previous entry is overwritten. The no form of the command removes the aggregate.		
Default	no aggregate		
Parameters	<i>ip-prefix/ip-prefix-length</i> — the destination address of the aggregate route		
	Values	<i>ipv4-prefix</i>	a.b.c.d (host bits must be 0)
		<i>ipv4-prefix-length</i>	0 to 30
		<i>ipv6-prefix</i>	x:x:x:x:x:x:x (eight 16-bit pieces)
			x:x:x:x:x:d.d.d.d
			x: [0 to FFFF]H

		d: [0 to 255]D
<i>ipv6-prefix-length</i>		0 to 128
summary-only — suppresses advertisement of more specific component routes for the aggregate. To remove the summary-only option, enter the same aggregate command without the summary-only parameter.		
as-set — creates an aggregate where the path advertised for this route is an AS_SET consisting of all elements contained in all paths that are being summarized. This parameter should be used carefully as it can increase the amount of route churn due to best path changes. The parameter is only applicable to BGP.		
<i>as-number:ip-address</i> — specifies the BGP aggregator path attribute to the aggregate route. When configuring the aggregator, a two-octet AS number used to form the aggregate route must be entered, followed by the IP address of the BGP system that created the aggregate route.		
Values	<i>as-number</i>	1 to 4294967295
	<i>ip-address</i>	a.b.c.d
<i>description-text</i> — a text description, up to 80 characters long, stored in the configuration file for a configuration context		

auto-bind-tunnel

Syntax	auto-bind-tunnel
Context	config>service>vprn
Description	This command enables the context to configure automatic binding of a VPRN service using tunnels to MP-BGP peers. The auto-bind-tunnel mode is simply a context to configure the binding of VPRN routes to tunnels. The user must configure the resolution option to enable auto-binding resolution to tunnels in TTM. When an explicit SDP to a BGP next hop is configured in a VPRN service (config>service>vprn>spoke-sdp), it overrides the auto-bind-tunnel selection for that BGP next hop only. There is no support for reverting automatically to the auto-bind-tunnel selection if the explicit SDP goes down. The user must delete the explicit spoke SDP in the VPRN service context to resume using the auto-bind-tunnel selection for the BGP next hop.

resolution

Syntax	resolution {any filter disabled}
Context	config>service>vprn>auto-bind-tunnel
Description	This command configures the resolution mode in the automatic binding of a VPRN service to tunnels to MP-BGP peers.

If the **resolution** option is explicitly set to **disabled**, the auto-binding to tunnels is removed.

If **resolution** is set to **any**, any supported tunnel type in the VPRN context will be selected following the TTM preference. If one or more explicit tunnel types are specified using the **resolution-filter** option, only these tunnel types will be selected again following the TTM preference.

The user must set **resolution** to **filter** to activate the list of tunnel types configured under **resolution-filter**.

- Parameters**
- any** — enables the binding to any supported tunnel type in the VPRN context following the TTM preference
 - filter** — enables the binding to the subset of tunnel types configured under **resolution-filter**
 - disabled** — disables the automatic binding of a VPRN service to tunnels to MP-BGP peers

resolution-filter

- Syntax** **resolution-filter**
- Context** config>service>vprn>auto-bind-tunnel
- Description** This command configures the subset of tunnel types that can be used in the resolution of VPRN prefixes within the automatic binding of VPRN service to tunnels to MP-BGP peers.
- The following tunnel types are supported in a VPRN context (in order of preference): RSVP (**rsvp**), segment routing TE (**sr-te**), LDP (**ldp**), segment routing OSPF (**sr-ospf**), segment routing IS-IS (**sr-isis**), and GRE (**gre**). The segment routing precedences can be configured. The selection of an SR tunnel in SR-ISIS when using multi-instance IS-IS is based on lowest instance ID.

gre

- Syntax** [no] gre
- Context** config>service>vprn>auto-bind-tunnel>resolution-filter
- Description** This command specifies the GRE type of automatic binding for the SDP assigned to this service. When **auto-bind-tunnel** is used, a spoke SDP does not need to be configured for the service.
- The **no** form of the command removes this type of automatic binding.
- Default** no gre

ldp

Syntax	[no] ldp
Context	config>service>vprn>auto-bind-tunnel>resolution-filter
Description	This command specifies the LDP tunnel type of automatic binding for the SDP assigned to this service. When auto-bind-tunnel is used, a spoke SDP does not need to be configured for the service. The ldp value instructs BGP to search for an LDP LSP with a FEC prefix corresponding to the address of the BGP next hop. The no form of the command removes this type of automatic binding.
Default	no ldp

rsvp

Syntax	[no] rsvp
Context	config>service>vprn>auto-bind-tunnel>resolution-filter
Description	This command specifies the RSVP tunnel type of automatic binding for the SDP assigned to this service. When auto-bind-tunnel is used, a spoke SDP does not need to be configured for the service. The rsvp value instructs BGP to search for the best metric RSVP LSP to the address of the BGP next hop. The LSP metric is provided by MPLS in the tunnel table. In the case of multiple RSVP LSPs with the same lowest metric, BGP selects the LSP with the lowest tunnel-id. The no form of the command removes this type of automatic binding.
Default	no rsvp

sr-isis

Syntax	[no] sr-isis
Context	config>service>vprn>auto-bind-tunnel>resolution-filter
Description	This command specifies the SR-ISIS tunnel type of automatic binding for the SDP assigned to this service. When auto-bind-tunnel is used, a spoke SDP does not need to be configured for the service. When the sr-isis value is enabled, an SR tunnel to the BGP next hop is selected in the TTM from the lowest-numbered IS-IS instance. The no form of the command removes this type of automatic binding.

Default no sr-isis

sr-ospf

Syntax [no] **sr-ospf**

Context config>service>vprn>auto-bind-tunnel>resolution-filter

Description This command specifies the SR-OSPF tunnel type of automatic binding for the SDP assigned to this service. When **auto-bind-tunnel** is used, a spoke SDP does not need to be configured for the service.

When the **sr-ospf** value is enabled, an SR tunnel to the BGP next hop is selected in the TTM from OSPF instance 0.

The **no** form of the command removes this type of automatic binding.

Default no sr-ospf

sr-te

Syntax [no] **sr-te**

Context config>service>vprn>auto-bind-tunnel>resolution-filter

Description This command specifies the SR-TE tunnel type of automatic binding for the SDP assigned to this service. When **auto-bind-tunnel** is used, a spoke SDP does not need to be configured for the service.

The **sr-te** value instructs the 7705 SAR to search for the best metric SR-TE LSP to the address of the BGP next hop. The LSP metric is provided by MPLS in the tunnel table. In the case of multiple SR-TE LSPs with the same lowest metric, BGP selects the LSP with the lowest **tunnel-id**.

The **no** form of the command removes this type of automatic binding.

Default no sr-te

autonomous-system

Syntax **autonomous-system** *as-number*
no autonomous-system

Context config>service>vprn

Description This command defines the autonomous system (AS) to be used by this VPN virtual routing/forwarding table (VRF).

The **no** form of the command removes the defined AS from the given VPRN context.

Default	no autonomous-system
Parameters	<i>as-number</i> — specifies the AS number for the VPRN service
Values	1 to 4294967295

ecmp

Syntax	ecmp <i>max-ecmp-routes</i> no ecmp
Context	config>service>vprn
Description	This command enables ECMP in the VPRN service context and configures the number of routes for path sharing; for example, the value 2 means two equal-cost routes will be used for cost sharing. ECMP (Equal-Cost Multipath Protocol) refers to the distribution of packets over two or more outgoing links that share the same routing cost. ECMP provides a fast local reaction to route failures. ECMP is supported on static routes and dynamic (OSPF, IS-IS, and BGP) routes. ECMP can only be used for routes with the same preference and same protocol. See the preference command (under the static-route-entry context) for information on preferences. When more ECMP routes are available at the best preference than configured in <i>max-ecmp-routes</i>, then the lowest next-hop IP address algorithm is used to select the number of routes configured in <i>max-ecmp-routes</i>. The no form of the command disables ECMP path sharing. If ECMP is disabled and multiple routes are available at the best preference and equal cost, the route with the lowest next-hop IP address is used. The no form of the command disables ECMP path sharing.
Default	no ecmp
Parameters	<i>max-ecmp-routes</i> — the maximum number of equal-cost routes allowed on this VPRN instance, expressed as a decimal integer. Setting ECMP <i>max-ecmp-routes</i> to 1 yields the same result as entering no ecmp. Values 0 to 8

encryption-keygroup

Syntax	encryption-keygroup <i>keygroup-id</i> direction { inbound outbound } no encryption-keygroup direction { inbound outbound }
Context	config>service>vprn
Description	This command is used to bind a key group to a VPRN service for inbound or outbound packet processing. When configured in the outbound direction, packets egressing the node use the active-outbound-sa associated with the key group configured. When configured in the inbound direction, received packets must be encrypted using one of the valid security associations configured for the key group. The encryption (enabled or disabled) configured on an SDP used to terminate a Layer 3 spoke SDP of a VPRN always overrides any VPRN-level configuration for encryption. Encryption is enabled once the outbound direction is configured. The no form of the command removes the key group from the service in the specified direction (inbound or outbound).
Default	n/a
Parameters	<i>keygroup-id</i> — the number of the key group being configured Values 1 to 15 or <i>keygroup-name</i> (up to 64 characters) direction {inbound outbound} — mandatory keywords when binding a key group to a service for a particular direction

entropy-label

Syntax	[no] entropy-label
Context	config>service>vprn config>service>vprn>interface>spoke-sdp
Description	This command enables or disables the use of entropy labels for spoke SDPs on a VPRN. If entropy-label is enabled, the entropy label and entropy label indicator (ELI) are inserted in packets for which at least one LSP in the stack for the far end of the tunnel used by the service has advertised entropy label capability. If the tunnel type is RSVP-TE, entropy-label can also be controlled by disabling entropy-label-capability under the config>router>rsvp or config>router>mpls>lsp contexts at the far-end LER. When the entropy-label and entropy-label-capability commands are both enabled, the entropy label value inserted at the iLER is always based on the service ID.

The entropy label and the hash label features are mutually exclusive. The entropy label cannot be configured on a spoke SDP or service where the hash label feature has already been configured.

Default no entropy-label

grt-lookup

Syntax **grt-lookup**

Context config>service>vprn

Description This command enters the context under which all GRT leaking commands are configured.

enable-grt

Syntax [no] **enable-grt**

Context config>service>vprn>grt-lookup

Description This command enables the functions required for looking up routes in the GRT when the lookup in the local VRF fails. If this command is enabled without the use of the **config>service>vprn>static-route-entry>grt** command, a lookup in the local VRF is preferred over the GRT. When the local VRF returns no route table lookup matches, the result from the GRT is preferred.

The **no** form of this command disables the global routing table lookup function when the lookup in the local VRF fails.

Default no enable-grt

allow-local-management

Syntax [no] **allow-local-management**

Context config>service>vprn>grt-lookup>enable-grt

Description This command enables management traffic from GRT leaking-enabled VPRN instances to reach local interfaces in the base router instance. The local interfaces can be system IP interfaces or loopback interfaces. Management traffic is traffic generated by Telnet, SNMP, and SSH. For a complete list of supported management protocols, see [Table 120](#).

Ping and traceroute responses from the base router interfaces are supported but are not configurable. The **allow-local-management** command does not control the support for management protocols terminating on VPRN interfaces directly.

Default no allow-local-management

export-grt

Syntax	export-grt <i>policy-name</i> [<i>policy-name...</i> (up to 5 max)] no export-grt
Context	config>service>vprn>grt-lookup
Description	This command uses configured route policies to determine which routes are exported from the VRF to the GRT along with all the forwarding information. On network egress, packets with a source IP address that matches the 7705 SAR system IP address and the destination IP address of the far-end node must perform a GRT lookup in order to be resolved. A route policy can be configured with the IP address prefix or loopback address of the far-end router and with the action to accept. This policy is configured under the config>router>policy-options context, and is installed in the GRT FIB using the export-grt command. The route installed in the GRT FIB will have a next hop of the IPsec tunnel. Up to five policies can be exported to the GRT FIB. The no form of the command restores the default of not exporting routes to the GRT FIB.
Default	no export-grt
Parameters	<i>policy-name</i> — the name of the route policy to be exported to the GRT FIB

export-limit

Syntax	export-limit <i>num-routes</i> no export-limit
Context	config>service>vprn>grt-lookup
Description	This command limits the number of IPv4 routes that can be exported from the VRF to the GRT. Setting the limit to 0 overrides the maximum limit. Setting the value to 0 does not limit the number of routes exported from the VRF to the GRT. Configuring the export-limit between 1 and 256 will limit the number of routes to the specified value. The no form of the command resets the limit to the default of allowing five routes per route policy to be exported from the VRF to the GRT.
Default	5
Parameters	<i>num-routes</i> — the number of routes per policy to be exported to the GRT
Values	0 to 256

export-v6-limit

Syntax	export-v6-limit <i>num-routes</i> no export-v6-limit
Context	config>service>vprn>grt-lookup
Description	This command limits the number of IPv6 routes that can be exported from the VRF to the GRT. Setting the limit to 0 overrides the maximum limit. Setting the value to 0 does not limit the number of routes exported from the VRF to the GRT. Configuring the export-limit between 1 and 256 will limit the number of routes to the specified value. The no form of the command resets the limit to the default of allowing five routes per route policy to be exported from the VRF to the GRT.
Default	5
Parameters	<i>num-routes</i> — the number of IPv6 routes per policy to be exported to the GRT
	Values 0 to 256

maximum-ipv6-routes

Syntax	maximum-ipv6-routes <i>number</i> [log-only] [threshold <i>percent</i>] no maximum-ipv6routes
Context	config>service>vprn
Description	This command specifies the maximum number of IPv6 routes that can be held within a VPN virtual routing /forwarding (VRF) context. Local, host, static, and aggregate routes are not counted. The VPRN service ID must be in a shutdown state before maximum-ipv6-routes command parameters can be modified. If the log-only parameter is not specified and the maximum-ipv6-routes value is set to a value below the existing number of IPv6 routes in a VRF, then the extra IPv6 routes will not be added to the VRF. The maximum IPv6 route threshold can dynamically change to increase the number of supported IPv6 routes even when the maximum has already been reached. Protocols will resubmit the IPv6 routes that were initially rejected. The no form of the command disables any limit on the number of IPv6 routes within a VRF context. Issue the no form of the command only when the VPRN instance is shut down.
Default	no maximum-ipv6routes (0 or disabled)
Parameters	<i>number</i> — the maximum number of IPv6 routes to be held in a VRF context
	Values 1 to 2147483647

log-only — specifies that if the maximum limit is reached, the event only will be logged.
The **log-only** parameter does not disable the learning of new IPv6 routes.

percent — the percentage at which a warning log message and SNMP will be used.
There are two warning levels: mid-level and high-level. A mid-level warning occurs when the **threshold percent** value is reached, and a high-level warning occurs at the halfway level between the maximum number of IPv6 routes and the *percent* value ($[(\text{max} + \text{mid}) / 2]$). For example, if the **maximum-ipv6-routes** number is 100, and *percent* is 60, then the mid-level warning occurs at 60 IPv6 routes, and the high-level warning occurs at 80 IPv6 routes.

Values 0 to 100

maximum-routes

Syntax	maximum-routes <i>number</i> [log-only] [threshold percent] no maximum-routes
Context	config>service>vprn
Description	This command specifies the maximum number of IPv4 routes that can be held within a VPN virtual routing /forwarding (VRF) context. Local, host, static, and aggregate routes are not counted. The VPRN service ID must be in a shutdown state before maximum-routes command parameters can be modified. If the log-only parameter is not specified and the maximum-routes value is set to a value below the existing number of IPv4 routes in a VRF, then the extra IPv4 routes will not be added to the VRF. The maximum IPv4 route threshold can dynamically change to increase the number of supported IPv4 routes even when the maximum has already been reached. Protocols will resubmit the IPv4 routes that were initially rejected. The no form of the command disables any limit on the number of IPv4 routes within a VRF context. Issue the no form of the command only when the VPRN instance is shut down.
Default	no maximum-routes (0 or disabled)
Parameters	<i>number</i> — the maximum IPv4 number of routes to be held in a VRF context Values 1 to 2147483647 log-only — specifies that if the maximum limit is reached, the event only will be logged. The log-only parameter does not disable the learning of new routes.

percent — the percentage at which a warning log message and SNMP will be used.

There are two warning levels: mid-level and high-level. A mid-level warning occurs when the **threshold** *percent* value is reached, and a high-level warning occurs at the halfway level between the maximum number of IPv4 routes and the *percent* value ($[(\text{max} + \text{mid}) / 2]$). For example, if the **maximum-routes** number is 100, and *percent* is 60, then the mid-level warning occurs at 60 IPv4 routes, and the high-level warning occurs at 80 IPv6 routes.

Values 0 to 100

route-distinguisher

Syntax	route-distinguisher [<i>rd</i>] no route-distinguisher										
Context	config>service>vpn										
Description	This command sets the identifier that gets attached to routes to which the VPN belongs. Each routing instance must have a unique (within the carrier's domain) route distinguisher associated with it. A route distinguisher must be defined for a VPRN to be operationally active. AS numbers can be either 2-byte or 4-byte values.										
Default	no route-distinguisher										
Parameters	<i>rd</i> — the route distinguisher value Values <i>ip-addr:comm-val</i> <i>2byte-asnumber:ext-comm-val</i> <i>4-byte-asnumber:comm-val</i> where <table> <tr> <td><i>ip-addr:</i></td><td>a.b.c.d</td></tr> <tr> <td><i>comm-val:</i></td><td>0 to 65535</td></tr> <tr> <td><i>2-byte-asnumber:</i></td><td>1 to 65535</td></tr> <tr> <td><i>ext-comm-val:</i></td><td>0 to 4294967295</td></tr> <tr> <td><i>4-byte-asnumber:</i></td><td>1 to 4294967295</td></tr> </table>	<i>ip-addr:</i>	a.b.c.d	<i>comm-val:</i>	0 to 65535	<i>2-byte-asnumber:</i>	1 to 65535	<i>ext-comm-val:</i>	0 to 4294967295	<i>4-byte-asnumber:</i>	1 to 4294967295
<i>ip-addr:</i>	a.b.c.d										
<i>comm-val:</i>	0 to 65535										
<i>2-byte-asnumber:</i>	1 to 65535										
<i>ext-comm-val:</i>	0 to 4294967295										
<i>4-byte-asnumber:</i>	1 to 4294967295										

router-id

Syntax	router-id <i>ip-address</i> no router-id
Context	config>service>vpn config>service>vpn>bgp
Description	This command sets the router ID for a specific VPRN context.

If neither the router ID nor system interface are defined, the router ID from the base router context is inherited.

The **no** form of the command removes the router ID definition from the given VPRN context.

Default	no router-id
Parameters	<i>ip-address</i> — the IP address, in dotted-decimal notation
Values	a.b.c.d

service-name

Syntax	service-name <i>service-name</i> no service-name
Context	config>service>vprn
Description	This command configures a service name that can be used for reference in configuration and show commands.
Parameters	<i>service-name</i> — up to 64 characters

sgt-qos

Syntax	sgt-qos
Context	config>service>vprn
Description	This command enables the context to configure DSCP/dot1p re-marking for self-generated traffic.

application

Syntax	application <i>dscp-app-name</i> dscp { <i>dscp-value</i> <i>dscp-name</i> } [fc-queue <i>fc-name</i> profile { in out }] application <i>dot1p-app-name</i> dot1p { <i>dot1p-priority</i> } [fc-queue <i>fc-name</i> profile { in out }] no application { <i>dscp-app-name</i> <i>dot1p-app-name</i> }
Context	config>service>vprn>sgt-qos
Description	This set of commands configures DSCP marking for self-generated IP traffic or dot1p marking for self-generated non-IP traffic (specifically, IS-IS and ARP traffic).

When an IP or Layer 3 application is configured using the *dscp-app-name* parameter, the specified DSCP name or DSCP value is used for all packets generated by this application within the router instance in which it is configured. The value set in this command sets the DSCP value in the egress IP header. The egress QoS policy will not overwrite this value.

When a Layer 2 application is configured using the *dot1p-app-name* parameter, the specified dot1p priority value is used for all packets generated by this application within the router instance in which it is configured.

Only one name or value can be configured per application. If multiple entries are configured, a subsequent entry overrides the previously configured entry.

The **fc-queue** option redirects SGT applications to egress data queues rather than the default control queue by assigning them to a forwarding class. If this option is configured, the profile state must be set. All packets that are assigned to this forwarding class will be considered in-profile or out-of-profile based on the configuration. In case of congestion, the in-profile packets are preferentially queued over the out-of-profile packets.

If the **fc-queue** option is used with the *dscp-app-name* application, any configuration done using the **sgt-qos>dscp** command is ignored for packets generated by this application, as illustrated in the following examples:

```
sgt-qos>application telnet dscp cp1
sgt-qos>dscp cp1 fc af
```

```
sgt-qos>application ftp dscp cp1 fc-queue be profile out
sgt-qos>dscp cp1 fc af
```

In the first example, all packets generated by the Telnet application use DSCP CP1 and map to FC AF as configured in the **dscp** command. The dot1p bits of the outgoing packets are marked from the value that FC AF points to in the egress QoS policy.

In the second example, all packets generated by the FTP application use DSCP CP1 and map to FC BE as dictated by the **fc-queue** redirection. The dot1p bits of the outgoing packets are marked from the value that FC BE points to in the egress QoS policy. Because redirection is configured, the mapping configured with the **dscp** command is ignored.

Note: The above behavior applies to all SGT IP applications with the exception of VRRP, where the dot1p value is always set to 7, regardless of the value in the FC egress QoS policy.

If the **fc-queue** option is used with the *dot1p-app-name* application, the dot1p bits of the outgoing packets are marked with the value set with the *dot1p-priority* parameter, regardless of the value in the FC egress queue policy.

The **no** form of this command resets the DSCP or dot1p value for the application to its default value and resets the application to use the egress control queue.

Default n/a

Table 126 Applications and Support for Configurable DSCP or dot1p Markings

Application	Supported Marking	Default DSCP/dot1p
ARP	dot1p	7
IS-IS	dot1p	7
BGP	DSCP	NC1
DHCP	DSCP	NC1
DNS	DSCP	AF41
FTP	DSCP	AF41
ICMP (ping)	DSCP	BE
IGMP	DSCP	NC1
LDP (T-LDP)	DSCP	NC1
MLD	DSCP	NC1
NDIS	DSCP	NC1
NTP	DSCP	NC1
OSPF	DSCP	NC1
PIM	DSCP	NC1
1588 PTP	DSCP	NC1
RADIUS	DSCP	AF41
RIP	DSCP	NC1
RSVP	DSCP	NC1
SNMP (get, set, etc.)	DSCP	AF41
SNMP trap/log	DSCP	AF41
SSH (SCP)	DSCP	AF41
syslog	DSCP	AF41
TACACS+	DSCP	AF41
Telnet	DSCP	AF41
TFTP	DSCP	AF41
Traceroute	DSCP	BE

Table 126 Applications and Support for Configurable DSCP or dot1p Markings (Continued)

Application	Supported Marking	Default DSCP/dot1p
VRRP	DSCP	NC1

Parameters *dscp-app-name* — the DSCP application name

Values bgp, dhcp, dns, ftp, icmp, igmp, ldp, mld, ndis, ntp, ospf, pim, ptp, radius, rip, rsvp, snmp, snmp-notification, ssh, syslog, tacplus, telnet, tftp, traceroute, vrrp

Note:

- PTP in the context of SGT QoS is defined as Precision Timing Protocol and is an application in the 7705 SAR. The PTP application name is also used in areas such as event-control and logging. Precision Timing Protocol is defined in IEEE 1588-2008.
- PTP in the context of IP filters is defined as Performance Transparency Protocol. IP protocols can be used as IP filter match criteria; the match is made on the 8-bit protocol field in the IP header.

dscp-value — the value that maps to the DSCP name (the value **none** specifies that the default DSCP value for the application be used; see [Table 126](#))

Values none | 0 to 63

dscp-name — the DSCP to be associated with the forwarding class. [Table 130](#) lists the valid DSCP names.

dot1p-app-name — the dot1p application name

Values arp, isis

dot1p-priority — the dot1p priority (the value **none** specifies that the default dot1p value for the application be used; see [Table 126](#))

Values none | 0 to 7

fc-name — the forwarding class assigned to SGT applications redirected to data queues

Values be, l2, af, l1, h2, ef, h1, nc

profile {in | out} — the profile state of packets assigned to the specified forwarding class; this parameter must be specified when the **fc-queue** parameter is configured

dscp

Syntax **dscp** *dscp-name* **fc** *fc-name*
no dscp *dscp-name*

Context config>service>vprn>sgt-qos

Description This command creates a mapping between the DSCP of the self-generated traffic and the forwarding class. The forwarding class dot1p SAP egress QoS policy mapping is used to mark the dot1p bits of the Layer 3 or IP application. For example, configuring the *dscp-name* parameter as **be** and the *fc-name* parameter as **l1** results in marking the dot1p bits of the outgoing Ethernet frame, which is transporting self-generated IP traffic with DSCP bits set to BE, to the value that FC L1 points to in the SAP egress QoS policy (as configured in the **config>qos>sap-egress>fc** context).

Note: The dot1p class of service may not apply to all IP traffic and is dependent on the egress port encapsulation type.

Based on this configured FC, the SAP egress QoS policy for the egress forwarding complex sets the IEEE 802.1 dot1p bits.

Multiple commands can be entered to associate some or all of the 64 DSCP values with the forwarding class. For undefined code points, packets are assigned to the default forwarding class for the DSCP value. [Table 127](#) lists the default forwarding class for each DSCP value.

The **no** form of the command resets the DSCP value to its default forwarding class.

Note: If the **fc-queue** option is configured in the **sgt-qos>application** *dscp-app-name* command, the mapping created with this command is ignored for packets generated by the applications that are configured with the option.

Table 127 DSCP-to-Default Forwarding Class Mapping (Continued)

DSCP Value	Default FC
cp60	be
cp61	be
cp62	be
cp63	be

Default See [Table 127](#) for the default forwarding class for each DSCP value.

Parameters *dscp-name* — the DSCP name to be associated with the forwarding class. DSCP can only be specified by its name and only an existing value can be specified. The software provides names for the well-known code points.

Values be, ef, cp1, cp2, cp3, cp4, cp5, cp6, cp7, cp9, cs1, cs2, cs3, cs4, cs5, nc1, nc2, af11, af12, af13, af21, af22, af23, af31, af32, af33, af41, af42, af43, cp11, cp13, cp15, cp17, cp19, cp21, cp23, cp25, cp27, cp29, cp31, cp33, cp35, cp37, cp39, cp41, cp42, cp43, cp44, cp45, cp47, cp49, cp50, cp51, cp52, cp53, cp54, cp55, cp57, cp58, cp59, cp60, cp61, cp62, cp63

fc-name — the forwarding class name. All packets with a DSCP value or MPLS EXP bits that are not defined will be placed in this forwarding class.

Values be, l2, af, l1, h2, ef, h1, nc

snmp-community

Syntax **snmp-community** *community-name* [**hash** | **hash2**] [**version** *SNMP-version*]
no snmp-community *community-name* [**hash** | **hash2**]

Context config>service>vprn

Description This command sets the SNMP community name to be used with the associated VPRN instance.

If an SNMP community name is not specified, SNMP access is not allowed.

The **no** form of the command removes the SNMP community name from the given VPRN context.

Default n/a

Parameters *community-name* — one or more SNMP community names

Values community-name: 32 characters (max)
hash-key: 33 characters (max)

hash2-key: 96 characters (max)

hash, hash2 — the hashing scheme for the community name

SNMP-version — the SNMP version

Values v1, v2c, both

source-address

Syntax	source-address
Context	config>service>vprn
Description	This command enters the context to specify the source address and application that should be used in all unsolicited packets.

application

Syntax	application app {[ping ptp ssh telnet traceroute]} {[<i>ip-int-name</i> <i>ip-address</i>]} no application app {[ping ptp ssh telnet traceroute]}
Context	config>service>vprn>source-address
Description	This command configures the application to use the IPv4 source address. The no form of the command removes the application name from using the IPv4 source address.
Parameters	app — the application name Values ping, ptp, ssh, telnet, traceroute <i>ip-int-name</i> <i>ip-address</i> — the name of the IPv4 interface or IPv4 address. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes. Values <i>ip-int-name</i> : up to 32 alphanumeric characters <i>ip-address</i> : a.b.c.d

application6

Syntax	application6 app {[ping telnet ssh traceroute]} <i>ipv6-address</i> no application6 app {[ping telnet ssh traceroute]}
Context	config>service>vprn>source-address
Description	This command configures the application to use the IPv6 source address.

The **no** form of the command removes the application name from using the IPv6 source address.

Parameters	app — the application name
	Values ping, telnet, ssh, traceroute
	<i>ipv6-address</i> — the IPv6 address
	Values
	<i>ipv6-address:</i> x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d
	x - [0 to FFFF]H
	d - [0 to 255] D

spoke-sdp

Syntax	[no] spoke-sdp <i>sdp-id</i>
Context	config>service>vprn
Description	This command binds a service to an existing Service Distribution Point (SDP). The SDP has an operational state that determines the operational state of the SDP within the service. For example, if the SDP is administratively or operationally down, the SDP for the service will be down. The SDP must already be defined in the config>service>sdp context in order to associate an SDP with a VPRN service. If the sdp <i>sdp-id</i> is not already configured, an error message is generated. If the <i>sdp-id</i> exists, a binding between that <i>sdp-id</i> and the service is created. SDPs must be explicitly associated and bound to a service. If an SDP is not bound to a service, no far-end routers can participate in the service. Alternatively, the auto-bind feature can be used. With auto-bind-tunnel, no vprn>spoke-sdp configuration is required. When both auto-bind-tunnel and spoke-sdp are configured, spoke-sdp takes precedence. The spoke-sdp configuration must be deconfigured for the auto-bind feature to take effect. The no form of this command removes the SDP binding from the service. The SDP configuration is not affected; only the binding of the SDP to a service is affected. Once the SDP is removed, no packets are forwarded to the far-end router.
Default	n/a
Special Cases	VPRN — several SDPs can be bound to a VPRN service. Each SDP must be destined for a different 7705 SAR, 7750 SR, or 7710 SR router. If two <i>sdp-id</i> bindings terminate on the same 7705 SAR, an error occurs and the second SDP binding is rejected.
Parameters	<i>sdp-id</i> — the SDP identifier
	Values 1 to 17407

static-route-entry

Syntax	static-route-entry { <i>ip-prefix</i> <i>prefix-length</i> } no static-route-entry { <i>ip-prefix</i> <i>prefix-length</i> }														
Context	config>service>vpn														
Description	This command creates a static route entry within the associated router instance. A prefix and prefix length must be specified. Once the static route context for the specified prefix and length has been created, additional parameters associated with the static routes may be specified. When configuring a static route, multiple types of static routes (blackhole, grt, indirect, ipsec-tunnel, and next-hop) can be applied to the same IPv4 or IPv6 prefix. If a static route that is forwarding traffic goes down, the default route will be used instead. The preference parameter specifies the order in which the routes are applied. If a blackhole static route has the same preference as another route with the same prefix, the blackhole route takes a lower precedence. Before the static route entry can be deleted, the next hops associated with the prefix must be shut down and deleted. The no form of the command deletes the static route entry. If a static route needs to be removed when multiple static routes exist to the same destination, as many parameters as are necessary to uniquely identify the static route must be entered.														
Default	no static-route-entry														
Parameters	<i>ip-prefix/prefix-length</i> — the destination address of the static route														
Values	<table><tr><td><i>ipv4-prefix</i>:</td><td>a.b.c.d (host bits must be 0)</td></tr><tr><td><i>ipv4-prefix-length</i>:</td><td>0 to 32</td></tr><tr><td><i>ipv6-prefix</i>:</td><td>x:x:x:x:x:x:x (eight 16-bit pieces)</td></tr><tr><td></td><td>x:x:x:x:x:d.d.d.d</td></tr><tr><td></td><td>x: [0 to FFFF]H</td></tr><tr><td></td><td>d: [0 to 255] D</td></tr><tr><td><i>ipv6-prefix-length</i>:</td><td>0 to 128</td></tr></table>	<i>ipv4-prefix</i> :	a.b.c.d (host bits must be 0)	<i>ipv4-prefix-length</i> :	0 to 32	<i>ipv6-prefix</i> :	x:x:x:x:x:x:x (eight 16-bit pieces)		x:x:x:x:x:d.d.d.d		x: [0 to FFFF]H		d: [0 to 255] D	<i>ipv6-prefix-length</i> :	0 to 128
<i>ipv4-prefix</i> :	a.b.c.d (host bits must be 0)														
<i>ipv4-prefix-length</i> :	0 to 32														
<i>ipv6-prefix</i> :	x:x:x:x:x:x:x (eight 16-bit pieces)														
	x:x:x:x:x:d.d.d.d														
	x: [0 to FFFF]H														
	d: [0 to 255] D														
<i>ipv6-prefix-length</i> :	0 to 128														

black-hole

Syntax	[no] black-hole
Context	config>service>vprn>static-route-entry
Description	This command specifies that the route is a blackhole route. If the destination address on a packet matches this static route, it will be silently discarded. If the static route is configured with the same destination address and subnet mask as a previously configured static route, the newly configured route replaces the previous one, and unless specified, the defaults for preference and metric are applied. Before the static route entry can be deleted, the next hops associated with the prefix must be shut down and deleted.
Default	no black-hole

metric

Syntax	[no] metric <i>metric</i>
Context	config>service>vprn>static-route-entry>black-hole config>service>vprn>static-route-entry>grt config>service>vprn>static-route-entry>indirect config>service>vprn>static-route-entry>ipsec-tunnel config>service>vprn>static-route-entry>next-hop
Description	This command specifies the cost (metric) for the static route, expressed as a decimal integer. This value is used when importing the static route into other protocols such as OSPF. When modifying the metric of an existing static route, the preference will not change unless specified. This value is also used to determine which static route to install in the forwarding table. • If there are multiple static routes with the same preference but different metrics, the lower-cost (lower metric) route will be installed. • If there are multiple static routes with equal preference and metrics, the 7705 SAR chooses the route with the lowest next-hop IP address as the best route. • If there are multiple routes with unequal preferences, the lower preference route is installed. The no form of this command returns the metric to the default value.
Default	no metric

Parameters *metric* — the metric value

Values 0 to 65535

Default 1

preference

Syntax **preference** *preference*
no preference

Context config>service>vprn>static-route-entry>black-hole
 config>service>vprn>static-route-entry>grt
 config>service>vprn>static-route-entry>indirect
 config>service>vprn>static-route-entry>ipsec-tunnel
 config>service>vprn>static-route-entry>next-hop

Description This command specifies the preference of this static route over routes from different sources such as BGP or OSPF. The preference is expressed as a decimal integer. A route with a lower preference value is preferred over a route with a higher preference value.

When modifying the preference value of an existing static route, the metric will not change unless specified. The **preference** command is also used to prioritize static routes applied to the same prefix. If a blackhole static route has the same preference as another route with the same prefix, the blackhole route takes a lower precedence.

If multiple routes are learned with an identical preference using the same protocol, the lowest-cost route is used. If multiple routes are learned with an identical preference using the same protocol and the costs (metrics) are equal, the decision of which route to use is determined by the [ecmp](#) command.

[Table 128](#) shows the default route preference based on the route source.

Table 128 Default Route Preference

Label	Preference	Configurable
Direct attached	0	No
Static route	5	Yes
OSPF internal routes	10	Yes
IS-IS level 1 internal	15	Yes
IS-IS level 2 internal	18	Yes
OSPF external	150	Yes
IS-IS level 1 external	160	Yes

Table 128 Default Route Preference (Continued)

Label	Preference	Configurable
IS-IS level 2 external	165	Yes
BGP	170	Yes

The **no** form of this command returns the static route preference to its default value.

Default 5

Parameters *preference* — the route preference value

Values 1 to 255

prefix-list

Syntax **[no] prefix-list** *prefix-list-name* {**all** | **none**}

Context config>service>vprn>static-route-entry>black-hole
config>service>vprn>static-route-entry>indirect
config>service>vprn>static-route-entry>next-hop

Description This command adds a constraint to the static route such that the static route is only active if **none** or **all** of the prefixes in the prefix list are present and active in the route table.

Default no prefix-list

Parameters *prefix-list-name* — the name of a currently configured prefix list

all — specifies that the static route condition is met if all prefixes in the prefix list are present in the active route table

none — specifies that the static condition is met if none of the prefixes in the prefix list are present in the active route table

tag

Syntax **[no] tag** *tag*

Context config>service>vprn>static-route-entry>black-hole
config>service>vprn>static-route-entry>indirect
config>service>vprn>static-route-entry>ipsec-tunnel
config>service>vprn>static-route-entry>next-hop

Description This command adds a 32-bit integer tag to the static route. The tag is used in route policies to control distribution of the route into other protocols.

Default	1
Parameters	<i>tag</i> — specifies an integer tag value
Values	1 to 4294967295

grt

Syntax	[no] grt
Context	config>service>vprn>static-route-entry
Description	This command creates a static route in a VPRN service context that points to the global routing context (base router). This is primarily used to allow traffic that ingresses through a VPRN service to be routed out of the global routing context. The grt type of next hop cannot be used in conjunction with any other next-hop types.
Default	no grt

indirect

Syntax	[no] indirect <i>ip-address</i>										
Context	config>service>vprn>static-route-entry										
Description	This command specifies that the route is indirect and specifies the next-hop IP address used to reach the destination. The configured <i>ip-address</i> is not directly connected to a network configured on this node. The destination can be reached via multiple paths. The indirect address can only be resolved via a dynamic routing protocol. Another static route cannot be used to resolve the indirect address. The <i>ip-address</i> can be either on the network side or the access side and is typically at least one hop away from the node.										
Default	no indirect										
Parameters	<i>ip-address</i> — the IP address of the IP interface										
Values	<table><tr><td><i>ipv4-address</i></td><td>a.b.c.d</td></tr><tr><td><i>ipv6-address</i></td><td>x:x:x:x:x:x:x (eight 16-bit pieces)</td></tr><tr><td></td><td>x:x:x:x:x:d.d.d.d</td></tr><tr><td></td><td>x: [0 to FFFF]H</td></tr><tr><td></td><td>d: [0 to 255]D</td></tr></table>	<i>ipv4-address</i>	a.b.c.d	<i>ipv6-address</i>	x:x:x:x:x:x:x (eight 16-bit pieces)		x:x:x:x:x:d.d.d.d		x: [0 to FFFF]H		d: [0 to 255]D
<i>ipv4-address</i>	a.b.c.d										
<i>ipv6-address</i>	x:x:x:x:x:x:x (eight 16-bit pieces)										
	x:x:x:x:x:d.d.d.d										
	x: [0 to FFFF]H										
	d: [0 to 255]D										

cpe-check

Syntax	[no] cpe-check <i>cpe-ip-address</i>										
Context	config>service>vprn>static-route-entry>indirect config>service>vprn>static-route-entry>next-hop										
Description	This command enables CPE connectivity check and specifies the IP address of the target CPE device. ICMP pings will be sent to this target IP address. This parameter must be configured to enable the CPE connectivity feature for the static route. The <i>cpe-ip-address</i> cannot be in the same subnet as the static route subnet to avoid possible circular references. CPE check and BFD support are mutually exclusive on a static route. If a CPE connectivity check target address is already being used as the target address in a different static route, cpe-check parameters must match. If they do not match, the new configuration command will be rejected. If a static-route-entry>indirect command or static-route-entry>next-hop command is issued with no cpe-check target but the destination <i>prefix/prefix-length</i> and the next hop match a static route that has an associated cpe-check, the cpe-check test is removed from the static route. The no form of this command disables the cpe-check option.										
Default	no cpe-check										
Parameters	<i>cpe-ip-address</i> — the IP address of the CPE device										
	Values <table> <tr> <td><i>ipv4-address</i></td><td>a.b.c.d</td></tr> <tr> <td><i>ipv6-address</i></td><td>x:x:x:x:x:x:x (eight 16-bit pieces)</td></tr> <tr> <td></td><td>x:x:x:x:x:x.d.d.d</td></tr> <tr> <td></td><td>x: [0 to FFFF]H</td></tr> <tr> <td></td><td>d: [0 to 255]D</td></tr> </table>	<i>ipv4-address</i>	a.b.c.d	<i>ipv6-address</i>	x:x:x:x:x:x:x (eight 16-bit pieces)		x:x:x:x:x:x.d.d.d		x: [0 to FFFF]H		d: [0 to 255]D
<i>ipv4-address</i>	a.b.c.d										
<i>ipv6-address</i>	x:x:x:x:x:x:x (eight 16-bit pieces)										
	x:x:x:x:x:x.d.d.d										
	x: [0 to FFFF]H										
	d: [0 to 255]D										

drop-count

Syntax	drop-count <i>count</i> no drop-count
Context	config>service>vprn>static-route-entry>indirect>cpe-check config>service>vprn>static-route-entry>next-hop>cpe-check
Description	This command specifies the number of consecutive ping replies that must be missed in order to declare the CPE down and to deactivate the static route.
Default	3

Parameters *count* — an integer count value
Values 1 to 255

interval

Syntax **interval** *seconds*
no interval

Context config>service>vprn>static-route-entry>indirect>cpe-check
config>service>vprn>static-route-entry>next-hop>cpe-check

Description This command specifies the interval, in seconds, between ICMP pings to the target IP address.

Default 1

Parameters *seconds* — an integer interval value
Values 1 to 255

log

Syntax **[no] log**

Context config>service>vprn>static-route-entry>indirect>cpe-check
config>service>vprn>static-route-entry>next-hop>cpe-check

Description This command enables the logging of transitions between active and inactive routes based on the CPE connectivity check. Events will be sent to the system log, syslog, and SNMP traps.

Default no log

ipsec-tunnel

Syntax **[no] ipsec-tunnel** *ipsec-tunnel-name*

Context config>service>vprn>static-route-entry

Description This command creates a static route in a VPRN service context that points to an IPsec tunnel.

If a static route is configured with the same destination address, subnet mask, and IPsec tunnel name as a previously configured static route, the newly configured route replaces the previous one, and unless specified, the default values for the **preference** and **metric** commands are applied.

Default no ipsec-tunnel

Parameters *ipsec-tunnel-name* — the IPsec tunnel name; the IPsec tunnel specifies the local and peer gateway addresses for the tunnel

next-hop

Syntax **[no] next-hop** {*ip-int-name* | *ip-address* | *ipv6-address*}

Context config>service>vprn>static-route-entry

Description This command specifies the directly connected next-hop IP address or interface used to reach the destination. If the next hop is over an unnumbered interface, the interface name of the unnumbered interface can be used.

The configured *ip-address* can be either on the network side or the access side on the node. The address must be associated with a network that is directly connected to a network configured on the node.

Default no next-hop

Parameters *ip-int-name*, *ip-address*, *ipv6-address* — the IP interface name, IPv4 address, or IPv6-address

Values

<i>ip-int-name</i>	32 characters max
<i>ipv4-address</i>	a.b.c.d
<i>ipv6-address</i>	x:x:x:x:x:x[-interface]
	x:x:x:x:x:d.d.d.d[-interface]
	x: [0 to FFFF]H
	d: [0 to 255]D
	interface: 32 characters maximum, mandatory for link local addresses

bfd-enable

Syntax **[no] bfd-enable**

Context config>service>vprn>static-route-entry>next-hop

Description This command associates the static route state with a BFD session between the local system and the configured next hop.

The remote end of the BFD session must also be configured to originate or accept the BFD session controlling the static route state.

The **no** form of this command removes the association of the static route state with the BFD session.

Default no bfd-enable

type

Syntax **type hub**
no type

Context config>service>vprn

Description This command designates the type of VPRN instance being configured for hub and spoke topologies.

The **no** form of the command resets to the default of a fully meshed VPRN.

Default no type

Parameters **hub** — a hub VPRN, which allows all traffic from the hub SAP to be routed directly to the destination, while all traffic from spoke VPRNs or network interfaces can only be routed to a hub SAP

vrf-export

Syntax **vrf-export** *policy-name* [*policy-name...*(up to 5 max)]
no vrf-export

Context config>service>vprn

Description This command specifies the export policies to control routes exported from the local VPN virtual routing/ forwarding table (VRF) to other VRFs on the same or remote PE routers (via MP-BGP). The policy (and *policy-name*) are defined under the **config>router>policy-options>policy-statement** command.

Aggregate routes are not advertised via MP-BGP protocols to the other MP-BGP peers.

The **no** form of the command removes all route policy names from the export list.

Default n/a

Parameters *policy-name* — the route policy statement name (up to 32 characters)

vrf-import

Syntax **vrf-import** *policy-name* [*policy-name...*(up to 5 max)]
no vrf-import

Context config>service>vprn

Description	This command sets the import policies to control routes imported to the local VPN virtual routing/ forwarding table (VRF) from other VRFs on the same or remote PE routers (via MP-BGP). BGP-VPN routes imported with a vrf-import policy will use the BGP preference value of 170 when imported from remote PE routers, or retain the protocol preference value of the exported route when imported from other VRFs on the same router, unless the preference is changed by the policy. The no form of the command removes all route policy names from the import list.
Default	n/a
Parameters	<i>policy-name</i> — the route policy statement name (up to 32 characters)

vrf-target

Syntax	vrf-target { <i>ext-community</i> {[export <i>ext-community</i>] [import <i>ext-community</i>]}} no vrf-target
Context	config>service>vprn
Description	This command facilitates a simplified method to configure the route target to be added to advertised routes or compared against received routes from other VRFs on the same or remote PE routers (via MP-BGP). BGP-VPN routes imported with a vrf-target statement will use the BGP preference value of 170 when imported from remote PE routers, or retain the protocol preference value of the exported route when imported from other VRFs in the same router. Specified vrf-import or vrf-export policies override the vrf-target policy. The no form of the command removes the route target from the VRF.
Default	no vrf-target
Parameters	<i>ext-community</i> — an extended BGP community in the <i>type:x:y</i> format. Values <i>ip-addr:comm-val</i> <i>2byte-asnumber:ext-comm-val</i> <i>4-byte-asnumber: comm-val</i> where <i>ip-addr:</i> a.b.c.d <i>comm-val:</i> 0 to 65535 <i>2-byte-asnumber:</i> 0 to 65535 <i>ext-comm-val:</i> 0 to 4294967295 <i>4-byte-asnumber:</i> 0 to 4294967295 export <i>ext-community</i> — communities allowed to be sent to remote PE neighbors import <i>ext-community</i> — communities allowed to be accepted from remote PE neighbors

7.8.2.1.3 BGP Commands

bgp

Syntax	[no] bgp
Context	config>service>vprn
Description	This command enables the BGP protocol on the VPRN service. The no form of this command disables the BGP protocol on the VPRN service.
Default	no bgp

advertise-inactive

Syntax	[no] advertise-inactive
Context	config>service>vprn>bgp config>service>vprn>bgp>group config>service>vprn>bgp>group>neighbor
Description	This command enables the advertising of inactive BGP routes to other BGP peers. By default, BGP only advertises BGP routes to other BGP peers if a given BGP route is chosen by the route table manager as the most preferred route within the system and is active in the forwarding plane. This command allows system administrators to advertise a BGP route even though it is not the most preferred route within the system for a given destination. The no form of this command disables the advertising of inactive BGP routes to other BGP peers.
Default	no advertise-inactive

aggregator-id-zero

Syntax	[no] aggregator-id-zero
Context	config>service>vprn>bgp config>service>vprn>bgp>group config>service>vprn>bgp>group>neighbor
Description	This command is used to set the router ID in the BGP aggregator path attribute to 0 when BGP aggregates routes. This prevents different routers within an AS from creating aggregate routes that contain different AS paths.

When BGP is aggregating routes, it adds the aggregator path attribute to the BGP Update messages. By default, BGP adds the AS number and router ID to the aggregator path attribute.

When this command is enabled, BGP adds only the router ID (set to 0) to the aggregator path attribute. This command is used at the group level to revert to the value defined under the global level, and this command is used at the neighbor level to revert to the value defined under the group level.

The **no** form of the command used at the global level reverts to the default, where BGP adds the AS number and router ID to the aggregator path attribute.

The **no** form of the command used at the group level reverts to the value defined at the global level.

The **no** form of the command used at the neighbor level reverts to the value defined at the group level.

Default no aggregator-id-zero

as-override

Syntax [no] as-override

Context config>service>vprn>bgp>group
config>service>vprn>bgp>group>neighbor

Description This command replaces all instances of the peer's AS number with the local AS number in a BGP route's AS path.

This command breaks the BGP loop detection mechanism. It should be used carefully.

Default no as-override

auth-keychain

Syntax auth-keychain *name*
no auth-keychain

Context config>service>vprn>bgp
config>service>vprn>bgp>group
config>service>vprn>bgp>group>neighbor

Description This command associates an authentication keychain with the BGP protocol. The keychain is a collection of keys used to authenticate BGP messages from remote neighbors. The keychain allows the rollover of authentication keys during the lifetime of a session and also supports stronger authentication algorithms than clear text and MD5.

The keychain must already be defined in the **config>system>security>keychain** context.

Either the **authentication-key** command or the **auth-keychain** command can be used by BGP, but both cannot be supported at the same time. If both commands are configured, the **auth-keychain** configuration will be applied and the **authentication-key** command will be ignored.

By default, authentication is not enabled.

Default	no auth-keychain
Parameters	<i>name</i> — the name of an existing keychain, up to 32 characters

authentication-key

Syntax	authentication-key { <i>authentication-key</i> <i>hash-key</i> } [hash hash2] no authentication-key
Context	config>service>vprn>bgp config>service>vprn>bgp>group config>service>vprn>bgp>group>neighbor
Description	This command configures the BGP authentication key. Authentication is performed between neighboring routers before setting up the BGP session by verifying the password. Authentication is performed using the MD5 message-based digest. The authentication key can be any combination of ASCII characters up to 255 characters long. Either the authentication-key command or the auth-keychain command can be used by BGP, but both cannot be supported at the same time. If both commands are configured, the auth-keychain configuration will be applied and the authentication-key command will be ignored. The no form of the command removes the authentication password from the configuration and effectively disables authentication.
Default	Authentication is disabled and the authentication password is empty.
Parameters	<i>authentication-key</i> — the authentication key. The key can be any combination of ASCII characters up to 255 characters in length (unencrypted). If spaces are used in the string, the entire string must be enclosed in quotation marks (" "). <i>hash-key</i> — the hash key. The key can be any combination of ASCII characters up to 342 characters in length (encrypted). If spaces are used in the string, the entire string must be enclosed in quotation marks (" "). This is useful when a user must configure the parameter, but for security purposes, the actual unencrypted key value is not provided.

hash — specifies that the key is entered in an encrypted form. If the **hash** parameter is not used, the key is assumed to be in a non-encrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** parameter specified.

hash2 — specifies that the key is entered in a more complex encrypted form. If the **hash2** parameter is not used, the less encrypted **hash** form is assumed.

backup-path

Syntax	[no] backup-path [ipv4] [ipv6]
Context	config>service>vprn>bgp
Description	This command enables BGP Fast Reroute (FRR) with Prefix-Independent Convergence (PIC), allowing for the creation of a backup path for IPv4 or IPv6 BGP learned prefixes belonging to a VPRN. Multiple paths must be received for a prefix in order to take advantage of this feature. When a prefix has a backup path, and its primary paths fail, the affected traffic is rapidly diverted to the backup path without waiting for control plane reconvergence to occur. The time to reroute the traffic is independent of the number of prefixes sharing the primary or backup paths. The no form of the command disables BGP FRR with PIC.
Default	no backup-path
Parameters	ipv4 — enables a backup path for IPv4 BGP learned prefixes ipv6 — enables a backup path for IPv6 BGP learned prefixes

best-path-selection

Syntax	best-path-selection
Context	config>service>vprn>bgp
Description	This command enables path selection configuration.

always-compare-med

Syntax	always-compare-med [zero infinity] always-compare-med strict-as [zero infinity] no always-compare-med
Context	config>service>vprn>bgp>path-selection
Description	This command specifies how the Multi-Exit Discriminator (MED) path attribute is used in the BGP route selection process. If this command is used without the strict-as option, the MEDs of two paths are always compared even if the paths have a different neighbor AS. If the strict-as option is used, the MEDs of two paths are compared only if they come from the same neighboring AS. The zero and infinity options specify how to treat paths that do not have a MED attribute; for example, always-compare-med zero means that if one path is missing a MED attribute, it is treated as though it had a MED attribute with the value of 0. If neither option is specified, the zero option is implied. The no form of the command means that only the MEDs of paths that have the same neighbor AS are compared.
Default	no always-compare-med
Parameters	zero — specifies that for routes learned without a MED attribute, a zero (0) value is used in the MED comparison. The routes with the lowest metric are the most preferred. infinity — specifies that for routes learned without a MED attribute, a value of infinity (4294967295) is used in the MED comparison. This, in effect, makes these routes the least desirable. strict-as — specifies that the MEDs of two paths are compared only if they come from the same neighboring AS

as-path-ignore

Syntax	as-path-ignore [ipv4] [ipv6] no as-path-ignore
Context	config>service>vprn>bgp>path-selection
Description	This command determines whether the AS path is used to determine the best BGP route. If this command is enabled, the AS paths of incoming routes are not used in the route selection process.

When **as-path-ignore** is used without specifying one or more keywords, then all keywords are configured. When one or more keywords are specified, then only those keywords are configured.

The **no** form of the command means that the AS paths of incoming routes are used to determine the best BGP route.

Default	no as-path-ignore
Parameters	ipv4 — specifies support for IPv4 routes ipv6 — specifies support for IPv6 routes

bfd-enable

Syntax	[no] bfd-enable
Context	config>service>vprn>bgp config>service>vprn>bgp>group config>service>vprn>bgp>group>neighbor
Description	This command enables the use of bidirectional forwarding (BFD) to control the state of the associated protocol interface. By enabling BFD on a given protocol interface, the state of the protocol interface is tied to the state of the BFD session between the local node and the remote node. The parameters used for BFD are set via the BFD command under the IP interface. The no form of this command removes BFD from the associated BGP protocol peering.
Default	no bfd-enable

connect-retry

Syntax	connect-retry <i>seconds</i> no connect-retry
Context	config>service>vprn>bgp config>service>vprn>bgp>group config>service>vprn>bgp>group>neighbor
Description	This command configures the BGP connect retry timer value in seconds. When this timer expires, BGP tries to reconnect to the configured peer. This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in group) or neighbor level (only applies to specified peer). The most specific value is used. The no form of the command used at the global level reverts to the default value. The no form of the command used at the group level reverts to the value defined at the global level.

The **no** form of the command used at the neighbor level reverts to the value defined at the group level.

Default	120 s
Parameters	<i>seconds</i> — the BGP connect retry timer value, in seconds, expressed as a decimal integer
Values	1 to 65535

damping

Syntax	[no] damping
Context	config>service>vprn>bgp config>service>vprn>bgp>group config>service>vprn>bgp>group>neighbor
Description	This command enables BGP damping for learned routes that are defined within the VPRN service. Damping parameters are set at the route policy level. Refer to the 7705 SAR Router Configuration Guide, “Route Policy Command Reference”. The no form of the command disables learned route damping. The no form of the command used at the group level reverts to the value defined at the global level. The no form of the command used at the neighbor level reverts to the value defined at the group level.
Default	no damping

disable-communities

Syntax	disable-communities [standard] [extended] no disable-communities
Context	config>service>vprn>bgp config>service>vprn>bgp>group config>service>vprn>bgp>group>neighbor
Description	This command configures BGP to disable sending communities.
Default	no disable-communities
Parameters	standard — specifies standard communities that existed before VPRNs or RFC 2547 extended — specifies BGP communities that were expanded after the concept of RFC 2547 was introduced, to include handling the route target in the VRF

disable-fast-external-failover

Syntax	[no] disable-fast-external-failover
Context	config>service>vprn>bgp config>service>vprn>bgp>group config>service>vprn>bgp>group>neighbor
Description	This command configures BGP fast external failover. For EBGP neighbors, fast external failover controls whether the router should drop an EBGP session immediately upon an interface-down event, or whether the BGP session is kept up until the hold-time expires. When fast external failover is disabled, the EBGP session stays up until the hold-time expires or the interface comes back up again. If the BGP routes become unreachable as a result of the interface going down, they are immediately withdrawn from other peers.
Default	no disable-fast-external-failover

dynamic-neighbor

Syntax	dynamic-neighbor
Context	config>service>vprn>bgp>group
Description	This command enables the context to configure dynamic BGP sessions for a peer group.

prefix

Syntax	[no] prefix <i>ip-prefix/ip-prefix-length</i>
Context	config>service>vprn>bgp>group>dynamic-neighbor
Description	This command configures a prefix to accept dynamic BGP sessions, which are sessions from source IP addresses that do not match any configured (static) neighbor addresses. A dynamic session is associated with the group having the longest-match prefix entry for the source IP address of the peer. There is no limit on the number of prefixes that can be configured. The group association determines local parameters that apply to the session, including the local AS, local IP address, MP-BGP families, and import and export policies. The no form of this command removes a prefix entry.
Default	none
Parameters	<i>ip-prefix/ip-prefix-length</i> — specifies a prefix from which to accept dynamic BGP sessions
Values	<i>ipv4-prefix</i> — a.b.c.d (host bits must be 0)

ipv4-prefix-length — 0 to 32
ipv6-prefix — x:x:x:x:x:x:x:x (eight 16-bit pieces)
 x:x:x:x:x:d.d.d.d
 x — [0 to FFFF]H
 d — [0 to 255]D
ipv6-prefix-length — 0 to 128

dynamic-neighbor-limit

Syntax	dynamic-neighbor-limit <i>peers</i> no dynamic-neighbor-limit
Context	config>service>vprn>bgp config>service>vprn>bgp>group
Description	This command configures the maximum number of dynamic BGP sessions that will be accepted from remote peers associated with the global BGP instance or a specific peer group. If accepting a new dynamic session would cause either the group limit or the global limit to be exceeded, the new session attempt is rejected and a notification message is sent back to the remote peer. The no form of this command removes the limit on the number of dynamic sessions.
Default	no dynamic-neighbor-limit
Parameters	<i>peers</i> — specifies the maximum number of dynamic BGP sessions Values 1 to 8192

enable-bgp-vpn-backup

Syntax	[no] enable-bgp-vpn-backup [ipv4] [ipv6]
Context	config>service>vprn>bgp
Description	This command allows BGP-VPN routes imported into the VPRN to be used as backup paths for IPv4 or IPv6 BGP learned prefixes.
Parameters	ipv4 — allow BGP-VPN routes to be used as backup paths for IPv4 prefixes ipv6 — allow BGP-VPN routes to be used as backup paths for IPv6 prefixes

enable-peer-tracking

Syntax **[no] enable-peer-tracking**

Context config>service>vprn>bgp
 config>service>vprn>bgp>group
 config>service>vprn>bgp>group>neighbor

Description This command enables BGP peer tracking. BGP peer tracking allows a BGP peer to be dropped immediately if the route used to resolve the BGP peer address is removed from the IP routing table and there is no alternative available. The BGP peer will not wait for the hold timer to expire; therefore, the BGP reconvergence process is accelerated.

The **no** form of the command disables peer tracking.

Default no enable-peer-tracking

export

Syntax **export** *policy-name* [*policy-name*...(up to 5 max)]
no export

Context config>service>vprn>bgp
 config>service>vprn>bgp>group
 config>service>vprn>bgp>group>neighbor

Description This command specifies the export policies used to control routes advertised to BGP neighbors. Route policies are configured in the **config>router>policy-options** context. Refer to the section on “Route Policy” in the 7705 SAR Router Configuration Guide.

When multiple policy names are specified, the policies are evaluated in the order in which they are specified. A maximum of five (5) policy names can be configured. The first policy that matches is applied.

If a non-existent route policy is applied to a VPRN instance, the CLI generates a warning message. This message is only generated during an interactive CLI session. No warning message is generated when a non-existent route policy is applied to a VPRN instance in a configuration file or when SNMP is used.

The **no** form of this command removes all route policy names from the export list.

Default no export—BGP routes are advertised and non-BGP routes are not advertised

Parameters *policy-name* — the route policy name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

family

Syntax **family** [ipv4] [ipv6]
no family

Context	config>service>vprn>bgp config>service>vprn>bgp>group config>service>vprn>bgp>group>neighbor
Description	This command specifies the address families to be negotiated with one or more multiprotocol BGP peers of the VPRN. The no form of this command removes the specified address family from the associated BGP sessions.
Default	ipv4
Parameters	ipv4 — provisions IPv4 support ipv6 — provisions IPv6 support

graceful-restart

Syntax	[no] graceful-restart
Context	config>service>vprn>bgp config>service>vprn>bgp>group config>service>vprn>bgp>group>neighbor
Description	This command enables graceful restart for BGP in the VPRN context. If the control plane of a GR-capable router fails, the VPRN BGP peers (GR helpers) temporarily preserve neighbor information, so packets continue to be forwarded through the failed GR router using the last known routes. The helper state remains until the peer completes its restart or exits if the GR timer value is exceeded. The 7705 SAR acts as a GR helper; it does not request graceful restart but agrees to graceful restart requests from a peer. The no form of the command disables graceful restart and removes all graceful restart configurations in the VPRN BGP instance.
Default	no graceful-restart

stale-routes-time

Syntax	stale-routes-time <i>time</i> no stale-routes-time
Context	config>service>vprn>bgp>graceful-restart config>service>vprn>bgp>group>graceful-restart config>service>vprn>bgp>group>neighbor>graceful-restart
Description	This command configures the maximum amount of time in seconds that stale routes should be maintained after a graceful restart is initiated.

The **no** form of the command resets the stale routes time back to the default value.

Default	360 s
Parameters	<i>time</i> — the amount of time that stale routes should be maintained after a graceful restart is initiated
Values	1 to 3600 s

group

Syntax	[no] group <i>name</i>
Context	config>service>vprn>bgp
Description	This command creates a context to configure a BGP peer group. The no form of the command deletes the specified peer group and all configurations associated with the peer group. The group must be shut down before it can be deleted.
Default	no group—no peer groups are defined
Parameters	<i>name</i> — the peer group name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

neighbor

Syntax	[no] neighbor <i>ip-address</i>
Context	config>service>vprn>bgp>group
Description	This command creates a BGP peer/neighbor instance within the context of the BGP group. This command can be issued repeatedly to create multiple peers and their associated configurations. The no form of the command is used to remove the specified neighbor and the entire configuration associated with the neighbor. The neighbor must be administratively shut down before it can be deleted. If the neighbor is not shut down, the command will not result in any action except a warning message on the CLI indicating that the neighbor is still administratively up.
Default	no neighbor—no neighbors are defined
Parameters	<i>ip-address</i> — the IP address of the BGP peer router
Values	<i>ipv4-address:</i> a.b.c.d

ipv6-address: x:x:x:x:x:x[-interface]
 x:x:x:x:x:x.d.d.d[-interface]
 interface - 32 chars max,
 mandatory for link local addresses
 x: [0 to FFFF]H
 d: [0 to 255]D

hold-time

Syntax	hold-time <i>seconds</i> [strict] no hold-time
Context	config>service>vprn>bgp config>service>vprn>bgp>group config>service>vprn>bgp>group>neighbor
Description	This command configures the BGP hold time, expressed in seconds. The BGP hold time specifies the maximum time BGP waits between successive messages (either Keepalive or Update) from its peer, before closing the connection. This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in group) or neighbor level (only applies to specified peer). The most specific value is used. The strict option ensures that the negotiated hold time value is not set to a value less than the configured value. Even though the 7705 SAR implementation allows setting the keepalive time separately, the configured keepalive timer is overridden by the hold-time value under the following circumstances. • If the specified hold-time is less than the configured keepalive time, then the operational keepalive time is set to a third of the hold-time; the configured keepalive time is not changed. • If the hold-time is set to 0, then the operational value of the keepalive time is set to 0; the configured keepalive time is not changed. This means that the connection with the peer is up permanently and no keepalive packets are sent to the peer. The no form of the command used at the global level reverts to the default value. The no form of the command used at the group level reverts to the value defined at the global level. The no form of the command used at the neighbor level reverts to the value defined at the group level.
Default	90 s

Parameters	<i>seconds</i> — the hold-time, in seconds, expressed as a decimal integer. A value of 0 indicates the connection to the peer is permanently up. Values 0, 3 to 65535 strict — when used, the advertised BGP hold time from the far-end BGP peer must be greater than or equal to the specified hold-time value

import

Syntax	import <i>policy-name</i> [<i>policy-name...</i> (up to 5 max)] no import
Context	config>service>vprn>bgp config>service>vprn>bgp>group config>service>vprn>bgp>group>neighbor
Description	This command specifies the import route policy to be used to determine which routes are accepted from peers. Route policies are configured in the config>router>policy-options context. Refer to the section on “Route Policy” in the 7705 SAR Router Configuration Guide. When multiple policy names are specified, the policies are evaluated in the order in which they are specified. A maximum of five (5) policy names can be specified. The first policy that matches is applied. When multiple import commands are issued, the last command entered will override the previous command. The no form of the command removes all route policy names from the import list.
Default	no import—BGP routes are accepted by default
Parameters	<i>policy-name</i> — the route policy name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

keepalive

Syntax	keepalive <i>seconds</i> no keepalive
Context	config>service>vprn>bgp config>service>vprn>bgp>group config>service>vprn>bgp>group>neighbor
Description	This command configures the BGP keepalive timer. A Keepalive message is sent every time this timer expires.

The **keepalive** parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in group) or neighbor level (only applies to specified peer). The most specific value is used. The **keepalive** value is generally one-third of the **hold-time** interval. Even though the 7705 SAR implementation allows the **keepalive** value and the **hold-time** interval to be independently set, under the following circumstances, the configured **keepalive** value is overridden by the **hold-time** value.

- If the specified **keepalive** value is greater than the configured **hold-time**, then the specified value is ignored, and the **keepalive value** is set to one third of the current **hold-time** value.
- If the specified **hold-time** interval is less than the configured **keepalive** value, then the **keepalive** value is reset to one third of the specified **hold-time** interval.
- If the **hold-time** interval is set to 0, then the configured value of the **keepalive** value is ignored. This means that the connection with the peer is up permanently and no **keepalive** packets are sent to the peer.

The **no** form of the command used at the global level reverts to the default value.

The **no** form of the command used at the group level reverts to the value defined at the global level.

The **no** form of the command used at the neighbor level reverts to the value defined at the group level.

Default	30 s
Parameters	<i>seconds</i> — the keepalive timer, in seconds, expressed as a decimal integer
Values	0 to 21845

local-address

Syntax	local-address <i>ip-address</i> no local-address
Context	config>service>vprn>bgp>group config>service>vprn>bgp>group>neighbor
Description	This command configures the local IP address used by the group or neighbor when communicating with BGP peers.

Outgoing connections use the **local-address** as the source of the TCP connection when initiating connections with a peer.

When a local address is not specified, the 7705 SAR uses the interface address for directly connected EBGp peers. This command is used at the neighbor level to revert to the value defined under the group level.

The **no** form of the command removes the configured local address for BGP.

The **no** form of the command used at the group level reverts to the value defined at the global level.

The **no** form of the command used at the neighbor level reverts to the value defined at the group level.

Default	no local-address
Parameters	<i>ip-address</i> — the local address. The allowed value is a valid routable IP address on the router, either an interface or system IP address.
Values	<i>ipv4-address:</i> a.b.c.d <i>ipv6-address:</i> x:x:x:x:x:x:x (eight 16-bit pieces) x:x:x:x:x:d.d.d.d x: [0 to FFFF]H d: [0 to 255]D

local-as

Syntax	local-as <i>as-number</i> [private] no local-as
Context	config>service>vprn>bgp config>service>vprn>bgp>group config>service>vprn>bgp>group>neighbor
Description	This command configures a BGP virtual autonomous system (AS) number. In addition to the AS number configured for BGP in the config>router>autonomous-system context, a virtual (local) AS number is configured. The virtual AS number is added to the as-path attribute before the router's AS number makes the virtual AS the second AS in the AS path. This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in group) or neighbor level (only applies to specified peer). By specifying this parameter at each neighbor level, it is possible to have a separate AS number per EBGP session. When a command is entered multiple times for the same AS, the last command entered is used in the configuration. The private attribute can be added or removed dynamically by reissuing the command. Changing the local AS at the global level in an active BGP instance causes the BGP instance to restart with the new local AS number. Changing the local AS at the group level in an active BGP instance causes BGP to re-establish the peer relationships with all peers in the group with the new local AS number. Changing the local AS at the neighbor level in an active BGP instance causes BGP to re-establish the peer relationship with the new local AS number.

This is an optional command and can be used in the following example:

Example: Provider router P is moved from AS1 to AS2. The customer router that is connected to P, however, is configured to belong to AS1. To avoid reconfiguring the customer router, the **local-as** value on router P can be set to AS1. Thus, router P adds AS1 to the as-path message for routes it advertises to the customer router.

The **no** form of the command used at the global level will remove any virtual AS number configured.

The **no** form of the command used at the group level reverts to the value defined at the global level.

The **no** form of the command used at the neighbor level reverts to the value defined at the group level.

Default	no local-as
Parameters	<i>as-number</i> — the virtual autonomous system number expressed as a decimal integer
Values	1 to 4294967295
	private — specifies that the local AS is hidden in paths learned from the peering

local-preference

Syntax	local-preference <i>local-preference</i> no local-preference
Context	config>service>vprn>bgp config>service>vprn>bgp>group config>service>vprn>bgp>group>neighbor
Description	This command configures the default value of the BGP local preference attribute if it is not already specified in incoming routes. This value is used if the BGP route arrives from a BGP peer without the local-preference integer set. The specified value can be overridden by any value set via a route policy. This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in group) or neighbor level (only applies to specified peer). The most specific value is used. The no form of the command at the global level specifies that incoming routes with local preference set are not overridden and routes arriving without local preference set are interpreted as if the route had a local preference value of 100. The no form of the command used at the group level reverts to the value defined at the global level.

The **no** form of the command used at the neighbor level reverts to the value defined at the group level.

Default	no local-preference
Parameters	<i>local-preference</i> — the local preference value to be used as the override value, expressed as a decimal integer
Values	0 to 4294967295

loop-detect

Syntax	loop-detect { drop-peer discard-route ignore-loop off } no loop-detect
Context	config>service>vprn>bgp config>service>vprn>bgp>group config>service>vprn>bgp>group>neighbor
Description	This command configures how the BGP peer session handles loop detection in the AS path. This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in group) or neighbor level (only applies to specified peer). The most specific value is used. When applied to an ongoing BGP peer session, this command does not take effect until the BGP peer session is re-established. The no form of the command used at the global level reverts to the default (ignore-loop). The no form of the command used at the group level reverts to the value defined at the global level. The no form of the command used at the neighbor level reverts to the value defined at the group level.
Default	ignore-loop
Parameters	drop-peer — sends a notification to the remote peer and drops the session discard-route — discards routes received from a peer with the same AS number as the router itself. This option prevents routes looped back to the router from being added to the routing information base and consuming memory. When this option is changed, the change will not be active for an established peer until the connection is re-established for the peer. ignore-loop — ignores routes with loops in the AS path, but maintains peering off — disables loop detection

med-out

Syntax	med-out [<i>number</i> igp-cost] no med-out
Context	config>service>vprn>bgp config>service>vprn>bgp>group config>service>vprn>bgp>group>neighbor
Description	This command enables advertising the Multi-Exit Discriminator (MED) and assigns the value used for the path attribute for the advertised MED to BGP peers if the MED is not already set. The specified value can be overridden by any value set via a route policy. This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in group) or neighbor level (only applies to specified peer). The most specific value is used. The no form of the command used at the global level reverts to the default where the MED is not advertised. The no form of the command used at the group level reverts to the value defined at the global level. The no form of the command used at the neighbor level reverts to the value defined at the group level.
Default	no med-out
Parameters	<i>number</i> — the MED path attribute value, expressed as a decimal integer Values 0 to 4294967295 igp-cost — the MED is set to the IGP cost of the IP prefix that is defined via a route policy

min-route-advertisement

Syntax	min-route-advertisement <i>seconds</i> no min-route-advertisement
Context	config>service>vprn>bgp config>service>vprn>bgp>group config>service>vprn>bgp>group>neighbor
Description	This command configures the minimum interval, in seconds, at which a prefix can be advertised to a peer. This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in group) or neighbor level (only applies to specified peer). The most specific value is used.

The **no** form of the command used at the global level reverts to the default.

The **no** form of the command used at the group level reverts to the value defined at the global level.

The **no** form of the command used at the neighbor level reverts to the value defined at the group level.

Default	30 s
Parameters	<i>seconds</i> — the minimum route advertising interval, in seconds, expressed as a decimal integer
Values	1 to 255

multihop

Syntax	multihop <i>ttl-value</i> no multihop
Context	config>service>vprn>bgp config>service>vprn>bgp>group config>service>vprn>bgp>group>neighbor
Description	This command configures the time to live (TTL) value at an originating EBGp peer. The TTL value is entered in the IP header of packets that are sent to a terminating EBGp peer that is multiple hops away. The no form of the command used at the global level reverts to the default value. The no form of the command used at the group level reverts to the value defined at the global level. The no form of the command used at the neighbor level reverts to the value defined at the group level.
Default	1 — EBGp peers are directly connected
Parameters	<i>ttl-value</i> — the TTL value that will be entered in the IP header of packets that are sent to a terminating EBGp peer that is multiple hops away
Values	1 to 255

multipath

Syntax	multipath <i>max-paths</i> no multipath
Context	config>service>vprn>bgp

Description	This command enables BGP multipath. When multipath is enabled, BGP load-shares traffic across multiple links. Multipath can be configured to load-share traffic across a maximum of 16 routes. If the equal-cost routes available are more than the configured value, then routes with the lowest next-hop IP address value are chosen. This configuration parameter is set at the global level (applies to all peers). Multipath is disabled if the value is set to 1. When multipath is disabled and multiple equal-cost routes are available, the route with the lowest next-hop IP address will be used. The no form of the command reverts to the default where multipath is disabled.
Default	no multipath
Parameters	<i>max-paths</i> — the number of equal-cost routes to use for multipath routing
Values	1 to 16

next-hop-resolution

Syntax	next-hop-resolution
Context	config>service>vprn>bgp
Description	This command enters the context to configure next-hop resolution parameters.

policy

Syntax	policy <i>policy-name</i> no policy
Context	config>service>vprn>bgp>next-hop-res
Description	This command specifies the name of a policy statement to use with the BGP next-hop resolution process. The policy controls which IP routes in the RTM are eligible to resolve the BGP next-hop addresses of IPv4 and IPv6 routes. The policy has no effect on the resolution of BGP next hops to MPLS tunnels. If a BGP next hop of an IPv4 or IPv6 route is resolved in the RTM and the longest matching route for the next-hop address is an IP route that is rejected by the policy, the route is unresolved; if the route is accepted by the policy, it becomes the resolving route. If the no form of the command is used, the default next-hop-resolution policy is to use the longest matching active route in the RTM that is not a BGP route or an aggregate route.
Default	no policy

Parameters *policy-name* — specifies an existing route policy name. Route policies are configured in the **config>router>policy-options** context.

next-hop-self

Syntax **[no] next-hop-self**

Context config>service>vprn>bgp>group
config>service>vprn>bgp>group>neighbor

Description This command configures the group or neighbor to always set the next-hop path attribute to its own physical interface when advertising to a peer.

 This command is primarily used to avoid third-party route advertisements when connected to a multi-access network.

 The **no** form of the command used at the group level allows third-party route advertisements in a multi-access network.

 The **no** form of the command used at the neighbor level reverts to the value defined at the group level.

Default no next-hop-self

passive

Syntax **[no] passive**

Context config>service>vprn>bgp>group
config>service>vprn>bgp>group>neighbor

Description This command enables and disables passive mode for the BGP group or neighbor. When in passive mode, BGP will not attempt to actively connect to the configured BGP peers but responds only when it receives a connect open request from the peer.

 The **no** form of the command used at the group level disables passive mode, and BGP actively attempts to connect to its peers.

 The **no** form of the command used at the neighbor level reverts to the value defined at the group level.

Default no passive

peer-as

Syntax **peer-as as-number**
no peer-as

Context	config>service>vprn>bgp>group config>service>vprn>bgp>group>neighbor
Description	This command configures the autonomous system number for the remote peer. The peer AS number must be configured for each configured peer. For EBGP peers, the peer AS number configured must be different from the autonomous system number configured for this router under the global level. This requirement is necessary since the peer will be in a different autonomous system than that of this router. This command may be configured under the group level for all neighbors in a particular group.
Default	no AS numbers defined
Parameters	<i>as-number</i> — the autonomous system number, expressed as a decimal integer
Values	1 to 4294967295

peer-tracking-policy

Syntax	peer-tracking-policy <i>policy-name</i> no peer-tracking-policy
Context	config>service>vprn>bgp
Description	This command specifies the name of a policy statement to use with the BGP peer-tracking function on the BGP sessions where the peer-tracking-policy command is enabled. The policy controls which IP routes in the RTM are eligible to indicate reachability of IPv4 and IPv6 BGP neighbor addresses. If the longest matching route in the RTM for a BGP neighbor address is an IP route that is rejected by the policy or a BGP route accepted by the policy, or if there is no matching route, the neighbor is considered unreachable and BGP tears down the peering session and holds it in the idle state until a valid route is once again available and accepted by the policy. The no form of the command defaults to using the longest matching active route in the RTM that is not an aggregate route.
Default	no peer-tracking-policy
Parameters	<i>policy-name</i> — specifies an existing route policy name. Route policies are configured in the config>router>policy-options context.

preference

Syntax	preference <i>preference</i> no preference
Context	config>service>vprn>bgp config>service>vprn>bgp>group

	config>service>vprn>bgp>group>neighbor
Description	This command configures the route preference for routes learned from the configured peers. This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in group) or neighbor level (only applies to specified peer). The most specific value is used. The lower the preference, the higher the chance of the route being the active route. The 7705 SAR assigns the highest default preference to BGP routes as compared to routes that are direct, static, or learned via MPLS or OSPF. The no form of the command used at the global level reverts to the default value. The no form of the command used at the group level reverts to the value defined at the global level. The no form of the command used at the neighbor level reverts to the value defined at the group level.
Default	170
Parameters	<i>preference</i> — the route preference, expressed as a decimal integer Values 1 to 255

prefix-limit

Syntax	prefix-limit <i>family limit</i> [threshold <i>percentage</i>] [idle-timeout {<i>minutes</i> forever} log-only] [post-import] no prefix-limit <i>family</i>
Context	config>service>vprn>bgp>group config>service>vprn>bgp>group>neighbor
Description	This command configures the maximum number of BGP routes that can be received from a peer before administrative action is taken. The administrative action can be the generation of a log event or the taking down of the session. If a session is taken down, it can be brought back up automatically after an idle-timeout period or it can be configured to stay down (forever) until the operator performs a reset. The prefix-limit command allows each address family to have its own limit; a set of address family limits can be applied to one neighbor or to all neighbors in a group. The no form of the command removes the prefix-limit.
Default	No prefix limits for any address family
Parameters	<i>family</i> — specifies the address family to which the limit applies Values ipv4, vpn-ipv4, ipv6, vpn-ipv6, mvpn-ipv4, route-target, label-ipv4

limit — specifies the number of routes that can be learned from a peer, expressed as a decimal integer

Values 1 to 4294967295

percentage — specifies the threshold value, as a percentage, that triggers a warning message to be sent

Values 1 to 100

minutes — specifies the length of time, in minutes, before automatically re-establishing a session

Values 1 to 1024

forever — specifies that the session is re-established only after the **clear router bgp** command is executed

log-only — enables a warning message to be sent at the specified threshold percentage and also when the limit is reached. However, the BGP session is not taken down.

post-import — specifies that the limit should be applied only to the number of routes that are accepted by import policies

rapid-withdrawal

Syntax [no] **rapid-withdrawal**

Context config>service>vprn>bgp

Description This command disables the delay on issuing BGP withdrawals.

By default, BGP withdrawals (messages containing the routes that are no longer valid) are delayed up to the **min-route-advertisement** to allow for efficient packing of BGP Update messages. However, when the **rapid-withdrawal** command is enabled, the delay on sending BGP withdrawals is disabled.

The **no** form of the command returns BGP withdrawal processing to its default behavior.

Default no rapid-withdrawal

remove-private

Syntax [no] **remove-private** [limited]

Context config>service>vprn>bgp
config>service>vprn>bgp>group
config>service>vprn>bgp>group>neighbor

Description This command allows all private AS numbers to be removed from the AS path before advertising them to BGP peers. The **no** form of the command includes private AS numbers in the AS path attribute.

If the **limited** keyword is included, only the leading private ASNs up to the first public ASN are removed.

When the **remove-private** parameter is set at the global level, it applies to all peers regardless of group or neighbor configuration. When the parameter is set at the group level, it applies to all peers in the group regardless of the neighbor configuration.

The 7705 SAR recognizes the set of AS numbers that are defined by IANA as private. These are AS numbers in the range 64512 through 65535, inclusive.

The **no** form of the command used at the global level reverts to the default value.

The **no** form of the command used at the group level reverts to the value defined at the global level.

The **no** form of the command used at the neighbor level reverts to the value defined at the group level.

Default no remove-private

rib-management

Syntax	rib-management
Context	config>service>vprn>bgp
Description	This command enables the context to configure RIB management parameters. Under the RIB management context are options for ipv4 and ipv6 .

route-table-import

Syntax	route-table-import <i>policy-name</i> no route-table-import
Context	config>service>vprn>bgp>rib-management>ipv4 config>service>vprn>bgp>rib-management>ipv6
Description	This command specifies the name of a route policy to control the importation of active routes from the IP route table into one of the BGP RIBs. If the route-table-import command is not configured, or if the command refers to an empty policy, all non-BGP routes from the IP route table are imported into the applicable RIB.

If the **route-table-import** command is configured, routes that are dropped or rejected by the configured policy are not installed in the associated RIB. Rejected routes cannot be advertised to BGP peers associated with the RIB, but they can still be used to resolve BGP next hops of routes in that RIB. If the active route for a prefix is rejected by the **route-table-import** policy, then the best BGP route for that prefix in the BGP RIB can be advertised to peers as though it is used.

Aggregate routes are always imported into the applicable RIB, independent of the **route-table-import** policy.

Route modifications specified in the actions of a **route-table-import** policy are ignored and have no effect on the imported routes.

Default no route-table-import

Parameters *policy-name* — specifies the name of a policy-statement; the policy statement must already have been created

split-horizon

Syntax [no] **split-horizon**

Context config>service>vprn>bgp
config>service>vprn>bgp>group
config>service>vprn>bgp>group>neighbor

Description This command enables the use of split-horizon. When applied globally, to a group, or a specific peer, split-horizon prevents routes from being reflected back to a peer that sends the best route. It applies to routes of all address families and to any type of sending peer: confed-EBGP, EBGp, or IBGP.

The configuration default is **no split-horizon**, meaning that no effort is taken to prevent a best route from being reflected back to the sending peer.

Caution: Use of the **split-horizon** command may have a detrimental impact on peer and route scaling; therefore, operators are encouraged to use it only when absolutely needed.

The **no** form of the command disables split-horizon, which allows the lower level to inherit the setting from an upper level.

Default no split-horizon

ttl-security

Syntax	ttl-security <i>min-ttl-value</i> no ttl-security
Context	config>service>vprn>bgp>group config>service>vprn>bgp>group>neighbor
Description	This command configures TTL security parameters for incoming packets. When the feature is enabled, BGP accepts incoming IP packets from a peer only if the TTL value in the packet is greater than or equal to the minimum TTL value configured for that peer. The no form of the command disables TTL security.
Default	no ttl-security
Parameters	<i>min-ttl-value</i> — the minimum TTL value for an incoming packet
	Values 1 to 255
	Default 1

7.8.2.1.4 OSPF and OSPFv3 Commands

ospf

Syntax	[no] ospf
Context	config>service>vprn
Description	This command enables access to the context to define OSPF parameters for VPRN. When an OSPF instance is created, the protocol is enabled. To start or suspend execution of the OSPF protocol without affecting the configuration, use the no shutdown command. The no form of the command deletes the OSPF protocol instance and removes all associated configuration parameters.
Default	no ospf

ospf3

Syntax	[no] ospf3
Context	config>service>vprn
Description	This command enables access to the context to define OSPFv3 parameters for VPRN. When an OSPFv3 instance is created, the protocol is enabled. To start or suspend execution of the OSPF protocol without affecting the configuration, use the no shutdown command. The no form of the command deletes the OSPFv3 protocol instance and removes all associated configuration parameters.
Default	no ospf3

area

Syntax	[no] area <i>area-id</i>
Context	config>service>vprn>ospf config>service>vprn>ospf3
Description	This command enables the context to configure an OSPF or OSPFv3 area. An area is a collection of network segments within an AS that have been administratively grouped together. The area ID can be specified in dotted-decimal notation or as a 32-bit decimal integer.

The **no** form of the command deletes the specified area from the configuration. Deleting the area also removes the OSPF or OSPFv3 configuration of all the interfaces, virtual links, address ranges, and so on, that are currently assigned to this area.

The 7705 SAR supports a maximum of four areas.

Default	no area — no OSPF or OSPFv3 areas are defined
Parameters	<i>area-id</i> — the OSPF or OSPFv3 area ID expressed in dotted-decimal notation or as a 32-bit decimal integer
Values	0.0.0.0 to 255.255.255.255 (dotted decimal) 0 to 4294967295 (decimal integer)

area-range

Syntax	area-range <i>ip-prefix/mask</i> [advertise not-advertise] no area-range <i>ip-prefix/mask</i> area-range <i>ipv6-prefix/prefix-length</i> [advertise not-advertise] no area-range <i>ipv6-prefix/prefix-length</i>
Context	config>service>vprn>ospf>area config>service>vprn>ospf3>area config>service>vprn>ospf>area>nssa config>service>vprn>ospf3>area>nssa
Description	This command creates ranges of addresses on an Area Border Router (ABR) for the purpose of route summarization or suppression. When a range is created, the range is configured to be advertised or not advertised to other areas. Multiple range commands can be used to summarize or hide ranges. In the case of overlapping ranges, the most specific range command applies. ABRs send summary link advertisements to describe routes to other areas. To minimize the number of advertisements that are flooded, you can summarize a range of IP addresses and send reachability information about these addresses in an LSA. The <i>ip-prefix/mask</i> parameter applies in the ospf context. The <i>ipv6-prefix/prefix-length</i> parameter applies in the ospf3 context. The no form of the command deletes the range advertisement or non-advertisement.
Default	no area-range — no range of addresses is defined
Special Cases	NSSA context — in the NSSA context, the option specifies that the range applies to external routes (via type 7 LSAs) learned within the NSSA when the routes are advertised to other areas as type 5 LSAs Area context — if this command is not entered under the NSSA context, the range applies to summary LSAs even if the area is an NSSA

Parameters	<i>ip-prefix/mask</i> — the IP prefix for the range in dotted-decimal notation and the subnet mask for the range, expressed as a decimal integer	
Values	<i>ip-prefix</i>	a.b.c.d (host bits must be 0)
	<i>mask</i>	0 to 32
	<i>ipv6-prefix/prefix-length</i> — the IPv6 prefix for the range in hexadecimal notation	
Values	<i>ipv6-prefix</i>	x::x::x::x::x::x (eight 16-bit pieces) x::x::x::x::d.d.d.d x: [0 to FFFF]H d: [0 to 255]D
	<i>prefix-length</i>	0 to 128
	advertise not-advertise — specifies whether to advertise the summarized range of addresses to other areas	
Default	advertise	

blackhole-aggregate

Syntax	[no] blackhole-aggregate
Context	config>service>vprn>ospf>area config>service>vprn>ospf3>area
Description	This command installs a low-priority blackhole route for the entire aggregate. Existing routes that make up the aggregate will have a higher priority and only the components of the range for which no route exists will be blackholed. When performing area aggregation, addresses may be included in the range for which no actual route exists. This can cause routing loops. To avoid this problem, configure the blackhole aggregate option. The no form of this command removes this option.
Default	blackhole-aggregate

interface

Syntax	interface <i>ip-int-name</i> [secondary] no interface <i>ip-int-name</i>
Context	config>service>vprn>ospf>area config>service>vprn>ospf3>area
Description	This command creates a context to configure an OSPF or OSPFv3 interface.

By default, interfaces are not activated in any interior gateway protocol, such as OSPF or OSPFv3, unless explicitly configured.

The **no** form of the command deletes the OSPF or OSPFv3 interface configuration for this interface. The **shutdown** command in the **config>router>ospf>interface** context or **config>router>ospf3>interface** context can be used to disable an interface without removing the configuration.

Default	no interface
Parameters	<i>ip-int-name</i> — the IP interface name. Interface names must be unique within the group of defined IP interfaces for the config>service>vprn>interface and config>router>interface commands. An interface name cannot be in the form of an IP address. Interface names can be any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes. If the IP interface exists in a different area, the configuration will be rejected with an error message unless the keyword secondary is specified. secondary — enables multiple secondary adjacencies to be established over this IP interface (refer to the 7705 SAR Routing Protocols Guide, “Multi-area Adjacencies”, for information on this feature)

advertise-subnet

Syntax	[no] advertise-subnet
Context	config>service>vprn>ospf>area>interface
Description	This command enables advertising point-to-point interfaces as subnet routes (network number and mask). When disabled, point-to-point interfaces are advertised as host routes. This command is not supported in the ospf3 context. The no form of the command disables advertising point-to-point interfaces as subnet routes, meaning they are advertised as host routes.
Default	advertise-subnet

auth-keychain

Syntax	auth-keychain <i>name</i> no auth-keychain
Context	config>service>vprn>ospf>area>interface config>service>vprn>ospf>area>virtual-link

Description	This command associates an authentication keychain with the OSPF interface or virtual link. The keychain is a collection of keys used to authenticate OSPF messages from remote peers. The keychain allows the rollover of authentication keys during the lifetime of a session and also supports stronger authentication algorithms than clear text and MD5. The keychain must already be defined in the config>system>security>keychain context. Either the authentication-key command or the auth-keychain command can be used by OSPF, but both cannot be supported at the same time. If both commands are configured, the auth-keychain configuration will be applied and the authentication-key command will be ignored. By default, authentication is not enabled.
Default	no auth-keychain
Parameters	<i>name</i> — the name of an existing keychain, up to 32 characters

authentication

Syntax	authentication bidirectional <i>sa-name</i> authentication inbound <i>sa-name</i> outbound <i>sa-name</i> no authentication
Context	config>service>vprn>ospf3>area>interface config>service>vprn>ospf3>area>virtual-link
Description	This command configures an interface with a static security association (SA) used to authenticate OSPFv3 packets. This command is not supported in the ospf context. The no form of the command removes the SA name from the configuration.
Parameters	bidirectional <i>sa-name</i> — specifies the IPSec SA name used for transmitting and receiving OSPFv3 packets inbound <i>sa-name</i> — specifies the IPSec SA name used for receiving OSPFv3 packets outbound <i>sa-name</i> — specifies the IPSec SA name used for transmitting OSPFv3 packets

authentication-key

Syntax	authentication-key { <i>authentication-key</i> <i>hash-key</i> } [hash hash2] no authentication-key
Context	config>service>vprn>ospf>area>interface config>service>vprn>ospf>area>virtual-link

Description	This command configures the password used by the OSPF interface or virtual link to send and receive OSPF protocol packets on the interface when simple password authentication is configured. All neighboring routers must use the same type of authentication and password for correct protocol communication. If the authentication-type is configured as password, the authentication key must be configured. By default, no authentication key is configured. Either the authentication-key command or the auth-keychain command can be used by OSPF, but both cannot be supported at the same time. If both commands are configured, the auth-keychain configuration will be applied and the authentication-key command will be ignored. This command is not supported in the ospf3 context. The no form of the command removes the authentication key.
Default	no authentication-key
Parameters	<i>authentication-key</i> — the authentication key can be any combination of ASCII characters up to 8 characters in length (unencrypted). If spaces are used in the string, enclose the entire string in quotation marks (" "). <i>hash-key</i> — the hash key can be any combination of ASCII characters up to 22 characters in length (hash parameter is used) or 121 characters in length (if the hash2 parameter is used). If spaces are used in the string, enclose the entire string in quotation marks (" "). This is useful when a user must configure the parameter, but for security purposes, the actual unencrypted key value is not provided. hash — specifies that the key is entered in an encrypted form. If the hash parameter is not used, the key is assumed to be in a non-encrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the hash parameter specified. hash2 — specifies that the key is entered in a more complex encrypted form. If the hash2 parameter is not used, the less encrypted hash form is assumed.

authentication-type

Syntax	authentication-type {password message-digest} no authentication-type
Context	config>service>vprn>ospf>area>interface config>service>vprn>ospf>area>virtual-link
Description	This command enables authentication and specifies the type of authentication to be used on the OSPF interface or virtual link.

Both simple **password** and **message-digest** authentication are supported.

By default, authentication is not enabled on an interface or link.

This command is not supported in the **ospf3** context.

The **no** form of the command disables authentication on the interface or link.

Default	no authentication-type
Parameters	password — enables simple password (plain text) authentication. If authentication is enabled and no authentication type is specified in the command, simple password authentication is enabled. message-digest — enables message digest MD5 authentication in accordance with RFC 1321. If this option is configured, at least one message-digest-key must be configured.

bfd-enable

Syntax	bfd-enable [remain-down-on-failure] no bfd-enable
Context	config>service>vprn>ospf>area>interface config>service>vprn>ospf3>area>interface
Description	This command enables the use of bidirectional forwarding detection (BFD) to control the state of the associated OSPF or OSPFv3 interface. By enabling BFD on an OSPF or OSPFv3 interface, the state of the interface is tied to the state of the BFD session between the local node and the remote node. The parameters used for BFD are set using the bfd command under the IP interface. The optional remain-down-on-failure parameter can be specified on OSPF or OSPFv3 interfaces that are enabled for BFD, to keep OSPF or OSPFv3 from reaching the Full state if the BFD session to that neighbor cannot be established. This option is disabled by default and should be used only if there is a chance that unicast packets might be discarded while multicast packets are forwarded. The no form of this command removes BFD from the associated OSPF or OSPFv3 adjacency.
Default	no bfd-enable
Parameters	remain-down-on-failure — forces adjacency down on BFD failure

dead-interval

Syntax	dead-interval <i>seconds</i> no dead-interval
Context	config>service>vprn>ospf>area>interface config>service>vprn>ospf3>area>interface config>service>vprn>ospf>area>virtual-link config>service>vprn>ospf3>area>virtual-link
Description	This command configures the time, in seconds, that OSPF or OSPFv3 waits before declaring a neighbor router or virtual-link neighbor down. If no Hello packets are received from a neighbor for the duration of the dead interval, the router or link is assumed to be down. The minimum interval must be two times the hello interval. The no form of the command resets the configured interval to the default value.
Default	40
Special Cases	OSPF or OSPFv3 interface — if the dead-interval configured applies to an interface, all nodes on the subnet must have the same dead interval Virtual link — if the dead-interval configured applies to a virtual link, the interval on both endpoints of the virtual link must have the same dead interval
Parameters	<i>seconds</i> — the dead interval in seconds, expressed as a decimal integer Values 1 to 65535

hello-interval

Syntax	hello-interval <i>seconds</i> no hello-interval
Context	config>service>vprn>ospf>area>interface config>service>vprn>ospf3>area>interface config>service>vprn>ospf>area>virtual-link config>service>vprn>ospf3>area>virtual-link
Description	This command configures the interval between OSPF or OSPFv3 Hellos issued on the interface or virtual link. The hello interval, in combination with the dead interval, is used to establish and maintain the adjacency. Reducing the interval, in combination with an appropriate reduction in the associated dead-interval, allows for faster detection of link and/or router failures but results in higher processing costs. The no form of this command resets the configured interval to the default value.

Default	10
Special Cases	OSPF or OSPFv3 interface — if the hello-interval configured applies to an interface, all nodes on the subnet must have the same hello interval Virtual link — if the hello-interval configured applies to a virtual link, the interval on both endpoints of the virtual link must have the same hello interval
Parameters	<i>seconds</i> — the hello interval in seconds, expressed as a decimal integer Values 1 to 65535

interface-type

Syntax	interface-type {broadcast point-to-point} no interface-type
Context	config>service>vprn>ospf>area>interface config>service>vprn>ospf3>area>interface
Description	This command configures the interface type to be either broadcast or point-to-point. Use this command to set the interface type of an Ethernet link to point-to-point to avoid having to carry the broadcast adjacency maintenance overhead of the link, provided that the link is used as a point-to-point link. If the interface type is not known when the interface is added to OSPF or OSPFv3, and the IP interface is subsequently bound (or moved) to a different interface type, this command must be entered manually. The no form of the command resets the configured interface type to the default value.
Default	broadcast – if the physical interface is Ethernet or unknown point-to-point – if the physical interface is T1, E1, or SONET/SDH
Special Cases	Virtual link — a virtual link is always regarded as a point-to-point interface and is not configurable
Parameters	broadcast — configures the interface to maintain this link as a broadcast link. To significantly improve adjacency forming and network convergence, a network should be configured as point-to-point if only two routers are connected, even if the network is a broadcast media such as Ethernet. point-to-point — configures the interface to maintain this link as a point-to-point link

lfa-policy-map

Syntax	lfa-policy-map route-nh-template <i>template-name</i> no lfa-policy-map

Context	config>service>vprn>ospf>area>interface config>service>vprn>ospf3>area>interface
Description	This command applies a route next-hop policy template to an OSPF or OSPFv3 interface. When a route next hop policy template is applied to an interface, it is applied in all areas. However, this command can only be executed under the area in which the specified interface is primary. When the command is executed, the template is applied in that area and in all other areas where the interface is secondary. If the user attempts to execute the command under an area where the interface is secondary, the command will fail. If the interface has been excluded from LFA with the loopfree-alternate-exclude command, the LFA policy has no effect on the interface. If the route next-hop policy template is applied to a loopback interface or to the system interface, the command will not be rejected, but the policy will have no effect on the interface. The no form of the command deletes the mapping of a route next-hop policy template to an OSPF or OSPFv3 interface.
Default	no lfa-policy-map
Parameters	<i>template-name</i> — the name of an existing template

loopfree-alternate-exclude

Syntax	[no] loopfree-alternate-exclude
Context	config>service>vprn>ospf>area config>service>vprn>ospf3>area config>service>vprn>ospf>area>interface config>service>vprn>ospf3>area>interface
Description	This command instructs OSPF or OSPFv3 to exclude a specific interface or all interfaces participating in a specific OSPF or OSPFv3 area from the LFA SPF calculation. The LFA SPF calculation can therefore be run only where it is needed. If an interface is excluded from the LFA SPF calculation, it is excluded in all areas. However, this command can only be executed under the area in which the specified interface is primary. When the command is executed, the interface is excluded in that area and in all other areas where the interface is secondary. If the user attempts to execute the command under an area where the interface is secondary, the command will fail.
Default	no loopfree-alternate-exclude

message-digest-key

Syntax	message-digest-key <i>key-id</i> md5 { <i>key</i> <i>hash-key</i> <i>hash2-key</i> } [hash hash2]

	no message-digest-key <i>key-id</i>
Context	config>service>vprn>ospf>area>interface config>service>vprn>ospf>area>virtual-link
Description	This command configures a message digest key when MD5 authentication is enabled on the interface or virtual link. Multiple message digest keys can be configured. This command is not supported in the ospf3 context. The no form of the command removes the message digest key identified by the <i>key-id</i>.
Default	no message-digest-key
Parameters	<i>key-id</i> — the <i>key-id</i> is expressed as a decimal integer Values 1 to 255 <i>key</i> — the MD5 key, any alphanumeric string up to 16 characters in length <i>hash-key</i> — the MD5 hash key, any combination of ASCII characters up to 33 characters in length (hash parameter is used). If spaces are used in the string, enclose the entire string in quotation marks (" "). This is useful when a user must configure the parameter, but for security purposes, the actual unencrypted key value is not provided. <i>hash2-key</i> — the MD5 hash key, any combination of ASCII characters up to 132 characters in length (hash2 parameter is used). If spaces are used in the string, enclose the entire string in quotation marks (" "). This is useful when a user must configure the parameter, but for security purposes, the actual unencrypted key value is not provided. hash — specifies that the key is entered in an encrypted form. If the hash parameter is not used, the key is assumed to be in a unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the hash parameter specified. hash2 — specifies that the key is entered in a more complex encrypted form. If the hash2 parameter is not used, the less encrypted hash form is assumed.

metric

Syntax	metric <i>metric</i> no metric
Context	config>service>vprn>ospf>area>interface config>service>vprn>ospf3>area>interface
Description	This command configures an explicit route cost metric for the OSPF or OSPFv3 interface that overrides the metrics calculated based on the speed of the underlying link.

The **no** form of the command deletes the manually configured interface metric, so the interface uses the computed metric based on the **reference-bandwidth** command setting and the speed of the underlying link.

Default	no metric
Parameters	<i>metric</i> — the metric to be applied to the interface, expressed as a decimal integer
Values	1 to 65535

mtu

Syntax	mtu <i>bytes</i> no mtu
Context	config>service>vprn>ospf>area>interface config>service>vprn>ospf3>area>interface
Description	This command configures the OSPF or OSPFv3 interface MTU value used when negotiating an OSPF or OSPFv3 adjacency.

The operational OSPF MTU value is calculated as follows.

If this command is not configured:

- the OSPF or OSPFv3 interface operational MTU derives the MTU value from the IP interface MTU (which is derived from the port MTU); for example, port MTU minus 14 bytes for a null-encapsulated Ethernet port
 - for OSPF (not OSPFv3), if the derived MTU value is less than 576 bytes, the OSPF interface operational MTU is set to 576 bytes. If a lower interface MTU is required, you must explicitly configure it using this command.

If this command is configured:

- for OSPF (not OSPFv3):
 - if the OSPF interface MTU is less than 576 bytes, it becomes the operational OSPF MTU, regardless of the port MTU value
 - if the OSPF interface MTU is equal to or greater than 576 bytes, and the derived interface MTU is less than 576 bytes, the operational OSPF MTU is set to 576 bytes
 - if the OSPF interface MTU is equal to or greater than 576 bytes, and the derived interface MTU is greater than 576 bytes, the operational OSPF MTU is set to the lesser of the values configured with this command and the derived MTU

The port MTU must be set to 512 bytes or higher, since OSPF cannot support port MTU values lower than 512 bytes.

- for OSPFv3:
 - the operational OSPF MTU is set to the lesser of the values configured with this command and the derived MTU

- this applies only when the port MTU is set to 1280 bytes or higher, since OSPFv3 cannot support port MTU values less than 1280 bytes

To determine the actual packet size, add 14 bytes for an Ethernet packet and 18 bytes for a tagged Ethernet packet to the size of the OSPF (IP) packet MTU configured with this command.

If the OSPF **mtu** command is configured to a value less than the interface or port MTU value, the OSPF MTU value will be used to transmit OSPF packets.

Use the **no** form of this command to revert to the default.

Default	no mtu — uses the value derived from the port MTU
Parameters	<i>bytes</i> — the MTU to be used by OSPF or OSPFv3 for this logical interface in bytes
Values	OSPF: 512 to 9710 (9724 – 14) (depends on the physical media) OSPFv3: 1280 to 9710 (9724 – 14) (depends on the physical media)

passive

Syntax	[no] passive
Context	config>service>vprn>ospf>area>interface config>service>vprn>ospf3>area>interface
Description	This command adds the passive property to an OSPF or OSPFv3 interface. By default, only interface addresses that are configured for OSPF or OSPFv3 will be advertised as OSPF or OSPFv3 interfaces. The passive parameter allows an interface to be advertised as an OSPF or OSPFv3 interface without running the OSPF or OSPFv3 protocol. While in passive mode, the interface will ignore ingress OSPF or OSPFv3 protocol packets and will not transmit any OSPF or OSPFv3 protocol packets. The no form of the command removes the passive property from the OSPF or OSPFv3 interface.
Default	no passive

priority

Syntax	priority <i>number</i> no priority
Context	config>service>vprn>ospf>area>interface config>service>vprn>ospf3>area>interface

Description	This command configures the priority of the OSPF or OSPFv3 interface that is used in an election of the designated router on the subnet. This parameter is only used if the interface is of type broadcast. The router with the highest-priority interface becomes the designated router. A router with priority 0 is not eligible to be a designated router or backup designated router. The no form of the command resets the interface priority to the default value.
Default	1
Parameters	<i>number</i> — the interface priority expressed as a decimal integer
Values	0 to 255

retransmit-interval

Syntax	retransmit-interval <i>seconds</i> no retransmit-interval
Context	config>service>vprn>ospf>area>interface config>service>vprn>ospf3>area>interface config>service>vprn>ospf>area>virtual-link config>service>vprn>ospf3>area>virtual-link
Description	This command specifies the length of time, in seconds, that OSPF or OSPFv3 will wait before retransmitting an unacknowledged LSA to an OSPF or OSPFv3 neighbor. The value should be longer than the expected round-trip delay between any two routers on the attached network. If the retransmit interval expires and no acknowledgment has been received, the LSA will be retransmitted. The no form of this command resets the configuration to the default interval.
Default	5
Parameters	<i>seconds</i> — the retransmit interval in seconds, expressed as a decimal integer
Values	1 to 1800

transit-delay

Syntax	transit-delay <i>seconds</i> no transit-delay
Context	config>service>vprn>ospf>area>interface config>service>vprn>ospf3>area>interface config>service>vprn>ospf>area>virtual-link config>service>vprn>ospf3>area>virtual-link

Description	This command configures the estimated time, in seconds, that it takes to transmit an LSA on the interface or virtual link. The no form of this command resets the configuration to the default delay time.
Default	1
Parameters	<i>seconds</i> — the transit delay in seconds, expressed as a decimal integer Values 1 to 1800

key-rollover-interval

Syntax	key-rollover-interval <i>key-rollover-interval</i> no key-rollover-interval
Context	config>service>vprn>ospf3>area
Description	This command configures the key rollover interval. The no form of the command resets the configured interval to the default setting.
Default	10
Parameters	<i>key-rollover-interval</i> — specifies the time, in seconds, after which a key rollover will start Values 10 to 300

nssa

Syntax	[no] nssa
Context	config>service>vprn>ospf>area config>service>vprn>ospf3>area
Description	This command enables the context to configure an OSPF or OSPFv3 Not So Stubby Area (NSSA) and adds or removes the NSSA designation from the area. NSSAs are similar to stub areas in that no external routes are imported into the area from other OSPF or OSPFv3 areas. The major difference between a stub area and an NSSA is that an NSSA has the capability to flood external routes that it learns throughout its area and via an ABR to the entire OSPF or OSPFv3 domain. Existing virtual links of a non-stub area or NSSA are removed when the designation is changed to NSSA or stub. An area can be designated as stub or NSSA but never both at the same time. By default, an area is not configured as an NSSA area.

The **no** form of the command removes the NSSA designation and configuration context from the area.

Default no nssa

originate-default-route

Syntax	originate-default-route [type-7] [adjacency-check] originate-default-route [type-nssa] [adjacency-check] no originate-default-route
Context	config>service>vprn>ospf>area>nssa config>service>vprn>ospf3>area>nssa
Description	This command enables the generation of a default route and its LSA type into an NSSA by an NSSA ABR or ASBR. The functionality of the type-7 parameter and the type-nssa parameter is the same. The type-7 parameter is available in the ospf context; the type-nssa parameter is available in the ospf3 context. Include the type-7 or type-nssa parameter to inject a type 7 LSA default route instead of a type 3 LSA into the NSSA configured with no summaries. To return to a type 3 LSA, enter the originate-default-route command without the type-7 or type-nssa parameter. When configuring an NSSA with no summaries, the ABR will inject a type 3 LSA default route into the NSSA area. Some older implementations expect a type 7 LSA default route. The no form of the command disables origination of a default route.
Default	no originate-default-route
Parameters	type-7 type-nssa — specifies that a type 7 LSA should be used for the default route Default type 3 LSA for the default route adjacency-check — specifies whether adjacency checks are performed before originating a default route. If this parameter is configured, an area 0 adjacency is required for the ABR to advertise the default route.

redistribute-external

Syntax	[no] redistribute-external
Context	config>service>vprn>ospf>area>nssa config>service>vprn>ospf3>area>nssa
Description	This command enables the redistribution of external routes into the NSSA on an NSSA ABR that is exporting the routes into non-NSSA areas.

NSSAs are similar to stub areas in that no external routes are imported into the area from other OSPF or OSPFv3 areas. The major difference between a stub area and an NSSA is that the NSSA has the capability to flood external routes that it learns (providing it is an ASBR) throughout its area and via an ABR to the entire OSPF or OSPFv3 domain.

The **no** form of the command disables the default behavior to automatically redistribute external routes into the NSSA area from the NSSA ABR.

Default redistribute-external

summaries

Syntax [no] summaries

Context config>service>vprn>ospf>area>nssa
config>service>vprn>ospf3>area>nssa
config>service>vprn>ospf>area>stub
config>service>vprn>ospf3>area>stub

Description This command enables sending summary (type 3) advertisements into a stub area or NSSA on an ABR.

This parameter is particularly useful to reduce the size of the routing and link-state database (LSDB) tables within the stub or NSSA area.

By default, summary route advertisements are sent into the stub area or NSSA.

The **no** form of the command disables sending summary route advertisements and, for stub areas, only the default route is advertised by the ABR.

Default summaries

stub

Syntax [no] stub

Context config>service>vprn>ospf>area
config>service>vprn>ospf3>area

Description This command enables access to the context to configure an OSPF or OSPFv3 stub area and adds or removes the stub designation from the area.

External routing information is not flooded into stub areas. All routers in the stub area must be configured with the **stub** command.

Existing virtual links of a non-stub area or NSSA are removed when its designation is changed to NSSA or stub.

An OSPF or OSPFv3 area cannot be both an NSSA and a stub area at the same time.

By default, an area is not a stub area.

The **no** form of the command removes the stub designation and configuration context from the area.

Default no stub

default-metric

Syntax **default-metric** *metric*
no default-metric

Context config>service>vprn>ospf>area>stub
config>service>vprn>ospf3>area>stub

Description This command configures the metric used by the ABR for the default route into a stub area.

The default metric should only be configured on an ABR of a stub area.

An ABR generates a default route if the area is a **stub** area.

The **no** form of the command resets the configuration to the default value.

Default default-metric 1

Parameters *metric* — the metric, expressed as a decimal integer, for the default route cost to be advertised to the stub area

Values 1 to 16777215

virtual-link

Syntax [**no**] **virtual-link** *router-id* **transit-area** *area-id*

Context config>service>vprn>ospf>area
config>service>vprn>ospf3>area

Description This command configures a virtual link to connect ABRs to the backbone.

The backbone area (area 0.0.0.0) must be contiguous and all other areas must be connected to the backbone area. If it is not practical or possible to connect an area to the backbone, the ABRs must be connected via a virtual link. The two ABRs form a point-to-point-like adjacency across the transit area. A virtual link can only be configured while in the area 0.0.0.0 context.

The *router-id* specified in this command must be associated with the virtual neighbor. The transit area cannot be a stub area or an NSSA.

The **no** form of the command deletes the virtual link.

Default	no virtual-link
Parameters	<i>router-id</i> — the router ID of the virtual neighbor in IP address dotted-decimal notation <i>area-id</i> — the area ID specified identifies the transit area that links the backbone area to the area that has no physical connection with the backbone, expressed in dotted-decimal notation or as a 32-bit decimal integer Values 0.0.0.0 to 255.255.255.255 (dotted-decimal) 0 to 4294967295 (decimal integer)

export

Syntax	export <i>policy-name</i> [<i>policy-name</i> ...(up to 5 max)] no export
Context	config>service>vprn>ospf config>service>vprn>ospf3
Description	This command specifies export route policies to determine which routes are exported from the routing table manager to OSPF or OSPFv3. Export policies are only in effect if OSPF or OSPv3 is configured as an ASBR. If no export policy is specified, routes that are not OSPF or OSPFv3 are not exported from the routing table manager to OSPF or OSPFv3. If multiple policy names are specified, the policies are evaluated in the order they are specified. The first policy that matches is applied. If multiple export commands are issued, the last command entered will override the previous command. A maximum of five policy names can be specified. The no form of the command removes all policies from the configuration. Refer to the 7705 SAR Router Configuration Guide for information on defining route policies.
Default	no export — no export route policies specified
Parameters	<i>policy-name</i> — the name of an existing route policy

external-db-overflow

Syntax	external-db-overflow <i>limit seconds</i> no external-db-overflow
Context	config>service>vprn>ospf config>service>vprn>ospf3

Description	This command enables limits on the number of non-default, AS-external LSA entries that can be stored in the link-state database (LSDB) and specifies a wait timer before processing these entries after the limit is exceeded. The <i>limit</i> value specifies the maximum number of entries that can be stored in the LSDB. Placing a limit on these LSAs in the LSDB protects the router from receiving an excessive number of external routes that consume excessive memory or CPU resources. If the number of routes reaches or exceeds the <i>limit</i>, the table is in an overflow state. When in an overflow state, the router will not originate any new AS-external LSAs and will withdraw all the self-originated non-default external LSAs. The <i>seconds</i> value specifies the time to wait after an overflow state before regenerating and processing non-default, AS-external LSAs. The waiting period acts like a dampening period, preventing the router from continuously running shortest path first (SPF) calculations caused by the excessive number of non-default, AS-external LSAs. The external-db-overflow must be set identically on all routers attached to any regular OSPF or OSPFv3 area. OSPF or OSPFv3 stub areas and NSSAs are excluded. The no form of the command disables limiting the number of non-default, AS-external LSA entries.
Default	no external-db-overflow
Parameters	<i>limit</i> — the maximum number of non-default, AS-external LSA entries that can be stored in the LSDB before going into an overflow state, expressed as a decimal integer Values -1 to 2147483647 <i>seconds</i> — the number of seconds after entering an overflow state before attempting to process non-default, AS-external LSAs, expressed as a decimal integer Values 0 to 2147483647

external-preference

Syntax	external-preference <i>preference</i> no external-preference
Context	config>service>vprn>ospf config>service>vprn>ospf3
Description	This command configures the preference for OSPF or OSPFv3 external routes. The preference for internal routes is set with the preference command. A route can be learned by the router from different protocols, in which case, the costs are not comparable. When this occurs, the preference is used to decide which route will be used. Different protocols should not be configured with the same preference. If this occurs, the tiebreaker is based on the default preferences as defined in Table 129.

Table 129 Route Preference Defaults by Route Type

Route Type	Preference	Configurable
Direct attached	0	No
Static routes	5	Yes
OSPF/OSPFv3 internal	10	Yes
IS-IS level 1 internal	15	Yes
IS-IS level 2 internal	18	Yes
OSPF/OSPFv3 external	150	Yes
IS-IS level 1 external	160	Yes
IS-IS level 2 external	165	Yes

If multiple routes are learned with the same preference using the same protocol, the lowest-cost route is used. If multiple routes are learned with the same preference using the same protocol and the costs (metrics) are equal, the decision of which route to use is determined by the configuration of ECMP in the **config>router** context. Refer to the 7705 SAR Router Configuration Guide for information on ECMP.

Note: To configure a preference for static routes, use the **config>router>static-route-entry** command. Refer to the 7705 SAR Router Configuration Guide for information.

The **no** form of the command returns the setting to the default value.

Default external-preference 150 — OSPF or OSPFv3 external routes have a default preference of 150

Parameters *preference* — the preference for external routes, expressed as a decimal integer

Values 1 to 255

ignore-dn-bit

Syntax [no] ignore-dn-bit

Context config>service>vprn>ospf
config>service>vprn>ospf3

Description This command specifies whether to ignore the DN (down) bit for OSPF or OSPFv3 LSA packets for this instance of OSPF or OSPFv3 on the router. When enabled, the DN bit for OSPF or OSPFv3 LSA packets will be ignored. When disabled, the DN bit will not be ignored for OSPF or OSPFv3 LSA packets.

Default no ignore-dn-bit

import

Syntax **import** *policy-name* [*policy-name...*(up to 5 max)]
no import

Context config>service>vprn>ospf3

Description This command applies one or more (up to 5) route policies as OSPFv3 import policies. When a prefix received in an OSPFv3 LSA is accepted by an entry in an OSPFv3 import policy, it is installed in the routing table if it is the most preferred route to the destination. When a prefix received in an OSPFv3 LSA is rejected by an entry in an OSPFv3 import policy, it is not installed in the routing table even if it has the lowest preference value among all the routes to that destination. The flooding of LSAs is unaffected by OSPFv3 import policy actions.

Default no import

loopfree-alternate

Syntax [**no**] **loopfree-alternate**

Context config>service>vprn>ospf
 config>service>vprn>ospf3

Description This command enables Loop-Free Alternate (LFA) computation by SPF under the OSPF or OSPFv3 routing protocol instance.

When this command is enabled, the OSPF or OSPFv3 SPF attempts to precalculate both a primary next hop and a LFA backup next hop for every learned prefix. When found, the LFA next hop is populated into the routing table along with the primary next hop for the prefix.

The **no** form of this command disables the LFA SPF calculation.

Default no loop-free alternate

loopfree-alternate-exclude

Syntax **loopfree-alternate-exclude prefix-policy** *prefix-policy* [*prefix-policy...*(up to 5 max)]
no loop-free-alternate-exclude

Context	config>service>vprn>ospf config>service>vprn>ospf3
Description	This command excludes from the LFA SPF calculation any prefixes that match a prefix entry in a prefix policy. If a prefix is excluded, it is not included in the LFA SPF calculation, regardless of its priority. Prefix policies are created with the command config>router>policy-options>prefix-list (for information on prefix lists, refer to the 7705 SAR Router Configuration Guide, “Route Policies”). The default action of the loopfree-alternate-exclude command, when not explicitly specified in the prefix policy, is to “reject”. Therefore, even if the default-action reject statement was not explicitly stated for the prefix policy, a prefix that does not match any entry in the policy will be used in the LFA SPF calculation. The no form of the command deletes the excluded prefix policy.
Default	no loop-free-alternate-exclude
Parameters	<i>prefix-policy</i> — the name of an existing prefix policy

overload

Syntax	overload [timeout seconds] no overload
Context	config>service>vprn>ospf config>service>vprn>ospf3
Description	This command changes the overload state of the local router so that it appears to be overloaded. When overload is enabled, the router can participate in OSPF or OSPFv3 routing, but is not used for transit traffic. Traffic destined for directly attached interfaces continues to reach the router. To put the IGP in an overload state, enter a timeout value. The IGP will enter the overload state until the timeout timer expires or a no overload command is executed. If no timeout is specified, the overload state is maintained indefinitely. If the overload command is encountered during the execution of an overload-on-boot command, the overload command takes precedence. This situation could occur as a result of a saved configuration file where both parameters are saved. When the file is saved by the system, the overload-on-boot command is saved after the overload command. Use the no form of this command to return to the default. When the no overload command is executed, the overload state is terminated regardless of the reason the protocol entered the overload state.
Default	no overload

Parameters	<i>seconds</i> — the number of seconds to reset overloading
Values	60 to 1800

overload-include-stub

Syntax	[no] overload-include-stub
Context	config>service>vprn>ospf config>service>vprn>ospf3
Description	This command is used to determine if the OSPF or OSPFv3 stub networks should be advertised with a maximum metric value when the system goes into an overload state for any reason. When enabled, the system uses the maximum metric value. When this command is enabled and the router is in overload, all stub interfaces, including loopback and system interfaces, will be advertised at the maximum metric.
Default	no overload-include-stub

overload-on-boot

Syntax	overload-on-boot [timeout <i>seconds</i>] no overload-on-boot
Context	config>service>vprn>ospf config>service>vprn>ospf3
Description	When the router is in an overload state, the router is used only if there is no other router to reach the destination. This command configures OSPF or OSPFv3 upon boot-up in the overload state until one of the following events occurs: • the timeout timer expires (if a timeout has been specified) • a manual override of the current overload state is entered with the no overload command If no timeout is specified, the overload state is maintained indefinitely. The no overload command does not affect the overload-on-boot function. The no form of the command removes the overload-on-boot functionality from the configuration.
Default	no overload-on-boot
Parameters	<i>seconds</i> — the number of seconds to reset overloading
Values	60 to 1800

preference

Syntax	preference <i>preference</i> no preference
Context	config>service>vprn>ospf config>service>vprn>ospf3
Description	This command configures the preference for OSPF or OSPFv3 internal routes. A route can be learned by the router from different protocols, in which case, the costs are not comparable. When this occurs, the preference is used to decide which route will be used. Different protocols should not be configured with the same preference. If this occurs, the tiebreaker is based on the default preferences as defined in Table 129. If multiple routes are learned with the same preference using the same protocol and the costs (metrics) are equal, the decision of which route to use is determined by the configuration of ECMP in the config>router context. Refer to the 7705 SAR Router Configuration Guide for information on ECMP. The no form of the command resets the preference configuration to the default value.
Default	preference 10 — OSPF or OSPFv3 internal routes have a preference of 10
Parameters	<i>preference</i> — the preference for internal routes, expressed as a decimal integer Values 1 to 255

reference-bandwidth

Syntax	reference-bandwidth <i>bandwidth-in-kbps</i> reference-bandwidth [tbps <i>Tera-bps</i>] [gbps <i>Giga-bps</i>] [mbps <i>Mega-bps</i>] [kbps <i>Kilo-bps</i>] no reference-bandwidth
Context	config>service>vprn>ospf config>service>vprn>ospf3
Description	This command configures the reference bandwidth used to calculate the default costs of interfaces based on their underlying link speed. The default interface cost is calculated as follows: $\text{cost} = \text{reference bandwidth} / \text{bandwidth}$ The default reference bandwidth is 100 000 000 kb/s or 100 Gb/s; therefore, the default auto-cost metrics for various link speeds are as follows: • 10 Mb/s link: default cost of 10000 • 100 Mb/s link: default cost of 1000 • 1 Gb/s link: default cost of 100

The **reference-bandwidth** command assigns a default cost to the interface based on the interface speed. To override this default cost on an interface, use the **metric** command in the **config>router>ospf>area>interface** *ip-int-name* context or **config>router>ospf3>area>interface** *ip-int-name* context.

The **no** form of the command resets the reference bandwidth to the default value.

Default	reference-bandwidth 100000000
Parameters	<i>bandwidth-in-kbps</i> — the reference bandwidth in kilobits per second, expressed as a decimal integer Values 1 to 400000000 <i>Tera-bps</i> — the reference bandwidth in terabits per second, expressed as a decimal integer Values 1 to 4 <i>Giga-bps</i> — the reference bandwidth in gigabits per second, expressed as a decimal integer Values 1 to 999 <i>Mega-bps</i> — the reference bandwidth in megabits per second, expressed as a decimal integer Values 1 to 999 <i>Kilo-bps</i> — the reference bandwidth in kilobits per second, expressed as a decimal integer Values 1 to 999

router-id

Syntax	router-id <i>ip-address</i> no router-id
Context	config>service>vprn>ospf config>service>vprn>ospf3
Description	This command configures the router ID for a specific VPRN context. If the router ID is not defined under VPRN, the router ID from the base router context is inherited. When configuring the router ID in the base instance of OSPF or OSPFv3, the value overrides the router ID configured in the config>router context. The default value for the base instance is inherited from the configuration in the config>router context. If the router ID in the config>router context is not configured, the following applies: the system uses the system interface address (which is also the loopback address)

- if a system interface address is not configured, the last 4 bytes of the chassis MAC address are used

When configuring a new router ID, the instance is not automatically restarted with the new router ID. The next time the instance is initialized, the new router ID is used.

To force the new router ID to be used, issue the **shutdown** and **no shutdown** commands for the instance, or reboot the entire router.

The **no** form of the command to resets the router ID to the default value.

Default	0.0.0.0 (base OSPF)
Parameters	<i>ip-address</i> — a 32-bit, unsigned integer uniquely identifying the router in the Autonomous System

super-backbone

Syntax	[no] super-backbone
Context	config>service>vprn>ospf
Description	This command specifies whether CE-PE functionality is required. The OSPF super-backbone indicates the type of the LSA generated as a result of routes redistributed into OSPF. When enabled, the redistributed routes are injected as summary, external, or NSSA LSAs. When disabled, the redistributed routes are injected as either external or NSSA LSAs only.
Default	no super-backbone

suppress-dn-bit

Syntax	[no] suppress-dn-bit
Context	config>service>vprn>ospf config>service>vprn>ospf3
Description	This command specifies whether to suppress the setting of the DN (down) bit for OSPF or OSPFv3 LSA packets generated by this instance of OSPF or OSPFv3 on the router. When enabled, the DN bit will not be set. When disabled, this instance of the OSPF or OSPFv3 router will follow the usual procedure to determine whether to set the DN bit.
Default	no suppress-dn-bit

timers

Syntax	timers
Context	config>service>vprn>ospf config>service>vprn>ospf3
Description	This command enables the context that allows for the configuration of OSPF or OSPFv3 timers. Timers control the delay between receipt of an LSA requiring an SPF calculation and the minimum time between successive SPF calculations. Changing the timers affects CPU usage and network reconvergence times. Lower values reduce reconvergence time but increase CPU usage. Higher values reduce CPU usage but increase reconvergence time.
Default	n/a

lsa-arrival

Syntax	lsa-arrival <i>lsa-arrival-time</i> no lsa-arrival
Context	config>service>vprn>ospf>timers config>service>vprn>ospf3>timers
Description	This command defines the minimum delay that must pass between receipt of the same LSAs arriving from neighbors. It is recommended that the configured lsa-generate <i>lsa-second-wait</i> interval for the neighbors be equal to or greater than the <i>lsa-arrival-time</i>. Use the no form of this command to return to the default.
Default	no lsa-arrival
Parameters	<i>lsa-arrival-time</i> — the timer in milliseconds
Values	0 to 600000

lsa-generate

Syntax	lsa-generate <i>max-lsa-wait</i> [<i>lsa-initial-wait</i> [<i>lsa-second-wait</i>]] no lsa-generate
Context	config>service>vprn>ospf>timers config>service>vprn>ospf3>timers

Description	This command customizes the throttling of OSPF or OSPFv3 LSA generation. Timers that determine when to generate the first, second, and subsequent LSAs can be controlled with this command. Subsequent LSAs are generated at increasing intervals of the <i>lsa-second-wait</i> timer until a maximum value is reached. It is recommended that the <i>lsa-arrival-time</i> be equal to or less than the <i>lsa-second-wait</i> interval. Use the no form of this command to return to the default.
Default	no lsa-generate
Parameters	<i>max-lsa-wait</i> — the maximum interval, in milliseconds, between two consecutive occurrences of an LSA being generated Values 10 to 600000 Default 5000 <i>lsa-initial-wait</i> — the first waiting period between LSAs generated, in milliseconds. When the LSA exceeds the <i>lsa-initial-wait</i> timer value and the topology changes, there is no wait period and the LSA is immediately generated. When an LSA is generated, the initial wait period commences. If, within the specified <i>lsa-initial-wait</i> period, another topology change occurs, the <i>lsa-initial-wait</i> timer applies. Values 10 to 600000 Default 5000 <i>lsa-second-wait</i> — the hold time, in milliseconds, between the first and second LSA generation. The next topology change is subject to this second wait period. With each subsequent topology change, the wait time doubles (that is, two times the previous wait time). This assumes that each failure occurs within the relevant wait period. Values 10 to 600000 Default 5000

spf-wait

Syntax	spf-wait <i>max-spf-wait</i> [<i>spf-initial-wait</i> [<i>spf-second-wait</i>]] no spf-wait
Context	config>service>vprn>ospf>timers config>service>vprn>ospf3>timers

Description	This command defines the maximum interval between two consecutive SPF calculations in milliseconds. Timers that determine when to initiate the first, second, and subsequent SPF calculations after a topology change occurs can be controlled with this command. Subsequent SPF runs (if required) will occur at exponentially increasing intervals of the <i>spf-second-wait</i> interval. For example, if the <i>spf-second-wait</i> interval is 1000, the next SPF will run after 2000 ms, and the next SPF will run after 4000 ms, and so on, until it reaches the spf-wait value. The SPF interval will stay at the spf-wait value until there are no more SPF runs scheduled in that interval. After a full interval without any SPF runs, the SPF interval will drop back to <i>spf-initial-wait</i>. The timer must be entered in increments of 100 ms. Values entered that do not match this requirement will be rejected. Use the no form of this command to return to the default.
Default	no spf-wait
Parameters	<i>max-spf-wait</i> — the maximum interval, in milliseconds, between two consecutive SPF calculations Values 10 to 120000 Default 1000 <i>spf-initial-wait</i> — the initial SPF calculation delay, in milliseconds, after a topology change Values 10 to 100000 Default 1000 <i>spf-second-wait</i> — the hold time, in milliseconds, between the first and second SPF calculation Values 10 to 100000 Default 1000

vpn-domain

Syntax	vpn-domain <i>id</i> {0005 0105 0205 8005} no vpn-domain
Context	config>service>vprn>ospf
Description	This command specifies the type of extended community attribute exchanged using BGP to carry the OSPF VPN domain ID. The command applies to VPRN instances of OSPF only. An attempt to modify the value of this attribute will result in an inconsistent value error when the instance is not a VPRN instance. The parameters are mandatory and can be entered in any order. This command is not supported in the ospf3 context.

Default	no vpn-domain
Parameters	<i>id</i> — specifies the 6-octet OSPF VPN domain identifier in the format “xxxx.xxxx.xxxx”. This ID is exchanged using BGP in the extended community attribute associated with a prefix. This parameter applies to VPRN instances of OSPF only. 0005 0105 0205 8005 — specifies the type of extended community attribute exchanged using BGP to carry the OSPF VPN domain ID

vpn-tag

Syntax	vpn-tag <i>vpn-tag</i> no vpn-tag
Context	config>service>vpn>ospf
Description	This command specifies the route tag for an OSPF VPN on a PE router and is used mainly to prevent routing loops. This field is set in the tag field of the OSPF external LSAs generated by the PE. The command applies to VPRN instances of OSPF only. An attempt to modify the value of this tag will result in an inconsistent value error when the instance is not a VPRN instance. This command is not supported in the ospf3 context.
Default	vpn-tag 0
Parameters	<i>vpn-tag</i> — specifies the route tag for an OSPF VPN Values 0 to 4294967295

7.8.2.1.5 IGMP Commands

igmp

Syntax	[no] igmp
Context	config>service>vprn
Description	This command enables the context to configure IGMP parameters. The no form of the command disables IGMP.
Default	disabled

interface

Syntax	[no] interface <i>ip-int-name</i>
Context	config>service>vprn>igmp
Description	This command enables the context to configure IGMP interface parameters.
Parameters	<i>ip-int-name</i> — specifies the name of the IP interface. Interface names can be from 1 to 32 alphanumeric characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed between double quotes.

disable-router-alert-check

Syntax	[no] disable-router-alert-check
Context	config>service>vprn>igmp>if
Description	This command enables or disables the IGMP router alert check option. The no form of the command enables the router alert check.
Default	no disable-router-alert-check

import

Syntax	import <i>policy-name</i> no import
Context	config>service>vprn>igmp>if
Description	This command imports a policy to filter IGMP packets on this interface.

The **no** form of the command removes the policy association from the IGMP instance.

Default	no import
Parameters	<i>policy-name</i> — the import route policy name. The specified names must already be defined.

max-groups

Syntax	max-groups <i>value</i> no max-groups
Context	config>service>vprn>igmp>if
Description	This command specifies the maximum number of groups for which IGMP can have local receiver information based on received IGMP reports on this interface. When this configuration is changed dynamically to a value lower than the currently accepted number of groups, the groups that are already accepted are not deleted. Only new groups will not be allowed. The no form of the command removes the value.
Default	0 — no limit to the number of groups
Parameters	<i>value</i> — specifies the maximum number of groups for this interface Values 1 to 2047

max-grp-sources

Syntax	max-grp-sources <i>max-grp-sources</i> no max-grp-sources
Context	config>service>vprn>igmp>if
Description	This command configures the maximum number of group sources for which IGMP can have local receiver information based on received IGMP reports on this interface. When this configuration is changed dynamically to a value lower than the currently accepted number of group sources, the group sources that are already accepted are not deleted. Only new group sources will not be allowed. The no form of the command reverts to the default.
Default	0
Parameters	<i>max-grp-sources</i> — specifies the maximum number of group sources Values 1 to 2407

ssm-translate

Syntax	ssm-translate
Context	config>service>vprn>igmp config>service>vprn>igmp>if
Description	This command enables the context to configure group ranges that are translated to SSM (S,G) entries. If the static entry needs to be created, it must be translated from an IGMPv1 or IGMPv2 request to a Source Specific Multicast (SSM) join request. An SSM translate source can only be added when the starg command is not enabled. An error message is generated when trying to configure the source command while the starg command is enabled.

grp-range

Syntax	[no] grp-range <i>start end</i>
Context	config>service>vprn>igmp>ssm-translate config>service>vprn>igmp>if>ssm-translate
Description	This command is used to configure group ranges that are translated to SSM (S,G) entries.
Parameters	<i>start</i> — specifies the start address of the multicast group range, in a.b.c.d format <i>end</i> — specifies the end address of the multicast group range, in a.b.c.d format. This value should always be greater than or equal to the <i>start</i> value.

source

Syntax	[no] source <i>ip-address</i>
Context	config>service>vprn>igmp>ssm-translate>grp-range config>service>vprn>igmp>if>ssm-translate>grp-range
Description	This command specifies the source IP address for the group range. Whenever a (*,G) report is received and is in the range specified by grp-range <i>start</i> and <i>end</i> parameters, it is translated to an (S,G) report where <i>ip-address</i> is the source address.
Parameters	<i>ip-address</i> — specifies the unicast source address, in a.b.c.d format

static

Syntax	static
Context	config>service>vprn>igmp>if

Description This command accesses the context to test forwarding on an interface without a receiver host. When enabled, data is forwarded to an interface without having received membership reports from host members.

Default n/a

group

Syntax **[no] group** *grp-ip-address*

Context config>service>vprn>igmp>if>static

Description This command adds a static multicast group as either a (*,G) record or one or more (S,G) records. Use IGMP static group memberships to test multicast forwarding when there is no receiver host. When IGMP static groups are enabled, data is forwarded to an interface without receiving membership reports from host members.

When static IGMP group entries on point-to-point links that connect routers to a rendezvous point (RP) are configured, the static IGMP group entries do not generate join messages toward the RP.

Default n/a

Parameters *grp-ip-address* — specifies an IGMP multicast group address that receives data on an interface. The IP address must be unique for each static group. The address must be in dotted-decimal notation.

source

Syntax **[no] source** *ip-address*

Context config>service>vprn>igmp>if>static>group

Description This command specifies the source address of the multicast group. It is an IPv4 unicast address. By specifying the source address, a multicast receiver host signals to the router that the multicast group will only be receiving multicast traffic from this specific source.

The **source** command and the specification of individual sources for the same group are mutually exclusive.

The **source** command, in combination with the **group** command, is used to create a specific (S,G) static group entry.

The **no** form of the command removes the source from the configuration.

Default n/a

Parameters	<i>ip-address</i> — specifies the IPv4 unicast address
Values	a.b.c.d

subnet-check

Syntax	[no] subnet-check
Context	config>service>vprn>igmp>if
Description	This command enables or disables subnet checking for IGMP messages received on this interface. All IGMP packets with a source address that is not in the local subnet are dropped. The no form of the command disables subnet-check.
Default	enabled

version

Syntax	version <i>version</i> no version
Context	config>service>vprn>igmp>if
Description	This command specifies the IGMP version. If routers run different versions of IGMP, they negotiate the lowest common version of IGMP that is supported by hosts on their subnet and operate in that version. For IGMP to function correctly, all routers on a LAN should be configured to run the same version of IGMP. For IGMPv3, a multicast router that is also a group member performs both parts of IGMPv3, receiving and responding to its own IGMP message transmissions as well as those of its neighbors.
Default	3
Parameters	<i>version</i> — specifies the IGMP version number
Values	1, 2, or 3

query-interval

Syntax	query-interval <i>seconds</i> no query-interval
Context	config>service>vprn>igmp

Description	This command specifies the frequency at which the querier router transmits general host-query messages. The host-query messages solicit group membership information and are sent to the all-systems multicast group address, 224.0.0.1.
Default	125
Parameters	<i>seconds</i> — specifies the frequency, in seconds, at which the router transmits general host-query messages
Values	2 to 1024

query-last-member-interval

Syntax	query-last-member-interval <i>seconds</i> no query-last-member-interval
Context	config>service>vprn>igmp
Description	This command configures the frequency at which the querier sends group-specific query messages, including messages sent in response to leave-group messages; the shorter the interval, the faster the detection of the loss of the last member of a group.
Default	1
Parameters	<i>seconds</i> — specifies the frequency, in seconds, at which query messages are sent
Values	1 to 1023

query-response-interval

Syntax	query-response-interval <i>seconds</i> no query-response-interval
Context	config>service>vprn>igmp
Description	This command specifies how long the querier router waits to receive a response to a host-query message from a host.
Default	10
Parameters	<i>seconds</i> — specifies the length of time, in seconds, that the router waits to receive a response to the host-query message from the host
Values	1 to 1023

robust-count

Syntax	robust-count <i>robust-count</i> no robust-count
Context	config>service>vprn>igmp
Description	This command configures the robust count. The <i>robust-count</i> allows adjusting for the expected packet loss on a subnet. If a subnet anticipates losses, the <i>robust-count</i> can be increased.
Default	2
Parameters	<i>robust-count</i> — specifies the robust count value
	Values 2 to 10

7.8.2.1.6 PIM Commands

pim

Syntax	[no] pim
Context	config>service>vprn
Description	This command configures a Protocol Independent Multicast (PIM) instance in the VPRN service. When a PIM instance is created, the protocol is enabled. PIM is used for multicast routing within the network. Devices in the network can receive the requested multicast feed and non-participating routers can be pruned. The router supports PIM sparse mode (PIM-SM). The no form of the command deletes the PIM protocol instance, removing all associated configuration parameters.
Default	n/a

apply-to

Syntax	apply-to {all none}
Context	config>service>vprn>pim
Description	This command creates a PIM interface configured with default parameters. If a manually created interface or a modified interface is deleted, the interface will be recreated when the apply-to command is executed. If PIM is not required on a specific interface, execute a shutdown command on the interface. The apply-to command is saved first in the PIM configuration structure; all subsequent apply-to commands either create new structures or modify the defaults as created by the apply-to command.
Default	none
Parameters	all — specifies that all VPRN and non-VPRN interfaces are automatically applied in PIM none — specifies that no interfaces are automatically applied in PIM; PIM interfaces must be manually configured

import

Syntax	import { join-policy register-policy } <i>policy-name</i> [<i>policy-name...</i> (up to 5 max)] no import { join-policy register-policy }
Context	config>service>vprn>pim
Description	This command specifies up to five import route policies to be used for determining which routes are accepted from peers. Route policies are configured in the config>router>policy-options context. When an import policy is not specified, BGP routes are accepted by default. The no form of the command removes the policy associations from the PIM instance for the specified type.
Default	no import join-policy no import register-policy
Parameters	join-policy — specifies filtering PIM join messages to prevent unwanted multicast streams from traversing the network register-policy — specifies filtering PIM messages to prevent register messages from being processed by the RP. This filter can only be defined on an RP. When a match is found, the RP immediately sends back a register-stop message. <i>policy-name</i> — specifies the route policy name

interface

Syntax	[no] interface <i>ip-int-name</i>
Context	config>service>vprn>pim
Description	This command enables PIM on an interface and enables the context to configure interface-specific parameters. By default, interfaces are activated in PIM based on the apply-to command and do not have to be configured on an individual basis unless the default values must be changed. The no form of the command deletes the PIM interface configuration for this interface. If the apply-to command parameter is configured, then the no interface form must be saved in the configuration to avoid automatic recreation of the interface after the next apply-to command is executed as part of a reboot. The shutdown command can be used to disable an interface without removing the configuration for the interface.
Default	Interfaces are activated in PIM based on the apply-to command.
Parameters	<i>ip-int-name</i> — specifies the interface name up to 32 characters; if the string contains special characters (#, \$, spaces, etc.), then the entire string must be enclosed between double quotes

assert-period

Syntax	assert-period <i>assert-period</i> no assert-period
Context	config>service>vprn>pim>if
Description	This command configures the time between refreshes of PIM assert messages on an interface. The no form of the command reverts to the default.
Default	60
Parameters	<i>assert-period</i> — specifies the time, in seconds, between refreshes of PIM assert messages on an interface
Values	1 to 300

bsm-check-rtr-alert

Syntax	[no] bsm-check-rtr-alert
Context	config>service>vprn>pim>if
Description	This command enables the checking of the router alert option in the bootstrap messages received on this interface.
Default	no bsm-check-rtr-alert

bfd-enable

Syntax	[no] bfd-enable [ipv4]
Context	config>service>vprn>pim>if
Description	This command enables the use of bidirectional forwarding (BFD) to control the state of the associated protocol interface. By enabling BFD on a protocol interface, the state of the protocol interface is tied to the state of the BFD session between the local node and the remote node. The parameters used for the BFD session are set via the bfd command under the IP interface. The no form of this command removes BFD from the associated IGP protocol adjacency.
Default	no bfd-enable

hello-interval

Syntax	hello-interval <i>hello-interval</i> no hello-interval
Context	config>service>vprn>pim>if
Description	This command configures the interval at which PIM hello messages are transmitted on this interface. The no form of this command reverts to the default value.
Default	30
Parameters	<i>hello-interval</i> — specifies the hello interval, in seconds; a 0 value disables the sending of hello messages Values 0 to 255

hello-multiplier

Syntax	hello-multiplier <i>deci-units</i> no hello-multiplier
Context	config>service>vprn>pim>if
Description	This command configures the multiplier used to determine the hold time for a PIM neighbor. The hello-multiplier in conjunction with the hello-interval determines the hold time for a PIM neighbor.
Parameters	<i>deci-units</i> — specifies the value of the hello-multiplier, in multiples of 0.1, for the formula used to calculate the hello hold-time $\text{hello hold-time} = (\text{hello-interval} * \text{hello-multiplier}) / 10$ This allows the PIMv2 default timeout of 3.5 s to be supported. For example, if hello-interval = 1 s, and hello-multiplier = 35 deci-units, then hold-time = (1 * 35) / 10 = 3.5 s. Values 20 to 100 Default 35 (3.5 s)

improved-assert

Syntax	[no] improved-assert
Context	config>service>vprn>pim>if

Description	This command enables improved assert processing on this interface. The PIM assert process establishes a forwarder node for a LAN and requires interaction between the control and forwarding planes. The assert process is started when data is received on an outgoing interface. There can be an impact on performance if data is continuously received on an outgoing interface. When enabled, the PIM assert process occurs entirely on the control plane, with no interaction between the control and forwarding planes.
Default	enabled

instant-prune-echo

Syntax	[no] instant-prune-echo
Context	config>service>vprn>pim>if
Description	This command enables or disables instant PruneEcho for a PIM interface.
Default	no instant-prune-echo

ipv4-multicast-disable

Syntax	[no] ipv4-multicast-disable
Context	config>service>vprn>pim config>service>vprn>pim>if
Description	This command administratively disables or enables PIM operation for IPv4.
Default	no ipv4-multicast-disable

max-groups

Syntax	max-groups <i>value</i> no max-groups
Context	config>service>vprn>pim>if
Description	This command configures the maximum number of groups for which PIM can have a downstream state based on received PIM join messages on this interface. This number does not include IGMP local receivers on the interface. When this configuration is changed dynamically to a value lower than the currently accepted number of groups, the groups that are already accepted are not deleted. Only new groups will not be allowed. When this configuration has a value of 0, there is no limit to the number of groups.

Parameters	<i>value</i> — specifies the maximum number of groups for this interface
Values	1 to 2047

multicast-senders

Syntax	multicast-senders { auto always never } no multicast-senders
Context	config>service>vprn>pim>if
Description	This command configures the way subnet matching is done for incoming data packets on this interface. An IP multicast sender is a user entity to be authenticated in a receiving host.
Parameters	auto — specifies that subnet matching is automatically performed for incoming data packets on this interface always — specifies that subnet matching is always performed for incoming data packets on this interface never — specifies that subnet matching is never performed for incoming data packets on this interface

priority

Syntax	priority <i>dr-priority</i> no priority
Context	config>service>vprn>pim>if
Description	This command sets the priority value for the interface to become the designated router (DR), so that multiple PIM routers do not exist on one Layer 2 network. The no form of the command resets the priority to the default value.
Default	1 (the router is least likely to become the designated router)
Parameters	<i>dr-priority</i> — specifies the priority to become the designated router; greater values have higher priority Values 1 to 4294967295

sticky-dr

Syntax	sticky-dr [priority <i>dr-priority</i>] no sticky-dr
Context	config>service>vprn>pim>if

Description	This command enables sticky-dr operation on this interface. When enabled, the priority value used in PIM hello messages sent on this interface when elected as the designated router (DR) is changed to the value configured with this command. This is done to avoid forwarding delays caused by DR recovery, which occurs when switching back to the old DR on a LAN when the old DR comes back up. By enabling sticky-dr on this interface, the interface continues to act as the DR for the LAN even after the old DR comes back up. When sticky-dr is used without the priority keyword, the sticky-dr priority value is 1024 (default). The no form of the command disables sticky-dr operation on this interface.				
Default	disabled (no sticky-dr)				
Parameters	<i>dr-priority</i> — when sticky-dr operation is enabled, <i>dr-priority</i> sets the DR priority sent in PIM hello messages after the election of that interface as the DR <table><tr><td>Default</td><td>1024</td></tr><tr><td>Values</td><td>1 to 4294967295</td></tr></table>	Default	1024	Values	1 to 4294967295
Default	1024				
Values	1 to 4294967295				

three-way-hello

Syntax	[no] three-way-hello
Context	config>service>vprn>pim>if
Description	This command configures the compatibility mode to enable three-way hello. By default, three-way hello is disabled on all interfaces and the standard two-way hello is supported.
Default	no three-way-hello

tracking-support

Syntax	[no] tracking-support
Context	config>service>vprn>pim>if
Description	This command sets the T-bit in the LAN prune delay option of the hello message. This indicates the router's capability to disable join-message suppression.
Default	no tracking-support

non-dr-attract-traffic

Syntax	[no] non-dr-attract-traffic
Context	config>service>vprn>pim
Description	This command specifies whether the router should ignore the designated router state and attract traffic even when it is not the designated router.

An operator can configure an interface (router or IES or VPRN interfaces) with IGMP and PIM. The interface IGMP state will be synchronized to the backup node if it is associated with the redundant peer port. The interface can be configured to use PIM, which will cause multicast streams to be sent to the elected DR only. The DR will also be the router sending traffic to the DSLAM. Since it may be required to attract traffic to both routers, a **non-dr-attract-traffic** flag can be used in the PIM context to have the router ignore the DR state and attract traffic when it is not the DR. While using this flag, the router may not send the stream to the DSLAM when it is not the DR.

The **no** form of the command disables the DR state. When disabled, the DR state is used.

Default	no non-dr-attract-traffic

rp

Syntax	rp
Context	config>service>vprn>pim
Description	This command enables access to the context to configure the rendezvous point (RP) of a PIM protocol instance.

A PIM router acting as an RP must respond to a PIM register message that specifies an SSM multicast group address by sending stop register messages to the first-hop router. The PIM router does not build an (S, G) shortest path tree toward the first-hop router. An SSM multicast group address can be an address either from the SSM default range of 232/8 or from a multicast group address range that was explicitly configured for SSM.

Default	rp enabled when PIM is enabled

anycast

Syntax	[no] anycast <i>rp-ip-address</i>
Context	config>service>vprn>pim>rp
Description	This command configures a PIM anycast protocol instance for the RP being configured. Anycast enables fast convergence when a PIM RP router fails by allowing receivers and sources to rendezvous at the closest RP.

The **no** form of the command removes the anycast instance from the configuration.

Default	none
Parameters	<i>rp-ip-address</i> — specifies the loopback IP address shared by all routes that form the RP set for this anycast instance. Only a single address can be configured. If a subsequent anycast command is entered with an address then the old address will be replaced with the new address. If no <i>ip-address</i> is entered then the command is used to enter the anycast CLI level.
Values	a.b.c.d (any valid loopback address configured on the node)

rp-set-peer

Syntax	[no] rp-set-peer ip-address
Context	config>service>vprn>pim>rp>anycast
Description	This command configures a peer in the anycast RP-set. The <i>ip-address</i> identifies the address used by the other node as the RP candidate address for the same multicast group address range as configured on this node.

Caution: This is a manual procedure. Caution should be taken to produce a consistent configuration of an RP-set for a given multicast group address range. The priority should be identical on each node and be a higher value than any other configured RP candidate that is not a member of this RP-set.

Although there is no set maximum number of addresses that can be configured in an RP-set, up to 15 multicast addresses is recommended.

The **no** form of the command removes an entry from the list.

Default	none
Parameters	<i>ip-address</i> — specifies the address used by the other node as the RP candidate address for the same multicast group address range as configured on this node.
Values	a.b.c.d

auto-rp-discovery

Syntax	[no] auto-rp-discovery
Context	config>service>vprn>pim>rp

Description	This command enables auto-RP protocol in discovery mode. In discovery mode, RP-mapping and RP-candidate messages are received and forwarded to downstream nodes. RP-mapping messages are received locally to learn about availability of RP nodes present in the network. Either bsr-candidate for IPv4 or auto-rp-discovery can be configured; the two mechanisms cannot be enabled together. The auto-rp-discovery command cannot be enabled together with mdt-type sender-only or mdt-type receiver-only, or wildcard-spmsi configurations. The no form of the command disables auto-RP discovery.
Default	no auto-rp-discovery

bootstrap-export

Syntax	bootstrap-export <i>policy-name</i> [<i>policy-name</i> ... (up to 5 max)] no bootstrap-export
Context	config>service>vprn>pim>rp
Description	This command exports policies to control the flow of bootstrap messages from the RP. Up to five policies can be defined. The no form of this command removes the specified policy names from the configuration.
Default	n/a
Parameters	<i>policy-name</i> — specifies the policy name, where the policy statement must already be configured in the config>router>policy-options context

bootstrap-import

Syntax	bootstrap-import <i>policy-name</i> [<i>policy-name</i> ... (up to 5 max)] no bootstrap-import
Context	config>service>vprn>pim>rp
Description	This command imports policies to control the flow of bootstrap messages to the RP. Up to five policies can be defined. The no form of this command removes the specified policy names from the configuration.
Default	n/a
Parameters	<i>policy-name</i> — specifies the policy name, where the policy statement must already be configured in the config>router>policy-options context

bsr-candidate

Syntax	bsr-candidate
Context	config>service>vprn>pim>rp
Description	This command enables the context to configure candidate bootstrap router (BSR) parameters. Either bsr-candidate for IPv4 or auto-rp-discovery can be configured; the two mechanisms cannot be enabled together.
Default	bsr-candidate shutdown

address

Syntax	[no] address <i>ip-address</i>
Context	config>service>vprn>pim>rp>bsr-candidate config>service>vprn>pim>rp>rp-candidate
Description	This command configures a static bootstrap or rendezvous point (RP) as long as the source is not directly attached to this router. Use the no form of this command to remove the static RP from the configuration.
Default	no address
Parameters	<i>ip-address</i> — specifies the IP host address that will be used by the IP interface within the subnet. This address must be a unique unicast address within the subnet and specified in dotted decimal notation (1.0.0.0 to 223.255.255.255).
Values	a.b.c.d

hash-mask-len

Syntax	hash-mask-len <i>hash-mask-length</i> no hash-mask-len
Context	config>service>vprn>pim>rp>bsr-candidate
Description	This command is used to configure the length of the mask that is combined with the group address before the hash function is called. All groups with the same hash result will map to the same RP. For example, if the <i>hash-mask-length</i> value is 24, only the first 24 bits of the group addresses matter. This mechanism is used to map one group or multiple groups to an RP.
Default	30

Parameters *hash-mask-length* — the hash mask length
Values 0 to 32

priority

Syntax **priority** *bootstrap-priority*

Context config>service>vprn>pim>rp>bsr-candidate

Description This command defines the priority used when determining the rendezvous point (RP). The higher the priority value the more likely that this router becomes the RP. If there is a tie, the router with the highest IP address is elected.

Parameters *bootstrap-priority* — the priority value used to become the bootstrap router
Values 0 to 255
Default 0 (the router is not eligible to be the bootstrap router)

rp-candidate

Syntax **rp-candidate**

Context config>service>vprn>pim>rp

Description This command enables the context to configure the candidate rendezvous point (RP) parameters.

Default enabled when PIM is enabled

group-range

Syntax [**no**] **group-range** {*grp-ip-prefix/mask* | *grp-ip-prefix netmask*}

Context config>service>vprn>pim>rp>rp-candidate

Description This command configures the group address or range of group addresses for which this router can be the rendezvous point (RP).

 Use the **no** form of this command to remove the group address or range of group addresses for which this router can be the RP from the configuration.

Default none

Parameters *grp-ip-address* — specifies the multicast group IP address expressed in dotted decimal notation (224.0.0.0 to 239.255.255.255)
Values a.b.c.d (multicast group address)

mask — specifies the mask associated with the IP prefix expressed as a mask length or in dotted decimal notation; for example /16 for a sixteen-bit mask. The mask can also be entered in dotted decimal notation (255.255.0.0).

Values 4 to 32

netmask — specifies the subnet mask in dotted decimal notation (0.0.0.0 to 255.255.255.255)

Values a.b.c.d (network bits all 1 and host bits all 0)

holdtime

Syntax	holdtime <i>holdtime</i> no holdtime <i>holdtime</i>
Context	config>service>vprn>pim>rp>rp-candidate
Description	This command defines the length of time a neighboring router considers this router to be up. The no form of this command reverts to the default value.
Default	150
Parameters	<i>holdtime</i> — specifies the length of time, in seconds, that neighbor should consider the sending router to be operational Values 5 to 255

priority

Syntax	priority <i>priority</i> no priority <i>priority</i>
Context	config>service>vprn>pim>rp>rp-candidate
Description	This command defines the priority used to determine the rendezvous point (RP). The higher the priority value, the more likely that this router will become the RP. Use the no form of this command to revert to the default value.
Default	192
Parameters	<i>priority</i> — specifies the priority to become the designated router Values 0 to 255

static

Syntax	static
Context	config>service>vprn>pim>rp
Description	This command enables access to the context to configure a static rendezvous point (RP) for a PIM-SM protocol instance.
Default	none

address

Syntax	[no] address <i>ip-address</i>
Context	config>service>vprn>pim>rp>static
Description	This command configures the static rendezvous point (RP) address. The no form of this command removes the static RP entry from the configuration.
Default	none
Parameters	<i>ip-address</i> — specifies the IP host address in dotted decimal notation (1.0.0.0 to 223.255.255.255). Values a.b.c.d

group-prefix

Syntax	[no] group-prefix { <i>grp-ip-address/mask</i> <i>grp-ip-address netmask</i> }
Context	config>service>vprn>pim>rp>static
Description	The command defines a range of multicast IP addresses for which a certain RP is applicable. The no form of the command removes the criterion.
Default	none
Parameters	<i>grp-ip-address</i> — specifies the multicast IP address Values a.b.c.d (multicast group address) <i>mask</i> — defines the mask of the multicast-ip-address Values 4 to 32 <i>netmask</i> — the subnet mask in dotted decimal notation Values a.b.c.d (network bits all 1 and host bits all 0)

override

Syntax	[no] override
Context	config>service>vprn>pim>rp>static
Description	This command changes the precedence of static RP over dynamically-learned RP. When enabled, the static group-to-RP mappings take precedence over the dynamically-learned mappings.
Default	no override

spt-switchover-threshold

Syntax	spt-switchover-threshold { <i>grp-ip-address/mask</i> <i>grp-ip-address netmask</i> } <i>spt-threshold</i> no spt-switchover-threshold { <i>grp-ip-address/mask</i> <i>grp-ip-address netmask</i> }
Context	config>service>vprn>pim
Description	This command configures a shortest path tree (SPT) switchover threshold for a group prefix. PIM-SM routers with directly connected routers receive multicast traffic initially on a shared tree rooted at the rendezvous point (RP). Once the traffic arrives on the shared tree and the source of the traffic is known, a switchover to the SPT tree rooted at the source is attempted. For a group that falls in the range of a prefix configured in the table, the corresponding threshold value determines when the router should switch over from the shared tree to the source specific tree. The switchover is attempted only if the traffic rate on the shared tree for the group exceeds the configured threshold. In the absence of any matching prefix in the table, the default behavior is to switchover when the first packet is seen. In the presence of multiple prefixes matching a given group, the most specific entry is used.
Parameters	<i>grp-ip-address</i> — specifies the multicast group address Values a.b.c.d (multicast group address) <i>mask</i> — defines the mask of the multicast IP address Values 4 to 32 <i>netmask</i> — the subnet mask in dotted decimal notation Values a.b.c.d (network bits all 1 and host bits all 0)

spt-threshold — specifies the configured threshold, in kilobits per second (kb/s), for the group to which this (S,G) belongs. For a group (G) configured with a threshold, switchover to SPT for an (S,G) is attempted only if the (S,G) rate exceeds this configured threshold. When the **infinity** keyword is specified, no switchover will occur at any time, regardless of the traffic level detected.

Values 1 to 4294967294 | infinity (threshold in kbps)

ssm-default-range-disable

Syntax	[no] ssm-default-range-disable ipv4
Context	config>service>vprn>pim
Description	This command specifies whether to disable the use of default range (232/8) for SSM so that it can be used by ASM to process (*,G). When enabled, the use of the default range is disabled for SSM and it (the default range) can be used by ASM. When disabled, the SSM default range is enabled. The no form of the command enables the use of the default range.
Default	no ssm-default-range-disable (enabled)

ssm-groups

Syntax	[no] ssm-groups
Context	config>service>vprn>pim
Description	This command enables access to the context to enable a source-specific multicast (SSM) configuration instance.
Default	none

group-range

Syntax	[no] group-range {ip-prefix/mask ip-prefix netmask}
Context	config>service>vprn>pim>ssm-groups
Description	This command configures the group address or range of group addresses for which this router can be the rendezvous point (RP). Use the no form of this command to remove the group address or range of group addresses for which this router can be the RP from the configuration.
Default	none

Parameters	<i>ip-prefix</i> — specifies the addresses or address ranges for which this router can be an RP
Values	a.b.c.d
	<i>mask</i> — specifies the address mask used with the address to define a range of addresses
Values	0 to 32
	<i>netmask</i> — specifies the subnet mask in dotted decimal notation
Values	a.b.c.d (network bits all 1 and host bits all 0)

7.8.2.1.7 RIP Commands

rip

Syntax	[no] rip
Context	config>service>vprn
Description	This command enables the RIP protocol on a VPRN interface. The no form of the command disables the RIP protocol on a VPRN interface.

authentication-key

Syntax	authentication-key [<i>authentication-key</i> <i>hash-key</i>] [hash hash2] no authentication-key
Context	config>service>vprn>rip config>service>vprn>rip>group config>service>vprn>rip>group>neighbor
Description	This command sets the authentication password to be passed between RIP neighbors. The authentication type and authentication key must match exactly in order for the RIP message to be considered authentic. The authentication key can be any combination of ASCII characters up to 16 characters long. The hash-key can be any combination of ASCII characters up to 33 characters long. The no form of the command removes the authentication password from the configuration and disables authentication.
Default	no authentication-key
Parameters	<i>authentication-key</i> — the authentication key. The key can be any combination of ASCII characters up to 16 characters in length (unencrypted). If spaces are used in the string, the entire string must be enclosed in double quotes. <i>hash-key</i> — the hash key. The key can be any combination of ASCII characters up to 33 characters in length (encrypted). If spaces are used in the string, the entire string must be enclosed in double quotes. hash — specifies the key is entered in an encrypted form. If the hash parameter is not used, the key is assumed to be in a unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the hash parameter specified. hash2 — specifies the key is entered in a more complex encrypted form. If the hash2 parameter is not used, the less encrypted hash form is assumed.

authentication-type

Syntax	authentication-type {none password message-digest-20}
Context	config>service>vprn>rip config>service>vprn>rip>group config>service>vprn>rip>group>neighbor
Description	This command sets the type of authentication to be used between RIP neighbors. Authentication type can be specified regardless of the configured send and receive parameters, but will only apply to RIPv2 packets. The type and password must match exactly for the RIP message to be considered authentic and processed. The no form of the command removes the authentication type from the configuration and disables authentication.
Default	no authentication-type
Parameters	none — disables authentication password — enables simple password (plain text) authentication. If authentication is enabled and no authentication type is specified in the command, simple password authentication is enabled. message-digest-20 — configures 16-byte message digest for MD5 authentication. If this option is configured, then at least one message-digest key must be configured.

check-zero

Syntax	check-zero {enable disable} no check-zero
Context	config>service>vprn>rip config>service>vprn>rip>group config>service>vprn>rip>group>neighbor
Description	This command enables checking for zero values in fields specified to be zero by the RIPv1 and RIPv2 specifications. The check-zero enable command enables checking of the mandatory zero fields in the RIPv1 and RIPv2 specifications and rejecting of non-compliant RIP messages. The check-zero disable command disables this check and allows the receipt of RIP messages even if the mandatory zero fields are non-zero. The check-zero command can be enabled at all three RIP levels. The most specific value is used. If no check-zero value is set (no check-zero), the setting from the less-specific level is inherited by the lower level.

The **no** form of the command disables check-zero on the configuration.

Default	no check-zero
Parameters	enable — configures the router to reject RIP messages that do not have zero in the mandatory fields disable — configures the router to accept RIP messages that do not have zero in the mandatory fields

export

Syntax	export <i>policy-name</i> [<i>policy-name...</i> (up to 5 max)]
Context	<pre>config>service>vprn>rip config>service>vprn>rip>group config>service>vprn>rip>group>neighbor</pre>
Description	This command specifies the export policies to be used to control routes advertised to RIP neighbors. By default, when no export policies are specified, RIP routes are advertised and non-RIP routes are not advertised. The no form of the command removes all route policy names from the export list.
Default	no export
Parameters	<i>policy-name</i> — the route policy name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

export-limit

Syntax	export-limit <i>number</i> [log <i>percentage</i>] no export-limit
Context	config>service>vprn>rip
Description	This command configures the maximum number of routes (prefixes) that can be exported into RIP from the route table. The no form of the command removes the configured parameter values.
Default	no export-limit

Parameters	<i>number</i> — specifies the maximum number of routes (prefixes) that can be exported into RIP from the route table
Values	1 to 4294967295
	<i>percentage</i> — specifies the percentage of the export-limit, that when reached, causes a warning log message and SNMP notification to be sent
Values	1 to 100

group

Syntax	[no] group <i>group-name</i>
Context	config>service>vprn>rip
Description	This command creates a context for configuring a RIP group of neighbors. RIP groups logically associate RIP neighbor interfaces to facilitate a common configuration for RIP interfaces. The no form of the command deletes the RIP neighbor interface group. Deleting the group will also remove the RIP configuration of all the neighbor interfaces currently assigned to this group.
Default	no group
Parameters	<i>group-name</i> — the RIP group name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

import

Syntax	import <i>policy-name</i> [<i>policy-name</i> ... (up to 5 max)]
Context	config>service>vprn>rip config>service>vprn>rip>group config>service>vprn>rip>group>neighbor
Description	This command specifies the import policy to be used to control routes advertised from RIP neighbors. By default, RIP accepts all routes from RIP neighbors. Import policies can be used to limit or modify the routes accepted and their corresponding parameters and metrics. The no form of the command removes all route policy names from the import list.
Default	no import

Parameters *policy-name* — the route policy name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

message-size

Syntax **message-size** *max-num-of-routes*
no message-size

Context config>service>vprn>rip
 config>service>vprn>rip>group
 config>service>vprn>rip>group>neighbor

Description This command configures the maximum number of routes per RIP update message.

By default, each update can contain a maximum of 25 route advertisements. This limit is imposed by RIP specifications. RIP can be configured to send as many as 255 routes per update.

The **no** form of the command reverts to the default value.

Default no message-size

Parameters *max-num-of-routes* — an integer value

Default	25
Values	25 to 255

metric-in

Syntax **metric-in** *metric*
no metric-in

Context config>service>vprn>rip
 config>service>vprn>rip>group
 config>service>vprn>rip>group>neighbor

Description This command configures the metric added to routes received from a RIP neighbor. The specified metric value is added to the hop count and shortens the maximum distance of the route.

When applying an export policy to a RIP configuration, the policy overrides the metric values determined through calculations involving the **metric-in** and **metric-out** values.

The **no** form of the command reverts to the default value.

Default no metric-in

Parameters	<i>metric</i> — the value added to the metric of routes received from a RIP neighbor, expressed as a decimal integer
Values	1 to 16

metric-out

Syntax	metric-out <i>metric</i> no metric-out
Context	config>service>vprn>rip config>service>vprn>rip>group config>service>vprn>rip>group>neighbor
Description	This command configures the metric added to routes exported into RIP and advertised to RIP neighbors. The specified metric value is added to the hop count and shortens the maximum distance of the route. When applying an export policy to a RIP configuration, the policy overrides the metric values determined through calculations involving the metric-in and metric-out values. The no form of the command removes the command from the configuration and resets the metric-in value to the default.
Default	no metric-out
Parameters	<i>metric</i> — the value added to the metric of routes exported into RIP and advertised to RIP neighbors, expressed as a decimal integer
Values	1 to 16

neighbor

Syntax	[no] neighbor <i>ip-int-name</i>
Context	config>service>vprn>rip>group
Description	This command creates a context for configuring a RIP neighbor interface. By default, interfaces are not activated unless explicitly configured. The no form of the command deletes the RIP interface configuration for this interface. The shutdown command in the config>router>rip>group>neighbor context can be used to disable an interface without removing the configuration for the interface.
Default	no neighbor

Parameters *ip-int-name* — the IP interface name. Interface names must be unique within the group of defined IP interfaces for **config>router>interface** and **config>service>vprn>interface** commands. An interface name cannot be in the form of an IP address. Interface names can be any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

preference

Syntax **preference** *preference*
no preference

Context config>service>vprn>rip
 config>service>vprn>rip>group
 config>service>vprn>rip>group>neighbor

Description This command configures the route preference assigned to RIP routes. This value can be overridden by route policies.

 The **no** form of the command reverts to the default value.

Default no preference

Parameters *preference* — the route preference, expressed as an integer value

Default 100

Values 1 to 255

propagate-metric

Syntax **[no] propagate-metric**

Context config>service>vprn>rip

Description This command allows the RIP metric to be used to set the MP-BGP MED attribute when RIP is used as the CE-PE routing protocol for VPRNs. This is similar to the way the OSPF metric can be used to set the MP-BGP metric when OSPF is used as the CE-PE protocol.

 MP-BGP uses the RIP metric to set the MED attribute, which is flooded throughout the MP-BGP peers and is then used to set the RIP metric at the other end and re-advertise the RIP metric to the far-end RIP neighbors.

receive

Syntax	receive <i>receive-type</i> no receive								
Context	config>service>vprn>rip config>service>vprn>rip>group config>service>vprn>rip>group>neighbor								
Description	This command configures the types of RIP updates that will be accepted and processed. If you specify both or version-2, the RIP instance listens for, and accepts, packets sent to the broadcast (255.255.255.255) and multicast (224.0.0.9) addresses. If version-1 is specified, the router only listens for and accepts packets sent to the broadcast address. The default behavior is to accept and process both RIPv1 and RIPv2 messages. The no form of the command reverts to the default value.								
Default	both								
Parameters	<i>receive-type</i> — configures the type of RIP updates that will be accepted and processed Values <i>receiver-type</i> values are both, none, version-1, and version-2, where: <table> <tr> <td>both</td><td>specifies that RIP updates in either version 1 or version 2 format will be accepted</td></tr> <tr> <td>none</td><td>specifies that RIP updates will not be accepted</td></tr> <tr> <td>version-1</td><td>specifies that only RIP updates in version 1 format will be accepted</td></tr> <tr> <td>version-2</td><td>specifies that only RIP updates in version 2 format will be accepted</td></tr> </table>	both	specifies that RIP updates in either version 1 or version 2 format will be accepted	none	specifies that RIP updates will not be accepted	version-1	specifies that only RIP updates in version 1 format will be accepted	version-2	specifies that only RIP updates in version 2 format will be accepted
both	specifies that RIP updates in either version 1 or version 2 format will be accepted								
none	specifies that RIP updates will not be accepted								
version-1	specifies that only RIP updates in version 1 format will be accepted								
version-2	specifies that only RIP updates in version 2 format will be accepted								

send

Syntax	send <i>send-type</i> no send
Context	config>service>vprn>rip config>service>vprn>rip>group config>service>vprn>rip>group>neighbor
Description	This command specifies the type of RIP messages sent to RIP neighbors. If multicast is specified, the router sends RIPv2 messages to the multicast (224.0.0.9) destination address.

If **broadcast**, or **version-1** is specified, the router only listens for and accepts packets sent to the broadcast address.

The **no** form of this command reverts to the default value.

Default	broadcast
Parameters	<i>send-type</i> — configures the type of RIP messages that will be sent to RIP neighbors
Values	<i>send-type</i> values are broadcast, multicast, none, and version-1, where: broadcast: sends RIPv2 formatted messages to the broadcast address multicast: sends RIPv2 formatted messages to the multicast address none: does not to send any RIP messages (silent listener) version-1: sends RIPv1 formatted messages to the broadcast address

split-horizon

Syntax	split-horizon {enable disable} no split-horizon
Context	config>service>vprn>rip config>service>vprn>rip>group config>service>vprn>rip>group>neighbor
Description	This command enables the use of split-horizon. RIP uses split-horizon with poison-reverse to protect from such problems as “counting to infinity”. Split-horizon with poison reverse means that routes learned from a neighbor through an interface are advertised in updates out of the same interface but with a metric of 16 (infinity). The split-horizon disable command enables split-horizon without poison-reverse. This allows the routes to be re-advertised on interfaces other than the interface that learned the route, with the advertised metric equaling an increment of the metric-in value. This parameter can be set at three levels: global level (applies to all groups and neighbor interfaces), group level (applies to all neighbor interfaces in the group), or neighbor level (only applies to the specified neighbor interface). The most specific value is used. If no value is set (no split-horizon), the setting from the less-specific level is inherited by the lower level. The no form of the command disables split-horizon.
Default	enable
Parameters	enable — enables split-horizon and poison-reverse disable — disables poison-reverse but leaves split-horizon enabled

timers

Syntax	timers <i>update timeout flush</i>												
Context	config>service>vprn>rip config>service>vprn>rip>group config>service>vprn>rip>group>neighbor												
Description	This command configures values for the update, timeout, and flush RIP timers. The RIP update timer determines how often RIP updates are sent. If the route is not updated by the time the RIP timeout timer expires, the route is declared invalid but is maintained in the RIP database. The RIP flush timer determines how long a route is maintained in the RIP database after it has been declared invalid. After the flush timer expires, the route is removed from the RIP database. The no form of the command reverts all timers to their default values.												
Default	no timers												
Parameters	<i>update</i> — the RIP update timer value, in seconds, expressed as a decimal integer <table><tr><td>Values</td><td>1 to 600</td></tr><tr><td>Default</td><td>30</td></tr></table> <i>timeout</i> — the RIP timeout value, in seconds, expressed as a decimal integer <table><tr><td>Values</td><td>1 to 1200</td></tr><tr><td>Default</td><td>180</td></tr></table> <i>flush</i> — the RIP flush timer value, in seconds, expressed as a decimal integer <table><tr><td>Values</td><td>1 to 1200</td></tr><tr><td>Default</td><td>120</td></tr></table>	Values	1 to 600	Default	30	Values	1 to 1200	Default	180	Values	1 to 1200	Default	120
Values	1 to 600												
Default	30												
Values	1 to 1200												
Default	180												
Values	1 to 1200												
Default	120												

7.8.2.1.8 VPRN Security Configuration Commands

zone

Syntax	zone { <i>zone-id</i> <i>zone-name</i> } [create] no zone <i>zone-id</i>
Context	config>service>vprn
Description	This command creates or specifies a security zone within a VPRN context. Each zone must have a unique ID. All zones must be explicitly created with the create keyword. If no zones are created within a service or router context, a zone will not exist on that object. Enter an existing zone without the create keyword to edit zone parameters. The no form of this command deletes the zone. When a zone is deleted, all configuration parameters for the zone are also deleted.
Parameters	<i>zone-id</i> — the zone ID number. The zone ID must be unique within the system.
Values	1 to 65534

abort

Syntax	abort
Context	config>service>vprn>zone
Description	This command discards changes made to a security feature.
Default	n/a

begin

Syntax	begin
Context	config>service>vprn>zone
Description	This command enters the mode to create or edit security features.
Default	n/a

commit

Syntax	commit
Context	config>service>vprn>zone
Description	This command saves changes made to security features.
Default	n/a

auto-bind

Syntax	auto-bind no auto-bind
Context	config>service>vprn>zone
Description	This command creates a security zone on automatically bound GRE, MPLE, or LDP transport tunnels configured for this service. Depending on how the security policy is configured, any traffic entering or exiting the zone is firewalled; traffic traveling between auto-bind LSPs in the zone is not firewalled.
Default	n/a

inbound

Syntax	inbound
Context	config>service>vprn>zone
Description	This command enables the context to configure limit parameters on inbound security sessions.
Default	n/a

outbound

Syntax	outbound
Context	config>service>vprn>zone
Description	This command enables the context to configure limit parameters for outbound security sessions on the CSM.
Default	n/a

limit

Syntax	limit
Context	config>service>vprn>zone>inbound config>service>vprn>zone>outbound
Description	This command enables the context to configure limits on concurrent sessions for inbound or outbound firewall sessions on the CSM.
Default	n/a

concurrent-sessions

Syntax	concurrent-sessions { tcp udp icmp other } <i>sessions</i> no concurrent-sessions { tcp udp icmp other }
Context	config>service>vprn>zone>inbound>limit config>service>vprn>zone>outbound>limit
Description	This command configures the maximum number of concurrent firewall sessions that can be established per zone, in either the inbound or outbound direction.
Default	n/a
Parameters	tcp — specifies that TCP connection traffic is to be firewalled udp — specifies that UDP connection traffic is to be firewalled icmp — specifies that ICMP connection traffic is to be firewalled other — specifies that the traffic to be firewalled is other than TCP, UDP, or ICMP <i>sessions</i> — the maximum number of concurrent firewall sessions that can be created in a zone for the configured direction Values 1 to 16383

interface

Syntax	[no] interface <i>ip-int-name</i>
Context	config>service>vprn>zone
Description	This command creates a logical IP routing interface for a zone. Once created, attributes such as an IP address can be associated with the IP interface. Multiple interfaces can be configured on a zone. The no form of this command removes the IP interface and all the associated configurations.

Parameters *ip-int-name* — the name of the interface to be configured within the zone

Values 1 to 32 characters (must start with a letter)

log

Syntax **log** {*log-id* | *name*}
no log

Context config>service>vprn>zone

Description This command configures a log identifier for the specified zone. A log identifier can be configured in the **config>router>zone** context and the **config>security>policy** context.

The **no** form of this command removes logging for the zone.

Parameters *log-id* — specifies the identifier for the log

Values 1 to 32 characters

name

Syntax **name** *zone-name*
no name

Context config>service>vprn>zone

Description This command configures a zone name. The zone name is unique within the system. It can be used to refer to the zone under configure, show, and clear commands.

Parameters *zone-name* — specifies the name of the zone

Values 1 to 32 characters (must start with a letter). If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

nat

Syntax **nat**

Context config>service>vprn>zone

Description This command enters the context to configure NAT security parameters for a zone.

pool

Syntax	pool <i>pool-id</i> [create] no pool <i>pool-id</i>
Context	config>service>vprn>zone>nat
Description	This command configures the NAT pool for the security zone within a VPRN service. Each pool must have a unique ID. All pools must be explicitly created with the create keyword. Enter an existing pool without the create keyword to edit pool parameters. The no form of this command deletes the specified NAT pool. When a pool is deleted, all configuration parameters for the pool will also be deleted.
Parameters	<i>pool-id</i> — the pool ID number
Values	1 to 100

direction

Syntax	direction { zone-outbound zone-inbound both } no direction
Context	config>service>vprn>zone>nat>pool
Description	This command configures the NAT pool direction for the security zone. A specific NAT pool can be configured for different directions while using the same policy. For example, if the security policy entry direction is set to both, separate inbound and outbound pools can be created for that policy. The no form of this command deletes the direction.
Parameters	zone-outbound — configures a pool for the policy outbound traffic zone-inbound — configures a pool for the policy inbound traffic both — configures a pool for policy inbound and outbound traffic

entry

Syntax	entry <i>entry-id</i> [create] no entry <i>entry-id</i>
Context	config>service>vprn>zone>nat>pool
Description	This command configures a NAT pool entry within a VPRN service.

The **no** form of this command deletes the entry with the specified ID. When an entry is deleted, all configuration parameters for the entry will also be deleted.

Parameters *entry-id* — the entry ID number

Values 1 to 65535

ip-address

Syntax **ip-address** *ip-address* [**to** *ip-address*] **interface** *ip-int-name*
no ip-address

Context config>service>vprn>zone>nat>pool>entry

Description This command configures the source IP address or IP address range to which packets that match NAT policy are routed using NAT. An interface can also be configured, in which case all packets that match NAT policy are routed to the interface IP address. If the interface IP address is changed dynamically, NAT is updated accordingly. Only one IP address can be associated with an IP interface. Source IP addresses and interfaces cannot be used together in a single NAT pool.

The IP address for the interface must be entered in dotted-decimal notation.

The **no** form of the command removes the IP address assignment. The **no** form of this command can only be performed when the IP interface is administratively shut down. Shutting down the IP interface brings the interface operationally down.

Parameters *ip-address* — the source IP address to be used by NAT. The *ip-address* portion of the **ip-address** command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted-decimal notation.

Values 1.0.0.0 to 223.255.255.255

ip-int-name — the name of the interface to be used by NAT

port

Syntax **port** *port* [**to** *port*]
no port

Context config>service>vprn>zone>nat>pool>entry

Description This command configures the UDP/TCP port or port range. Packets that match NAT policy undergo network port address translation (NPAT) and are routed to their source UDP/TCP port. Configuring a UDP/TCP port pool requires an IP-address pool because the 7705 SAR does not support port address translation (PAT) alone.

The **no** form of this command deletes the port or port range.

Parameters *port* — the UDP/TCP port or range of ports to which NPAT is applied

name

Syntax **name** *pool-name*
no name

Context config>service>vprn>zone>nat>pool

Description This command configures a zone pool name. Pool names must be unique within the group of pools defined for a zone. It can be used to refer to the pool under configure, show, and clear commands.

Parameters *pool-name* — specifies the name of the pool. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

Values 1 to 32 characters (must start with a letter).

policy

Syntax **policy** {*policy-id* | *policy-name*}
no policy *policy-id*

Context config>service>vprn>zone

Description This command sets the policy to be used by the security zone to build its matching criteria for incoming packets.

The **no** form of this command deletes the specified policy.

Parameters *policy-id* — the number of the referenced policy

Values 1 to 65535

7.8.2.1.9 VPRN Raw Socket IP Transport Configuration Commands

ip-transport

Syntax	[no] ip-transport <i>ipt-id</i> [create] no ip-transport <i>ipt-id</i>
Context	config>service>vprn
Description	This command creates an IP transport subservice within a VPRN service. An IP transport subservice is used to transmit serial raw socket data to and from a local host and remote host. All IP transport subservices must be explicitly created using the create keyword. An IP transport subservice is owned by the service within which it is created. An IP transport subservice can only be associated with a single service. The create keyword is not needed when editing parameters for an existing IP transport subservice. An IP transport subservice must be first shut down before changes can be made to the configured parameters. The no form of this command deletes the IP transport subservice with the specified <i>ipt-id</i>. When an IP transport subservice is deleted, all configured parameters for the IP transport subservice are also deleted.
Default	no ip-transport
Parameters	<i>ipt-id</i> — the IP transport subservice physical port identifier. The <i>ipt-id</i> must reference an RS-232 serial port that has been configured as a socket and has its encapsulation type set to raw. Refer to the 7705 SAR Interface Configuration Guide, “Serial Commands”, for more information. Values value in the format <i>slot/mda/port.channel</i> create — creates this IP transport subservice

dscp

Syntax	dscp <i>dscp-name</i>
Context	config>service>vprn>ip-transport
Description	This command configures the DSCP name used to mark the DSCP field in IP transport packets originating from this node. Raw socket traffic redirection to a specific queue is enabled by the fc command.
Default	ef
Parameters	<i>dscp-name</i> — the DSCP name used to mark the DSCP field in IP transport packets. Table 130 lists the valid DSCP names.

Table 130 **Valid DSCP Names**

dscp-name
be, ef, cp1, cp2, cp3, cp4, cp5, cp6, cp7, cp9, cs1, cs2, cs3, cs4, cs5, nc1, nc2, af11, af12, af13, af21, af22, af23, af31, af32, af33, af41, af42, af43, cp11, cp13, cp15, cp17, cp19, cp21, cp23, cp25, cp27, cp29, cp31, cp33, cp35, cp37, cp39, cp41, cp42, cp43, cp44, cp45, cp47, cp49, cp50, cp51, cp52, cp53, cp54, cp55, cp57, cp58, cp59, cp60, cp61, cp62, cp63

fc

Syntax	fc <i>fc-name</i> profile { in out }
Context	config>service>vprn>ip-transport
Description	This command configures the forwarding class and profile marking for IP transport packets originating from this node.
Default	ef for fc, in for profile
Parameters	<i>fc-name</i> — the forwarding class name to use for the IP transport packets Values be, l2, af, l1, h2, ef, h1, nc profile { in out } — specifies the profile marking for the IP transport packets, either in or out

filter-unknown-host

Syntax	[no] filter-unknown-host
Context	config>service>vprn>ip-transport
Description	This command filters connections from unknown hosts. An unknown host is any host that is not configured as a remote host. The no form of this command disables the filter.
Default	no filter-unknown-host

local-host

Syntax	local-host <i>ip-addr ip-addr port-num port-num protocol {tcp udp}</i> no local-host
Context	config>service>vprn>ip-transport
Description	This command creates the local host within the IP transport subservice. The local host is required to accept TCP/UDP sessions initiated from far-end remote hosts, and for the node to initiate sessions towards the far-end remote hosts. The no form of this command deletes the local host.
Default	no local-host
Parameters	<i>ip-addr</i> — the IP address that is used for this local host. The IP address must be the same as a loopback or local interface IP address that is already configured within this service. Values a.b.c.d (IPv4 address) <i>port-num</i> — the port number that is used by remote hosts to establish TCP/UDP sessions to this local host Values 1026 to 49150 protocol {tcp udp} — the protocol type that is used for all sessions to and from this local host, either tcp or udp

remote-host

Syntax	remote-host <i>host-id ip-addr ip-addr port-num port-num [create]</i> no remote-host <i>host-id</i>
Context	config>service>vprn>ip-transport
Description	This command creates a remote host within the IP transport subservice. Multiple remote hosts may be created in order to send serial raw socket IP transport data to multiple destinations. The create keyword must be used for each remote host that is created. The no form of this command deletes the remote host.
Default	no remote-host
Parameters	<i>host-id</i> — the remote host identifier Values 1 to 2147483647 or a name string up to 64 characters long <i>ip-addr</i> — the IP address that is used to reach the remote host in order to route IP transport packets to that remote host Values a.b.c.d (IPv4 address)

port-num — the destination port number that is used to reach the serial port socket on the remote host

Values 1 to 65535

create — creates this remote host

name

Syntax **name** *host-name*
no name

Context config>service>vprn>ip-transport>remote-host

Description This command configures a unique name for this remote host.
The **no** form of this command deletes the remote host name.

Default n/a

Parameters *host-name* — a unique name for this remote host, up to 64 characters long

tcp

Syntax **tcp**

Context config>service>vprn>ip-transport

Description This command enables the context to configure TCP parameters within this IP transport subservice.

Default n/a

inactivity-timeout

Syntax **inactivity-timeout** *seconds*

Context config>service>vprn>ip-transport>tcp

Description This command specifies how long to wait before disconnecting a TCP connection due to traffic inactivity over the connection.

Default 30 s

Parameters *seconds* — how long to wait, in seconds, before disconnecting a TCP connection

Values 1 to 65535

max-retries

Syntax	max-retries <i>number</i>
Context	config>service>vprn>ip-transport>tcp
Description	This command specifies the number of times that a remote host, acting as a client, tries to establish a TCP connection after the initial attempt fails.
Default	5
Parameters	<i>number</i> — the number of attempts to establish a TCP connection after the initial attempt fails Values 1 to 10

retry-interval

Syntax	retry-interval <i>seconds</i>
Context	config>service>vprn>ip-transport>tcp
Description	This command specifies how long to wait before each TCP max-retries attempt.
Default	5 s
Parameters	<i>seconds</i> — how long to wait, in seconds, before each TCP max-retries attempt Values 1 to 300

7.8.2.1.10 Multicast VPN Commands

mvpn

Syntax	mvpn
Context	config>service>vprn
Description	This command enables the context to configure MVPN-related parameters for the IP VPN.

auto-discovery

Syntax	auto-discovery [default]
Context	config>service>vprn>mvpn
Description	This command enables MVPN membership auto-discovery through BGP. When auto-discovery is enabled, PIM peering on the inclusive provider tunnel is disabled. Changing the auto-discovery configuration requires a shutdown of this VPRN instance.
Default	default
Parameters	default — enables auto-discovery route exchange based on the format defined in NG-MVPN (RFC 6514)

c-mcast-signaling

Syntax	c-mcast-signaling bgp
Context	config>service>vprn>mvpn
Description	This command specifies BGP for PE-to-PE signaling of CE multicast states.
Default	bgp
Parameters	bgp — specifies to use BGP for PE-to-PE signaling of CE multicast states. Auto-discovery must be enabled.

mdt-type

Syntax	mdt-type {sender-only receiver-only sender-receiver} no mdt-type
Context	config>service>vprn>mvpn

Description	This command allows the restriction of an MVPN instance per PE node to a specific role. By default, an MVPN instance on a PE node assumes the role of a sender as well as a receiver. This creates a mesh of MDT/PMSI across all PE nodes from this PE. This command provides an option to configure either a sender-only or receiver-only mode per PE node. Restricting the role of a PE node avoids creating a full mesh of MDT/PMSI across all PE nodes that are participating in the MVPN instance. The no version of this command restores the default (sender-receiver).
Default	sender-receiver
Parameters	sender-only — MVPN has only senders connected to the PE node receiver-only — MVPN has only receivers connected to the PE node sender-receiver — MVPN has both senders and receivers connected to the PE node

provider-tunnel

Syntax	provider-tunnel
Context	config>service>vprn>mvpn
Description	This command enables the context to configure tunnel parameters for the MVPN.

inclusive

Syntax	inclusive
Context	config>service>vprn>mvpn>pt
Description	This command enables the context for specifying inclusive provider tunnels.

mldp

Syntax	[no] mldp
Context	config>service>vprn>mvpn>pt>inclusive config>service>vprn>mvpn>provider-tunnel>selective
Description	This command enables the use of an mLDP LSP for the provider tunnel.
Default	no mldp

shutdown

Syntax	[no] shutdown
Context	config>service>vprn>mvpn>ptl>inclusive>mldp config>service>vprn>mvpn>provider-tunnel>selective>mldp
Description	This command administratively disables or enables the use of an mLDP LSP for the provider tunnel.
Default	no shutdown

selective

Syntax	selective
Context	config>service>vprn>mvpn>provider-tunnel
Description	This command enables the context to specify selective provider tunnel parameters.
Default	n/a

data-delay-interval

Syntax	data-delay-interval <i>value</i> no data-delay-interval
Context	config>service>vprn>mvpn>provider-tunnel>selective
Description	This command specifies the interval, in seconds, before a PE router connected to the source switches traffic from the inclusive provider tunnel to the selective provider tunnel. The no form of the command resets the value to the default.
Default	3 s
Parameters	<i>value</i> — specifies the data delay interval, in seconds Values 3 to 180

data-threshold

Syntax	data-threshold { <i>c-grp-ip-addr/mask</i> <i>c-grp-ip-addr netmask</i> } <i>s-pmsi-threshold</i> no data-threshold { <i>c-grp-ip-addr/mask</i> <i>c-grp-ip-addr netmask</i> }
Context	config>service>vprn>mvpn>provider-tunnel>selective

Description	This command specifies the data rate threshold that triggers the switch from the inclusive provider tunnel to the selective provider tunnel for (C-S, C-G) within the group range. Optionally, PE thresholds for creating or deleting NG-MVPN S-PMSI may also be specified. Omitting the PE thresholds preserves the currently set value (or defaults, if never set). Multiple statements (one per unique group) are allowed in the configuration. The no form of the command removes the values from the configuration.										
Default	no data-threshold										
Parameters	<i>c-grp-ip-addr/mask</i> <i>c-grp-ip-addr netmask</i> — specifies an IPv4 multicast group address and netmask length or network mask <table> <tr> <td>Values</td><td></td></tr> <tr> <td><i>c-grp-ip-addr</i></td><td>multicast group address a.b.c.d</td></tr> <tr> <td><i>mask</i></td><td>4 to 32</td></tr> <tr> <td><i>netmask</i></td><td>a.b.c.d (network bits all 1 and host bits all 0)</td></tr> </table> <i>s-pmsi-threshold</i> — specifies the rate, in kb/s. If the rate for a (C-S, C-G) within the specified group range exceeds the threshold, traffic for the (C-S, C-G) will be switched to the selective provider tunnel. <table> <tr> <td>Values</td><td>1 to 4294967294</td></tr> </table>	Values		<i>c-grp-ip-addr</i>	multicast group address a.b.c.d	<i>mask</i>	4 to 32	<i>netmask</i>	a.b.c.d (network bits all 1 and host bits all 0)	Values	1 to 4294967294
Values											
<i>c-grp-ip-addr</i>	multicast group address a.b.c.d										
<i>mask</i>	4 to 32										
<i>netmask</i>	a.b.c.d (network bits all 1 and host bits all 0)										
Values	1 to 4294967294										

maximum-p2mp-spmsi

Syntax	maximum-p2mp-spmsi <i>range</i> no maximum-p2mp-spmsi				
Context	config>service>vprn>mvpn>provider-tunnel>selective				
Description	This command specifies the maximum number of LDP point-to-multipoint S-PMSI tunnels for the MVPN. When the limit is reached, no more LDP point-to-multipoint S-PMSI tunnels are created and traffic over the data threshold will stay on I-PMSI.				
Default	10				
Parameters	<i>number</i> — specifies the maximum number of LDP point-to-multipoint S-PMSI tunnels for the MVPN <table> <tr> <td>Values</td><td>1 to 4000</td></tr> <tr> <td>Default</td><td>10</td></tr> </table>	Values	1 to 4000	Default	10
Values	1 to 4000				
Default	10				

umh-selection

Syntax	umh-selection { highest-ip hash-based unicast-rt-pref } no umh-selection
Context	config>service>vprn>mvpn
Description	This command specifies which upstream multicast hop (UMH) selection mechanism to use, highest IP address, hash-based, or preferred unicast route. The no form of the command resets it back to the default.
Default	umh-selection highest-ip
Parameters	highest-ip — specifies that the highest IP address is selected as the UMH hash-based — specifies that the UMH selection is based on the hash based procedures unicast-rt-pref — when selected, preferred unicast route will decide which UMH is chosen. All PE routers must prefer the same route to the UMH for the UMH selection criterion (for example, BGP path selection criteria must not influence one PE to choose a different UMH from another PE).

vrf-export

Syntax	vrf-export unicast vrf-export <i>policy-name</i> [<i>policy-name...</i> (up to 15 max)] no vrf-export
Context	config>service>vprn>mvpn
Description	This command specifies the export policy (up to 15) to control MVPN routes exported from the local VRF to other VRFs on the same or remote PE routers.
Default	vrf-export unicast
Parameters	unicast — specifies to use the unicast VRF export policy for the MVPN <i>policy-name</i> — the route policy name

vrf-import

Syntax	vrf-import unicast vrf-import <i>policy-name</i> [<i>policy-name...</i> (up to 15 max)] no vrf-import
Context	config>service>vprn>mvpn

Description	This command specifies the import policy (up to 15) to control MVPN routes imported to the local VRF from other VRFs on the same or remote PE routers.
Default	vrf-import unicast
Parameters	unicast — specifies to use a unicast VRF import policy for the MVPN <i>policy-name</i> — the route policy name

vrf-target

Syntax	vrf-target { unicast <i>ext-community</i> export unicast <i>ext-community</i> import unicast <i>ext-community</i> } no vrf-target
Context	config>service>vprn>mvpn
Description	This command specifies the route target to be added to the advertised routes or compared against the received routes from other VRFs on the same or remote PE routers. The VRF import or VRF export policies override the VRF target policy. The no form of the command removes the VRF target.
Default	no vrf-target
Parameters	unicast — specifies to use the unicast vrf-target <i>ext-community</i> for the multicast VPN <i>ext-community</i> — an extended BGP community in the type:x:y format. The value x can be an integer or IP address. The type can be the target or origin. The x and y values are 16-bit integers.

Values

target:{ <i>ip-address:comm-val</i> <i>2byte-asnumber:ext-comm-val</i> <i>4byte-asnumber:comm-val</i> }	
<i>ip-address:</i>	a.b.c.d
<i>comm-val:</i>	0 to 65535
<i>2byte-asnumber:</i>	0 to 65535
<i>ext-comm-val:</i>	0 to 4294967295
<i>4byte-asnumber</i>	0 to 4294967295

export

Syntax	export { unicast <i>ext-community</i> }
Context	config>service>vprn>mvpn>vrf-target
Description	This command specifies communities to be sent to peers.

Parameters **unicast** — specifies to use the unicast **vrf-target** *ext-community* for the multicast VPN
ext-community — an extended BGP community in the **type:x:y** format. The value **x** can be an integer or IP address. The **type** can be the target or origin. The **x** and **y** values are 16-bit integers.

Values

target:{*ip-address:comm-val* | *2byte-asnumber:ext-comm-val* | *4byte-asnumber:comm-val*}

<i>ip-address:</i>	a.b.c.d
<i>comm-val:</i>	0 to 65535
<i>2byte-asnumber:</i>	0 to 65535
<i>ext-comm-val:</i>	0 to 4294967295
<i>4byte-asnumber</i>	0 to 4294967295

import

Syntax **import** {**unicast** | *ext-community*}

Context config>service>vprn>mvpn>vrf-target

Description This command specifies communities to be accepted from peers.

Parameters **unicast** — specifies to use the unicast **vrf-target** *ext-community* for the multicast VPN
ext-community — an extended BGP community in the **type:x:y** format. The value **x** can be an integer or IP address. The **type** can be the target or origin. The **x** and **y** values are 16-bit integers.

Values

target:{*ip-address:comm-val* | *2byte-asnumber:ext-comm-val* | *4byte-asnumber:comm-val*}

<i>ip-address:</i>	a.b.c.d
<i>comm-val:</i>	0 to 65535
<i>2byte-asnumber:</i>	0 to 65535
<i>ext-comm-val:</i>	0 to 4294967295
<i>4byte-asnumber</i>	0 to 4294967295

7.8.2.1.11 MSDP Commands

msdp

Syntax	[no] msdp
Context	config>service>vprn
Description	This command enables a Multicast Source Discovery Protocol (MSDP) instance. When an MSDP instance is created, the protocol is enabled. To start or suspend execution of the MSDP protocol without affecting the configuration, use the [no] shutdown command. For MSDP to function, at least one peer must be configured. When MSDP is configured and started, an event message is generated. Before the no form of the command is executed, all sessions are terminated and an event message is generated. When all peering sessions are terminated, event messages are not generated for each peer. The no form of the command deletes the MSDP instance, removing all associated configuration parameters.
Default	no msdp

active-source-limit

Syntax	active-source-limit <i>number</i> no active-source-limit
Context	config>service>vprn>msdp config>service>vprn>msdp>group config>service>vprn>msdp>group>peer config>service>vprn>msdp>peer config>service>vprn>msdp>source
Description	This command controls the maximum number of source-active (SA) messages that will be accepted by MSDP, which controls the number of active sources that can be stored on the system. The no form of this command resets the SA message limit to its default operation.
Default	no active-source-limit
Parameters	<i>number</i> — defines how many active sources can be maintained by MSDP Values 0 to 1000000

data-encapsulation

Syntax	[no] data-encapsulation
Context	config>service>vprn>msdp
Description	This command configures a rendezvous point (RP) that uses MSDP to encapsulate multicast data received in MSDP register messages inside forwarded MSDP SA messages.
Default	data-encapsulation

export

Syntax	export <i>policy-name</i> [<i>policy-name...</i> (up to 5 max)] no export
Context	config>service>vprn>msdp config>service>vprn>msdp>peer config>service>vprn>msdp>group config>service>vprn>msdp>group>peer
Description	This command specifies the policies to export the SA state from the SA list into MSDP. If multiple policy names are specified, the policies are evaluated in the order they are specified. A maximum of five policy names can be specified. The first policy that matches is applied. If multiple export commands are issued, the last command entered will override the previous command. If you configure an export policy at the global level, each individual peer inherits the global policy. If you configure an export policy at the group level, each individual peer in a group inherits the group's policy. If you configure an export policy at the peer level, the policy only applies to the peer where it is configured. The no form of the command removes all policies from the configuration and all SA entries are allowed.
Default	no export
Parameters	<i>policy-name</i> — specifies the export policy name. Up to five policy names can be specified.

group

Syntax	[no] group <i>group-name</i>
Context	config>service>vprn>msdp

Description	This command enables access to the context to create or modify an MSDP group. To configure multiple MSDP groups, multiple group statements must be included in the configuration. By default, the group's parameter settings are inherited from the global MSDP parameter settings. To override the global settings, group-specific settings within the group can be configured. If the specified group name is already configured, this command enables the context to configure or modify group-specific parameters. If the specified group name is not already configured, this command creates the group and enables the context to configure the group-specific parameters. For a group to be functional, at least one peer must be configured.
Default	no group
Parameters	<i>group-name</i> — specifies a unique name for the MSDP group

import

Syntax	import <i>policy-name</i> [<i>policy-name...</i> (up to 5 max)] no import
Context	<pre>config>service>vprn>msdp config>service>vprn>msdp>peer config>service>vprn>msdp>group config>service>vprn>msdp>group>peer</pre>
Description	This command specifies the policies to import the SA state from MSDP into the SA list. If multiple policy names are specified, the policies are evaluated in the order they are specified. A maximum of five policy names can be specified. The first policy that matches is applied. If multiple import commands are issued, the last command entered will override the previous command. If you configure an import policy at the global level, each individual peer inherits the global policy. If you configure an import policy at the group level, each individual peer in a group inherits the group's policy. If you configure an import policy at the peer level, the policy only applies to the peer where it is configured. The no form of the command removes all policies from the configuration and all SA messages are allowed.
Default	no import

Parameters *policy-name* — specifies the import policy name. Up to five policy names can be specified.

local-address

Syntax **local-address** *address*
no local-address

Context config>service>vprn>msdp
 config>service>vprn>msdp>peer
 config>service>vprn>msdp>group
 config>service>vprn>msdp>group>peer

Description This command configures the local end of an MSDP session. For MSDP to function, at least one peer must be configured. When configuring a peer, you must include this **local-address** command. This address must be present on the node and is used to validate incoming connections to the peer and to establish connections to the remote peer.

When the address is configured, it is validated and will be used as the local address for MSDP peers from that point. If a subsequent **local-address** command is entered, it will replace the existing configuration and existing sessions will be terminated.

Similarly, when the **no** form of this command is entered, the existing **local-address** will be removed from the configuration and the existing sessions will be terminated.

Whenever a session is terminated, all information pertaining to and learned from that peer will be removed.

Whenever a new peering session is created or a peering session is lost, an event message is generated.

The **no** form of this command removes the **local-address** from the configuration.

Default no local-address

Parameters *address* — specifies an existing address on the node

mode

Syntax **mode** {**mesh-group** | **standard**}

Context config>service>vprn>msdp>group

Description This command configures groups of peers either in non-meshed mode or in a full mesh topology to limit excessive flooding of SA messages to neighboring peers. When the mode is specified as **mesh-group**, SA messages received from a mesh group member are always accepted but are not flooded to other members of the same mesh group. These SA messages are only flooded to non-mesh-group peers or members of other mesh groups.

In a meshed configuration, all members of the group must have a peer connection with every other mesh group member. If this rule is not adhered to, unpredictable results may occur.

Default standard

Parameters **mesh-group** — specifies that all members of the group have full mesh MSDP connectivity with each other
standard — specifies a non-meshed mode

peer

Syntax **[no] peer** *peer-address*

Context config>service>vprn>msdp
 config>service>vprn>msdp>group

Description This command configures an MSDP peer or MDSP group peer. MSDP must have at least one peer configured. A peer is defined by configuring a **local-address** that is used by the local node to set up a peering session and by configuring the address of a remote MSDP router. It is the address of this remote peer that is configured with this command.

After peer relationships are established, the MSDP peers exchange messages to advertise active multicast sources. If multiple peering sessions are required, multiple peer statements should be included in the configuration.

By default, the parameters applied to a peer are inherited from the global or group level. To override these inherited settings, the parameters must be configured at the peer level.

If the specified peer address is already a configured peer, this command enables the context to configure or modify the peer-specific parameters.

If the specified peer address is not already a configured peer, this command creates the peer instance and enables the context to configure the peer-specific parameters.

The peer address is validated and, if valid, will be used as the remote address for an MSDP peering session.

When the **no** form of this command is entered, the existing peering address is removed from the configuration and the existing session is terminated. Whenever a session is terminated, all SA information pertaining to and learned from that peer is removed. Whenever a new peering session is created or a peering session is lost, an event message is generated.

Default n/a

Parameters *peer-address* — specifies the peer address that identifies the remote MSDP router with which the peering session will be established

authentication-key

Syntax	authentication-key [<i>authentication-key</i> <i>hash-key</i>] [hash hash2] no authentication-key
Context	config>service>vprn>msdp>group>peer config>service>vprn>msdp>peer
Description	This command configures a Message Digest 5 (MD5) authentication key to be used with a specific MSDP peering session. The authentication key must be configured per peer; therefore, no global or group configuration is possible. Using the no form of the command accepts all MSDP messages and disables the MD5 signature option authentication key.
Default	no authentication-key
Parameters	<i>authentication-key</i> — specifies the authentication key. Allowed values are any string up to 256 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed in quotation marks (" "). <i>hash-key</i> — specifies the hash key. The key can be any combination of ASCII characters up to 451 characters in length (encrypted). If spaces are used in the string, the entire string must be enclosed in quotation marks (" "). This parameter is useful when a user must configure the parameter, but for security purposes, the actual unencrypted key value is not provided. hash — specifies that the key is entered in an encrypted form. If the hash or hash2 parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the hash or hash2 parameter specified. hash2 — specifies that the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the hash2 encrypted variable cannot be copied and pasted. If the hash or hash2 parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the hash or hash2 parameter specified.

default-peer

Syntax	[no] default-peer
Context	config>service>vprn>msdp>peer config>service>vprn>msdp>group>peer
Description	This command enables the default peer mechanism, where a peer can be selected as the default MSDP peer. As a result, all SA messages from the peer will be accepted without the usual peer reverse path forwarding (RPF) check.

The MSDP peer-RPF check is different from the normal multicast RPF checks. The peer-RPF check is used to stop SA messages from looping. A router validates SA messages originated from other routers in a deterministic fashion.

A set of rules is applied to validate received SA messages, and the first rule that applies determines the peer-RPF neighbor. All SA messages from other routers are rejected. The following rules are applied to SA messages originating at router_S and received at router_R from router_N.

- If router_N and router_S are the same, the message is originated by a direct peer-RPF neighbor and is accepted.
- If router_N is a configured peer or a member of the router_R mesh group, its SA messages are accepted.
- If router_N is the BGP next hop of the active multicast RPF route toward router_S, then router_N is the peer-RPF neighbor and its SA messages are accepted.
- If router_N is an external BGP peer of router_R and the last autonomous system (AS) number in the BGP AS-path to router_S is the same as router_N's AS number, then router_N is the peer-RPF neighbor and its SA messages are accepted.
- If router_N uses the same next hop as the next hop to router_S, then router_N is the peer-RPF neighbor and its SA messages are accepted.
- If router_N fits none of the above rules, then router_N is not a peer-RPF neighbor and its SA messages are rejected.

When the **no** form the command is issued, no default peer is established and all SA messages are RPF checked.

Default no default-peer

receive-msdp-msg-rate

Syntax	receive-msdp-msg-rate <i>number interval seconds</i> [threshold <i>number</i>] no receive-msdp-msg-rate
Context	config>service>vprn>msdp config>service>vprn>msdp>group config>service>vprn>msdp>group>peer config>service>vprn>msdp>peer
Description	This command limits the number of MSDP messages that are read from the TCP session to prevent an MSDP RP router from receiving a large number of MSDP message packets in an SA message. After the number of MSDP packets (including SA messages) defined by the threshold <i>number</i> have been processed, all other MSDP packets are rate-limited. Messages from the TCP session are no longer accepted until the configured interval seconds has elapsed. Setting the threshold is useful during at system startup and initialization. No limit is placed on the number of MSDP and SA messages that will be accepted.

The **no** form of this command resets the message limit to its default operation.

Default	n/a
Parameters	receive-msdp-msg-rate <i>number</i> — specifies the number of MSDP messages (including SA messages) that are read from the TCP session per interval <i>seconds</i> Values 10 to 10000 Default 0 <i>seconds</i> — specifies the interval of time in which the number of MSDP messages set by the receive-msdp-msg-rate <i>number</i> parameter are read from the TCP session Values 1 to 600 Default 0 threshold <i>number</i> — specifies the number of MSDP messages that can be processed before the MSDP message rate-limiting function is activated Values 1 to 1000000 Default 0

rpf-table

Syntax	rpf-table {rtable-m rtable-u both} no rpf-table
Context	config>service>vprn>msdp
Description	This command configures the sequence of route tables used to find an RPF interface for a particular multicast route. By default, only the unicast route table is looked up to calculate an RPF interface towards the source/rendezvous point. However, the operator can specify one of the following options: • use the unicast route table only • use the multicast route table only • use both route tables
Default	rtable-u
Parameters	rtable-m — specifies that only the multicast route table is used by the multicast protocol (PIM) for IPv4 RPF checks. This route table contains routes submitted by static routes, ISIS, and OSPF. rtable-u — specifies that only the unicast route table is used by the multicast protocol (PIM) for IPv4 RPF checks. This route table contains routes submitted by all unicast routing protocols.

both — specifies that the first lookup is always in the multicast route table, and if there is a route, it will use it. If PIM does not find a route in the first lookup, it tries to find it in the unicast route table.

sa-timeout

Syntax	sa-timeout <i>seconds</i> no sa-timeout
Context	config>service>vprn>msdp
Description	This command configures the timeout value for the SA entries in the cache. If these entries are not refreshed within the timeout value, they are removed from the cache. Normally, the entries are refreshed at least once a minute. However, under high load with many MSDP peers, the refresh cycle could be incomplete. A higher timeout value (more than 90 seconds) could be useful to prevent instabilities in the MSDP cache.
Default	90
Parameters	<i>seconds</i> — specifies the time, in seconds, to wait for a response from the peer before declaring the peer unavailable Values 90 to 600

source

Syntax	[no] source <i>ip-prefix/mask</i>
Context	config>service>vprn>msdp
Description	This command configures an MSDP source. If the specified prefix and mask is already configured, this command enables the context to configure or modify the source-specific parameters. If the specified prefix and mask is not already configured, this command creates the source node instance and enables the context to configure the source-specific parameters. The SA msdp messages are not rate-limited based on the source address range. The no form of this command removes the sources in the address range.
Default	n/a
Parameters	<i>ip-prefix</i> — specifies the IP prefix, in dotted-decimal notation, for the MSDP source Values a.b.c.d (host bits must be 0)

mask — specifies the subnet mask for the range, expressed as a decimal integer mask length or in dotted-decimal notation

Values 0 to 32 (mask length)
 0.0.0.0 to 255.255.255.255 (dotted-decimal)

7.8.2.1.12 Router Advertisement Commands

router-advertisement

Syntax	[no] router-advertisement
Context	config>service>vprn
Description	This command enables the context to configure router advertisement properties for all VPRN IPv6-enabled interfaces. By default, the command is disabled for all IPv6-enabled interfaces. The no form of the command disables router advertisement on all IPv6 interfaces.
Default	no router-advertisement

interface

Syntax	[no] interface <i>ip-int-name</i>
Context	config>service>vprn>router-advertisement
Description	This command configures router advertisement properties on a specified interface. The interface name must already exist in the config>service>vprn>interface context. The no form of the command disables router advertisement on the specified router interface.
Default	n/a
Parameters	<i>ip-int-name</i> — a 1 to 32 character name (must start with a letter) of the IP interface. Interface names must be unique within the group of defined IP interfaces for the config>service>vprn>interface command. An interface name cannot be in the form of an IP address. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

current-hop-limit

Syntax	current-hop-limit <i>number</i> no current-hop-limit
Context	config>service>vprn>router-advertisement>interface
Description	This command configures the current hop limit in the router advertisement messages. It informs the nodes on the subnet about the hop limit when originating IPv6 packets.
Default	64

Parameters	<i>number</i> — the hop limit
Values	0 to 255 (a value of 0 means that there are an unspecified number of hops)

managed-configuration

Syntax	[no] managed-configuration
Context	config>service>vprn>router-advertisement>interface
Description	This command sets the managed address configuration flag. This flag indicates that DHCPv6 is available for address configuration in addition to any address autoconfigured using stateless address autoconfiguration.
Default	no managed-configuration

max-advertisement-interval

Syntax	max-advertisement-interval <i>seconds</i> no max-advertisement-interval
Context	config>service>vprn>router-advertisement>interface
Description	This command configures the maximum interval between sending router advertisement messages.
Default	600
Parameters	<i>seconds</i> — the maximum interval, in seconds, between sending router advertisement messages
Values	4 to 1800

min-advertisement-interval

Syntax	min-advertisement-interval <i>seconds</i> no min-advertisement-interval
Context	config>service>vprn>router-advertisement>interface
Description	This command configures the minimum interval between sending ICMPv6 router advertisement messages.
Default	200

Parameters	<i>seconds</i> — the minimum interval, in seconds, between sending ICMPv6 router advertisement messages
Values	3 to 1350

mtu

Syntax	mtu <i>mtu-bytes</i> no mtu
Context	config>service>vprn>router-advertisement>interface
Description	This command configures the MTU for the nodes to use when sending packets on the link. The no form of the command means that the MTU option is not sent in the router advertisement messages.
Default	no mtu
Parameters	<i>mtu-bytes</i> — the MTU for the nodes to use when sending packets
Values	1280 to 9212

other-stateful-configuration

Syntax	[no] other-stateful-configuration
Context	config>router>vprn>router-advertisement>interface
Description	This command sets the “Other configuration” flag. This flag indicates that DHCPv6lite is available for autoconfiguration of other (non-address) information such as DNS-related information or information on other servers in the network.
Default	no other-stateful configuration

prefix

Syntax	prefix <i>ipv6-prefix/prefix-length</i> no prefix
Context	config>service>vprn>router-advertisement>interface
Description	This command configures an IPv6 prefix in the router advertisement messages. To support multiple IPv6 prefixes, use multiple prefix statements. No prefix is advertised until it is explicitly configured using prefix statements.
Default	n/a

Parameters	<i>ipv6-prefix/prefix-length</i> — the IPv6 prefix		
	Values	<i>ipv6-prefix</i>	x::x::x::x::x::x (eight 16-bit pieces) x::x::x::x::d.d.d.d x: [0 to FFFF]H d: [0 to 255]D
		<i>prefix-length</i>	0 to 128

autonomous

Syntax	[no] autonomous
Context	config>service>vprn>router-advertisement>if>prefix
Description	This command specifies whether the prefix can be used for stateless address autoconfiguration.
Default	autonomous

on-link

Syntax	[no] on-link
Context	config>service>vprn>router-advertisement>if>prefix
Description	This command specifies whether the prefix can be used for on-link determination.
Default	on-link

preferred-lifetime

Syntax	preferred-lifetime { <i>seconds</i> infinite } no preferred-lifetime
Context	config>service>vprn>router-advertisement>if>prefix
Description	This command configures the time that this prefix will continue to be preferred. The address generated from a prefix that is no longer preferred should not be used as a source address in new communications. However, packets received on such an interface are processed as expected.
Default	604800
Parameters	<i>seconds</i> — the length of time, in seconds, that this prefix will be preferred
	Values 1 to 4294967294

infinite — the prefix will always be preferred. A value of 4294967295 also represents infinity.

valid-lifetime

Syntax	valid-lifetime { <i>seconds</i> infinite } no valid-lifetime
Context	config>service>vprn>router-advertisement>if>prefix
Description	This command specifies the length of time, in seconds, that the prefix is valid for the purpose of onlink determination. The address generated from an invalidated prefix should not appear as the destination or source address of a packet.
Default	2592000
Parameters	<i>seconds</i> — the remaining length of time, in seconds, that this prefix will be valid Values 1 to 4294967294 infinite — the prefix will always be valid. A value of 4294967295 also represents infinity.

reachable-time

Syntax	reachable-time <i>milli-seconds</i> no reachable-time
Context	config>service>vprn>router-advertisement>interface
Description	This command configures how long the router should be considered reachable by other nodes on the link after receiving a reachability confirmation.
Default	no reachable-time
Parameters	<i>milli-seconds</i> — the length of time, in milliseconds, that the router should be considered reachable Values 0 to 3600000

retransmit-time

Syntax	retransmit-time <i>milli-seconds</i> no retransmit-time
Context	config>service>vprn>router-advertisement>interface
Description	This command configures the retransmission frequency of neighbor solicitation messages.

Default	no retransmit-time
Parameters	<i>milli-seconds</i> — the amount of time, in milliseconds, that a host should wait before retransmitting neighbor solicitation messages
Values	0 to 1800000

router-lifetime

Syntax	router-lifetime <i>seconds</i> no router-lifetime
Context	config>service>vprn>router-advertisement>interface
Description	This command configures the router lifetime.
Default	no router-lifetime
Parameters	<i>seconds</i> — the length of time, in seconds, that the prefix is valid for route determination
Values	0, 4 to 9000 (a value of 0 means that the router is not a default router on this link)

use-virtual-mac

Syntax	[no] use-virtual-mac
Context	config>service>vprn>router-advertisement>interface
Description	This command enables the sending of router advertisement messages using the VRRP virtual MAC address, provided that the virtual router is currently the master. If the virtual router is not the master, no router advertisement messages are sent. The no form of the command disables the sending of router advertisement messages.
Default	no use-virtual-mac

7.8.2.1.13 Local DHCP and DHCPv6 Server Commands

For complete descriptions of all local DHCP and DHCPv6 server commands, refer to the Router Configuration Guide, “Local DHCP and DHCPv6 Server Commands”.

local-dhcp-server

Syntax	local-dhcp-server <i>server-name</i> [create] no local-dhcp-server <i>server-name</i>
Context	config>service>vprn>dhcp config>service>vprn>dhcp6
Description	This command creates a local DHCP or DHCPv6 server instance. A local DHCP or DHCPv6 server can serve multiple interfaces but is limited to the routing context in which it was created. The no form of the command removes the local DHCP or DHCPv6 server instance.
Default	n/a
Parameters	<i>server-name</i> — the name of the local DHCP or DHCPv6 server Values up to 32 alphanumeric characters create — keyword is mandatory when creating a local DHCP or DHCPv6 server

7.8.2.1.14 Interface Commands

interface

Syntax	interface <i>ip-int-name</i> no interface <i>ip-int-name</i>
Context	config>service>vprn
Description	This command creates a logical IP routing interface for a Virtual Private Routed Network (VPRN). Once created, attributes such as an IP address and a service access point (SAP) can be associated with the IP interface. The interface command, under the context of services, is used to create and maintain IP routing interfaces within VPRN service IDs. The interface command can be executed in the context of a VPRN service ID. The IP interface created is associated with the VPRN service routing instance and VPRN service routing table. Interface names are case-sensitive and must be unique within the group of defined IP interfaces defined for config router interface and config service vprn interface. Interface names must not be in the dotted-decimal notation of an IP address. For example, the name "1.1.1.1" is not allowed, but "int-1.1.1.1" is allowed. Show commands for router interfaces use either interface names or the IP addresses. Use unique IP address values and IP address names to maintain clarity. It could be unclear to the user if the same IP address and IP address name values are used. Although not recommended, duplicate interface names can exist in different router instances. When a new name is entered, a new logical router interface is created. When an existing interface name is entered, the user enters the router interface context for editing and configuration. There are no default IP interface names defined within the system. All VPRN IP interfaces must be explicitly defined. Interfaces are created in an enabled state. The no form of this command removes the interface and all the associated configurations. The interface must be administratively shut down before issuing the no interface command.
Parameters	<i>ip-int-name</i> — the name of the IP interface. Interface names must be unique within the group of defined IP interfaces for config router interface and config service vprn interface commands. An interface name cannot be in the form of an IP address. Interface names can be from 1 to 32 alphanumeric characters and must start with a letter. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

address

Syntax	address { <i>ip-address/mask</i> <i>ip-address netmask</i> } [broadcast { all-ones host-ones }] no address { <i>ip-address/mask</i> <i>ip-address netmask</i> }
Context	config>service>vprn>interface
Description	This command assigns an IP address, IP subnet, and broadcast address format to a VPRN IP router interface.

An IP address must be assigned to each VPRN IP interface. An IP address and a mask are used together to create a local IP prefix. The defined IP prefix must be unique within the context of the routing instance. It cannot overlap with other existing IP prefixes defined as local subnets on other IP interfaces in the same routing context within the 7705 SAR.

The IP address for the interface can be entered in either CIDR (Classless Inter-Domain Routing) or traditional dotted-decimal notation. The **show** commands display CIDR notation, which is stored in configuration files.

By default, no IP address or subnet association exists on an IP interface until it is explicitly created.

Use the **no** form of this command to remove the IP address assignment from the IP interface. When the **no address** command is entered, the interface becomes operationally down, as shown in [Table 131](#).

Table 131 VPRN Interface State and IP Address

Address	Administrative State	Operational State
No address	Up	Down
No address	Down	Down
1.1.1.1	Up	Up
1.1.1.1	Down	Down

The operational state is a read-only variable, and the only controlling variables are the address and administrative states. The address and administrative states are independent and can be set independently. If an interface is in an administratively up state and an address is assigned, it becomes operationally up and the protocol interfaces and the MPLS LSPs associated with that IP interface will be reinitialized.

Parameters	<i>ip-address</i> — the IP address of the IP interface. The <i>ip-address</i> portion of the address command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted-decimal notation.

Values a.b.c.d (no multicast/broadcast address)
(1.0.0.0 to 223.255.255.255 (with support of /31 subnets))

The “/” (forward slash) is a parameter delimiter that separates the *ip-address* portion of the IP address from the *mask*, which defines the scope of the local subnet. No spaces are allowed between the *ip-address*, the “/”, and the *mask*. If a forward slash does not immediately follow the *ip-address*, a dotted-decimal *mask* must follow the prefix.

mask — the subnet mask length when the IP prefix is specified in CIDR notation. When the IP prefix is specified in CIDR notation, a forward slash separates the *ip-address* from the *mask*. The *mask* indicates the number of bits used for the network portion of the IP address; the remainder of the IP address is used to determine the host portion of the IP address.

Values 0 to 32

netmask — the subnet mask, in dotted-decimal notation. When the IP prefix is not specified in CIDR notation, a space separates the *ip-address* from a traditional dotted-decimal mask. The *netmask* parameter indicates the complete mask that will be used in a logical “AND” function to derive the local subnet of the IP address.

Values 128.0.0.0 to 255.255.255.252
(network bits all 1 and host bits all 0)
(255.255.255.255 is reserved for system IP addresses)

broadcast — the optional **broadcast** parameter overrides the default broadcast address used by the IP interface when sourcing IP broadcasts on the IP interface. If no broadcast format is specified for the IP address, the default value is **host-ones**, which indicates a subnet broadcast address. Use this parameter to change the broadcast address to **all-ones** or revert to a broadcast address of **host-ones**.

The broadcast format on an IP interface can be specified when the IP address is assigned or changed.

This parameter does not affect the type of broadcasts that can be received by the IP interface. A host sending either the local broadcast (**all-ones**) or the valid subnet broadcast address (**host-ones**) will be received by the IP interface.

Default host-ones

all-ones — specifies that the broadcast address used by the IP interface for this IP address will be 255.255.255.255, also known as the local broadcast

host-ones — specifies that the broadcast address used by the IP interface for this IP address will be the subnet broadcast address. This is an IP address that corresponds to the local subnet described by the *ip-address* and the *mask*, or the *mask* with all the host bits set to binary one. This is the default broadcast address used by an IP interface.

The **broadcast** parameter within the **address** command does not have a negation feature, which is usually used to revert a parameter to the default value. To change the broadcast type to **host-ones** after being changed to **all-ones**, the address command must be executed with the **broadcast** parameter defined.

allow-directed-broadcasts

Syntax	allow-directed-broadcasts no allow-directed-broadcasts
Context	config>service>vprn>interface
Description	This command controls the forwarding of directed broadcasts out of the IP interface. A directed broadcast is a packet received on a local router interface destined for the subnet broadcast address on another IP interface. The allow-directed-broadcasts command on an IP interface enables or disables the transmission of packets destined for the subnet broadcast address of the egress IP interface. When enabled, a frame destined for the local subnet on this IP interface will be sent as a subnet broadcast out this interface. Care should be exercised when allowing directed broadcasts as it is a well-known mechanism used for denial-of-service attacks. When disabled, directed broadcast packets discarded at this egress IP interface will be counted in the normal discard counters for the egress SAP. By default, directed broadcasts are not allowed and will be discarded at this egress IP interface. The no form of this command disables the forwarding of directed broadcasts out of the IP interface.
Default	no allow-directed-broadcasts

arp-retry-timer

Syntax	arp-retry-timer <i>ms-timer</i> no arp-retry-timer
Context	config>service>vprn>interface
Description	This command specifies the length of time, in 100s of milliseconds, that the system waits before reissuing a failed ARP request. The no form of the command resets the interval to the default value. Note: The ARP retry default value of 5000 ms is intended to protect CPU cycles on the 7705 SAR, especially when it has a large number of interfaces. Configuring the ARP retry timer to a value shorter than the default should be done only on mission-critical links, such as uplinks or aggregate spoke SDPs transporting mobile traffic; otherwise, the retry interval should be left at the default value.
Default	50 (in 100s of ms)

Parameters *ms-timer* — the time interval, in 100s of milliseconds, the system waits before retrying a failed ARP request

Values 1 to 300

arp-timeout

Syntax **arp-timeout** *seconds*
no arp-timeout

Context config>service>vprn>interface

Description This command configures the minimum time, in seconds, that an ARP entry learned on the IP interface will be stored in the ARP table. ARP entries are automatically refreshed when an ARP request or gratuitous ARP is seen from an IP host; otherwise, the ARP entry is aged from the ARP table. If **arp-timeout** is set to a value of 0 s, ARP aging is disabled.

The **no** form of this command restores **arp-timeout** to the default value.

Default 14400 s

Parameters *seconds* — the minimum number of seconds a learned ARP entry will be stored in the ARP table, expressed as a decimal integer. A value of 0 specifies that the timer is inoperative and learned ARP entries will not be aged.

Values 0 to 65535

bfd

Syntax **bfd** *transmit-interval* [**receive** *receive-interval*] [**multiplier** *multiplier*] [**echo-receive** *echo-interval*] [**type np**]
no bfd

Context config>service>vprn>interface
config>service>vprn>if>ipv6

Description This command specifies the BFD parameters for the associated IP interface. If no parameters are defined, the default values are used.

The multiplier specifies the number of consecutive BFD messages that must be missed from the peer before the BFD session state is changed to down. In addition, the Route Table Manager (RTM) is notified and the static routes with BFD enabled will go down, based on BFD status.

The **no** form of the command removes BFD from the associated IGP protocol adjacency.

Default no bfd

Parameters	<i>transmit-interval</i> — sets the transmit interval for the BFD session
Values	10 to 100000 in milliseconds
Default	100
	<i>receive-interval</i> — sets the receive interval for the BFD session
Values	10 to 100000 milliseconds
Default	100
	<i>multiplier</i> — sets the multiplier for the BFD session
Values	3 to 20
Default	3
	<i>echo-interval</i> — (does not apply to IPv6 interfaces) sets the minimum echo receive interval for the BFD session
Values	100 to 100000 milliseconds
Default	100
	<i>type np</i> — (does not apply to IPv6 interfaces) controls the value range of the <i>transmit-interval</i> and <i>receive-interval</i> parameters. If the type np option is not specified, the range of the <i>transmit-interval</i> and <i>receive-interval</i> parameter values is from 100 ms to 100000 ms. If the type np option is specified, the range of the <i>transmit-interval</i> and <i>receive-interval</i> parameter values is from 10 ms to 1000 ms, with the restriction that the maximum receiving detection time for the missing BFD packets must be less than or equal to 3000 ms. The maximum receiving detection time is the <i>receive-interval</i> parameter multiplied by the <i>multiplier</i> parameter.

Note: The BFD session must be disabled before the **type np** parameter can be changed. The **type np** parameter is only supported on VPRN services for SAPs.

cflowd-parameters

Syntax	cflowd-paramaters
Context	config>service>vprn>interface
Description	This command enables the context to configure Cflowd parameters for the specified IP interface. Cflowd is used for network planning and traffic engineering, capacity planning, security, application and user profiling, performance monitoring, usage-based billing, and SLA measurement.
Default	n/a

sampling

Syntax	sampling {unicast multicast} type {interface} [direction {ingress-only egress-only both}] no sampling {unicast multicast}
Context	config>service>vprn>if>cflowd-parameters
Description	This command configures the Cflowd sampling behavior to collect traffic flow samples through a router for analysis. This command can be used to configure the sampling parameters for unicast and multicast traffic separately. If Cflowd sampling is enabled with no direction parameter specified, ingress-only sampling is enabled by default. The no form of the command disables the specified type of traffic sampling on the interface.
Default	no sampling unicast no sampling multicast
Parameters	unicast — Cflowd will sample unicast traffic on the interface multicast — Cflowd will sample multicast traffic on the interface interface — specifies that all traffic entering or exiting the interface is subject to sampling. Interface is the only sampling type supported on the 7705 SAR and must be specified with this command. direction — specifies the direction in which to collect traffic flow samples: ingress-only, egress-only, or both

ip-mtu

Syntax	ip-mtu <i>octets</i> no ip-mtu
Context	config>service>vprn>interface
Description	This command configures the IP maximum transmit unit (packet) for this interface. The default value is derived from the port MTU. The no form of the command returns the default value.
Default	no ip-mtu — uses the value derived from the port MTU
Parameters	<i>octets</i> — specifies the MTU for this interface Values 128 to 9732

ipcp

Syntax	ipcp
Context	config>service>vprn>interface
Description	This command allows access to the Internet Protocol Control Protocol (IPCP) context within the interface configuration. Within this context, IPCP extensions can be configured to define such things as the remote IP address and DNS IP address to be signaled via IPCP on the associated PPP interface. This command is only applicable if the associated SAP/port is a PPP/MLPPP interface.
Default	n/a

dns

Syntax	dns <i>ip-address</i> [secondary <i>ip-address</i>] dns secondary <i>ip-address</i> no dns [<i>ip-address</i>] [secondary <i>ip-address</i>]
Context	config>service>vprn>if>ipcp
Description	This command defines the DNS addresses to be assigned to the far end of the associated PPP/MLPPP link via IPCP extensions. This command is only applicable if the associated SAP/port is a PPP/MLPPP interface with an IPCP encapsulation. The no form of the command deletes the specified primary DNS address, the secondary DNS address, or both addresses from the IPCP extension peer-ip-address configuration.
Default	no dns
Parameters	<i>ip-address</i> — a unicast IPv4 address for the primary DNS server to be signaled to the far end of the associated PPP/MLPPP link via IPCP extensions Values a.b.c.d (unicast only) secondary <i>ip-address</i> — a unicast IPv4 address for the secondary DNS server to be signaled to the far end of the associated PPP/MLPPP link via IPCP extensions Values a.b.c.d (unicast only)

peer-ip-address

Syntax	peer-ip-address <i>ip-address</i> no peer-ip-address
Context	config>service>vprn>if>ipcp
Description	This command defines the remote IP address to be assigned to the far end of the associated PPP/ MLPPP link via IPCP extensions. This command is only applicable if the associated SAP/port is a PPP/MLPPP interface with an IPCP encapsulation. The interface must be shut down to modify the IPCP configuration. The no form of the command deletes the IPCP extension peer-ip-address configuration.
Default	no peer-ip-address (0.0.0.0)
Parameters	<i>ip-address</i> — a unicast IPv4 address to be signaled to the far end of the associated PPP/ MLPPP link by IPCP extensions Values a.b.c.d (unicast only)

load-balancing

Syntax	load-balancing
Context	config>service>vprn>interface
Description	This command enables the context to configure load balancing hashing options on the interface. The options enabled at the interface level overwrite parallel system-level configurations.
Default	n/a

I4-load-balancing

Syntax	I4-load-balancing <i>hashing-algorithm</i> no I4-load-balancing
Context	config>service>vprn>interface>load-balancing
Description	This command configures Layer 4 load balancing at the interface level. Configuration must be done on the ingress network interface (that is, the interface on the node that the packet is received on). When enabled, Layer 4 source and destination port fields of incoming TCP/UDP packets are included in the hashing calculation to randomly determine the distribution of packets.

You can add additional fields to generate more randomness and more equal distribution of packets with the [teid-load-balancing](#) command.

The default configuration on the interface is to match the Layer 4 load-balancing configuration in the **config>system** context. Using this command to modify Layer 4 load-balancing configuration on an interface overrides the system-wide load-balancing settings for that interface.

Parameters	<i>hashing-algorithm</i> — specifies that Layer 4 source and destination port fields are included in or excluded from the hashing calculation
Values	includeL4: include Layer 4 source and destination port fields in the hashing calculation for TCP/UDP packets excludeL4: exclude Layer 4 source and destination port fields in the hashing calculation for TCP/UDP packets
Default	the system configuration setting (under the config>system context)

spi-load-balancing

Syntax	[no] spi-load-balancing
Context	config>service>vprn>interface>load-balancing
Description	This command enables use of the SPI in hashing for ESP/AH encrypted IPv4 or IPv6 traffic at the interface level. The no form of this command disables SPI hashing.
Default	no spi-load-balancing

teid-load-balancing

Syntax	[no] teid-load-balancing
Context	config>service>vprn>interface>load-balancing
Description	This command configures TEID load balancing at the interface level. Configuration must be done on the ingress network interface (that is, the interface on the node that the packet is received on). The TEID attribute is included in the header of GTP (general packet radio system tunneling protocol) packets. When TEID load balancing is enabled, the TEID field of incoming TCP/UDP packets is included in the hashing calculation to randomly determine the distribution of packets. You can add additional fields to generate more randomness and more equal distribution of packets with the l4-load-balancing command.
Default	no teid-load-balancing

local-dhcp-server

Syntax	[no] local-dhcp-server <i>local-server-name</i>
Context	config>service>vprn>interface
Description	This command associates the interface with a local DHCP server configured on the system. A routed VPLS interface may not be associated with a local DHCP server. The no form of the command removes the association of the interface with the local DHCP server.
Default	none
Parameters	<i>local-server-name</i> — the name of the local DHCP server
Values	up to 32 alphanumeric characters

local-proxy-arp

Syntax	[no] local-proxy-arp
Context	config>service>vprn>interface
Description	This command enables local proxy ARP on the interface. Local proxy ARP allows the 7705 SAR to respond to ARP requests received on an interface for an IP address that is part of a subnet assigned to the interface. The router responds to all requests for IP addresses within the subnet with its own MAC address and forwards all traffic between the hosts in the subnet. Local proxy ARP is used on subnets where hosts are prevented from communicating directly. When local-proxy-arp is enabled, ICMP redirects on the ports associated with the service are automatically blocked.
Default	no local-proxy-arp

loopback

Syntax	[no] loopback
Context	config>service>vprn>interface
Description	This command specifies that the interface is a loopback interface that has no associated physical interface. If this command is enabled, a SAP cannot be defined on the interface.
Default	no loopback

mac

Syntax	mac <i>ieee-address</i> no mac [<i>ieee-address</i>]
Context	config>service>vprn>interface
Description	This command assigns a specific MAC address to a VPRN IP interface. The no form of this command returns the MAC address of the IP interface to the default value.
Default	the physical MAC address associated with the Ethernet interface that the SAP is configured on
Parameters	<i>ieee-address</i> — a 48-bit MAC address in the form <i>aa:bb:cc:dd:ee:ff</i> or <i>aa-bb-cc-dd-ee-ff</i> , where <i>aa</i> , <i>bb</i> , <i>cc</i> , <i>dd</i> , <i>ee</i> , and <i>ff</i> are hexadecimal numbers and cannot be all zeros. Allowed values are any non-broadcast, non-multicast MAC, and non-IEEE reserved MAC addresses.

proxy-arp-policy

Syntax	proxy-arp-policy <i>policy-name</i> [<i>policy-name...</i> (up to 5 max)] no proxy-arp-policy
Context	config>service>vprn>interface
Description	This command enables proxy ARP on the interface and specifies an existing policy statement that controls the flow of routing information by analyzing match and action criteria. The policy statement is configured in the config>router>policy-options context (refer to the 7705 SAR Router Configuration Guide, “Route Policy Command Reference, Route Policy Options”). When proxy ARP is enabled, the 7705 SAR responds to ARP requests on behalf of another device.
Default	no proxy-arp-policy
Parameters	<i>policy-name</i> — the route policy statement name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes. The policy statement must already be defined.

remote-proxy-arp

Syntax	[no] remote-proxy-arp
Context	config>service>vprn>interface
Description	This command enables remote proxy ARP on the interface, allowing a router on one network to respond to ARP requests intended for another node that is physically located on another network. The router effectively pretends to be the destination node by sending an ARP response to the originating node that associates the router's MAC address with the destination node's IP address (acts as a proxy for the destination node). The router then takes responsibility for routing traffic to the real destination.
Default	no remote-proxy-arp

secondary

Syntax	secondary { <i>ip-address/mask</i> <i>ip-address netmask</i> } [broadcast all-ones host-ones] [igp-inhibit] no secondary { <i>ip-address/mask</i> <i>ip-address netmask</i> }
Context	config>service>vprn>interface
Description	This command assigns an secondary IP address, IP subnet, and broadcast address format to the interface.
Default	no secondary
Parameters	<i>ip-address</i> — the IP address of the IP interface. The <i>ip-address</i> portion of the secondary command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted-decimal notation. Values a.b.c.d (1.0.0.0 to 223.255.255.255 (with support of /31 subnets)) The "/" (forward slash) is a parameter delimiter that separates the <i>ip-address</i> portion of the IP address from the <i>mask</i>, which defines the scope of the local subnet. No spaces are allowed between the <i>ip-address</i>, the "/", and the <i>mask</i>. If a forward slash does not immediately follow the <i>ip-address</i>, a dotted-decimal <i>mask</i> must follow the prefix. <i>mask</i> — the subnet mask length when the IP prefix is specified in CIDR notation. When the IP prefix is specified in CIDR notation, a forward slash separates the <i>ip-address</i> from the <i>mask</i>. The <i>mask</i> indicates the number of bits used for the network portion of the IP address; the remainder of the IP address is used to determine the host portion of the IP address. Values 0 to 32

netmask — the subnet mask, in dotted-decimal notation. When the IP prefix is not specified in CIDR notation, a space separates the *ip-address* from a traditional dotted-decimal mask. The *netmask* parameter indicates the complete mask that will be used in a logical “AND” function to derive the local subnet of the IP address.

Values 128.0.0.0 to 255.255.255.252
(network bits all 1 and host bits all 0)
(255.255.255.255 is reserved for system IP addresses)

broadcast — the optional **broadcast** parameter overrides the default broadcast address used by the IP interface when sourcing IP broadcasts on the IP interface. If no broadcast format is specified for the IP address, the default value is **host-ones**, which indicates a subnet broadcast address. Use this parameter to change the broadcast address to **all-ones** or revert to a broadcast address of **host-ones**.

The broadcast format on an IP interface can be specified when the IP address is assigned or changed.

This parameter does not affect the type of broadcasts that can be received by the IP interface. A host sending either the local broadcast (**all-ones**) or the valid subnet broadcast address (**host-ones**) will be received by the IP interface.

Default host-ones

all-ones — specifies that the broadcast address used by the IP interface for this IP address will be 255.255.255.255, also known as the local broadcast

host-ones — specifies that the broadcast address used by the IP interface for this IP address will be the subnet broadcast address. This is an IP address that corresponds to the local subnet described by the *ip-address* and the *mask*, or the *mask* with all the host bits set to binary one. This is the default broadcast address used by an IP interface.

The **broadcast** parameter within the **secondary** command does not have a negation feature, which is usually used to revert a parameter to the default value. To change the broadcast type to **host-ones** after being changed to **all-ones**, the **secondary** command must be executed with the **broadcast** parameter defined.

igp-inhibit — specifies that this secondary IP interface should not be recognized as a local interface by the running IGP. For OSPF and IS-IS, this means that the secondary IP interface will not be injected and used as a passive interface and will not be advertised as an internal IP interface into the IGP link state database. For RIP, this means that the secondary IP interface will not source RIP updates.

static-arp

Syntax **static-arp** *ip-address* *ieee-address*
no static-arp *ip-address* [*ieee-address*]
static-arp *ieee-address* **unnumbered**
no static-arp [*ieee-address*] **unnumbered**

Context config>service>vprn>interface

Description	This command configures a static address resolution protocol (ARP) entry associating a subscriber IP address with a MAC address for the core router instance. This static ARP will appear in the core routing ARP table. A static ARP can only be configured if it exists on the network attached to the IP interface. If an entry for a particular IP address already exists and a new MAC address is configured for the IP address, the existing MAC address will be replaced with the new MAC address. Static ARP is used when a 7705 SAR needs to know about a device on an interface that cannot or does not respond to ARP requests. Therefore, the 7705 SAR configuration can specify to send a packet with a particular IP address to the corresponding ARP address. The no form of the command removes a static ARP entry.
Default	n/a
Parameters	<i>ip-address</i> — the IP address for the static ARP in dotted-decimal notation Values a.b.c.d <i>ieee-address</i> — the 48-bit MAC address for the static ARP. Allowed values are any non-broadcast, non-multicast MAC, and non-IEEE reserved MAC addresses. Values aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff (where aa, bb, cc, dd, ee, and ff are hexadecimal numbers and cannot be all zeros) unnumbered — specifies the static ARP MAC addresses for an unnumbered interface. Unnumbered interfaces also support dynamic ARP. If this parameter is configured, it overrides any dynamic ARP.

tcp-mss

Syntax	tcp-mss <i>value</i> no tcp-mss
Context	config>service>vprn>interface config>service>vprn>if>ipv6
Description	This command configures the maximum segment size (MSS) in a TCP SYN or SYN-ACK packet during the establishment of a TCP connection. A tcp-mss value can be specified on an ingress interface, egress interface, or both. When configured on two interfaces, the smaller of the two values is used. If the TCP SYN packet has no TCP MSS field, the 7705 SAR assigns it the MSS value configured on the interface and recalculates the IP checksum. If the TCP SYN or SYN-ACK packet has an MSS field and the value is greater than the value configured on the interface, the 7705 SAR overwrites the packet MSS value with the lower value. If the MSS value is less than the value configured on the interface, the packet MSS value does not change. This command is supported on interfaces with IPv4 and IPv6 traffic, and a different MSS value can be configured for the IPv4 and IPv6 interfaces. This command is supported on IPsec private interfaces in a VPRN.

Default	no tcp-mss
Parameters	<i>value</i> — the MSS, in bytes, to be used in a TCP SYN or SYN-ACK packet
Values	384 to 9732

unnumbered

Syntax	unnumbered { <i>ip-int-name</i> <i>ip-address</i> } no unnumbered
Context	config>service>vprn>interface
Description	This command configures an IP interface as an unnumbered interface and specifies an IP address or interface name to be used for the interface. Unnumbered interfaces are point-to-point interfaces that are not explicitly configured with a dedicated IP address and subnet; instead, they borrow (or link to) an IP address from another interface on the system (the system IP address, another loopback interface, or any other numbered interface) and use it as the source IP address for packets originating from the interface. By default, no IP address exists on an IP interface until it is explicitly created. The no form of the command removes the IP address assignment from the IP interface.
Default	no unnumbered
Parameters	<i>ip-int-name</i> <i>ip-address</i> — the IP interface name or address to associate with the unnumbered IP interface
Values	<i>ip-int-name</i> : 1 to 32 characters (must start with a letter) <i>ip-address</i> : a.b.c.d

7.8.2.1.15 IPv6 Interface Commands

ipv6

Syntax	[no] ipv6
Context	config>service>vprn>interface
Description	This command enables the context to configure parameters for a VPRN IPv6 interface.

address

Syntax	address <i>ipv6-address/prefix-length</i> [eui-64] [preferred] no address <i>ipv6-address/prefix-length</i>
Context	config>service>vprn>if>ipv6
Description	This command assigns an address to the IPv6 interface.
Parameters	<i>ipv6-address/prefix-length</i> — the address of the IPv6 interface Values <i>ipv6-address</i> x:x:x:x:x:x:x (eight 16-bit pieces) x:x:x:x:x:x:d.d.d.d x: [0 to FFFF]H d: [0 to 255]D <i>prefix-length</i> 0 to 128 eui-64 — when the eui-64 keyword is specified, a complete IPv6 address from the supplied prefix and 64-bit interface identifier is formed. The 64-bit interface identifier is derived from the MAC address on Ethernet interfaces. For interfaces without a MAC address, for example ATM interfaces, the base MAC address of the chassis is used. preferred — specifies that the IPv6 address is the preferred IPv6 address for this interface. A preferred address is an address assigned to an interface whose use by upper layer protocols is unrestricted. A preferred address may be used as the source or destination address of packets sent from or to the interface.

dhcp6-relay

Syntax	[no] dhcp6-relay
Context	config>service>vprn>if>ipv6
Description	This command enables the context to configure DHCPv6 relay parameters for the interface. The no form of the command disables DHCPv6 relay.

option

Syntax	[no] option
Context	config>service>vprn>if>ipv6>dhcp6-relay
Description	This command enables the context to configure DHCPv6 relay information options. The no form of the command disables DHCPv6 relay information options.

interface-id

Syntax	interface-id interface-id ascii-tuple interface-id ifindex interface-id sap-id interface-id <i>string</i> no interface-id
Context	config>service>vprn>if>ipv6>dhcp6-relay>option
Description	This command enables the sending of interface ID options in the DHCPv6 relay packet. The no form of the command disables the sending of interface ID options in the DHCPv6 relay packet.
Parameters	ascii-tuple — specifies that the ASCII-encoded concatenated tuple will be used (consists of the access-node-identifier, service-id, and interface-name, separated by " ") ifindex — specifies that the interface index will be used. (The If Index of a router interface can be displayed using the command show>router>if>detail .) sap-id — specifies that the SAP identifier will be used string — a string of up to 32 characters long, composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

remote-id

Syntax	[no] remote-id
Context	config>service>vprn>if>ipv6>dhcp6-relay>option
Description	This command enables the sending of the remote ID option in the DHCPv6 relay packet. The client DHCP Unique Identifier (DUID) is used as the remote ID.

The **no** form of the command disables the sending of remote ID option in the DHCPv6 relay packet.

server

Syntax	[no] server <i>ipv6z-address</i>
Context	config>service>vprn>if>ipv6>dhcp6-relay
Description	This command configures an IPv6 address to the DHCPv6 server. The no form of the command disables the specified IPv6 address.
Parameters	<i>ipv6z-address</i> — the IPv6 address of the DHCPv6 server (a maximum of eight addresses can be configured)
Values	<i>ipv6z-address</i> x:x:x:x:x:x:x [-interface] x:x:x:x:x:x:d.d.d [-interface] x: [0 to FFFF]H d: [0 to 255]D interface: 32 characters maximum, mandatory for link local addresses

source-address

Syntax	[no] source-address <i>ipv6-address</i>
Context	config>service>vprn>if>ipv6>dhcp6-relay
Description	This command assigns the source IPv6 address of the DHCPv6 relay messages. The no form of the command disables the specified IPv6 address.
Parameters	<i>ipv6-address</i> — the source IPv6 address of the DHCPv6 relay messages
Values	<i>ipv6-address</i> x:x:x:x:x:x:x (eight 16-bit pieces) x:x:x:x:x:x:d.d.d x: [0 to FFFF]H d: [0 to 255]D

dhcp6-server

Syntax	[no] dhcp6-server
Context	config>service>vprn>if>ipv6

Description This command enables the context to configure DHCPv6 server parameters for the VPRN interface.

The **no** form of the command disables the DHCPv6 server.

max-nbr-of-leases

Syntax **max-nbr-of-leases** *max-nbr-of-leases*
no max-nbr-of-leases

Context config>service>vprn>if>ipv6>dhcp6-server

Description This command configures the maximum number of lease states installed by the DHCPv6 server function allowed on this interface.

The **no** form of the command returns the value to the default.

Default 8000

Parameters *max-nbr-of-leases* — the maximum number of lease states installed by the DHCPv6 server function allowed on this interface

Values 0 to 8000

prefix-delegation

Syntax [**no**] **prefix-delegation**

Context config>service>vprn>if>ipv6>dhcp6-server

Description This command configures prefix delegation options for delegating a long-lived prefix from a delegating router to a requesting router, where the delegating router does not require knowledge about the topology of the links in the network to which the prefixes will be assigned.

The **no** form of the command disables prefix delegation.

prefix

Syntax [**no**] **prefix** *ipv6-address/prefix-length*

Context config>service>vprn>if>ipv6>dhcp6-server>pfx-delegate

Description This command specifies the IPv6 prefix that is delegated by the system.

Parameters *ipv6-address/prefix-length* — the address of the IPv6 interface

Values	<i>ipv6-address</i>	x:x:x:x:x:x:x (eight 16-bit pieces) x:x:x:x:x:x:d.d.d.d x: [0 to FFFF]H d: [0 to 255]D
	<i>prefix-length</i>	0 to 128

duid

Syntax	duid <i>duid</i> [iaid <i>iaid</i>] no duid
Context	config>service>vprn>if>ipv6>dhcp6>pfx-delegate>prefix
Description	This command configures the DHCP Unique Identifier (DUID) of the DHCPv6 server client.
Parameters	<i>duid</i> — the ID of the requesting router. If set to a non-zero value, the prefix defined will only be delegated to this router. If set to 0, the prefix will be delegated to any requesting router. <i>iaid</i> — the identity association identification (IAID) from the requesting router that needs to match in order to delegate the defined prefix. If set to 0, no match on the received IAID is done.

preferred-lifetime

Syntax	preferred-lifetime <i>seconds</i> preferred-lifetime infinite no preferred-lifetime
Context	config>service>vprn>if>ipv6>dhcp6>pfx-delegate>prefix
Description	This command configures the IPv6 prefix preferred lifetime. The preferred-lifetime value cannot be larger than the valid-lifetime value. The no form of the command reverts to the default value.
Default	604800 seconds (7 days)
Parameters	<i>seconds</i> — the time, in seconds, that this prefix remains preferred Values 1 to 4294967294 infinite — specifies that this prefix remains preferred infinitely

valid-lifetime

Syntax	valid-lifetime <i>seconds</i> valid-lifetime infinite no valid-lifetime
Context	config>service>vprn>if>ipv6>dhcp6>pfx-delegate>prefix
Description	This command configures the time, in seconds, that the prefix is valid. The no form of the command reverts to the default value.
Default	2592000 seconds (30 days)
Parameters	<i>seconds</i> — the time, in seconds, that this prefix remains valid Values 1 to 4294967295 infinite — specifies that this prefix remains valid infinitely

icmp6

Syntax	icmp6
Context	config>service>vprn>if>ipv6
Description	This command configures ICMPv6 parameters for the interface.

packet-too-big

Syntax	packet-too-big [<i>number seconds</i>] no packet-too-big
Context	config>service>vprn>if>ipv6>icmp6
Description	This command specifies whether, and how often, “packet-too-big” ICMPv6 messages should be sent. When enabled, ICMPv6 “packet-too-big” messages are generated by this interface. The no form of the command disables the sending of ICMPv6 “packet-too-big” messages.
Default	100 10
Parameters	<i>number</i> — the number of “packet-too-big” ICMPv6 messages to send in the time frame specified by the <i>seconds</i> parameter Values 10 to 1000 Default 100

seconds — the time frame, in seconds, that is used to limit the number of “packet-too-big” ICMPv6 messages issued

Values 1 to 60

Default 10

param-problem

Syntax **param-problem** [*number seconds*]
no packet-too-big

Context config>service>vprn>if>ipv6>icmp6

Description This command specifies whether, and how often, “parameter-problem” ICMPv6 messages should be sent. When enabled, “parameter-problem” ICMPv6 messages are generated by this interface.

The **no** form of the command disables the sending of “parameter-problem” ICMPv6 messages.

Default 100 10

Parameters *number* — the number of “parameter-problem” ICMPv6 messages to send in the time frame specified by the *seconds* parameter

Values 10 to 1000

Default 100

seconds — the time frame, in seconds, that is used to limit the number of “parameter-problem” ICMPv6 messages issued

Values 1 to 60

Default 10

time-exceeded

Syntax **time-exceeded** [*number seconds*]
no time-exceeded

Context config>service>vprn>if>ipv6>icmp6

Description This command specifies whether, and how often, “time-exceeded” ICMPv6 messages should be sent. When enabled, ICMPv6 “time-exceeded” messages are generated by this interface.

Default 100 10

Parameters	<i>number</i> — the number of “time-exceeded” ICMPv6 messages are to be issued in the time frame specified by the <i>seconds</i> parameter Values 10 to 1000 Default 100 <i>seconds</i> — the time frame, in seconds, that is used to limit the number of “time-exceeded” ICMPv6 messages to be issued Values 1 to 60 Default 10

unreachables

Syntax	unreachables [<i>number seconds</i>] no unreachables
Context	config>service>vprn>if>ipv6>icmp6
Description	This command specifies whether, and how often, ICMPv6 host and network destination unreachable messages are generated by this interface.
Default	100 10
Parameters	<i>number</i> — the number of destination unreachable ICMPv6 messages to send issued in the time frame specified by the <i>seconds</i> parameter Values 10 to 1000 Default 100 <i>seconds</i> — the time frame, in seconds, that is used to limit the number of destination unreachable ICMPv6 messages to be sent Values 1 to 60 Default 10

link-local-address

Syntax	link-local-address <i>ipv6-address</i> [preferred] no link-local-address
Context	config>service>vprn>if>ipv6
Description	This command configures the IPv6 link-local address. The no form of the command removes the configured link-local address, and the router automatically generates a default link-local address.

Removing a manually configured link-local address may impact routing protocols that have a dependency on that address.

Default	n/a
Parameters	<i>ipv6-address</i> — the IPv6 link local address
Values	x:x:x:x:x:x:x (eight 16-bit pieces) x:x:x:x:x:d.d.d.d x: [0 to FFFF]H d: [0 to 255]D
	preferred — specifies that the IPv6 address is the preferred IPv6 address for this interface. A preferred address is an address assigned to an interface whose use by upper layer protocols is unrestricted. A preferred address may be used as the source or destination address of packets sent from or to the interface.

neighbor

Syntax	neighbor <i>ipv6-address mac-address</i> no neighbor <i>ipv6-address</i>
Context	config>service>vprn>if>ipv6
Description	This command configures IPv6-to-MAC address mapping on the interface.
Default	n/a
Parameters	<i>ipv6-address</i> — the address of the IPv6 interface for which to display information Values x:x:x:x:x:x:x (eight 16-bit pieces) x:x:x:x:x:d.d.d.d x: [0 to FFFF]H d: [0 to 255]D prefix-length [1 to 128] <i>mac-address</i> — the 48-bit MAC address for the IPv6-to-MAC address mapping in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff, where aa, bb, cc, dd, ee and ff are hexadecimal numbers. Allowed values are any unicast MAC addresses and non-IEEE reserved MAC addresses

reachable-time

Syntax	reachable-time <i>seconds</i> no reachable-time
Context	config>service>vprn>if>ipv6
Description	This command specifies the time that an IPv6 neighbor remains in a reachable state.

Default	no reachable-time
Parameters	<i>seconds</i> — the number of seconds that an IPv6 neighbor remains in a reachable state
Values	30 to 3600
Default	30

stale-time

Syntax	stale-time <i>seconds</i> no stale-time
Context	config>service>vprn>if>ipv6
Description	This command specifies the time that an IPv6 neighbor cache entry remains in a stale state. When the specified time elapses, the system removes the neighbor cache entry.
Default	no stale-time
Parameters	<i>seconds</i> — the number of seconds that an IPv6 neighbor remains in a stale state
Values	60 to 65535
Default	14400

7.8.2.1.16 Interface DHCP Commands

dhcp

Syntax	dhcp
Context	config>service>vprn>interface
Description	This command enables the context to configure DHCP parameters.

gi-address

Syntax	gi-address <i>ip-address</i> [src-ip-addr] no gi-address
Context	config>service>vprn>if>dhcp
Description	This command configures the gateway interface address for the DHCP Relay Agent. By default, the GIADDR used in the relayed DHCP packet is the primary address of an interface. Specifying the GIADDR allows the user to choose a secondary address.
Default	no gi-address
Parameters	<i>ip-address</i> — the IP address of the gateway interface in dotted-decimal notation Values a.b.c.d (host bits must be 0) src-ip-addr — specifies that the GIADDR is to be used as the source IP address for DHCP relay packets

option

Syntax	[no] option
Context	config>service>vprn>if>dhcp
Description	This command enables DHCP Option 82 (Relay Agent Information Option) parameters processing and enters the context for configuring Option 82 suboptions. The no form of this command returns the system to the default.
Default	no option

action

Syntax	action {replace drop keep} no action
Context	config>service>vprn>if>dhcp>option
Description	This command configures the processing required when the 7705 SAR receives a DHCP request that already has a Relay Agent Information Option (Option 82) field in the packet. The no form of this command returns the system to the default value.
Default	keep—(as per RFC 3046, <i>DHCP Relay Agent Information Option</i> , section 2.1.1, Reforwarded DHCP requests, the default is to keep the existing information intact. The exception to this occurs if the gi-addr (gateway interface address) of the received packet is the same as the ingress address on the router. In this case, the packet is dropped and an error is logged.)
Parameters	replace — in the upstream direction (from the user), the existing Option 82 field is replaced with the Option 82 field from the router. In the downstream direction (towards the user) the Option 82 field is stripped (in accordance with RFC 3046). drop — the packet is dropped, and an error is logged keep — the existing information is kept in the packet and the router does not add any additional information. In the downstream direction, the Option 82 field is not stripped and is sent on towards the client. The behavior is slightly different in the case of Vendor Specific Options (VSOs). When the keep parameter is specified, the router will insert its own VSO into the Option 82 field. This will only be done when the incoming message has an Option 82 field already. If no Option 82 field is present, the router will not create the Option 82 field. In this case, no VSO will be added to the message.

circuit-id

Syntax	circuit-id [ascii-tuple ifindex sap-id vlan-ascii-tuple] no circuit-id
Context	config>service>vprn>if>dhcp>option
Description	This command sends either an ASCII tuple or the interface index (If Index) on the specified SAP ID in the circuit-id suboption of the DHCP packet. The If Index of a router interface can be displayed using the command show>router>interface>detail. This option specifies data that must be unique to the router that is relaying the circuit. If disabled, the circuit-id suboption of the DHCP packet is left empty. The no form of this command returns the system to the default.
Default	ascii-tuple

-
- Parameters**
- ascii-tuple** — the ASCII-encoded concatenated “tuple” will be used, where the “tuple” consists of the *access-node-identifier*, *service-id*, and *interface-name*, separated by the syntax symbol “|”
 - ifindex** — the interface index will be used
 - sap-id** — the SAP ID will be used
 - vlan-ascii-tuple** — specifies that the format will include VLAN-id and dot1p bits, in addition to the **ascii-tuple**. The format is supported on dot1q and qinq ports only. Thus, when the Option 82 bits are stripped, dot1p bits will be copied to the Ethernet header of an outgoing packet.

remote-id

- Syntax** **remote-id** [**mac** | **string** *string*]
no remote-id
- Context** config>service>vprn>if>dhcp>option
- Description** This command sends the MAC address of the remote end (typically, the DHCP client) in the **remote-id** suboption of the DHCP packet. This command identifies the host at the other end of the circuit. If disabled, the **remote-id** suboption of the DHCP packet will be left empty.
- The **no** form of this command returns the system to the default.
- Default** remote-id
- Parameters** **mac** — the MAC address of the remote end is encoded in the suboption
 string — the remote ID
- Values** up to 32 alphanumeric characters

vendor-specific-option

- Syntax** [**no**] **vendor-specific-option**
- Context** config>service>vprn>if>dhcp>option
- Description** This command enables the Nokia vendor-specific suboption of the DHCP relay packet and enters the context for configuring the vendor-specific suboptions.

client-mac-address

Syntax	[no] client-mac-address
Context	config>service>vprn>if>dhcp>option>vendor
Description	This command enables the sending of the MAC address in the Nokia vendor-specific suboption of the DHCP relay packet. The no form of the command disables the sending of the MAC address in the Nokia vendor-specific suboption of the DHCP relay packet.
Default	no client-mac-address

sap-id

Syntax	[no] sap-id
Context	config>service>vprn>if>dhcp>option>vendor
Description	This command enables the sending of the SAP ID in the Nokia vendor-specific suboption of the DHCP relay packet. The no form of the command disables the sending of the SAP ID in the Nokia vendor-specific suboption of the DHCP relay packet.
Default	no sap-id

service-id

Syntax	[no] service-id
Context	config>service>vprn>if>dhcp>option>vendor
Description	This command enables the sending of the service ID in the Nokia vendor-specific suboption of the DHCP relay packet. The no form of the command disables the sending of the service ID in the Nokia vendor-specific suboption of the DHCP relay packet.
Default	no service-id

string

Syntax	string <i>text</i> no string
Context	config>service>vprn>if>dhcp>option>vendor
Description	This command specifies the vendor-specific suboption string of the DHCP relay packet. The no form of the command returns the default value.
Default	no string
Parameters	<i>text</i> — any combination of ASCII characters up to 32 characters in length. If spaces are used in the string, the entire string must be enclosed within double quotes.

system-id

Syntax	[no] system-id
Context	config>service>vprn>if>dhcp>option>vendor
Description	This command specifies whether the system ID is encoded in the Nokia vendor-specific suboption of Option 82.
Default	n/a

server

Syntax	server <i>server1</i> [<i>server2</i> ...(up to 8 max)] no server
Context	config>service>vprn>if>dhcp
Description	This command specifies a list of servers where requests will be forwarded. The list of servers can be entered as either IP addresses or fully qualified domain names. There must be at least one server specified for DHCP Relay to work. If there are multiple servers specified, the request is forwarded to all of the servers in the list. There can be a maximum of 8 DHCP servers configured.
Default	no server
Parameters	<i>server</i> — the DHCP server IP address

trusted

Syntax	[no] trusted
Context	config>service>vprn>if>dhcp
Description	This command enables or disables trusted mode on an IP interface. According to RFC 3046, <i>DHCP Relay Agent Information Option</i>, a DHCP request where the gi-addr (gateway interface address) is 0.0.0.0 and which contains an Option 82 field in the packet, should be discarded, unless it arrives on a “trusted” circuit. If trusted mode is enabled on an IP interface, the relay agent (the 7705 SAR) will modify the request gi-addr to be equal to the ingress interface and forward the request. This behavior only applies when the action in the Relay Agent Information Option is “keep”. In the case where the Option 82 field is being replaced by the relay agent (action = “replace”), the original Option 82 information is lost. Thus, in this case, there is no reason for enabling the trusted option. The no form of this command returns the system to the default.
Default	no trusted

7.8.2.1.17 Interface ICMP Commands

icmp

Syntax	icmp
Context	config>service>vprn>interface
Description	This command configures Internet Control Message Protocol (ICMP) parameters on a VPRN service and enters the context for configuring ICMP.

mask-reply

Syntax	[no] mask-reply
Context	config>service>vprn>if>icmp
Description	This command enables responses to ICMP mask requests on the router interface. If a local node sends an ICMP mask request to the router interface, the mask-reply command configures the router interface to reply to the request. By default, the router instance will reply to mask requests. The no form of this command disables replies to ICMP mask requests on the router interface.
Default	mask-reply

ttl-expired

Syntax	ttl-expired <i>number seconds</i> no ttl-expired [<i>number seconds</i>]
Context	config>service>vprn>if>icmp
Description	This command configures the rate at which ICMP TTL-expired messages are issued by the IP interface. By default, generation of ICMP TTL-expired messages is enabled at a maximum rate of 100 per 10-s time interval. The no form of this command disables limiting the rate of TTL-expired messages on the router interface.
Default	ttl-expired 100 10

Parameters	<i>number</i> — the maximum number of ICMP TTL-expired messages to send, expressed as a decimal integer. This parameter must be specified along with the <i>seconds</i> parameter. Values 10 to 100 <i>seconds</i> — the time, in seconds, used to limit the number of ICMP TTL-expired messages that can be issued, expressed as a decimal integer Values 1 to 60

unreachables

Syntax	unreachables <i>number seconds</i> no unreachables [<i>number seconds</i>]
Context	config>service>vprn>if>icmp
Description	This command enables and configures the rate of ICMP host and network destination unreachable messages issued on the router interface. The unreachables command enables the generation of ICMP destination unreachables on the router interface. The rate at which ICMP unreachables is issued can be controlled with the <i>number</i> and <i>seconds</i> parameters by indicating the maximum number of destination unreachable messages that can be issued on the interface for a given time interval. By default, generation of ICMP destination unreachable messages is enabled at a maximum rate of 100 per 10-s time interval. The no form of this command disables the generation of ICMP destination unreachable messages on the router interface.
Default	unreachables 100 10
Parameters	<i>number</i> — the maximum number of ICMP unreachable messages to send. This parameter must be specified along with the <i>seconds</i> parameter. Values 10 to 100 <i>seconds</i> — the time frame, in seconds, used to limit the number of ICMP unreachable messages that can be issued Values 1 to 60

7.8.2.1.18 Interface SAP Commands

sap

Syntax	sap <i>sap-id</i> [create] no sap <i>sap-id</i>
Context	config>service>vprn>interface
Description	This command creates a Service Access Point (SAP) within a service when used with the create keyword. The create keyword is not needed when entering an existing SAP to edit SAP parameters. A SAP is a combination of port and encapsulation parameters that identify the service access point on the interface and within the 7705 SAR. Each SAP must be unique. All SAPs must be explicitly created. If no SAPs are created within a service or on an IP interface, a SAP will not exist on that object. The SAP is owned by the service in which it was created. A SAP can only be associated with a single service. A SAP can only be defined on a port that has been configured as an access port using the config interface <i>port-type port-id mode access</i> command. Channelized TDM ports are always access ports. If a port is shut down with the shutdown command, all SAPs on that port become operationally down. When a service is shut down, SAPs for the service are not displayed as operationally down although all traffic traversing the service will be discarded. The operational state of a SAP is relative to the operational state of the port on which the SAP is defined. To configure a VPRN interface SAP that is used for a private IPsec tunnel interface, see sap in Service Interface Tunnel Commands. If the VPRN interface has been configured as a loopback interface with the loopback command, a SAP cannot be defined on the interface. The no form of this command deletes the SAP with the specified port. When a SAP is deleted, all configuration parameters for the SAP will also be deleted.
Default	no SAPs are defined
Parameters	<i>sap-id</i> — the physical port identifier portion of the SAP definition. See Table 41 for a full list of SAP IDs. create — keyword used to create a SAP instance

accounting-policy

Syntax	accounting-policy <i>acct-policy-id</i> no accounting-policy [<i>acct-policy-id</i>]
Context	config>service>vprn>if>sap
Description	This command creates the accounting policy context that can be applied to an interface SAP. An accounting policy must be defined before it can be associated with a SAP. Accounting policies are configured in the config log context. A maximum of one accounting policy can be associated with a SAP at one time. If the <i>acct-policy-id</i> does not exist, an error message is generated. The no form of this command removes the accounting policy association from the SAP, and the accounting policy reverts to the default.
Default	no accounting policy
Parameters	<i>acct-policy-id</i> — the accounting <i>policy ID</i> as configured in the config log accounting-policy context
Values	1 to 99

collect-stats

Syntax	[no] collect-stats
Context	config>service>vprn>if>sap
Description	This command enables accounting and statistical data collection for either an interface SAP or network port. When applying accounting policies, the data, by default, is collected in the appropriate records and written to the designated billing file. When the no collect-stats command is issued, the statistics are still accumulated. However, the CPU will not obtain the results and write them to the billing file. If a subsequent collect-stats command is issued, then the counters written to the billing file include all the traffic while the no collect-stats command was in effect.
Default	collect-stats

egress

Syntax	egress
Context	config>service>vprn>if>sap
Description	This command enables the context to configure egress SAP QoS policies and filter policies.

If no sap-egress QoS policy is defined, the system default sap-egress QoS policy is used for egress processing. If no egress filter policy is defined, no filtering is performed.

ingress

Syntax	ingress
Context	config>service>vprn>if>sap
Description	This command enables the context to configure ingress SAP QoS policies and filter policies. If no sap-ingress QoS policy is defined, the system default sap-ingress QoS policy is used for ingress processing. If no ingress filter policy is defined, no filtering is performed.

agg-rate-limit

Syntax	agg-rate-limit <i>agg-rate</i> [cir <i>cir-rate</i>] no agg-rate-limit
Context	config>service>vprn>if>sap>egress config>service>vprn>if>sap>ingress
Description	This command sets the aggregate rate limits (PIR and CIR) for the SAP. The <i>agg-rate</i> sets the PIR value. The <i>cir-rate</i> sets the CIR value. When aggregate rate limits are configured on a second-generation (Gen-2) Ethernet adapter card, the scheduler mode must be set to 16-priority. On a third-generation (Gen-3) Ethernet adapter card, the scheduler mode is always 4-priority. For information on adapter card generations, refer to the “Evolution of Ethernet Adapter Cards, Modules, and Platforms” section in the 7705 SAR Interface Configuration Guide. Configuring the <i>cir-rate</i> is optional. If a <i>cir-rate</i> is not entered, then the <i>cir-rate</i> is set to its default value (0 kb/s). If a <i>cir-rate</i> has been set and the <i>agg-rate</i> is changed without re-entering the <i>cir-rate</i>, the <i>cir-rate</i> automatically resets to 0 kb/s. For example, to change the <i>agg-rate</i> from 2000 to 1500 while maintaining a <i>cir-rate</i> of 500, use the command agg-rate-limit 1500 cir 500. If the specified SAP is a LAG SAP, then <i>agg-rate</i> and <i>cir-rate</i> can be configured regardless of the scheduler mode setting on Gen-2 or Gen-3 hardware—it is not configurable if one of the ports configured in the LAG SAP is on Gen-1 hardware. If the active port is on a Gen-3 card or platform, then <i>agg-rate</i> and <i>cir-rate</i> are applicable. If the active port is on a Gen-2 card or platform, then <i>agg-rate</i> and <i>cir-rate</i> apply when the scheduler mode is set to 16-priority. If the active port is on a Gen-1 card, then <i>agg-rate</i> and <i>cir-rate</i> are not applicable. For details on the behavior of a mix-and-match LAG SAP, refer to the “LAG Support on Third-Generation Ethernet Adapter Cards, Ports, and Platforms” and “Network LAG Traffic Management” sections in the 7705 SAR Interface Configuration Guide.

Note: Starting with Release 7.0.R6, schedulers on Gen-3 adapter cards and platforms have been updated to better align with the scheduling behavior supported on the other 7705 SAR adapter cards and platforms. The updated scheduler mode is called “4-priority” scheduler-mode throughout the CLI. Prior to Release 7.0.R6, the CLI designation was “4-priority-hqos”. In the updated mode of operation, arbitration among different flows at the second-tier aggregate (per-SAP or per-VLAN) and third-tier aggregate (per-customer (MSS)) levels are carried out in a round-robin manner, scheduling *cir-rate* first from the shapers, followed by the *pir-rate*.

Caution: Any Gen-3 adapter card or platform running Release 7.0.R6 or later software uses 4-priority scheduling instead of 4-priority-hqos scheduling, which was supported previously. The migration of scheduler mode is automatic with an upgrade and there is no operator action required. As part of the migration, all CIR values at second-tier (per-SAP and per-VLAN) and third-tier (per-customer (MSS)) aggregate shaper levels are set to zero. Operators must exercise caution when performing an upgrade to Release 7.0.R6 or later from a previous Release 7.0 version, and must adjust the affected CIR values in accordance with the needs of their applications as soon as possible.

The **no** form of the command sets the *agg-rate* to the maximum and the *cir-rate* to 0 kb/s.

Default	no agg-rate-limit
Parameters	<i>agg-rate</i> — sets the PIR for the aggregate of all the queues on the SAP. The max keyword applies the maximum physical port rate possible. Values 1 to 10000000 kb/s, or max Default max <i>cir-rate</i> — sets the CIR for the aggregate of all the queues on the SAP Values 0 to 10000000 kb/s, or max Default 0 kb/s

filter

Syntax	<pre>filter ip ip-filter-id no filter ip [ip-filter-id] filter ipv6 ipv6-filter-id no filter ipv6 [ipv6-filter-id] filter [ip ip-filter-id] [ipv6 ipv6-filter-id] no filter [[ip [ip-filter-id]] [[ipv6 [ipv6-filter-id]]]</pre>
Context	<pre>config>service>vprn>if>sap>egress config>service>vprn>if>sap>ingress</pre>

Description	This command associates an IPv4 or IPv6 filter policy with an ingress or egress SAP or IP interface. Filter policies control the forwarding and dropping of packets based on IP matching criteria. The filter command is used to associate a filter policy with a specified <i>ip-filter-id</i> or <i>ipv6-filter-id</i> with an ingress or egress SAP. The <i>ip-filter-id</i> or <i>ipv6-filter-id</i> must already be defined before the filter command is executed. If the filter policy does not exist, the operation will fail and an error message will be returned. Only one filter ID can be assigned to an interface unless the interface is dual-stack (supports both IPv4 and IPv6). A dual-stack interface can have one IPv4 and one IPv6 filter ID assigned to it. In general, filters applied to SAPs apply to all packets on the SAP. One exception is that IP match criteria are not applied to non-IP packets, in which case the default action in the filter policy applies to these packets. The no form of this command removes any configured filter ID association with the SAP or IP interface. The filter ID is not removed from the system unless the scope of the created filter is set to local. To avoid deletion of the filter ID and only break the association with the service object, use the scope command within the filter definition to change the scope to local or global. The default scope of a filter is local.
Parameters	<i>ip-filter-id</i> — the IPv4 filter policy. The filter ID or filter name must already exist within the created IPv4 filters. Values 1 to 65535 or <i>filter-name</i> (up to 64 characters) <i>ipv6-filter-id</i> — the IPv6 filter policy. The filter ID or filter name must already exist within the created IPv6 filters. Values 1 to 65535 or <i>ipv6-filter-name</i> (up to 64 characters)

match-qinq-dot1p

Syntax	match-qinq-dot1p {top bottom} no match-qinq-dot1p
Context	config>service>vprn>if>sap>ingress
Description	This command specifies which dot1q tag position (top or bottom) in a qinq-encapsulated packet should be used when QoS evaluates dot1p classification. The no form of the command restores the default dot1p evaluation behavior for the SAP, which means that the inner (bottom) tag (second tag) dot1p bits are used for classification. By default, the dot1p bits from the inner tag service-delineating dot1q tag are used.

Table 132 shows which set of dot1p bits are used for QoS purposes when **match-qinq-dot1p** is configured. To use the table, find the row that represents the settings for **Port/SAP Type** and **Match-QinQ-Dot1p Setting**. Use the **Existing Packet Tags** column to identify which dot1q tags are available in the packet. Then use the **P-bits Used for Match** column to identify which dot1q tag contains the dot1p bits that are used for QoS dot1p classification.

Default no match-qinq-dot1p

Parameters **top** — the **top** parameter and **bottom** parameter are mutually exclusive. When the **top** parameter is specified, the outer tag's dot1p bits (topmost P-bits) are used (if existing) to match any **dot1p** *dot1p-value* entries

bottom — the **bottom** parameter and **top** parameter are mutually exclusive. When the **bottom** parameter is specified, the bottommost P-bits (second tag's P-bits) are used (if existing) to match any **dot1p** *dot1p-value* entries.

Table 132 Match-QinQ-Dot1p Matching Behavior

Port/ SAP Type	Match-QinQ-Dot1p Setting ¹	Existing Packet Tags	P-bits Used for Match
Null	n/a	None	None
Null	n/a	Dot1p (VLAN ID 0)	None ²
Null	n/a	Dot1q	None ²
Null	n/a	TopQ BottomQ	None ²
Dot1q	n/a	None	None
Dot1q	n/a	Dot1p (default SAP VLAN ID 0)	Dot1p P-bits
Dot1q	n/a	Dot1q	Dot1q P-bits
QinQ/ X.Y	Top	TopQ BottomQ	TopQ P-bits
QinQ/ X.Y	Default or Bottom	TopQ BottomQ	BottomQ P-bits
QinQ/ X.0	Top	TopQ	TopQ P-bits
QinQ/ X.0	Default or Bottom	TopQ	TopQ P-bits
QinQ/ X.0	Top	TopQ BottomQ	TopQ P-bits
QinQ/ X.0	Default or Bottom	TopQ BottomQ	BottomQ P-bits
QinQ/ X.*	Top	TopQ	TopQ P-bits
QinQ/ X.*	Default or Bottom	TopQ	TopQ P-bits
QinQ/ X.*	Top	TopQ BottomQ	TopQ P-bits
QinQ/ X.*	Default or Bottom	TopQ BottomQ	BottomQ P-bits

Table 132 Match-QinQ-Dot1p Matching Behavior (Continued)

Port/ SAP Type	Match-QinQ-Dot1p Setting ¹	Existing Packet Tags	P-bits Used for Match
QinQ/ 0.*	Top	None	None
QinQ/ 0.*	Default or Bottom	None	None
QinQ/ 0.*	Top	TopQ	TopQ P-bits
QinQ/ 0.*	Default or Bottom	TopQ	TopQ P-bits
QinQ/ 0.*	Top	TopQ BottomQ	TopQ P-bits
QinQ/ 0.*	Default or Bottom	TopQ BottomQ	BottomQ P-bits
QinQ/ *.*	Top	None	None
QinQ/ *.*	Default or Bottom	None	None
QinQ/ *.*	Top	TopQ	TopQ P-bits
QinQ/ *.*	Default or Bottom	TopQ	TopQ P-bits
QinQ/ *.*	Top	TopQ BottomQ	TopQ P-bits
QinQ/ *.*	Default or Bottom	TopQ BottomQ	BottomQ P-bits

Notes:

1. "Default" in this column refers to the **no** form of the **match-qinq-dot1p** command.
2. For null encapsulation, the 7705 SAR does not process dot1p bits.

qinq-mark-top-only

Syntax [no] **qinq-mark-top-only**

Context config>service>vprn>if>sap>egress

Description When enabled, the **qinq-mark-top-only** command specifies which P-bits to mark during packet egress. When disabled, both sets of P-bits are marked. When enabled, only the P-bits in the top Q-tag are marked. The **no** form of the command is the default state (disabled).

[Table 133](#) shows the dot1p remarking behavior for different egress port type/SAP type combinations and **qinq-mark-top-only** state, where "False" represents the default (disabled) state.

If a new tag is pushed, the dot1p bits of the new tag will be zero (unless the new tag is re-marked by the egress policy. The dot1p bits are configured using the **dot1p** parameter under the **config>qos** context.

Table 133 Dot1P Re-marking Behavior for the QinQ-mark-top-only Command

Egress Port Type/SAP Type	QinQ-mark-top-only State	Egress P-Bits Marked or Re-marked
Null ¹	n/a	None
Dot1q/ X ¹	n/a	Outer tag
Dot1q/ * ²	n/a	None
Dot1q/ 0 ²	n/a	Outer tag
QinQ/ X.Y ¹	False	Two outer tags ³
	True	Outer tag ³
QinQ/ X.* ¹	True or False	Outer tag
QinQ/ X.0 ¹	True or False	Outer tag
QinQ/ 0.* ¹	True or False	None
QinQ/ *.* ²	True or False	None

Notes:

1. This port type/SAP type is supported by the following services: Epipe, Ipipe, VPLS, IES, and VPRN.
2. This port type/SAP type is supported by the following services: Epipe and VPLS.
3. Normally, when a new tag is pushed, the dot1p bits of the new tag will be zero, unless the P-bits are remarked by the egress policy. However, an exception to this occurs when the egress SAP type is X.Y and only one new outer tag must be pushed. In this case, the new outer tag will have its dot1p bits set to the inner tag's dot1p bits.

Default no qinq-mark-top-only

qos

Syntax **qos** *policy-id*
no qos [*policy-id*]

Context config>service>vprn>if>sap>egress
config>service>vprn>if>sap>ingress

Description This command associates a QoS policy with an ingress or egress SAP. QoS ingress and egress policies are important for the enforcement of SLA agreements. The policy ID must be defined prior to associating the policy with a SAP. If the *policy-id* does not exist, an error will be returned.

The **qos** command is used to associate both ingress and egress QoS policies. The **qos** command only allows ingress policies to be associated on SAP ingress and egress policies on SAP egress. Attempts to associate a QoS policy of the wrong type returns an error; for example, trying to associate an egress policy on SAP ingress.

Only one ingress and one egress QoS policy can be associated with a SAP at one time. Attempts to associate a second QoS policy of a given type returns an error.

By default, no specific QoS policy is associated with the SAP for ingress or egress, so the default QoS policy is used.

The **no** form of this command removes the QoS policy association from the SAP, and the QoS policy reverts to the default.

Parameters *policy-id* — the ingress or egress policy ID to associate with the SAP on ingress or egress. The policy ID or name must already exist.

Values 1 to 65535, or *policy-name* (up to 64 characters)

scheduler-mode

Syntax **scheduler-mode {4-priority | 16-priority}**

Context config>service>vprn>if>sap>egress
config>service>vprn>if>sap>ingress

Description This command sets the scheduler mode for the SAP and is part of the hierarchical QoS (H-QoS) feature on the 7705 SAR.

If the mode is 4-priority, then the SAP is considered an unshaped 4-priority SAP and the [agg-rate-limit](#) cannot be changed from its default values.

If the mode is 16-priority and the **agg-rate limit** parameters are configured to be non-default values, then the SAP is considered a shaped SAP. If the **agg-rate limit** parameters are left in their default settings, the SAP is considered an unshaped, 16-priority SAP.

This command is blocked on third-generation (Gen-3) Ethernet adapter cards and platforms, such as the 6-port Ethernet 10Gbps Adapter card and the 7705 SAR-X, which only support 4-priority scheduling mode.

If the specified SAP is a LAG SAP, **scheduler-mode** can be configured but is not applied to Gen-3 adapter cards and platforms. If one of the ports in the LAG is on a Gen-1 adapter card, then **scheduler-mode** cannot be configured.

Default 4-priority

Parameters **4-priority** — sets the scheduler mode for the SAP to be 4-priority mode
16-priority — sets the scheduler mode for the SAP to be 16-priority mode

shaper-group

Syntax	[no] shaper-group <i>shaper-group-name</i>
Context	config>service>vprn>if>sap>egress config>service>vprn>if>sap>ingress
Description	This command applies a shaper group to a SAP. The shaper group must already be created and must be within the shaper policy assigned to the Ethernet MDA (for ingress) or port (for egress). A shaper group is a dual-rate aggregate shaper used to shape aggregate access ingress or egress SAPs at a shaper group rate. Multiple aggregate shaper groups ensure fair sharing of available bandwidth among different aggregate shapers. The default shaper group cannot be deleted. The no form of this command removes the configured shaper-group.
Default	shaper-group "default"
Parameters	<i>shaper-group-name</i> — the name of the shaper group. To access the default shaper group, enter "default". create — keyword used to create a shaper group

7.8.2.1.19 Interface Spoke SDP Commands

spoke-sdp

Syntax	spoke-sdp <i>sdp-id:vc-id</i> [create] no spoke-sdp <i>sdp-id:vc-id</i>
Context	config>service>vprn>interface
Description	This command binds a service to an existing Service Distribution Point (SDP). A spoke SDP is treated like the equivalent of a traditional bridge “port”, where flooded traffic received on the spoke SDP is replicated on all other “ports” (other spoke SDPs or SAPs) and not transmitted on the port it was received on. The SDP has an operational state that determines the operational state of the SDP within the service. For example, if the SDP is administratively or operationally down, the SDP for the service is down. The SDP must already be defined in the config>service>sdp context in order to associate it with a service. If the sdp <i>sdp-id</i> is not already configured, an error message is generated. If the <i>sdp-id</i> does exist, a binding between that <i>sdp-id</i> and the service is created. SDPs must be explicitly associated and bound to a service. If an SDP is not bound to a service, no far-end devices can participate in the service. Class-based forwarding is not supported on a spoke SDP used for termination on an IES or VPRN service. All packets are forwarded over the default LSP. The no form of this command removes the SDP binding from the service. The SDP configuration is not affected; only the binding of the SDP to the service. Once the binding is removed, no packets are forwarded to the far-end router. The spoke SDP must be shut down first before it can be deleted from the configuration.
Default	n/a
Special Cases	VPRN — several SDPs can be bound to a VPRN service. Each SDP must be destined for a different 7705 SAR router. If two <i>sdp-id</i> bindings terminate on the same 7705 SAR, an error occurs and the second SDP binding is rejected.
Parameters	<i>sdp-id</i> — the SDP identifier Values 1 to 17407 <i>vc-id</i> — the virtual circuit identifier Values 1 to 4294967295

egress

Syntax	egress
Context	config>service>vprn>if>spoke-sdp
Description	This command enables the context to configure egress SDP parameters.

vc-label

Syntax	vc-label <i>egress-vc-label</i> no vc-label [<i>egress-vc-label</i>]
Context	config>service>vprn>if>spoke-sdp>egress
Description	This command configures the static MPLS VC label used by the 7705 SAR to send packets to the far-end device in this service via this SDP.
Parameters	<i>egress-vc-label</i> — a VC egress value that indicates a specific connection Values 16 to 1048575

ingress

Syntax	ingress
Context	config>service>vprn>if>spoke-sdp
Description	This command enables the context to configure ingress SDP parameters.

filter

Syntax	filter ip <i>ip-filter-id</i> filter ipv6 <i>ipv6-filter-id</i> no filter [ip <i>ip-filter-id</i>] [ipv6 <i>ipv6-filter-id</i>]
Context	config>service>vprn>if>spoke-sdp>ingress
Description	This command associates an IPv4 or IPv6 filter policy with a spoke SDP. Filter policies control the forwarding and dropping of packets based on IP or MAC matching criteria. The <i>ip-filter-id</i> or <i>ipv6-filter-id</i> must already be defined before the filter command is executed. If the filter policy does not exist, the operation will fail and an error message will be returned. Only one filter ID can be assigned to an interface unless the interface is dual-stack (supports both IPv4 and IPv6). A dual-stack interface can have one IPv4 and one IPv6 filter ID assigned to it.

In general, filters applied to ingress spoke SDPs will apply to all packets on the spoke SDP. One exception is that non-IP packets are not applied to IP match criteria, so the default action in the filter policy applies to these packets.

The **no** form of this command removes any configured filter ID association with the spoke SDP.

Parameters *ip-filter-id* — the IP filter policy. The filter ID or filter name must already exist within the created IP filters.

Values 1 to 65535 or IPv4 *filter-name* (up to 64 characters)

ipv6-filter-id — specifies the IPv6 filter policy. The filter ID or filter name must already exist within the created IPv6 filters.

Values 1 to 65535 or *ipv6-filter-name* (up to 64 characters)

vc-label

Syntax **vc-label** *ingress-vc-label*

no vc-label [*ingress-vc-label*]

Context config>service>vprn>if>spoke-sdp>ingress

Description This command configures the static MPLS VC label used by the far-end device to send packets to the 7705 SAR in this service via this SDP.

Parameters *ingress-vc-label* — a VC ingress value that indicates a specific connection

Values 2048 to 18431

7.8.2.1.20 Routed VPLS Commands

vpls

Syntax	vpls <i>service-name</i> no vpls
Context	config>service>vprn>interface
Description	This command within the IP interface context binds the IP interface to the specified VPLS service name. The system does not attempt to resolve the service name until the IP interface is placed into the administratively up state (no shutdown). Once the IP interface is administratively up, the system scans the available VPLS services that have the allow-ip-int-binding flag set for a VPLS service associated with the service name. If the IP interface is already in the administratively up state, the system immediately attempts to resolve the given service name.
Parameters	<i>service-name</i> — specifies the service name that the system attempts to resolve to an allow-ip-int-binding enabled VPLS service associated with the service name. The specified service name is an ASCII string of up to 32 characters.

ingress

Syntax	ingress
Context	config>service>vprn>if>vpls
Description	This command within the VPLS binding context defines the routed IPv4 optional filter override.

v4-routed-override-filter

Syntax	v4-routed-override-filter <i>ip-filter-id</i> no v4-routed-override-filter
Context	config>service>vprn>if>vpls>ingress
Description	This command specifies an IPv4 filter ID applied to all ingress packets entering the VPLS service. The filter overrides the existing ingress IPv4 filter applied to SAPs or SDP bindings for packets associated with the routing IP interface. The override filter is optional, and if not defined or removed, the IPv4 routed packets use the existing ingress IPv4 filter on the VPLS virtual ports.

The **no** form of the command removes the IPv4 routed override filter from the ingress IP interface.

Default	n/a
Parameters	<i>ip-filter-id</i> — specifies the IPv4 filter policy. The filter ID or filter name must already exist within the created IP filters.
Values	1 to 65535 or <i>filter-name</i> (up to 64 characters)

v6-routed-override-filter

Syntax	v6-routed-override-filter <i>ipv6-filter-id</i> no v6-routed-override-filter
Context	config>service>vprn>if>vpls>ingress
Description	This command specifies an IPv6 filter ID applied to all ingress packets entering the VPLS service. The filter overrides the existing ingress IPv6 filter applied to SAPs or SDP bindings for packets associated with the routing IP interface. The override filter is optional, and if not defined or removed, the IPv6 routed packets use the existing ingress IPv6 filter on the VPLS virtual ports. The no form of the command removes the IPv6 routed override filter from the ingress IP interface.
Default	n/a
Parameters	<i>ipv6-filter-id</i> — the IPv6 filter policy. The filter ID or filter name must already exist within the created IP filters.
Values	1 to 65535 or <i>ipv6-filter-name</i> (up to 64 characters)

7.8.2.1.21 Interface VRRP Commands

vrrp

Syntax	vrrp <i>virtual-router-id</i> [owner] no vrrp <i>virtual-router-id</i>
Context	config>service>vprn>interface config>service>vprn>if>ipv6
Description	This command creates or edits a virtual router ID on the service IP interface. A virtual router ID is internally represented in conjunction with the IP interface name. This allows the virtual router ID to be used on multiple IP interfaces while representing different virtual router instances. Two VRIDs can be defined on an IP interface. One, both, or none may be defined as owner. The no form of this command removes the specified virtual router ID from the IP interface. This terminates VRRP participation for the virtual router and deletes all references to the virtual router ID. The virtual router ID does not need to be shut down in order to remove the virtual router instance.
Default	n/a
Parameters	<i>virtual-router-id</i> — specifies a new virtual router ID or one that can be modified on the IP interface Values 1 to 255 owner — defines the virtual router instance as an owner

authentication-key

Syntax	authentication-key [<i>authentication-key</i> <i>hash-key</i>] [hash hash2] no authentication-key
Context	config>service>vprn>if>vrrp
Description	This command assigns a simple text password authentication key to generate master VRRP advertisement messages and validate received VRRP advertisement messages. If the command is re-executed with a different password key defined, the new key will be used immediately. If a no authentication-key command is executed, the password authentication key is restored to the default value. The authentication-key command can be executed at any time. To change the current in-use password key on multiple virtual router instances: • identify the current master

- shut down the virtual router instance on all backups
- execute the **authentication-key** command on the master to change the password key
- execute the **authentication-key** command and **no shutdown** command on each backup

The **no** form of this command restores the default value of the key.

Default The authentication data field contains the value 0 in all 16 octets.

Parameters *authentication-key* — identifies the simple text password used when VRRP Authentication Type 1 is enabled on the virtual router instance. Type 1 uses a string eight octets long that is inserted into all transmitted VRRP advertisement messages and compared against all received VRRP advertisement messages. The authentication data fields are used to transmit the key.

The *authentication-key* parameter is expressed as a string consisting up to eight alphanumeric characters. Spaces must be contained in quotation marks (" "). The quotation marks are not considered part of the string.

The string is case-sensitive and is left-justified in the VRRP advertisement message authentication data fields. The first field contains the first four characters with the first octet containing the first character. The second field holds the fifth through eighth characters. Any unspecified portion of the authentication data field is padded with the value 0 in the corresponding octet.

Values	any 7-bit printable ASCII character		
	exceptions:	double quote	ASCII 34
		carriage return	ASCII 13
		line feed	ASCII 10
		tab	ASCII 9
		backspace	ASCII 8

hash-key — can be any combination of ASCII characters up to 22 characters in length (encrypted) for a hash key or up to 121 characters for a hash2 key. If spaces are used in the string, the entire string must be enclosed in quotation marks (" ").

This option is useful when a user must configure the parameter, but for security purposes, the actual unencrypted key value is not provided.

hash — specifies that the key is entered in an encrypted form. If the **hash** keyword is not used, the key is assumed to be in a non-encrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** keyword specified.

hash2 — specifies that the key is entered in a more complex encrypted form. If the **hash2** keyword is not used, the less-encrypted hash form is assumed.

backup

Syntax	[no] backup <i>ip-address</i> [no] backup <i>ipv6-address</i>
Context	config>service>vprn>if>vrrp config>service>vprn>if>ipv6>vrrp
Description	This command configures virtual router IP addresses for backup.
Default	n/a
Parameters	<i>ip-address</i> — specifies the destination IPv4 address for the backup interface Values a.b.c.d <i>ipv6-address</i> — specifies the destination IPv6 address for the backup interface Values x:x:x:x:x:x:x (eight 16-bit pieces)

bfd-enable

Syntax	[no] bfd-enable interface <i>interface-name</i> dst-ip <i>ip-address</i> [no] bfd-enable service-id interface <i>interface-name</i> dst-ip <i>ip-address</i>
Context	config>service>vprn>if>vrrp config>service>vprn>if>ipv6>vrrp
Description	This command assigns a BFD session that provides a heartbeat mechanism for a VRRP instance. Only one BFD session can be assigned to a VRRP instance, but multiple VRRP instances can use the same BFD session. BFD controls the state of the associated interface. By enabling BFD on a protocol interface, the state of the protocol interface is tied to the state of the BFD session between the local node and the remote node. The parameters used for the BFD session are set with the bfd-enable command under the IP interface specified in this command. The no form of this command removes BFD from the configuration.
Default	n/a
Parameters	<i>service-id</i> — specifies the service ID or name of the interface running BFD Values 1 to 214748690 or <i>service-name</i> <i>interface-name</i> — specifies the name of the interface running BFD <i>ip-address</i> — specifies the destination address to be used for the BFD session Values ipv4-address: a.b.c.d

ipv6-address: x:x:x:x:x:x:x (eight 16-bit pieces)
 x:x:x:x:x:d.d.d.d
 x - [0 to FFFF]H
 d - [0 to 255]D

init-delay

Syntax	init-delay <i>seconds</i> no init-delay
Context	config>service>vprn>if>vrrp config>service>vprn>if>ipv6>vrrp
Description	This command configures a VRRP initialization delay timer.
Default	no init-delay
Parameters	<i>seconds</i> — specifies the length of time in seconds for the initialization delay timer for VRRP Values 1 to 65535

mac

Syntax	mac <i>mac-address</i> no mac
Context	config>service>vprn>if>vrrp config>service>vprn>if>ipv6>vrrp
Description	This command assigns a specific MAC address to a VPRN IP interface. The no form of the command returns the MAC address of the IP interface to the default value.
Default	the physical MAC address associated with the Ethernet interface that the SAP is configured on (the default MAC address assigned to the interface, assigned by the system)
Parameters	<i>mac-address</i> — specifies the 48-bit MAC address for the static ARP in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff, where aa, bb, cc, dd, ee, and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.

master-int-inherit

Syntax	[no] master-int-inherit
Context	config>service>vprn>if>vrrp config>service>vprn>if>ipv6>vrrp
Description	This command allows the master instance to dictate the master down timer (non-owner context only). The master down interval is the time that the master router can be down before the backup router takes over. The master down interval is used to specify the master down timer. If the master down timer expires, the backup virtual router enters the master state. Refer to "Master Down Interval" in the "VRRP" chapter of the 7705 SAR Router Configuration Guide for details.
Default	no master-int-inherit

message-interval

Syntax	message-interval {[seconds] [milliseconds milliseconds]} no message-interval
Context	config>service>vprn>if>vrrp config>service>vprn>if>ipv6>vrrp
Description	This command sets the advertisement timer and indirectly sets the master down timer on the virtual router instance. The message-interval setting must be the same for all virtual routers with the same VRID. Any VRRP advertisement message received with an advertisement interval field different from the virtual router instance configured message-interval value will be silently discarded. Configuring the message interval value can be done in three ways: using only the milliseconds value, using only the seconds value, or using a combination of the two values. Table 134 shows the ranges for each way of configuring the message interval.

Table 134 Message Interval Configuration Ranges

Configuration	IPv4	IPv6
Using milliseconds value only	100 to 900 ms	10 to 990 ms
Using seconds value only	1 to 255 s	1 to 40 s
Using combination milliseconds and seconds values	1 s 100 ms to 255 s 900 ms (1.1 s to 255.9 s)	1 s 10 ms to 40s 990 ms (1.01 s to 40.99 s)
Default setting	1 s	1 s

The **message-interval** command is available for both non-owner and owner virtual routers. If the **message-interval** command is not executed, the default message interval is 1 s.

The **no** form of this command restores the default message-interval value of 1 s to the virtual router instance.

Default	1 s
Parameters	<i>seconds</i> — the time interval, in seconds, between sending advertisement messages
Values	IPv4: 1 to 255 IPv6: 1 to 40
	<i>milliseconds</i> — specifies the time interval, in milliseconds, between sending advertisement messages. This parameter is not supported on non-redundant chassis.
Values	IPv4: 100 to 900 IPv6: 10 to 990

ping-reply

Syntax	[no] ping-reply
Context	config>service>vprn>if>vrrp config>service>vprn>if>ipv6>vrrp
Description	This command enables the non-owner master to reply to ICMP echo requests directed to the virtual router instance IP addresses. The ping request can be received on any routed interface. Ping must not have been disabled at the management security level (either on the parent IP interface or based on the ping source host address). When ping reply is not enabled, ICMP echo requests to non-owner master virtual IP addresses are silently discarded. Non-owner backup virtual routers never respond to ICMP echo requests regardless of the setting of the ping reply configuration. The ping-reply command is only available for non-owner virtual routers. The no form of this command restores the default operation of discarding all ICMP echo request messages destined for the non-owner virtual router instance IP addresses.
Default	no ping-reply

policy

Syntax	policy <i>vrrp-policy-id</i> no policy
Context	config>service>vprn>if>vrrp config>service>vprn>if>ipv6>vrrp
Description	This command associates a VRRP priority control policy with the virtual router instance (non-owner context only). VRRP policies are defined under the config>vrrp>policy context. For details, refer to the “VRRP” chapter in the 7705 SAR Router Configuration Guide.
Default	n/a
Parameters	<i>vrrp-policy-id</i> — specifies a VRRP priority control policy. The VRRP policy ID must already exist in the system for the policy command to be successful.
Values	1 to 9999

preempt

Syntax	preempt no preempt
Context	config>service>vprn>if>vrrp config>service>vprn>if>ipv6>vrrp
Description	This command provides the ability to override an existing non-owner master with a virtual router backup that has a higher priority. Enabling preempt mode enhances the operation of the base priority and VRRP policy ID definitions on the virtual router instance. If the virtual router cannot preempt an existing non-owner master, the effect of the dynamic changing of the in-use priority is greatly diminished. The preempt command is only available for non-owner VRRP virtual routers. The owner cannot be preempted because the priority of non-owners can never be higher than the owner. The owner will always preempt all other virtual routers when it is available. Non-owner backup virtual router instances will only preempt when preempt is set and the current master has an in-use message priority value less than the backup virtual router instance in-use priority. A master non-owner virtual router will only allow itself to be preempted when the incoming VRRP advertisement message priority field value is one of the following: • greater than its in-use priority value • equal to the in-use priority value, and the source IP address (primary IP address) is greater than its primary IP address The no form of this command prevents a non-owner virtual router instance from preempting another, less-desirable, virtual router.

Default preempt

priority

Syntax **priority** *priority*
no priority

Context config>service>vprn>if>vrrp
 config>service>vprn>if>ipv6>vrrp

Description This command configures a specific priority value for the virtual router instance. In conjunction with the optional **policy** command, the base priority derives the in-use priority of the virtual router instance.

The **priority** command is only available for non-owner VRRP virtual routers. The priority of owner virtual router instances is permanently set to 255 and cannot be changed. For non-owner virtual router instances, if the priority command is not executed, the base priority is set to 100.

The **no** form of this command restores the default value of 100.

Parameters *priority* — specifies the base priority used by the virtual router instance. If a VRRP priority control policy is not defined, the base priority will be the in-use priority for the virtual router instance.

Values 1 to 254

Default 100

ssh-reply

Syntax [no] **ssh-reply**

Context config>service>vprn>if>vrrp

Description This command enables the non-owner master to reply to SSH requests directed at the IP addresses of the virtual router instances. The SSH request can be received on any routed interface. SSH must not have been disabled at the management security level (either on the parent IP interface or based on the SSH source host address). Proper login and CLI command authentication are enforced.

When the **ssh-reply** command is not enabled, SSH packets to non-owner master virtual IP addresses are silently discarded.

Non-owner backup virtual routers never respond to SSH requests regardless of the SSH reply configuration.

The **ssh-reply** command is only available for non-owner VRRP virtual routers.

The **no** form of this command restores the default operation of discarding all SSH packets destined to the non-owner virtual router instance IP addresses.

Default no ssh-reply

standby-forwarding

Syntax [no] standby-forwarding

Context config>service>vprn>if>vrrp
config>service>vprn>if>ipv6>vrrp

Description This command allows the forwarding of packets by a standby router when sent to the virtual router MAC address.

The **no** form of the command specifies that a standby router should not forward traffic sent to the virtual router MAC address. The standby router should forward traffic sent to the real MAC address of the standby router.

Default no standby-forwarding

telnet-reply

Syntax [no] telnet-reply

Context config>service>vprn>if>vrrp
config>service>vprn>if>ipv6>vrrp

Description This command enables the non-owner master to reply to TCP port 23 Telnet requests directed at the IP addresses of the virtual router instance. The Telnet request can be received on any routed interface. Telnet must not have been disabled at the management security level (either on the parent IP interface or based on the Telnet source host address). Proper login and CLI command authentication are enforced.

If the **telnet-reply** command is not enabled, TCP port 23 Telnet packets to non-owner master virtual IP addresses are silently discarded.

Non-owner backup virtual routers never respond to Telnet requests regardless of the Telnet reply configuration.

The **telnet-reply** command is only available for non-owner VRRP virtual routers.

The **no** form of this command restores the default operation of discarding all Telnet packets destined for the non-owner virtual router instance IP addresses.

Default no telnet-reply

traceroute-reply

Syntax	[no] traceroute-reply
Context	config>service>vprn>if>vrrp config>service>vprn>if>ipv6>vrrp
Description	This command enables a non-owner master to reply to traceroute requests directed to the virtual router instance IP addresses. The command is valid only if the VRRP virtual router instance associated with this entry is a non-owner. A non-owner backup virtual router never responds to traceroute requests regardless of the traceroute reply status.
Default	no traceroute-reply

7.8.2.1.22 VPRN Static One-to-One NAT Configuration Commands

static-nat-inside

Syntax	[no] static-nat-inside
Context	config>service>vprn>interface
Description	This command configures an interface as an inside (private) interface. By default, all interfaces are outside (public) interfaces. The no form of this command returns the interface to the default setting.
Default	no static-nat-inside

static-nat

Syntax	[no] static-nat
Context	config>service>vprn
Description	This command enables the context to configure static one-to-one NAT. The no form of this command disables static one-to-one NAT.
Default	no static-nat

drop-packets-without-nat-entry

Syntax	[no] drop-packets-without-nat-entry
Context	config>service>vprn>static-nat
Description	This command configures the router to drop packets that are traveling from either an inside network to an outside network or an outside network to an inside network that do not have a NAT mapping entry. By default, packets traveling from either an inside network to an outside network or an outside network to an inside network are forwarded whether or not there is a NAT mapping entry. The no form of this command returns the router to the default behavior.
Default	no drop-packets-without-nat-entry

inside

Syntax	inside
Context	config>service>vprn>static-nat
Description	This command creates a static one-to-one NAT mapping from an inside network to an outside network. When configured, a packet traveling from an inside network to an outside network that matches a NAT mapping entry will have NAT applied to its source IP address. Similarly, a packet traveling from an outside network to an inside network that matches a NAT mapping entry will have NAT applied to its destination IP address.
Default	n/a

map

Syntax	map start <i>ip-address</i> end <i>ip-address</i> to <i>ip-address</i> no map start <i>ip-address</i> end <i>ip-address</i>
Context	config>service>vprn>static-nat>inside
Description	This command maps a range of inside source IP addresses that will undergo NAT to a specified outside IP address range. For example, to map the entire range of inside addresses within 192.168.0.0/16 to the outside address 10.10.0.0/16, the configuration would be: map start 192.168.0.0 end 192.168.255.255 to 10.10.0.0 The 7705 SAR will then map each inside source IP address to its corresponding outside IP address sequentially; for example: • inside address 192.168.0.1 maps to 10.10.0.1 • inside address 192.168.10.10 maps to 10.10.10.10 • inside address 192.168.254.100 maps to 10.10.254.100 The no form of this command removes the NAT mapping.
Default	no map start <i>ip-address</i> end <i>ip-address</i>
Parameters	start <i>ip-address</i> — identifies the start of the range of inside IPv4 addresses that will undergo NAT to an outside address, in the format a.b.c.d end <i>ip-address</i> — identifies the end of the range of inside IPv4 addresses that will undergo NAT to an outside address, in the format a.b.c.d to <i>ip-address</i> — identifies the outside IPv4 address that the range of inside addresses maps to, in the format a.b.c.d

shutdown

Syntax	[no] shutdown
Context	config>service>vprn>static-nat>inside>map
Description	This command administratively disables the static NAT map entry. The no form of this command administratively enables the static NAT map entry.
Default	no shutdown

7.8.2.1.23 TWAMP Light Commands

twamp-light

Syntax	twamp-light
Context	config>service>vprn
Description	This command enables the context for configuring TWAMP Light functionality.
Default	disabled

reflector

Syntax	reflector
Context	config>service>vprn>twamp-light
Description	This command enables the context for configuring TWAMP Light session reflector functionality. The reflector functionality is enabled using the no shutdown command.
Default	disabled

prefix

Syntax	[no] prefix ip-prefix/prefix-length [create]		
Context	config>service>vprn>twamp-light>reflector		
Description	This command configures an IP address prefix containing one or more TWAMP Light session controllers. It is used to define which TWAMP Light packet prefixes the reflector will process. Once the prefix is configured, the TWAMP Light session reflector only responds to TWAMP Light packets from source addresses that are part of the prefix list.		
Default	no prefix		
Parameters	<i>ip-prefix/ip-prefix-length</i> — the IPv4 or IPv6 address prefix		
	Values	<i>ipv4-prefix</i>	a.b.c.d (host bits must be 0)
		<i>ipv4-prefix-length</i>	0 to 32
		<i>ipv6-prefix</i>	x:x:x:x:x:x:x (eight 16-bit pieces)
			x:x:x:x:x:d.d.d.d
			x: [0 to FFFF]H
			d: [0 to 255]D
		<i>ipv6-prefix-length</i>	{0 to 128} {0 to 64 128}

udp-port

Syntax	udp-port <i>number</i> no udp-port
Context	config>service>vprn>twamp-light>reflector
Description	This command configures the specific UDP port that the session reflector listens to for TWAMP Light packets. The session controller launching the TWAMP Light packets must have the same UDP port configured as on the session reflector.
Default	no udp-port
Parameters	<i>number</i> — the UDP port number
	Values 1024 to 65535

7.8.2.2 Show Service Commands

Note: The following command outputs are examples only; actual displays may differ depending on supported functionality and user configuration.

egress-label

Syntax	egress-label <i>start-label</i> [<i>end-label</i>]
Context	show>service
Description	This command displays service information using the range of egress labels. If only the mandatory <i>start-label</i> parameter is specified, only services using the specified label are displayed. If both <i>start-label</i> and <i>end-label</i> parameters are specified, the services using the labels in the specified range are displayed. Use the show router ldp bindings command to display dynamic labels.
Parameters	<i>end-label</i> — the ending egress label value for which to display services using the label range Values 2049 to 131071 Default the <i>start-label</i> value <i>start-label</i> — the starting egress label value for which to display services using the label range. If only <i>start-label</i> is specified, services only using <i>start-label</i> are displayed. Values 0, or 2048 to 131071
Output	The following output is an example of service egress label information, and Table 135 describes the fields.

Output Example

In the example below, services 3, 5 and 6 are IES, and services 5000 and 5001 are VPLS services.

```
*A:ALU-12>show>service# egress-label 0 131071

Table 135 Service Egress Field Descriptions

Label	Description
Svc Id	The ID that identifies a service
Sdp Binding	The ID that identifies an SDP
Type	Indicates whether the SDP binding is a spoke or a mesh
I. Lbl	The VC label used by the far-end device to send packets to this device in this service by the SDP
E. Lbl	The VC label used by this device to send packets to the far-end device in this service by the SDP
Number of Bindings Found	The total number of SDP bindings that exist within the specified label range

id

Syntax `id service-id`

Context `show>service`

Description This command accesses the context to display information for a particular service ID. Once the particular service context has been accessed, the filtering commands listed below are available.

Parameters `service-id` — the unique service identification number or name that identifies the service in the service domain

all — detailed information about the service

arp — ARP entries for the service

base — basic service information

dhcp — DHCP entries for the service

endpoint — service endpoint information

fdb — FDB entries for the service

interface — service interfaces

labels — labels being used by this service

mac-move — MAC move related information about this service

sap — SAPs associated to the service

sdp — SDPs associated with the service

split-horizon — service split horizon groups

static-host — static hosts configured on this service

all

Syntax	all
Context	show>service>id
Description	This command displays detailed information for all aspects of the service.
Output	The following output is an example of service ID all information, and Table 136 describes the fields.

Output Example

```
*A:7705:Dut-A# show service id 1 all

Table 136 **Service ID All Field Descriptions**

Label	Description
Service Detailed Information	
Service Id	The service identifier
Service Type	The type of service (VPRN)
Name	The service name
Description	A description of the service
Customer Id	The customer identifier
Last Status Change	The date and time of the most recent change in the administrative or operating status of the service
Last Mgmt Change	The date and time of the most recent management-initiated change to this service
Admin State	The desired state of the service
Oper State	The current operational state of the service
Route Dist.	The route distribution number
VPRN Type	Only valid in services that accept mesh SDP bindings. It validates the VC ID portion of each mesh SDP binding defined in the service.
AS Number	The autonomous system number
Router Id	The router ID for this service
ECMP	Displays equal cost multipath information
ECMP Max Routes	The maximum number of routes that can be received from the neighbors in the group or for the specific neighbor
Max IPv4 Routes	The maximum number of routes that can be used for path sharing

Table 136 Service ID All Field Descriptions (Continued)

Label	Description
Max IPv6 Routes	Not applicable
Auto Bind	The automatic binding type for the SDP assigned to this service
Vrf Target	The route target in the VRF applied to this service
Vrf Import	The VRF import policy applied to this service
Vrf Export	The VRF export policy applied to this service
SAP Count	The number of SAPs specified for this service
SDP Bind Count	The number of SDPs bound to this service
Service Destination Points (SDPs)	
SDP Id	The SDP identifier
Type	Indicates whether this service SDP binding is a spoke or a mesh
VC Type	The VC type: ether or vlan
VC Tag	The explicit dot1q value used when encapsulating to the SDP far end
Admin Path MTU	The desired largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented
Oper Path MTU	The actual largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented
Far End	Specifies the IP address of the remote end of the GRE, MPLS, or IP tunnel defined by this SDP
Tunnel Far End	n/a
LSP Types	Indicates the supported LSP types: R = RSVP, L = LDP, B = BGP, I = SR-ISIS, O = SR-OSPF, T = SR-TE, n/a = not applicable
Delivery	Specifies the type of delivery used by the SDP: GRE, MPLS, or IP
Admin State	The administrative state of this SDP
Oper State	The operational state of this SDP
Acct. Pol	The accounting policy applied to the SDP

Table 136 Service ID All Field Descriptions (Continued)

Label	Description
Collect Stats	Specifies whether accounting statistics are collected on the SDP
Ingress Label	The label used by the far-end device to send packets to this device in this service by this SDP
Egress Label	The label used by this device to send packets to the far-end device in this service by this SDP
Ing mac Fltr	Not applicable
Egr mac Fltr	Not applicable
Ing ip Fltr	The SDP ingress filter policy ID
Egr ip Fltr	The SDP egress filter policy ID
Ing ipv6 Fltr	Not applicable
Egr ipv6 Fltr	Not applicable
Admin ControlWord	The administrative state of the control word: Preferred (control word enabled) or Not Preferred (control word disabled)
Oper ControlWord	The operational state of the control word: True (control word enabled) or False (control word disabled)
Last Status Change	The date and time of the most recent status change to this SDP
Signaling	The signaling protocol used to obtain the ingress and egress labels used in frames transmitted and received on this SDP
Last Mgmt Change	The date and time of the most recent management-initiated change to this SDP
Class Fwding State	Not applicable

Table 136 Service ID All Field Descriptions (Continued)

Label	Description
Flags	Specifies the conditions that affect the operating status of this SAP. Display output includes: ServiceAdminDown, SapAdminDown, InterfaceAdminDown, PortOperDown, PortMTUTooSmall, L2OperDown, SapIngressQoSMismatch, SapEgressQoSMismatch, RelearnLimitExceeded, RxProtSrcMac, ParentIfAdminDown, NoSapPipeCelpAddr, TodResourceUnavail, TodMssResourceUnavail, SapParamMismatch, CemSapNoEcidOrMacAddr, StandByForMcRing, ServiceMTUTooSmall, SapIngressNamedPoolMismatch, SapEgressNamedPoolMismatch, NoSapEpipeRingNode
KeepAlive Information	
Admin State	The operating status of the keepalive protocol
Oper State	The current status of the keepalive protocol
Hello Time	Specifies how often the SDP echo request messages are transmitted on this SDP
Hello Msg Len	The length of the SDP echo request messages transmitted on this SDP
Max Drop Count	The maximum number of consecutive SDP Echo Request messages that can be unacknowledged before the keepalive protocol reports a fault
Hold Down Time	The time to wait before the keepalive operating status is eligible to enter the alive state
Statistics	
I. Fwd. Pkts.	The number of forwarded ingress packets
I. Dro. Pkts.	The number of dropped ingress packets
I. Fwd. Octs.	The number of forwarded ingress octets
I. Dro. Octs.	The number of dropped ingress octets
E. Fwd. Pkts.	The number of forwarded egress packets
E. Fwd. Octets	The number of forwarded egress octets

Table 136 Service ID All Field Descriptions (Continued)

Label	Description
Associated LSP LIST	If the SDP type is MPLS, a list of LSPs used to reach the far-end router displays. All the LSPs in the list must terminate at the IP address specified in the far-end field. If the SDP type is GRE, the following message displays: SDP delivery mechanism is not MPLS
Number of SDPs	The total number of SDPs applied to this service ID
Service Access Points	
Service Id	The service identifier
SAP	The SAP identifier
Encap	The encapsulation type of the SAP
Admin State	The administrative state of the SAP
Oper State	The operating state of the SAP
Flags	Specifies the conditions that affect the operating status of this SAP. Display output includes: ServiceAdminDown, SapAdminDown, InterfaceAdminDown, PortOperDown, PortMTUTooSmall, L2OperDown, SapIngressQoSMismatch, SapEgressQoSMismatch, RelearnLimitExceeded, RxProtSrcMac, ParentIfAdminDown, NoSapPipeCelpAddr, TodResourceUnavail, TodMssResourceUnavail, SapParamMismatch, CemSapNoEcidOrMacAddr, StandByForMcRing, ServiceMTUTooSmall, SapIngressNamedPoolMismatch, SapEgressNamedPoolMismatch, NoSapEpipeRingNode
Multi Svc Site	Indicates the multiservice site that the SAP is a member of
Last Status Change	The time of the most recent operating status change to this SAP
Last Mgmt Change	The time of the most recent management-initiated change to this SAP
Sub Type	The supported sub type: regular
Dot1Q Ethertype	The value of the dot1q Ethertype
QinQ Ethertype	The value of the qinq Ethertype

Table 136 Service ID All Field Descriptions (Continued)

Label	Description
Admin MTU	The desired largest service frame size (in octets) that can be transmitted through the SAP to the far-end router, without requiring the packet to be fragmented
Oper MTU	The actual largest service frame size (in octets) that can be transmitted through the SAP to the far-end router, without requiring the packet to be fragmented
Ingr IP Fltr-Id	The ingress filter policy ID assigned to the SAP
Egr IP Fltr-Id	The egress filter policy ID assigned to the SAP
Ingr Mac Fltr-Id	Not applicable
Ingr IPv6 Fltr-ID	Not applicable
Egr IPv6 Fltr-ID	Not applicable
tod-suite	Indicates whether a time-based policy is applied to a multiservice site
qinq-pbit-marking	Indicates the qinq P-bit marking for the service: both or top
Ing Scheduler Mode	Indicates the ingress scheduler mode for the SAP
Egr Scheduler Mode	Indicates the egress scheduler mode for the SAP
Ing Agg Rate Limit	Indicates the PIR rate limit in the access ingress direction for the aggregate of the SAP queues
Egr Agg Rate Limit	Indicates the PIR rate limit in the access egress direction for the aggregate of the SAP queues
Ing Agg cir	Indicates the CIR rate limit in the access ingress direction for the aggregate of the SAP queues
Egr Agg cir	Indicates the CIR rate limit in the access egress direction for the aggregate of the SAP queues
Ing Shaper Group	Indicates the ingress shaper group for the SAP
Egr Shaper Group	Indicates the egress shaper group for the SAP
Q Frame-Based Acct	Not applicable
Acct. Pol	The accounting policy applied to the SAP
Collect Stats	Specifies whether accounting statistics are collected on the SAP
Anti Spoofing	Not applicable

Table 136 Service ID All Field Descriptions (Continued)

Label	Description
Nbr Static Hosts	Not applicable
QOS	
Ingress qos-policy	The SAP ingress QoS policy ID
Egress qos-policy	The SAP egress QoS policy ID
Shared Q plcy	Not applicable
Multipoint shared	Not applicable
Segment Routing	
ISIS	Indicates the state of segment routing for IS-IS: enabled or disabled
LSP Id	The LSP identifier
Oper Instance Id	The IS-IS instance identifier for the SR IS-IS instance
OSPF	Indicates the state of segment routing for OSPF: enabled or disabled
TE-LSP	Indicates the state of segment routing for TE LSP: enabled or disabled
TWAMP-Light Reflector	
Admin State	Displays one of the following: Up—the server or prefix is administratively enabled (no shutdown) in configuration Down—the server or prefix is administratively disabled (shutdown) in configuration
Up Time	The time since the server process was started, measured in days (d), hours, minutes, and seconds
Configured UDP Port	The UDP port number used
Test Packets Rx	The total number of test packets received from session senders
Test Packets Tx	The total number of test packets sent to session senders
TWAMP Light Controller Prefix List	The IP address prefixes of TWAMP Light clients

Table 136 Service ID All Field Descriptions (Continued)

Label	Description
SAP Statistics	
Last Cleared time	The date and time that a clear command was issued on the statistics
Forwarding Engine Stats (Ingress)	
Dropped	The number of packets or octets dropped by the forwarding engine
Off. HiPrio	The number of high-priority packets or octets offered to the forwarding engine
Off. LowPrio	The number of low-priority packets offered to the forwarding engine
Queueing Stats (Ingress QoS Policy)	
Dro. HiPrio	The number of high-priority packets or octets discarded, as determined by the SAP ingress QoS policy
Dro. LowPrio	The number of low-priority packets discarded, as determined by the SAP ingress QoS policy
For. InProf	The number of in-profile packets or octets (rate below CIR) forwarded, as determined by the SAP ingress QoS policy
For. OutProf	The number of out-of-profile packets or octets (rate above CIR) forwarded, as determined by the SAP ingress QoS policy
Queueing Stats (Egress QoS Policy)	
Dro. InProf	The number of in-profile packets or octets discarded, as determined by the SAP egress QoS policy
Dro. OutProf	The number of out-of-profile packets or octets discarded, as determined by the SAP egress QoS policy
For. InProf	The number of in-profile packets or octets (rate below CIR) forwarded, as determined by the SAP egress QoS policy
For. OutProf	The number of out-of-profile packets or octets (rate above CIR) forwarded, as determined by the SAP egress QoS policy

Table 136 Service ID All Field Descriptions (Continued)

Label	Description
Sap per Queue stats	
Ingress Queue <i>n</i>	The index of the ingress QoS queue of this SAP, where <i>n</i> is the index number
Off. HiPrio	The number of packets or octets of high-priority traffic for the SAP (offered)
Off. LoPrio	The number of packets or octets count of low-priority traffic for the SAP (offered)
Dro. HiPrio	The number of high-priority traffic packets or octets dropped
Dro. LoPrio	The number of low-priority traffic packets or octets dropped
For. InProf	The number of in-profile packets or octets (rate below CIR) forwarded
For. OutProf	The number of out-of-profile packets or octets (rate above CIR) forwarded
Egress Queue <i>n</i>	The index of the egress QoS queue of the SAP, where <i>n</i> is the index number
For. InProf	The number of in-profile packets or octets (rate below CIR) forwarded
For. OutProf	Number of out-of-profile packets or octets (rate above CIR) forwarded
Dro. InProf	The number of in-profile packets or octets dropped for the SAP
Dro. OutProf	The number of out-of-profile packets or octets discarded
Service Interfaces	
Interface	
If Name	The name used to refer to the interface
Admin State	The desired state of the interface
Oper (v4/v6)	The operating state of the interface
Protocols	The protocols supported on the interface
IP Addr/mask	The IP address/IP subnet/broadcast address of the interface

Table 136 Service ID All Field Descriptions (Continued)

Label	Description
Details	
If Index	The index corresponding to this interface. The primary index is 1. For example, all interfaces are defined in the Base virtual router context.
Virt. If Index	The virtual interface index of the VPRN interface
Last Oper Chg	The date and time of the last operating state change on the interface
Global If Index	The global interface index of the VPRN interface
TOS Marking	Specifies whether the ToS marking is trusted or untrusted for the interface
If Type	The interface type
SNTP B.Cast	Specifies whether SNTP broadcast client mode is enabled or disabled
MAC Address	The 48-bit IEEE 802.3 MAC address
Arp Timeout	The timeout for an ARP entry learned on the interface
IP MTU	The IP maximum transmit unit for the interface
ICMP Mask Reply	Specifies whether ICMP mask reply is enabled or disabled
ARP Populate	Specifies if ARP is enabled or disabled
Host Conn Verify	Not applicable
LdpSyncTimer	Not applicable
Proxy ARP Details	
Rem Proxy ARP	Indicates whether remote proxy ARP is enabled or disabled
Local Proxy ARP	Indicates whether local proxy ARP is enabled or disabled
Policies	Specifies the policy statements applied to proxy ARP
DHCP Details	
Admin State	The desired state of DHCP
Lease Populate	Not applicable

Table 136 Service ID All Field Descriptions (Continued)

Label	Description
Action	The processing required that occurs when the 7705 SAR receives a DHCP request that already has a Relay Agent Information Option (Option 82):
Trusted	Indicates whether trusted mode is enabled or disabled on the IP interface
ICMP Details	
Redirects	The rate for ICMP redirect messages
Unreachables	The rate for ICMP unreachable messages
TTL Expired	The rate for ICMP TTL messages
IPCP Address Extension Details	
Peer IP Addr	Specifies the remote IP address to be assigned to the far-end of the associated PPP/MLPPP link via IPCP extensions
Peer Pri DNS Addr	Specifies a unicast IPv4 address for the primary DNS server to be signaled to the far-end of the associate PPP/MLPPP link via IPCP extensions
Peer Sec DNS Addr	Specifies a unicast IPv4 address for the secondary DNS server to be signaled to the far-end of the associate PPP/MLPPP link via IPCP extensions

arp

Syntax **arp** [*ip-address*] | [**mac** *ieee-address*] | [**sap** *sap-id*] | [**interface** *ip-int-name*]

Context show>service>id

Description This command displays the ARP table for the VPRN instance.

Parameters *ip-address* — the IP address for which ARP entries will be displayed

Values a.b.c.d (1.0.0.0 to 223.255.255.255)

Default all IP addresses

ieee-address — the 48-bit MAC address for which ARP entries will be displayed. The MAC address can be expressed in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff, where aa, bb, cc, dd, ee and ff are hexadecimal numbers.

Values xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx

Default all MAC addresses

sap-id — the SAP ID for which ARP entries will be displayed. See [Table 41](#) for a full list of SAP IDs.

ip-int-name — the IP interface name for which to display matching ARPs

Output The following output is an example of service ID ARP information, and [Table 137](#) describes the fields.

Output Example

```
*A:ALU-12>show>service>id# arp
=====
ARP Table
=====
IP Address      MAC Address      Type    Expiry    Interface      SAP
-----
192.168.86.45   98-90-96-B9-9D-61 Other    00:00:00   ies-100-190.11.1 1/1/11:0
=====
*A:ALU-12>show>service>id#
```

Table 137 Service ID ARP Field Descriptions

Label	Description
IP Address	The IP address of the ARP entry
MAC Address	The MAC address of the ARP entry
Type	Dyn—the ARP entry is a dynamic ARP entry Inv—the ARP entry is an inactive static ARP entry (invalid). Oth—the ARP entry is a local or system ARP entry Sta—the ARP entry is an active static ARP entry
Expiry	The age of the ARP entry
Interface	The IP interface name associated with the ARP entry
SAP	The port identifier of the SAP

base

Syntax **base**

Context show>service>id

Description This command displays basic information about the service ID, including service type, description, SAPs and SDPs.

Output The following output is an example of service ID base information, and [Table 138](#) describes the fields.

Output Example

```
*A:ALU-12>show>service>id# base

Table 138 Service ID Base Field Descriptions

Label	Description
Service Id	The service identifier
Service Type	The type of service: VPRN
Name	The service name
Description	Generic information about the service
Customer Id	The customer identifier
Last Status Change	The date and time of the most recent status change to this service

Table 138 Service ID Base Field Descriptions (Continued)

Label	Description
Last Mgmt Change	The date and time of the most recent management-initiated change to this service
Admin State	The desired state of the service
Oper State	The operating state of the service
Route Dist.	The largest frame size (in octets) that the service can handle
VPRN Type	Only valid in services that accept mesh SDP bindings. It validates the VC ID portion of each mesh SDP binding defined in the service.
AS Number	The autonomous system number
Router ID	The router ID for this service
ECMP	Displays equal cost multipath information
ECMP Max Routes	The maximum number of routes that can be received from the neighbors in the group or for the specific neighbor
Max IPv4 Routes	The maximum number of routes that can be used for path sharing
Auto Bind	The automatic binding type for the SDP assigned to this service
Max IPv6 Routes	Not applicable
Vrf Target	The route target in the VRF applied to this service
Vrf Import	The VRF import policy applied to this service
Vrf Export	The VRF export policy applied to this service
SAP Count	The number of SAPs defined on the service
SDP Bind Count	The number of SDPs bound to the service
Service Access and Destination Points	
Identifier	The service access (SAP) and destination (SDP) points
Type	The signaling protocol used to obtain the ingress and egress labels used in frames transmitted and received on the SDP
AdmMTU	The desired largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented

Table 138 Service ID Base Field Descriptions (Continued)

Label	Description
OprMTU	The actual largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented
Adm	The administrative state of the SAP or SDP
Opr	The operating state of the SAP or SDP

dhcp

Syntax	dhcp
Context	show>service>id
Description	This command enables the context to display DHCP information for the specified service.

statistics

Syntax	statistics [interface <i>ip-int-name</i> <i>ip-address</i>]
Context	show>service>id>dhcp
Description	This command displays DHCP statistics information.
Parameters	<i>ip-int-name</i> — the interface name for which DHCP statistics will be displayed <i>ip-address</i> — the IP address of the interface for which to display information Values a.b.c.d (host bits must be 0)
Output	The following output is an example of server ID DHCP statistics information, and Table 139 describes the fields.

Output Example

```
*A:ALU-12>show>service>id>dhcp# statistics
=====

Table 139 Service ID DHCP Statistics Field Descriptions

Label	Description
DHCP Global Statistics, service x	
Rx Packets	The number of packets received from the DHCP clients
Tx Packets	The number of packets transmitted to the DHCP clients
Rx Malformed Packets	The number of corrupted/invalid packets received from the DHCP clients
Rx Untrusted Packets	The number of untrusted packets received from the DHCP clients. In this case, a frame is dropped due to the client sending a DHCP packet with Option 82 filled in before “trust” is set under the DHCP interface command.
Client Packets Discarded	The number of packets received from the DHCP clients that were discarded
Client Packets Relayed	The number of packets received from the DHCP clients that were forwarded
Server Packets Discarded	The number of packets received from the DHCP server that were discarded
Server Packets Relayed	The number of packets received from the DHCP server that were forwarded

summary

Syntax	summary [interface <i>interface-name</i> saps]
Context	show>service>id>dhcp
Description	This command displays DHCP configuration summary information.
Parameters	<i>interface-name</i> — the interface name for which DHCP summary statistics will be displayed saps — displays SAPs per interface
Output	The following output is an example of service ID DHCP summary information, and Table 140 describes the fields.

Output Example

```
*A:ALU-12>show>service>id>dhcp# summary
=====
DHCP Summary, service 6

```

Table 140 **Service ID DHCP Summary Field Descriptions**

Label	Description
DHCP Summary, service x	
Interface Name Sap/Sdp	The name of the interface
Arp Populate	Specifies whether ARP populate is enabled or disabled
Used/Provided	Used—the number of lease-states that are currently in use on the specified interface, that is, the number of clients on the interface that got an IP address by DHCP. This value is always less than or equal to the “Provided” field.
	Provided—the lease-populate value that is configured for a specific interface
Info Option	Keep—the existing information is kept on the packet and the router does not add any additional information
	Replace—on ingress, the existing information-option is replaced with the information-option from the router
	Drop—the packet is dropped and an error is logged
Admin State	The administrative state

interface

Syntax **interface** {[*ip-address* | *ip-int-name*] [*interface-type*] [*detail*] [*family*]} | **summary**

Context show>service>id

Description This command displays information for the IP interfaces associated with the service.

If no optional parameters are specified, a summary of all IP interfaces associated to the service are displayed.

- Parameters**

ip-address — the IP address of the interface for which to display information

Values

ipv4-address: a.b.c.d (host bits must be 0)
ipv6-address: x:x:x:x:x:x:x (eight 16-bit pieces)
x:x:x:x:x:d.d.d.d
x: [0 to FFFF]H
d [0 to 255]D
- ip-int-name* — the IP interface name for which to display information
- interface type* — displays either group or subscriber interfaces
- detail** — displays detailed IP interface information
- family** — displays the IP interface family

Values

ipv4, ipv6
- summary** — displays summary IP interface information

Output The following output is an example of service ID interface information, and [Table 141](#) describes the fields.

Output Example

```

Table 141 Service ID Interface Detailed Field Descriptions

Label	Description
Interface	
If Name	The name used to refer to the interface
Admin State	The desired state of the interface
Oper (v4/v6)	The operating state of the interface
Protocols	The protocols supported on this interface
IP Addr/mask	The IP address/IP subnet/broadcast address of the interface
Details	
If Index	The index corresponding to this interface. The primary index is 1. For example, all interfaces are defined in the Base virtual router context.
Virt. If Index	The virtual interface index of the VPRN interface
Last Oper Chg	The date and time of the last operating state change on the interface
Global If Index	The global interface index of the VPRN interface
TOS Marking	Specifies whether the ToS marking is trusted or untrusted for the interface
If Type	The interface type
SNTP B.Cast	Specifies whether SNTP broadcast client mode is enabled or disabled
MAC Address	The 48-bit IEEE 802.3 MAC address
Arp Timeout	The timeout for an ARP entry learned on the interface
IP MTU	The IP maximum transmit unit for the interface
ICMP Mask Reply	Specifies whether ICMP mask reply is enabled or disabled
ARP Populate	Specifies if ARP is enabled or disabled
Host Conn Verify	Not applicable
LdpSyncTimer	Not applicable
Proxy ARP Details	
Rem Proxy ARP	Indicates whether remote proxy ARP is enabled or disabled
Local Proxy ARP	Indicates whether local proxy ARP is enabled or disabled

Table 141 Service ID Interface Detailed Field Descriptions (Continued)

Label	Description
Policies	Specifies the policy statements applied to proxy ARP
DHCP Details	
Admin State	The administrative state of DHCP
Lease Populate	Not applicable
Action	The processing required that occurs when the 7705 SAR receives a DHCP request that already has a Relay Agent Information Option (Option 82):
Trusted	Indicates whether trusted mode is enabled or disabled on the IP interface
ICMP Details	
Redirects	The rate for ICMP redirect messages
Unreachables	The rate for ICMP unreachable messages
TTL Expired	The rate for ICMP TTL messages
IPCP Address Extension Details	
Peer IP Addr	The remote IP address to be assigned to the far end of the associated PPP/MLPPP link via IPCP extensions
Peer Pri DNS	The unicast IPv4 address for the primary DNS server to be signaled to the far end of the associate PPP/MLPPP link via IPCP extensions
Peer Sec DNS	The unicast IPv4 address for the secondary DNS server to be signaled to the far end of the associate PPP/MLPPP link via IPCP extensions

ip-transport

Syntax	ip-transport <i>ipt-id</i> [detail statistics]
Context	show>service>id
Description	This command displays information for a specified IP transport subservice within this VPRN service. If no IP transport subservice is specified, summary information is displayed for all IP transport subservices associated with the VPRN service.
Parameters	<i>ipt-id</i> — the physical port associated with the IP transport subservice, in the format <i>slot/mda/port.channel</i>

detail — displays detailed information for the specified IP transport subservice

statistics — displays statistical information for the specified IP transport subservice

Output The following output is an example of IP transport subservice summary information for a specified service, and [Table 142](#) describes the fields.

Output Example

```
*A:ALU-12# show service id 100 ip-transport

Table 142 Service IP Transport Subservice Summary Field Descriptions

Label	Description
IP Transport (Summary), Service x	
IptId	The IP transport subservice physical port identifier
LocalIP	The IP address (IPv4) that is used for the local host
LocalPort	The port number that is used by remote hosts to establish TCP/UDP sessions to the local host
Proto	The protocol type that is used for all sessions to and from the local host (either TCP or UDP)
RemHost	The number of remote hosts associated with the IP transport subservice
DSCP	The DSCP name used to mark the DSCP field in IP transport packets
FC	The FC name used for IP transport packets
FltrUnkn	Indicates whether the filter-unknown-host command is enabled or disabled on the IP transport subservice
Adm	The administrative state of the IP transport subservice
Opr	The operational state of the IP transport subservice
Entries found:	The number of IP transport subservices associated with this service

Table 143 Service IP Transport Subservice Detailed Field Descriptions

Label	Description
IP Transport	
Service Id	The ID that identifies the service (the service type is shown in brackets)
IP Transport Id	The physical port identifier for this IP transport subservice
Description	The description associated with this IP transport subservice
Admin State	The administrative state of this IP transport subservice
Oper State	The operational state of this IP transport subservice
Oper Flags	The operational flags associated with this IP transport subservice
Local IP Address	The IP address (IPv4) that is used for the local host
Local Port Number	The port number that is used by remote hosts to establish TCP/UDP sessions to the local host
Local IP Protocol	The protocol type that is used for all sessions to and from the local host (either TCP or UDP)
DSCP	The DSCP name used to mark the DSCP field in IP transport packets
Filter Unknown Host	Indicates whether the filter-unknown-host command is enabled or disabled for this IP transport subservice
FC	The FC name used for IP transport packets
Profile	The profile marking for the IP transport packets (in or out)
TCP Inact Timeout	The configured inactivity timeout value for TCP connections
TCP Max Retries	The configured maximum retry value for TCP connections
TCP Retry Interval	The configured retry interval value for TCP connections
Num Remote Hosts	The number of remote hosts associated with this IP transport subservice
Last Mgmt Change	The date and time of the most recent management-initiated change to this IP transport subservice
Last Oper Change	The date and time of the most recent operational status change for this IP transport subservice

Table 143 Service IP Transport Subservice Detailed Field Descriptions

Label	Description
IP Transport Accumulated Statistics	
Known Remote Hosts	
Packets sent	The number of packets sent to the host
Characters sent	The number of data characters sent to the host
Packets received	The number of packets received from the host
Characters received	The number of data characters received from the host
Connections To From	The number of connections to and from the host
Connection retries	The number of connection retries to the host
Connection failures	The number of connection failures to the host
Currently connected	The number of hosts currently connected
Unknown Remote Hosts	
Packets sent	The number of packets sent to the host
Characters sent	The number of data characters sent to the host
Packets received	The number of packets received from the host
Characters received	The number of data characters received from the host
Successful connections from	The number of successful connections from the host
Rejected due to unknown host filter	The number of rejected connection attempts from the host due to the filter-unknown-host command being enabled
Rejected due to out of resource	The number of connection attempts from the host that were rejected due to the unavailability of resources
Inactivity timeouts	The number of connections from the host that timed out due to inactivity
Last RemIp:RemPort	The IP address (IPv4) and port number used by the host for the last connection
Currently connected	The number of hosts that are currently connected
Dropped packets due to no remote hosts	The number of packets dropped due to no hosts being connected

remote-host

Syntax	remote-host <i>host-id</i> [detail statistics]
Context	show>service>id>ip-transport
Description	This command displays information for a specified remote host within this IP transport subservice within this service. If no remote host is specified, summary information is displayed for all remote hosts within this IP transport subservice.
Parameters	<i>host-id</i> — the remote host identifier Values 1 to 2147483647 or a name string up to 64 characters long detail — displays detailed information for a specified remote host statistics — displays summary information for a specified remote host
Output	The following output is an example of IP transport subservice remote host summary information when no remote host is specified, and Table 144 describes the fields.

Output Example

```

Table 145 IP Transport Subservice Remote Host Detailed Field Descriptions

Label	Description
IP Remote Host	
Service Id	The ID that identifies the service (the service type is shown in brackets)
IP Transport Id	The physical port identifier for the IP transport subservice
Remote host Id	The host identifier associated with this remote host
Name	The name associated with this remote host
Description	The description associated with this remote host
IP Address	The IP address associated with this remote host
Port Number	The port number associated with this remote host
Last Mgmt Change	The date and time of the most recent management-initiated change to this remote host
Session State	The operational state of the packet transport session to this host
Up Time	The amount of time that this remote host has been connected
Last Connect	Indicates whether the last connection attempt to this remote host was successful or unsuccessful
IP Remote Host Statistics	
Sent Pkts	The number of packets sent to this remote host
Sent Chars	The number of data characters sent to this remote host
Dropped Pkts	The number of packets destined for this remote host that were dropped
Dropped Chars	The number of data characters destined for this remote host that were dropped

Table 145 IP Transport Subservice Remote Host Detailed Field Descriptions (Continued)

Label	Description
Rcvd Pkts	The number of packets received from this remote host
Rcvd Chars	The number of data characters received from this remote host
Session information	
Connections	
To	The number of connections made to this host
From	The number of connections made from the host
Connection retries	The number of connection retries to this host
Connection failures	The number of connection failures to this host
Closed by far end	The number of connections closed by the far end
Inactivity timeouts	The number of connection that were timed out due to inactivity

sap

Syntax **sap** [*sap-id* [**detail**]]

Context show>service>id

Description This command displays information for the SAPs associated with the service.
If no optional parameters are specified, a summary of all associated SAPs is displayed.

Parameters *sap-id* — the SAP ID for which SAP information will be displayed. See [Table 41](#) for a full list of SAP IDs.

detail — displays detailed information for the SAP

Output The following output is an example of service SAP information, and [Table 146](#) describes the fields.

Output Example

```
*A:ALU-12>show>service>id# sap

Table 146 Service ID SAP Detailed Field Descriptions

Label	Description
Service Id	The service identifier
SAP	The SAP identifier
Encap	The encapsulation type of the SAP
Admin State	The administrative state of the SAP
Oper State	The operating state of the SAP
Flags	Specifies the conditions that affect the operating status of this SAP. Display output includes: ServiceAdminDown, SapAdminDown, InterfaceAdminDown, PortOperDown, PortMTUTooSmall, L2OperDown, SapIngressQoSMismatch, SapEgressQoSMismatch, RelearnLimitExceeded, RxProtSrcMac, ParentIfAdminDown, NoSapPipeCelpAddr, TodResourceUnavail, TodMssResourceUnavail, SapParamMismatch, CemSapNoEcidOrMacAddr, StandByForMcRing, ServiceMTUTooSmall, SapIngressNamedPoolMismatch, SapEgressNamedPoolMismatch, NoSapEpipeRingNode
Last Status Change	The time of the most recent operating status change to this SAP

Table 146 Service ID SAP Detailed Field Descriptions (Continued)

Label	Description
Last Mgmt Change	The time of the most recent management-initiated change to this SAP
Sub Type	The supported sub type: regular
Dot1Q Ethertype	The value of the dot1q Ethertype
QinQ Ethertype	The value of the qinq Ethertype
Admin MTU	The desired largest service frame size (in octets) that can be transmitted through the SAP to the far-end router, without requiring the packet to be fragmented
Oper MTU	The actual largest service frame size (in octets) that can be transmitted through the SAP to the far-end router, without requiring the packet to be fragmented
Ingr IP Fltr-Id	The ingress filter policy ID assigned to the SAP
Egr IP Fltr-Id	The egress filter policy ID assigned to the SAP
Ingr Mac Fltr-Id	Not applicable
Egr Mac Fltr-Id	Not applicable
tod-suite	Indicates whether a time-based policy is applied to a multiservice site
qinq-pbit-marking	Indicates the qinq P-bit marking for the service: both or top
Ing Scheduler Mode	The scheduler mode for the SAP in the access ingress direction: 4-priority or 16-priority
Egr Scheduler Mode	The scheduler mode for the SAP in the access egress direction: 4-priority or 16-priority
Ing Agg Rate Limit	The PIR rate limit in the access ingress direction for the aggregate of the SAP queues
Egr Agg Rate Limit	The PIR rate limit in the access egress direction for the aggregate of the SAP queues
Ing Agg cir	The CIR rate limit in the access ingress direction for the aggregate of the SAP queues
Egr Agg cir	The CIR rate limit in the access egress direction for the aggregate of the SAP queues
Ing Shaper Group	The ingress shaper group for the SAP
Egr Shaper Group	The egress shaper group for the SAP

Table 146 Service ID SAP Detailed Field Descriptions (Continued)

Label	Description
Acct. Pol	The accounting policy ID assigned to the SAP
Collect Stats	Specifies whether accounting statistics are collected on the SAP
Anti Spoofing	Not applicable
Nbr Static Hosts	Not applicable
QOS	
Ingress qos-policy	The ingress QoS policy ID assigned to the SAP
Egress qos-policy	The egress QoS policy ID assigned to the SAP
Shared Q plcy	Not applicable
Multipoint shared	Not applicable
Sap Statistics	
Last Cleared Time	The date and time that a clear command was issued on statistics
Forwarding Engine Stats (Ingress)	
Dropped	The number of packets or octets dropped by the forwarding engine
Off. HiPrio	The number of high-priority packets or octets offered to the forwarding engine
Off. LowPrio	The number of low-priority packets offered to the forwarding engine
Queueing Stats (Ingress QoS Policy)	
Dro. HiPrio	The number of high-priority packets or octets discarded, as determined by the SAP ingress QoS policy
Dro. LowPrio	The number of low-priority packets discarded, as determined by the SAP ingress QoS policy
For. InProf	The number of in-profile packets or octets (rate below CIR) forwarded, as determined by the SAP ingress QoS policy
For. OutProf	The number of out-of-profile packets or octets (rate above CIR) forwarded, as determined by the SAP ingress QoS policy
Queueing Stats (Egress QoS Policy)	
Dro. InProf	The number of in-profile packets or octets discarded, as determined by the SAP egress QoS policy

Table 146 Service ID SAP Detailed Field Descriptions (Continued)

Label	Description
Dro. OutProf	The number of out-of-profile packets or octets discarded, as determined by the SAP egress QoS policy
For. InProf	The number of in-profile packets or octets (rate below CIR) forwarded, as determined by the SAP egress QoS policy
For. OutProf	The number of out-of-profile packets or octets (rate above CIR) forwarded, as determined by the SAP egress QoS policy
Sap per Queue stats	
Ingress Queue <i>n</i>	The index of the ingress QoS queue of this SAP, where <i>n</i> is the index number
Off. HiPrio	The number of packets or octets of high-priority traffic for the SAP (offered)
Off. LoPrio	The number of packets or octets count of low-priority traffic for the SAP (offered)
Dro. HiPrio	The number of high-priority traffic packets or octets dropped
Dro. LoPrio	The number of low-priority traffic packets or octets dropped
For. InProf	The number of in-profile packets or octets (rate below CIR) forwarded
For. OutProf	The number of out-of-profile packets or octets (rate above CIR) forwarded
Egress Queue <i>n</i>	The index of the egress QoS queue of the SAP, where <i>n</i> is the index number
For. InProf	The number of in-profile packets or octets (rate below CIR) forwarded
For. OutProf	The number of out-of-profile packets or octets (rate above CIR) forwarded
Dro. InProf	The number of in-profile packets or octets dropped for the SAP
Dro. OutProf	The number of out-of-profile packets or octets discarded

ingress-label

Syntax `ingress-label start-label [end-label]`

Context `show>service`

- Description

This command displays service information using the range of ingress labels.

If only the mandatory *start-label* parameter is specified, only services using the specified label are displayed.

If both *start-label* and *end-label* parameters are specified, the services using the labels in the specified range are displayed.

Use the **show router ldp bindings** command to display dynamic labels.
- Parameters

end-label — the ending ingress label value for which to display services using the label range

Values

2049 to 131071

Default

the *start-label* value

start-label — the starting ingress label value for which to display services using the label range. If only *start-label* is specified, services only using *start-label* are displayed.

Values

0, or 2048 to 131071
- Output

The following output is an example of service ingress label information, and [Table 147](#) describes the fields.

Output Example

In the example below, services 3, 5 and 6 are IES, and services 5000 and 5001 are VPLS services.

```
*A:ALU-12>show>service# ingress-label 0 131071

Table 147 Service Ingress Output Fields

Label	Description
Svc Id	The ID that identifies a service

Table 147 Service Ingress Output Fields (Continued)

Label	Description
Sdp Binding	The ID that identifies an SDP
Type	Indicates whether the SDP binding is a spoke or a mesh
I. Lbl	The VC label used by the far-end device to send packets to this device in this service by the SDP
E. Lbl	The VC label used by this device to send packets to the far-end device in this service by the SDP
Number of Bindings Found	The total number of SDP bindings that exist within the specified label range

ip-transport-using

Syntax	ip-transport-using [ip-transport <i>ipt-id</i>]
Context	show>service
Description	This command displays IP transport subservice information for a specified port. If no port is specified, the command displays a summary of all IP transport subservices defined for the VPRN service.
Parameters	<i>ipt-id</i> — the physical port associated with the IP transport subservice, in the format <i>slot/mda/port.channel</i>
Output	The following output is an example of ip-transport-using information, and Table 148 describes the fields.

Output Example

```
*A:ALU-48# show service ip-transport-using

Label	Description
IP Transports	
IptId	The IP transport subservice physical port identifier
SvcId	The service identifier
Type	The type of service
Adm	The administrative state of the IP transport subservice
Opr	The operational state of the IP transport subservice
Entries found	The number of IP transport subservices using this service

sdp

Syntax **sdp** {[*sdp-id*[:*vc-id*] | **far-end** *ip-addr*]} [**detail**]
sdp [*sdp-id*[:*vc-id*]]

Context show>service>id

Description This command displays information for the SDPs associated with the service. If no optional parameters are specified, a summary of all associated SDPs is displayed.

Parameters *sdp-id* — the SDP ID for which SDP information will be displayed

Values 1 to 17407

Default all SDPs

vc-id — the virtual circuit ID on the SDP ID

Values 1 to 4294967295

ip-addr — displays only SDPs matching with the specified far-end IP address

detail — displays detailed SDP information

Output The following output is an example of service ID SDP information, and [Table 149](#) describes the fields.

Output Example

```

Table 149 Service ID SDP Detailed Field Descriptions

Label	Description
Sdp Id	The SDP identifier
Type	Indicates whether the SDP is a spoke or a mesh
VC Type	The VC type: ether or vlan
VC Tag	The explicit dot1q value used when encapsulating to the SDP far end
Admin Path MTU	The operating path MTU of the SDP is equal to the admin path MTU (when one is set) or the dynamically computed tunnel MTU, when no admin path MTU is set (the default case)
Oper Path MTU	The actual largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented
Far End	The IP address of the remote end of the GRE, MPLS, or IP tunnel defined by this SDP.
Delivery	Specifies the type of delivery used by the SDP: GRE, MPLS, or IP
Admin State	The administrative state of this SDP
Oper State	The operational state of this SDP
Acct. Pol	The accounting policy applied to the SDP
Collect Stats	Specifies whether accounting statistics are collected on the SDP
Ingress Label	The label used by the far-end device to send packets to this device in this service by this SDP
Egress Label	The label used by this device to send packets to the far-end device in this service by the SDP

Table 149 Service ID SDP Detailed Field Descriptions (Continued)

Label	Description
Ing mac Fltr	Not applicable
Egr mac Fltr	Not applicable
Ing ip Fltr	The ingress filter policy ID assigned to the SDP
Egr ip Fltr	The egress filter policy ID assigned to the SDP
Admin ControlWord	The administrative state of the control word: Preferred (control word enabled) or Not Preferred (control word disabled)
Oper ControlWord	The operational state of the control word: True (control word enabled) or False (control word disabled)
Last Status Change	The date and time of the most recent change to the SDP
Signaling	The signaling protocol used to obtain the ingress and egress labels used in frames transmitted and received on this SDP
Last Mgmt Change	The date and time of the most recent management-initiated change to this SDP
Class Fwding State	Not applicable
Flags	Specifies the conditions that affect the operating status of this SAP. Display output includes: ServiceAdminDown, SapAdminDown, InterfaceAdminDown, PortOperDown, PortMTUTooSmall, L2OperDown, SapIngressQoSMismatch, SapEgressQoSMismatch, RelearnLimitExceeded, RxProtSrcMac, ParentIfAdminDown, NoSapPipeCelpAddr, TodResourceUnavail, TodMssResourceUnavail, SapParamMismatch, CemSapNoEcidOrMacAddr, StandByForMcRing, ServiceMTUTooSmall, SapIngressNamedPoolMismatch, SapEgressNamedPoolMismatch, NoSapEpipeRingNode
KeepAlive Information	
Admin State	The administrative state of the keepalive process
Oper State	The operational state of the keepalive process
Hello Time	Specifies how often the SDP echo request messages are transmitted on this SDP
Hell Msg Length	The length of the SDP echo request messages transmitted on this SDP

Table 149 Service ID SDP Detailed Field Descriptions (Continued)

Label	Description
Max Drop Count	The maximum number of consecutive SDP echo request messages that can be unacknowledged before the keepalive protocol reports a fault
Hold Down Time	The time to wait before the keepalive operating status is eligible to enter the alive state
Statistics	
I. Fwd. Pkts.	The number of forwarded ingress packets
I. Dro. Pkts.	The number of dropped ingress packets
I. Fwd. Octs.	The number of forwarded ingress octets
I. Dro. Octs.	The number of dropped ingress octets
E. Fwd. Pkts.	The number of forwarded egress packets
E. Fwd. Octets	The number of forwarded egress octets
Associated LSP LIST	If the SDP type is MPLS, a list of LSPs used to reach the far-end router displays. All the LSPs in the list must terminate at the IP address specified in the far-end field. If the SDP type is GRE, the following message displays: SDP delivery mechanism is not MPLS.
Number of SDPs	The total number of SDPs applied to this service ID

twamp-light

Syntax	twamp-light
Context	show>service>id
Description	This command displays OAM TWAMP Light status information.
Output	The following output is an example of TWAMP Light information, and Table 150 describes the fields.

Output Example

```
*A:ALU-3# show service id 10 twamp-light
=====
TWAMP Light Reflector
-----

*A:ALU-3#

```

Table 150 TWAMP Light Field Descriptions

Label	Description
TWAMP Light Reflector	
Admin State	Displays one of the following: Up—the server or prefix is administratively enabled (no shutdown) in configuration Down—the server or prefix is administratively disabled (shutdown) in configuration
Up Time	The time since the server process was started, measured in days (d), hours, minutes, and seconds
Configured UDP Port	The UDP port number used
Test Packets Rx	The total number of test packets received from session senders
Test Packets Tx	The total number of test packets sent to session senders
TWAMP Light Controller Prefix List	The IP address prefixes of TWAMP Light clients

service-using

- Syntax** `service-using vprn [sdp sdp-id] [customer customer-id]`
- Context** `show>service`
- Description** This command displays the services matching certain usage properties.
- If no optional parameters are specified, all services defined on the system are displayed.
- Parameters** **vprn** — displays matching VPRN services
- sdp-id** — displays only services bound to the specified SDP ID
- Values** 1 to 17407

customer-id — displays only those services associated with the specified customer ID

Values 1 to 2147483647

Output The following output is an example of service-using information, and [Table 151](#) describes the fields.

Output Example

```

Table 151 Service Service-Using Field Descriptions

Label	Description
Service Id	The service identifier
Type	The service type configured for the service ID
Name	The service name
Description	A description of the service
Adm	The desired state of the service
Opr	The operating state of the service

Table 151 Service Service-Using Field Descriptions (Continued)

Label	Description
CustomerID	The ID of the customer who owns this service
Last Mgmt Change	The date and time of the most recent management-initiated change to this service
Matching Services	The number of services of the same type

7.8.2.3 Show Router Commands

Note: The following command outputs are examples only; actual displays may differ depending on supported functionality and user configuration.

router

Syntax	router [<i>service-id</i>]
Context	show
Description	This command provides access to the show commands for the service specified by the <i>service-id</i>. Using <i>service-id</i> with this command applies only to VPN service.
Parameters	<i>service-id</i> — specifies the <i>service-id</i> Values 1 to 2147483647 or <i>service-name</i>

aggregate

Syntax	aggregate [active]
Context	show>router
Description	This command displays aggregated routes.
Parameters	active — filters out inactive aggregates
Output	The following output is an example of aggregate route information, and Table 152 describes the fields.

Output Example

```
*A:ALU-12# show router 104 aggregate
=====
Aggregates (Service: 104)
=====
Prefix                               Aggr IP-Address  Aggr AS
  Summary                             AS Set          State
-----
No. of Aggregates: 0
=====
*A:ALU-12#
```

Table 152 Aggregate Table Field Descriptions

Label	Description
Prefix	The destination address of the aggregate route in dotted-decimal notation
Summary	Specifies whether the aggregate or more specific components are advertised
AS Set	Displays an aggregate where the path advertised for the route consists of all elements contained in all paths that are being summarized
Aggr AS	The aggregator path attribute to the aggregate route
Aggr IP-Address	The IP address of the aggregated route
State	The operational state of the aggregated route
No. of Aggregates	The total number of aggregated routes

arp

Syntax **arp** [*ip-address* | *ip-int-name* | **mac** *ieee-mac-addr*] [**sdp** *sdp-id:vc-id*] [**summary**]

Context show>router

Description This command displays the router ARP table sorted by IP address.

If no command line options are specified, all ARP entries are displayed.

Parameters *ip-addr* — the IP address for which ARP entries will be displayed
ip-int-name — the interface name for which ARP entries will be displayed
ieee-mac-addr — the MAC address for which ARP entries will be displayed
sdp-id — the SDP ID for which ARP entries will be displayed

Values 1 to 17407

Default all SDPs

vc-id — the virtual circuit ID on the SDP ID

Values 1 to 4294967295

summary — displays summary APR table information

Output The following output is an example of ARP table information, and [Table 153](#) describes the fields.

Output Example

```
*A:ALU-12# show router 6 arp
=====
ARP Table (Service: 6)
=====
IP Address      MAC Address      Expiry    Type    Interface
-----
10.10.10.103    04:67:ff:00:00:01 00h00m00s Oth     system
10.10.4.3       00:00:00:00:00:00 00h00m00s Oth     ALU-1-2
-----
No. of ARP Entries: 2
=====
*A:ALU-12#
```

Table 153 ARP Table Field Descriptions

Label	Description
IP Address	The IP address of the ARP entry
MAC Address	The MAC address of the ARP entry
Expiry	The age of the ARP entry
Type	Dyn—the ARP entry is a dynamic ARP entry
	Inv—the ARP entry is an inactive static ARP entry (invalid)
	Oth—the ARP entry is a local or system ARP entry
	Sta—the ARP entry is an active static ARP entry
Interface	The IP interface name associated with the ARP entry
No. of ARP Entries	The number of ARP entries displayed in the list

bgp

Syntax	bgp
Context	show>router
Description	This command enables the context to display BGP-related information.

damping

Syntax **damping** [*ip-prefix*[/*ip-prefix-length*]] [*damp-type*] [**detail**] [**ipv4**]
damping [*ip-prefix*[/*ip-prefix-length*]] [*damp-type*] [**detail**] **ipv6**
damping [*ip-prefix*[/*ip-prefix-length*]] [*damp-type*] [**detail**] **vpn-ipv4**
damping [*ip-prefix*[/*ip-prefix-length*]] [*damp-type*] [**detail**] **vpn-ipv6**
damping [*ip-prefix*[/*ip-prefix-length*]] [*damp-type*] [**detail**] **mvpn-ipv4**

Context show>router>bgp

Description This command displays BGP routes that have been dampened due to route flapping. This command can be entered with or without a route parameter. If no parameters are included, all dampened routes are listed.

If the keyword **detail** is included, more detailed information is displayed.

If a *damp-type* is specified, only those types of dampened routes (decayed, history, or suppressed) are displayed. Routes that have a state of **decayed** have gained penalties for flapping but have not yet reached the suppression limit. Routes that have a state of **history** have had a route flap and have been withdrawn. Routes that have a state of **suppressed** have reached the suppression limit and are not considered in BGP path selection.

Parameters *ip-prefix/ip-prefix-length* — displays damping information for the specified IP address

Values	<i>ipv4-prefix</i>	a.b.c.d (host bits must be 0)
	<i>ipv4-prefix-length</i>	0 to 30
	<i>ipv6-prefix</i>	x:x:x:x:x:x:x (eight 16-bit pieces)
		x:x:x:x:x:d.d.d.d
		x: [0 to FFFF]H
		d: [0 to 255]D
	<i>ipv6-prefix-length</i>	0 to 128

damp-type — displays damping information for routes with the specified damp type

Values decayed, history, suppressed

detail — displays detailed information

ipv4 — displays dampened routes for the IPv4 address family

ipv6 — displays dampened routes for the IPv6 address family

vpn-ipv4 — displays dampened routes for the VPN-IPv4 address family

vpn-ipv6 — displays dampened routes for the VPN-IPv6 address family

mvpn-ipv4 — displays dampened routes for the MVPN-IPv4 address family

Output The following output is an example of BGP damping information, and [Table 154](#) describes the fields.

Output Example

```

*A:ALU-12# show router 6 bgp neighbor damping

Table 154 BGP Damping Field Descriptions

Label	Description
BGP Router ID	The local BGP router ID
AS	The configured autonomous system number

Table 154 BGP Damping Field Descriptions (Continued)

Label	Description
Local AS	The configured or inherited local AS for the specified peer group; if not configured, it is the same value as the AS
Network	The IP prefix and mask length for the route
Flag/Flags	Legend: Status codes: u-used, s-suppressed, h-history, d-decayed, *-valid (if an * is not present, the status is invalid) Origin codes: i-IGP, e-EGP, ?-incomplete, >-best
From	The originator ID path attribute value
Reuse/Reuse time	The time when a suppressed route can be used again
AS-Path	The BGP AS path for the route
Peer	The router ID of the advertising router
NextHop	The BGP next hop for the route
Peer AS	The autonomous system number of the advertising router
Peer Router-Id	The router ID of the advertising router
Local Pref	The BGP local preference path attribute for the route
Age	The time elapsed since the service was enabled
Last update	The time that BGP was last updated
FOM Present	The current Figure of Merit (FOM) value
FOM Last upd.	The last updated FOM value
Number of Flaps	The number of flaps in the neighbor connection
Reuse time	The time when the route can be reused
Path	The BGP AS path for the route
Applied Policy	The applied route policy name

group

Syntax **group** [*name*] [*detail*]

Context show>router>bgp

Description This command displays group information for a BGP peer group. This command can be entered with or without parameters.

When this command is entered without a group name, information about all peer groups displays.

When the command is issued with a specific group name, information only pertaining to that specific peer group displays.

The “State” field displays the BGP group’s operational state. Valid states are:

- Up — BGP global process is configured and running
- Down — BGP global process is administratively shut down and not running
- Disabled — BGP global process is operationally disabled. The process must be restarted by the operator.

Parameters *name* — displays information for the specified BGP group

detail — displays detailed information

Output The following output is an example of BGP group information, and [Table 155](#) describes the fields.

Output Example

```
*A:ALU-12# show router 6 bgp neighbor group

Table 155 BGP Group Field Descriptions

Label	Description
Group	The BGP group name
Group Type	No Type: peer type not configured External: peer type configured as external BGP peers Internal: peer type configured as internal BGP peers
State	Disabled: the BGP peer group has been operationally disabled Down: the BGP peer group is operationally inactive Up: the BGP peer group is operationally active
Peer AS	The configured or inherited peer AS for the specified peer group

Table 155 BGP Group Field Descriptions (Continued)

Label	Description
Local AS	The configured or inherited local AS for the specified peer group
Local Address	The configured or inherited local address for originating peering for the specified peer group
Loop Detect	The configured or inherited loop detect setting for the specified peer group
Connect Retry	The configured or inherited connect retry timer value
Authentication	None: no authentication is configured MD5: MD5 authentication is configured
Local Pref	The configured or inherited local preference value
MED Out	The configured or inherited MED value that is assigned to advertised routes
Multihop	The maximum number of router hops a BGP connection can traverse
AS Override	The setting of the AS override
Min Route Advt.	The minimum amount of time that must pass between route updates for the same IP prefix
Min AS Originate	The minimum amount of time that must pass between updates for a route originated by the local router
Prefix Limit	No Limit: no route limit assigned to the BGP peer group 1 — 4294967295: the maximum number of routes BGP can learn from a peer
Passive	Disabled: BGP attempts to establish a BGP connection with a neighbor in the specified peer group Enabled: BGP will not actively attempt to establish a BGP connection with a neighbor in the specified peer group
Next Hop Self	Disabled: BGP is not configured to send only its own IP address as the BGP next hop in route updates to neighbors in the peer group Enabled: BGP sends only its own IP address as the BGP next hop in route updates to neighbors in the specified peer group

Table 155 BGP Group Field Descriptions (Continued)

Label	Description
Aggregator ID 0	Disabled: BGP is not configured to set the aggregator ID to 0.0.0.0 in all originated route aggregates sent to the neighbor in the peer group Enabled: BGP is configured to set the aggregator ID to 0.0.0.0 in all originated route aggregates sent to the neighbor in the peer group
Remove Private	Disabled: BGP will not remove all private AS numbers from the AS path attribute in updates sent to the neighbor in the peer group Enabled: BGP removes all private AS numbers from the AS path attribute in updates sent to the neighbor in the peer group
Damping	Disabled: the peer group is configured not to dampen route flaps Enabled: the peer group is configured to dampen route flaps
Import Policy	The configured import policies for the peer group
Export Policy	The configured export policies for the peer group
Hold Time	The configured hold-time setting
Keep Alive	The configured keepalive setting
Min Hold Time	The configured minimum hold-time setting
Cluster Id	The configured route reflector cluster ID None: No cluster ID has been configured
Client Reflect	Disabled: the BGP route reflector will not reflect routes to this neighbor Enabled: the BGP route reflector is configured to reflect routes to this neighbor
NLRI	The type of network layer reachability information that the specified peer group can accept Unicast: IPv4 unicast routing information can be carried
Preference	The configured route preference value for the peer group
TTL Security	Enabled: TTL security is enabled Disabled: TTL security is disabled
Min TTL Value	The minimum TTL value configured for the peer
Graceful Restart	The state of graceful restart
Stale Routes Time	The length of time that stale routes are kept in the route table

Table 155 BGP Group Field Descriptions (Continued)

Label	Description
Auth key chain	The value for the authentication key chain
Bfd Enabled	Enabled: BFD is enabled Disabled: BFD is disabled
Creation Origin	The creation method of the peer group
Split Horizon	The configured split-horizon setting
List of Peers	A list of BGP peers configured under the peer group
Total Peers	The total number of peers configured under the peer group
Established	The total number of peers that are in an established state
Peer Groups	The number of peer groups

neighbor

Syntax

```

neighbor [ip-address [detail]]
neighbor [as-number [detail]]
neighbor ip-address [family [type mvpn-type]] filter1 [brief]
neighbor ip-address [family] filter2
neighbor as-number [family] filter2
neighbor ip-address orf [filter3]
neighbor ip-address graceful-restart
neighbor [dynamic]

```

Context show>router>bgp

Description This command displays BGP neighbor information. This command can be entered with or without any parameters.

When this command is issued without any parameters, information about all BGP peers displays.

When the command is issued with a specific IP address or ASN, information regarding only that specific peer or peers with the same AS displays.

Note: This information is not available when using SNMP.

Parameters	<i>ip-address</i> — the specified IP address for which to display information
Values	<i>ipv4-address:</i> a.b.c.d (host bits must be 0) <i>ipv6-address:</i> x:x:x:x:x:x:x[-interface] x:x:x:x:x:x:d.d.d.d[-interface] interface - 32 chars max, mandatory for link local addresses x: [0 to FFFF]H d: [0 to 255]D
	detail — displays detailed information
	<i>as-number</i> — the specified AS number for which to display information
Values	1 to 4294967295
	<i>family</i> — the type of routing information to be distributed by this peer group
Values	ipv4 — displays only those BGP peers that have the IPv4 family enabled and not those capable of exchanging VPN-IPv4 routes label-ipv4 — displays only those BGP peers that have the label-IPv4 family enabled vpn-ipv4 — displays only those BGP peers that have the VPN-IPv4 family enabled mvpn-ipv4 — displays only those BGP peers that have the MVPN-IPv4 family enabled
	type — displays information for the MVPN type
	<i>mvpn-type</i> — the specified MVPN type for which to display information
Values	intra-ad inter-ad spmsi-ad leaf-ad source-ad shared-join source-join
	<i>filter1</i> — displays information for the specified IP address
Values	received-routes — displays the number of routes received from this peer advertised-routes — displays the number of routes advertised by this peer
	<i>filter2</i> — displays information for the specified AS number
Values	history — displays statistics for dampened routes suppressed — displays the number of paths from this peer that have been suppressed by damping

Note: When either **received-routes** or **advertised-routes** is specified, the routes that are received from or sent to the specified peer are listed. When either **history** or **suppressed** is specified, the routes that are learned from those peers that either have a history or are suppressed are listed.

brief — displays information in a brief format. This parameter is only supported with **received-routes** and **advertised-routes**.

orf — displays outbound route filtering for the BGP instance. ORF (Outbound Route Filtering) is used to inform a neighbor of targets (using target-list) that it is willing to receive. This mechanism helps lessen the update exchanges between neighbors and saves CPU cycles to process routes that could have been received from the neighbor only to be dropped/ignored.

filter3 — displays path information for the specified IP address

Values **send** — displays the number of paths sent to this peer

receive — displays the number of paths received from this peer

graceful-restart — displays neighbors configured for graceful restart

dynamic — displays information for dynamic BGP neighbors

Output The following outputs are examples of BGP neighbor information:

- BGP neighbor (standard, detailed, and dynamic) ([Output Example - BGP Neighbor \(standard, detailed, and dynamic\)](#), [Table 156](#))
- BGP neighbor (advertised and received) ([Output Example - BGP Neighbor \(advertised-routes and received-routes\)](#), [Table 157](#))
- BGP neighbor (graceful restart) ([Output Example - BGP Neighbor \(graceful restart\)](#), [Table 158](#))

Output Example - BGP Neighbor (standard, detailed, and dynamic)

Table 156 BGP Neighbor (Standard, Detailed, and Dynamic) Field Descriptions

Label	Description
Peer	The IP address of the configured BGP peer
Group	The BGP peer group to which this peer is assigned

Table 156 BGP Neighbor (Standard, Detailed, and Dynamic) Field Descriptions (Continued)

Label	Description
Peer AS	The configured or inherited peer AS for the peer group
Peer Address	The configured address for the BGP peer
Peer Port	The TCP port number used on the far-end system
Local AS	The configured or inherited local AS for the peer group
Local Address	The configured or inherited local address for originating peering for the peer group
Local Port	The TCP port number used on the local system
Peer Type	External: peer type configured as external BGP peers
	Internal: peer type configured as internal BGP peers
Dynamic Peer	Yes: the session is dynamic (that is, unconfigured)
	No: the session is statically configured
State	Idle: The BGP peer is not accepting connections. (Shutdown) is also displayed if the peer is administratively disabled.
	Active: BGP is listening for and accepting TCP connections from this peer
	Connect: BGP is attempting to establish a TCP connection with this peer
	Open Sent: BGP has sent an OPEN message to the peer and is waiting for an OPEN message from the peer
	Open Confirm: BGP has received a valid OPEN message from the peer and is awaiting a KEEPALIVE or NOTIFICATION
	Established: BGP has successfully established a peering session and is exchanging routing information

Table 156 BGP Neighbor (Standard, Detailed, and Dynamic) Field Descriptions (Continued)

Label	Description
Last State	Idle: The BGP peer is not accepting connections
	Active: BGP is listening for and accepting TCP connections from this peer
	Connect: BGP is attempting to establish a TCP connections with this peer
	Open Sent: BGP has sent an OPEN message to the peer and is waiting for an OPEN message from the peer
	Open Confirm: BGP has received a valid OPEN message from the peer and is awaiting a KEEPALIVE or NOTIFICATION
Last Event	start: BGP has initialized the BGP neighbor
	stop: BGP has disabled the BGP neighbor
	open: BGP transport connection is opened
	close: BGP transport connection is closed
	openFail: BGP transport connection failed to open
	error: BGP transport connection error
	connectRetry: the connect retry timer expired
	holdTime: the hold time timer expired
	keepAlive: the keepalive timer expired
	recvOpen: BGP has received an OPEN message
	revKeepalive: BGP has received a KEEPALIVE message
	recvUpdate: BGP has received an UPDATE message
	recvNotify: BGP has received a NOTIFICATION message
	None: no events have occurred
Last Error	The last BGP error and subcode to occur on the BGP neighbor
Local Family	The configured local family value
Remote Family	The configured remote family value
Connect Retry	The configured or inherited connect retry timer value

Table 156 BGP Neighbor (Standard, Detailed, and Dynamic) Field Descriptions (Continued)

Label	Description
Local Pref.	The configured or inherited local preference value
Min Route Advt.	The minimum amount of time that must pass between route updates for the same IP prefix
Min AS Originate	The minimum amount of time that must pass between updates for a route originated by the local router
Multihop	The maximum number of router hops a BGP connection can traverse
Damping	Disabled: the BGP neighbor is configured not to dampen route flaps
	Enabled: the BGP neighbor is configured to dampen route flaps
Loop Detect	Ignore: The BGP neighbor is configured to ignore routes with an AS loop
	Drop: The BGP neighbor is configured to drop the BGP peering if an AS loop is detected
	Off: AS loop detection is disabled for the neighbor
MED Out	The configured or inherited MED value that is assigned to advertised routes
Authentication	None: no authentication is configured
	MD5: MD5 authentication is configured
Next Hop Self	Disabled: BGP is not configured to send only its own IP address as the BGP next hop in route updates to the specified neighbor
	Enabled: BGP will send only its own IP address as the BGP next hop in route updates to the neighbor
AggregatorID Zero	Disabled: the BGP neighbor is not configured to set the aggregator ID to 0.0.0.0 in all originated route aggregates
	Enabled: the BGP neighbor is configured to set the aggregator ID to 0.0.0.0 in all originated route aggregates
Remove Private	Disabled: BGP will not remove all private AS numbers from the AS path attribute in updates sent to the specified neighbor
	Enabled: BGP will remove all private AS numbers from the AS path attribute in updates sent to the specified neighbor

Table 156 BGP Neighbor (Standard, Detailed, and Dynamic) Field Descriptions (Continued)

Label	Description
Passive	Disabled: BGP will actively attempt to establish a BGP connection with the specified neighbor
	Enabled: BGP will not actively attempt to establish a BGP connection with the specified neighbor
Peer Identifier	The IP identifier for the peer router
Prefix Limit	No Limit: no route limit assigned to the BGP peer group
	1 — 4294967295: the maximum number of routes BGP can learn from a peer
Pref Limit Idle Time*	The length of time that the session is held in the idle state after it is taken down as a result of reaching the prefix limit
Hold Time	The configured hold-time setting
Keep Alive	The configured keepalive setting
Min Hold Time	The configured minimum hold-time setting
Active Hold Time	The negotiated hold time, if the BGP neighbor is in an established state
Active Keep Alive	The negotiated keepalive time, if the BGP neighbor is in an established state
Cluster Id	The configured route reflector cluster ID
	None: no cluster ID has been configured
Client Reflect	Disabled: The BGP route reflector is configured not to reflect routes to this neighbor
	Enabled: The BGP route reflector is configured to reflect routes to this neighbor
Preference	The configured route preference value for the peer group
Num of Flaps	The number of route flaps in the neighbor connection
Recd. Paths	The number of unique sets of path attributes received from the BGP neighbor
IPv4 Recd. Prefixes	The number of unique sets of IPv4 path attributes received from the BGP neighbor
IPv4 Active Prefixes	The number of IPv4 routes received from the BGP neighbor and active in the forwarding table

Table 156 BGP Neighbor (Standard, Detailed, and Dynamic) Field Descriptions (Continued)

Label	Description
IPv4 Suppressed Pfxs	The number of unique sets of IPv4 path attributes received from the BGP neighbor and suppressed due to route damping
VPN-IPv4 Suppr. Pfxs	The number of unique sets of VPN-IPv4 path attributes received from the BGP neighbor and suppressed due to route damping
VPN-IPv4 Recd. Pfxs	The number of unique sets of VPN-IPv4 path attributes received from the BGP neighbor
VPN-IPv4 Active Pfxs	The number of VPN-IPv4 routes received from the BGP neighbor and active in the forwarding table
IPv6 Suppressed. Pfxs	The number of unique sets of IPv6 path attributes received from the BGP neighbor and suppressed due to route damping
IPv6 Recd. Prefixes	The number of unique sets of IPv6 path attributes received from the BGP neighbor
IPv6 Active Prefixes	The number of IPv6 routes received from the BGP neighbor and active in the forwarding table
VPN-IPv6 Recd. Pfxs	The number of unique sets of VPN-IPv6 path attributes received from the BGP neighbor
VPN-IPv6 Active Pfxs	The number of VPN-IPv6 routes received from the BGP neighbor and active in the forwarding table
VPN-IPv6 Suppr. Pfxs	The number of unique sets of VPN-IPv6 path attributes received from the BGP neighbor and suppressed due to route damping
MVPN-IPv4 Suppr. Pfxs	The number of unique sets of MVPN-IPv4 path attributes received from the BGP neighbor and suppressed due to route damping
MVPN-IPv4 Recd. Pfxs	The number of unique sets of MVPN-IPv4 path attributes received from the BGP neighbor
MVPN-IPv4 Active Pfxs	The number of MVPN-IPv4 routes received from the BGP neighbor and active in the forwarding table
Flow-IPv4 Suppr. Pfxs	N/A
Flow-IPv4 Recd. Pfxs	N/A
Flow-IPv4 Active Pfxs	N/A

Table 156 BGP Neighbor (Standard, Detailed, and Dynamic) Field Descriptions (Continued)

Label	Description
Rte-Tgt Suppr. Pfxs	The number of unique sets of route target path attributes received from the BGP neighbor and suppressed due to route damping
Rte-Tgt Recd. Pfxs	The number of unique sets of route target path attributes received from the BGP neighbor
Rte-Tgt Active. Pfxs	The number of route target routes received from the BGP neighbor and active in the forwarding table
Backup IPv4 Pfxs	The number of BGP Fast Reroute backup path IPv4 prefixes
Backup IPv6 Pfxs	The number of BGP Fast Reroute backup path IPv6 prefixes
Mc Vpn Ipv4 Suppr. P*	N/A
Backup Vpn IPv4 Pfxs	The number of BGP Fast Reroute backup path VPN IPv4 prefixes
Backup Vpn IPv6 Pfxs	The number of BGP Fast Reroute backup path VPN IPv6 prefixes
Input Queue	The number of BGP messages to be processed
Output Queue	The number of BGP messages to be transmitted
i/p Messages	The total number of packets received from the BGP neighbor
o/p Messages	The total number of packets sent to the BGP neighbor
i/p Octets	The total number of octets received from the BGP neighbor
o/p Octets	The total number of octets sent to the BGP neighbor
i/p Updates	The total number of updates received from the BGP neighbor
o/p Updates	The total number of updates sent to the BGP neighbor
Evpn Suppr. Pfxs	The number of unique sets of EVPN-IPv4 path attributes received from the BGP neighbor and suppressed due to route damping
Evpn Recd. Pfxs	The number of unique sets of EVPN-IPv4 path attributes received from the BGP neighbor
Evpn Active Pfxs	The number of EVPN-IPv4 routes received from the BGP neighbor and active in the forwarding table
MS-PW Suppr. Pfxs	N/A
MS-PW Recd. Pfxs	N/A

Table 156 BGP Neighbor (Standard, Detailed, and Dynamic) Field Descriptions (Continued)

Label	Description
MS-PW Active Pfxs	N/A
TTL Security	Enabled: TTL security is enabled Disabled: TTL security is disabled
Min TTL Value	The minimum TTL value configured for the peer
Graceful Restart	The state of graceful restart
Stale Routes Time	The length of time that stale routes are kept in the route table
Advertise Inactive	The state of advertising inactive BGP routes to other BGP peers (enabled or disabled)
Peer Tracking	The state of tracking a neighbor IP address in the routing table for a BGP session
Advertise Label	Indicates the enabled address family for supporting RFC 3107 BGP label capability
Auth key chain	The value for the authentication key chain
Disable Cap Nego	N/A
Bfd Enabled	Enabled: BFD is enabled Disabled: BFD is disabled
Flowspec Validate	N/A
Default Route Tgt	Indicates that the default RTC route (zero prefix length) is originated towards the selected peers
Aigp Metric	Indicates whether accumulated IGP (AIGP) path attribute support with one or more BGP peers is enabled or disabled
Split Horizon	Indicates whether split horizon is enabled or disabled. When enabled, split horizon prevents routes from being reflected back to a peer that sends the best route.
Local Capability	The capability of the local BGP speaker; for example, route refresh, MP-BGP, ORF
Remote Capability	The capability of the remote BGP peer; for example, route refresh, MP-BGP, ORF
Local AddPath Capabi*	The state of the local BGP add-paths capabilities. The add-paths capability allows the router to send and receive multiple paths per prefix to or from a peer.
Remote AddPath Capab*	The state of the remote BGP add-paths capabilities

Table 156 BGP Neighbor (Standard, Detailed, and Dynamic) Field Descriptions (Continued)

Label	Description
Import Policy	The configured import policies for the peer group
Export Policy	The configured export policies for the peer group
Origin Validation	N/A
EBGP Link Bandwidth	N/A
IPv4 Rej. Pfxs	The number of unique sets of IPv4 path attributes received from the BGP neighbor and rejected by the router
IPv6 Rej. Pfxs	The number of unique sets of IPv6 path attributes received from the BGP neighbor and rejected by the router
VPN-IPv4 Rej. Pfxs	The number of unique sets of VPN-IPv4 path attributes received from the BGP neighbor and rejected by the router
VPN-IPv6 Rej. Pfxs	The number of unique sets of VPN-IPv6 path attributes received from the BGP neighbor and rejected by the router
Mc IPv4 Rej. Pfxs	The number of unique sets of MC IPv4 path attributes received from the BGP neighbor and rejected by the router
Mc IPv6 Rej. Pfxs	The number of unique sets of MC IPv6 path attributes received from the BGP neighbor and rejected by the router
MVPN-IPv4 Rej. Pfxs	The number of unique sets of MVPN-IPv4 path attributes received from the BGP neighbor and rejected by the router
MVPN-IPv6 Rej. Pfxs	The number of unique sets of MVPN-IPv6 path attributes received from the BGP neighbor and rejected by the router
Flow-IPv4 Rej. Pfxs	The number of unique sets of path attributes received from the BGP neighbor and rejected by the router
Flow-IPv6 Rej. Pfxs	The number of unique sets of Flow-IPv6 path attributes received from the BGP neighbor and rejected by the router
L2-VPN Rej. Pfxs	The number of unique sets of L2-VPN path attributes received from the BGP neighbor and rejected by the router
MDT-SAFI Rej. Pfxs	The number of unique sets of MDT-SAFI path attributes received from the BGP neighbor and rejected by the router
Rte-Tgt Rej. Pfxs	The number of unique sets of route target path attributes received from the BGP neighbor and rejected by the router
MS-PW Rej. Pfxs	The number of unique sets of MS-PW path attributes received from the BGP neighbor and rejected by the router

Table 156 BGP Neighbor (Standard, Detailed, and Dynamic) Field Descriptions (Continued)

Label	Description
Mc Vpn Ipv4 Rej. Pfxs	The number of unique sets of MC VPN IPv4 path attributes received from the BGP neighbor and rejected by the router
Evpn Rej. Pfxs	The number of unique sets of EVPN path attributes received from the BGP neighbor and rejected by the router
Label-v4 Suppr. Pfxs	The number of unique sets of label-IPv4 path attributes received from the BGP neighbor and suppressed due to route damping
Label-v4 Recd. Pfxs	The number of unique sets of label-IPv4 path attributes received from the BGP neighbor
Label-v4 Active Pfxs	The number of label-IPv4 routes received from the BGP neighbor and active in the forwarding table
Label-v4 Rej. Pfxs	The number of unique sets of label-IPv4 path attributes received from the BGP neighbor and rejected by the router
Label-v6 Suppr. Pfxs	The number of unique sets of label-IPv6 path attributes received from the BGP neighbor and suppressed due to route damping
Label-v6 Recd. Pfxs	The number of unique sets of label-IPv6 path attributes received from the BGP neighbor
Label-v6 Active Pfxs	The number of label-IPv6 routes received from the BGP neighbor and active in the forwarding table
Label-v6 Rej. Pfxs	The number of unique sets of label-IPv6 path attributes received from the BGP neighbor and rejected by the router
Bgp-Ls Suppr. Pfxs	The number of unique sets of BGP LS path attributes received from the BGP neighbor and suppressed due to route damping
Bgp-Ls Recd. Pfxs	The number of unique sets of BGP LS path attributes received from the BGP neighbor
Bgp-Ls Active Pfxs	The number of BGP LS routes received from the BGP neighbor and active in the forwarding table
Bgp-Ls Rej. Pfxs	The number of unique sets of BGP LS path attributes received from the BGP neighbor and rejected by the router

Table 158 BGP Neighbor (Graceful Restart) Field Descriptions

Label	Description
BGP Neighbor	The IP address of the BGP neighbor
Graceful Restart locally configured for peer	The configured state of graceful restart for the local router
Peer's Graceful Restart feature	The configured state of graceful restart for the peer router
NLRI(s) that peer supports restart for	The families supported by the peer router for graceful restart
NLRI(s) that peer saved forwarding for	The families for which the peer router continued to forward packets after graceful restart

Table 158 BGP Neighbor (Graceful Restart) Field Descriptions (Continued)

Label	Description
NLRI(s) that restart is negotiated for	The families that negotiate restart during graceful restart
NLRI(s) of received end-of-rib markers	The families for which end-of-RIB markers have been received
NLRI(s) of all end-of-rib markers sent	The families for which end-of-RIB markers have been sent
Restart time locally configured for peer	The length of time configured on the local router for the peer router's graceful restart
Restart time requested by the peer	The length of time requested by the peer router for graceful restart
Time stale routes from peer are kept for	The length of time that the local router continues to support stale routes
Graceful restart status on the peer	The status of graceful restart on the peer router
Number of Restarts	The number of restarts since graceful restart is enabled between peers
Last Restart at	The local time of the last graceful restart

next-hop

Syntax	next-hop [<i>family</i>] [<i>ip-address</i>] [detail]
Context	show>router>bgp
Description	This command displays BGP next-hop information.
Parameters	<i>family</i> — the type of routing information to be distributed by the BGP instance Values ipv4 — displays only those BGP peers that have the IPv4 family enabled and not those capable of exchanging VPN-IPv4 routes ipv6 — displays only those BGP peers that have the IPv6 family enabled and not those capable of exchanging VPN-IPv6 routes label-ipv4 — displays only those BGP peers that support the IPv4 unicast (labeled) address family vpn-ipv4 — displays only those BGP peers that have the VPN-IPv4 family enabled vpn-ipv6 — displays only those BGP peers that have the VPN-IPv6 family enabled

mvpn-ipv4 — displays only those BGP peers that have the MVPN-IPv4 family enabled

ip-address — displays the next hop information for the specified IP address

Values *ipv4-address:* a.b.c.d
 ipv6-address: x::x::x::x::x[-*interface*]
 x::x::x::x::d.d.d.d[-*interface*]
 interface - 32 chars max,
 mandatory for link local addresses
 x: [0 to FFFF]H
 d: [0 to 255]D

detail — displays the more detailed version of the output

Output The following output is an example of BGP next-hop information, and [Table 159](#) describes the fields.

Output Example

```
*A:ALU-12# show router 6 bgp next-hop

Table 159 BGP Next-Hop Field Descriptions

Label	Description
BGP Router ID	The local BGP router ID
AS	The configured autonomous system number
Local AS	The configured local AS setting. If not configured, then the value is the same as the AS.
Next Hop	The next-hop address
Resolving Prefix	The prefix of the best next hop
Pref: Preference	The BGP preference attribute for the routes
Metric	The metric derived from the IGP for a particular next hop
Reference Count	The number of routes using the resolving prefix
Owner	The routing protocol used to derive the best next hop

Table 159 BGP Next-Hop Field Descriptions (Continued)

Label	Description
Resolved Next Hop	The IP address of the next hop
Egress Label	The VPN label used for VPN-IPv4 data
Next Hops	The number of next hops

paths

Syntax	paths
Context	show>router>bgp
Description	This command displays a summary of BGP path attributes.
Output	The following output is an example of BGP path information, and Table 160 describes the fields.

Output Example

```
*A:ALU-12# show router 6 bgp paths
=====

Table 160 BGP Path Field Descriptions

Label	Description
BGP Router ID	The local BGP router ID
AS	The configured autonomous system number
Local AS	The configured local AS setting. If not configured, then the value is the same as the AS.
Path	The AS path attribute
Next Hop	The advertised BGP next hop
Origin	EGP: the NLRI is learned by an EGP protocol
	IGP: the NLRI is interior to the originating AS
	Incomplete: NLRI was learned another way
Segments	The number of segments in the AS path attribute
MED	The Multi-Exit Discriminator value
Local Preference	The local preference value. This value is used if the BGP route arrives from a BGP peer without the Local Pref attribute set. It is overridden by any value set via a route policy.
Refs	The number of routes using a specified set of path attributes
ASes	The number of autonomous system numbers in the AS path attribute
Flags	IBGP-learned: path attributes learned by an IBGP peering
Community	The BGP community attribute list
Cluster List	The route reflector cluster list
Originator ID	The originator ID path attribute value

```

Context show>router>bgp

Description This command displays BGP route information.

When this command is issued without any parameters, the entire BGP routing table displays.

When this command is issued with an IP prefix/mask or IP address, the best match for the parameter displays.

Note: To apply a family filter to the route output of the command, the family name must be specified before all other filtering parameters except for the IP prefix/mask or IP address, which, if present, must be placed before the family name in the command.

Parameters

ip-prefix/mask | ip-address — displays parameters that match the specified IPv4 prefix and mask length, or IPv6 address (256 characters maximum)

Values

<i>ip-prefix:</i>	a.b.c.d (host bits must be 0)
<i>mask:</i>	0 to 32
<i>ip-address:</i>	x:x:x:x:x:x:x[-interface] x:x:x:x:x:x:d.d.d.d[-interface] <i>interface</i> - 32 chars max, mandatory for link local addresses x: [0 to FFFF]H d: [0 to 255]D

aspath-regex *reg-exp* — displays all routes with an AS path matching the specified regular expression (80 characters maximum)

brief — provides a summarized display of the set of peers to which a BGP route is advertised; this option is only supported when no IP prefix/mask or IP address is specified

community — displays all routes with the specified BGP community; community matching is based only on RIB-In communities, not RIB-Out communities

comm-id — specifies community IDs, in the format *as-number1:comm-val1 | ext-comm | well-known-comm*

Values

<i>as-number1</i>	0 to 65535
<i>comm-val1</i>	0 to 65535
<i>ext-comm</i>	<i>type</i> : { <i>ip-address:comm-val1 as-number1:comm-val2 as-number2:comm-val1 as-number1:val-in-mbps</i> } <i>ext:xyxy:ovstate</i> where <i>type</i> : target origin bandwidth (keywords) <i>ip-address</i> : <i>ipv4-address</i> : a.b.c.d <i>ipv6-address</i> :: x:x:x:x:x:x:x[-interface] x:x:x:x:x:x:d.d.d.d[-interface] <i>interface</i> - 32 chars max, mandatory for link local addresses x: [0 to FFFF]H d: [0 to 255]D

ext:xyy:ovstate xx: 43
 yy: 0
 ovstate: 0, 1, 2 (0 for valid, 1 for not-found, 2 for invalid)
 well-known-comm **null | no-export | no-export-subconfed | no-advertise** (keywords)

group-ip *ipv4 address | ipv6 address* — displays the group IPv4 or IPv6 address

originator-ip *ip-address* — displays the originating IPv4 or IPv6 address

source-ip *ipv4 address | ipv6 address* — displays the source IPv4 or IPv6 address

detail — displays a more detailed version of the output

source-as *as-number* — displays the source AS number

hunt — displays entries for the specified route in the RIB-In, RIB-Out, and RTM

ipv4 — displays only those BGP peers that have the IPv4 family enabled

ipv6 — displays only those BGP peers that have the IPv6 family enabled

label-ipv4 — displays only those BGP peers for the IPv4 unicast (labeled) address family

longer — displays the specified route and subsets of the route

mvpn-ipv4 — displays the BGP peers that are MVPN-IPv4 capable

mvpn-type — the specified MVPN type for which to display information

Values intra-ad | inter-ad | spmsi-ad | leaf-ad | source-ad | shared-join | source-join

route-target — displays a summary of route target constrained routes for this BGP peer

rtc-prefix *rtc-prefix* — displays route target constraint prefix information, in the format *source-as:{ip-addr:comm-val | 2byte-asnumber:ext-comm-val | 4byte-asnumber:comm-val}/prefix-length*

Values *ip-addr:*
 ipv4-address: a.b.c.d
 ipv6-address: x:x:x:x:x:x:x[-*interface*]
 x:x:x:x:x:x.d.d.d.d[-*interface*]
 interface - 32 chars max,
 mandatory for link local addresses
 x: [0 to FFFF]H
 d: [0 to 255]D

 comm-val: 0 to 65535
 2byte-asnumber: 0 to 65535
 ext-comm-val: 0 to 4294967295
 4byte-asnumber: 0 to 4294967295

prefix-length: 0 to 96

rd *rd* — displays the route distinguisher value, in the format *ip-addr:comm-val* | *2byte-asnumber:ext-comm-val* | *4-byte-asnumber:comm-val*

Values

ip-addr:

ipv4-address: a.b.c.d

ipv6-address: x:x:x:x:x:x:x[-*interface*]
 x:x:x:x:x:x:d.d.d.d[-*interface*]
interface - 32 chars max,
 mandatory for link local addresses
 x: [0 to FFFF]H
 d: [0 to 255]D

comm-val: 0 to 65535

2byte-asnumber: 0 to 65535

ext-comm-val: 0 to 4294967295

4byte-asnumber: 0 to 4294967295

vpn-ipv4 — displays the BGP VPN IPv4 routes

vpn-ipv6 — displays the BGP VPN IPv6 routes

originator-ip *ip-address* — filters BGP MVPN routes by the originating router IP address that is found in the intra-AD (auto-discovery) MVPN routes

source-ip *ip-address* — filters BGP MVPN routes by the source IP address that is found in the source-join, source-AD, or S-PMSI-AD MVPN routes

group-ip *ip-address* — filters BGP MVPN routes by the multicast group IP address that is found in the source-join, source-AD, or S-PMSI-AD MVPN routes

source-as *as-number* — filters BGP MVPN routes by source-AS (autonomous system) extended community attribute

Output The following output is an example of BGP route information, and [Table 161](#) describes the fields.

Output Example

Table 161 BGP Route Field Descriptions

Label	Description
BGP Router ID	The local BGP router ID
AS	The configured autonomous system number
Local AS	The configured local AS setting. If not configured, the value is the same as the AS.

Table 161 BGP Route Field Descriptions (Continued)

Label	Description
Flag/Flags	Legend: Status codes: u - used s - suppressed h - history d - decayed * - valid If an * is not present, the status is invalid l - leaked x - stale > - best b - backup p - purge Origin codes: i - IGP e - EGP ? - incomplete > - best
Network	The IP prefix and mask length
Nexthop	The BGP next hop
AS-Path	The BGP AS path attribute
Local Pref.	The local preference value. This value is used if the BGP route arrives from a BGP peer without the Local Pref attribute set. It is overridden by any value set via a route policy.
MED	The MED metric value
	none: MED metrics are not present
VPN Label	The label generated by the PE label manager
Original Attributes	The received BGP attributes of a route from a peer without any modification from any policy
Modified Attributes	The final BGP attributes of a route after the policies evaluation
Route Dist.	The route distinguisher identifier attached to routes that distinguishes the VPN it belongs to
From	The advertising BGP neighbor IP address

Table 161 BGP Route Field Descriptions (Continued)

Label	Description
Res. Nexthop	The resolved next hop
Aggregator AS	The aggregator AS value
	none: aggregator AS attributes are not present
Aggregator	The aggregator attribute value
	none: aggregator attributes are not present
Atomic Aggr.	Atomic: the atomic aggregator flag is set
	Not Atomic: the atomic aggregator flag is not set
Community	The BGP community attribute list
Cluster	The route reflector cluster list
Originator Id	The originator ID path attribute value
	none: the originator ID attribute is not present
Peer Router Id	The router ID of the advertising router
TieBreakReason	The step in the BGP decision process where a BGP route lost the tiebreaker with the next BGP route for the same prefix LocalPref — this route is not the best because the next better route has a higher LOCAL_PREF AIGP — this route is not the best because the next better route has a lower derived AIGP metric value ASPathLen — this route is not the best because the next better route has a shorter AS PATH length Origin — this route is not the best because the next better route has a lower origin value MED — this route is not the best because the next better route has a lower MED, and MED comparison of the routes was allowed IBGP — this IBGP route is not the best because the next better route is an EBGp route NHCost — this route is not the best because the next better route has a lower metric value to reach the BGP NEXT HOP BGPID — this route is not the best because the next better route has a lower originator ID or BGP identifier ClusterLen — this route is not the best because the next better route has a shorter cluster list length PeerIP — this route is not the best because the next better route has a lower neighbor IP address

Table 161 BGP Route Field Descriptions (Continued)

Label	Description
VPRN Imported	The VPRNs where a particular BGP-VPN received route has been imported and installed

summary

Syntax **summary** [**all**]
summary [**family** *family*] [**neighbor** *ip-address*]

Context show>router>bgp

Description This command displays a summary of BGP neighbor information.

If confederations are not configured, that portion of the output will not display.

The “State” field displays the global BGP operational state. The valid values are:

- Up — BGP global process is configured and running
- Down — BGP global process is administratively shut down and not running
- Disabled — BGP global process is operationally disabled. The process must be restarted by the operator.

For example, if a BGP peer is operationally disabled, then the state in the summary table shows the state ‘Disabled’.

Parameters **all** — displays BGP peers in all instances

family — the type of routing information to be distributed by the BGP instance

Values ipv4, vpn-ipv4, ipv6, vpn-ipv6, mvpn-ipv4, label-ipv4

ipv4, ipv6 — displays only those BGP peers that have the IPv4 or IPv6 family enabled

label-ipv4 — displays only those BGP peers that have the IPv4 unicast (labeled) family enabled

vpn-ipv4, vpn-ipv6 — displays the BGP peers that are IPv4-VPN capable or IPv6-VPN capable

mvpn-ipv4 — displays the BGP peers that are MVPN-IPv4 capable

ip-address — clears damping information for entries received from the BGP neighbor

Values *ipv4-address:* a.b.c.d

```

ipv6-address:    x:x:x:x:x:x:x[-interface]
                  x:x:x:x:x:d.d.d.d[-interface]
                  interface - 32 chars max,
                  mandatory for link local addresses
x: [0 to FFFF]H
d: [0 to 255]D

```

Output The following output is an example of BGP summary information, and [Table 162](#) describes the fields.

Output Example

```

Table 162 BGP Summary Field Descriptions

Label	Description
BGP Router ID	The local BGP router ID
AS	The configured autonomous system number
Local AS	The configured local AS setting. If not configured, then the value is the same as the AS.
BGP Admin State	Down: BGP is administratively disabled
	Up: BGP is administratively enabled
BGP Oper State	Down: BGP is operationally disabled
	Up: BGP is operationally enabled
Total Peer Groups	The total number of configured BGP peer groups
Total Peers	The total number of configured BGP peers
Total BGP Paths	The total number of unique sets of BGP path attributes learned from BGP peers
Total Path Memory	The total amount of memory used to store the path attributes
Total IPv4 Remote Rts	The total number of IPv4 routes learned from BGP peers
Total IPv4 Remote Act. Rts	The total number of IPv4 routes used in the forwarding table
Total Suppressed Rts	The total number of suppressed routes due to route damping
Total Hist. Rts	The total number of routes with history due to route damping
Total Decay Rts	The total number of decayed routes due to route damping
Total VPN Peer Groups	The total number of configured VPN peer groups
Total VPN Peers	The total number of configured VPN peers
Total VPN Local Rts	The total number of configured local VPN routes
Total VPN-IPv4 Rem. Rts	The total number of configured remote VPN-IPv4 routes
Total VPN-IPv4 Rem. Act. Rts	The total number of active remote VPN-IPv4 routes used in the forwarding table
Total VPN Supp. Rts	The total number of suppressed VPN routes due to route damping

Table 162 BGP Summary Field Descriptions (Continued)

Label	Description
Total VPN Hist. Rts	The total number of VPN routes with history due to route damping
Total VPN Decay Rts	The total number of decayed routes due to route damping
Neighbor	The BGP neighbor address
AS (Neighbor)	The BGP neighbor autonomous system number
PktRcvd	The total number of packets received from the BGP neighbor
PktSent	The total number of packets sent to the BGP neighbor
InQ	The number of BGP messages to be processed
OutQ	The number of BGP messages to be transmitted
Up/Down	The amount of time that the BGP neighbor has either been established or not established depending on its current state
State Recv/Actv/Sent (Addr Family)	The BGP neighbor's current state (if not established) or the number of received routes, active routes and sent routes (if established), along with the address family

servers

Syntax	servers [all]
Context	show>router>dhcp show>router>dhcp6
Description	This command lists the local DHCP or DHCPv6 servers.
Parameters	all — displays DHCP or DHCPv6 servers in all instances
Output	The following output is an example of DHCP server information, and Table 163 describes the fields.

Output Example

```
*A:ALU-1# show router dhcp servers
=====
Overview of DHCP Servers
=====
Active Leases:      1
Maximum Leases:    4096

Router              Server              Admin State
-----

Service: 102        vprnServer           inService
=====
*A:ALU-1#
```

Table 163 DHCP or DHCPv6 Server Field Descriptions

Label	Description
Active Leases	The number of active leases
Maximum Leases	The maximum number of leases available
Router	The name of the router
Server	The name of the DHCP or DHCPv6 server
Admin State	The administrative state of the DHCP or DHCPv6 server

statistics

- Syntax** **statistics** [**interface** *ip-int-name* | *ip-address*]
- Context** show>router>dhcp
show>router>dhcp6
- Description** This command displays statistics for DHCP Relay and DHCPv6 Relay.
- If no interface name or IP address is specified, then all configured interfaces are displayed. If the **statistics** command is used in the **dhcp6** context, the interface name or IP address cannot be specified.
- Parameters** *ip-int-name* | *ip-address* — displays statistics for the specified IP interface
- Output** The following outputs are examples of DHCP or DHCPv6 statistics information:
- DHCP statistics ([Output Example, Table 164](#))
 - DHCPv6 statistics ([Output Example, Table 165](#))

Output Example

```
*A:ALU-1# show router dhcp statistics
=====
DHCP Global Statistics (Router: Base)

=====
*A:ALU-48#

```

Table 166 DHCP Summary Field Descriptions

Label	Description
DHCP Summary (Router: Base)	
Interface Name SapId/Sdp	The name of the interface or SAP/SDP identifier
Arp Populate	Specifies whether ARP populate is enabled or disabled
Used/Provided	Used — number of lease-states that are currently in use on the specified interface; that is, the number of clients on the interface that got an IP address by DHCP. This number is always less than or equal to the “Provided” field.
	Provided — lease-populate value configured for the specified interface
Info Option	Keep — the existing information is kept on the packet and the router does not add any additional information
	Replace — on ingress, the existing information-option is replaced with the information-option from the router
	Drop — the packet is dropped and an error is logged
Admin State	The administrative state
Interfaces	The total number of DHCP interfaces

Output Example

```

*A:ALU-48# show router dhcp6 summary

Table 167 DHCPv6 Summary Field Descriptions

Label	Description
DHCP Summary (Router: Base)	
Interface Name SapId	The name of the interface or SAP/SDP identifier
Nbr Resol.	Yes — neighbor resolution (discovery) is enabled
	No — neighbor resolution (discovery) is disabled
Used/Max Relay:	Used — number of relay routes currently being used on the interface
	Max Relay — maximum number of relay routes on the interface
Used/Max Server	Used — number of server routes currently being used on the interface
	Max Server — maximum number of server routes currently being used on the interface
Admin	The administrative state
Oper Relay	The operating state of the relay routes
Oper Server	The operating state of the server routes
Interfaces	The total number of DHCPv6 interfaces

interface

Syntax **interface** *[[ip-address | ip-int-name] [detail]]* | **[summary]** | **[exclude-services]**

Context show>router

Description This command displays the router IP interface table sorted by interface index.

Parameters *ip-address* — the IP address of the interface for which to display information
ip-int-name — the IP interface name for which to display information
detail — displays detailed IP interface information for the router
summary — displays summary IP interface information for the router
exclude-services — displays IP interface information, excluding IP interfaces configured for customer services. Only core network IP interfaces are displayed.

Output The following output is an example of standard IP interface information, and [Table 168](#) describes the fields.

Output Example

```

*A:ALU-12# show router 6 interface

Adm	The administrative state of the interface
Opr (v4/v6)	The operational state of the interface (only ipv4 addresses apply)
Type	The service type
Port/SapId PfxState	The port or SAP associated with the interface

msdp

- Syntax** **msdp**
- Context** show>router
- Description** This command enables the context to display MSDP information.

group

- Syntax** **group** [group-name] [detail]
- Context** show>router>msdp
- Description** This command displays information about MSDP groups.

Parameters *group-name* — displays information about the specified group. If no *group-name* is specified, information about all groups is displayed.

detail — displays detailed MSDP group information

Output The following output is an example of MSDP group information, and [Table 169](#) describes the fields.

Output Example

```

Table 169 MSDP Group Field Descriptions

Label	Description
Group Name	Displays the MSDP group name
Mode	Displays the mode of peers in the group, either Mesh-group or Standard
Act Srcs	Displays the configured maximum number of SA messages that will be accepted by MSDP
Local Address	Displays the local end of an MSDP session
Admin State	Displays the administrative state
Receive Msg Rate	Displays the rate that the messages are read from the TCP session
Receive Msg Time	Displays the time interval in which the number of MSDP messages set by the receive-msdp-msg-rate <i>number</i> parameter are read from the TCP session
Receive Msg Thd	Displays the configured threshold for the number of MSDP messages that can be processed before the MSDP message rate-limiting function is activated
SA Limit	Displays the SA message limit
Export Policy	Displays whether an export policy is configured or inherited
Import Policy	Displays whether an import policy is configured or inherited

peer

Syntax **peer** [*ip-address*] [**group** *group-name*] [**detail**]

Context show>router>msdp

Description This command displays information about an MSDP peer.

Parameters *ip-address* — displays information about the peer with the specified IP address. If no IP address is specified, information about all MSDP peers is displayed.

group-name — displays information about peers in the specified group. If no *group-name* is specified, information about all MSDP peers display is displayed.

detail — displays detailed MSDP peer information

Output The following output is an example of MSDP peer information, and [Table 170](#) describes the fields.

source

- Syntax** `source [ip-address/mask] [type {configured | dynamic | both}] [detail]`
- Context** `show>router>msdp`
- Description** This command displays the discovery method for the specified multicast source. By default, all user-created sources are displayed.
- Parameters** *ip-address/mask* — specifies the IP address and mask for a multicast source
- Values** *ip-address* is in the format a.b.c.d
mask range is from 1 to 32
- configured** — displays user-created sources
- dynamic** — displays dynamically created sources
- both** — displays both user-configured and dynamically created sources
- detail** — displays detailed MSDP source information
- Output** The following output is an example of MSDP source information and [Table 171](#) describes the fields.

Output Example

```

Label	Description
Source	Displays the IP address of the MSDP peer
Type	Displays the type of peer
SA Limit	Displays the local IP address
Num Excd	Displays the number of times the global active source limit has been exceeded
Last Exceeded	Displays the date and time of the last state change of the peer

source-active

Syntax	source-active [{ group <i>ip-address</i> local originator <i>ip-address</i> peer <i>ip-address</i> source <i>ip-address</i> group <i>ip-address</i> source <i>ip-address</i> }] [detail]
Context	show>router>msdp
Description	This command displays source-active (SA) messages accepted by MSDP.
Parameters	group <i>ip-address</i> — displays information about the specified group IP address local — displays information about local SA messages originator <i>ip-address</i> — displays information about the specified originator IP address peer <i>ip-address</i> — displays information about the specified peer IP address source <i>ip-address</i> — displays information about the specified source IP address detail — displays detailed MSDP SA information
Output	The following output is an example of accepted MSDP SA messages information, and Table 172 describes the fields.

Output Example

Table 172 MSDP SA Field Descriptions

Label	Description
Grp Address	Displays the IP address of the group
Src Address	Displays the IP address of the source
Origin RP	Displays the originating rendezvous point (RP) address
Peer Address	Displays the IP address of the peer
State Timer	Displays the state timeout value. If the value reaches 0, the SA entry is removed.

source-active-rejected

- Syntax** **source-active-rejected** [**peer-group** *name*] [**group** *ip-address*] [**source** *ip-address*] [**originator** *ip-address*] [**peer** *ip-address*]
- Context** show>router>msdp
- Description** This command displays SA messages rejected by MSDP.
- Parameters** *name* — displays information about rejected SA messages for the specified peer group

group *ip-address* — displays information about the specified group IP address

source *ip-address* — displays information about the source address of the source-active entry that is rejected

originator *ip-address* — displays information about the specified originator IP address

peer *ip-address* — displays information about the peer from which this rejected source-active entry was last received

Output The following output is an example of rejected MSDP SA messages information, and [Table 173](#) describes the fields.

Output Example

```
*A:ALA-48# show router 100 msdp source-active-rejected

Table 175 **MSDP Status Field Descriptions**

Label	Description
Admin State	Displays the administrative state
Local Address	Displays the local IP address
Global Statistics	Displays global MSDP statistics
Active Src Limit	Displays the active source limit
Act Src Lim Excd	Displays the number of times that the active source limit was exceeded
Num. Peers	Displays the number of peers
Num. Peers Estab	Displays the number of peers established
Num. Source Active	Displays the number of active sources
Policies	Specifies the policy used to export the SA state from the SA list into MSDP
Data Encapsulation	Specifies whether the rendezvous point (RP) encapsulates multicast data received in MSDP register messages inside forwarded MSDP SA messages
Rate	The receive message rate
Time	The receive message interval
Threshold	The number of MSDP messages that can be processed before the MSDP message rate-limiting function is activated
Last Msdp Enabled	The time the last MSDP was triggered

route-table

Syntax	route-table [<i>family</i>] [<i>ip-prefix[/prefix-length]</i>] [longer exact protocol <i>protocol-name</i>] [all] [next-hop-type <i>type</i>] [alternative] route-table [<i>family</i>] summary route-table [<i>family</i>] [<i>ip-prefix[/prefix-length]</i>] [longer exact protocol <i>protocol-name</i>] extensive [all]		
Context	show>router		
Description	This command displays the active routes in the routing table. If no command line arguments are specified, all routes are displayed, sorted by prefix. The following adapter cards and platforms support the full IPv6 subnet range for IPv6 static routes: • 6-port Ethernet 10Gbps Adapter card • 8-port Gigabit Ethernet Adapter card, version 2 and version 3 • 2-port 10GigE (Ethernet) Adapter card (on the v-port) • 10-port 1GigE/1-port 10GigE X-Adapter card • 7705 SAR-X For these cards and platforms, the supported route range for statically provisioned or dynamically learned routes is from /1 to /128. For all other cards, modules, and ports (including the v-port on the 2-port 10GigE (Ethernet) module), the supported range for statically provisioned or dynamically learned routes is from /1 to /64 or is /128 (indicating a host route).		
Parameters	<i>family</i> — specifies the type of routing information to be distributed by this peer group		
	Values	ipv4 — displays the routes that have the IPv4 family enabled, excluding IP-VPN routes ipv6 — displays the routes that are IPv6-capable, including IPv6 static routes mcast-ipv4 — displays the routes that are IPv4 multicast-capable mcast-ipv6 — displays the routes that are IPv6 multicast-capable	
		<i>ip-prefix/prefix-length</i> — displays only those entries matching the specified IP prefix and prefix length	
	Values	<i>ipv4-prefix</i>	a.b.c.d (host bits must be 0)
		<i>ipv4-prefix-length</i>	0 to 32
		<i>ipv6-prefix</i>	x:x:x:x:x:x:x (eight 16-bit pieces)
			x:x:x:x:x:x.d.d.d.d
			x: [0 to FFFF]H
			d: [0 to 255]D

ipv6-prefix-length {0 to 128} | {0 to 64 | 128}

longer — displays routes matching the *ip-prefix/prefix-length* and routes with longer masks

exact — displays the exact route matching the *ip-prefix/prefix-length* masks

protocol-name — displays routes learned from the specified protocol

Values bgp, bgp-vpn, isis, local, ospf, rip, static, aggregate, vpn-leak, managed

all — displays all routes, including inactive routes

type — displays tunneled next-hop information

alternative — displays LFA and backup route details

extensive — displays next-hop FIB information for the route table

summary — displays route table summary information

Output The following outputs are examples of routing table information:

- standard and extensive route table information ([Output Example, Table 176](#))
- LFA and backup route table information ([Output Example, Table 177](#))

Output Example

```
*A:ALU# show router route-table

Table 176 Standard and Extensive Route Table Field Descriptions

Label	Description
Dest Prefix	The route destination address and mask
[Flags]	n — Number of times nexthop is repeated Backup — BGP backup route LFA — Loop-free alternate next hop S — Sticky ECMP requested
Next Hop	The next-hop IP address for the route destination
Type	Local — the route is a local route
	Remote — the route is a remote route
Protocol	The protocol through which the route was learned
Age	The route age in seconds for the route
Metric	The route metric value for the route
Pref	The route preference value for the route
No. of Routes	The number of routes displayed in the list
Interface	The interface name of the next hop
QoS	The FC and priority associated with the next hop
Source-Class	The source class value, 0 to 255
Dest-Class	The destination class value, 0 to 255
ECMP-Weight	The fractional share of bandwidth for the next hop, either N/A or 1 to 32
No. of Destinations	The total number of next-hop destinations

Syntax	sgt-qos
Context	show>router
Description	This command displays QoS information about self-generated traffic.
Parameters	<i>service-id</i> — specifies the service identifier of the service
Values	1 to 2147483647 or <i>service-name</i>

application

Syntax	application [<i>app-name</i>] [dscp dot1p]
Context	show>router>sgt-qos
Description	This command displays application QoS settings.
Parameters	<i>app-name</i> — the specified application
Values	arp, bgp, cflowd, dhcp, dns, ftp, icmp, igmp, isis, ldp, mld, ndis, ntp, ospf, pim, ptp, radius, rip, rsvp, snmp, snmp-notification, ssh, syslog, tacplus, telnet, tftp, traceroute, vrrp

- Note:**
- PTP in the context of SGT QoS is defined as Precision Timing Protocol and is an application in the 7705 SAR. The PTP application name is also used in areas such as event-control and logging. Precision Timing Protocol is defined in IEEE 1588-2008.
 - PTP in the context of IP filters is defined as Performance Transparency Protocol. IP protocols can be used as IP filter match criteria; the match is made on the 8-bit protocol field in the IP header.

dscp — specifies to show all DSCP applications

dot1p — specifies to show all dot1p applications

Output The following output is an example of application QoS information, and [Table 178](#) describes the fields.

Output Example

```
*A:ALU-1>show# router 6 sgt-qos application

Table 178 Application QoS Field Descriptions

Label	Description
Application	The DSCP or dot1p application
DSCP Value	The DSCP name or value assigned to the application; if you assign a value to the application (0 to 63), the DSCP name that maps to the value is displayed
Default DSCP Value	The default DSCP value
Dot1p Value	The dot1p priority assigned to the application (applies only to ARP and IS-IS)
Default Dot1p Value	The default dot1p value

dscp-map

Syntax	dscp-map [<i>dscp-name</i>]
Context	show>router>sgt-qos
Description	This command displays the DSCP-to-FC mappings.
Parameters	<i>dscp-name</i> — the specified DSCP name.
Values	be ef cp1 cp2 cp3 cp4 cp5 cp6 cp7 cp9 cs1 cs2 cs3 cs4 cs5 nc1 nc2 af11 af12 af13 af21 af22 af23 af31 af32 af33 af41 af42 af43 cp11 cp13 cp15 cp17 cp19 cp21 cp23 cp25 cp27 cp29 cp31 cp33 cp35 cp37 cp39 cp41 cp42 cp43 cp44 cp45 cp47 cp49 cp50 cp51 cp52 cp53 cp54 cp55 cp57 cp58 cp59 cp60 cp61 cp62 cp63
Output	The following output is an example of DSCP-to-FC mapping information, and Table 179 describes the fields.

Output Example

```

Table 179 DSCP-to-FC Mapping Field Descriptions

Label	Description
DSCP Value	The DSCP values (displayed as names) of the self-generated traffic
FC Value	The FC value mapped to each DSCP value
Default FC Value	The default FC value

static-arp

Syntax	static-arp [<i>ip-address</i> <i>ip-int-name</i> mac <i>ieee-mac-addr</i>]
Context	show>router
Description	This command displays the router static ARP table sorted by IP address. If no options are present, all ARP entries are displayed.
Parameters	<i>ip-address</i> — the IP address for which static ARP entries are displayed <i>ip-int-name</i> — the interface name for which static ARP entries are displayed <i>ieee-mac-addr</i> — the MAC address for which static ARP entries are displayed
Output	The following output is an example of static ARP table information, and Table 180 describes the fields.

Output Example

```
*A:ALU-12# show router 6 static-arp
=====
ARP Table (Service: 6)
=====
IP Address      MAC Address      Expiry    Type    Interface

10.200.0.253    00:00:5a:40:00:01 00:00:00  Sta    to-ser1
12.200.1.1      00:00:5a:01:00:33 00:00:00  Inv     to-ser1a
-----
No. of ARP Entries: 2
=====
*A:ALU-12#
```

Table 180 Static ARP Table Field Descriptions

Label	Description
IP Address	The IP address of the static ARP entry
MAC Address	The MAC address of the static ARP entry
Expiry	The age of the ARP entry. Static ARPs always have 00:00:00 for the age.
Type	Inv—the ARP entry is an inactive static ARP entry (invalid)
	Sta—the ARP entry is an active static ARP entry
Interface	The IP interface name associated with the ARP entry
No. of ARP Entries	The number of ARP entries displayed in the list

static-route

Syntax	static-route [family] [ip-prefix/prefix-length] preference preference next-hop ip-address tag tag] [detail]		
Context	show>router		
Description	This command displays the static entries in the routing table.		
	If no options are present, all static routes are displayed sorted by prefix.		
	The following adapter cards and platforms support the full IPv6 subnet range for IPv6 static routes:		
	• 6-port Ethernet 10Gbps Adapter card • 8-port Gigabit Ethernet Adapter card, version 2 and version 3 • 2-port 10GigE (Ethernet) Adapter card (on the v-port) • 10-port 1GigE/1-port 10GigE X-Adapter card • 7705 SAR-X		
	For these cards and platforms, the supported route range for statically provisioned or dynamically learned routes is from /1 to /128.		
	For all other cards, modules, and ports (including the v-port on the 2-port 10GigE (Ethernet) module), the supported range for statically provisioned or dynamically learned routes is from /1 to /64 or is /128 (indicating a host route).		
Parameters	family — displays only the static routes with the specified family		
	Values	ipv4, ipv6, mcast-ipv4, or mcast-ipv6	
	ip-prefix/prefix-length — displays only the static routes matching the specified IP prefix and mask		
	Values	ipv4-prefix	a.b.c.d (host bits must be 0)
		ipv4-prefix-length	0 to 32
	Values	ipv6-prefix	x::x::x::x::x::x (eight 16-bit pieces)
			x::x::x::x::d.d.d.d
			x: [0 to FFFF]H
			d: [0 to 255]D
		ipv6-prefix-length	{0 to 128} {0 to 64 128}
	preference — displays static routes with the specified route preference		
Values	0 to 65535		
	ip-address — only displays static routes with the specified next-hop IP address		
Values	ipv4-address	a.b.c.d (host bits must be 0)	

ipv6-address x:x:x:x:x:x:x (eight 16-bit pieces)
 x:x:x:x:x:x:d.d.d.d
 x: [0 to FFFF]H
 d: [0 to 255]D

tag — displays the 32-bit integer tag added to the static route. The tag is used in route policies to control distribution of the route into other protocols.

Values 0 to 4294967295

detail — displays detailed information about the static route

Output The following output is an example of static route information, and [Table 181](#) describes the fields.

Output Example

```
*A:ALU-12# show router 6 static-route

Table 181 Static Route Field Descriptions

Label	Description
Prefix	The static route destination address and mask
Next Hop Nexthop	The next hop for the static route destination
Tag	The 32-bit integer tag added to the static route
Met Metric	The route metric value for the static route
Pref Preference	The route preference value for the static route
Type	BH—the static route is a blackhole route, where the next hop for this type of route is black-hole
	ID—the static route is an indirect route, where the next hop for this type of route is the non-directly connected next hop
	NH—the route is a static route with a directly connected next hop
	GRT—the route is a static route for the GRT next hop
	IPSec—the route is a static route for the IPSec tunnel next hop
Act Active	N—the static route is inactive; for example, the static route is disabled or the next-hop IP interface is down
	Y—the static route is active
Interface	The egress IP interface name for the static route n/a — indicates there is no current egress interface because the static route is inactive or a black hole route
Prefix List	Identifies the prefix list used for this static route
Prefix List Type	Identifies the type of prefix list used for this static route
Admin State	The administrative state for this static route
Creation Origin	The method by which the static route was created: manual or automatic (dynamic)
BFD	The BFD state for this static route (enabled or disabled)
CPE-check	The configured state of CPE check for this static route (enabled or disabled)
Tunnel Resolution	n/a

Table 181 Static Route Field Descriptions (Continued)

Label	Description
Disallow-IGP	n/a
RSVP-TE Tunnels	n/a
LDP Tunnels	n/a
SR-ISIS Tunnels	n/a
SR-OSPF Tunnels	n/a
SR-TE Tunnels	n/a
Inactive Reason	Indicates the reason for the static route being inactive
No. of Static Routes:	The number of static routes displayed in the list

tunnel-table

Syntax **tunnel-table summary** [ipv4 | ipv6]
tunnel-table [protocol *protocol*] {ipv4 | ipv6}
tunnel-table [*ip-prefix[/mask]*] [alternative] [ipv4 | ipv6] detail
tunnel-table [*ip-prefix[/mask]*] [alternative]
tunnel-table [*ip-prefix[/mask]*] protocol *protocol* [detail]
tunnel-table [*ip-prefix[/mask]*] sdp *sdp-id*

Context show>router

Description This command displays tunnel table information.

If the **auto-bind-tunnel** command is used when configuring a VPRN service, it means that the MP-BGP next-hop resolution is referring to the core routing instance for IP reachability. For a VPRN service, the next hop specifies the lookup to be used by the routing instance if no SDP to the destination exists.

Parameters *ip-prefix[/mask]* — displays the specified tunnel table destination IP address and mask

Values

ipv4-prefix:	a.b.c.d
ipv4-prefix-length:	[0..30]
ipv6-prefix:	x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d
	x - [0 to FFFF]H
	d - [0 to 255]D
ipv6-prefix-length:	[0 to 126]

protocol — displays protocol information

Values bgp, ldp, rsvp, sdp, ospf, isis, sr-te, fpe

sdp-id — displays information pertaining to the specified SDP

Values 1 to 17407

summary — displays summary tunnel table information

detail — displays detailed tunnel table information

alternative — displays backup route details

ipv4 — displays information for IPv4 entries only

ipv6 — displays information for IPv6 entries only

Output The following output is an example of tunnel table information, and [Table 182](#) describes the fields.

Output Example

```
*A:Sar18 Dut-B>show>router# tunnel-table summary

Table 182 Tunnel Table Field Descriptions

Label	Description
Destination	The route destination address and mask
Owner	The tunnel owner (protocol)
Encap	The tunnel encapsulation type
Tunnel ID	The tunnel (SDP) identifier

Table 182 Tunnel Table Field Descriptions (Continued)

Label	Description
Pref Preference	The route preference for routes learned from the configured peers
Nexthop	The next hop for the route destination
Metric	The route metric value for the route
CBF Classes	n/a
Tunnel Flags	The tunnel flags
Tunnel Label	The tunnel label
Tunnel Metric	The tunnel metric
Tunnel MTU	The tunnel MTU
Max Label Stack	The maximum label stack depth
Age	The tunnel age (that is, how long the tunnel has been operational)

7.8.2.4 Clear Service Commands

msdp

Syntax	msdp
Context	clear>router
Description	This command enables the context to clear and reset Multicast Source Discovery Protocol (MSDP) entities and statistics.

cache

Syntax	cache [peer <i>ip-address</i>] [group <i>ip-address</i>] [source <i>ip-address</i>] [originrp <i>ip-address</i>]
Context	clear>router>msdp
Description	This command clears IP addresses from the MSDP cache.
Parameters	peer <i>ip-address</i> — clears the specified peer address group <i>ip-address</i> — clears the specified group address source <i>ip-address</i> — clears the specified source address originrp <i>ip-address</i> — clears the specified originating rendezvous point (RP) address

statistics

Syntax	statistics [peer <i>ip-address</i>]
Context	clear>router>msdp
Description	This command clears IP address statistics for the peer to which MSDP SA requests for groups matching this entry's group range were sent.
Parameters	<i>ip-address</i> — clears the MSDP statistics for the specified IP address

id

Syntax	id <i>service-id</i>
Context	clear>service clear>service>statistics
Description	This command clears data for a specific service.

Parameters	<i>service-id</i> — the ID that uniquely identifies a service
Values	1 to 2147483647 or <i>service-name</i> (64 characters maximum)

arp

Syntax	arp
Context	clear>service>id
Description	This command clears all ARP entries.

dhcp

Syntax	dhcp
Context	clear>service>id
Description	This command enables the context to clear and reset DHCP entities.

statistics

Syntax	statistics [sap <i>sap-id</i> sdp <i>sdp-id:vc-id</i> interface { <i>ip-int-name</i> <i>ip-address</i> }]
Context	clear>service>id>dhcp
Description	This command clears DHCP statistics for a specified IP interface.
Parameters	<i>ip-int-name</i> — the name of the IP interface on which to clear DHCP statistics, up to 32 characters (must start with a letter) <i>sap-id</i> — the SAP ID on which to clear DHCP statistics. See Table 41 for a full list of SAP IDs. <i>sdp-id</i> — the spoke SDP ID on which to clear DHCP statistics Values 1 to 17407 <i>vc-id</i> — the virtual circuit ID on the SDP ID for which to clear DHCP information Values 1 to 4294967295 <i>ip-address</i> — the IP address of the IP interface

dhcp6

Syntax	dhcp6
Context	clear>service>id
Description	This command enables the context to clear and reset DHCPv6 entities.

statistics

Syntax	statistics [interface { <i>ip-int-name</i> <i>ipv6-address</i> }]
Context	clear>service>id>dhcp6
Description	This command clears DHCPv6 statistics for this IP interface.
Parameters	interface — clears only DHCPv6 statistics for a specified interface name <i>ip-int-name</i> — the name of the IPv6 interface <i>ipv6-address</i> — the address of the IPv6 interface

ip-transport

Syntax	ip-transport <i>ipt-id</i>
Context	clear>service>id
Description	This command clears configured information pertaining to a specified IP transport subservice. If no port identifier is specified, information is cleared for all IP transport subservices.
Parameters	<i>ipt-id</i> — the IP transport subservice physical port identifier, in the format <i>slot/mda/port.channel</i>

remote-host

Syntax	remote-host <i>host-id</i>
Context	clear>service>id>ip-transport
Description	This command clears configured information pertaining to a specified remote host assigned to this IP transport subservice.
Parameters	<i>host-id</i> — the remote host identifier Values 1 to 2147483647 or a name string up to 64 characters long

statistics

Syntax	statistics
Context	clear>service>id>ip-transport clear>service>id>ip-transport>remote-host
Description	This command clears statistics-related information pertaining to all configured IP transport subservices or to all configured remote hosts for a specified IP transport subservice.

mesh-sdp

Syntax	mesh-sdp <i>sdp-id</i> [: <i>vc-id</i>] ingress-vc-label
Context	clear>service>id
Description	This command clears and resets the mesh SDP binding for the service.
Parameters	<i>sdp-id</i> — the mesh SDP ID to be reset Values 1 to 17407 <i>vc-id</i> — the virtual circuit ID on the SDP ID to be reset Values 1 to 4294967295

mfib

Syntax	mfib
Context	clear>service>id
Description	This command enables the context to clear Multicast Forwarding Information Base (MFIB)-related data.

statistics

Syntax	statistics { all ip mac group <i>grp-address</i> }
Context	clear>service>id>mfib
Description	This command clears MFIB statistics.
Parameters	all — clears all MFIB statistics for the service ID ip — clears MFIB statistics for the specified IP address Values a.b.c.d mac — clears MFIB statistics for the specified MAC address

grp-address — clears MFIB statistics for the specified group address

Values *ip-address:* a.b.c.d
 ieee-address: xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx

spoke-sdp

Syntax **spoke-sdp** *sdp-id:vc-id ingress-vc-label*

Context clear>service>id

Description This command clears and resets the spoke SDP binding for the service.

Parameters *sdp-id* — the spoke SDP ID to be reset

Values 1 to 17407

vc-id — the virtual circuit ID on the SDP ID to be reset

Values 1 to 4294967295

ingress-vc-label — the locally assigned ingress service label

statistics

Syntax **statistics**

Context clear>service>statistics

Description This command enables the context to clear statistics data.

cem

Syntax **cem**

Context clear>service>statistics>id

Description This command clears Circuit Emulation (CEM) statistics for the service.

counters

Syntax **counters**

Context clear>service>statistics>id

Description This command clears all traffic queue counters statistics associated with the service.

mesh-sdp

Syntax	mesh-sdp <i>sdp-id[:vc-id]</i> { all counters stp }
Context	clear>service>statistics>id
Description	This command clears and resets the mesh SDP binding statistics for the service.
Parameters	<i>sdp-id</i> — the mesh SDP ID to be reset Values 1 to 17407 <i>vc-id</i> — the virtual circuit ID on the SDP ID to be reset Values 1 to 4294967295

spoke-sdp

Syntax	spoke-sdp <i>sdp-id:vc-id</i> { all counters }
Context	clear>service>statistics>id
Description	This command clears statistics for the spoke SDP bound to the service.
Parameters	<i>sdp-id</i> — the spoke SDP ID for which to clear statistics Values 1 to 17407 <i>vc-id</i> — the virtual circuit ID on the SDP ID to be reset Values 1 to 4294967295 all — clears all queue statistics associated with the SDP counters — clears all queue counters associated with the SDP

sap

Syntax	sap <i>sap-id</i> { all cem counters }
Context	clear>service>statistics
Description	This command clears statistics for the SAP bound to the service.
Parameters	<i>sap-id</i> — specifies the physical port identifier portion of the SAP definition. See Table 41 for a full list of SAP IDs. all — clears all queue statistics associated with the SAP cem — clears all CEM statistics associated with the SAP counters — clears all queue counters associated with the SAP

sap-aggregation-group

Syntax	sap-aggregation-group <i>svclId-id:groupName</i> { all counters }
Context	clear>service>statistics
Description	This command clears statistics for a specified SAP aggregation group.
Parameters	<i>svclId-id:groupName</i> — the service ID or group name, up to 96 characters all — clears all queue statistics associated with the SAP aggregation group counters — clears all queue counters associated with the SAP aggregation group

sdp

Syntax	sdp <i>sdp-id</i> keep-alive
Context	clear>service>statistics
Description	This command clears keepalive statistics associated with the SDP ID.
Parameters	<i>sdp-id</i> — the SDP ID for which to clear statistics Values 1 to 17407 keep-alive — clears the keepalive history associated with this SDP ID

7.8.2.5 Debug MSDP Commands

msdp

Syntax	[no] msdp
Context	debug>router
Description	This command enables debugging for Multicast Source Discovery Protocol (MSDP). The no form of the command disables MSDP debugging.

packet

Syntax	packet [<i>pkt-type</i>] [peer <i>ip-address</i>]
Context	debug>router>msdp
Description	This command enables debugging for MSDP packets. The no form of the command disables MSDP packet debugging.
Parameters	<i>pkt-type</i> — debugs information associated with the specified packet type Values keep-alive, source-active, sa-request, sa-response <i>ip-address</i> — debugs information associated with the specified peer IP address

pim

Syntax	pim [<i>grp-address</i>] no pim
Context	debug>router>msdp
Description	This command enables debugging for MSDP PIM. The no form of the command disables MSDP PIM debugging.
Parameters	<i>grp-address</i> — debugs the IP multicast group address for which this entry contains information

rtm

Syntax	rtm [<i>rp-address</i>] no rtm
Context	debug>router>msdp
Description	This command enables debugging for MSDP route table manager (RTM). The no form of the command disables MSDP RTM debugging.
Parameters	<i>rp-address</i> — debugs the IP multicast address for which this entry contains information

sa-db

Syntax	sa-db [group <i>grpAddr</i>] [source <i>srcAddr</i>] [rp <i>rpAddr</i>] no sadb
Context	debug>router>msdp
Description	This command enables debugging for MSDP source-active (SA) requests. The no form of the command disables the MSDP SA database debugging.
Parameters	<i>grpAddr</i> — debugs the IP address of the group <i>srcAddr</i> — debugs the source IP address <i>rpAddr</i> — debugs the specified rendezvous point RP address

7.8.2.6 Debug Service Commands

id

Syntax	id <i>service-id</i> no id <i>service-id</i>
Context	debug>service
Description	This command enables the debugging context for a specific service. The no form of the command disables debugging for the service.
Parameters	<i>service-id</i> — the ID that uniquely identifies a service Values 1 to 2147483647 or <i>service-name</i>

dhcp

Syntax	dhcp no dhcp
Context	debug>service>id
Description	This command enables the context for DHCP debugging. The no form of the command disables DHCP debugging.

detail-level

Syntax	detail-level { low medium high } no detail-level
Context	debug>service>id>dhcp debug>service>id>dhcp6
Description	This command enables DHCP and DHCPv6 detail level tracing. The no form of the command disables the detail level tracing.

mac

Syntax	mac <i>ieee-address</i> no mac <i>ieee-address</i>
Context	debug>service>id>dhcp debug>service>id>dhcp6
Description	This command enables debugging for a specified MAC address. The no form of the command disables debugging for the MAC address.
Parameters	<i>ieee-address</i> — the MAC address Values xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx

mode

Syntax	mode { dropped-only ingr-and-dropped egr-ingr-and-dropped } no mode
Context	debug>service>id>dhcp
Description	This command enables the DHCP tracing mode. The no form of the command disables the tracing mode.

sap

Syntax	sap <i>sap-id</i> no sap <i>sap-id</i>
Context	debug>service>id>dhcp debug>service>id>dhcp6
Description	This command enables debugging for a specific SAP. The no form of the command disables the debugging for the SAP.
Parameters	<i>sap-id</i> — the physical port identifier portion of the SAP definition. See Table 41 for a full list of SAP ID

sdp

Syntax	sdp <i>sdp-id:vc-id</i> no sdp <i>sdp-id:vc-id</i>
Context	debug>service>id>dhcp
Description	This command enables debugging for a specific SDP. The no form of the command disables the debugging for the SDP.
Parameters	<i>sdp-id</i> — the mesh SDP or spoke SDP ID; for a mesh SDP, the VC ID is optional Values 1 to 17407 <i>vc-id</i> — the virtual circuit ID on the SDP ID Values 1 to 4294967295

dhcp6

Syntax	dhcp6 no dhcp6
Context	debug>service>id
Description	This command enables the context for DHCPv6 debugging. The no form of the command disables DHCPv6 debugging.

mode

Syntax	mode { all dropped-only } no mode
Context	debug>service>id>dhcp6
Description	This command enables the DHCPv6 tracing mode. The no form of the command disables the tracing mode.

event-type

Syntax	event-type { config-change svc-oper-status-change sap-oper-status-change sdpbind-oper-status-change } no event-type
Context	debug>service>id
Description	This command enables debugging for an event type. The no form of the command disables debugging on the event type.

sap

Syntax	sap <i>sap-id</i> no sap <i>sap-id</i>
Context	debug>service>id
Description	This command enables debugging for a specific SAP. The no form of the command disables debugging for the SAP.
Parameters	<i>sap-id</i> — the physical port identifier portion of the SAP definition. See Table 41 for a full list of SAP IDs.

sdp

Syntax	sdp <i>sdp-id:vc-id</i> no sdp <i>sdp-id:vc-id</i>
Context	debug>service>id
Description	This command enables debugging for a specific SDP. The no form of the command disables the debugging for the SDP.
Parameters	<i>sdp-id</i> — the mesh SDP or spoke SDP ID Values 1 to 17407 <i>vc-id</i> — the virtual circuit ID on the SDP ID Values 1 to 4294967295

8 IPSec

This chapter provides information to configure security parameters.

Topics in this chapter include:

- [IPSec Overview](#)
- [Public Key Infrastructure \(PKI\)](#)
- [Best Practices Recommendations](#)
- [Configuration Notes](#)
- [Configuring IPSec with CLI](#)
- [IPSec Command Reference](#)

8.1 IPSec Overview

This section contains the following topics:

- [IPSec Implementation](#)
- [X.509v3 Certificate Overview](#)
- [Using Certificates For IPSec Tunnel Authentication](#)
- [Trust Anchor Profile](#)
- [Certificate Profile](#)
- [Certificate Management Protocol Version 2 \(CMPv2\)](#)
- [OCSP](#)
- [Applications](#)
- [NAT-Traversal for IKEv1/v2 and IPSec](#)
- [BFD over IPSec Tunnel](#)
- [QoS for IPSec Support for Private VPRN Service Features](#)
- [Fragmentation and IP MTU](#)
- [Support for Private VPRN Service Features](#)
- [Routing in Private Services](#)
- [IPSec on the 10-port 1GigE/1-port 10GigE X-Adapter Card](#)
- [IPSec Sequence Number](#)

8.1.1 IPSec Implementation

This section contains the following topics:

- [IPSec Overview](#)
- [Hardware Support](#)
- [IPSec Encryption Features](#)
- [SHA2 Support](#)
- [IPSec Security Policy, IKE Policy, and IPSec Transform](#)
- [IKEv2 Fragmentation](#)
- [Tunnel Group](#)
- [Tunnel Interfaces and SAPs](#)
- [IPSec Tunnel Configuration](#)
- [IPSec over MPLS with Public Service IES](#)
- [IPSec Transport Tunnels with Public Service VPRN](#)
- [GRE-Encapsulated VLLs/VPLS over IPSec VPNs](#)
- [GRE-Encapsulated VLLs/VPLS over IPSec over MPLS](#)

8.1.1.1 IPSec Overview

IPSec is a structure of open standards to ensure private, secure communications over Internet Protocol (IP) networks by using cryptographic security services.

For IPSec, the 7705 SAR supports VPRN for the private side of the tunnel and IES or VPRN for the public side of the tunnel. In [Figure 130](#), a public service instance (IES, VPRN, or network) connects to the public network and a private service instance (VPRN) connects to the private network, which originates the traffic that is to be encrypted.

Figure 130 IPSec Implementation Architecture

24019

In [Figure 130](#), all ingress customer traffic from the trusted network is aggregated into the private VPN service, where a VPN static route directs the traffic into the encryption engine. The encryption engine encrypts the customer traffic using configurable encryption and authentication protocols, and adds the IPSec tunnel outer IP header. The source IP address of the outer IP header is the local security gateway address, and the destination IP address is the peer security gateway address.

The encrypted IPSec packet exits the node via an IES, VPN, or router interface that is configured on an encryption-capable adapter card; it gets routed to its destination via a standard FIB lookup.

IPSec traffic ingressing a public-side VPN that is not configured for IPSec is dropped.

If the traffic passes all security checks, it is decrypted and the customer traffic is routed through the associated VPN. Any traffic that does not match the tunnel security configuration is dropped.

8.1.1.2 Hardware Support

The 7705 SAR supports IPSec on the following nodes and adapter cards:

- 7705 SAR-8 with one of the following:
 - 8-port Gigabit Ethernet Adapter card, version 3
 - 6-port Ethernet 10Gbps Adapter card
 - 2-port 10GigE (Ethernet) Adapter card
- 7705 SAR-18 with one of the following:
 - 8-port Gigabit Ethernet Adapter card, version 3
 - 10-port 1GigE/1-port 10GigE X-Adapter card, version 2
 - 6-port Ethernet 10Gbps Adapter card
 - 2-port 10GigE (Ethernet) Adapter card
- 7705 SAR-Ax
- 7705 SAR-H
- 7705 SAR-Hc
- 7705 SAR-W
- 7705 SAR-Wx
- 7705 SAR-X

Note: On the 7705 SAR-X, each Ethernet port has its own encryption engine.

8.1.1.3 IPSec Encryption Features

IPSec provides a variety of encryption features required to establish bidirectional IPSec tunnels, including:

Control plane:

- manual keying
- dynamic keying: Internet key exchange version 1, version 2 (IKEv1, IKEv2)
- IKEv1 mode: main or aggressive
- authentication: pre-shared-key (PSK)
- perfect forward secrecy (PFS)
- dead peer detection (DPD)

- NAT-traversal (NAT-T)
- security policy

Data plane:

- Encapsulating security payload (ESP) (with authentication) tunnel mode
- IPSec transform (NULL cannot be used for authentication and encryption at the same time):
 - authentication algorithm: NULL/MD5/SHA1/SHA256/SHA384/SHA512
 - encryption algorithm: NULL/DES/3DES/AES128/AES192/AES256
- IPSec IKE policy (NULL is not supported):
 - authentication algorithm: MD5/SHA1/SHA256/SHA384/SHA512
 - encryption algorithm: DES/3DES/AES128/AES192/AES256
- DH-Group: 1/2/5/14/15

Note: The 7705 SAR uses a configured authentication algorithm in an IKE policy for the pseudorandom function (PRF).

The 7705 SAR supports the use of IPSec and segment routing with entropy label for:

- IPSec over BGP 3107 over segment routing with entropy label
- IPSec over static route over segment routing with entropy label
- VLL over GRE over IPSec over BGP 3107 over segment routing with entropy label
- VLL over GRE over IPSec over static route over segment routing with entropy label

8.1.1.4 SHA2 Support

The 7705 SAR supports RFC 4868. For data origin authentication and integrity verification functions in the IKEv1 or IKEv2 and ESP protocols, the 7705 SAR supports the following HMAC-SHA-256+ algorithms:

- AUTH_HMAC_SHA2_256_128
- AUTH_HMAC_SHA2_384_192
- AUTH_HMAC_SHA2_512_256

For pseudorandom functions (PRF) with IKEv1 or IKEv2, the 7705 SAR supports the following HMAC-SHA-256+ algorithms:

- PRF_HMAC_SHA2_256_128
- PRF_HMAC_SHA2_384_192
- PRF_HMAC_SHA2_512_256

8.1.1.5 IPSec Security Policy, IKE Policy, and IPSec Transform

An IPSec security policy defines the type of traffic allowed to pass in or out of an IPSec tunnel. The policy does this through the configuration of local and remote IP address pairs. The behavior of an IPSec security policy is similar to IP filtering. IPSec security policies are created for a VPRN service context and applied to an IPSec tunnel in that service.

An IKE policy defines how the 7705 SAR encrypts and authenticates an IPSec tunnel that uses that policy. Its configuration includes specifics on Diffie-Hellman key derivation algorithms, encryption and authentication protocols to be used for establishing phase 1 and phase 2 security associations, and so on.

An IPSec transform defines the algorithms used for IPSec SA. The transform configuration dictates the algorithms that customer traffic uses for encryption and authentication.

8.1.1.6 IKEv2 Fragmentation

IKEv2 uses UDP as the transport protocol for its messages. Most IKEv2 messages are relatively small. In some cases, though, an IKEv2 message can be large; for example, an IKE_AUTH message with a certificate payload. If the IKEv2 message size exceeds the network path MTU, it gets fragmented at the IP level into smaller IP fragments. However, some devices (such as firewalls) do not allow IP fragments to pass through the network. If the fragments do not pass through, IKE negotiation fails.

To address this problem, the 7705 SAR supports IKEv2 fragmentation, as specified in RFC 7383. With IKEv2 fragmentation, IKEv2 messages are fragmented at the IKEv2 protocol level into smaller messages. The resulting IP packets are smaller than the network path MTU and are therefore not fragmented through the network and can traverse network devices that do not allow IP fragments to pass through.

IKEv2 fragmentation is enabled in the **ike-policy** context by configuring the **ikev2-fragment** command with an MTU. The MTU specified is the maximum size of the IKEv2 packet.

The system enables IKEv2 fragmentation for a tunnel only if the **ikev2-fragment** command is configured and if the peer also announces its support by sending an IKEV2_FRAGMENTATION_SUPPORTED notification.

8.1.1.7 Tunnel Group

A tunnel group is a collection of IPSec tunnels. The 7705 SAR supports one tunnel group that always uses tunnel ID 1.

An IPSec tunnel belongs to only one tunnel group. The **show>isa>tunnel-group** command allows the operator to view information about the configured tunnel group.

8.1.1.8 Tunnel Interfaces and SAPs

There are two types of tunnel interfaces and associated SAPs:

- public tunnel interface: configured on the public-side IES or public-side VPRN service; outgoing tunnel packets have a source IP address (local gateway address) in this subnet
 - public tunnel SAP: associated with the public tunnel interface
- private tunnel interface: configured on the private-side VPRN service
 - private tunnel SAP: associated with the private tunnel interface, logically linked to the public tunnel SAP

8.1.1.8.1 Public Tunnel SAPs

An IES or VPRN service (the delivery service) must have at least one IP interface associated with a public tunnel SAP to receive and process the following types of packets associated with IPSec tunnels:

- IPSec ESP (IP protocol 50)
- IKEv1/v2 (UDP)

The public tunnel SAP type has the format **tunnel-tunnel-group-id.public:tag**, where *tunnel-group-id* is always 1. See [Configuring IPSec and IPSec Tunnels in Services](#) for a CLI configuration example.

8.1.1.8.2 Private Tunnel SAPs

The private (VPRN) service must have an IP interface to an IPSec tunnel in order to forward IP packets into the tunnel, causing them to be encapsulated according to the tunnel configuration, and to receive IP packets from the tunnel after the encapsulation has been removed (and decrypted). That IP interface is associated with a private tunnel SAP.

The private tunnel SAP has the format **tunnel-tunnel-group-id.private:tag**, where *tunnel-group-id* is always 1. The **tunnel** keyword must be used when creating the private tunnel interface. See [Configuring IPSec and IPSec Tunnels in Services](#) for a CLI configuration example.

8.1.1.8.3 IP Interface Configuration

The IP MTU of a private tunnel SAP interface can be configured. This sets the maximum payload IP packet size (including IP header) that can be sent into the tunnel and applies to the packet size before the tunnel encapsulation is added. When an IPv4 payload packet that needs to be forwarded to the tunnel is larger than M bytes, one of the following behaviors occurs.

- If the DF bit is clear (not set), the payload packet is fragmented to the MTU size prior to tunnel encapsulation.
- If the DF bit is set, the payload packet is discarded and (if allowed by the ICMP setting of the sending interface) an ICMP type 3/code 4 is returned to the sender (with the MTU of the private tunnel SAP interface in the payload).

8.1.1.9 IPSec Tunnel Configuration

To bind an IPSec tunnel to a private tunnel SAP, the **ipsec-tunnel** command is configured under the SAP context, where the **ipsec-tunnel** context provides access to the following parameters:

- security policy
- local gateway address
- dynamic keying
- IKE policy
- pre-shared key
- transform

The local gateway address must belong to the same subnet as the delivery-service (IES or VPRN) public tunnel interface address. The local gateway address and peer gateway address are the source and destination addresses for the outgoing IPSec traffic.

A private tunnel SAP can have only one IPSec tunnel.

8.1.1.10 IPSec over MPLS with Public Service IES

IPSec messages can be routed over MPLS tunneled routes. The 7705 SAR supports resolution of IPSec routes to the secure gateway address by using either BGP 3107 label routes or IGP shortcuts. When BGP learns IPv4 addresses as 3107 label routes, BGP resolves the next hops for these routes with an LDP or RSVP-TE tunnel. These BGP routes create BGP tunnels that can be used to resolve an IPSec secure gateway address. When an IGP shortcut is enabled on the 7705 SAR by using the **config>router>ospf>rsvp-shortcut** command, OSPF installs an OSPF route in the RIB, with an RSVP-TE LSP as the next hop. If this OSPF route is determined as the overall best route, then the next hop is an RSVP-TE tunnel. For information about setting up BGP 3107 label routes or IGP shortcuts to resolve IPSec routes, see [Configuring IPSec over MPLS](#).

8.1.1.11 IPSec Transport Tunnels with Public Service VPRN

Configuring VPRN as the public-side service of an IPSec tunnel ensures that IPSec traffic from different customers arriving at the 7705 SAR is kept separate. Keeping the traffic from different customers separated gives service providers another layer of security because a specific VPRN is assigned to a specific customer, and only the IPSec tunnels encrypted by that customer will arrive on that VPRN. In contrast, when IES is used for the public-side service of an IPSec tunnel, all IPSec traffic arrives in the GRT and fans out to its corresponding private service through the IPSec public gateway.

When the public-side service of an IPSec tunnel is a VPRN, IPSec traffic is transported over MPLS or GRE. The 7705 SAR supports the transport of GRE-encapsulated VLLs (Cpipes and Epipes) over IPSec tunnels that use VPRN as the public-side service of the IPSec tunnel.

MP-BGP services can be provisioned using auto-bind tunnels or SDPs to push IPSec packets over MPLS or GRE transport tunnels.

An MP-BGP VC label is pushed on top of the IPSec packet and a transport tunnel label is pushed next. The transport tunnel can include BGP-labeled unicast (BGP-LU) routes (3107 label routes).

Figure 131 shows the concept of a VPRN as the public-side service of an IPSec tunnel.

Figure 131 VPRN Public Service IPSec Transport Tunnels

27826

8.1.1.12 GRE-Encapsulated VLLs/VPLS over IPSec VPNs

The 7705 SAR can provide secure transport of Cpipe, Epipe, and VPLS traffic by routing it as GRE-encapsulated traffic over IPSec VPNs. This is achieved by enabling route processing in the GRT FIB through a GRT lookup at ingress to the VRF and GRT leaking at egress from the VRF. The 7705 SAR leaks only IPSec tunnels into the GRT as the available next hop; no other tunnel type is leaked from the VRF into the GRT as a next hop. This route processing is enabled with the **config>service>vprn>grt-lookup>enable-grt** command.

When a packet arrives at the VRF and the **grt-lookup>enable-grt** command is configured, the following sequence occurs.

- The packet undergoes a route lookup in the VRF FIB to determine the next hop.
- If there is no matching route found in the VRF, a route lookup is then performed in the GRT FIB.
- If there is a match for the route in the GRT FIB and the packet is:
 - an IP packet with a local address, it will be extracted to the CSM and processed as a management packet
 - a GRE packet with a local address, it will be processed as a service packet
 - an IP or GRE packet with no local address, it will be routed to the available next hop as found in the GRT FIB

In order for a packet to leave the VRF, the route that needs to be resolved — the destination prefix — must be leaked to the GRT. The destination prefix is configured in a route policy using the **config>router>policy-options>prefix-list** command; that policy is then leaked into the GRT by referencing it in the **config>service>vpn>grt-lookup>export-grt** command. Packets with the matching route found in the GRT FIB are routed via the IPSec tunnel configured within the VPN.

The 7705 SAR supports the following packet types for GRT lookup in the VRF FIB:

- self-generated GRE packets for Cpipe, Epipe, and VPLS traffic
- self-generated IP packets for management, BGP, and T-LDP traffic
- transiting GRE packets over access and network interfaces
- transiting IP packets over access or network interfaces

The 7705 SAR supports the following packets types arriving in the VRF via the IPSec tunnel:

- IP packets, including management packets, with a local address
- GRE packets with a local address
- transiting IP packets via the GRT lookup
- transiting GRE packets via the GRT lookup

The 7705 SAR terminates GRE packets at a system IP address or any local interface IP address. When GRE-encapsulated packets are transported over an IPSec VPN, the IPSec tunnel can terminate on a 7705 SAR or 7750 SR and the GRE packets are processed on the secure gateway.

When configuring **grt-lookup**, the **config>service>vpn>static-route-entry>grt** command must be configured for the local IP address that will be looked up in the GRT. The next hop is set to the desired local IP address and is used on ingress to force a second route lookup in the GRT. If that lookup is successful, and the packet is a GRE packet destined to a local interface, it is forwarded for PW processing. If the packet is destined to a system IP address and is not GRE packet, it is forwarded for management processing. A second static route is required in the IPSec VPN in order to point the far-end IP address to the IPSec tunnel. It is used on egress and is configured for the far-end IP address with a next hop set to the IPSec tunnel.

By enabling GRT lookup, signaling packets such as T-LDP can be routed securely between two system IP addresses by using the IPSec tunnel. However, IGP protocols such as OSPF or IS-IS, which use a multicast destination, cannot use the IPSec tunnel.

Figure 132 shows an example of route leaking configured to resolve the far-end system IP address 10.0.0.2 using an IPSec VPN. Although the example shows GRE to a system IP address on the 7705 SAR for illustrative purposes, GRE to any other local IP address on the 7705 SAR can be substituted.

Figure 132 Routing GRE-Encapsulated Packets over IPSec

Based on Figure 132, the CLI example below shows the configuration of a routing policy that will be used to leak the far-end system IP address into the GRT. The command **config>router>policy-options>prefix-list>prefix** creates a prefix entry with the system IP address of the far-end node (10.0.0.2/32) in the route policy prefix list. The policy option is configured using the prefix specified above (10.0.0.32) with the action **accept**. The policy **preference** should be set so that it is lower than the IGP advertised preference.

```
#-----
*A:7705:Dut-A>config>router>policy-options# info
#-----
prefix-list "grt"
```

```

        prefix 10.0.0.2/32 exact
    exit
    policy-statement "grt"
        entry 1
            from
                prefix-list "grt"
            exit
            action accept
                local-preference 3
                preference 3
                metric-set 1
            exit
        exit
    exit

```

The far-end system IP address 10.0.0.2 is resolved using a static route configured with an IPSec tunnel next hop of “tunnel2”. The GRT lookup at the ingress VRF is enabled using the **config>service>vprn>grt-lookup>enable-grt** command and a second static route is configured to enable lookup at ingress for the local system IP address 10.0.0.14/32, as shown in the CLI example below:

```

#-----
*A:7705:Dut-A>config>sevice>vprn# info
#-----
        static-route-entry 10.10.0.2
            ipsec-tunnel "tunnel2"
            no shutdown
        exit
    exit
    static-route-entry 10.0.0.14/32
        grt
            no shutdown
        exit
    exit
    grt-lookup
        enable-grt
        export-grt grt
        exit
    exit
exit

```

The far-end system IP address with a next hop IPSec tunnel (“tunnel2”) is leaked into the GRT using the command **config>service>vprn>grt-lookup>export-grt**, referencing the routing policy configured above (“grt”).

A GRE-encapsulated SDP to the far-end system IP address is configured using the commands **config>service>sdp sdp-id gre create** and **config>service>sdp>far-end**. A Cpipe, Epipe, or VPLS is then configured using that SDP. For information about configuring a Cpipe or Epipe, see [Configuring a VLL Service with CLI](#) and [Configuring VLL Components](#) in this guide. For information about configuring a VPLS, see [Configuring a VPLS Service with CLI](#) in this guide.

For information about GRT lookup for management traffic, see “In-Band Management using a VPRN” in the VPRN Services chapter of this guide.

8.1.1.13 GRE-Encapsulated VLLs/VPLS over IPSec over MPLS

The 7705 SAR can route Cpipe, Epipe, or VPLS traffic over IPSec using either BGP 3107 Label routes or RSVP-TE IGP shortcuts.

When GRE-encapsulated Cpipe, Epipe, or VPLS traffic is routed over IPSec, the GRE packets and T-LDP packets can be routed to the far-end system IP address using the IPSec tunnel. However, there must be special consideration for the MPLS tunnel, in particular for BGP 3107 label routes using IBGP, since MPLS signaling packets cannot use an IPSec tunnel.

8.1.1.13.1 VLLs/VPLS over IPSec over MPLS (Using BGP 3107 Label Routes) Solution 1: Changing BGP Signaling to Loopback Interface

When resolving an IPSec route to the secure gateway address with a BGP 3107 label route, BGP can be set up to use either IBGP or EBGP.

The IBGP 3107 label route is usually set up to the system IP address. However, the Layer 2 services to be protected by IPSec are also set up to the system IP address. In this case routing the IBGP 3107 label routes via the IPSec tunnel creates some complexities.

To avoid routing both Layer 2 services and the IBGP (used for 3107) over the IPSec tunnel, IBGP should be setup to a loopback interface rather than to the system IP address. Also, all MPLS LSPs that will resolve these 3107 labels should be setup to the same loopback interface. For RSVP-TE this means the far end has to be the loopback interface and for LDP this means an originate-fec needs to be configured to the loopback interface.

Figure 133 shows an example of a BGP 3107 label route configured with a loopback interface.

Figure 133 VLL/VPLS over IPSec over MPLS Using BGP 3107 Label Routes

26202

Based on [Figure 133](#), the CLI example below shows BGP configured to a neighbor loopback address and the BGP local address configured as a local loopback address. BGP for 3107 label route advertisement is enabled using the **advertise-label ipv4** keyword.

```
#-----
*A:7705:Dut-A>config>router>bgp# info
#-----
    local-as 10
    group "2"
        peer-as 10
        local-address 10.10.0.14
        neighbor 10.10.0.2
            family vpn-ipv4
            export "gw"
            advertise-label ipv4
        exit
    exit
no shutdown
```

In addition, IGP must be configured to make the loopback IP addresses reachable for BGP.

The BGP 3107 label route can be resolved with either an LDP or an RSVP-TE tunnel. To use an LDP tunnel, an LDP FEC must be configured to advertise the local loopback IP address to the neighbor, as shown in the CLI example below:

```
#-----
*A:7705:Dut-A>config>router>ldp# info
#-----
    fec-originate 10.10.0.14/32 advertised-label 32 pop
```

To use an RSVP-TE tunnel, an LSP is created to the neighbor loopback IP address, as shown in the CLI example below:

```
#-----
*A:7705:Dut-A>config>router>mpls# info
#-----
    lsp "to-14-loop"
        to 10.10.0.2
        cspf
        no shutdown
    exit
```

With EBGp, BGP communicates between the local and neighbor IP interface so IGP is not required to resolve the BGP 3107 label routes. In the example shown in [Figure 133](#), the configuration would use Layer 3 interfaces rather than loopback addresses, as shown in the CLI example:

```
#-----
*A:7705:Dut-A>config>router>bgp# info
#-----
    local-as 10
```

```

group "2"
  peer-as 10
  neighbor 10.14.1.2
    family vpn-ipv4
    export "gw"
    advertise-label ipv4
  exit
exit
no shutdown

```

To use an LDP tunnel, an LDP FEC is configured to advertise the local interface IP address:

```

#-----
*A:7705:Dut-A>config>router>ldp# info
#-----
fec-originate 10.14.2.2/32 advertised-label 32 pop

```

To use an RSVP-TE tunnel, an LSP is created to the neighbor interface IP address:

```

#-----
*A:7705:Dut-A>config>router>mpls# info
#-----
lsp "to-14-loop"
  to 10.14.1.2
  cspf
  no shutdown
exit

```

8.1.1.13.2 VLLs/VPLS over IPSec over MPLS (Using BGP 3107 label Routes) Solution 2: GRE to Local Interface on 7705 SAR

When transporting a GRE-encapsulated VLL or VPLS over IPSec over MPLS, the 7705 SAR can terminate the GRE tunnel to a loopback address. In this scenario, the VLL or VPLS is created between the loopback interfaces and the BGP 3107 label route uses the system IP address to resolve the IPSec gateway. This relies on GRT lookup and leaking, but the far-end loopback IP address is used instead of the system IP address in the routing policy. [Figure 134](#) shows an example of VLL/VPLS over IPSec over MPLS using a loopback address, followed by CLI configuration examples.

Figure 134 VLL/VPLS over IPSec over MPLS using a Loopback Address

26203

Based on [Figure 134](#), a local loopback interface is configured on the 7705 SAR:

```
#-----
*A:7705:Dut-A>config>router# info
#-----
        interface "loop1"
            address 10.10.0.14
            loopback
            no shutdown
        exit
```

T-LDP signaling is configured to the far-end loopback IP address:

```
#-----
*A:7705:Dut-A>config>router>ldp# info
#-----
        targeted-session
            peer 10.10.0.2
            local-lsr-id "loop1"
            no shutdown
        exit
    exit
```

A routing policy is configured on the 7705 SAR using the loopback address of the secure gateway:

```
#-----
*A:7705:Dut-A>config>router>policy-options# info
#-----
        prefix-list "loop"
            prefix 10.10.0.2/32 exact
        exit
        policy-statement "loop"
            entry 1
                from
                    prefix-list "loop"
                exit
                action accept
                    local-preference 3
                    preference 3
                    metric-set 1
```

```

        exit
    exit
exit

```

The routing policy is then used to enable GRT lookup and leaking in the VPRN:

```

#-----
*A:7705:Dut-A>config>sevice>vprn# info
#-----
    static-route-entry 10.10.0.2
        ipsec-tunnel "tunnel2"
        no shutdown
    exit
exit
static-route-entry 10.0.0.14/32
    grt
        no shutdown
    exit
exit
grt-lookup
    enable-grt
    export-grt loop
    exit
    exit
exit

```

The GRE SDP is then created to the far-end loopback IP address:

```

#-----
*A:7705:Dut-A>config>sevice# info
#-----
    sdp 200 gre create
        far-end 10.10.0.2
        keep-alive
        shutdown
    exit
    no shutdown
exit

```

8.1.1.13.3 VLLs/VPLS over IPSec over MPLS (Using IGP Shortcuts)

BGP can route VLL or VPLS traffic over an IPSec VPN using an IGP shortcut to resolve the secure gateway address, as described in [Configuring IPSec over MPLS](#). Although the VLL or VPLS traffic destined for the far-end system IP address will be routed using an IPSec tunnel, the IGP packets themselves are destined for a multicast address and are not resolved over the IPSec tunnel.

8.1.2 X.509v3 Certificate Overview

X.509v3 is an ITU-T standard that consists of a hierarchical system of certificate authorities (CAs) that issue certificates that bind a public key to particular entity's identification. The entity's identification could be a distinguished name or an alternative name, such as a fully qualified domain name (FQDN) or an IP address.

An end entity (EE) is an entity that is not a CA. For example, an end entity can be a web server, a VPN client, or a VPN gateway.

A CA issues a certificate by signing an entity's public key with its own private key. A CA can issue certificates for an end entity as well as for another CA. When a CA certificate is issued for itself (signed by its own private key), this CA is called the root CA. Therefore, an end entity's certificate can be issued by the root CA or by a subordinate CA (that is, issued by another subordinate CA or root CA). When there are multiple CAs involved, this is called a chain of CAs.

In addition to issuing certificates, the public key infrastructure (PKI) also includes a mechanism for revoking certificates due to reasons such as a compromised private key.

A certificate can be used for authentication. Typically, the certificate authentication process functions as follows.

- The system trusts a CA as the trust anchor CA (which typically is a root CA). This means that all certificates issued by a trust anchor CA, or the certificates issued by a subordinate CA that have been issued by the trust anchor CA, are considered trusted.
- A peer that is to be authenticated presents its certificate along with a signature over some shared data between the peer and system, and the certificate is signed using a private key.
- The signature is verified by using the public key in the certificate. In addition, the certificate itself is verified as being issued by the trust anchor CA or a subordinate CA that is part of the chain leading up to the trust anchor CA. The system can also check if the peer's certificate has been revoked. Only when all these verifications succeed does the certificate authentication succeed.

8.1.2.1 X.509v3 Certificate Support on the 7705 SAR

The 7705 SAR PKI implementation supports the following features:

- certificate enrollment:
 - locally generated RSA/DSA key

- offline enrollment via PKCS#10 (public key cryptography standards)
 - online enrollment via CMPv2
- support for CA chain
- certificate revocation check:
 - certificate revocation list (CRL) for both EE and CA certificates
 - online certificate status protocol (OCSP) for EE certificate only

8.1.2.2 Local Storage

The 7705 SAR requires the following objects to be stored locally as a file:

- CA certificate
- CRL
- the system's own certificate
- the system's own key

All these objects must be imported with the **admin certificate import** command before they can be used by the 7705 SAR. The import process converts the format of the input file to distinguished encoding rules (DER), encrypts the key file, and saves it in the **cf3:/system-pki** directory.

The imported file can also be exported using a specified format by means of the **admin certificate export** command.

The **admin certificate import** and **admin certificate export** commands support the following formats:

- certificates can be imported and exported using the following formats:
 - PKCS #12
 - PKCS #7 (DER and PEM) (privacy enhanced mail)
 - PEM
 - DER

If there are multiple certificates in the file, only the first one is used.

- key pairs can be imported and exported using the following formats:
 - PKCS #12
 - PEM
 - DER
- the CRL can be imported and exported using the following formats:

- PKCS #7 (DER and PEM)
- PEM
- DER
- The PKCS #12 file can be encrypted with a password.

8.1.2.3 CA Profile

On the 7705 SAR, the CA-related configuration is stored in a CA profile that contains the following configurable items:

- name and description
- CA's certificate — an imported certificate
- CA's CRL— an imported CRL
- revocation check method — specifies the way the CA checks the revocation status of the certificate it issued
- CMPv2 — a CMPv2 server-related configuration
- OCSP— an OCSP responder-related configuration

When a user enables a **ca-profile (no shutdown)**, the system loads the specified CA certificate and CRL into memory. The following checks are performed:

- for the CA certificate:
 - all mandatory fields defined in section 4.1 of RFC 5280, *Internet X.509 Public Key Infrastructure Certificate and Certificate Revocation List (CRL) Profile*, exist and conform to the RFC 5280 defined format
 - the version field value is 0x2
 - the validity field indicates that the certificate is still in its validity period
 - the X.509 Basic Constraints extension exists and the CA Boolean value is true
 - if the Key Usage extension exists, at the least), the **keyCertSign** and **cRLSign** are asserted
- for the CRL:
 - all mandatory fields defined in section 5.1 of RFC 5280 exist and conform to the RFC 5280 defined format
 - if the version field exists, the value is 0x1
 - the delta CRL indicator does not exist (delta CRL is not supported)
 - the CRL is signed by the configured CA certificate

The CRL is required in order to enable **ca-profile**.

8.1.2.4 CA Chain Computation

When verifying a certificate with a CA or a chain of CAs, the system must identify the issuer CA of the certificate. The 7705 SAR looks through all configured CA profiles to find the issuer CA. The following is the method that the system uses to find the issuer CA:

- the issuer CA's certificate subject must match the issuer field of the certificate in question
- if present, the authority key identifier of the certificate in question must match the subject key identifier of the issuer CA's certificate
- if present, the key usage extension of the issuer CA's certificate must permit certificate signing

8.1.2.5 Certificate Enrollment

The 7705 SAR supports two certificate enrollment methods:

- the offline method using PKCS #10
- the online method using CMPv2

To use the offline method, perform the following steps:

Step 1. Generate a key pair using the **admin certificate gen-keypair** command.
For example: **admin certificate gen-keypair cf3:/segw.key size 2048 type rsa**

Step 2. Generate a PKCS#10 certificate signing request with the key generated in Step 1 using the **admin certificate gen-local-cert-req** command.
For example: **admin certificate gen-local-cert-req keypair cf3:/segw.key subject-dn C=US,ST=CA,O=ALU,CN=SeGW domain-name segw-1.alu.com file cf3:/segw.pkcs10**

As well as specifying the subject of the certificate request, you can optionally specify an FQDN and an IP address as SubjectAltName.

Step 3. Import the key file using the **admin certificate import** command.
Example: **admin certificate import type key input cf3:/segw.key output segw.key format der**

- Step 4.** Because the key is imported, remove the key file generated in Step 1 for security reasons.
- Step 5.** Send the PKCS #10 file to the CA via an offline method such as email. The CA signs the request and returns the certificate.
- Step 6.** Import the returned certificate using the **admin certificate import** command.
- Example: **admin certificate import type cert input cf3:/segw.cert output segw.cert format pem**

For the online method using CMPv2-based enrollment, see the [Certificate Management Protocol Version 2 \(CMPv2\)](#).

8.1.2.6 Certificate Revocation Check

A revocation check is a process that checks whether a certificate has been revoked by the issuer CA.

The 7705 SAR supports two methods for the certificate revocation check:

- CRL
- OCSP

The CRL can be used for both EE and CA certificate checks, while OCSP can only be used for an EE certificate check.

For an IPSec application, users can configure multiple check methods with a priority order for an EE certificate. Using the **status-verify** command in the **ipsec-tunnel** configuration context, users can configure a primary method, a secondary method, and a default result. The primary and secondary methods can be either OCSP or CRL. The default result is either **good** or **revoked**. If the system does not get an answer from the primary method, it falls back to the secondary method. If the secondary method does not return an answer, the system uses the default result.

By default, the system uses the CRL to check the revocation status of a certificate, whether it is an end entity certificate or a CA certificate. This makes the CRL a mandatory configuration in the **ca-profile**.

For details about OCSP, see [OCSP](#).

8.1.2.7 Certificate, CRL, and Key Cache

Configured certificates, CRLs, and keys are cached in memory before they are used by the system.

Every certificate, CRL, and key has one system-wide cache copy.

For a CA certificate and a CRL, the cache is created when there is a CA profile and when a **no shutdown** is performed and removed.

For an IPSec tunnel using legacy **cert** and **key** configurations, the cache is created only when the first tunnel using the cache is in a **no shutdown** state, and it is cleared when the last tunnel that used it is shut down.

For an IPSec tunnel using a **cert-profile**, the cache is created when the first **cert-profile** using the cache is in a **no shutdown** state, and it is removed when the last **cert-profile** that used it is shut down.

If a certificate or key is configured with both a **cert-profile** and legacy **cert** or **key** command, the cache is created when the first object (an **ipsec-tunnel** or a **cert-profile**) using it is in a **no shutdown** state, and it is removed when the last object using it is shut down.

In order to update a certificate or key without a shutdown **ca-profile** or **ipsec-tunnel**, the CLI command **admin>certificate>reload** manually reloads the certificate and key cache.

8.1.3 Using Certificates For IPSec Tunnel Authentication

The 7705 SAR supports X.509v3 certificate authentication for an IKEv2 tunnel (LAN-to-LAN tunnel and remote-access tunnel). The 7705 SAR also supports asymmetric authentication. This means that the 7705 SAR and the IKEv2 peer can use different methods to authenticate. For example, one side of the tunnel could use a pre-shared key and the other side could use a certificate.

The 7705 SAR supports certificate chain verification. For a static LAN-to-LAN tunnel, the command **trust-anchor-profile** specifies which CAs are expected to be present in the certificate chain before reaching the root CA (self-signed CA) configured in the system.

The key and certificate for the 7705 SAR are also configurable on a per-tunnel basis.

When using certificate authentication, the 7705 SAR uses the subject of the configured certificate as its ID by default.

8.1.4 Trust Anchor Profile

The 7705 SAR supports multiple trust anchors for each IPSec tunnel. A trust anchor profile can be configured with up to eight CAs. The system builds a certificate chain by using the certificate in the first certificate payload in the received IKEv2 message. If any of the configured trust anchor CAs in the trust anchor profile appear in the chain, then authentication is successful; otherwise, authentication fails.

Note: The 7705 SAR only supports processing of up to 16 hashes for the trust anchor list from other products. If the remote end sends more than 16 hashes and a certificate match is in the 17th or later hash, the tunnel remains down due to authentication failure.

8.1.5 Certificate Profile

The 7705 SAR supports sending different certificates and chains according to the received IKEv2 certificate-request payload. This is done by configuring a **cert-profile** that allows up to eight entries. Each entry includes a certificate and a key and, optionally, a chain of CA certificates.

The system loads the certificate and/or key in the **cert-profile** into memory and builds a compare-chain for the certificate configured in each entry of the **cert-profile** upon a **no shutdown** of the **cert-profile**. These chains are used for IKEv2 certificate authentication. If a chain computation cannot be completed for a configured certificate, the corresponding compare-chain will be empty or only partially computed.

Because there can be multiple entries configured in the **cert-profile**, the system must pick the certificate and key in the entry that the other side expects to receive. This is done by looking up the CAs within the received certificate request payload in the compare-chain and picking the first entry that has a certificate request CA appearing in its chain. If there is no such **cert**, the system picks the first entry in the **cert-profile**. The first entry is the first configured entry in the **cert-profile**. The *entry-id* of the first entry does not have to be "1".

For example, assume there are three CAs listed in the certificate-request payload: CA-1, CA-2 and CA-3, and there are two entries configured in the **cert-profile**, as shown in the following configuration:

```
cert-profile "cert-profile-1"
  entry 1
    cert "cert-1"
    key "key-1"
  entry 2
    cert "cert-2"
```

```
key "key-2"
send-chain
  ca-profile "CA-1"
  ca-profile "CA-2"
```

The system builds two compare-chains: chain-1 for cert-1 and chain-2 for cert-2. Assume CA-2 appears in chain-2, but CA-1 and CA-3 do not appear in either chain-1 or chain-2. In that case, the system will pick entry 2.

After a certificate profile entry is selected, the system generates the AUTH payload by using the configured key in the selected entry. The system also sends the certificate in the selected entry as "certificate" payload to the peer.

If a chain is configured in the selected entry, then one certificate payload is needed for each certificate in the configured chain. The first certificate payload in the IKEv2 message will be the signing certificate, which is configured by the **cert** command in the chosen **cert-profile** entry. In the preceding example, the system will send three certificate payloads: cert-2, CA-1, and CA-2.

The following CA chain-related enhancements are supported.

- The **no shutdown** of a **ca-profile** triggers a recomputation of the compute-chain in related certificate profiles. The system also generates a new log-1 to indicate that a new compute-chain has been generated; the log includes the CA profile names on the new chain. Another log, log-2, is generated if the **send-chain** in a **cert-profile** entry is not in a compute-chain due to this CA profile change. Another log is generated if the hash calculation for a certificate under a **ca-profile** has changed.
- When performing a **no shutdown** command on a **cert-profile**, the system allows the CAs in the **send-chain**, not in the compute-chain. The system also generates log-2, as above.
- The system allows changes to the configuration of the **send-chain** without shutting down **cert-profile**.

8.1.6 Certificate Management Protocol Version 2 (CMPv2)

CMPv2 is a protocol between a Certificate Authority (CA) and an end entity (EE) based on RFC 4210, *Internet X.509 Public Key Infrastructure Certificate Management Protocol (CMP)*. It provides multiple certificate management functions, such as certificate enrollment, certificate update, and so on.

The 7705 SAR supports the following CMPv2 operations:

- initial registration — the process by which the 7705 SAR enrolls a certificate with a certain CA for the first time, where:
 - a public/private key pair must be preprovisioned before enrollment by means of local generation or other methods
 - optionally, users can include a certificate or certificate chain in the extraCerts field of the initial registration request
- key pair update — a process by which the 7705 SAR updates an existing certificate for any reason (for example, a refresh of a key or certificate before it expires)
- certificate update — a process by which an initialized 7705 SAR obtains additional certificates
- polling — in some cases, the CA may not immediately return the certificate for reasons such as “request processing needs manual intervention”. In such cases, the 7705 SAR supports polling requests and responds as described in Section 5.3.22, Polling Request and Response, in RFC 4210.

The following list provides implementation details.

- HTTP is the only supported transport protocol for CMPv2. HTTP 1.1 and 1.0 are supported and configurable.
- All CMPv2 messages sent by the 7705 SAR consist of only one PKI message. In all cases, the size of the sequence for PKI messages is 1.
- Both password-based MAC and public key-based signature CMPv2 message protection are supported.
- The 7705 SAR only allows one outstanding **ir/cr/kur** request for each CMPv2 server. This means that no new requests are allowed if a pending request is present.

8.1.7 OCSP

The Online Certificate Status Protocol (OCSP) is used by 7705 SAR applications to determine the revocation state of an identified certificate, based on RFC 2560, *X.509 Internet Public Key Infrastructure Online Certificate Status Protocol - OCSP*. Unlike the CRL, which relies on checking against an offline file, OCSP provides timely, online information regarding the revocation status of a certificate.

IPSec is the only supported application that uses OCSP. The 7705 SAR supports both the CRL and OCSP as the certificate revocation status checking method. For a given IPSec tunnel, the user can configure a primary method, a secondary method, and a default result to achieve a hierarchical fallback mechanism. If the primary method fails to return a result, the system falls back to the secondary method. If the secondary method fails, the system uses the default result.

The following list provides implementation details.

- Only an OCSP client function is supported.
- HTTP is the only supported transport protocol.
- OCSP server access via a management routing instance is not supported.
- The 7705 SAR does not sign an OCSP request.
- The OCSP response must be signed. The system will verify the response by using the signer's certificate included in the response. If there is no such certificate, the CA certificate in the **ca-profile** will be used.
- If a nextUpdate exists in the OCSP response, the 7705 SAR checks the current time to determine if it is earlier than the nextUpdate. If yes, then the response is valid; otherwise, the response is considered unreliable and the 7705 SAR moves to the next revocation checking method.
- The revocation status result from a valid OCSP response is cached in the system.
- OCSP can only be used to verify the revocation status of the EE certificate. The CRL is still needed to verify the status of a CA certificate.

8.1.8 Applications

Two mobile backhaul applications are described in this section:

- [Metrocell Deployment](#): a solution for providers who are looking for security in the transmission medium to manage remote private networks in a metrocell deployment. IPSec is used as an encrypted uplink for OAM and mobile traffic to connect the remote network to the MTSO. The 7705 SAR-initiated IPSec tunnels can provide a secure means for managing the 7705 SAR and any private network behind the 7705 SAR, while NAT can provide scalability of IPSec tunnels over a single public IP address.
- [Small Business Deployment](#): the use of LTE and IP NodeBs, as an alternative to PWs, to provide a better match for an operator's choice of transport network (that is, IPSec over public network compared to MPLS/PWs over a private network)

8.1.8.1 Metrocell Deployment

As shown in [Figure 135](#), in a typical metrocell deployment, the cell site network is divided into two separate segments: the private domain and the public domain. An IPSec tunnel generated from the 7705 SAR-H is used to backhaul the management and OAM traffic of the private network, including the management traffic of the switches and the 7705 SAR-H itself. All OAM traffic is aggregated within a VPRN service and uses the IPSec tunnel as the uplink tunnel to the 7750 SR gateway.

Figure 135 Typical Metrocell Deployment

8.1.8.2 Small Business Deployment

In a small business deployment, the network is usually designed with a hub and spoke topology. The spoke sites connect to the hub through a leased line or a public non-secure domain. IPSec provides the security and encryption needed to connect the spoke sites to the centralized office (hub). The hub and spoke topology in a small business deployment is favorable because of the security that the hub side can provide to the entire network. IPS/IDS and anti-virus appliances can be deployed to the hub site, which examines arriving traffic from the spoke sites. SPAM and viruses can be filtered out on the hub site by these appliances. If additional spoke-to-spoke connectivity is required, then additional IPSec tunnels can be established. See [Figure 136](#).

Figure 136 Typical Small Business Deployment

24014

8.1.9 NAT-Traversal for IKEv1/v2 and IPSec

The 7705 SAR supports NAT-T (Network Address Translation-Traversal) for IKEv1 and IKEv2. NAT-T is functionality belonging to IPSec and IKEv1/v2. It is not functionality belonging to the NAT device.

In a private network where the entire network is hidden behind a single public IP address, NAT-T for IPSec is used to support the fan-out of multiple IPSec tunnels in the private network.

IPSec is an IP protocol and as such does not use ports. [Figure 137](#) illustrates how the UDP header is injected into the packet as well as the many-to-one to one-to-many mappings. NAT relies on port mapping, so in order to allow traversal of a NAT device, NAT-T adds a UDP header with port 4500 to the IPSec traffic when the NAT device is detected. The UDP header is added to the IPSec packet above the ESP header and IKEv1/v2 already uses UDP port 500. This UDP header can be used by the NAT device to uniquely map each IPSec tunnel and assign a different source port to each individual tunnel. That is, many IP addresses using UDP 4500 lead to a NAT mapping where a single public IP address uses many UDP ports.

In [Figure 137](#), the 7750 SR performs the following functions:

- tracks the different metrocell IKEv2 port-to-session mappings
- tracks the different metrocell IPSec port-to-tunnel mappings
- transmits traffic to each metrocell on the appropriate UDP port

Figure 137 UDP Header Injected by a NAT-T-enabled IPSec Tunnel

24016

8.1.10 BFD over IPSec Tunnel

To configure BFD for an IPSec tunnel, do the following:

- configure BFD on a loopback interface in the private VPRN
- configure at least two IPSec tunnels:
 - one tunnel is a BFD-designate tunnel over which BFD packets are exchanged; this BFD-designate tunnel does not go down when BFD goes down
 - the other tunnels are tunnels that use the BFD-designate tunnel's BFD session; these tunnels go down when BFD goes down
- configure a static route in the private VPRN, where the static route points to the destination node's private-side loopback interface, using the BFD-designate tunnel as the next hop
- configure BFD under the BFD-designate tunnel using the loopback interface and point to the far-end loopback address
- configure BFD under the protected tunnels also using the loopback interface (same configuration as under the BFD-designate tunnel)

8.1.11 QoS for IPSec

This section contains information on the following topics:

- [Network and Access Ingress QoS \(Decryption QoS\)](#)
- [Network and Access Egress QoS \(Encryption QoS\)](#)

8.1.11.1 Network and Access Ingress QoS (Decryption QoS)

IPSec traffic arriving on network ingress is classified based on network policy and network queue policy when the uplink interface is a network interface (refer to the 7705 SAR Quality of Service Guide). This classification is done based on the DSCP marking of the IPSec outer IP header.

The IPSec (encrypted) traffic destined for the secure gateway (SeGW) of the 7705 SAR is mapped to two queues (expedited and best effort) of the decryption engine on the ingress adapter card. This means that encrypted traffic is mapped to the decryption queue.

The encrypted traffic is mapped to one of these two queues based on the queue-type of its mapped network ingress queue, as determined by the result of the network ingress classification. For example, at network ingress, the QoS network policy determines a forwarding class (FC) for the packet. Then, the network-ingress queue policy maps the FC to a queue. The configured queue-type of network-ingress queue (**expedited**, **best-effort**, or **auto-expedite**) is used to choose the queue for the decryption engine on the ingress adapter card (where the uplink interface resides).

The uplink interface for the SeGW can be configured as a network interface or as an access IES interface. For an access IES interface, the decryption-queue mapping is based on the queue-type of the access ingress queue of the IES interface SAP. For example, at IES ingress, the SAP ingress policy determines a forwarding class (FC) for the packet. The FC is mapped to a SAP ingress queue. The queue-type of this SAP ingress queue (**expedited**, **best-effort**, or **auto-expedite**) is used to choose the queue for the decryption engine on the ingress adapter card where the IES interface SAP resides.

The decrypted customer traffic with removed IPSec tunnel header is queued on network and access ingress queues (the uplink interface can be a network interface or an IES interface) based on the network and access ingress policy, and the DSCP bits of the IPSec outer IP header are used for the classification.

8.1.11.1.1 Network Ingress QoS Tunnel Override

When a network QoS policy is enabled on an ingress network interface, IPSec packets arriving at that interface are assigned to encryption queues based on the IPSec outer IP header. However, if the QoS network policy of the arriving network interface is configured with **ler-use-dscp**, then after decryption, all the datapath or firewall queuing is based on the DSCP marking of the IPSec inner IP header rather than on the DSCP marking of the IPSec outer IP header. For more information about the **ler-use-dscp** command, refer to the 7705 SAR Quality of Service Guide, “QoS Policy Network Commands”.

8.1.11.2 Network and Access Egress QoS (Encryption QoS)

Customer packets arriving on access ingress in the VPRN are classified based on the SAP ingress policy (refer to the 7705 SAR Quality of Service Guide).

Customer packets arriving in the VPRN that are destined for the IPSec tunnel are enqueued before the encryption engine on the egress adapter card. There are three queues servicing the encryption engine on the egress adapter card (expedited, best effort, and CTL).

All CSM traffic over IPSec (BFD, ping, and so on) is queued in the CTL queue, while data (customer) traffic is mapped to the expedited or best-effort queue.

The customer traffic to the two data queues is mapped based on the queue-type of the ingress SAP queue. For example, at access VPRN SAP ingress, the ingress SAP policy determines a forwarding class (FC) for the packet. The FC is mapped to a SAP ingress queue. The queue-type of the SAP ingress queue (**expedited**, **best-effort**, or **auto-expedite**) is used to choose the queue for the decryption engine on the egress adapter card (where the uplink interface resides).

Note: If DSCP egress re-marking is configured on the network interface or access interface (uplink interface), DSCP bits are re-marked on the IPSec outer IP header.

8.1.12 Fragmentation and IP MTU

On the 7705 SAR, unencrypted IP packets arriving on a VPRN access interface and destined for an IPSec uplink will be fragmented if the incoming packet is larger than:

- the VPRN private interface MTU
- the IPSec tunnel MTU
- the difference between the uplink MTU and the IPSec overhead (uplink interface MTU minus IPSec overhead), where the IPSec overhead values are calculated as follows:

- IPSec overhead if NAT-T is enabled

**IPSec overhead = outer IPSec (20) + UDP (8) + ESP (24) + trailer (17) +
ICV (32) = 101 bytes**

- IPSec overhead if NAT-T is disabled (**no nat-t**)

**IPSec overhead = outer IP (20) + ESP (24) + trailer (17) + ICV (32)
= 93 bytes**

For example, if a private tunnel interface has its IP MTU set to 1000 bytes, then a packet larger than 1000 bytes will be fragmented. As another example, if an uplink interface has its IP MTU set to 1000 bytes, then a packet that is larger than 1000 – IPSec overhead will be fragmented. Both these examples assume that the DF bit is not set or the **clear-df-bit** command is enabled.

8.1.12.1 Fragmentation Configuration

By default, the 7705 SAR sets the DF bit on the IPSec tunnel IP header.

There are some configurations where the customer IP header DF bit needs to be copied into the IPSec tunnel IP header. The **copy-df-bit** command under the **config>service>vprn>if>sap>ipsec-tunnel** context enables copying the customer clear text IP header DF bit into IPSec tunnel IP header.

The **clear-df-bit** command, also under the **ipsec-tunnel** context, clears the customer clear text IP header DF bit (if it is set). This allows the customer packet to be fragmented into the IPSec tunnel even if the customer packet has the DF bit set. However, the fragmented customer clear text packet is not be reassembled at the far end of IPSec tunnel.

8.1.12.2 Reassembly

The 7705 SAR does not support reassembly of fragmented IPSec packets.

8.1.13 Support for Private VPRN Service Features

Private VPRN access features are only supported on non-IPSec interfaces. That is, they are only supported for Layer 3 interfaces that are not configured with a private IPSec tunnel.

Some of the features supported include r-VPLS, VRRP and VRRPv3, ECMP, and LAG. See [VPRN Services](#) for information on these features.

8.1.14 Routing in Private Services

For static LAN-to-LAN tunnels, the static route with the IPSec tunnel as the next-hop could be exported to a routing protocol by a route policy. The protocol type remains static.

8.1.15 IPSec on the 10-port 1GigE/1-port 10GigE X-Adapter Card

The 10-port 1GigE/1-port 10GigE X-Adapter card has two encryption engines that share the encryption/decryption load. Therefore, the 10-port 1GigE/1-port 10GigE X-Adapter card has the potential for double the encryption/decryption throughput when compared with other adapter cards and nodes with a single encryption engine (the 8-port Gigabit Ethernet Adapter card, 7705 SAR-Ax, 7705 SAR-H, 7705 SAR-Hc, 7705 SAR-W, 7705 SAR-Wx, and 7705 SAR-X).

To utilize the potential of the 10-port 1GigE/1-port 10GigE X-Adapter card, the IPSec security associations (SAs) are load-balanced between the two engines based on a round-robin algorithm. When there is an SA download to the 10-port 1GigE/1-port 10GigE X-Adapter card, the upper layer software load-balances the SA on the two engines.

8.1.16 IPSec Sequence Number

The IPSec sequence number is used to prevent replay attacks. A replay attack is a network attack in which valid data transmission is repeated or delayed for fraudulent purposes. The 7705 SAR supports a 32-bit sequence number, where the transmission of each packet increments the sequence number. If there is a sequence number rollover, the 7705 SAR performs the rollover by resignaling the phase-2 IKE negotiation.

8.1.17 PBR and MFC

Both PBR (policy-based routing) and MFC (multi-field classification) are part of the ingress ACL (access control list) configuration on the 7705 SAR. Hence, both PBR and MFC are supported by IPSec on the 7705 SAR, as discussed below:

- [PBR](#)
- [MFC](#)

8.1.17.1 PBR

PBR configuration can be applied in two places for an IPSec service.

The first place is for VPRN and applies to all incoming access traffic into a private VPRN. In this case, PBR can be used to direct the customer traffic into uplink IPSec tunnels by means of ACL matching criteria. The filtering action of forwarding to an indirect next hop can be used to direct customer traffic into the appropriate IPSec tunnel. The security policy works only on the original (customer packet) IP header; that is, the PBR next hop is not used in making the security policy decision.

The second place is for IPSec traffic entering the 7705 SAR from the public domain. A PBR filter can be placed on the network interface, the VPRN interface, or the IES interface to direct the IPSec packet based on the matching/forwarding criteria. In this case, IPSec packets are processed by the PBR filter in the same way as any other IP packet.

For more information on PBR, refer to the “Policy-Based Routing” section in the 7705 SAR Router Configuration Guide.

**Note:**

- All routing decisions are made based on the PBR configuration; therefore, it is possible that even if the packet is destined for the local node security gateway (SeGW), the PBR filter might redirect the packet to another interface.
- Alternatively, for IPSec packets that are not destined for the local node SeGW, PBR can force the packets into the local node SeGW. In this case, the encapsulating security payload (ESP) index of the IPSec packet will not match the SeGW ESP configuration and the packet will be dropped. Thus, it is the responsibility of the network administrator to ensure that the PBR configuration is correct and meets the network needs.

8.1.17.2 MFC

Multi-field classification (MFC) is supported on the private IPSec service (VPRN). MFC functions in the same manner as the VPRN configuration of traditional services.

For more information on MFC, refer to the “Multi-field Classification” section in the 7705 SAR Router Configuration Guide.

8.1.18 OSPFv3 Packet Authentication with IPv6 IPSec

The 7705 SAR supports the use of IPv6 IPSec to authenticate OSPFv3 packets. The following features are supported:

- two types of encryption and authentication protocols: authentication header (AH) and IP encapsulation security payload (ESP)
- IPSec transport mode to authenticate the IP payload
- manually keyed IPSec security associations (SA)
- the MD5 and SHA1 authentication algorithms

In order to be authenticated, OSPFv3 peers must be configured with matching inbound and outbound SAs using the same parameters (for example, SPIs and encryption keys). One SA can be used for both inbound and outbound directions.

Authentication of OSPFv3 packets is supported on VPRN interfaces, network interfaces, and virtual links.

The 7705 SAR supports the rekeying procedure defined in RFC 4552, *Authentication/Confidentiality for OSPFv3*.

- For every router on the link, create an additional inbound SA for the interface being rekeyed using a new SPI and the new key.
- The SA replacement operation is atomic, meaning that no OSPFv3 packets are sent on the link until the replacement operation is complete. This ensures that no packets are sent without authentication or encryption.
- For every router on the link, remove the original inbound SA.

The key rollover procedure automatically starts when the operator changes the configuration of the inbound static security association or bidirectional static security association under an interface or virtual link. Within the KeyRolloverInterval time period, OSPFv3 accepts packets with both the previous inbound static SA and the new inbound static SA; the previous outbound static SA will continue to be used. When the timer expires, OSPFv3 will only accept packets with the new inbound static SA. For outgoing OSPFv3 packets, the new outbound static SA will be used instead.

8.1.19 Statistics

All statistics for security association and tunnel statistics on the 7705 SAR are retrieved from the datapath on demand. When the user requests the statistics for a tunnel, the statistics are retrieved directly from the datapath; the retrieved statistics are not cached on the 7705 SAR. This means that on redundant platforms (that is, on the 7705 SAR-8 or 7705 SAR-18), statistics will not synchronize over to the inactive CSM and at the time of a CSM switchover, all statistics will be lost. Also, in the case of statistics rollover in the datapath, the newly retrieved statistics will start from 0 (zero) again.

Note: From Release 9.0.R7, an extra 4-byte overhead is appended to the internal overhead for any IP traffic destined for an IPSec tunnel. The extra 4-byte internal overhead is discarded at egress before scheduling. Therefore, shaping rates at ingress and for fabric policies may need to be adjusted accordingly. In addition, the 4-byte internal overhead may be included in any affected ingress queue statistics counters.

8.1.20 Security Support

IPSec on the 7705 SAR requires a public service (IES or VPRN) and a private service (VPRN). All IPSec traffic on the public service is encrypted. By the time the traffic is routed to the private service, it has been decrypted and can be examined by the 7705 SAR firewall engine.

The public interface of IPSec service is a secure gateway (SeGW). Because packets arriving on and leaving this interface are encrypted with an IPSec header, they are not firewalled. However, NAT can be applied to traffic traversing the public interface of IPSec security zones.

After being decrypted, the customer traffic may traverse a second security zone configured within the VPRN, to sanitize any of these packets according to the firewall rules. This security zone can be extended to have NAT performed on the customer clear text packets.

For more information about configuring security parameters, refer to the 7705 SAR Router Configuration Guide, “Configuring Security Parameters”.

8.2 Public Key Infrastructure (PKI)

Public Key Infrastructure (PKI) is a cryptographic technique that enables users to securely communicate on an insecure public network, and reliably verify and authenticate the identity of a user through the use of digital signatures.

PKI is a system for creating, storing, and distributing digital certificates, which are used to verify that a particular public key belongs to a particular entity. PKI creates digital certificates that map public keys to entities and securely stores these certificates in a central repository, revoking them as needed.

PKI includes the following components:

- X.509v3 identity certificates
- a certificate authority (CA), which has the following properties:
 - has a secure server
 - can sign and publish X.509v3 certificates
 - is trusted by all users of the system
- public/private key pairs
- the ability to be deployed as flat architecture or hierarchical architecture (chained certificates)

8.2.1 CA Role in PKI

The role of a CA in PKI includes the following items.

- The CA is a trusted third-party organization or company that issues digital certificates.
- The CA may or may not be a third party from the end entity's (EE's) point of view.
- The CA often belongs to the same organization as the EEs it supports.
- The CA can be a root CA or a subordinate CA:
 - root CA – a CA that is directly trusted by an end entity.
 - subordinate CA – CAs that are not root CAs. The first subordinate CA in a hierarchy obtains its CA certificate from the root CA. This first subordinate CA can, in turn, use this key to issue certificates that verify the integrity of another subordinate CA.
- The CA verifies digital certificates using a chain of trust, the root CA being the trust anchor for the digital certificate.

- The root CA issues a root certificate, which is the top-most certificate of the certificate tree. The root certificate's private key is used to sign other certificates. All certificates immediately below the root certificate inherit the trustworthiness of the root certificate.

8.2.2 Digital Signature and Certificates

Digital signatures and digital certificates are not the same objects.

A digital signature is an electronic signature that can be used to demonstrate the authenticity of a message. Digital signatures use hashing and asymmetric encryption. There are two aspects to a digital signature:

- signature construction
- signature verification

A digital certificate is an electronic document that uses a digital signature to bind a public key with an identity that has been digitally signed by a CA.

8.2.2.1 Certificates

PKI uses two types of certificates:

- root certificate
 - created by a well-known root CA (see [CA Role in PKI](#))
 - used to validate the authenticity of provider certificates
 - must be installed on the 7705 SAR manually, where the installation method can be FTP, SFTP, or SC, into the cf3: directory of the 7705 SAR
- provider certificate
 - created by each vendor for its own authentication needs
 - contains the public RSA or DSA keys that are used in PKI for the encryption of the phase 1 IKE message
 - must be signed by the root CA to prove the authenticity of the vendor certificate to the far-end node

8.2.2.1.1 Vendor Certificate Signature by the Root CA

For each vendor, the 7705 SAR must have a vendor certificate signed by the CA and stored internally.

The sequence of events is as follows:

1. The 7705 SAR creates an X.509v3 certificate and the key pair (public/private key).
2. The 7705 SAR sends the certificate to the CA to be signed by the CA private key.
 - i. The CA runs the hash over the X.509v3 certificate.
 - ii. The result of the hash is encrypted via the CA public key (digital signature).
 - iii. The digital signature is appended to the certificate and, consequently, the signed vendor certificate.

8.2.2.1.2 Vendor Certificate Authentication by a Peer

While the IKE is being initiated, phase 1 of the IKE can be authenticated via PKI. Therefore, the certificate from [Vendor Certificate Signature by the Root CA](#) is sent to the peer as part of the IKE authorization stage. The peer must ensure that this certificate is generated by the correct 7705 SAR and not an intermediary node.

Upon receiving the certificate, the peer does the following.

1. The peer runs a hash over the X.509v3 part of the certificate.
2. The peer decrypts the digital signature of the certificate.
3. If the hash calculated in step 1 and the hash decrypted in step 2 match, then the certificate is authenticated.
4. The peer can use the public key in the certificate to encrypt the IKE phase 2 channel.

8.2.2.1.3 Example of PKI Operation

In the following scenario, which provides an example of PKI operation, the 7705 SAR and 7750 SR trust the same CAs and they have already obtained the CA's certificate (which includes the CA's public key) using an out-band method. The CA issues a certificate for the 7705 SAR, as follows.

- The CA calculates a hash of the contents of the 7705 SAR certificate, which includes the 7705 SAR public key, name, validity date, allowed uses for the certificate, and so on.
- The CA encrypts this hash using its private key, and attaches the resulting signature to the 7705 SAR certificate.

The 7705 SAR can now present this signed certificate to the 7750 SR during the IKE phase.

The 7750 SR verifies the received certificate as follows.

- The 7750 SR calculates its own hash of the 7705 SAR certificate contents.
- The 7750 SR decrypts the signed hash in the certificate using the CA's public key, and if the hashes match the 7750 SR knows that this certificate was signed by the CA.
- Optionally, the 7750 SR consults the CA's certificate revocation list (CRL) and checks that the certificate from the 7705 SAR has not been revoked.

8.2.2.1.4 Certificate Chain

A peer's certificate may be issued by an intermediate CA. In this case, a user must have and trust all the intermediate CA certificates up to and including the root CA installed in the peer for authentication of an end entity.

The 7705 SAR supports the following implementation.

- When receiving a certificate, all subordinate CAs must be installed locally (that is, only an EE certificate can be received from the peer and processed by the 7705 SAR). Even if a certificate chain is received from the peer, the 7705 SAR processes the EE certificate only.
- The **send-chain** command under **cert-profile** is for third-party peers that support receiving a chain certificate. In this case, the 7705 SAR can send a chain certificate to be used in the entire chain if the third-party peer supports receiving a chained certificate. The 7705 SAR does not support receiving chained certificates.

8.2.3 Certificate Storage

The 7705 SAR IPSec configuration expects the keys and certificates to be stored in a particular directory on the 7705 SAR compact flash. This directory is called `cf3:\system-pki` and is created automatically when the first file is imported into this folder.

The following files can be imported and exported to and from the `cf3:\system-pki` directory. An example of the directory is shown after the list.

- key pair – this file is encrypted during the import process
- certificates
- certificate revocation list (CRL)

```
A:ALU-A>file cf3:\system-pki\ # dir
Directory of cf3:\system-pki\
09/09/2015  09:17a    <DIR>        ./
09/09/2015  09:17a    <DIR>        ../
09/22/2015  11:38a                906 CMS1-ROOTCA-CERT
09/22/2015  11:41a                458 CMS1-ROOTCA-CRL
09/24/2015  08:18a                864 cert-1
09/25/2015  08:18a            1192 SAR-key-1
09/25/2015  09:32a                905 cal_cert_CMS1-SUBCA
09/25/2015  09:32a                457 cal_crl_CMS1-SUBCA
        6 File(s)                4732 bytes.
        2 Dir(s)                65605632 bytes free.
```

Note: Always use the **import** and **export** commands to move files in and out of this directory. Do not copy any files directly to or from the system PKI directory.

8.2.4 CMPv2 Certificate Management

The Certificate Management Protocol (CMP) is an Internet protocol used for obtaining X.509v3 digital certificates in a PKI. It is described in RFC 4210. CMP messages are encoded in ASN.1 using the DER method and are usually transported over HTTP.

A CA issues the certificates and acts as the secure server in PKI using CMP. One of the clients obtains its digital certificates by means of this protocol and is called the end entity (EE).

The 7705 SAR supports the following CMPv2 operations:

- initial registration (**ir**)

This is the process that the 7705 SAR uses to enroll a certificate with a certain CA for the first time.

A public/private key pair must be preprovisioned before enrollment by means of local generation or another method.

- certificate update (**cr**)

This is the process whereby an initialized 7705 SAR obtains additional certificates.

- key pair update (**kur**)

This is the process where the 7705 SAR updates an existing certificate due to any reason, such as a key or certificate refresh before the key or certificate expires.

- polling

In some cases, the CA may not return the certificate immediately, for reasons such as “request processing needs manual intervention”. In such cases, the 7705 SAR supports polling requests and responses, as described in Section 5.3.22, *Polling Request and Response*, in RFC 4210.

8.2.4.1 CMPv2 Initial Registration

Initial registration is a process that the end entity uses to enroll a certificate with a certain CA for the first time. The result of this process is that a CA issues a certificate for an end entity’s public key, returning that certificate to the end entity or posting that certificate in a public repository (or both).

The 7705 SAR must be preprovisioned with the operator CA certificate.

The 7705 SAR public/private key pair is always preprovisioned before enrollment by means of local generation or another method.

The 7705 SAR uses the CMPv2 initial registration process to enroll its preprovisioned key with an operator’s CA. The result of this process is a certificate issued by the operator’s CA.

There are two authentication methods (PKI message protection) in this process, which are chosen using the CLI:

- **MSG_MAC_ALG**: uses a pre-shared key and a reference number that is pre-issued by the CA
- **MSG_SIG_ALG**: uses a CLI-provided protection key to sign the message; if a protection key is not provided, the key to be certified is used

8.2.4.2 Key Update

When a key pair is due to expire, the relevant end entity (EE) may request a key update. That is, the EE may request that the CA issue a new certificate for a new key pair or, under certain circumstances, a new certificate for the same key pair. The request is made using a key update request (**kur**) message, also known as a certificate update operation.

This command requests a new certificate from the CA in order to update an existing certificate due to reasons such as the need to refresh a key or to replace a compromised key.

If the EE already has a signing key pair with a corresponding verification certificate, then communication between the EE and the CA will be protected by the EE's digital signature.

If the request is successful, the CA returns the new certificate in a key update response (**kup**) message, which is syntactically identical to a CertRepMessage.

8.2.4.3 CRL

In the operation of some cryptosystems, such as PKIs, a certificate revocation list (CRL) is used. A CRL is list of certificates (or more specifically, a list of serial numbers for certificates) that have been revoked. Entities presenting those revoked certificates should not be trusted.

The CRL must be obtained and imported via CMPv2.

8.2.5 OCSP

The online certificate status protocol (OCSP) enables applications to determine the revocation status of an X.509v3 digital certificate. OCSP was created as an alternative to using CRLs and can be used to obtain additional status information. OCSP is described in RFC 6960.

Messages communicated via OCSP are encoded in ASN.1 and are usually communicated over HTTP. OCSP consists of a request message and a response message.

An OCSP responder may return a signed response indicating that the certificate specified in the request is good, revoked, or unknown. The Enterprise Java Bean Certificate Authority (EJBCA) server contains, by default, an internal OCSP responder and, therefore, can be used in conjunction with the 7705 SAR.

Ensure that both the 7705 SAR and the OCSP server are running NTP so that both devices are synchronized with respect to their timing.

8.3 Best Practices Recommendations

This section provides best practices recommendations.

8.3.1 IPSec Best Practices

To avoid high CPU loads and some complex cases, the following are suggestions to configure the IKEv2 lifetime.

- Both the IKE_SA and CHILD_SA lifetime on one side should be approximately 2 or 3 times larger than the other side.
- With the previous rule, the lifetime of the side with the smaller lifetime should NOT be too small:
 - IKE_SA: greater than or equal to 86 400 s
 - CHILD_SA: greater than or equal to 3600 s
- With the first rule, on the side with the smaller lifetime, the IKE_SA lifetime should be at least 3 times larger than the CHILD_SA lifetime.

The IKE protocol is the control plane of IPSec; therefore, the IKE packet should be treated as high QoS priority in the end-to-end path of public service.

- On a public interface, a SAP-ingress QoS policy should be configured to ensure that the IKE packet gets high QoS priority.

8.4 Configuration Notes

This section describes operational conditions and IPSec configuration guidelines and caveats.

- A tunnel group that is in use cannot be deleted. Changes are allowed only when the tunnel group is in a shutdown state.
- A change to the IPSec transform policy is allowed at any time. The change will not impact tunnels that have been established until they are renegotiated. If the change is required immediately, the tunnel must be cleared (reset) for force renegotiation.
- A change to the IKE policy is allowed at any time. The change will not impact tunnels that have been established until they are renegotiated. If the change is required immediately, the tunnel must be cleared (reset) for force renegotiation.
- An IPSec tunnel must be shut down before the transform policy can be modified.
- The public interface address can be changed at any time (current behavior). If changed, tunnels that were configured to use it will require a configuration change. If the subnet has been changed, the tunnels will be in an operationally down state until their configuration is corrected. The public service cannot be deleted while tunnels are configured to use it. A public service is the IES or VPRN service that holds an interface with a public tunnel SAP that connects the node to the public network. A private service connects to the private protected service.
- The 7705 SAR supports only one tunnel group (tunnel-group 1).
- A change to the security policy is not allowed while a tunnel is active and using the policy.
- The tunnel local gateway address, peer address, or delivery router parameters cannot be changed while the tunnel is operationally up (**shutdown** makes the tunnel both administratively down and operationally down).
- A tunnel security policy cannot be changed while the tunnel is operationally up. An IPSec transform policy or IKE policy assignment to a tunnel requires the tunnel to be shut down.

8.4.1 Reference Sources

For information on supported IEEE standards, IETF drafts and standards as well as standard and proprietary MIBs, refer to [Standards and Protocol Support](#).

8.5 Configuring IPSec with CLI

This section provides information to configure IPSec using the command line interface.

Topics in this section include:

- [Basic Configuration Overview](#)
- [Common Configuration Tasks](#)
- [Configuring IPSec over MPLS](#)
- [Service Management Tasks](#)

8.6 Basic Configuration Overview

The following list provides a high-level outline for setting up IPSec on the 7705 SAR.

- Create an IPSec tunnel group.
- Configure an IPSec IKE policy.
- Configure an IPSec transform policy.
- Create a private-side tunnel interface on a VPRN service.
 - Create an interface using the **tunnel** keyword and private tunnel SAP.
 - Create the IPSec tunnel and configure its parameters, which include local and peer gateway IP addresses, IP MTU, keying (manual or dynamic), and so on.
- Create a public-side tunnel interface on an IES or VPRN service.
 - Create an interface and public tunnel SAP.
- Configure a VPRN static route for the IPSec tunnel.

8.7 Common Configuration Tasks

This section provides a brief overview of the following common configuration tasks that must be performed to configure IPSec:

- [Configuring an IPSec Tunnel Group](#)
- [Configuring Router Interfaces for IPSec](#)
- [Configuring IPSec Parameters](#)
- [Configuring IPSec and IPSec Tunnels in Services](#)
- [Configuring IPSec IPv6 Parameters for a VPRN Private Service](#)
- [Configuring X.509v3 Certificate Parameters](#)
- [Configuring CMPv2](#)
- [Configuring OCSP](#)

8.7.1 Configuring an IPSec Tunnel Group

The following output displays an IPSec group configuration in the ISA context. The 7705 SAR supports only one tunnel-group. The *tunnel-group-id* is always 1.

```
*A:7705custDoc:Sar18>config>isa# info detail
-----
      tunnel-group 1 create
      shutdown
      no description
      exit
-----
*A:7705custDoc:Sar18>config>isa#
```

8.7.2 Configuring Router Interfaces for IPSec

An IPSec tunnel requires the following three interfaces:

- public tunnel interface (under IES or VPRN)
- private tunnel interface (under VPRN)
- physical untrusted network/Internet-facing interface: IES, VPRN, or router

The physical interface is the one that must reside on an encryption-capable adapter card.

The following example displays an interface ("internet") configured using a network port (1/1/1) and an IES interface ("public") configuration using SAP 1/1/8.

```
*A:ALU-49>config>router# info
-----
...
router
  interface "internet"
    address 10.10.7.118/11
    port 1/1/1
  exit
  interface "system"
    address 10.20.1.118/12
  exit
  autonomous-system 123
exit
...
-----
*A:ALU-49>config>router#

*A:7705:Dut-A>config>service>ies# info
-----
description "ies interface towards internet"
interface "public" create
  address 10.1.1.1/1
  sap 1/1/8 create
  description "sap-100-10.1.1.1"
  exit
exit
no shutdown
-----
```

8.7.3 Configuring IPSec Parameters

Under the IPSec context, configure the IKE policy and IPSec transform parameters.

The following example displays the IPSec parameter configuration output.

```
*A:7705custDoc:Sar18>config>ipsec# info
#-----
ipsec
  ike-policy 2 create
  ike-version 2
  own-auth-method psk
  dh-group 14
  ipsec-lifetime 48000
  isakmp-lifetime 60000
  pfs dh-group 5
  auth-algorithm sha384
  encryption-algorithm aes192
  nat-traversal keep-alive-interval 240
  no ikev2-fragment
  dpd interval 25
```

```

    exit
    ipsec-transform 2 create
        esp-auth-algorithm md5
        esp-encryption-algorithm 3des
    exit
exit
#-----

```

8.7.4 Configuring IPSec and IPSec Tunnels in Services

IPSec is configured under IES and VPRN services.

For the private-side IPSec tunnel interface and SAP, under the VPRN service context, configure IPSec security policies, and create tunnel interfaces, private tunnel SAPs, IPSec tunnels, and IPSec tunnel parameters. The **tunnel** keyword must be used when creating an interface for a private tunnel SAP.

For a public-side IPSec tunnel interface and SAP, under the IES or VPRN service context, create an interface and public tunnel SAP. The **tunnel** keyword is not used when creating an interface for a public tunnel SAP.

Private-side and public-side tunnels function in pairs, where a pair is defined by the service ID and the interface subnet.

The local gateway address and delivery service configured using the VPRN **ipsec-tunnel>local-gateway-address** command correspond to the IES or VPRN interface address and service ID where the public-side tunnel interface is defined. In the example below, the **local-gateway-address** is 10.10.10.11 and the **delivery-service** is 10.

The following example displays the configuration output when configuring IPSec for a private-side VPRN service and a public-side IES.

```

*A:7705custDoc:Sar18>config>service>vprn# info detail
-----
...
    ipsec
        security-policy 1 create
            entry 1 create
                local-ip any
                remote-ip any
            exit
        entry 2 create
            local-ip 198.51.100.0/24
            remote-ip 198.51.100.0/24
        exit
    exit
    security-policy 15 create
        entry 15 create
            no local-ip

```

```

        no remote-ip
    exit
exit
exit
...

-----
*A:7705custDoc:Sar18>config>service>ies#

```

8.7.5 Configuring IPSec IPv6 Parameters for a VPRN Private Service

Use the following CLI syntax to configure IPSec IPv6 parameters for a VPRN private service:

CLI Syntax:

```

config>service# vprn service-id [customer customer-id]
[create]
    ipsec
        security-policy security-policy-id [create]
            entry entry-id [create]
                local-v6-ip {ipv6-prefix/prefix-length | any}
                remote-v6-ip {ipv6-prefix/prefix-length | any}

```

Example:

```

A:ALU-41>config>service# vprn 1011
A:ALU-41>config>service>vprn$ ipsec
A:ALU-41>config>service>vprn>ipsec>security-policy$ 1
create
A:ALU-41>config>service>vprn>ipsec>sec-plcy>entry$ 1
create
A:ALU-41>config>service>vprn>ipsec>sec-plcy>entry>local-v6-ip$ 2001:db8:a::123/64
A:ALU-41>config>service>vprn>ipsec>sec-plcy>entry>local-v6-ip$ exit
A:ALU-41>config>service>vprn>ipsec>sec-plcy>entry>remote-v6-ip$ 2001:db8:a::222/64
A:ALU-41>config>service>vprn>ipsec>sec-plcy>entry>remote-v6-ip$ exit
A:ALU-41>config>service>vprn>ipsec>sec-plcy>entry$ exit
A:ALU-41>config>service>vprn>ipsec>security-policy$ exit
A:ALU-41>config>service>vprn>ipsec$ exit

```

The following example displays IPSec IPv6 parameters configuration output.

```

*A:7705:Dut-A>config>service>vprn# info
-----
ipsec

```

```

security-policy 1 create
  entry 1 create
    local-v6-ip 2001:db8:a::123/64
    remote-v6-ip 2001:db8:a::222/64
  exit
exit
exit

```

8.7.6 Configuring X.509v3 Certificate Parameters

Perform the following steps to configure certificate enrollment.

Step 1. Generate a key:

```
admin certificate gen-keypair cf3:/key_plain_rsa2048 size 2048 type
rsa
```

Step 2. Generate a certificate request:

```
admin certificate gen-local-cert-req keypair cf3:/key_plain_rsa2048
subject-dn "C=US,ST=CA,CN=7705" file 7705_req.csr
```

Step 3. Send the certificate request to CA-1 to sign and get the signed certificate.

Step 4. Import the key:

```
admin certificate import type key input cf3:/key_plain_rsa2048 output
key1_rsa2048 format der
```

Step 5. Import the signed certificate:

```
admin certificate import type cert input cf3:/7705_cert.pem output
7705cert format pem
```

Perform the following steps to import the CA certificate and CRL.

Step 1. Import the CA certificate:

```
admin certificate import type cert input cf3:/CA_1_cert.pem output
ca_cert format pem
```

Step 2. Import the CA's CRL:

```
admin certificate import type crl input cf3:/CA_1_crl.pem output
ca_crl format pem
```

The following example displays a certificate authentication for IKEv2 static LAN-to-LAN tunnel configuration.

```

config>system>security>pki# info
-----
ca-profile "alu-root" create
cert-file "alu_root.cert"
crl-file "alu_root.crl"

```

```

        no shutdown
        exit
-----
config>ipsec# info
-----
        ike-policy 1 create
        auth-method cert-auth
        exit
        ipsec-transform 1 create
        exit
        cert-profile "segw" create
        entry 1 create
        cert segw.cert
        key segw.key
        exit
        no shutdown
        exit
        trust-anchor-profile "alu" create
        trust-anchor "alu-root"
        exit

config>service>vpn>if>sap
-----
        ipsec-tunnel "t50" create
        security-policy 1
        local-gateway-address 192.168.55.30 peer 192.168.33.100 delivery-
            service 300
        dynamic-keying
        ike-policy 1
        transform 1
        cert
            trust-anchor-profile "alu"
            cert-profile "segw"
        exit
        exit
        no shutdown
        exit

```

The following example displays the syntax to import a certificate from the PEM format.

```
*A:ALU-A# admin certificate import type cert input cf3:/pre-import/R1-0cert.pem output R1-0cert.der format pem
```

The following example displays the syntax to export a certificate to the PEM format.

```
*A:ALU-A# admin certificate export type cert input R1-0cert.der output cf3:/R1-0cert.pem format pem
```

8.7.7 Configuring CMPv2

CMPv2 server information is configured under a corresponding **ca-profile** by using the following CLI commands:

CLI Syntax:

```
config>system>security>pki>ca-profile
    cmpv2
        url url-string [service-id service-id]
        response-signing-cert filename
        key-list
            key password [hash | hash2] reference
                reference-number
```

The **url** command specifies the HTTP URL of the CMPv2 server and the **service-id** specifies the routing instance that the system used to access the CMPv2 server (if the service ID is omitted, the system uses the base routing instance).

The service ID is only needed for in-band connections to the server via VPRN services. IES services are not referenced by the service ID, since an IES service routing instance is considered to be a base routing instance.

The **response-signing-cert** command specifies an imported certificate that is used to verify CMP response messages if they are protected by a signature. If this command is not configured, the CA's certificate is used.

The **key-list** command specifies a list of pre-shared-keys used for CMPv2 initial registration message protection.

Example:

```
config>system>security>pki>ca-profile>
    cmpv2
        url "http://cmp.example.com/request" service-
            id 100
        key-list
            key passwordToBeUsed [hash | hash2]
                reference "1"
```

All CMPv2 operations are invoked by using the **admin certificate cmpv2** command.

If there is no **key-list** defined under the **cmpv2** configuration, the system defaults to the **cmpv2** transaction that was input for the command line related to authenticating a message without a sender ID. If there is no sender ID in the response message and there is a **key-list** defined, the system chooses the lexicographical first entry only, and if that fails, there is a fail result for the transaction.

The system supports optional commands (such as **always-set-sender-ir**) to support inter-operation with CMPv2 servers. Refer to the [IPSec Command Reference](#) for details about syntax and usage.

8.7.8 Configuring OCSP

OCSP server information is configured under the corresponding **ca-profile**:

CLI Syntax:

```
config>system>security>pki>ca-profile>
    oosp
        responder-url url-string
        service service-id
```

The **responder-url** command specifies the HTTP URL of the OCSP responder. The **service** command specifies the routing instance that the system used to access the OCSP responder.

Example:

```
config>system>security>pki>ca-profile>
    oosp
        responder-url "http://ocsp.example.com/
            request"
        service 100
```

For a given IPSec tunnel, the user can configure a primary method, a secondary method, and a default result.

```
config>service>vpn>if>sap>ipsec-tun>
    cert
        status-verify
        primary {ocsp | crl}
        secondary {ocsp | crl}
        default-result {revoked | good}
```

Example:

```
config>service>vpn>if>sap>ipsec-tun>
    cert
        status-verify
        primary ocsp
        secondary crl
```

8.8 Configuring IPSec over MPLS

On the 7705 SAR, IPSec routes to the secure gateway address can be resolved by using either a BGP 3107 label route or an IGP shortcut. When BGP learns IPv4 addressed as BGP 3107 label routes, BGP resolves the next hops for these routes with an LDP or RSVP-TE tunnel. These BGP routes create BGP tunnels that can be used to resolve an IPSec secure gateway address. When an IGP shortcut is enabled on the 7705 SAR by using the **config>router>ospf>rsvp-shortcut** command, OSPF installs an OSPF route in the RIB, with an RSVP-TE LSP as the next hop. If this OSPF route is determined as the overall best route, then the next hop is an RSVP-TE tunnel.

The IPSec implementation on the 7705 SAR is VPN-based. In order to configure IPSec, a private VPRN and a public IES or VPRN must both be configured; the encryption and decryption functions occur between these two services.

This section shows a configuration example of an IPSec route resolved by a BGP 3107 label route and a configuration example of an IPSec route resolved by an IGP shortcut.

8.8.1 IPSec over BGP 3107 Label Route

To route IPSec traffic using BGP 3107 label routes, the following components must be configured:

- a static LAN-to-LAN tunnel for IPSec traffic
- a policy option to advertise the IPSec gateway using BGP
- BGP with a BGP 3107 label route configured
- an LDP or RSVP-TE tunnel to resolve the BGP 3107 label route

[Figure 138](#) shows a scenario where IPSec traffic is routed over a BGP 3107 label route. In this example, both the BGP 3107 tunnel and the IPSec tunnel are set up between Dut-A and Dut-F. The nature of BGP 3107 requires the LDP or RSVP-TE tunnel to be set up inside the autonomous system between Dut-A and Dut-E.

Figure 138 IPSec over BGP 3107 Label Route

8.8.1.1 Static LAN-to-LAN Tunnel Configuration

Setting up a static LAN-to-LAN tunnel for IPSec traffic involves configuring a number of elements, including:

- VPRN private-side service parameters, including the following:
 - BGP parameters
 - route distinguisher parameter
 - **auto-bind-tunnel** parameter or VPRN spoke SDP
 - VRF route-target associations or VRF import/export policies
 - OSPF parameters
 - a VPRN interface and its SAP parameters
 - spoke-SDP parameters on the VPRN interface
- IES or VPRN public-side service parameters
- IPSec parameters

The CLI output below is an example of a static LAN-to-LAN tunnel configuration.

```
*A:7705:Dut-A>config>service>vprn# info

8.8.2 IPSec over IGP Shortcut

To route IPSec traffic over an IGP shortcut, the following must be configured:

- a static LAN-to-LAN tunnel
- an IGP shortcut (by creating an RSVP-TE tunnel in the OSPF context)
- an RSVP-TE LSP to the system IP address or loopback address, with CSPF enabled

8.8.2.1 Static LAN-to-LAN Tunnel Configuration

The CLI output below is an example of a static LAN-to-LAN tunnel configuration.

```

#-----
echo "IPsec Configuration"
#-----
    ipsec
        ike-policy 1 create
        description "ikePolicy_1"
        own-auth-method psk
        dh-group 1
        auth-algorithm md5
        dpd interval 10 max-retries 2
    exit
    ipsec-transform 1 create

```

```

        esp-auth-algorithm sha512
        esp-encryption-algorithm aes256
    exit
exit
#-----
echo "Service Configuration"
#-----
service
    customer 1 create
        description "Default customer"
    exit

            exit
        exit
    exit
exit
#-----

```

8.8.2.2 IGP Shortcut Configuration

The CLI output below is an example of an IGP shortcut configuration. An IGP shortcut is created using the **rsvp-shortcut** command in the **ospf** context.

```

#-----
echo "OSPFv2 Configuration"
#-----
    ospf
        traffic-engineering
        timers
            spf-wait 1000 1000 1000
        exit
        rsvp-shortcut
        area 0.0.0.0
            interface "system"
                hello-interval 5
                dead-interval 15
                no shutdown
            exit
            interface "network"
                hello-interval 5
                dead-interval 15
                metric 100
                no shutdown

```

```

        exit
    exit
exit
#-----

```

8.8.2.3 RSVP-TE LSP Configuration

The CLI output below is an example of an RSVP-TE LSP with CSPF enabled.

```

#-----
echo "MPLS Configuration"
#-----
    mpls
        interface "system"
            no shutdown
        exit
        interface "network"
            no shutdown
        exit
    exit
#-----
echo "RSVP Configuration"
#-----
    rsvp
        interface "system"
            no shutdown
        exit
        interface "network"
            no shutdown
        exit
        no shutdown
    exit
#-----
echo "MPLS LSP Configuration"
#-----
    mpls
        path "Path1AToC"
            no shutdown
        exit
        lsp "Lsp1AToC"
            to 10.10.20.1
            cspf
            retry-timer 20
            metric 100
            primary "Path1AToC"
            exit
            no shutdown
        exit
        no shutdown
    exit
exit
#-----

```

8.9 Service Management Tasks

This section provides a brief overview of the following service management tasks:

- [Deleting an IPSec IKE Policy or an IPSec Transform](#)
- [Deleting a Public-Side IPSec Tunnel SAP and Interface](#)
- [Deleting a Private-Side IPSec Tunnel SAP and Interface](#)
- [Deleting an IPSec Security Policy](#)
- [Deleting an IPSec Tunnel](#)

8.9.1 Deleting an IPSec IKE Policy or an IPSec Transform

An IPSec IKE policy or transform cannot be deleted if it is being used by an IPSec tunnel. To delete an IKE policy or IPSec transform:

CLI Syntax:

```
config>service>vprn>if>sap>ipsec-tunnel# dynamic-keying
config>service>vprn>if>sap>ipsec-tunnel>dynamic-keying#
no ike-policy
config>service>vprn>if>sap>ipsec-tunnel>dynamic-keying#
no transform
config>service>vprn>if>sap>ipsec-tunnel>dynamic-keying#
exit all
config>ipsec# no ike-policy ike-policy-id
config>ipsec# no ipsec-transform transform-id
```

Example:

```
config>service>vprn>if>sap>ipsec-tunnel# dynamic-keying
config>service>vprn>if>sap>ipsec-tunnel>dynamic-keying#
no ike-policy
config>service>vprn>if>sap>ipsec-tunnel>dynamic-keying#
no transform
config>service>vprn>if>sap>ipsec-tunnel>dynamic-keying#
exit all
config>ipsec# no ike-policy 2
config>ipsec# no ipsec-transform 2
```

8.9.2 Deleting a Public-Side IPSec Tunnel SAP and Interface

A public-side IPSec tunnel interface and SAP are created under an IES or VPRN service. The output below uses the CLI syntax and an example from the IES context to show how to delete a public-side IPSec tunnel interface and SAP:

CLI Syntax: `config>service>ies>interface# no sap tunnel-
 id.public:tag
config>service>ies# no interface ip-int-name`

Example: `config>service>ies>interface# no sap tunnel-1.public:22
config>service>ies# no interface ies_tunnelPublicSide_1`

8.9.3 Deleting a Private-Side IPSec Tunnel SAP and Interface

A private-side IPSec tunnel interface and SAP are created under a VPRN service. To delete a private-side IPSec tunnel interface and SAP:

CLI Syntax: `config>service>vprn>interface# no sap tunnel-
 id.private:tag
config>service>vprn# no interface ip-int-name`

Example: `config>service>vprn>interface# no sap tunnel-
 1.private:22
config>service>vprn# no interface vprn-tunnel`

8.9.4 Deleting an IPSec Security Policy

Security policies are created under the VPRN service. To delete an IPSec security policy:

CLI Syntax: `config>service>vprn>ipsec# no security-policy security-
 policy-id`

Example: `config>service>vprn# no security-policy 35`

8.9.5 Deleting an IPSec Tunnel

IPSec tunnels are created under the VPRN service. Although an IPSec tunnel is created on the private side of the tunnel in the CLI, the configuration itself is general and can apply to either the public or private side of the tunnel. To delete an IPSec tunnel:

CLI Syntax: `config>service>vprn>if>sap# no ipsec-tunnel ipsec-tunnel-name`

Example: `config>service>vprn>if>sap# no ipsec-tunnel
 ies_tunnelPublicSide_1`

 — [no] dynamic-keying
 — [no] auto-establish
 — ike-policy ike-policy-id
 — no ike-policy
 — local-id type {ipv4 | fqdn} value value
 — no local-id
 — pre-shared-key key [hash | hash2]
 — no pre-shared-key
 — transform transform-id [transform-id...(up to 4
 max)]
 — no transform
 — ip-mtu octets
 — no ip-mtu
 — local-gateway-address ip-address peer ip-address
 delivery-service service-id
 — no local-gateway-address
 — [no] manual-keying
 — security-association security-entry-id
 authentication-key authentication-key
 encryption-key encryption-key spi spi
 transform transform-id direction {inbound |
 outbound}
 — no security-association security-entry-id
 direction {inbound | outbound}
 — security-policy security-policy-id
 — no security-policy

```

### 8.10.1.1.5 Service Static Route Commands

```

config
 — service
 — vprn service-id
 — [no] static-route-entry ip-prefix/prefix-length
 — [no] ipsec-tunnel ipsec-tunnel-name
 — [no] description description-string
 — [no] metric metric
 — [no] preference preference
 — [no] shutdown
 — [no] tag tag

```

See [VPRN Service Configuration Commands](#) in [VPRN Services Command Reference](#) for the command descriptions.

### 8.10.1.2 PKI Configuration Commands

#### 8.10.1.2.1 X.509 and Certificate Commands

```

admin
 — certificate
 — clear-ocsp-cache [entry-id]
 — cmpv2

### 8.10.1.2.2 PKI Infrastructure Commands

```

configure
 — system
 — security
 — pki
 — ca-profile name [create]
 — no ca-profile name
 — cert-file filename
 — no cert-file
 — cmpv2
 — [no] accept-unprotected-errormsg
 — [no] accept-unprotected-pkiconf
 — [no] always-set-sender-for-ir
 — http-response-timeout timeout
 — no http-response-timeout
 — http-version {1.0 | 1.1}
 — key-list
 — key password [hash | hash2] reference
 reference-number
 — no key reference reference-number
 — response-signing-cert filename
 — no response-signing-cert
 — [no] same-recipnonce-for-pollreq
 — url url-string [service-id service-id]
 — no url
 — crl-file filename
 — no crl-file
 — description description-string
 — no description
 — ocsp
 — responder-url url-string
 — no responder-url
 — service service-id
 — no service
 — [no] shutdown
 — certificate-display-format {ascii | utf8}
 — maximum-cert-chain-depth level
 — no maximum-cert-chain-depth

```

### 8.10.1.2.3 IPSec PKI Commands

```

config
 — ipsec
 — cert-profile profile-name [create]
 — no cert-profile profile-name
 — entry entry-id [create]
 — no entry entry-id
 — cert cert-filename
 — no cert
 — key key-filename
 — no key
 — [no] send-chain
 — [no] ca-profile name
 — ike-policy ike-policy-id [create]
 — no ike-policy ike-policy-id
 — auth-method {psk | cert-auth}
 — no auth-method
 — own-auth-method {psk | cert}
 — no auth-method
 — [no] shutdown
 — trust-anchor-profile name [create]
 — no trust-anchor-profile name

```

### 8.10.1.2.4 IKE PKI Commands

```

config
 — service
 — vpn
 — interface ip-int-name [tunnel] [create]
 — no interface ip-int-name
 — sap sap-id [create]
 — no sap sap-id
 — ipsec-tunnel ipsec-tunnel-name [create]
 — no ipsec-tunnel ipsec-tunnel-name
 — cert
 — cert-profile profile
 — no cert-profile
 — status-verify
 — default-result {revoked | good}
 — no default-result
 — primary {crl | ocsp}
 — no primary
 — secondary {crl | ocsp}
 — no secondary
 — trust-anchor-profile profile-name
 — no trust-anchor-profile

```

### 8.10.1.3 Show Commands

#### show

- **certificate**
  - **ca-profile** *name* [**association**]
  - **ocsp-cache** *entry-id*
  - **statistics**
- **ipsec**
  - **cert-profile** *name* **association**
  - **cert-profile** [*name*]
  - **cert-profile** *name* **entry** [1..8]
  - **ike-policy** *ike-policy-id*
  - **ike-policy**
  - **security-policy** **service** *service-id* [**security-policy-id** *security-policy-id*]
  - **security-policy**
  - **transform** [*transform-id*]
  - **trust-anchor-profile** **trust-anchor-profile** **association**
  - **trust-anchor-profile** [*trust-anchor-profile*]
  - **tunnel**
  - **tunnel** *ipsec-tunnel-name*
  - **tunnel** **count**

#### show

- **mda** *slot/mda*
  - **statistics** {**source-mda** | **dest-mda** | **security** [**encryption**] } (for 7705 SAR-18 and 7705 SAR-8 (with CSMv2) )
- **mda aggregate-statistics** (for 7705 SAR-Ax, 7705 SAR-H, 7705 SAR-Hc, 7705 SAR-W, and 7705 SAR-Wx)

Refer to the section “Show, Monitor, Clear, and Debug Command Reference” in the 7705 SAR Interface Configuration Guide for information on the **show>mda** commands.

#### show

- **router**
  - **interface** *ip-int-name* **statistics**

Refer to the section “IP Router Command Reference” in the 7705 SAR Router Configuration Guide for information on the **show>router >interface statistics** command.

---

### 8.10.1.4 Clear Commands

**clear**

- **mda** {*slot/mda* | **all**}
- **mda all statistics**
- **mda** *slot/mda* **statistics security** [**encryption**]

### 8.10.1.5 Debug Commands

**debug**

- [no] **cmpv2**
  - [no] **ca-profile** *profile-name*
- **ipsec**
  - [no] **certificate** *filename*
  - **tunnel** [*ipsec-tunnel-name*] [**detail**]
  - **no tunnel** [*ipsec-tunnel-name*]

---

### 8.10.2.1.1 Generic Commands

#### description

|                    |                                                                                                                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>description</b> <i>description-string</i><br><b>no description</b>                                                                                                                                                                                                                         |
| <b>Context</b>     | config>ipsec>ike-policy<br>config>isa>tunnel-group<br>config>service>ies>interface<br>config>service>ies>if>sap<br>config>service>vpn>interface<br>config>service>vpn>if>sap<br>config>service>vpn>if>sap>ipsec-tunnel                                                                        |
| <b>Description</b> | This command creates a text description stored in the configuration file for a configuration context.<br><br>The <b>no</b> form of this command removes the string from the context.                                                                                                          |
| <b>Default</b>     | No description is associated with the configuration context.                                                                                                                                                                                                                                  |
| <b>Parameters</b>  | <i>description-string</i> — the description character string. Allowed values are any string up to 80 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes. |

#### shutdown

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] shutdown</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Context</b>     | config>isa>tunnel-group<br>config>service>ies>interface<br>config>service>ies>if>sap<br>config>service>vpn>interface<br>config>service>vpn>if>sap                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | The <b>shutdown</b> command administratively disables an entity. The operational state of the entity is disabled as well as the operational state of any entities contained within. When disabled, an entity does not change, reset, or remove any configuration settings or statistics. Many objects must be shut down before they may be deleted. Many entities must be explicitly enabled using the <b>no shutdown</b> command.<br><br>The <b>no</b> form of this command places the entity into an administratively enabled state.<br><br>Services are created in the administratively down state ( <b>shutdown</b> ). When a <b>no shutdown</b> command is entered, the service becomes administratively up and then tries to enter the operationally up state. |

---

### 8.10.2.1.2 ISA Tunnel Commands

#### isa

|                    |                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] isa</b>                                                                                                          |
| <b>Context</b>     | config                                                                                                                   |
| <b>Description</b> | This command creates an ISA tunnel configuration context.<br><br>The <b>no</b> form of this command removes the context. |
| <b>Default</b>     | n/a                                                                                                                      |

#### tunnel-group

|                    |                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>tunnel-group</b> <i>tunnel-group-id</i> [ <b>create</b> ]<br><b>no tunnel-group</b> <i>tunnel-group-id</i>                                                                                                                                                                                                                                     |
| <b>Context</b>     | config>isa                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | This command enables a tunnel group to be created or edited. The 7705 SAR can have only one tunnel group ( <b>tunnel-group</b> 1).<br><br>The <b>no</b> form of the command deletes the specified tunnel group from the configuration.                                                                                                            |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <i>tunnel-group-id</i> — specifies an integer value that uniquely identifies the tunnel group<br><br><b>Values</b> 1 to 16 (1 is the only valid value)<br><br><b>create</b> — mandatory keyword required when creating a tunnel group. The <b>create</b> keyword requirement can be enabled/disabled in the <b>environment&gt;create</b> context. |

### 8.10.2.1.3 Internet Key Exchange (IKE) and Transform Commands

#### ipsec

|                    |                                                                                                                                                                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ipsec</b>                                                                                                                                                                                                                                                |
| <b>Context</b>     | config                                                                                                                                                                                                                                                      |
| <b>Description</b> | This command enables the context to configure Internet Protocol security (IPSec) parameters. IPSec is a structure of open standards to ensure private, secure communications over Internet Protocol (IP) networks by using cryptographic security services. |

#### ike-policy

|                    |                                                                                                                                                                                                                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ike-policy</b> <i>ike-policy-id</i> [ <b>create</b> ]<br><b>no ike-policy</b> <i>ike-policy-id</i>                                                                                                                                                                                                  |
| <b>Context</b>     | config>ipsec                                                                                                                                                                                                                                                                                           |
| <b>Description</b> | This command enables provisioning of IKE policy parameters.<br><br>The <b>no</b> form of the command removes the IKE policy.                                                                                                                                                                           |
| <b>Parameters</b>  | <i>ike-policy-id</i> — specifies a policy ID value to identify the IKE policy<br><br><b>Values</b> 1 to 2048<br><br><b>create</b> — mandatory keyword required when creating an IKE policy. The <b>create</b> keyword requirement can be enabled/disabled in the <b>environment&gt;create</b> context. |

#### auth-algorithm

|                    |                                                                                                                                                                                                                                                                                  |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>auth-algorithm</b> { <b>md5</b>   <b>sha1</b>   <b>sha256</b>   <b>sha384</b>   <b>sha512</b> }<br><b>no auth-algorithm</b>                                                                                                                                                   |
| <b>Context</b>     | config>ipsec>ike-policy                                                                                                                                                                                                                                                          |
| <b>Description</b> | This command specifies which hashing algorithm to use for the IKE authentication function. The <b>no</b> form of the command returns the parameter to its default value.                                                                                                         |
| <b>Default</b>     | sha1                                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <b>md5</b> — specifies the hmac-md5 algorithm for authentication<br><b>sha1</b> — specifies the hmac-sha1 algorithm for authentication<br><b>sha256</b> — specifies the sha256 algorithm for authentication<br><b>sha384</b> — specifies the sha384 algorithm for authentication |

---

**sha512** — specifies the sha512 algorithm for authentication

## auth-method

|                    |                                                                                                                                                                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>auth-method psk</b><br><b>no auth-method</b>                                                                                                                                                                                                                                                                                          |
| <b>Context</b>     | config>ipsec>ike-policy                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | <p>This command specifies the authentication method used with this IKE policy. Configuring the policy for pre-shared key (PSK) or <b>no auth-method</b> produces the same result since PSK is both the default value and the only option.</p> <p>The <b>no</b> form of the command returns the parameter to its default value (psk).</p> |
| <b>Default</b>     | no auth-method                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <b>psk</b> — both the client and the gateway authenticate each other by a hash derived from a secret PSK. Both client and gateway must have the PSK. This works with both IKEv1 and IKEv2.                                                                                                                                               |

## dh-group

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>dh-group {1   2   5   14   15}</b><br><b>no dh-group</b>                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Context</b>     | config>ipsec>ike-policy                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | <p>This command specifies which Diffie-Hellman group is used to calculate session keys:</p> <ul style="list-style-type: none"><li>• Group1: 768 bits</li><li>• Group2: 1024 bits</li><li>• Group5: 1536 bits</li><li>• Group14: 2048 bits</li><li>• Group15: 3072 bits</li></ul> <p>More bits provide a higher level of security but require more processing.</p> <p>The <b>no</b> form of the command returns the parameter to its default value (Group2).</p> |
| <b>Default</b>     | no dh-group (Group2)                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## dpd

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Description</b> | This command specifies the encryption algorithm to use for the IKE session.<br><br>The <b>no</b> form of the command returns the algorithm to its default value (aes128).                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Default</b>     | aes128                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <p><b>des</b> — configures the 56-bit <b>des</b> algorithm for encryption. This is an older algorithm, with relatively weak security. It should only be used when a strong algorithm is not available at both ends at an acceptable performance level.</p> <p><b>3des</b> — configures the <b>3-des</b> algorithm for encryption. This is a modified application of the <b>des</b> algorithm that uses multiple <b>des</b> operations for more security.</p> <p><b>aes128</b> — configures the <b>aes</b> algorithm with a block size of 128 bits. This is the mandatory implementation size for <b>aes</b>.</p> |

**aes192** — configures the **aes** algorithm with a block size of 192 bits. This is a stronger version of **aes**.

**aes256** — configures the **aes** algorithm with a block size of 256 bits. This is the strongest available version of **aes**.

| <b>Description</b> | <p>This command specifies the mode of operation for IKEv1 phase 1, either main mode or aggressive mode. The difference between the modes is the number of messages used to establish the session. IKEv1 phase 1 main mode uses three pairs of messages (for a total of six messages) between IPSec peers. IKEv1 phase 1 aggressive mode has only three message exchanges.</p> <p>This command does not apply to IKEv2.</p> <p>The <b>no</b> form of the command removes the mode of operation.</p> |
| <b>Default</b>     | main                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <p><b>main</b> — specifies that IKEv1 phase 1 will operate in main mode</p> <p><b>aggressive</b> — specifies that IKEv1 phase 1 will operate in aggressive mode</p>                                                                                                                                                                                                                                                                                                                                |

| <b>Context</b>     | config>ipsec>ike-policy                                                                                                                                        |
| <b>Description</b> | <p>This parameter specifies the lifetime of a phase 2 SA.</p> <p>The <b>no</b> form of the command returns the <i>ipsec-lifetime</i> value to the default.</p> |
| <b>Default</b>     | 3600 (1 hr)                                                                                                                                                    |
| <b>Parameters</b>  | <p><i>ipsec-lifetime</i> — specifies the lifetime of the phase 2 IKE key, in seconds</p> <p><b>Values</b> 1200 to 172800</p>                                   |

## isakmp-lifetime

|                    |                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>isakmp-lifetime</b> <i>isakmp-lifetime</i><br><b>no isakmp-lifetime</b>                                                        |
| <b>Context</b>     | config>ipsec>ike-policy                                                                                                           |
| <b>Description</b> | This command specifies the lifetime of a phase 1 SA. ISAKMP stands for Internet Security Association and Key Management Protocol. |

The **no** form of the command returns the *isakmp-lifetime* value to the default value.

**Default** 86400

**Parameters** *isakmp-lifetime* — specifies the lifetime of the phase 1 IKE key, in seconds

**Values** 1200 to 172800

## nat-traversal

**Syntax** **nat-traversal** [**force**] [**keep-alive-interval** *keep-alive-interval*] [**force-keep-alive**]  
**no nat-traversal**

**Context** config>ipsec>ike-policy

**Description** This command specifies whether NAT-T (Network Address Translation Traversal) is enabled, disabled, or in force mode. Enabling NAT-T enables the NAT detection mechanism. If a NAT device is detected in the path between the 7705 SAR and its IPSec peer, then UDP encapsulation is done on the IPSec packet to allow the IPSec traffic to traverse the NAT device.

When **nat-traversal** is used without any parameters, NAT-T is enabled and sending keepalive packets is disabled (*keep-alive-interval* is 0 s).

When the **force** keyword is used, the IPSec tunnel always uses a UDP value in its header, regardless of whether a NAT device is detected.

The **force-keep-alive** keyword specifies whether keepalive packets are sent only when a NAT device is detected or are always sent (regardless of detection of a NAT device). When **force-keep-alive** is used, packets are always sent and the “Behind NAT Only” field in the **show>ipsec>ike-policy** *ike-policy-id* indicates False. When **force-keep-alive** is not used, packets are may or may not be sent, depending on the whether NAT-T is enabled or disabled. In this case, the “Behind NAT Only” field indicates True.

The **keep-alive-timer** keyword defines the frequency, where “0” means that keepalives are disabled.

The **no** form of the command returns the parameters to the default values (NAT-T is disabled, *keep-alive-interval* is 0 s, and **force-keep-alive** is True).

**Default** no nat-traversal

**Parameters** **force** — when specified, forces NAT-T to be enabled

*keep-alive-interval* — specifies the keepalive interval for NAT-T. If the value is 0 s, then keepalive messages are disabled.

**Values** 120 to 600 s

**Default** 0 s

---

**force-keep-alive** — specifies that NAT-T keepalive packets are always sent, regardless of NAT detection results

## own-auth-method

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Context</b>     | config>ipsec>ike-policy                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | <p>This command enables Perfect Forward Secrecy (PFS) on the IPSec tunnel using this policy. PFS provides for a new Diffie-Hellman key exchange each time the SA key is renegotiated. After each SA expires, the key is forgotten and another key is generated (if the SA remains up). This means that an attacker who cracks part of the exchange can only read the part that used the key before the key changed. Thus, there is no advantage to cracking the other parts of the exchange if an attacker has already cracked one.</p> <p>When <b>pfs</b> is used without the <b>dh-group</b> command, the default DH group (Group 2) is used.</p> <p>The <b>no</b> form of the command disables PFS. If <b>pfs</b> is turned off during an active SA, then when the SA expires and it is time to re-key the session, the original Diffie-Hellman primes is used to generate the new keys.</p> |
| <b>Default</b>     | no pfs                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Parameters</b>  | <b>dh-group {1   2   5}</b> — when <b>dh-group</b> is used, specifies which Diffie-Hellman group to use for calculating session keys. Higher dh-group values translate to higher level of security, but require more processing. Three groups are supported:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

- Group 1: 768 bits
- Group 2: 1024 bits
- Group 5: 1536 bits

| <b>Context</b>     | config>ipsec                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | <p>This command enables the context to create an <b>ipsec-transform</b> policy. IPSec transform policies can be shared between IPSec tunnels by using the <a href="#">transform</a> command.</p> <p>IPSec transform policy assignments to a tunnel require the tunnel to be shut down.</p> <p>The <b>no</b> form of the command removes the transform ID from the configuration.</p> |
| <b>Parameters</b>  | <p><i>transform-id</i> — specifies a policy ID value to identify the IPSec transform policy</p> <p><b>Values</b> 1 to 2048</p> <p><b>create</b> — mandatory keyword required when creating an <b>ipsec-transform</b> policy. The <b>create</b> keyword requirement can be enabled/disabled in the <b>environment&gt;create</b> context.</p>                                          |

## esp-auth-algorithm

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Description</b> | <p>This command specifies which hashing algorithm should be used for the authentication function Encapsulating Security Payload (ESP). Both ends of a tunnel must share the same configuration parameters in order for the IPSec tunnel to enter the operational state.</p> <p>The <b>null</b> keyword in this command and the <b>null</b> keyword in the <b>esp-encryption-algorithm</b> command are mutually exclusive.</p> <p>The <b>no</b> form of the command returns the parameter to its default value.</p> |
| <b>Default</b>     | sha1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <p><b>null</b> — a very fast algorithm specified in RFC 2410, which provides no authentication</p> <p><b>md5</b> — configures ESP to use the <b>hmac-md5</b> algorithm for authentication</p> <p><b>sha1</b> — configures ESP to use the <b>hmac-sha1</b> algorithm for authentication</p>                                                                                                                                                                                                                         |

**sha256** — configures ESP to use the **sha256** algorithm for authentication

**sha384** — configures ESP to use the **sha384** algorithm for authentication

**sha512** — configures ESP to use the **sha512** algorithm for authentication

## esp-encryption-algorithm

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Context</b>     | config>ipsec>transform                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | <p>This command specifies the encryption algorithm to use for the IPSec session. Encryption only applies to Encapsulating Security Payload (ESP) configurations.</p> <p>For IPSec tunnels to come up, both ends of the IPSec tunnel (both private-side endpoints) must be configured with the same encryption algorithm. That is, the configuration for <b>vprn&gt;if&gt;sap&gt; ipsec-tunnel transform</b> must match at both nodes.</p> <p>The <b>null</b> keyword in this command and the <b>null</b> keyword in the <b>esp-auth-algorithm</b> command are mutually exclusive.</p> <p>The <b>no</b> form of the command returns the parameter to its default value.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Default</b>     | aes128                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <p><b>null</b> — configures the high-speed null algorithm, which does nothing. This is the same as not having encryption turned on.</p> <p><b>des</b> — configures the 56-bit <b>des</b> algorithm for encryption. This is an older algorithm, with relatively weak security. Although slightly better than no encryption, it should only be used when a strong algorithm is not available at both ends at an acceptable performance level.</p> <p><b>3des</b> — configures the <b>3-des</b> algorithm for encryption. This is a modified application of the <b>des</b> algorithm that uses multiple <b>des</b> operations to make things more secure.</p> <p><b>aes128</b> — configures the <b>aes</b> algorithm with a block size of 128 bits. This is the mandatory implementation size for <b>aes</b>. This is a very strong algorithm choice.</p> <p><b>aes192</b> — configures the <b>aes</b> algorithm with a block size of 192 bits. This is a stronger version of <b>aes</b>.</p> <p><b>aes256</b> — configures the <b>aes</b> algorithm with a block size of 256 bits. This is the strongest available version of <b>aes</b>.</p> |

## static-sa

|                    |                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>static-sa</b> <i>sa-name</i> [ <b>create</b> ]<br><b>no static-sa</b> <i>sa-name</i> |
| <b>Context</b>     | config>ipsec                                                                            |
| <b>Description</b> | This command configures an IPSec static security association (SA).                      |
| <b>Default</b>     | no static-sa                                                                            |
| <b>Parameters</b>  | <i>sa-name</i> — specifies the name of the IPSec static SA, up to 32 characters         |

## authentication

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|                    |                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>spi</b> <i>spi</i><br><b>no spi</b>                                                                                                                                                                                                                                 |
| <b>Context</b>     | config>ipsec>static-sa                                                                                                                                                                                                                                                 |
| <b>Description</b> | This command configures the Security Parameter Index (SPI) key value for the specified IPSec SA.<br><br>The SPI is used to look up the instruction to verify and decrypt the incoming IPSec packets when the value of the <b>direction</b> command is <b>inbound</b> . |

The SPI value specifies the SPI that will be used in the encoding of the outgoing packets when the value of the **direction** command is **outbound**. The remote node can use this SPI to look up the instruction to verify and decrypt the packet.

If no SPI is configured, the static SA cannot be used. The **no** form of the command removes the configured SPI.

**Default** none

**Parameters** *spi* — specifies the SPI for this SA

**Values** 256 to 16383

#### 8.10.2.1.4 Service Configuration Commands

##### ipsec

|                    |                                                               |
|--------------------|---------------------------------------------------------------|
| <b>Syntax</b>      | <b>ipsec</b>                                                  |
| <b>Context</b>     | config>service>vpn                                            |
| <b>Description</b> | This command enables the context to configure IPSec policies. |
| <b>Default</b>     | n/a                                                           |

##### security-policy

|                    |                                                                                                                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>security-policy</b> <i>security-policy-id</i> [ <b>create</b> ]<br><b>no security-policy</b> <i>security-policy-id</i>                                                                                                                                                                                                     |
| <b>Context</b>     | config>service>vpn>ipsec                                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | This command configures a security policy to use for an IPSec tunnel. An <b>entry</b> specifying local and remote IP addresses must be defined before the policy can be used.<br><br>The <b>no</b> form of the command removes the policy. Policy entries must be deleted before the policy can be removed.                   |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <i>security-policy-id</i> — specifies an identifier value to be assigned to a security policy<br><br><b>Values</b> 1 to 8192<br><br><b>create</b> — mandatory keyword used to create the security policy instance. The <b>create</b> keyword requirement can be enabled/disabled in the <b>environment&gt;create</b> context. |

##### entry

|                    |                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>entry</b> <i>entry-id</i> [ <b>create</b> ]<br><b>no entry</b> <i>entry-id</i>                                   |
| <b>Context</b>     | config>service>vpn>ipsec>sec-plcy                                                                                   |
| <b>Description</b> | This command configures an IPSec security policy entry.<br><br>The <b>no</b> form of the command removes the entry. |
| <b>Default</b>     | n/a                                                                                                                 |

---

|                   |                                                                                                                                                                          |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>entry-id</i> — specifies an identifier value for the IPSec security policy entry                                                                                      |
| <b>Values</b>     | 1 to 16                                                                                                                                                                  |
| <b>create</b>     | — mandatory keyword used to create the security policy entry. The <b>create</b> keyword requirement can be enabled/disabled in the <b>environment&gt;create</b> context. |

## local-ip

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Description</b> | <p>This command configures the local (from the VPN) IP prefix/mask for the policy parameter entry.</p> <p>Only one entry is necessary to describe a potential traffic flow. The <b>local-ip</b> and <b>remote-ip</b> commands can be defined only once. The system will evaluate the local IP as the source IP when traffic is examined in the direction of the VPN to the tunnel and as the destination IP when traffic flows from the tunnel to the VPN. The remote IP will be evaluated as the source IP when traffic flows from the tunnel, and as the destination IP to the VPN when traffic flows from the VPN to the tunnel.]</p> <p>The <b>no</b> form of the command clears the IP entry.</p> |
| <b>Default</b>     | no local-ip                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <p><i>ip-prefix</i> — the destination address of the aggregate route in dotted-decimal notation</p> <p><b>Values</b> a.b.c.d (host bits must be 0) (0.0.0.0 is not allowed)<br/><i>prefix-length</i>: 1 to 32</p> <p><i>netmask</i> — the subnet mask in dotted-decimal notation</p> <p><b>Values</b> a.b.c.d (network bits all 1 and host bits all 0) (0.0.0.0 is not allowed)</p> <p><b>any</b> — keyword to specify that it can be any address</p>                                                                                                                                                                                                                                                  |

## local-v6-ip

|                    |                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>local-v6-ip</b> { <i>ipv6-prefix / prefix-length</i>   <b>any</b> }<br><b>no local-v6-ip</b> |
| <b>Context</b>     | config>service>vpn>ipsec>sec-plcy>entry                                                         |
| <b>Description</b> | This command configures the local (from the VPN) IPv6 address for the policy parameter entry.   |

Only one entry is necessary to describe a potential traffic flow. The **local-v6-ip** and **remote-v6-ip** commands can be defined only once. The system will evaluate the local IPv6 address as the source IPv6 address when traffic is examined in the direction of the VPN to the tunnel and as the destination IPv6 address when traffic flows from the tunnel to the VPN. The remote IPv6 address will be evaluated as the source IPv6 address when traffic flows from the tunnel to the VPN and as the destination IPv6 address when traffic flows from the VPN to the tunnel.

The **no** form of the command clears the IPv6 address entry.

**Default** no local-v6-ip

**Parameters** *ipv6-prefix / prefix-length* — the local IPv6 address

|               |                      |                                                                                                                                             |
|---------------|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------|

|               | <i>prefix-length</i> | 0 to 128                                                                                                                                    |

**any** — keyword to specify that it can be any address

remote-ip

**Syntax** **remote-ip** {*ip-prefix / prefix-length* | *ip-prefix netmask* | **any**}  
**no remote-ip**

**Context** config>service>vpn>ipsec>sec-plcy>entry

**Description** This command configures the remote (from the tunnel) IP prefix/mask for the policy parameter entry.

Only one entry is necessary to describe a potential traffic flow. The **local-ip** and **remote-ip** commands can be defined only once. The system will evaluate the local IP as the source IP when traffic is examined in the direction of the VPN to the tunnel and as the destination IP when traffic flows from the tunnel to the VPN. The remote IP will be evaluated as the source IP when traffic flows from the tunnel to the VPN and as the destination IP when traffic flows from the VPN to the tunnel.

The **no** form of the command clears the IP entry.

**Default** no remote-ip

**Parameters** *ip-prefix* — specifies the destination address of the aggregate route in dotted-decimal notation

|               |                                                                                          |
|---------------|------------------------------------------------------------------------------------------|
| <b>Values</b> | a.b.c.d (host bits must be 0) (0.0.0.0 is not allowed)<br><i>prefix-length</i> : 1 to 32 |
|---------------|------------------------------------------------------------------------------------------|

*netmask* — the subnet mask in dotted-decimal notation

**Values**      a.b.c.d (network bits all 1 and host bits all 0) (0.0.0.0 is not allowed)

**any** — keyword to specify that it can be any address

remote-v6-ip

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | <i>prefix-length</i> | 0 to 128                                                                                                                                    |
|                    | <b>any</b> — keyword to specify that it can be any address                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                      |                                                                                                                                             |

### 8.10.2.1.5 Service Interface Tunnel Commands

#### interface

|                    |                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>interface</b> <i>ip-int-name</i> [ <b>tunnel</b> ] [ <b>create</b> ]<br><b>no interface</b> <i>ip-int-name</i>                                                                                                                                                                                                                             |
| <b>Context</b>     | config>service>vpn<br>config>service>ies                                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | This command creates a logical IP routing interface.<br><br>When creating tunnel interfaces, the <b>tunnel</b> keyword must be used for private-side (VPRN) interfaces. The <b>tunnel</b> keyword is not used for public-side (IES or VPRN) interfaces.                                                                                       |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <i>ip-int-name</i> — specifies an IP interface name up to 32 characters in length<br><b>tunnel</b> — specifies that the interface is a private tunnel<br><b>create</b> — mandatory keyword required when creating an IP interface. The <b>create</b> keyword requirement can be enabled/disabled in the <b>environment&gt;create</b> context. |

#### sap

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Context</b>     | config>service>vpn>if<br>config>service>ies>if                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b> | This command creates a SAP.<br><br>For IES and VPRN services using tunnel interfaces, the <i>sap-id</i> for private and public tunnel interfaces are shown below. An IES or VPRN public tunnel SAP is created when the <i>sap-id</i> includes the <b>tunnel</b> and <b>public</b> keywords. The VPRN private tunnel SAP allows provisioning of an IPSec tunnel, and is created when the VPRN <i>sap-id</i> includes the <b>tunnel</b> and <b>private</b> keywords<br><br>See <a href="#">sap</a> In the VLL Services Command Reference for details on configuring all SAPs. |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Parameters** *sap-id* — specifies the port identifier portion of the SAP definition. For a tunnel interface, the *sap-id* is as follows:

|               |                                                           |
|---------------|-----------------------------------------------------------|
| <b>Values</b> | <i>tunnel-id</i> . <i>[private   public]</i> : <i>tag</i> |
|               | tunnel keyword                                            |
|               | <i>id</i> 1 to 16 (only the value 1 is allowed)           |
|               | private keyword                                           |
|               | public keyword                                            |
|               | <i>tag</i> 0 to 4094                                      |

**create** — mandatory keyword required when creating a SAP. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

## ipsec-tunnel

**Syntax** **ipsec-tunnel** *ipsec-tunnel-name* [**create**]  
**no ipsec-tunnel** *ipsec-tunnel-name*

**Context** config>service>vpn>if>sap

**Description** This command specifies an IPSec tunnel name. Configuring the commands under the **ipsec-tunnel** context defines where the IPSec tunnel originates and terminates, and how it is secured.

**Default** n/a

**Parameters** *ipsec-tunnel-name* — specifies an IPSec tunnel name up to 32 characters in length

**create** — mandatory keyword required when creating an IPSec tunnel instance. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

## bfd-designate

**Syntax** [**no**] **bfd-designate**

**Context** config>service>vpn>if>sap>ipsec-tunnel

**Description** This command specifies whether this IPSec tunnel is the BFD-designated tunnel.

A BFD-designated tunnel is the tunnel over which a BFD session is established. A BFD-designated tunnel does not go down when BFD goes down. Other tunnels that use that BFD-designated tunnel's BFD session will go down based on the state of the BFD session.

**Default** no bfd-designate

# bfd-enable

| <b>Description</b> | This command assigns a BFD session to provide the heartbeat mechanism for the specified IPSec tunnel. There can be only one BFD session assigned to any given IPSec tunnel, but there can be multiple IPSec tunnels using same BFD session. BFD controls the state of the associated tunnel; if the BFD session goes down, the system will also bring down the associated non-designated IPSec tunnel.                                                                                                                                                                                                                                                                                 |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Description</b> | <p>This command enables dynamic keying for the IPSec tunnel. Dynamic keying means that the IKE protocol is used to dynamically exchange keys and establish IPSec-SAs. When IKE is used, a tunnel will have ISAKMP-SA for phase 1 (used by IKE) and IPSEC-SA for phase 2 (used for traffic encryption).</p> <p>The <b>dynamic-keying</b> and <b>manual-keying</b> commands are mutually exclusive. One of these commands must be configured to make the tunnel operational.</p> <p>The <b>no</b> form of the command returns the SA keying type to its default value.</p> |
| <b>Default</b>     | no dynamic-keying                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## auto-establish

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] auto-establish</b>                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Context</b>     | config>service>vpn>if>sap>ipsec-tunnel>dynamic-keying                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b> | <p>This command specifies whether to attempt to establish a phase 1 exchange automatically. The <b>auto-establish</b> command should only be enabled on one side of the tunnel. A tunnel with <b>auto-establish</b> enabled acts as an IKE initiator and does not respond to a new phase 1 request.</p> <p>The <b>no</b> form of the command disables the automatic attempts to establish a phase 1 exchange.</p> |
| <b>Default</b>     | no auto-establish                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Description</b> | <p>This command specifies the pre-shared key (PSK), or secret passphrase, that will be used to initiate the tunnel IKE session. If the <b>hash</b> or <b>hash2</b> parameter is not used, the key is a clear text key; otherwise, the key text is encrypted. For security, all keys are stored in encrypted form in the configuration file with the <b>hash</b> or <b>hash2</b> parameter specified.</p> <p>The <b>no</b> form of the command removes the pre-shared key.</p>                                                                   |
| <b>Default</b>     | no pre-shared-key                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <p><b>key</b> — specifies a pre-shared key for dynamic keying, where the key is up to 64 ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within parentheses.</p> <p><b>hash</b> — specifies that the key is entered in an encrypted form</p> <p><b>hash2</b> — specifies that the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the <b>hash2</b> encrypted variable cannot be copied and pasted</p> |

| <b>Description</b> | <p>This command associates the IPSec transform set allowed for this tunnel. A maximum of four transforms can be specified. The transforms are listed in decreasing order of preference (the first one specified is the most preferred). The list of <i>transform-ids</i> is overwritten each time the command is issued. Transforms are defined using the <a href="#">ipsec-transform</a> command.</p> <p>The <b>no</b> form of the command returns the command to its default state.</p> |
| <b>Default</b>     | no transform                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b>  | <p><i>transform-id</i> — specifies the value used for transforms for dynamic keying</p> <p><b>Values</b> 1 to 2048</p>                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Context</b>     | config>service>vprn>if>sap>ipsec-tunnel                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Description</b> | <p>This command configures the IP maximum transmit unit (MTU) (packet) for this interface.</p> <p>The <b>ip-mtu</b> command instructs the 7705 SAR to perform IP packet fragmentation prior to IPSec encryption and encapsulation, based on the configured MTU value.</p> <p>On the 7705 SAR, unencrypted IP packets arriving on a VPRN access interface and destined for an IPSec uplink will be fragmented if the incoming packet is larger than:</p> <ul style="list-style-type: none"> <li>• the VPRN private interface MTU</li> <li>• the IPSec tunnel MTU</li> <li>• the difference between the uplink MTU and the IPSec overhead (uplink interface MTU minus IPSec overhead), where the IPSec overhead values are calculated as follows: <ul style="list-style-type: none"> <li>– IPSec overhead if NAT-T is enabled<br/> <b>IPSec overhead = outer IPSec (20) + UDP (8) + ESP (24) + trailer (17) + ICV (32)</b><br/> <b>= 101 bytes</b></li> <li>– IPSec overhead if NAT-T is disabled (<b>no nat-t</b>)<br/> <b>IPSec overhead = outer IP (20) + ESP (24) + trailer (17) + ICV (32) = 93 bytes</b></li> </ul> </li> </ul> <p>The actual overhead depends on the payload size, and the encryption and authentication algorithms used.</p> <p>The <b>no ip-mtu</b> command, corresponding to the default behavior, disables fragmentation of IP packets by the 7705 SAR; all IP packets, regardless of size or DF bit setting, are allowed into the tunnel.</p> |
| <b>Default</b>     | no ip-mtu                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <i>octets</i> — specifies the MTU for the IP packet, expressed as the number of octets<br><b>Values</b> 512 to 9000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## local-gateway-address

|                    |                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>local-gateway-address</b> <i>ip-address</i> <b>peer</b> <i>ip-address</i> <b>delivery-service</b> <i>service-id</i><br><b>no local-gateway-address</b> |
| <b>Context</b>     | config>service>vprn>if>sap>ipsec-tunnel                                                                                                                   |
| <b>Description</b> | This command specifies the local gateway address used by the tunnel and the remote gateway address at the other end of the tunnel.                        |

The local gateway address is the source address of the outgoing encrypted packet and the peer gateway address is the destination address. The delivery service is the IES service that has the corresponding public tunnel interface configured under it.

The local gateway address must be in the same subnet as the public tunnel interface.

**Parameters** *ip-address* — IPv4 address of the local and peer ends of the tunnel

**Values** a.b.c.d

*service-id* — specifies the ID of the IES or VPRN (front-door) delivery service of this tunnel. Use this *service-id* to find the VPRN used for delivery.

**Values** *service-id*: 1 to 2147483647 or *svc-name*, which specifies an existing service name up to 64 characters in length

## manual-keying

**Syntax** [no] manual-keying

**Context** config>service>vprn>if>sap>ipsec-tunnel

**Description** This command allows manual configuration of tunnel Security Associations. Manual keying can be used in lieu of dynamic keying and IKE.

The **dynamic-keying** and **manual-keying** commands are mutually exclusive. One of these commands must be configured to make the tunnel operational.

When manual keying is used, both encryption and authentication must be entered manually for inbound and outbound SAs. Encryption and authentication modes, along with associated keys, must match on both sides of the tunnel. Inbound SA configuration on the near-end system must match outbound SA configuration on the far-end system, and vice versa. Make sure to use the correct key length, based on the **ipsec-transform** configuration.

A configuration example for manual keying is shown below:

**Example:**

```
ipsec-transform 2 create
 esp-auth-algorithm sha512
 esp-encryption-algorithm aes128
exit
ipsec-tunnel "privateTunnel" create
 security-policy 4
 local-gateway-address 10.1.1.2 peer 10.3.3.2
 delivery-service 100
 manual-keying
 security-association 8 direction inbound spi 500
 transform 2 encryption-key 5253c408a123817358
 authentication-key 0x1c4a94f71e5366f3760863
 security-association 8 direction outbound spi 600
 transform 2 encryption-key 0xe9ffb43d2ddd
 authentication-key 0x1db443f855693f0fe45d
```

```
exit
no shutdown
exit
```

The **no** form of the command returns the SA keying type to its default value.

**Default**      no manual-keying

security-association

**Syntax**      **security-association** *security-entry-id* **authentication-key** *authentication-key*  
                 **encryption-key** *encryption-key* **spi** *spi* **transform** *transform-id* **direction** {inbound |  
                 outbound}  
         **no security-association** *security-entry-id* **direction** {inbound | outbound}

**Context**      config>service>vpn>if>sap>ipsec-tunnel>>manual-keying

**Description**    This command configures the information required for manual keying SA creation.

**Default**       n/a

**Parameters**    *security-entry-id* — specifies the ID of an SA entry  
                 **Values**      1 to 16  
*authentication-key* — specifies the key used for the authentication algorithm  
                 **Values**      none or 0x0 to 0xFFFFFFFF...(max 128 hex nibbles)  
*encryption-key* — specifies the key used for the encryption algorithm  
                 **Values**      none or 0x0 to 0xFFFFFFFF...(max 64 hex nibbles)  
*spi* — specifies the SPI (Security Parameter Index) used to look up the instruction to  
                 verify and decrypt the incoming IPSec packets when the direction is inbound. When  
                 the direction is outbound, the SPI will be used in the encoding of the outgoing  
                 packets. The remote node can use this SPI to look up the instruction to verify and  
                 decrypt the packet.  
                 **Values**      256 to 16383  
*transform-id* — specifies the transform entry that will be used by this SA entry. This object  
                 should be specified for all the entries created that are manual SAs.  
                 **Values**      1 to 2048  
**direction {inbound | outbound}** — specifies the direction of the IPSec tunnel

## security-policy

|                    |                                                                                                                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>security-policy</b> <i>security-policy-id</i><br><b>no security-policy</b>                                                                                                                                                                             |
| <b>Context</b>     | config>service>vpn>if>sap>ipsec-tunnel                                                                                                                                                                                                                    |
| <b>Description</b> | <p>This command identifies an IPSec security policy (defined under the <b>vpn&gt;ipsec</b> context) that is to be used for this IPSec tunnel.</p> <p>The <b>no</b> form of the command returns the <b>security-policy</b> to its default state (n/a).</p> |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <i>security-policy-id</i> — specifies the IPSec security policy that the tunnel will use                                                                                                                                                                  |
| <b>Values</b>      | 1 to 8192                                                                                                                                                                                                                                                 |

| <b>Description</b> | <p>This command requests an additional certificate after the system has obtained the initial certificate from the CA.</p> <p>The request is authenticated by a signature signed by the <b>current-key</b>, along with the <b>current-cert</b>. The hash algorithm used for the signature depends on the key type:</p> <ul style="list-style-type: none"> <li>• DSA key: SHA1</li> <li>• RSA key: MD5   SHA1   SHA224   SHA256   SHA384   SHA512; the default is SHA1</li> </ul> <p>In some cases, the CA may not return a certificate immediately, due to reasons such as the request processing needs manual intervention. In such cases, the <b>admin certificate cmpv2 poll</b> command can be used to poll the status of the request.</p> |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Description</b> | <p>This command requests the initial certificate from the CA by using the CMPv2 initial registration procedure.</p> <p>The <b>ca</b> keyword specifies a <b>ca-profile</b> that includes CMP server information.</p> <p>The <b>key-to-certify</b> keyword is an imported key file to be certified by the CA.</p>                                                                                                                                                                                                                                                    |

The **protection-key** keyword is an imported key file used to for message protection if **protection-alg** is configured as **signature**.

The request is authenticated using either of the following methods:

- a password and a reference number that is predistributed by the CA using out-of-band means. The specified password and reference number are not necessarily in the **CMP key-list** configured in the corresponding **ca-profile**.
- a signature signed by the **protection-key** or **key-to-certify**, optionally along with the corresponding certificate. If the **protection-key** is not specified, the system will use the **key-to-certify** keyword for message protection. The hash algorithm used for the signature depends on the key type:
  - DSA key: SHA1
  - RSA key: MD5 | SHA1 | SHA224 | SHA256 | SHA384 | SHA512; the default is SHA1

Optionally, the system could also send a certificate or a chain of certificates in the extraCerts field. The certificate is specified by the **cert cert-file-name** parameter; it must include the public key of the key used for message protection.

Sending a chain is enabled by specifying the **send-chain** keyword.

The **subject-dn** keyword specifies the subject of the requesting certificate.

The **save-as** keyword specifies the full path name to save the result certificate to.

In some cases, the CA may not return the certificate immediately; for example, because the request processing requires manual intervention. In such cases, the **admin certificate cmpv2** poll command could be used to poll the status of the request. If the **key-list** command is not configured in the corresponding **ca-profile**, then the system will use the existing password to authenticate the CMPv2 packets from the server if it is in password protection.

If **key-list** is configured in the corresponding **ca-profile** and the server does not send a SenderKID message, then the system will use the lexicographical first key in the **key-list** to authenticate the CMPv2 packets from the server in case it is in password protection.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Parameters</b> | <p><b>ca</b> <i>ca-profile-name</i> — specifies a certificate authority profile name that includes CMP server information, up to 32 characters</p> <p><b>key-to-certify</b> <i>key-filename</i> — the filename of the key to certify, up to 95 characters</p> <p><i>password</i> — an ASCII string, up to 64 characters</p> <p><i>ref-number</i> — the reference number for this CA initial authentication key, up to 64 characters</p> <p><i>cert-file-name</i> — specifies the certificate filename, up to 95 characters</p> <p><b>send-chain with-ca</b> <i>ca-profile-name</i> — sends the chain</p> <p><b>protection-key</b> <i>key-file-name</i> — the protection key associated with the action on the CA profile</p> |

**hash-alg** — the hash algorithm for the RSA key

**Values** md5, sha1, sha224, sha256, sha384, sha512

**dn** — the subject of the requesting certificate, up to 256 characters

**Values** attr1=val1,attr2=val2... where: attrN = {C | ST | O | OU | CN}

**save-path-of-result-cert** — the full path name to save the result certificate to, up to 200 characters

## key-update

| <b>Description</b> | <p>This command displays the contents of an input file in plain text. When displaying the key file contents, only the key size and type are displayed.</p> <p>The following list summarizes the formats supported by this command:</p> <ul style="list-style-type: none"> <li>• System <ul style="list-style-type: none"> <li>– system format</li> <li>– PKCS #12</li> <li>– PKCS #7 PEM encoded</li> <li>– PKCS #7 DER encoded</li> <li>– RFC4945</li> </ul> </li> </ul> |

- Certificate Request
  - PKCS #10
- Key
  - system format
  - PKCS #12
- CRL
  - system format
  - PKCS #7 PEM encoded
  - PKCS #7 DER encoded
  - RFC4945

**Default** n/a

**Parameters** *url-string* — the local compact flash URL of the input file

**Values**

|                   |   |                                          |
|-------------------|---|------------------------------------------|
| <i>url-string</i> | : | <i>local-url</i> , 99 characters maximum |
| <i>local-url</i>  | : | <i>cflash-id/file-path</i>               |
| <i>cflash-id</i>  | : | cf1:, cf2:, cf3:                         |

**type** — the type of input file; possible values are cert, key, crl, or cert-request

**Values** cert, key, crl, cert-request

**format** — the format of the input file

**Values** pkcs10, pkcs12, pkcs7-der, pkcs7-pem, pem, der

*password* — the password to decrypt the input file if it is an encrypted PKCS# 12 file, up to 32 characters

## export

**Syntax** **export type {cert | key | crl} input filename output url-string format output-format**  
**[password password] [pkey pkey-filename]**

**Context** admin>certificate

**Description** This command performs certificate operations.

## gen-keypair

**Syntax** **gen-keypair url-string [size {512 | 1024 | 2048}] [type {rsa | dsa}]**

**Context** admin>certificate

**Description** This command generates an RSA or DSA private key/public key pair and stores it in a local file in the cf3:\system-pki\key directory.

---

|                   |                                                                                                                                                      |

| <b>Parameters</b>  | <i>url-string</i> — the name of the key file in cf3:\system-pki\key that is used to generate a certificate request<br><b>Values</b> <i>url-string</i> : <i>local-url</i> , 99 characters maximum<br><i>local-url</i> : <i>cflash-id/file-path</i><br><i>cflash-id</i> : cf1:, cf2:, cf3:<br><i>subject-dn</i> — the distinguishing name that is used as the subject in a certificate request, including: <ul style="list-style-type: none"> <li>• C – Country</li> <li>• ST – State</li> <li>• O – Organization name</li> <li>• OU – Organization Unit name</li> <li>• CN – common name</li> </ul> This parameter is formatted as a text string including any of the above attributes. The attribute and its value are linked by using "=", and "," is used to separate different attributes. |

For example: C=US,ST=CA,O=ALU,CN=SR12

**Values** attr1=val1,attr2=val2... where: attrN = {C | ST | O | OU | CN}, up to 256 characters

*domain-name* — optionally, a domain name string can be specified and included as the `dnsName` in the Subject Alternative Name extension of the certificate request, up to 255 characters

*ip-address* | *ipv6-address* — optionally, an IPv4 or IPv6 address string can be specified and included as the `ipAddress` in the Subject Alternative Name extension of the certificate request

*url-string* — a local compact flash path and filename to save the certificate request to, or an FTP URL to upload the certificate request

*hash-algorithm* — the hash algorithm to be used in a certificate request

**Values** sha1, sha224, sha256, sha384, sha512

**use-printable** — encodes the certificate in printable text format instead of in UTF8

## import

| <b>Description</b> | <p>This command converts an input file (either key, certificate, or CRL) to a system format file. The following list summarizes the formats supported by this command.</p> <ul style="list-style-type: none"> <li>• Certificate <ul style="list-style-type: none"> <li>– PKCS #12</li> <li>– PKCS #7 PEM encoded</li> <li>– PKCS #7 DER encoded</li> <li>– PEM</li> <li>– DER</li> </ul> </li> <li>• Key <ul style="list-style-type: none"> <li>– PKCS #12</li> <li>– PEM</li> <li>– DER</li> </ul> </li> <li>• CRL <ul style="list-style-type: none"> <li>– PKCS #7 PEM encoded</li> <li>– PKCS #7 DER encoded</li> <li>– PEM</li> <li>– DER</li> </ul> </li> </ul> |

If there are multiple objects with same type in the input file, only the first object will be extracted and converted.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                   |                                            |                  |                              |                  |                    |

| <b>Description</b> | <p>This command reloads an imported certificate or key file or both at the same time. This command is typically used to update a certificate and/or key file without shutting down the IPSec tunnel, <b>cert-profile</b>, or <b>ca-profile</b>.</p> <ul style="list-style-type: none"> <li>• If the new file exists and is valid, then for each tunnel using it: <ul style="list-style-type: none"> <li>– if the key matches the certificate, then the new file will be downloaded to the 7705 SAR to be used the next time. Tunnels currently up are not affected.</li> <li>– if the key does not match the certificate: <ul style="list-style-type: none"> <li>• if the <b>cert</b> and <b>key</b> configuration is used instead of <b>cert-profile</b>, then the tunnel will be brought down</li> <li>• if the <b>cert-profile</b> is used, then <b>cert-profile</b> will be brought down. The next authentication will fail but the established tunnels are not affected.</li> </ul> </li> </ul> </li> </ul> |

If the new file does not exist or is invalid, then this command will abort.

| <b>Context</b>     | config>system>security>pki                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b> | <p>This command creates a new certificate authority profile or enters the configuration context of an existing certificate authority profile. Up to 128 CA profiles can be created in the system. A <b>shutdown</b> of the <b>ca-profile</b> will not affect the current up and running <b>ipsec-tunnel</b> associated with the <b>ca-profile</b>; however, subsequent authentication will fail.</p> <p>Executing a <b>no shutdown</b> command in this context will cause the system to reload the configured <b>cert-file</b> and <b>crl-file</b>.</p> <p>A <b>ca-profile</b> can be applied under the <b>ipsec-tunnel</b> configuration.</p> <p>The <b>no</b> form of the command removes the name parameter from the configuration. A CA profile cannot be removed until all the associations (IPSec tunnels) have been removed.</p> |
| <b>Parameters</b>  | <p><i>name</i> — the name of the <b>ca-profile</b>, a string up to 32 characters</p> <p><b>create</b> — the keyword used to create a new <b>ca-profile</b>. The <b>create</b> keyword requirement can be enabled or disabled in the <b>environment&gt;create</b> context.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

#### cert-file

|                    |                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>cert-file</b> <i>filename</i><br><b>no cert-file</b>                                                                    |
| <b>Context</b>     | config>system>security>pki>ca-profile                                                                                      |
| <b>Description</b> | This command specifies the name of a file in the cf3:\system-pki\cert directory as the CA's certificate of the CA profile. |

The system performs the following checks against a configured **cert-file** when a **no shutdown** command is issued.

- The configured **cert-file** is a DER-formatted X.509v3 certificate file.
- All mandatory fields defined in section 4.1 of RFC 5280 exist and conform to the RFC 5280-defined format.
- The Version field has a value of 0x2.
- The Validity field indicates that the certificate is still valid.
- The X.509 basic constraints extension exists, and the CA Boolean is true.
- If the Key Usage extension exists, then at least keyCertSign and cRLSign are asserted.
- If the certificate is not a self-signing certificate, then the system will look for the issuer's CA's certificate to verify that this certificate is signed by the issuer's CA. If there is no such CA profile configured, then the system will just proceed with a warning message.
- If the certificate is not a self-signing certificate, then the system will look for the issuer's CA's CRL to verify that it has not been revoked. If there is no such CA profile configured or there is no such CRL, then the system will just proceed with a warning message.

If any of above checks fails, then the **no shutdown** command will fail.

Changing or removing the **cert-file** is only allowed when the **ca-profile** is in a shutdown state.

The **no** form of the command removes the filename from the configuration.

**Parameters** *filename* — the local compact flash file URL

## cmpv2

**Syntax** **cmpv2**

**Context** config>system>security>pki>ca-profile

**Description** This command enables the context to configure CMPv2 parameters. Changes are not allowed when the CA profile is enabled (**no shutdown**).

## accept-unprotected-errormsg

**Syntax** [**no**] **accept-unprotected-errormsg**

**Context** config>system>security>pki>ca-profile>cmpv2

**Description** This command enables the system to accept both protected and unprotected CMPv2 error messages. Without this command, the system will accept only protected error messages.

The **no** form of the command causes the system to accept only protected PKI error messages.

**Default** no accept-unprotected-errormsg

---

## accept-unprotected-pkiconf

|                    |                                                                                                                                                                                                                                                                                                                        |

| <b>Context</b>     | config>system>security>pki>ca-profile>cmpv2>key-list                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b> | <p>This command specifies a pre-shared key used for CMPv2 initial registration. Multiples of key commands are allowed to be configured under this context.</p> <p>The <i>password</i> and <i>reference-number</i> parameters are distributed by the CA using out-of-band means.</p> <p>The configured password is stored in a configuration file in an encrypted form by using a 7705 SAR hash2 algorithm.</p> <p>The <b>no</b> form of the command removes the parameters from the configuration.</p>                                                                                                                                            |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <p><i>password</i> — a printable ASCII string, up to 64 characters</p> <p><b>hash</b> — specifies that the given password is already hashed using hashing algorithm version 1. A semantic check is performed on the given password field to verify that it is a valid hash 1 key to store in the database.</p> <p><b>hash2</b> — specifies that the given password is already hashed using hashing algorithm version 2. A semantic check is performed on the given password field to verify that it is a valid hash 2 key to store in the database.</p> <p><i>reference-number</i> — Specifies a printable ASCII string, up to 64 characters.</p> |

## response-signing-cert

|                    |                                                                                                                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>response-signing-cert</b> <i>filename</i><br><b>no response-signing-cert</b>                                                                                                                             |
| <b>Context</b>     | config>system>security>pki>ca-profile>cmpv2                                                                                                                                                                 |
| <b>Description</b> | This command specifies an imported certificate that is used to verify the CMP response messages if they are protected by a signature. If this command is not configured, then the CA's certificate is used. |
| <b>Default</b>     | n/a                                                                                                                                                                                                         |
| <b>Parameters</b>  | <i>filename</i> — the filename of the imported certificate                                                                                                                                                  |

## same-recipnonce-for-pollreq

|                    |                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] same-recipnonce-for-pollreq</b>                                                                   |
| <b>Context</b>     | config>system>security>pki>ca-profile>cmpv2                                                               |
| <b>Description</b> | This command enables the system to use the same recipNonce as the last CMPv2 response for a poll request. |
| <b>Default</b>     | n/a                                                                                                       |

## url

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Context</b>     | config>system>security>pki>ca-profile>cmpv2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b> | <p>This command specifies the HTTP URL of the CMPv2 server. The URL must be unique across all configured CA profiles.</p> <p>The URL will be resolved by the DNS server configured (if configured) in the corresponding router context.</p> <p>If the <i>service-id</i> is 0 or omitted, then the system will try to resolve the FQDN using the DNS server configured in bof.cfg. After resolution, the system will first connect to the address in the management routing instance, then to the address in the base routing instance.</p> <p>If the service is VPRN, then the system only allows HTTP ports 80 and 8080.</p> |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <i>url-string</i> — Specifies the HTTP URL of the CMPv2 server, up to 180 characters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**service-id** *service-id* — the service or router instance that is used to reach the CMPv2 server

**Values**      service-id: 1 to 2147483647

| <b>Description</b> | <p>This command specifies the name of a file in the cf3:\system-pki\crl directory as the Certification Revoke List file of the <b>ca-profile</b>.</p> <p>The system performs the following checks against a configured <b>crl-file</b> when a <b>no shutdown</b> command is issued.</p> <ul style="list-style-type: none"> <li>• A valid <b>cert-file</b> of the <b>ca-profile</b> is already configured.</li> <li>• A configured <b>crl-file</b> is a DER-formatted CRLv2 file.</li> <li>• All mandatory fields defined in section 5.1 of RFC 5280 exist and conform to the RFC 5280-defined format.</li> <li>• The version field has a value of 0x1.</li> <li>• The delta CRL Indicator does not exist (delta CRL is not supported).</li> <li>• The CRL's signature is verified by using the <b>cert-file</b> of the <b>ca-profile</b>.</li> </ul> <p>If any of above checks fail, the <b>no shutdown</b> command will fail.</p> <p>Changing or removing the <b>crl-file</b> is only allowed when the <b>ca-profile</b> is in a <b>shutdown</b> state.</p> <p>The <b>no</b> form of the command removes the filename from the configuration.</p> |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <i>filename</i> — the name of CRL file stored in cf3:\system-pki\crl                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## description

|                    |                                                                       |
|--------------------|-----------------------------------------------------------------------|
| <b>Syntax</b>      | <b>description</b> <i>description-string</i><br><b>no description</b> |
| <b>Context</b>     | config>system>security>pki>ca-profile                                 |
| <b>Description</b> | This command configures a description of the specified CA profile.    |
| <b>Default</b>     | n/a                                                                   |

---

**Parameters**    *description-string* — describe the CA profile, up to 80 characters

## ocsp

**Syntax**        **ocsp**

**Context**        config>system>security>pki>ca-profile

**Description**    This command enables the context to configure OCSP parameters.

## responder-url

**Syntax**        **responder-url** *url-string*  
**no responder-url**

**Context**        config>system>security>pki>ca-profile>ocsp

**Description**    This command specifies the HTTP URL of the OCSP responder for the CA. This URL will only be used if there is no OCSP responder defined in the AIA extension of the certificate to be verified.

**Default**        no responder-url

**Parameters**    *url-string* — the HTTP URL of the OCSP responder

## service

**Syntax**        **service** *service-id*  
**no service**

**Context**        config>system>security>pki>ca-profile>ocsp

**Description**    This command specifies the service or routing instance that is used to contact the OCSP responder. This applies to OCSP responders that are either configured in the CLI or defined in the AIA extension of the certificate to be verified.

The **responder-url** is resolved by using the DNS server configured in the configured routing instance.

For a VPRN service, the system verifies that the specified *service-id* or *service-name* is an existing VPRN service at the time of CLI configuration; if it is not, the configuration will fail.

**Parameters**    *service-id* — specifies an existing service or router instance to be used in the match criteria

**Values**        service-id: 1 to 2147483647  
                   base-router: 0

| <b>Description</b> | <p>This command enables or disables the <b>ca-profile</b>. The system will verify the configured <b>cert-file</b> and <b>crl-file</b>. If the verification fails, then the <b>no shutdown</b> command will fail.</p> <p>A <b>ca-profile</b> in a <b>shutdown</b> state cannot be used in certificate authentication.</p> <p>In the <b>config&gt;ipsec&gt;cert-profile</b> context, this command enables or disables the certificate profile.</p> |
| <b>Default</b>     | shutdown                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## certificate-display-format

|                    |                                                                                                                                                                                      |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>certificate-display-format {ascii   utf8}</b>                                                                                                                                     |
| <b>Context</b>     | config>system>security>pki                                                                                                                                                           |
| <b>Description</b> | This command specifies the display format used for the Certificates and Certificate Revocation Lists.                                                                                |
| <b>Default</b>     | ascii                                                                                                                                                                                |
| <b>Parameters</b>  | <b>ascii</b> — use the ASCII format for the Certificates and Certificate Revocation Lists<br><b>utf8</b> — use the UTF8 format for the Certificates and Certificate Revocation Lists |

## maximum-cert-chain-depth

|                    |                                                                                                                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>maximum-cert-chain-depth <i>level</i></b><br><b>no maximum-cert-chain-depth</b>                                                                                                         |
| <b>Context</b>     | config>system>security>pki                                                                                                                                                                 |
| <b>Description</b> | <p>This command defines the maximum depth of certificate chain verification. This value is applied system-wide.</p> <p>The <b>no</b> form of the command reverts to the default value.</p> |
| <b>Default</b>     | 7                                                                                                                                                                                          |

---

**Parameters**    *level* — specifies the maximum depth of certificate chain verification. The certificate under verification is not counted in the chain. For example, if this parameter is set to 1, then the certificate under verification must be directly signed by the trust anchor CA.

**Values**        1 to 7

| <b>Description</b> | This command enters the configuration context of send-chain in the <b>cert-profile</b> entry.<br><br>This command is optional. By default, the system sends the certificate specified by the <b>cert</b> command in the selected entry to the peer. This command allows the system to send additional CA certificates to the peer. These additional CA certificates must be in the certificate chain of the certificate specified by the <b>cert</b> command in the same entry. |

## ca-profile

|                    |                                                                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] ca-profile</b> <i>name</i>                                                                                                                                                                                             |
| <b>Context</b>     | config>ipsec>cert-profile>entry>send-chain                                                                                                                                                                                     |
| <b>Description</b> | This command specifies that a certificate authority (CA) certificate in the specified <b>ca-profile</b> is to be sent to the peer.<br><br>Multiple configurations (up to seven) of this command are allowed in the same entry. |
| <b>Default</b>     | n/a                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <i>name</i> — the profile name, up to 32 characters in length                                                                                                                                                                  |

---

## ike-policy

|                    |                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ike-policy</b> <i>ike-policy-id</i> [ <b>create</b> ]<br><b>no ike-policy</b> <i>ike-policy-id</i>                         |
| <b>Context</b>     | config>ipsec                                                                                                                  |
| <b>Description</b> | This command enables the context to configure an IKE policy.<br><br>The <b>no</b> form of the command deletes the IKE policy. |
| <b>Parameters</b>  | <i>ike-policy-id</i> — specifies a policy ID value to identify the IKE policy<br><b>Values</b> 1 to 2048                      |

## auth-method

|                    |                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>auth-method</b> { <b>psk</b>   <b>cert-auth</b> }<br><b>no auth-method</b>                                                                                                                                                                                                                                                                            |
| <b>Context</b>     | config>ipsec>ike-policy                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | This command specifies the authentication method used with this IKE policy.<br><br>The <b>no</b> form of the command removes the parameter from the configuration.                                                                                                                                                                                       |
| <b>Default</b>     | no auth-method                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <b>psk</b> — both the client and gateway authenticate each other by a hash derived from a pre-shared secret. Both client and gateway must have the PSK. This works with both IKEv1 and IKEv2.<br><br><b>cert-radius</b> — use the certificate, public/private key and RADIUS to authenticate. This parameter applies to IKEv2 remote-access tunnel only. |

## own-auth-method

|                    |                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>own-auth-method</b> { <b>psk</b>   <b>cert</b> }<br><b>no own-auth-method</b>             |
| <b>Context</b>     | config>ipsec>ike-policy                                                                      |
| <b>Description</b> | This command configures the authentication method used with this IKE policy on its own side. |

---

## trust-anchor-profile

|                    |                                                                                                                                                                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>trust-anchor-profile</b> <i>name</i> [create]<br><b>no trust-anchor-profile</b> <i>name</i>                                                                                                                                             |
| <b>Context</b>     | config>ipsec                                                                                                                                                                                                                               |
| <b>Description</b> | This command specifies the <b>trust-anchor-profile</b> for the IPSec tunnel. This command will override the <b>trust-anchor-profile</b> configuration in the <b>config&gt;service&gt;vpn&gt;if&gt;sap&gt;ipsec-tunnel&gt;cert</b> context. |
| <b>Default</b>     | no trust-anchor-profile                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <i>profile-name</i> — the <b>trust-anchor-profile</b> name                                                                                                                                                                                 |

### 8.10.2.2.4 IKE PKI Commands

#### cert-profile

|                    |                                                                                                                                                                                                                                      |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>cert-profile</b> <i>profile-name</i> [ <b>create</b> ]<br><b>no cert-profile</b> <i>profile-name</i>                                                                                                                              |
| <b>Context</b>     | config>service>vpn>if>sap>ipsec-tunnel>cert                                                                                                                                                                                          |
| <b>Description</b> | This command creates a new certificate profile or enters the configuration context of an existing certificate profile.<br><br>The <b>no</b> form of the command removes the profile name from the <b>cert-profile</b> configuration. |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                  |
| <b>Parameters</b>  | <i>profile-name</i> — the name of the certificate profile, up to 32 characters in length                                                                                                                                             |

#### status-verify

|                    |                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>status-verify</b>                                                                                    |
| <b>Context</b>     | config>service>vpn>if>sap>ipsec-tunnel>cert                                                             |
| <b>Description</b> | This command enters the context to configure verification parameters for certificate revocation status. |
| <b>Default</b>     | n/a                                                                                                     |

#### default-result

|                    |                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>default-result</b> { <b>revoked</b>   <b>good</b> }<br><b>no default-result</b>                               |
| <b>Context</b>     | config>service>vpn>if>sap>ipsec-tunnel>cert>status-verify                                                        |
| <b>Description</b> | This command specifies the default result when both the primary and secondary methods fail to provide an answer. |
| <b>Default</b>     | revoked                                                                                                          |
| <b>Parameters</b>  | <b>good</b> — the certificate is considered acceptable<br><b>revoked</b> — the certificate is considered revoked |

---

## primary

|                    |                                                                                                                                                                                                                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>primary {crl   ocsp}</b><br><b>no primary</b>                                                                                                                                                                                                                                                                                               |
| <b>Context</b>     | config>service>vpn>if>sap>ipsec-tunnel>cert>status-verify                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | <p>This command configures the primary method used to verify the revocation status of the peer's certificate. The method can be either CRL or OCSP.</p> <p>To verify the revocation status of the peer's certificate, the CRL or OCSP uses the corresponding configuration in the CA profile of the issuer of the certificate in question.</p> |
| <b>Default</b>     | crl                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <b>crl</b> — the CRL file is configured in the corresponding CA profile<br><b>ocsp</b> — the OCSP server is configured in the corresponding CA profile                                                                                                                                                                                         |

## secondary

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|                    |                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>trust-anchor-profile</b> <i>profile-name</i><br><b>no trust-anchor-profile</b>                                                                                                                |
| <b>Context</b>     | config>service>vpn>if>sap>ipsec-tunnel>cert                                                                                                                                                      |
| <b>Description</b> | This command configures the <b>trust-anchor-profile</b> for the specified IPSec tunnel. This command overrides the <b>trust-anchor-profile</b> configured in the <b>config&gt;ipsec</b> context. |
| <b>Default</b>     | no trust-anchor-profile                                                                                                                                                                          |
| <b>Parameters</b>  | <i>profile-name</i> — the name of the <b>trust-anchor-profile</b>                                                                                                                                |

### 8.10.2.3 Show Commands

**Note:** The following command outputs are examples only; actual displays may differ depending on supported functionality and user configuration.

#### ca-profile

**Syntax** `ca-profile name [association]`

**Context** `show>certificate`

**Description** This command displays IPSec certificate profile information for root and subordinate CAs.

**Parameters** *name* — specifies an existing CA profile name, up to 32 characters  
*association* — displays information for which this CA profile is associated

**Output** The following output is an example of CA profile information.

#### Output Example

```
*A:Dut-A# show>certificate# ca-profile "test"
=====
PKI CA-Profile Information
=====
CA Profile : test Admin State : down
Description : (Not Specified)
CRL File : (Not Specified)
Cert File : (Not Specified)
Oper State : down
Oper Flags : adminDown
CMPv2

HTTP Timeout : 30 secs Router : base
CA URL : (Not Specified)
Sign Cert URL : (Not Specified)
Unprot Err Msg : disabled Unprot Pki Conf: disabled
Same RecipNonce: disabled
for Poll-reqs
Set Sndr for IR: True
HTTP version : 1.1
OCSP

Responder URL : (Not Specified)
Router : base
=====
*A:Dut-A# show>certificate#
```

## ocsp-cache

|                    |                                                                                  |
|--------------------|----------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ocsp-cache</b> [ <i>entry-id</i> ]                                            |
| <b>Context</b>     | show>certificate                                                                 |
| <b>Description</b> | This command displays OCSF cache information.                                    |
| <b>Parameters</b>  | <i>entry-id</i> — specifies the ID of an entry in the OCSF cache, from 1 to 2000 |

## statistics

|                    |                                                                                   |
|--------------------|-----------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>statistics</b>                                                                 |
| <b>Context</b>     | show>certificate                                                                  |
| <b>Description</b> | This command displays certificate-related statistics.                             |
| <b>Output</b>      | The following output is an example of certificate-related statistics information. |

| <b>Description</b> | This command displays trust anchor profile information. Specifying a trust anchor profile shows the CA certificates associated with that trust anchor profile. When a trust anchor profile is not specified, the command shows all trust anchor profiles configured on the system and the number of CAs that are down in each profile. When a trust anchor profile is specified along with the association <b>keyword</b> , the command displays the names of the IPSec tunnels that are using a particular trust anchor profile. |
| <b>Parameters</b>  | <i>trust-anchor-profile</i> — specifies a trust anchor profile name, up to 32 characters                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Output</b>      | The following output is an example of trust anchor profile information.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Description | This command displays provisioning parameters for a given IKE policy. When an <i>ike-policy-id</i> is not specified then a summary display showing all IKE policies is displayed. When an <i>ike-policy-id</i> is specified then a detailed display showing IKE policy settings for the specific IKE policy is displayed. |
| Parameters  | <i>ike-policy-id</i> — specifies the ID of an IKE policy entry<br><br><b>Values</b> 1 to 2048                                                                                                                                                                                                                             |
| Output      | The following output is an example of IPSec security policy information, and <a href="#">Table 183</a> describes the fields.                                                                                                                                                                                              |

| PFS                                          | Displays whether perfect forward secrecy (PFS) is used on the IPSec tunnel using this policy                                                                                                                                                                                                                                                           |
| PFS DH Group                                 | The Diffie-Hellman group (DH) used for calculating PFS keys                                                                                                                                                                                                                                                                                            |
| Auth Algorithm                               | The hashing algorithm used for the IKE authentication function                                                                                                                                                                                                                                                                                         |
| Encr Algorithm                               | The encryption algorithm used for the IKE session                                                                                                                                                                                                                                                                                                      |
| ISAKMP Lifetime                              | The lifetime of a phase 1 IKE key, in seconds                                                                                                                                                                                                                                                                                                          |
| IPsec Lifetime                               | The lifetime of a phase 2 IKE key, in seconds                                                                                                                                                                                                                                                                                                          |
| NAT Traversal                                | The state of Network Address Translation Traversal (NAT-T):<br>Enabled, Disabled, or Force                                                                                                                                                                                                                                                             |
| NAT-T Keep Alive                             | Displays the configured NAT-T keepalive interval, in seconds                                                                                                                                                                                                                                                                                           |
| Behind NAT Only                              | Indicates when NAT-T keepalive messages are sent<br><b>True</b> —keepalive messages are sent if a NAT device is detected. Detection is done by each IKE session, for each IPSec tunnel.<br><b>False</b> —keepalive messages are always sent<br>When <b>force-keep-alive</b> is specified, the state of Behind NAT Only is False, otherwise it is True. |

**Table 183** IPSec IKE-Policy Command Field Descriptions (Continued)

| Label           | Description                                                                                                   |
|-----------------|---------------------------------------------------------------------------------------------------------------|
| DPD             | The state of the Dead Peer Detection (DPD) mechanism: Enabled or Disabled                                     |
| DPD Interval    | The interval used to test connectivity to the tunnel peer                                                     |
| DPD Max Retries | The maximum number of retries before the tunnel is removed                                                    |
| Description     | A user-configured description of the IKE policy                                                               |
| IKE Version     | The IKE version                                                                                               |
| Own Auth Method | Indicates the authentication method used with this IKE policy to authenticate on the local side of the tunnel |

## security-policy

**Syntax** **security-policy service** *service-id* [**security-policy-id** *security-policy-id*]  
**security-policy**

**Context** show>ipsec

**Description** This command displays the provisioning parameters for a given security policy.

**Parameters** *service-id* — specifies the service ID or name of the tunnel delivery service

**Values** 1 to 2147483690 or *service-name*

*security-policy-id* — specifies the IPSec security policy entry that this service will use

**Values** 1 to 8192

**Output** The following output is an example of IPSec security policy information, and [Table 184](#) describes the fields.

### Output Example

```
*A:7705custDoc:Sar18>show>ipsec# security-policy
=====
IPsec Security Policies
=====
ServiceId SecurityPolicyId Security Policy Params
 Entry count

20 1 2
20 17 0

No. of IPsec Security Policies: 2
=====
```

```

**Table 185** IPSec Transform Command Field Descriptions

| Label                   | Description                                  |
|-------------------------|----------------------------------------------|
| <b>IPsec Transforms</b> |                                              |
| TransformId             | The identifier of the IPSec transform policy |

**Table 185**      **IPSec Transform Command Field Descriptions (Continued)**

| Label                    | Description                                                                                                       |
|--------------------------|-------------------------------------------------------------------------------------------------------------------|
| EspAuthAlgorithm         | Displays the type of Encapsulating Security Payload (ESP) authorization algorithm defined in the transform policy |
| EspEncryptionAlgorithm   | Displays the type of Encapsulating Security Payload (ESP) encryption algorithm defined in the transform policy    |
| No. of IPsec Transforms: | The number of IPsec transform policies                                                                            |

## tunnel

|                    |                                                                                                                                                                                      |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>tunnel</b><br><b>tunnel</b> <i>ipsec-tunnel-name</i><br><b>tunnel count</b>                                                                                                       |
| <b>Context</b>     | show>ipsec                                                                                                                                                                           |
| <b>Description</b> | This command displays the IPSec tunnel information for existing tunnels.                                                                                                             |
| <b>Parameters</b>  | <i>ipsec-tunnel-name</i> — specifies the configured name of the IPSec tunnel to be displayed, 32 characters maximum<br><br><b>count</b> — displays the total number of IPSec tunnels |
| <b>Output</b>      | The following output is an example of IPSec tunnel information, and <a href="#">Table 186</a> describes the fields.                                                                  |

| Service Id                               | The service identifier                                                                                          |
| Sap Id                                   | The SAP identifier                                                                                              |
| Tunnel Name                              | The specified name of the IPsec tunnel                                                                          |
| Description                              | The description configured for the IPsec tunnel                                                                 |
| Local Address                            | The IPv4 address of the local router                                                                            |
| Remote Address                           | The IPv4 address of the remote router                                                                           |
| Delivery Service                         | The service identifier of the delivery service                                                                  |
| Security Policy                          | The identifier of the security policy used                                                                      |
| Admin State                              | The administrative state of the IPsec tunnel                                                                    |
| Oper State                               | The operational state of the IPsec tunnel                                                                       |
| Last Oper Change                         | The timestamp indicating the last operational status change for the IPsec tunnel                                |
| Keying Type                              | The type of security keying for the tunnel: None, Manual, or Dynamic                                            |
| Replay Window                            | The size of the replay window used for anti-replay                                                              |
| TrustAnchor Prof                         | The trust anchor profile that is being used                                                                     |
| Match TrustAnchor                        | The actual CA certificate that has been selected from the trust anchor profile                                  |
| Cert Profile                             | The certification profile                                                                                       |
| Clear DF Bit                             | Indicates whether the tunnel is clearing the DF bit: true (clearing) or false (not clearing)                    |
| Copy DF Bit                              | Indicates whether the tunnel is copying the DF bit: true (copying) or false (not copying)                       |
| IP MTU                                   | The interface IP MTU. The value "max" indicates that the tunnel will receive whatever IP payload is sent to it. |
| Oper Flags                               | Displays the operational flags currently in effect                                                              |
| <b>BFD Interface</b>                     |                                                                                                                 |

**Table 186**      **IPSec Tunnel Command Field Descriptions (Continued)**

| Label                                                            | Description                                                                                                                                           |
|------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| BFD Designate                                                    | Displays whether a BFD designate has been specified: yes or no                                                                                        |
| <b>Dynamic Keying Parameters</b>                                 |                                                                                                                                                       |
| Transform Id1<br>Transform Id2<br>Transform Id3<br>Transform Id4 | The ipsec-transform IDs that are assigned under the VPRN <b>ipsec-tunnel</b> context                                                                  |
| Ike Policy Id                                                    | The IKE policy ID                                                                                                                                     |
| Auto Establish                                                   | Displays whether automatic establishing of an IPSec tunnel has been specified: yes or no                                                              |
| PreShared Key                                                    | The PSK or shared secret used with dynamic keying as defined under the VPRN <b>ipsec-tunnel</b> context                                               |
| Selected Cert                                                    | The actual certificate being used, selected from the <b>cert-profile</b>                                                                              |
| Selected Key                                                     | The actual key being used, selected from the <b>cert-profile</b>                                                                                      |
| Send Chain Prof                                                  | The send chain, if configured, under the <b>cert-profile</b>                                                                                          |
| <b>Certificate Status Verify</b>                                 |                                                                                                                                                       |
| Primary                                                          | The primary method used to verify the revocation status of the peer's certificate, either CRL or OCSP                                                 |
| Secondary                                                        | The secondary method used to verify the revocation status of the peer's certificate, either CRL or OCSP                                               |
| Default Result                                                   | The default result when both the primary and secondary methods fail to verify the revocation status of the peer's certificate, either good or revoked |
| Isakmp State                                                     | The state of ISAKMP: Up or Down                                                                                                                       |
| ISAKMP Statistics                                                | ISAKMP statistics are for traffic sent and received by the IKE protocol                                                                               |
| Tx Packets                                                       | The number of IKE packets transmitted                                                                                                                 |
| Rx Packets                                                       | The number of IKE packets received                                                                                                                    |
| Tx Errors                                                        | The number of IKE packet errors transmitted                                                                                                           |
| Rx Errors                                                        | The number of IKE packet errors received                                                                                                              |

**Table 186**      **IPSec Tunnel Command Field Descriptions (Continued)**

| Label                     | Description                                                     |
|---------------------------|-----------------------------------------------------------------|
| Tx DPD                    | The number of IKE Dead Peer Detection (DPD) packets transmitted |
| Rx DPD                    | The number of IKE DPD packets received                          |
| Tx DPD ACK                | The number of IKE DPD acknowledged packets transmitted          |
| Rx DPD ACK                | The number of IKE DPD acknowledged packets received             |
| DPD Timeouts              | The number of IKE DPD timeouts                                  |
| Rx DPD Errors             | The number of IKE DPD packet errors received                    |
| <b>IPsec Tunnel Count</b> |                                                                 |
| Total IPsec Tunnels       | The total number of IPsec tunnels on the local router           |

## 8.10.2.5 Debug Commands

### cmpv2

|                    |                                                                     |
|--------------------|---------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] cmpv2</b>                                                   |
| <b>Context</b>     | debug                                                               |
| <b>Description</b> | This command enables the context to perform CMPv2 debug operations. |

### ca-profile

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] ca-profile</b> <i>profile-name</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Context</b>     | debug>cmpv2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | <p>This command debugs the output from the specified CA profile.</p> <ul style="list-style-type: none"><li>• The protection method of each message is logged.</li><li>• All HTTP messages are logged. The format allows offline analysis using Wireshark.</li><li>• In the event of failed transactions, saved certificates are not deleted from the file system in order to allow for further debug and analysis.</li><li>• The system allows CMPv2 debugging for multiple CA profiles at the same time.</li></ul> |

### certificate

|                    |                                                                               |
|--------------------|-------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] certificate</b> <i>filename</i>                                       |
| <b>Context</b>     | debug>ipsec                                                                   |
| <b>Description</b> | This command enables debug for certificate chain computation in cert-profile. |
| <b>Parameters</b>  | <i>filename</i> — displays the filename of the imported certificate           |

### tunnel

|                    |                                                                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>tunnel</b> [ <i>ipsec-tunnel-name</i> ] [ <b>detail</b> ]<br><b>no tunnel</b> [ <i>ipsec-tunnel-name</i> ]                                                                                |
| <b>Context</b>     | debug>ipsec                                                                                                                                                                                  |
| <b>Description</b> | This command can be used to facilitate debugging related to IPSec tunnels. Multiple IPSec tunnels can be debugged at the same time; up to 16 instances of this command can run concurrently. |

---

**Parameters**    *ipsec-tunnel-name* — specifies an IPSec tunnel name up to 32 characters in length  
                  **detail** — enables detailed debug information

---

## 9 Network Group Encryption

This chapter provides information to configure network group encryption (NGE).

Topics in this chapter include:

- [NGE Overview](#)
- [Key Groups](#)
- [Services Encryption](#)
- [Router Interface Encryption](#)
- [Layer 2 Encryption](#)
- [NGE Packet Overhead and MTU Considerations](#)
- [1588v2 Encryption With NGE](#)
- [QoS for NGE Traffic](#)
- [Statistics](#)
- [Remote Network Monitoring \(RMON\) Support](#)
- [Configuration Notes](#)
- [Configuring NGE with the CLI](#)
- [NGE Command Reference](#)

## 9.1 NGE Overview

The network group encryption (NGE) feature enables end-to-end encryption of MPLS services, Layer 3 user traffic, and IP/MPLS control traffic. NGE is an encryption method that uses a group-based keying security architecture, which removes the need to configure individual encryption tunnels to achieve network-wide encryption.

NGE relies on the NSP NFM-P to manage the network and apply encryption to specific MPLS services, Layer 3 user traffic, or control plane traffic depending on the security requirements of the network. Operators designate traffic types that require added security and then apply NGE to those traffic types using the NSP NFM-P. The NSP NFM-P also acts as the network-wide NGE key manager, downloading encryption and authentication keys to nodes and performing hitless rekeying of the network at operator-defined intervals. For more information about managing NGE within a network, see the NSP NFM-P User Guide.

Figure 139 shows an NGE network with NSP NFM-P services, control plane configuration, and key management.

**Figure 139 NGE Network with NSP NFM-P Management**

26216

---

NGE is enabled on the 7705 SAR and provides three main types of encryption to secure an IP/MPLS network:

- SDP encryption — MPLS user plane encryption enabled on MPLS tunnels (SDPs) supporting VPRN or IES services using spoke SDPs, VPLS using spoke or mesh SDPs, routed VPLS into VPRN, Epipes, and Cpipes
- VPRN encryption
  - unicast VPRN — MP-BGP-based VPRN-level encryption using the auto-bind feature of LDP, GRE, RSVP-TE, or segment routing (SR-ISIS, SR-OSPF, or SR-TE) tunnels
  - multicast VPRN — NG-MVPN using mLDP with auto-discovery
- router interface and Ethernet port Layer 2 encryption — Layer 3 user plane and control plane encryption, Layer 2 encryption of IS-IS and LLDP

NGE is supported on the following adapter cards and platforms:

- 8-port Gigabit Ethernet Adapter card, version 3
- 6-port Ethernet 10Gbps Adapter card
- 10-port 1GigE/1-port 10GigE X-Adapter card, version 2
- 7705 SAR-Ax
- 7705 SAR-H (Ethernet and PPP/MLPPP network links)
- 7705 SAR-Hc
- 7705 SAR-W
- 7705 SAR-Wx
- 7705 SAR-X (Ethernet and PPP/MLPPP network links)

This section contains information on the following topics:

- [NGE Key Groups and Encryption Partitions](#)
- [NGE Domains](#)
- [Network Services Platform Management](#)

## 9.1.1 NGE Key Groups and Encryption Partitions

The NGE feature allows a tiered approach to managing encryption keys in a network using key groups. This is accomplished by the configuration of services, router interfaces, or Ethernet ports to use specific key groups depending on security policies for the service and network topology.

Figure 140 shows a typical application of NGE key-group partitioning in which there are several critical levels (tiers) of security that need to be considered. In this example, the protection of Distribution Automation and Field Area Network (DA/FAN) equipment might be considered less critical than the Transmission or Distribution Substation network equipment. It may be ideal to ensure that nodes more at risk of a security breach do not contain more critical information than is necessary. Therefore, encryption keys for the sensitive portions of the network (such as control center traffic) should not be available on nodes that are at risk. The 7705 SAR NGE feature enables operators to partition and distribute encryption keys among different services, NGE domains, or nodal groups in a network. NGE partitions are enabled by configuring different key groups per security partition and applying those key groups as needed.

Figure 140 Key-Group Partitioning

25080

Another application of key-group partitioning allows different parts of an organization to have their own method of end-to-end communication without the need to share encryption keys between each organization. If two partitions need to communicate between themselves, gateway nodes configured with both key groups allow inter-organization traffic flows between the key group partitions, as needed.

## 9.1.2 NGE Domains

An NGE domain is a group of nodes and router interfaces forming a network that uses a single key group to create a security domain. NGE domains are created when router interface encryption is enabled on router interfaces that need to participate in the NGE domain. The NSP NFM-P assists operators in managing the nodes and interfaces that participate in the NGE domain. See the NSP NFM-P User Guide for more information.

Figure 141 shows various traffic types crossing an NGE domain.

**Figure 141 NGE Domain Transit**

26217

In the figure, nodes A, B, C, and D have router interfaces configured with router interface encryption enabled (and optionally Layer 2 NGE on the Ethernet port). Traffic is encrypted when entering the NGE domain using the key group configured on the router interface and is decrypted when exiting the NGE domain.

---

Traffic may traverse multiple hops before exiting the NGE domain, yet decryption only occurs on the final node when the traffic exits the NGE domain. Various traffic types are supported and encrypted when entering the NGE domain, as illustrated by the following items on node A in [Figure 141](#):

- item 1: self-generated packets — these packets, which include all types of control plane and management packets such as OSPF, BGP, LDP, SNMPv3, SSH, ICMP, RSVP-TE, and 1588, are encrypted
- item 2: user Layer 3 packets — any Layer 3 user packets that are routed into the NGE domain from an interface outside the NGE domain are encrypted
- item 3: IPSec packets — IPSec packets are NGE-encrypted when entering the NGE domain to ensure that the IPSec packet's security association information does not conflict with the NGE domain

GRE-MPLS-based service traffic consists of Layer 3 packets, and router interface NGE is not applied to these types of packets. Instead, service-level NGE is used for encryption to avoid double-encrypting these packets and impacting throughput and latencies. The two types of GRE-MPLS packets that can enter the NGE domain are illustrated by items 4 and 5 in [Figure 141](#).

- item 4: GRE-MPLS packets (SDP or VPRN) with service-level NGE enabled — these encrypted packets use the key group that is configured on the service. The services key group may be different from the key group configured on the router interface where the GRE-MPLS packet enters the NGE domain.
- item 5: GRE-MPLS packets (SDP or VPRN) with NGE disabled — these packets are not encrypted and can traverse the NGE domain in clear text. If these packets require encryption, SDP or VPRN encryption must be enabled.

Creating an NGE domain from the NSP NFM-P requires the operator to determine the type of NGE domain being managed. This will indicate whether NGE gateway nodes are required to manage the NGE domain, and other operational considerations. The two types of NGE domains are:

- [Private IP/MPLS Network NGE Domain](#)
- [Private Over Intermediary Network NGE Domain](#)

### 9.1.2.1 Private IP/MPLS Network NGE Domain

One type of NGE domain is a private IP/MPLS network, as shown in [Figure 142](#).

**Figure 142 Private IP/MPLS Network NGE Domain**

26215

In a private IP/MPLS network NGE domain, all interfaces are owned by the operator and there is no intermediary service provider needed to interconnect nodes. Each interface is a point-to-point private link between private nodes. When a new node is added to this type of NGE domain (node D in [Figure 142](#)), the links that connect node D to the existing nodes in the NGE domain (nodes A, B, and C) must be enabled with NGE router interface encryption. Links from the new node to the existing nodes are enabled one at a time. The NSP NFM-P provides tools that simplify adding nodes to the NGE domain and enabling NGE on their associated interfaces. In this type of NGE domain, each interface is a direct link between two nodes and is not used to communicate with multiple nodes over a broadcast medium offered by an intermediary network. Also, there are no NGE gateway nodes required between the NSP NFM-P and new nodes entering the NGE domain.

### 9.1.2.2 Private Over Intermediary Network NGE Domain

The other type of NGE domain is a private IP/MPLS network that traverses an intermediary network NGE domain; the intermediary network is used to interconnect nodes in the NGE domain using a multipoint-to-multipoint service. The intermediary network is typically a service provider network that provides a private IP VPN service or a private VPLS service used to interconnect a private network that does not mimic point-to-point links as described in the [Private IP/MPLS Network NGE Domain](#) section.

This type of NGE domain is shown in [Figure 143](#).

**Figure 143 Private Over Intermediary Network NGE Domain**

26214

Private over intermediary network NGE domains have nodes with links that connect to a service provider network where a single link can communicate with multiple nodes over a Layer 3 service such as a VPRN or a Layer 2 service such as VPLS. In [Figure 143](#), node A has NGE enabled on its interface with the service provider and uses that single interface to communicate with nodes B and C, and eventually with node D when node D has been added to the NGE domain. This type of NGE domain requires the recognition of NGE gateway nodes that allow the NSP NFM-P to reach new nodes that enter the domain. Node C is designated as a gateway node.

When node D is added to the NGE domain, it must first have the NGE domain key group downloaded to it from the NSP NFM-P. The NSP NFM-P creates an NGE exception ACL on the gateway node, C, to allow communication with node D using SNMPv3 and SSH through the NGE domain. After the key group is downloaded, the NSP NFM-P enables router interface encryption on node D's interface with the service provider and node D is now able to participate in the NGE domain. The NSP NFM-P automatically removes the IP exception ACL from node C when node D enters the NGE domain.

See [Router Interface NGE Domain Concepts](#) for more information.

---

### 9.1.3 Network Services Platform Management

The NGE feature is tightly integrated with the NSP NFM-P. The following functions are provided by the NSP NFM-P:

- managing and synchronizing encryption and authentication keys within key groups on a network-wide basis
- configuring NGE on MPLS services and managing associated key groups
- configuring NGE on router interfaces and Ethernet ports and managing associated key groups
- coordinating network-wide rekeying of key groups

The NSP NFM-P acts as the key manager for NGE-enabled nodes and allocates the keys in key groups that are used to perform encryption and authentication. The NSP NFM-P ensures that all nodes in a key group are kept in synchronization and that only the key groups that are relevant to the associated nodes are downloaded with key information.

The NSP NFM-P performs network-wide hitless rekeying for each key group at the rekeying interval specified by the operator. Different key groups can be rekeyed at different times if desired, or all key groups can be rekeyed network-wide at the same time.

For more information on NSP NFM-P management, refer to the “Service Management” section in the NSP NFM-P User Guide.

---

## 9.2 Key Groups

Key groups are used to organize encryption keys into distinct groups that allow a user to partition the network based on security requirements. A key group contains the following elements:

- an encryption algorithm—see [Key Group Algorithms](#)
- an authentication algorithm—see [Key Group Algorithms](#)
- a list of security associations (SAs)—see [Security Associations \(SAs\)](#)
- an active outbound SA—see [Active Outbound SA](#)

[Figure 144](#) illustrates the use of key groups (KGs), security associations (SAs), and security parameter indexes (SPIs). The 7705 SAR-8 Shelf V2 and 7705 SAR-18 both have the same set of key groups configured. One path uses key group 1 (KG1) and the other uses key group 2 (KG2). Each key group contains the elements listed above. Key group 1 has four live keys, SPI\_1 through SPI\_4, and SPI\_3 is the active outbound SA. The active outbound SA is identified by its SPI, and this SPI is embedded in the NGE packet.

Each SA listed in a key group, indexed by an SPI, specifies a single key for encryption and a single key for authentication. Packets transmitted or received that reference a particular SPI use the keys in the SA for that SPI when performing encryption and authentication.

Before enabling encryption, key groups must be configured on the node. Only after a key group is configured can it be assigned to an SDP or VPRN services.

**Figure 144 Key Groups and a Typical NGE Packet**

25081

## 9.2.1 Key Group Algorithms

All SAs configured in a key group share the same encryption algorithm and the same authentication algorithm. The size and values required by a particular key depend on the requirements of the algorithms selected (see lists below). One encryption algorithm and one authentication algorithm must be selected per key group.

Encryption algorithms available per key group include:

- AES128 (a 128-bit key, requiring a 32-digit ASCII hexadecimal string)
- AES256 (a 256-bit key, requiring a 64-digit ASCII hexadecimal string)

Authentication algorithms available per key group include:

- HMAC-SHA-256 (a 256-bit key, requiring a 64-digit ASCII hexadecimal string)
- HMAC-SHA-512 (a 512-bit key, requiring a 128-digit ASCII hexadecimal string)

Encryption and authentication strengths can be mixed depending on the requirements of the application. For example, 256-bit strength encryption can be used with 512-bit strength authentication.

The configured algorithms cannot be changed when there is an existing SA configured for the key group. All SAs in a key group must be deleted before a key group algorithm can be modified.

Key values are not visible in CLI or retrievable using SNMP. Each node calculates a 32-bit CRC checksum for the keys configured against the SPI. The CRC can be displayed in the CLI or read by SNMP. The purpose of the CRC is to provide a tool to check consistency between nodes, thereby verifying that each node is set with the same key values while keeping the actual key values hidden.

### 9.2.1.1 Encapsulating Security Payload (ESP)

The NGE feature uses the Encapsulating Security Payload (ESP) protocol according to IETF RFC 4303. ESP maintains data integrity, ensuring privacy and confidentiality for encrypted traffic.

The ESP protocol used by NGE relies on symmetric ciphers, meaning that the same key is used for encryption and decryption. The 7705 SAR supports Cipher Block Chaining (CBC) encryption mode. Block ciphers used by NGE include:

- AES128 with a 128-bit key using 128-bit blocks
- AES256 with a 256-bit key using 128-bit blocks

For authentication, the integrity check value (ICV) size is as follows:

- HMAC-SHA-256 (16 bytes or 128 bits)
- HMAC-SHA-512 (32 bytes or 256 bits)

---

## 9.2.2 Security Associations (SAs)

Each key group has a list of up to four SAs. An SA is a reference to a pair of encryption and authentication keys that are used to decrypt and authenticate packets received by the node and to encrypt packets leaving the node.

For encrypted ingress traffic, any of the four SAs in the key group can be used for decryption if there is a match between the SPI in the traffic and the SPI in the SA. For egress traffic, only one of the SAs can be used for encryption and is designated as the active outbound SA. [Figure 144](#) illustrates these relationships.

As shown in [Figure 144](#), each SA is referenced by an SPI value, which is included in packets during encryption and authentication. SPI values must be numerically unique throughout all SAs in all key groups. If an SPI value is configured in one key group and an attempt is made to configure the same SPI value in another key group, the configuration is blocked.

**Note:** Keys are entered in clear text using the **security-association** command. Once entered, they are never displayed in their original, clear text form. Keys are displayed in a 7705 SAR-encrypted form, which is indicated by the system-appended **crypto** keyword when an **info** command is run. The 7705 SAR also includes the **crypto** keyword with an **admin>save** operation so that the 7705 SAR can decrypt the keys when reloading a configuration database. For security reasons, keys encrypted on one node are not usable on other nodes (that is, keys are not exchangeable between nodes).

### 9.2.2.1 Active Outbound SA

The active outbound SA is specified by the SPI referencing the specific SA used to encrypt and authenticate packets egressing the node for the SDP or service using the key group. The SPI value for the active outbound SA is included in the Encapsulating Security Payload (ESP) header of packets being encrypted and authenticated.

---

## 9.3 Services Encryption

The NGE feature provides the ability to encrypt MPLS services using key groups that are configured against these services. These services include:

- VLL service (Epipe and Cpipe)
- VPRN service using Layer 3 spoke-SDP termination
- IES service using Layer 3 spoke-SDP termination
- VPLS service using spoke and mesh SDPs
- routed VPLS service into a VPRN or IES
- MP-BGP-based VPRNs
- NG-MVPN

For services that use SDPs, all tunnels may be either MPLS LSPs (RSVP-TE, LDP, or static LSP) or GRE tunnels. NGE is not supported for IP tunnels.

For MP-BGP services, the auto-bind feature (**auto-bind-tunnel**) is supported using LDP, GRE, RSVP-TE, or segment routing (SR-ISIS, SR-OSPF, or SR-TE).

In addition, the 7705 SAR supports VLL, VPLS, and VPRN NGE interactions that use segment routing with entropy labels.

This section contains information on the following topics:

- [Services Encryption Overview](#)
- [Assigning Key Groups to Services](#)
- [Pseudowire Switching for NGE Traffic](#)
- [Pseudowire Control Word for NGE Traffic](#)
- [VPRN Layer 3 Spoke-SDP Encryption and MP-BGP-based VPRN Encryption Interaction](#)
- [NGE and RFC 3107](#)
- [NGE for NG-MVPN](#)

### 9.3.1 Services Encryption Overview

NGE adds a global encryption label to the label stack for encrypting MPLS services. The global encryption label must be a unique network-wide label; in other words, the same label must be used on all nodes in the network that require NGE services. The label must be configured on individual nodes before NGE can become operational on those nodes.

The global encryption label is used to identify packets that have an NGE-encrypted payload and is added to the bottom of the stack. This allows network elements such as LSRs, ABRs, ASBRs, and RRs to forward NGE packets without needing to understand NGE or to know that the contents of these MPLS packets are encrypted. Only when a destination PE (7705 SAR) receives a packet that needs to be understood at the service layer does the PE check for an encryption label, and then decrypt the packet.

Once the global encryption label is set, it should not be changed. If the label must be changed without impacting traffic, all key groups in the system should first be deleted. Next, the label should be changed, and then all key groups should be reconfigured.

The NSP NFM-P helps to coordinate the distribution of the global encryption label and ensures that all nodes in the network are using the same global encryption label.

Figure 145 illustrates the NGE MPLS/GRE label stack. Figure 146 illustrates VPRN and PW (with control word) packet formats using NGE encryption.

Figure 145 NGE MPLS/GRE Label Stack

35842

Figure 146 NGE Encryption and Packet Formats

35843

### 9.3.2 Assigning Key Groups to Services

Assigning key groups to services requires configuring an inbound and outbound key group for directional processing on a per-service basis (see [Figure 147](#)).

**Figure 147 Inbound and Outbound Key-Group Assignments**

25082

The outbound key group identifies which key group to use for traffic that egresses the node for the service. The inbound key group ensures that ingress traffic is using the correct key group for the service.

If the inbound key group is not set, the node ensures that packets are either unencrypted or are using one of the valid key groups configured in the system.

In most deployment scenarios, the inbound and outbound key groups are identical. However, it is possible to configure different key groups as the outbound and the inbound key groups, as this is not checked by the node. Using different key groups in this way is not typical.

Including an inbound and outbound direction when assigning key groups to services allows users to:

- gracefully enable and disable NGE for services
- move services from one key-group domain to another domain without halting encryption

The NGE feature makes use of the NSP NFM-P to help manage the assignment of key groups to services on a network-wide basis. Refer to the NSP NFM-P User Guide for more information.

---

### 9.3.3 Pseudowire Switching for NGE Traffic

For VLL services, the 7705 SAR supports pseudowire (PW) switching of encrypted traffic from one PW to another. There are three scenarios that are supported on the 7705 SAR with regard to PW switching of traffic:

- PW switch using the same key group

When a PW is using an encrypted SDP, the PW may be switched to another PW that is also using an encrypted SDP, and both SDPs are in the same key group. For this case, to perform the PW switch, the 7705 SAR leaves the encrypted payload unchanged and swaps the labels as needed for passing traffic between PWs.

- PW switch using different key groups

When a PW is using an encrypted SDP, the PW may be switched to another PW that is also using an encrypted SDP, but both SDPs are in different key groups. For this case, the 7705 SAR decrypts the traffic from the first SDP by using the configured key group for that SDP, and then re-encrypts the traffic by using the egress SDP's key group egress SPI ID.

- PW switch between an encrypted and unencrypted PW

When traffic is switched from an encrypted PW to an unencrypted PW, the traffic is decrypted before it is sent. The converse occurs in the reverse direction (that is, traffic from an unencrypted PW to an encrypted PW gets encrypted before it is sent).

See [Pseudowire Switching](#) for more information.

### 9.3.4 Pseudowire Control Word for NGE Traffic

The control word is a configurable option for PWs and is included in PW packets when it (the control word) is configured. When **control-word** is enabled and NGE is used, the datapath creates two copies of the CW. One CW is both encrypted and authenticated, and is inserted after the ESP header. The other CW is not encrypted (clear form) and is inserted before the ESP header.

For cases where PW switching is configured, the 7705 SAR ensures—in the CLI and with SNMP—that both segments of the PW have consistent configuration of the control word when encryption is being used.

See [Pseudowire Control Word](#) for more information.

### 9.3.5 VPRN Layer 3 Spoke-SDP Encryption and MP-BGP-based VPRN Encryption Interaction

The encryption configured on an SDP used to terminate the Layer 3 spoke SDP of a VPRN always overrides any VPRN-level configuration for encryption:

- When VPRN encryption is enabled, all routes resolved via MP-BGP are encrypted or decrypted using the VPRN key group.
- When Layer 3 spoke-SDP encryption is enabled, all routes resolved via the Layer 3 interface are encrypted or decrypted using the SDP's key group.

Some examples are as follows.

- If a VPRN is enabled for encryption while a Layer 3 spoke SDP for the same VPRN is using an SDP that is not enabled for encryption, then traffic egressing the spoke SDP is not encrypted.
- If a VPRN is disabled for encryption while a Layer 3 spoke SDP for the same VPRN is using an SDP that is enabled for encryption, then traffic egressing the spoke SDP is encrypted.
- If a VPRN is enabled for encryption using key group X, while a Layer 3 spoke SDP for the same VPRN is using key group Y, then traffic egressing the spoke SDP is encrypted using key group Y.

The commands used for these scenarios are **config>service>sdp>encryption-keygroup** and **config>service>vprn>encryption-keygroup**.

### 9.3.6 NGE and RFC 3107

When RFC 3107 is enabled on the node and NGE traffic is crossing the RR between two VPRN domains, the same key group must be used between the two domains.

**Note:** It is the responsibility of the network operator to ensure key group consistency across the RR.

---

### 9.3.7 NGE for NG-MVPN

NGE is supported for NG-MVPN services with multicast configurations that include:

- I-PMSI
- S-PMSI
- C-multicast signaling
- mLDP multicast tunnel LSPs

For more information on MVPN, see [Multicast VPN \(MVPN\)](#).

When r-VPLS is configured for the VPRN, the node can act as a receiver for an NG-MVPN service that is NGE -encrypted. The node cannot act as a source of NG-MVPN traffic from a VPLS service, so the source of this NG-MVPN traffic must originate from another node that supports that capability.

When NGE is enabled in a VPRN with NG-MVPN-based services, transit nodes (LSRs) have no knowledge that NGE is being employed or that the NGE encryption label is being used with an ESP header after the NGE label. Features that inspect packet contents to make further decisions are not supported and must be disabled for mLDP multicast paths that need to carry NG-MVPN traffic that is NGE-encrypted. These features include:

- ingress multicast path management (7750 SR only)
- IP-based LSR hashing

The packet inspection restriction includes any third-party routing function that may inspect the packet contents after the mLDP transport label and is expecting a non-encrypted payload in order to make hashing decisions.

## 9.4 Router Interface Encryption

The 7705 SAR supports Layer 3 encryption on router interfaces for IPv4 traffic. NGE is not supported on dual-stack IPv4/IPv6 or IPv6-only interfaces.

NGE is enabled on a router interface by configuring the **group-encryption** command on the router interface. The interface is considered part of the NGE domain, and any received packets that are NGE-encrypted are decrypted if the key group is configured on the node. To encrypt packets egressing the interface, the outbound key group must be configured on the interface. All IP packets, such as self-generated traffic or packets forwarded from router interfaces that are not inside the NGE domain, are encrypted when egressing the interface. There are some exceptions to this general behavior, as described in the sections below; for example, GRE-MPLS packets are not encrypted when router interface encryption is enabled.

The outbound and inbound key groups configured on the router interface determine which keys to use to encrypt and decrypt traffic.

To perform encryption, router interface encryption reuses the IPsec transport mode packet format as shown in [Figure 148](#).

**Figure 148 Router Interface Encryption Packet Format (IPsec Transport Mode)**

The protocol field in the IP header of an NGE packet is always set to “ESP”. Within an NGE domain, the SPI that is included in the ESP header is always an SPI for the key group configured on the router interface. Other fields in the IP header, such as the source and destination addresses, are not altered by NGE router interface encryption. Packets are routed through the NGE domain and decrypted when the packet leaves the NGE domain.

The group keys used on an NGE-enabled router interface provide encryption of broadcast and multicast packets within the GRT. For example, OSPF uses a broadcast address to establish adjacencies, which can be encrypted by NGE without the need to establish point-to-point encryption tunnels. Similarly, multicast packets are also encrypted without point-to-point encryption tunnels.

### 9.4.1 Router Interface NGE Domain Concepts

An NGE domain is a group of nodes whose router interfaces in the base routing context (GRT) are enabled for router interface NGE or whose ports are enabled for encryption of some types of Layer 2 traffic. An interface without router interface NGE enabled is considered to be outside the NGE domain. NGE domains use only one key group when the domain is created; however, two key groups may be active at once if some links within the NGE domain are in transition from one key group to the other.

Figure 149 illustrates the NGE domain concept. Table 187 describes the three configuration scenarios inside the NGE domain.

Figure 149 Inside and Outside NGE Domains

26180

Table 187 Inside and Outside NGE Domains — Configuration Scenarios

| Key | Description                                                                                                                                     |
|-----|-------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | NGE enabled, no inbound/outbound key group<br>Outbound packets are sent without encrypting. Inbound packets can be NGE-encrypted or clear text. |

**Table 187**      **Inside and Outside NGE Domains — Configuration Scenarios**

| Key | Description                                                                                                                                                                                    |
|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2   | Outbound key group, no inbound key group<br>Outbound packets are encrypted using the interface key group if not already encrypted. Inbound packets can be NGE-encrypted or clear text.         |
| 3   | Inbound and outbound key group<br>Outbound packets are encrypted using the interface key group if not already encrypted. Inbound packets must be encrypted using the interface key group keys. |
| 4   | Outside the NGE domain, the interface is not configured for NGE. Any ESP packets are IPSec packets.                                                                                            |

A router interface is considered to be inside the NGE domain when it has been configured with **group-encryption** on the interface. When **group-encryption** is configured on the interface, the router can receive unencrypted packets or NGE-encrypted packets from any configured key group on the router, but any other type of IPSec-formatted packet is not allowed. If an IPSec-formatted packet is received on an interface that has **group-encryption** enabled, it will not pass NGE authentication and will be dropped. Therefore, IPSec packets cannot exist within the NGE domain without first being converted to NGE packets. This conversion requirement delineates the boundary of the NGE domain and other IPSec services.

When NGE router interface encryption is enabled and only an outbound key group is configured, the interface can receive unencrypted packets or NGE-encrypted packets from any configured key group on the router. All outbound packets are encrypted using the outbound key group if the packet was not already encrypted further upstream in the network.

When NGE router interface encryption has been configured with both an inbound and outbound key group, only NGE packets encrypted with the key group security association can be sent and received over the interface.

When there is no NGE router interface encryption, the interface is considered outside the NGE domain where NGE is not applied.

---

## 9.4.2 GRE-MPLS Packets Inside the NGE Domain

NGE router interface encryption is never applied to GRE-MPLS packets that are used to transport MPLS services over Layer 3 networks; for example, GRE with the GRE protocol ID set to MPLS Unicast (0x8847) or Multicast (0x8848). GRE-MPLS packets that enter the NGE domain or transit the NGE domain are forwarded as is.

Because GRE-MPLS packets provide transport for MPLS-based services, they already use the NGE services-based encryption techniques for MPLS, such as SDP or VPRN-based encryption. To avoid double encryption, the packets are left in clear text when entering an NGE domain or crossing intermediate nodes in the NGE domain, and are simply forwarded as needed when exiting an NGE domain.

The payload of these GRE-MPLS packets can also be sent in clear text depending on the security requirements that are configured for the MPLS service.

GRE packets with the protocol set to other protocols are encrypted using NGE router interface encryption.

## 9.4.3 Router Encryption Exceptions using ACLs

In some cases, Layer 3 packets may need to cross the NGE domain in clear text, such as when an NGE-enabled router needs to peer with a non-NGE-capable router to exchange routing information. This can be accomplished by using a router interface NGE exception filter applied on the router interface for the required direction, inbound or outbound.

[Figure 150](#) shows the use of a router interface NGE exception filter.

**Figure 150 Router Interface NGE Exception Filter Example**

26277

The inbound or outbound exception filter is used to allow specific packet flows through the NGE domain in clear text, where there is an explicit inbound and outbound key group configured on the interface. The behavior of the exception filter for each router interface configuration is as follows:

- NGE enabled, no inbound/outbound key group — in this scenario, the router does not encrypt outbound traffic, and so the outbound exception filter is not applied. The router can still receive inbound NGE packets, so the exception filter is applied to inbound packets. If the filter detects a match, clear text packets can be received and forwarded by the router.
- outbound key group, no inbound key group — the outbound exception filter is applied to outbound traffic, and packets that match the filter are not encrypted on egress. The router can receive inbound NGE packets without an inbound key group set and applies the exception filter to inbound packets. If the filter detects a match, clear text packets can be received and forwarded by the router.
- inbound and outbound key group — the inbound and outbound exception filters are applied, and any packets that match are passed in clear text.

## 9.4.4 IPsec Packets Crossing an NGE Domain

IPsec packets can cross the NGE domain because they are still considered Layer 3 packets. To avoid confusion between the security association used in an IPsec packet and the one used in a router interface NGE packet, the router will always apply NGE to any IPsec packet that traverses the NGE domain.

IPsec packets that originate from a router within the NGE domain are not allowed to enter the NGE domain. The only exception to this restriction is OSPFv3 packets.

Figure 151 shows how IPsec packets can transit an NGE domain.

**Figure 151 IPsec Packets Transiting an NGE Domain**

26181

An IPsec packet enters the router from outside the NGE domain. When the router determines that the egress interface to route the packet is inside an NGE domain, it will select an NGE router interface with one of the following configurations.

- NGE enabled with no inbound or outbound key group configured — this link cannot forward the IPsec packet without adding the NGE ESP, but since nothing is configured for the outbound key group, the packet must be dropped.

- NGE enabled with outbound key group configured and no inbound key group configured — the packet originates outside the NGE domain, so the router adds an ESP header over the existing ESP and encrypts the payload using the NGE domain keys for the configured outbound key group.
- NGE enabled with both inbound and outbound key groups configured — the packet originates outside the NGE domain, so the router adds an ESP header over the existing ESP and encrypts the payload using the NGE domain keys for the configured outbound key group.

OSPFv3 IPsec support also uses IPsec transport mode packets. These packets originate from the CSM, which is considered outside the NGE domain; however, the above rules for encapsulating the packets with an NGE ESP apply and allow these packets to successfully transit the NGE domain.

## 9.4.5 Multicast Packets Traversing the NGE Domain

Multicast packets that traverse an NGE domain can be categorized into two main scenarios:

- Scenario 1 — multicast packets that ingress the router on an interface that is outside the NGE domain. These packets can egress a variety of interfaces that are either inside or outside the NGE domain.
- Scenario 2 — multicast packets that ingress the router on an interface that is inside the NGE domain. These packets can egress a variety of interfaces that are either inside or outside the NGE domain. This scenario has two cases:
  - Scenario 2a — the ingress multicast packet is not yet NGE-encrypted
  - Scenario 2b — the ingress multicast packet is NGE-encrypted

[Figure 152](#) shows these scenarios.

**Figure 152 Processing Multicast Packets**

26182

Multicast packets received from outside the NGE domain (Scenario 1) are processed similarly to multicast packets received from inside the NGE domain (Scenarios 2a and 2b).

The processing rule is that multicast packets are always forwarded as clear text over the fabric. This means that for Scenario 2b, when a multicast packet is received on an encryption-capable interface and is NGE-encrypted, the packet is always decrypted first so that it can be processed in the same way as packets in Scenarios 1 and 2a.

On egress, the following scenarios apply:

- egressing an interface outside the NGE domain — packets are processed in the same way as any multicast packets forwarded out a non-NGE interface
- egressing an NGE router interface and no inbound or outbound key group is configured — the router forwards these packets out from the egress interface without encrypting them since there is no outbound key group configured. This behavior also applies to unicast packets in the same scenario.
- egressing an NGE router interface with the outbound key group configured — the router encrypts the multicast packet using the SPI keys of the outgoing SA configured in the key group. This behavior also applies to unicast packets in the same scenario.

---

## 9.4.6 Assigning Key Groups to Router Interfaces

Assigning key groups to router interfaces involves the following three steps:

**Step 1.** Enable NGE with the **group-encryption** command.

**Step 2.** Configure the outbound key group.

**Step 3.** Configure the inbound key group.

Step 1 is required so that the router can initialize and differentiate the interface for NGE traffic before accepting or sending NGE packets. This assigns the interface to an NGE domain, and IPSec packets will no longer be accepted on the interface.

Assigning key groups to a router interface in steps 2 and 3 is similar to assigning key groups to SDPs or VPRN-based services. An outbound key group cannot be configured for a router interface without first enabling **group-encryption**.

When group-encryption is enabled and no inbound key group is configured, the router will accept NGE Layer 3 packets that were encrypted using keys from any security association configured in any key group on the system. If the packet specifies a security association that is not configured in any key group on the node, the packet is dropped.

The outbound key group references the key group to use when traffic egresses the router on the router interface. The inbound key group is used to make sure ingress traffic is using the correct key group on the router interface. If ingress traffic is not using the correct key group, the router counts these packets as errors.

## 9.4.7 Router Interface NGE Firewall Considerations

An interface that has been configured to exist inside the NGE domain cannot be added to a security zone; firewalls are not supported on NGE router interfaces, as shown in [Figure 153](#).

**Figure 153 Firewall Considerations**

26179

It is recommended that firewall security policies be enabled on interfaces outside the NGE domain before traffic is allowed to enter the NGE domain.

## 9.4.8 NGE and BFD Support

When NGE is enabled on a router interface, BFD packets that originate from the network processor on the adapter card or from the system are encrypted in the same way as BFD packets that are generated by the CSM.

## 9.4.9 NGE and ACL Interactions

When NGE is enabled on a router interface, the ACL function is applied as follows:

- on ingress — Normal ACLs are applied to traffic received on the interface that could be either NGE-encrypted or clear text. For NGE-encrypted packets, this implies that only the source, destination, and IP options are available to filter on ingress, as the protocol is ESP and the packet is encrypted. If an IP exception ACL is also configured on the interface, the IP exception ACL is applied first to allow any clear text packets to ingress as needed. After the IP exception ACL is applied and if another filter or ACL is configured on the interface, the other filter will process the remaining packet stream (NGE-encrypted and IP exception ACL packets), and other ACL functions such as PBR or Layer 4 information filtering could be applied to any clear text packets that passed the exception ACL.
- on egress — ACLs are applied to packets before they are NGE-encrypted as per normal operation without NGE enabled.

---

## 9.4.10 Router Interface NGE and ICMP Interactions Over the NGE Domain

Typically, ICMP works as expected over an NGE domain when all routers participating in the NGE domain are NGE-capable; this includes running an NGE domain over a private IP/MPLS network and over a Layer 2 service provider where dedicated point-to-point circuits are used to create single-hop links between NGE nodes. When an ICMP message is required, the NGE packet is decrypted first and the original packet is restored to create a detailed ICMP message using the original packet's header information.

When the NGE domain crosses a Layer 3 service provider, or crosses over routers that are not NGE-aware, it is not possible to create a detailed ICMP message using the original packet's information, as the NGE packet protocol is always set to ESP. Furthermore, the NGE router that receives these ICMP messages will drop them because the messages are not NGE-encrypted.

The combination of dropping ICMP messages at the NGE border node and the missing unencrypted packet details in the ICMP information can cause problems with diagnosing network issues.

To help with diagnosing network issues, additional statistics are available on the interface to show whether ICMP messages are being returned from a foreign node. The following statistics are included in the group encryption NGE statistics for an interface:

- Group Enc Rx ICMP DestUnRch Pkts
- Group Enc Rx ICMP TimeExc Pkts
- Group Enc Rx ICMP Other Pkts

These statistics are used when clear text ICMP messages are received on an NGE router interface. The Invalid ESP statistics are not used in this situation even though the packet does not have a correct NGE ESP header. If there is no ingress exception ACL configured on the interface to allow the ICMP messages to be forwarded, the messages are counted and dropped.

If more information is required for these ICMP messages, such as source or destination address information, a second ICMP filter can be configured on the interface to allow logging of the ICMP messages. If the original packet information is also required, an egress exception ACL can be configured with the respective source or destination address information, or other criteria, to allow the original packet to enter the NGE domain in clear text and determine which flows are causing the ICMP failures.

---

### **9.4.11 OAM Considerations for Router Interface Encryption**

CSM timestamping is supported when NGE router interface encryption is enabled.

## 9.5 Layer 2 Encryption

Layer 2 encryption allows IS-IS and LLDP Layer 2 protocols to be encrypted using NGE key groups. [Figure 154](#) shows the packet format for Layer 2 encryption.

**Figure 154 Encrypted Layer 2 Packet**

26178

Similar to router interface encryption, which reuses IPSec transport mode formatted packets, Layer 2 NGE encryption reuses the MACsec Ethertype and the ESP protocol, as defined in RFC 4303, to encrypt the payload of a Layer 2 packet.

Layer 2 NGE is configured on network Ethernet ports; access ports and hybrid ports do not support Layer 2 encryption. When Layer 2 encryption is configured, all IS-IS and LLDP packets are encrypted using NGE. Layer 2 encryption does not encrypt any Layer 3 packets using NGE router interface encryption or MPLS packets using MPLS service encryption.

---

Layer 2 NGE encryption is enabled by configuring an outbound key group and an inbound key group on the Ethernet port and is similar to assigning key groups for router interface encryption as described in [Assigning Key Groups to Router Interfaces](#). For example, to configure Layer 2 encryption on port 1/1/1:

**config port 1/1/1 ethernet group-encryption encryption-keygroup 1 direction outbound**

**config port 1/1/1 ethernet group-encryption encryption-keygroup 1 direction inbound**

The **group-encryption** command initializes the port for NGE Layer 2 encryption where both encrypted NGE Layer 2 packets and clear text packets can be received. The **group-encryption** command is used to add the port to an NGE domain and ensures that any received packets with the MACsec Ethertype are decrypted using NGE Layer 2 encryption.

The outbound key group references the key group to use for encrypting the supported Layer 2 packets egressing the router on the Ethernet port. The inbound key group is used to ensure that ingress traffic is using the correct key group. If ingress traffic that is not using the correct key group is detected, the packets are counted as errors.

If Layer 2 NGE is used for a LAG, each Ethernet port member of the LAG group must be configured with NGE. There is no NGE configuration inheritance from the primary port of a LAG group to its member ports. Each port operates based on its own NGE configuration.

For configuration guidelines for inbound and outbound key groups, see [Configuration Notes](#).

## 9.6 NGE Packet Overhead and MTU Considerations

NGE adds overhead packets to services. [Table 188](#) shows the additional overhead for the worst-case scenario of MPLS services encryption. [Table 189](#) shows the additional overhead for the worst-case scenario of router interface and Layer 2 encryption. Additional overhead depends on which encryption and authentication algorithms are chosen.

**Table 188** NGE Overhead for MPLS

| Item              | Number of Bytes |
|-------------------|-----------------|
| Encryption label  | 4               |
| ESP               | 24              |
| ICV               | 32              |
| Padding           | 17              |
| Control word copy | 4               |
| <b>Total</b>      | <b>81</b>       |

For MP-BGP-based VPRNs, the total is 77 bytes because the control word copy is not required.

**Table 189** NGE Overhead for Router Interface and Ethernet Port NGE

| Item         | Number of Bytes |
|--------------|-----------------|
| ESP          | 24              |
| ICV          | 32              |
| Padding      | 17              |
| <b>Total</b> | <b>73</b>       |

For Layer 3 packets for router interface encryption, and Layer 2 packets for Layer 2 encryption, the total is 73 bytes because the encryption label and control word copy are not required.

The overhead values in [Table 188](#) must be considered for services that are supported by NGE.

**Note:** Currently, the port MTU has a default value of 1572 bytes. This value is too low for outbound traffic when NGE is enabled. Users must configure new MTU values to adjust for the overhead associated with NGE, as outlined in [Table 190](#) for MPLS-based and GRE-based services. For details on configuring MTU, refer to the “MTU Configuration Guidelines” section in the 7705 SAR Interface Configuration Guide.

The calculations in [Table 190](#) show how NGE overhead affects SDP MTU and service MTU values for MPLS-based, GRE-based, and VPRN-based services. The calculations are with and without NGE enabled.

**Table 190     Accounting for NGE Overhead SDP and Service MTU — Calculation Examples**

| Service Type        | MTU Values With and Without NGE Enabled                                                                                                                                                                                                                           |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MPLS-based services | <b>SDP MTU (MPLS)</b><br>= 1572 (network port MTU) – 14 (Ethernet header) – 4 (outer label) – 4 (inner label)<br>= 1550 bytes (without NGE enabled)<br>=> 1469 bytes (with NGE enabled)                                                                           |
|                     | <b>Service MTU (MPLS) considerations with NGE enabled</b> <ul style="list-style-type: none"><li>• Layer 3 spoke IP MTU (MPLS)<br/>= 1469 – 14 (inner Ethernet header)<br/>= 1455 bytes</li><li>• PW spoke SDP MTU (MPLS)<br/>= SDP MTU<br/>= 1469 bytes</li></ul> |
| GRE-based services  | <b>SDP MTU (GRE)</b><br>= 1572 (network port MTU) – 14 (Ethernet header) – 20 (IP header) – 4 (GRE header) – 4 (inner label)<br>= 1530 bytes (without NGE enabled)<br>=> 1449 bytes (with NGE enabled)                                                            |
|                     | <b>Service MTU (GRE) considerations with NGE enabled</b> <ul style="list-style-type: none"><li>• Layer 3 Spoke IP MTU (GRE)<br/>= 1449 – 14 (inner Ethernet header)<br/>= 1435 bytes</li><li>• PW Spoke MTU (GRE)<br/>= SDP MTU<br/>= 1449 bytes</li></ul>        |

Table 190     Accounting for NGE Overhead SDP and Service MTU — Calculation Examples

| Service Type        | MTU Values With and Without NGE Enabled                                                                                                                                                                                                                    |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VPRN-based services | Each interface inherits its MTU from the SAP or spoke SDP to which it is bound and the MTU value can be manually changed using the <b>ip-mtu</b> command.                                                                                                  |
|                     | <b>MP-BGP-based VPRN services</b><br>The MTU of the egress IP interface is used. When NGE is enabled on a VPRN service, customers must account for the additional 77 bytes of overhead needed by NGE for any egress IP interface used by the VPRN service. |

When an unencrypted Layer 3 packet ingresses the node and routing determines that the egress interface is a router interface NGE-enabled interface, the node calculates whether the packet size will be greater than the MTU of the egress interface after the router interface NGE overhead is added. If the packet cannot be forwarded out from the network interface, an ICMP message is sent back to the sender and the packet is dropped. Users must configure new MTU values to adjust for the overhead associated with NGE.

If an IP exception ACL that matches the ingressing packet exists on the egress interface, the MTU check applied to the ingress packet includes the router interface NGE overhead. This is because the ingress interface cannot determine which IP exceptions are configured on the egress interface, and therefore the worst-case MTU check that includes the router interface NGE overhead is performed.

---

## 9.7 1588v2 Encryption With NGE

If a router interface is enabled for encryption and Layer 3 1588v2 packets are sent, they will be encrypted using NGE. This means that if port timestamping is enabled on a router interface with NGE, the port timestamp is applied to the Layer 3 1588v2 packet via software-based timestamping instead of hardware-based timestamping, and consequently timing accuracy may degrade. The exact level of timing or synchronization degradation is dependent on many factors, and testing is recommended to measure any impact.

If there is a need to support Layer 3 1588v2 with better accuracy for frequency or better time using port timestamping, an NGE exception ACL is required to keep the Layer 3 1588v2 packets in clear text. The exception ACL must enable UDP packets with destination port 319 to be sent in clear text.

Layer 2 1588v2 packets are always sent and received in clear text. When NGE is enabled on a Layer 2 port, encryption is not applied and existing Layer 2 1588v2 functions are not impacted.

---

## 9.8 QoS for NGE Traffic

The 7705 SAR provides priority and scheduling for traffic into the encryption and decryption engines on nodes that support NGE. This is described for the following traffic directions:

- [Network Ingress](#)
- [Network Egress](#)

For information on QoS and QoS policies, refer to the 7705 SAR Quality of Service Guide. Also, since QoS for NGE is similar to QoS for IPSec, see [QoS for IPSec](#) for more information.

### 9.8.1 Network Ingress

NGE traffic arriving on network ingress is classified based on the network QoS policy that is assigned to the network router interface. This classification is done using the EXP bits of the outer MPLS tunnel LSP or the DSCP markings on the IP packet of GRE packets.

There are two queues provided for mapping ingress NGE traffic into the decryption engine—an expedited queue and a best-effort queue. The encrypted traffic maps to one of these queues based on the queue-type configuration of the network ingress queue and the FC-to-queue (classification) mapping. Specifically, at network ingress, the following occurs (as shown in [Figure 155](#)):

- the network QoS policy determines the forwarding class (FC) for the packet (item 1)
- the ingress network queue QoS policy maps the FC to a queue, where the queue-type has been configured as expedited, best-effort, or auto-expedite (item 2)
- the queue-type is used again to map to the appropriate queue into the decryption engine (that is, the expedited and best-effort queue) (item 3)
- after decryption, normal QoS processing takes place as if NGE was not enabled for the service (item 4)

**Figure 155 QoS for NGE Traffic (Network Ingress)**

25102

For more information on QoS for network ingress, refer to the “Network Ingress” section in the 7705 SAR Quality of Service Guide.

## 9.8.2 Network Egress

Traffic egressing a network interface typically has a known FC based on the traffic management (TM) configuration at SAP ingress.

There are two queues provided for mapping egress NGE traffic into the encryption engine—an expedited queue and a best-effort queue. The traffic maps to one of these queues based on the FC of the packet, as determined at SAP ingress. Specifically, the following occurs:

- the SAP ingress QoS policy maps the FC to a queue-type, where the queue-type of the SAP-ingress queue has been configured as expedited, best-effort, or auto-expedite
- on the network egress side of the fabric, the ingress queue-type is used to map to the appropriate queue into the encryption engine (that is, the expedited and best-effort queue)

For more information on QoS for network egress, refer to the “Network Egress” section in the 7705 SAR Quality of Service Guide.

---

## 9.9 Statistics

Statistics specific to NGE are counted for the following main areas:

- key group
- SPI
- MDA
- service

---

## 9.10 Remote Network Monitoring (RMON) Support

Remote network Monitoring (RMON) can be used in conjunction with NGE statistics to provide event and alarm reporting. This can be used by customers to detect security breaches of NGE traffic flows and provide real-time reporting of such events.

Threshold crossing alerts and alarms using RMON are supported for SNMP MIB objects, including NGE.

---

## 9.11 Configuration Notes

This section describes NGE configuration guidelines and caveats. For more information about configuring NGE using the NSP NFM-P, see the NSP NFM-P User Guide.

To enable NGE for an SDP or VPRN service:

**Step 1.** Install the outbound direction key group on each node for the service.

**Step 2.** Install the inbound direction key group on each node for the service.

To enable NGE for a router interface:

**Step 1.** Enable **group-encryption** on the interface.

**Step 2.** Configure the outbound key group.

**Step 3.** Configure the inbound key group.

To change NGE from one key group to another key group for an SDP or VPRN service:

**Step 1.** Remove the inbound direction key group from each node for the service.

**Step 2.** Change the outbound direction key group on each node for the service.

**Step 3.** Install the new inbound direction key group on each node for the service.

To change NGE from one key group to another key group for a router interface:

**Step 1.** Remove the inbound key group.

**Step 2.** Configure the new outbound key group.

**Step 3.** Configure the new inbound key group.

To disable NGE for an SDP or VPRN service:

**Step 1.** Remove the inbound direction key group from each node providing the service.

**Step 2.** Remove the outbound direction key group from each node for the service.

To disable NGE for a router interface:

**Step 1.** Remove the inbound key group.

**Step 2.** Remove the outbound key group.

**Step 3.** Disable **group-encryption** on the interface.

---

**Caveats:**

- The authentication and encapsulation keys must contain the exact number of hexadecimal characters required by the algorithm used. For example, using sha256 requires 64 hexadecimal characters.
- The key group bound to an SDP or service must be unbound from that SDP or service before the active outgoing SA for the key group can be removed.
- The active outgoing SA must be removed (deconfigured) before the SPI can be deleted from the SA list in the key group.
- The encryption or authentication algorithm for a key group cannot be changed if there are any SAs in the key group.
- The encryption configured on an SDP used to terminate the Layer 3 spoke SDP of a VPRN (enabled or disabled) always overrides any VPRN-level configuration for encryption. See [VPRN Layer 3 Spoke-SDP Encryption and MP-BGP-based VPRN Encryption Interaction](#) for more information.
- The NSP NFM-P provides configuration parameters that are not configurable using the CLI. See [Network Services Platform Management](#) for more information.

## 9.11.1 Reference Sources

For information on supported IETF drafts and standards as well as standard and proprietary MIBS, refer to [Standards and Protocol Support](#).

---

## 9.12 Configuring NGE with the CLI

NGE is fully managed by the NSP NFM-P. The NSP NFM-P ensures proper network synchronization of key groups, services, and NGE domains. Managing NGE without the NSP NFM-P is not recommended. See the NSP NFM-P User Guide for more information.

This section provides information about configuring NGE using the command line interface.

Topics in this chapter include:

- [Basic NGE Configuration Overview](#)
- [Configuring NGE Components](#)
- [NGE Management Tasks](#)

---

## 9.13 Basic NGE Configuration Overview

Use the following steps to configure NGE for an MPLS service, router interface, or Ethernet port. The steps must be performed in order.

- Step 1.** Configure the group encryption label. The label must be unique, and the same label must be used on all nodes in the network group.
- Step 2.** Create a key group, duplicating this configuration on all nodes participating in this key group.
  - i. Configure the encryption and authentication algorithms for the group.
  - ii. Configure a security association (SA) that contains the encryption and authentication keys.
  - iii. Configure the active outbound SA for the group.
- Step 3.** Select the SDPs, VPRN services, router interfaces, or Ethernet ports that require encryption.
  - i. For each SDP, VPRN service, router interface, or Ethernet port, configure the outbound direction key group.
  - ii. For each SDP, VPRN service, router interface, or Ethernet port, configure the inbound direction key group.

---

## 9.14 Configuring NGE Components

Use the CLI syntax below to configure the following NGE parameters:

- [Configuring the Global Encryption Label](#)
- [Configuring a Key Group](#)
- [Assigning a Key Group to an SDP or VPRN Service](#)
- [Assigning a Key Group to a Router Interface](#)
- [Assigning a Key Group to an Ethernet Port](#)

### 9.14.1 Configuring the Global Encryption Label

The global encryption label is the network-wide, unique MPLS encryption label used for all nodes in the network group. The same encryption label must be configured on each node in the group.

Use the following CLI syntax to configure the global encryption label:

**CLI Syntax:**     `config>group-encryption`  
                  `group-encryption-label encryption-label`

The following example displays global encryption label usage:

**Example:**       `config# group-encryption`  
                  `config>grp-encryp# group-encryption-label 34`

The following example displays the global encryption label configuration:

```
ALU-1>config>grp-encryp# info

group-encryption-label 34

ALU-1>config>grp-encryp#
```

---

## 9.14.2 Configuring a Key Group

To configure a key group, set the following parameters:

- encryption and authentication algorithms
- security association
- active outbound SA

The authentication and encapsulation keys must contain the exact number of hexadecimal characters required by the algorithm used. For example, using sha256 requires 64 hexadecimal characters.

Keys are entered in clear text using the **security-association** command. Once entered, they are never displayed in their original, clear text form. Keys are displayed in a 7705 SAR-encrypted form, which is indicated by the system-appended **crypto** keyword when an **info** command is run (see the CLI Syntax, Example, and CLI output below). The 7705 SAR also includes the **crypto** keyword with an **admin>save** operation so that the 7705 SAR can decrypt the keys when reloading a configuration database. For security reasons, keys encrypted on one node are not usable on other nodes (that is, keys are not exchangeable between nodes).

Use the following CLI syntax to configure key group options:

**CLI Syntax:**

```
config# group-encryption
 encryption-keygroup keygroup-id [create]
 description description-string
 esp-auth-algorithm {sha256|sha512}
 esp-encryption-algorithm {aes128|aes256}
 keygroup-name keygroup-name
 security-association spi spi authentication-
 key authentication-key encryption-key
 encryption-key [crypto]
 active-outbound-sa spi
```

The following example displays key group command usage:

**Example:**

```
config>grp-encryp# encryption-keygroup KG1_secure
config>grp-encryp>encryp-keygrp# description
Main_secure_KG
config>grp-encryp>encryp-keygrp# esp-auth-algorithm
sha256
config>grp-encryp>encryp-keygrp# esp-encryption-
algorithm aes128
config>grp-encryp>encryp-keygrp# keygroup-name
KG1_secure
```

```

config>grp-encryp>encryp-keygrp# security-association
spi 2 authentication-key
0x88433A6DB4FA4F8A490EF661CBE69F010BFAE9C2784BED7059E5
ADAAB1A225C6 encryption-key
0x63DCDD501B66F85441E4A55B597DA617
config>grp-encryp>encryp-keygrp# security-association
spi 6 authentication-key
0x88433A6DB4FA4F8A490EF661CBE69F010BFAE9C2784BED7059E5
ADAAB1A225C5 encryption-key
0x63DCDD501B66F85441E4A55B597DA616
config>grp-encryp>encryp-keygrp# active-outbound-sa 6]

```

The following example displays the key group configuration:

```

ALU-1>config>grp-encryp# info detail

group-encryption-label 34
encryption-keygroup 2 create
description "Main_secure_KG"
keygroup-name "KG1_secure"
esp-auth-algorithm sha256
esp-encryption-algorithm aes128
security-association spi 2 authentication-

key 0x72bd9b87841dbebcb2d114031367ab5d9153a41b7c79c8f889ac56b950d8fffa crypto
active-outbound-sa 6
exit

ALU-1>config>grp-encryp#

```

### 9.14.3 Assigning a Key Group to an SDP or VPRN Service

A key group can be assigned to the following entities:

- SDPs
- VPRN services

NGE supports encryption of the following services when key groups are assigned to an SDP or VPRN service:

- VLL services (Epipe and Cpipe)
- VPRN services using Layer 3 spoke-SDP termination
- IES services using Layer 3 spoke-SDP termination
- VPLS services using spoke and mesh SDPs

- routed VPLS services into a VPRN or IES
- MP-BGP-based VPRNs
- NG-MVPN

For services that use SDPs, all tunnels may be either MPLS LSPs (RSVP-TE, LDP, or static LSP) or GRE tunnels. NGE is not supported on IP tunnels.

For VPRNs, the following encryptions are supported:

- unicast VPRN— MP-BGP-based VPRN-level encryption using the auto-bind feature of LDP, GRE, RSVP-TE, or segment routing (SR-ISIS, SR-OSPF, or SR-TE) tunnels
- multicast VPRN — NG-MVPN using mLDP with auto-discovery

Use the following CLI syntax to assign a key group to an SDP or a VPRN service:

**CLI Syntax:** `config>service# sdp sdp-id [create]  
encryption-keygroup keygroup-id direction  
{inbound|outbound}`

**CLI Syntax:** `config>service# vprn service-id  
encryption-keygroup keygroup-id direction  
{inbound|outbound}`

The following examples display a key group assigned to an SDP or a VPRN service:

```
Example: config>service# sdp 61 create
 config>service>sdp# encryption-keygroup 4 direction
 inbound
 config>service>sdp# encryption-keygroup 4 direction
 outbound
```

```
Example: config>service# vprn 22
 config>service>vprn# encryption-keygroup 2 direction
 inbound
 config>service>vprn# encryption-keygroup 2 direction
 outbound
```

The following example displays key group configuration for an SDP or a VPRN service.

```
ALU-1: Sar18>config>service# info

...
 sdp 61 create
 shutdown
 far-end 10.10.10.10
 exit
```

```

 encryption-keygroup 4 direction inbound
 encryption-keygroup 4 direction outbound
 exit
...
 vprn 22 customer 1 create
 shutdown
 encryption-keygroup 2 direction inbound
 encryption-keygroup 2 direction outbound
 exit
...

```

## 9.14.4 Assigning a Key Group to a Router Interface

Use the following CLI syntax to assign a key group to a router interface:

**CLI Syntax:**

```

config>router# interface ip-int-name [create]
 group-encryption
 encryption-keygroup keygroup-id direction
 {inbound | outbound}

```

The following example displays a key group assigned to a router interface:

**Example:**

```

config>router# interface demo
config>router>if# group-encryption
config>router>if>group-encryp# encryption-keygroup 6
 direction inbound
config>router>if>group-encryp# encryption-keygroup 6
 direction outbound

```

The following example displays key group configuration for a router interface.

```

ALU-1:Sal18>config>router# info

...
 interface demo
 group-encryption
 encryption-keygroup 6 direction inbound
 encryption-keygroup 6 direction outbound
 exit
 no shutdown
 exit
...

```

---

## 9.14.5 Assigning a Key Group to an Ethernet Port

Use the following CLI syntax to assign a key group to an Ethernet port:

**CLI Syntax:**

```
config# port port-id
 ethernet
 group-encryption
 encryption-keygroup keygroup-id direction
 {inbound | outbound}
```

The following example displays a key group assigned to an Ethernet port:

**Example:**

```
config# port 1/2/2
config>port# ethernet
config>port>ethernet# group-encryption
config>port>ethernet>group-encryp# encryption-keygroup 6
direction inbound
config>port>ethernet>group-encryp# encryption-keygroup 6
direction outbound
```

The following example displays key group configuration for an Ethernet port.

```
ALU-1:Sal18>config>port# info

...
 ethernet
 group-encryption
 encryption-keygroup 6 direction inbound
 encryption-keygroup 6 direction outbound
 exit
 no shutdown
 exit
 exit
...

```

---

## 9.15 NGE Management Tasks

This section discusses the following NGE management tasks:

- [Modifying a Key Group](#)
- [Removing a Key Group](#)
- [Changing Key Groups](#)
- [Deleting a Key Group from a 7705 SAR](#)

### 9.15.1 Modifying a Key Group

When modifying a key group, observe the following conditions.

- The encryption or authentication algorithm for a key group cannot be changed if there are any SAs in the key group.
- The active outgoing SA must be removed (deconfigured) before the SPI can be deleted from the SA list in the key group.
- Before the outgoing SA can be deconfigured, the key group must be removed from all services on the node that use the key group

In the following example, the active outgoing SA is deconfigured, the SAs are removed, and the encryption algorithm is changed. Then the SAs are reconfigured, followed by reconfiguration of the active outgoing SA. The output display shows the new configuration based on those shown in [Configuring a Key Group](#).

Use the following CLI syntax to modify a key group. The first syntax deconfigures the key-group items and the second syntax reconfigures them.

**CLI Syntax:**

```
config# group-encryption
 encryption-keygroup keygroup-id
 no active-outbound-sa
 no security-association spi spi
exit
```

**CLI Syntax:**

```
config# group-encryption
 encryption-keygroup keygroup-id
 security-association spi spi authentication-
 key auth-key encryption-key encrypt-key
 esp-encryption-algorithm {aes128|aes256}
exit
```

**Example:**

```
config>grp-encryp# encryption-keygroup KG1_secure
config>grp-encryp>encryp-keygrp# no active-outbound-sa
config>grp-encryp>encryp-keygrp# no security-association
spi 2
config>grp-encryp>encryp-keygrp# no security-association
spi 6
```

**Example:**

```
config>grp-encryp# encryption-keygroup KG1_secure
config>grp-encryp>encryp-keygrp# esp-encryption-
algorithm aes256
config>grp-encryp>encryp-keygrp# security-association
spi 2 authentication-key
0x0123456789012345678901234567890123456789012345678901
234567890123 encryption-key
0x0123456789012345678901234567890123456789012345678901
234567890123
config>grp-encryp>encryp-keygrp# security-association
spi 6 authentication-key
0x0123456789ABCDEF0123456789ABCDEF0123456789ABCDEF0123
456789ABCDEF encryption-key
0x0123456789ABCDEF0123456789ABCDEF0123456789ABCDEF0123
456789ABCDEF [crypto]
config>grp-encryp>encryp-keygrp# active-outbound-sa 2
```

The following example displays the commands used to modify a key group. The first example deconfigures the key-group items and the second example reconfigures them. The encryption algorithm is changed from 128 to 256, the keys are changed, and the active outbound SA is changed to SPI 2.

```
ALU-1>config>grp-encryp# info detail

group-encryption-label 34
encryption-keygroup 2 create
description "Main_secure_KG"
keygroup-name "KG1_secure"
esp-auth-algorithm sha256
esp-encryption-algorithm aes128
no security-association spi 2
no security-association spi 6
no active-outbound-sa
exit

ALU-1>config>grp-encryp#
```

```

ALU-1>config>grp-encryp# info detail

group-encryption-label 34
encryption-keygroup 2 create
description "Main_secure_KG"
keygroup-name "KG1_secure"

key 0x0123456789ABCDEF0123456789ABCDEF0123456789ABCDEF0123456789ABCDEF encryption-
key 0x0123456789ABCDEF0123456789ABCDEF0123456789ABCDEF0123456789ABCDEF crypto
active-outbound-sa 2
exit

ALU-1>config>grp-encryp#

```

## 9.15.2 Removing a Key Group

Both inbound and outbound direction key groups must be deconfigured before the key group can be removed (unbound). The inbound and outbound key groups must be deconfigured individually. Including *keygroup-id* is optional.

### 9.15.2.1 Removing a Key Group from an SDP or VPRN Service

Use the following CLI syntax to remove a key group from an SDP or a VPRN service:

**CLI Syntax:** `config>service# sdp sdp-id  
no encryption-keygroup keygroup-id direction  
{inbound|outbound}`

**CLI Syntax:** `config>service# vprn service-id  
no encryption-keygroup keygroup-id direction  
{inbound|outbound}`

The following examples display a key group removed from an SDP or a VPRN service:

**Example:** `config>service# sdp 61  
config>service>sdp# no encryption-keygroup 4 direction  
inbound  
config>service>sdp# no encryption-keygroup 4 direction  
outbound`

**Example:**

```
config>service# vprn 22
config>service>vprn# no encryption-keygroup 2 direction
inbound
config>service>vprn# no encryption-keygroup 2 direction
outbound
```

The following example shows that the key group configuration has been removed from an SDP or a VPRN service.

```
ALU-1:Sal18>config>service# info

...
 sdp 61 create
 shutdown
 far-end 10.10.10.10
 exit
 exit
...
...
 vprn 22 customer 1 create
 shutdown
 exit
...

ALU-1:Sal18>config>service# info
```

### 9.15.2.2 Removing a Key Group from a Router Interface

Use the following CLI syntax to remove a key group from a router interface:

**CLI Syntax:**

```
config>router# interface ip-int-name
group-encryption
 no encryption-keygroup keygroup-id direction
 {inbound | outbound}
```

The following example displays a key group removed from a router interface:

**Example:**

```
config>router# interface demo
config>router>if# group-encryption
config>router>if>group-encryp# no encryption-keygroup 6
direction inbound
config>router>if>group-encryp# no encryption-keygroup 6
direction outbound
```

The following example shows that the key group configuration has been removed from a router interface.

```
ALU-1:Sal18>config>router# info

...
 interface demo
 group-encryption
 exit
 no shutdown
 exit
 exit
...

```

### 9.15.2.3 Removing a Key Group from an Ethernet Port

Use the following CLI syntax to remove a key group from an Ethernet port:

**CLI Syntax:**

```
config# port port-id
 ethernet
 group-encryption
 no encryption-keygroup keygroup-id
 direction {inbound | outbound}
```

The following example displays a key group removed from an Ethernet port:

**Example:**

```
config# port 1/2/2
config>port# ethernet
config>port>ethernet# group-encryption
config>port>ethernet>group-encryp# no encryption-
 keygroup 6 direction inbound
config>port>ethernet>group-encryp# no encryption-
 keygroup 6 direction outbound
```

The following example shows that the key group configuration has been removed from an Ethernet port.

```
ALU-1:Sal18>config>port# info

...
 ethernet
 group-encryption
 exit
 no shutdown
 exit
 exit
...

```

## 9.15.3 Changing Key Groups

Use the following sequence of CLI commands to change key groups:

1. Remove the inbound direction key group.
2. Change the outbound direction key group.
3. Install the new inbound direction key group.

### 9.15.3.1 Changing the Key Group for an SDP or VPRN Service

Changing key groups for an SDP or VPRN service must be performed on all nodes for the service.

The following CLI syntax changes the key group on an SDP. The syntax for a VPRN service is similar. In the example below, the inbound and outbound key groups are changed from key group 4 to key group 6.

**CLI Syntax:**

```
config>service# sdp sdp-id
no encryption-keygroup keygroup-id direction
{inbound|outbound}
```

**Example:**

```
config>service# sdp 61
config>service>sdp# no encryption-keygroup 4 direction
inbound
config>service>sdp# encryption-keygroup 6 direction
outbound
config>service>sdp# encryption-keygroup 6 direction
inbound
```

The following example shows that the key group configuration has been changed for the SDP or the VPRN service.

```
ALU-1:Sarl8>config>service# info

...
sdp 61 create
shutdown
far-end 10.10.10.10
exit
encryption-keygroup 6 direction inbound
encryption-keygroup 6 direction outbound
exit
...
...
vprn 22 customer 1 create
shutdown
encryption-keygroup 2 direction inbound
```

```
 encryption-keygroup 2 direction outbound
 exit
 ...

ALU-1:Sar18>config>service# info
```

### 9.15.3.2 Changing the Key Group for a Router Interface

The following CLI syntax changes the key group on a router interface. In the example below, the inbound and outbound key groups are changed from key group 6 to key group 8.

**CLI Syntax:**

```
config>router# interface ip-int-name
group-encryption
no encryption-keygroup keygroup-id direction
{inbound|outbound}
```

**Example:**

```
config>router# interface demo
config>router>if# group-encryption
config>router>if>group-encryp# no encryption-keygroup 6
direction inbound
config>router>if>group-encryp# encryption-keygroup 8
direction outbound
config>router>if>group-encryp# encryption-keygroup 8
direction inbound
```

The following example shows that the key group configuration has been changed for the router interface.

```
ALU-1:Sar18>config>router# info

...
 interface demo
 group-encryption
 encryption-keygroup 8 direction inbound
 encryption-keygroup 8 direction outbound
 exit
 no shutdown
 exit
exit
...

```

---

### 9.15.3.3 Changing the Key Group for an Ethernet Port

The following CLI syntax changes the key group on an Ethernet port. In the example below, the inbound and outbound key groups are changed from key group 6 to key group 8.

**CLI Syntax:**

```
config# port port-id
 ethernet
 group-encryption
 no encryption-keygroup keygroup-id
 direction {inbound|outbound}
```

**Example:**

```
config# port 1/2/2
config>port# ethernet
config>port>ethernet# group-encryption
config>port>ethernet>group-encryp# no encryption-
keygroup 6 direction inbound
config>port>ethernet>group-encryp# encryption-keygroup 8
direction outbound
config>port>ethernet>group-encryp# encryption-keygroup 8
direction inbound
```

The following example shows that the key group configuration has been changed for the Ethernet port.

```
ALU-1:Sar18>config>port# info

...
 ethernet
 group-encryption
 encryption-keygroup 8 direction inbound
 encryption-keygroup 8 direction outbound
 exit
 no shutdown
 exit
 exit
...

```

---

## 9.15.4 Deleting a Key Group from a 7705 SAR

To delete a key group from a 7705 SAR, the key group must be removed (unbound) from all SDPs, VPRN services, router interfaces, and Layer 2 NGE-encrypted Ethernet ports that use it.

To locate the key group bindings, use the CLI command **show>group-encryption>encryption-keygroup** *keygroup-id*.

Use the following CLI syntax to delete a key group:

**CLI Syntax:**     `config# group-encryption`  
                  `no encryption-keygroup keygroup-id`

**Example:**       `config>grp-encryp# no encryption-keygroup 8`

---

## 9.16 NGE Command Reference

### 9.16.1 Command Hierarchies

- [Configuration Commands](#)
  - [NGE Commands](#)
  - [Services Commands](#)
  - [Router Interface Encryption Commands](#)
  - [Ethernet Port Encryption Commands](#)
- [Show Commands](#)
- [Clear Commands](#)

## 9.16.1.1 Configuration Commands

### 9.16.1.1.1 NGE Commands

```

config
 — group-encryption
 — encryption-keygroup keygroup-id [create]
 — no encryption-keygroup keygroup-id
 — active-outbound-sa spi
 — no active-outbound-sa
 — description description-string
 — no description
 — esp-auth-algorithm {sha256 | sha512}
 — no esp-auth-algorithm
 — esp-encryption-algorithm {aes128 | aes256}
 — no esp-encryption-algorithm
 — keygroup-name keygroup-name
 — no keygroup-name
 — security-association spi spi authentication-key authentication-key
 encryption-key encryption-key [crypto]
 — no security-association spi spi
 — group-encryption-label encryption-label
 — no group-encryption-label

```

### 9.16.1.1.2 Services Commands

```

config
 — service
 — sdp
 — encryption-keygroup keygroup-id direction {inbound | outbound}
 — no encryption-keygroup direction {inbound | outbound}
 — vprn
 — encryption-keygroup keygroup-id direction {inbound | outbound}
 — no encryption-keygroup direction {inbound | outbound}

```

See [Global Service Command Reference](#) for information on encryption key groups for an SDP and [VPRN Services Command Reference](#) for information on encryption key groups for a VPRN service.

### 9.16.1.1.3 Router Interface Encryption Commands

```

config
 — router
 — [no] interface ip-int-name
 — [no] group-encryption
 — encryption-keygroup keygroup-id direction {inbound | outbound}
 — no encryption-keygroup direction {inbound | outbound}
 — ip-exception filter-id direction {inbound | outbound}
 — no ip-exception direction {inbound | outbound}

```

Refer to the “IP Router Command Reference” section in the 7705 SAR Router Configuration Guide for information on router interface encryption commands.

### 9.16.1.1.4 Ethernet Port Encryption Commands

```

config
 — [no] port port-id
 — ethernet
 — [no] group-encryption
 — encryption-keygroup keygroup-id direction {inbound | outbound}
 — no encryption-keygroup direction {inbound | outbound}

```

Refer to the “Configuration Command Reference” section in the 7705 SAR Interface Configuration Guide for information on Ethernet port encryption commands.

### 9.16.1.2 Show Commands

```

show
 — group-encryption
 — encryption-keygroup keygroup-id
 — encryption-keygroup keygroup-id spi spi
 — summary

```

### 9.16.1.3 Clear Commands

```

clear
 — group-encryption
 — encryption-keygroup keygroup-id
 — encryption-keygroup keygroup-id spi spi

```

---

| <b>Description</b> | <p>This command is used to create a security association for a specific SPI value in a key group. The command is also used to enter the authentication and encryption key values for the security association, or to delete a security association.</p> <p>The SPI value used for the security association is a node-wide unique value, meaning that no two security associations in any key group on the node may share the same SPI value.</p> <p>Keys are entered in clear text. Once configured, they are never displayed in their original, clear text form. Keys are displayed in a 7705 SAR-encrypted form, which is indicated by the system-appended <b>crypto</b> keyword when an <b>info</b> or an <b>admin&gt;save</b> command is run. For security reasons, keys encrypted on one node are not usable on other nodes (that is, keys are not exchangeable between nodes).</p> <p>The <b>no</b> form of the command removes the security association and related key values from the list of security associations for the key group. If the <b>no</b> form of the command is attempted using the same SPI value that is configured for <b>active-outbound-sa</b>, then a warning is issued and the command is blocked. If the <b>no</b> form of the command is attempted on the last SPI in the key group and the key group is configured on a service, then the command is blocked.</p> |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

- authentication-key* — specifies the authentication key for the SPI, in hexadecimal format. The number of characters in the hexadecimal string must be 64 or 128, depending on whether the authentication algorithm is set to sha256 or sha512, respectively.
- encryption-key* — specifies the encryption key for the SPI, in hexadecimal format. The number of characters in the hexadecimal string must be 32 or 64, depending on whether the encryption algorithm is set to aes128 or aes256, respectively.
- crypto** — indicates that the keys showing on the CLI **info** display are in 7705 SAR-encrypted form

| <b>Syntax</b>      | <b>group-encryption-label</b> <i>encryption-label</i><br><b>no group-encryption-label</b>                                                                                                                                                                                                                                                                                                                                       |
| <b>Context</b>     | config>grp-encryp                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | <p>This command configures the group encryption label used to identify when an MPLS payload is encrypted. This label must be unique network-wide and must be configured consistently on all nodes participating in a network group encryption domain. The label cannot be changed or deleted when there are any key groups configured on the node.</p> <p>The <b>no</b> form of the command reverts to the default setting.</p> |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <i>encryption-label</i> — the network-wide, unique reserved MPLS label for group encryption                                                                                                                                                                                                                                                                                                                                     |
| <b>Values</b>      | 32 to 2047                                                                                                                                                                                                                                                                                                                                                                                                                      |

## 9.16.2.2 Show Commands

### group-encryption

|                    |                                                                    |
|--------------------|--------------------------------------------------------------------|
| <b>Syntax</b>      | <b>group-encryption</b>                                            |
| <b>Context</b>     | show                                                               |
| <b>Description</b> | This command accesses the <b>show&gt;group encryption</b> context. |

### encryption-keygroup

|                    |                                                                                                                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>encryption-keygroup</b> <i>keygroup-id</i><br><b>encryption-keygroup</b> <i>keygroup-id spi spi</i>                                                                                                                       |
| <b>Context</b>     | show>grp-encryp                                                                                                                                                                                                              |
| <b>Description</b> | This command displays NGE information for a key group.                                                                                                                                                                       |
| <b>Parameters</b>  | <i>keygroup-id</i> — specifies the key group identifier to use for the output display<br><b>Values</b> 1 to 15 or <i>keygroup-name</i> (up to 64 characters)<br><i>spi</i> — specifies the SPI to use for the output display |
| <b>Output</b>      | The following output is an example of encryption key group information, and <a href="#">Table 191</a> describes the fields.                                                                                                  |

#### Output Example

```
*A:7705custDoc:Sarl8>show>grp-encryp# encryption-keygroup 2

**Table 191 Encryption Key Group Field Descriptions**

| Label                                           | Description                                                  |
|-------------------------------------------------|--------------------------------------------------------------|
| <b>Encryption Keygroup Configuration Detail</b> |                                                              |
| Keygroup Id                                     | The key group identifier                                     |
| Keygroup Name                                   | The key group name                                           |
| Description                                     | The key group description                                    |
| Authentication Algo                             | The authentication algorithm used for the key group          |
| Encryption Algo                                 | The encryption algorithm used for the key group              |
| Active Outbound SA                              | The active outbound SA for the key group                     |
| Activation Time                                 | The date and time that the key group was activated           |
| <b>Security Associations</b>                    |                                                              |
| Spi                                             | The security parameter index for the SA in the key group     |
| Install Time                                    | The date and time that the SA was installed in the key group |
| Key CRC                                         | The CRC for the key belonging to the SA                      |
| <b>Encryption Keygroup Forwarded Statistics</b> |                                                              |
| Encrypted Pkts                                  | The number of encrypted packets forwarded by the key group   |
| Encrypted Bytes                                 | The number of encrypted bytes forwarded by the key group     |
| Decrypted Pkts                                  | The number of decrypted packets forwarded by the key group   |
| Decrypted Bytes                                 | The number of decrypted bytes forwarded by the key group     |

**Table 191 Encryption Key Group Field Descriptions (Continued)**

| Label                                                           | Description                                                                                                                                                                                                |
|-----------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Encryption Keygroup Outbound Discarded Statistics (Pkts)</b> |                                                                                                                                                                                                            |
| Total Discard                                                   | The total number of outbound packets discarded by the key group                                                                                                                                            |
| Unsupported Uplink                                              | The total number of outbound packets discarded by the key group due to an unsupported uplink                                                                                                               |
| Enqueue Error                                                   | The total number of outbound packets discarded by the key group due to an enqueueing error                                                                                                                 |
| Other                                                           | The total number of outbound packets discarded by the key group due to some other reason, such as an internal configuration error (for example, a key group that points to an SA, but the SA is not valid) |
| <b>Encryption Keygroup Inbound Discarded Statistics (Pkts)</b>  |                                                                                                                                                                                                            |
| Total Discard                                                   | The total number of inbound packets discarded by the key group                                                                                                                                             |
| Invalid Spi                                                     | The total number of inbound packets discarded by the key group due to an invalid SPI                                                                                                                       |
| Authentication Failure *                                        | The total number of inbound packets discarded by the key group due to an authorization failure                                                                                                             |
| Control Word Mismatch                                           | The total number of inbound packets discarded by the key group due to a control word (CW) mismatch between the encrypted (protected) CW in the ESP payload and the CW that is not encrypted                |
| Padding Error                                                   | The total number of inbound packets discarded by the key group due to a padding error                                                                                                                      |
| Enqueue Error                                                   | The total number of inbound packets discarded by the key group due to an enqueueing error                                                                                                                  |
| Other                                                           | The total number of inbound packets discarded by the key group due to some other reason (for example, an incoming packet length is incorrect)                                                              |
| <b>SDP Keygroup Association Table</b>                           |                                                                                                                                                                                                            |
| SDP ID                                                          | The SDP ID                                                                                                                                                                                                 |
| Direction                                                       | The direction in which key group authentication and encryption occurs for traffic on the SDP                                                                                                               |
| Inbound Keygroup SDP Association Count                          | The number of SDPs configured to use inbound SA                                                                                                                                                            |

**Table 191 Encryption Key Group Field Descriptions (Continued)**

| Label                                    | Description                                                                                   |
|------------------------------------------|-----------------------------------------------------------------------------------------------|
| Outbound Keygroup SDP Association Count  | The number of SDPs configured to use outbound SA                                              |
| <b>VPRN Keygroup Association Table</b>   |                                                                                               |
| VPRN SVC ID                              | The VPRN service identifier                                                                   |
| Direction                                | The direction in which key group authentication and encryption occurs for traffic on the VPRN |
| Inbound Keygroup VPRN Association Count  | The number of VPRNs configured to use inbound SA                                              |
| Outbound Keygroup VPRN Association Count | The number of VPRNs configured to use outbound SA                                             |

## summary

|                    |                                                                                                                    |

## 10 Ethernet Virtual Private Networks

This chapter provides an overview and configuration information about Ethernet Virtual Private Networks (EVPNs).

Topics in this chapter include:

- [Overview and EVPN Applications](#)
- [EVPN for MPLS Tunnels](#)
- [General EVPN Topics](#)
- [Configuring an EVPN Service With CLI](#)
- [EVPN Command Reference](#)

## 10.1 Overview and EVPN Applications

EVPN is an IETF technology as defined in RFC 7432, *BGP MPLS-Based Ethernet VPN*, that uses a new BGP address family and allows VPLS services to be operated as IP-VPNs, where the MAC addresses and the information to set up the flooding trees are distributed by BGP.

EVPN is designed to fill the gaps in other Layer 2 VPN technologies such as VPLS. The main objective of EVPN is to build Ethernet LAN (E-LAN) services similar to RFC 4364 IP-VPNs while supporting MAC address learning in the control plane (distributed by MP-BGP), efficient multi-destination traffic delivery, and active-active multihoming.

**Note:** EVPN is not supported on non-Ethernet and first-generation (Gen-1) adapter cards. Traffic that ingresses a non-Ethernet or Gen-1 adapter card may not be permitted to egress an EVPN endpoint, and EVPN egress traffic is not permitted on a non-Ethernet or Gen-1 adapter card. For information on adapter card generations, refer to the “Evolution of Ethernet Adapter Cards, Modules, and Platforms” section in the 7705 SAR Interface Configuration Guide.

EVPN can be used as the control plane for different data plane encapsulations. The 7705 SAR implementation supports the following data plane encapsulation:

- **EVPN for MPLS tunnels (EVPN-MPLS)**

In EVPN-MPLS, PEs are connected by any type of MPLS tunnel. Typically, EVPN-MPLS is used as an evolutionary step for VPLS services in the WAN, with Data Center Interconnect being one of the main applications.

### 10.1.1 EVPN for MPLS Tunnels in E-LAN Services

Figure 156 shows the use of EVPN for MPLS tunnels on the 7705 SAR. In this example, EVPN is used as the control plane for E-LAN services in the WAN.

**Figure 156 EVPN for MPLS in VPLS Services**

28731

EVPN-MPLS is standardized in RFC 7432 as a Layer 2 VPN technology that can fill the gaps in VPLS for E-LAN services. A significant number of service providers offering E-LAN services today require EVPN for its multihoming capabilities as well as for the optimization that EVPN provides. EVPN supports all-active multihoming and single-active multihoming.

Although VPLS already supports single-active multihoming, EVPN single-active multihoming is considered to be a superior technology due to its mass-withdrawal capabilities to speed up convergence in scaled environments.

EVPN technology provides significant benefits, including:

- superior multihoming capabilities
- IP-VPN-like operation and control for E-LAN services
- reduction and (in some cases) suppression of the BMU (broadcast, multicast, and unknown unicast) traffic in the network
- simple provisioning and management
- new set of tools to control the distribution of MAC addresses and ARP entries in the network

---

## 10.1.2 EVPN for MPLS Tunnels in E-Line Services

The MPLS network used by EVPN for E-LAN services can also be shared by Ethernet line (E-Line) services using EVPN in the control plane. EVPN for E-Line services (EVPN-VPWS, virtual private wire service) is a simplification of the RFC 7432 procedure, and is supported on the 7705 SAR in compliance with IETF *draft-ietf-bess-evpn-vpws*.

## 10.2 EVPN for MPLS Tunnels

This section provides information about EVPN for MPLS tunnels:

- [BGP-EVPN Control Plane for MPLS Tunnels](#)
- [EVPN-VPLS for MPLS Tunnels](#)
- [EVPN-VPWS for MPLS Tunnels](#)
- [EVPN for MPLS Tunnels in r-VPLS Services](#)
- [MPLS Entropy Label](#)

### 10.2.1 BGP-EVPN Control Plane for MPLS Tunnels

[Table 193](#) lists the EVPN route types supported on the 7705 SAR and their use in EVPN-MPLS.

**Table 193** EVPN Route Types and Usage

| EVPN Route Type                                 | Use                                                                 |
|-------------------------------------------------|---------------------------------------------------------------------|
| Type 1 – Ethernet Auto-Discovery route          | Mass-withdrawal, Ethernet segment identifier (ESI) labels, aliasing |
| Type 2 – MAC/IP Advertisement route             | MAC/IP advertisement, IP advertisement for ARP resolution           |
| Type 3 – Inclusive Multicast Ethernet Tag route | Flooding tree setup (BMU flooding)                                  |
| Type 4 – Ethernet Segment (ES) route            | ES discovery and DF election                                        |
| Type 5 – IP Prefix Advertisement route          | IP routing                                                          |

If EVPN multihoming is not required, two route types are needed to set up a basic EVPN instance (EVI) (see [Figure 157](#)):

- [EVPN Route Type 2 – MAC/IP Advertisement Route](#)
- [EVPN Route Type 3 – Inclusive Multicast Ethernet Tag Route](#)

If multihoming is required, two additional route types are needed (see [Figure 158](#)):

- [EVPN Route Type 1 – Ethernet Auto-Discovery Route \(AD Route\)](#)
- [EVPN Route Type 4 – Ethernet Segment Route \(ES Route\)](#)

The route fields and extended communities for route types 2 and 3 are shown in [Figure 157](#).

Figure 157 EVPN-MPLS Route Type 2 and Type 3 (Required Routes and Communities)

28734

When EVPN multihoming is enabled in the system, two more routes (route types 1 and 4) are required. [Figure 158](#) shows the fields in route types 1 and 4 and their associated extended communities.

Figure 158    EVPN Route Type 1 and Type 4

28732

### 10.2.1.1    EVPN Route Type 2 – MAC/IP Advertisement Route

The 7705 SAR generates route type 2 for advertising MAC addresses. If **mac-advertisement** is enabled, the router generates MAC advertisement routes for the following:

- learned MAC addresses on SAPs or SDP bindings
- conditional static MAC addresses

**Note:** The **unknown-mac-route** command is not supported for EVPN-MPLS services.

Route type 2 uses the fields and values shown in [Figure 157](#) and described in [Table 194](#). For type 2 BGP route key processing, the following fields are considered to be part of the prefix in the NLRI: Ethernet tag ID, MAC address length, MAC address, IP address length, and IP address.

**Table 194**      **Route Type 2 Fields and Values**

| Field                             | Value                                                                                                                                                                                                                                                                                               |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Route distinguisher               | Taken from the RD of the VPLS service within the BGP context. The RD can be configured or derived from the <b>bgp-evpn&gt;evi</b> value.                                                                                                                                                            |
| Ethernet segment identifier (ESI) | Zero for MAC addresses learned from single-homed CEs and non-zero for MAC addresses learned from multihomed CEs                                                                                                                                                                                     |
| Ethernet tag ID                   | 0                                                                                                                                                                                                                                                                                                   |
| MAC address length                | Always 48                                                                                                                                                                                                                                                                                           |
| MAC address                       | MAC address learned or statically configured                                                                                                                                                                                                                                                        |
| IP address and IP address length  | The IP address associated with the MAC address being advertised, with a length of 32 (or 128 for IPv6)<br>In general, any MAC route without an IP address has IPL=0 (IP length) and the IP address is omitted<br>When received, any IPL value not equal to 0, 32, or 128 discards the route         |
| MPLS label 1                      | Carries the MPLS label allocated by the system to the VPLS service. The label value is encoded in the high-order 20 bits of the field and is the same label used in route type 3 for the same service unless <b>bgp-evpn&gt;mpls&gt;ingress-replication-bum-label</b> is configured in the service. |
| MPLS label 2                      | 0                                                                                                                                                                                                                                                                                                   |
| MAC mobility extended community   | Used for signaling the sequence number in case of MAC moves and the sticky bit in case of advertising conditional static MAC addresses. If a MAC route is received with a MAC mobility extended community, the sequence number and the sticky bit are considered during route selection.            |

### 10.2.1.2      **EVPN Route Type 3 – Inclusive Multicast Ethernet Tag Route**

Route type 3 is used for setting up the flooding tree (BMU flooding) for a specified VPLS service. The received inclusive multicast routes add entries to the VPLS flood list in the 7705 SAR. Ingress replication is supported as the tunnel type in route type 3 when BGP-EVPN MPLS is enabled.

Figure 157 shows and Table 195 describes the route values used for EVPN-MPLS services. For type 3 BGP route key processing, the following fields are considered to be part of the prefix in the NLRI: Ethernet tag ID, IP address length, and originating router IP address.

**Table 195**      **Route Type 3 Fields and Values**

| Field                         | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Route distinguisher           | Taken from the RD of the VPLS service within the BGP context. The RD can be configured or derived from the <b>bgp-evpn&gt;evi</b> value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Ethernet tag ID               | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| IP address length             | Always 32                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Originating router IP address | Carries the system address (IPv4 only)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| PMSI attribute                | <p>The PMSI attribute can have different formats depending on the tunnel type enabled in the service</p> <p>Tunnel type = ingress replication (6)<br/> The route is referred to as an Inclusive Multicast Ethernet Tag IR (IMET-IR) route and the PMSI Tunnel Attribute (PTA) fields are populated as follows:</p> <p><b>Flags</b>—Leaf not required</p> <p><b>MPLS label</b>—Carries the MPLS label allocated for the service in the high-order 20 bits of the label field. Unless <b>bgp-evpn&gt;mpls&gt;ingress-replication-bum-label</b> is configured in the service, the MPLS label used is the same as that used in the MAC/IP routes for the service.</p> <p><b>Tunnel endpoint</b>—Equal to the originating IP address</p> |

### 10.2.1.3 EVPN Route Type 1 – Ethernet Auto-Discovery Route (AD Route)

The 7705 SAR generates route type 1 for advertising for multihoming functions. The system can generate the following two subtypes of Ethernet AD routes:

- Ethernet AD per-ESI route (Ethernet segment ID)
- Ethernet AD per-EVI route (EVPN instance)

The Ethernet AD per-ESI route uses the fields and values shown in Figure 158 and described in Table 196. For type 1 BGP route key processing, the following fields are considered to be part of the prefix in the NLRI: Ethernet segment identifier and Ethernet tag ID.

**Table 196** Route Type 1 Fields and Values (Ethernet AD per-ESI)

| Field                             | Value                                                                                                                            |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| Route distinguisher               | Taken from the system-level RD or service-level RD                                                                               |
| Ethernet segment identifier (ESI) | Contains a 10-byte identifier as configured in the system for a specified Ethernet segment                                       |
| Ethernet tag ID                   | MAX-ET (0xFFFFFFFF). This value is reserved and used only for AD routes per ESI.                                                 |
| MPLS label                        | 0                                                                                                                                |
| ESI label extended community      | Includes the single-active bit (0 for all-active and 1 for single-active) and ESI label for all-active multihoming split-horizon |
| Route target extended community   | Taken from the service-level RT or an RT set for the services defined on the Ethernet segment                                    |

The system can send either a separate Ethernet AD per-ESI route per service or several Ethernet AD per-ESI routes aggregating the route targets for multiple services. While both alternatives can interoperate, RFC 7432 states that the EVPN AD per-ES route must be sent with a set of route targets corresponding to all the EVIs defined on the Ethernet segment. Either alternative can be enabled using the **ad-per-es-route-target** command options.

The default option, **evi-rt**, configures the system to send a separate AD per-ES route per service.

The **evi-rt-set route-distinguisher ip-address** option, when enabled, allows the aggregation of routes; that is, a single AD per-ES route with the associated RD (*ip-address:1*) and a set of EVI route targets are advertised (to a maximum of 128 route targets). If the number of EVIs defined in the Ethernet segment is significantly large for the packet size, the system will send more than one route. For example:

- AD per-ES route for EVI-route-set 1 is sent with RD *ip-address:1*
- AD per-ES route for EVI-route-set 2 is sent with RD *ip-address:2*

The Ethernet AD per-EVI route uses the fields and values shown in [Figure 158](#) and described in [Table 197](#).

**Note:** The AD per-EVI route does not send the ESI label extended community field as is done for Ethernet AD per-ESI (see [Table 196](#)).

**Table 197 Route Type 1 Fields and Values (Ethernet AD per-EVI)**

| Field                             | Value                                                                                      |
|-----------------------------------|--------------------------------------------------------------------------------------------|
| Route distinguisher               | Taken from the service-level RD                                                            |
| Ethernet segment identifier (ESI) | Contains a 10-byte identifier as configured in the system for a specified Ethernet segment |
| Ethernet tag ID                   | 0                                                                                          |
| MPLS label                        | Encodes the unicast label allocated for the service (high-order 20 bits)                   |
| Route target extended community   | Taken from the service-level RT                                                            |

#### 10.2.1.4 EVPN Route Type 4 – Ethernet Segment Route (ES Route)

The 7705 SAR generates route type 4 for multihoming ES discovery and designated forwarder (DF) election.

The Ethernet segment route uses the fields and values shown in [Figure 158](#) and described in [Table 198](#). For type 4 BGP route key processing, the following fields are considered to be part of the prefix in the NLRI: Ethernet segment ID, IP address length, and originating router IP address.

**Table 198 Route Type 4 Fields and Values**

| Field                             | Value                                                                                                                                                                                  |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Route distinguisher               | Taken from the service-level RD                                                                                                                                                        |
| Ethernet segment identifier (ESI) | Contains a 10-byte identifier as configured in the system for a specified Ethernet segment                                                                                             |
| ES-import route target community  | Automatically derived value from the MAC address portion of the ESI. This extended community is treated as a route target and is supported by RT-constraint (route target BGP family). |

10.2.1.5    **EVPN Route Type 5 – IP Prefix Route**

EVPN route type 5 (IP prefix route) is supported for MPLS tunnels. The route fields for route type 5 are shown in [Figure 159](#) and described in [Table 199](#). For type 5 BGP route key processing, the following fields are considered to be part of the prefix in the NLRI: Ethernet tag ID, IP prefix length, and IP prefix.

All the routes in EVPN-MPLS are sent with the RFC 5512 tunnel encapsulation extended community, with the tunnel type value set to MPLS.

The router generates route type 5 for advertising IP prefixes in EVPN. The router generates IP prefix advertisement routes for:

- IP prefixes existing in a VPRN linked to the integrated routing and bridging (IRB) backhaul r-VPLS service

The IRB interface refers to an r-VPLS service bound to a VPRN IP interface.

**Figure 159    EVPN Route Type 5**

28912

**Table 199    Route Type 5 Fields and Values**

| Field                             | Value                                                                                  |
|-----------------------------------|----------------------------------------------------------------------------------------|
| Route distinguisher               | Taken from the RD configured in the IRB backhaul r-VPLS service within the BGP context |
| Ethernet segment identifier (ESI) | 0:0:0:0:0:0:0:0                                                                        |
| Ethernet tag ID                   | 0                                                                                      |
| IP address length                 | Any value in the range 0 to 128                                                        |

**Table 199 Route Type 5 Fields and Values (Continued)**

| Field         | Value                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IP address    | Any valid IPv4 or IPv6 address                                                                                                                                                                                                                                                                                                                                                                                |
| GW IP address | Can carry two different values:<br>- If different from 0, route type 5 carries the primary IP interface address of the VPRN behind which the IP prefix is known. This is the case for the regular IRB backhaul r-VPLS model.<br>- If 0.0.0.0, the route type 5 is sent with a MAC next-hop extended community that carries the VPRN interface MAC address. This is the case for the EVPN tunnel r-VPLS model. |
| MPLS label    | Carries the MPLS label allocated for the service<br>Only one MPLS label can be configured per VPLS service                                                                                                                                                                                                                                                                                                    |

### 10.2.1.6 RFC 5512 – BGP Tunnel Encapsulation Extended Community

The following routes are sent with the RFC 5512 BGP tunnel encapsulation extended community: route type 2 (MAC/IP), route type 3 (Inclusive Multicast Ethernet Tag), and route type 1 (Ethernet AD per-EVI). Route type 4 (Ethernet segment) and route type 1 (AD per-ESI) routes are not sent with this extended community.

The router processes the following BGP tunnel-encapsulation tunnel values registered by IANA for RFC 5512:

- MPLS encapsulation: 10

Any other tunnel value gives the route “treat-as-withdraw” status.

If the encapsulation value is MPLS, the BGP validates the high-order 20 bits of the label field, ignoring the low-order 4 bits.

If the encapsulation extended community is not present in a received route, BGP treats the route as an MPLS-based configuration of the **config>router>bgp>group>neighbor>def-recv-evpn-encap mpls** command. The command is also available at the **bgp** and **group** levels.

## 10.2.2 EVPN-VPLS for MPLS Tunnels

This section provides information on the following topics:

- [Overview](#)
- [EVPN and VPLS Integration](#)
- [Auto-derived Route Distinguisher \(RD\) in Services](#)
- [EVPN Multihoming in VPLS Services](#)

### 10.2.2.1 Overview

EVPN can be used in MPLS networks where PEs are interconnected through any type of tunnel, including RSVP-TE, segment routing TE, LDP, BGP, segment routing IS-IS, and segment routing OSPF. The selection of the tunnel to be used in a VPLS service with BGP-EVPN MPLS enabled is based on the **auto-bind-tunnel** command, which is similar to the way that VPRN services operate.

EVPN-MPLS is modeled using a VPLS service where EVPN-MPLS bindings can coexist with SAPs and SDP bindings. The following output shows an example of a VPLS service with EVPN-MPLS.

```
*A:PE-1>config>service>vpls# info

description "evpn-mpls-service"
bgp
bgp-evpn
 evi 10
 mpls
 no shutdown
 auto-bind-tunnel resolution any
sap 1/1/1:1 create
exit
spoke-sdp 1:1 create
```

The **bgp-evpn** context must be enabled when MPLS is not **shutdown**. In addition to the **mpls>no shutdown** command, the minimum set of commands needed to set up the EVPN-MPLS instance are the **bgp-evpn>evi** and the **bgp-evpn>mpls>auto-bind-tunnel resolution** commands. Users can also configure other command options. The minimum set and optional commands are listed below:

- **evi value** — the EVPN identifier value (EVI *value*) is unique in the system and can have a value between 1 and 65535. The EVI *value* is used for the service-carving algorithm (which is used for multihoming, if configured) and for auto-deriving route target and route distinguishers in the service.

If the **evi** value is not specified, its value is 0 and no route distinguisher or route targets are auto-derived from it. If the **evi** value is specified and no other route distinguisher or route targets are configured in the service, the following derivations apply:

- the route distinguisher is derived from *system-ip:evi* value
- the route target is derived from *autonomous-system:evi* value

**Note:** When the **vsi-import** and **vsi-export** policies are configured, the route target must be configured in the policies and the policy values take preference over the values of auto-derived route targets. The operational route target for a service is displayed using the **show service id service-id bgp** command.

When the **evi** command is configured, a **config>service>vpls>bgp** command is required—even if the context is empty—to allow the user to see the correct information when using the **show>service>id service-id>bgp** and **show>service>system>bgp-route-distinguisher** commands.

Although it is not mandatory, if multihoming is not configured, the configuration of the **evi** command is enforced for EVPN services with SAPs or SDP bindings defined in the **ethernet-segment** command. See [EVPN Multihoming in VPLS Services](#) for more information about the **ethernet-segment** command.

The following options are specific to EVPN-MPLS and defined in the **bgp-evpn>mpls** context:

- **control-word** — this command is required, as per RFC 7432, to avoid frame disordering. The user can enable and disable it so that interoperability with other vendors can be guaranteed.
- **auto-bind-tunnel** — this command is required and allows the user to decide what type of MPLS transport tunnels are used for a particular instance. The command is used in the same way as it is used in VPRN services.  
For BGP-EVPN MPLS, **bgp** is explicitly added to the **resolution-filter** in EVPN (**bgp** is implicit in VPRNs).
- **force-vlan-vc-forwarding** — this command allows the system to preserve the VLAN ID and P-bits of the service-delimiting qtag in a new tag added in the customer frame before sending the customer frame to the EVPN core.
- **split-horizon-group** — this command allows the association of a user-created split horizon group with all the EVPN-MPLS destinations. See [EVPN and VPLS Integration](#) for more information.
- **ecmp** — this command, when set to a value greater than 1, activates aliasing to the remote PEs that are defined in the same all-active multihoming Ethernet segment. See [EVPN Multihoming in VPLS Services](#) for more information.

- **ingress-replication-bum-label** — this command is only enabled when the user wants the PE to advertise a label for BMU traffic (Inclusive Multicast Ethernet Tag routes, route type 3) that is different from the label advertised for unicast traffic (with the MAC/IP routes). This is useful to avoid potential transient packet duplication in all-active multihoming.

In addition to the options above, the following **bgp-evpn** commands are also available for EVPN-MPLS services:

- **[no] mac-advertisement**
- **mac-duplication** and settings

When EVPN-MPLS is established among some PEs in the network, EVPN unicast and multicast bindings are created on each PE to the remote EVPN destinations. A specified ingress PE creates:

- a unicast EVPN-MPLS destination binding to a remote egress PE as soon as a MAC/IP route is received from that egress PE
- a multicast EVPN-MPLS destination binding to a remote egress PE, only if the egress PE advertises an Inclusive Multicast Ethernet Tag route (route type 3) with a BMU label. This is only possible if the egress PE is configured with **ingress-replication-bum-label**.

The unicast and multicast bindings, as well as the MAC addresses learned on them, can be checked using the **show** commands in the following example. In the example, the remote PE 192.0.2.69 is configured with **no ingress-replication-bum-label** and PE 192.0.2.70 is configured with **ingress-replication-bum-label**. Therefore, “Dut” has a single EVPN-MPLS destination binding to PE 192.0.2.69 and two bindings (unicast and multicast) to PE 192.0.2.70.

```

### 10.2.2.2 EVPN and VPLS Integration

The 7705 SAR EVPN implementation supports *draft-ietf-bess-evpn-vpls-seamless-integ* so that EVPN-MPLS and VPLS can be integrated into the same network and within the same service. This feature is useful for the integration between both technologies and for the migration of VPLS services to EVPN-MPLS.

The following behavior enables the integration of EVPN and SDP bindings in the same VPLS network. An illustration and configuration example follow the list.

- Systems with EVPN endpoints and SDP bindings to the same far end bring down the SDP bindings.
  - The router allows the establishment of an EVPN endpoint and an SDP binding to the same far end but the SDP binding is kept operationally down. Only the EVPN endpoint is operationally up. This is true for spoke SDPs and mesh SDPs.
  - If there is an existing EVPN endpoint to a specified far end and the establishment of a spoke SDP is attempted, the spoke SDP is set up but kept operationally down with an operational flag indicating that there is an EVPN route to the same far end.

- If there is an existing spoke SDP and a valid (used) EVPN route arrives, the EVPN endpoint is set up and the spoke SDP is brought operationally down with an operational flag indicating that there is an EVPN route to the same far end.
- If there is an SDP binding and EVPN endpoint to different far-end IP addresses on the same remote PE, both links will be operationally up. This can happen if the SDP binding is terminated in an IPv6 address or IPv4 address that is different from the system address where the EVPN endpoint is terminated.
- The user can add spoke SDPs and all the EVPN-MPLS endpoints in the same split horizon group.
  - The **split-horizon-group** *group-name* command under the **vpls>bgp-evpn>mpls** context allows the EVPN-MPLS endpoints to be added to a split horizon group.
  - The **bgp-evpn>mpls>split-horizon-group** must reference a user-configured split horizon group. User-configured split horizon groups can be configured within the **service>vpls** context. The same *group-name* can be associated with SAPs, spoke SDPs, and EVPN-MPLS endpoints.
  - If the **split-horizon-group** command is not used, the default split horizon group—which contains all the EVPN endpoints—is still used, but it is not possible to refer to it on SAPs and spoke SDPs.
- The system disables the advertisement of MAC addresses learned on SAPs and spoke SDPs that are part of an EVPN split horizon group.
  - When the SAPs and spoke SDPs are configured within the same split horizon group as the EVPN endpoints, MAC addresses are still learned on them but are not advertised in EVPN.
  - The SAPs and spoke SDPs added to an EVPN split horizon group should not be part of any EVPN multihomed ES. In this case, the PE still advertises the AD per-EVI route for the SAP or spoke SDP, attracting EVPN traffic that could not be forwarded to that SAP or SDP binding.

Figure 160 shows an example of EVPN-VPLS integration. In this example, if EVPN and SAPs and spoke SDPs are part of the same split horizon group, the traffic arriving on the SAPs and spoke SDPs is not forwarded to EVPN.

The spoke SDPs on PE2 are not part of an split horizon group, so they can forward traffic to EVPN. Spoke SDPs on PE5 are part of same split horizon group, so they cannot forward traffic to EVPN.

**Figure 160** EVPN-VPLS Integration

28733

A CLI configuration example for PE1, PE5, and PE2 is provided below.

```
*A:PE1>config>service# info

vpls 1 customer 1 create
 split-horizon-group "SHG-1" create
 bgp
 route-target target:65000:1
 bgp-evpn
 evi 1
 mpls
 no shutdown
 split-horizon-group SHG-1
 spoke-sdp 12:1 create
 exit
 sap 1/1/1:1 create
 exit

PE5#config>service# info

vpls 1 customer 1 create
 split-horizon-group "SHG-1" create
 exit
 stp
 shutdown
 exit
 endpoint "vpls20" create
 exit
 sap 1/1/7:2 create
 no shutdown
```

```

exit
spoke-sdp 64:2 split-horizon-group "SHG-1" endpoint "vpls20" create
no shutdown
exit
spoke-sdp 65:2 split-horizon-group "SHG-1" endpoint "vpls20" create
no shutdown
exit
no shutdown

*A:PE2>config>service# info

vpls 1 customer 1 create
end-point CORE create
no suppress-standby-signaling
spoke-sdp 21:1 end-point CORE
precedence primary
spoke-sdp 25:1 end-point CORE

```

PE1, PE3, PE4, and PE5 have BGP-EVPN enabled in VPLS-1. PE2 has active/standby spoke SDPs to PE1 and PE5. In this configuration:

- EVPN endpoints are instantiated within the same split horizon group, for example, SHG-1
- manual spoke SDPs from PE1 and PE5 to PE2 are not part of SHG-1

EVPN MAC advertisements are as follows.

- MAC addresses learned on FEC128 spoke SDPs are advertised normally in EVPN.
- MAC addresses learned on spoke SDPs that are part of SHG-1 are not advertised in EVPN because SHG-1 is the split horizon group used for **bgp-evpn>mpls**. This prevents any data plane MAC addresses learned on the split horizon group from being advertised in EVPN.

BMU operation on PE1 is as follows.

- When CE1 sends BMU traffic, PE1 floods it to all the active bindings.
- When CE2 sends BMU traffic, PE2 sends it to PE1 (active spoke SDP) and PE1 floods it to all the bindings and SAPs.
- When CE5 sends BMU traffic, PE5 floods it to the EVPN PEs. PE1 will flood the traffic to the active spoke SDP and SAPs but never to the EVPN PEs because they are part of the same split horizon group.

---

### 10.2.2.3 Auto-derived Route Distinguisher (RD) in Services

In a VPLS service, a single RD is used per service.

The following rules apply.

- The VPLS RD is selected based on the following precedence:
  - a manual RD always take precedence when configured
  - if there is no manual configuration, the RD is derived from the **bgp-evpn>evi** configuration
  - if there is no manual or **evi** configuration, there will not be an RD and the service will fail
- The selected RD is displayed in the “Oper Route Dist” field of the **show>service>id>bgp** command.
- The service supports dynamic RD changes, such as a new manual RD configuration.

**Note:** When the RD changes, the active routes for that VPLS are withdrawn and readvertised with the new RD.

- If the manual mechanism to derive the RD for a specified service is removed from the configuration, the system will select a new RD based on the above rules. In this case, the routes are withdrawn, the new RD is selected from the **evi** configuration, and the routes are readvertised with the new RD.

**Note:** This reconfiguration will fail if the new RD already exists in a different VPLS or Epipe service.

### 10.2.2.4 EVPN Multihoming in VPLS Services

EVPN multihoming implementation is based on the concept of the Ethernet segment and configured through the **ethernet-segment** command. An Ethernet segment is a logical structure that can be defined in one or more PEs and identifies the CE (or access network) that is multihomed to the EVPN PEs. An Ethernet segment is associated with port, LAG, or SDP objects and is shared by all the services defined on those objects. For virtual Ethernet segments, individual VID or VC-ID ranges can be associated with the port, LAG, or SDP objects defined in the Ethernet segment.

Each Ethernet segment has a unique identifier called the Ethernet segment identifier (ESI) that is 10 bytes long and is manually configured in the router.

**Note:** The **esi** esi value is advertised in the control plane to all the PEs in an EVPN network. Therefore, it is very important to ensure that the 10-byte esi value is unique throughout the entire network. Single-homed CEs are assumed to be connected to an Ethernet segment with esi = 0 (that is, single-homed Ethernet segments do not need to be explicitly configured).

This section describes the behavior of the EVPN multihoming implementation in an EVPN-MPLS service and includes the following topics:

- [EVPN All-Active Multihoming](#)
- [EVPN Single-Active Multihoming](#)

#### 10.2.2.4.1 EVPN All-Active Multihoming

This section contains information on the following topics:

- all-active multihoming service mode
- ES discovery and DF election procedures (all-active multihoming)
- aliasing
- network failures and convergence for all-active multihoming

As described in RFC 7432, all-active multihoming is only supported on access LAG SAPs. The CE must be configured with a LAG to avoid duplicated packets to the network. The use of LACP is optional.

Three different procedures are implemented in the 7705 SAR to provide all-active multihoming for a specified Ethernet segment:

- designated forwarder (DF) election (see [Figure 161](#))
- split horizon (see [Figure 162](#))
- aliasing (see [Figure 163](#))

[Figure 161](#) shows the need for DF election in all-active multihoming.

**Figure 161**    **DF Election**

28729

The DF election in an EVPN all-active multihoming scenario avoids duplicate packets on the multihomed CE. The DF election procedure is responsible for electing one DF PE per ESI per service; the other PEs are non-DF for the ESI and service. Only the DF forwards BMU traffic from the EVPN network toward the ES SAPs (the multihomed CE). The non-DF PEs do not forward BMU traffic to the local Ethernet segment SAPs (see [ES Discovery and DF Election Procedures \(all-active multihoming\)](#) for more information).

**Note:** BMU traffic from the CE to the network and known unicast traffic in any direction is allowed on both the DF and non-DF PEs.

Figure 162 shows the EVPN split-horizon concept for all-active multihoming.

**Figure 162**    **Split Horizon**

28737

The EVPN split-horizon procedure ensures that the BMU traffic originated by the multihomed PE and sent from the non-DF to the DF is not replicated back to the CE (echoed packets on the CE). To avoid these echoed packets, the non-DF (PE1) sends all the BMU packets to the DF (PE2) with an indication of the source Ethernet segment. That indication is the ESI label (ESI2 in the example), previously signaled by PE2 in the AD per-ESI route for the Ethernet segment. When PE2 receives an EVPN packet (after the EVPN label lookup), PE2 finds the ESI label that identifies its local Ethernet segment (ESI2). The BMU packet is replicated to other local CEs but not to the ESI2 SAP.

Figure 163 shows the EVPN aliasing concept for all-active multihoming.

**Figure 163 Aliasing**

28725

Because CE2 is multihomed to PE1 and PE2 using an all-active Ethernet segment, aliasing is the procedure by which PE3 can load-balance the known unicast traffic between PE1 and PE2, even if the destination MAC address was only advertised by PE1, as shown in the example. When PE3 installs MAC1 in the FDB, it associates MAC1 not only with the advertising PE (PE1) but also with all the PEs advertising the same **esi esi** (ESI2) for the service. In this example, PE1 and PE2 advertise an AD per-EVI route for ESI2. Therefore, PE3 installs the two next hops associated with MAC1.

Aliasing is enabled by configuring ECMP to be greater than 1 in the **bgp-evpn>mpls** context (see [Aliasing](#) for more information).

## All-Active Multihoming Service Model

The following shows an example where the PE1 configuration provides all-active multihoming to the CE2 shown in [Figure 163](#).

```
*A:PE1>config>lag(1)# info

```

The preceding configuration enables the all-active multihoming procedures. The following must be considered.

- The Ethernet segment must be configured with a name and a 10-byte **esi** value:
  - **config>service>system>bgp-evpn>ethernet-segment** *name* **create**
  - **config>service>system>bgp-evpn>ethernet-segment>esi** *esi*
- When configuring the *esi* value, the system enforces the rule that the six high-order octets after the type field are not 0 (so that the auto-derived route target for the ES route is different from 0). Otherwise, the entire *esi* value must be unique in the system.
- Only a LAG can be associated with the Ethernet segment. The LAG is used exclusively for EVPN multihoming. Other LAG ports in the system can still be used for MC-LAG and other services.
- When the LAG is configured on PE1 and PE2, the same *admin-key*, *system-priority*, and *system-id* must be configured on both PEs so that CE2 responds as though it is connected to the same system.
- Only one SAP per service can be part of the same Ethernet segment.

### ES Discovery and DF Election Procedures (all-active multihoming)

The Ethernet segment (ES) discovery and DF election is implemented in three steps (described below and illustrated in [Figure 164](#)).

- [Step 1 – ES Advertisement and Discovery](#)
- [Step 2 – DF Election](#)
- [Step 3 – DF and Non-DF Service Behavior](#)

**Figure 164 ES Discovery and DF Election**

28730

#### Step 1 – ES Advertisement and Discovery

Ethernet segment ESI-1 is configured as described in the previous section ([All-Active Multihoming Service Model](#)), with all the required parameters. When **ethernet-segment>no shutdown** is executed, PE1 and PE2 advertise an ES route for ESI-1. Both PEs include the route target auto-derived from the MAC address portion of the configured ESI. If the route target address family is configured in the network, it allows the RR to keep the dissemination of the ES routes under control.

In addition to the ES route, PE1 and PE2 advertise AD per-ESI routes and AD per-EVI routes.

- AD per-ESI routes announce the Ethernet segment capabilities, including the mode (single-active or all-active) and the ESI label for split horizon.
- AD per-EVI routes are advertised so that PE3 knows which services (EVIs) are associated with the ESI. These routes are used by PE3 for its aliasing and backup procedures.

## Step 2 – DF Election

When the exchange of ES routes between PE1 and PE2 is complete, both PEs run the DF election for all the services in the Ethernet segment.

PE1 and PE2 elect a DF for an ESI-service pair (that is, per ESI, per service). The default DF election mechanism in the 7705 SAR is service carving mode **auto**, as per RFC 7432. The following items apply when the default service carving mode is used on a specified PE. The DF election does not occur until the Ethernet segment is configured as **no shutdown**.

- An ordered list of PE IP addresses where ESI-1 resides is built. The IP addresses are obtained from the “Origin IP” fields of all the ES routes received for ESI-1 and also include the local system address. The lowest IP address is considered ordinal “0” in the list.
- The local IP address can only be considered a candidate after a successful **ethernet-segment>no shutdown** command for a specified service.

**Note:** The remote PE IP addresses must be present in the local PE's RTM so that they can participate in the DF election.

- A PE only considers a specified remote IP address as candidate for the DF election algorithm for a specified service if, in addition to the ES route, the corresponding AD per-ESI and per-EVI routes for that PE have been received and properly activated.
- All remote PEs receiving the AD per-ES routes (for example, PE3) interpret ESI-1 as all-active if all the PEs send their AD per-ES routes with the single-active bit = 0. Otherwise, if at least one PE sends an AD per-ESI route with the single-active flag set or if the local ESI configuration is single-active, the ESI behavior is single-active.
- An **es-activation-timer** can be configured at the **redundancy>bgp-evpn-multi-homing>es-activation-timer** level or at the **service>system>bgp-evpn>ethernet-segment>es-activation-timer** level. This timer, which is 3 seconds by default, delays the transition from non-DF to DF for a specified service after the DF election has run.
  - This use of the **es-activation-timer** with a value different from 0 minimizes the risk of loops and packet duplication due to multiple DFs in transient states.

- The same **es-activation-timer** value should be configured for all the PEs that are part of the same ESI. The user can configure a long timer to minimize the risk of loops or duplication or a short timer (even **es-activation-timer = 0**) to speed up the convergence for non-DF to DF transitions. When the user configures a specific value, the value configured at the Ethernet segment level supersedes the configured global value.
- The DF election is triggered by the following events.
  - The **config>service>system>bgp-evpn>eth-seg>no shutdown** command triggers the DF election for all the services in the ESI.
  - Reception of a new update or withdrawal of an ES route (containing an ESI configured locally) triggers the DF election for all the services in the ESI.
  - Reception of a new update or withdrawal of an AD per-ES route (containing an ESI configured locally) triggers the DF election for all the services associated with the list of route targets received along with the route.
  - Reception of a new update of an AD per-ES route with a change in the ESI-label extended community (single-active bit or MPLS label) triggers the DF election for all the services associated with the list of route targets received along with the route.
  - Reception of a new update or withdrawal of an AD per-EVI route (containing an ESI configured locally) triggers the DF election for that service.
- When the PE boots up, the boot timer allows the necessary time for the control plane protocols to come up before bringing up the Ethernet segment and running the DF algorithm. The boot timer is configured at the system level (**config>redundancy>bgp-evpn-multi-homing>boot-timer**) and should have a value long enough to allow the IOMs and BGP sessions to come up before exchanging ES routes and running the DF election for each EVI.
  - The system does not advertise ES routes until the boot timer expires. This guarantees that the peer ES PEs do not run the DF election until the PE is ready to become the DF, if necessary.
  - The following **show** command displays the configured boot timer value as well as the remaining timer value if the system is still in boot stage.

```
A:PE1# show redundancy bgp-evpn-multi-homing
=====
Redundancy BGP EVPN Multi-homing Information
=====
Boot-Timer : 10 secs
Boot-Timer Remaining : 0 secs
ES Activation Timer : 3 secs
=====
```

- When the **service-carving mode auto** command is configured (**auto** is the default mode), the DF election algorithm runs the following function to identify the DF for a specified service and ESI:

$$\mathbf{V \bmod N = i_{(ordinal)}}$$

where **V** is the EVI and **N** is the number of peers, for example:

- as shown in [Figure 164](#), PE1 and PE2 are configured with ESI-1. If **V** = 10 and **N** = 2, then **V mod N** = 0, and PE1 would be elected DF—its IP address is lower than PE2's IP address and it is the first PE in the candidate list.

**Note:** The algorithm uses the configured **evi** value in the service rather than the *service-id*. The **evi** value for a service must match for all the PEs that are part of the ESI. This guarantees that the election algorithm is consistent across all the PEs of the ESI. The **evi** value must always be configured in a service with SAPs or SDP bindings that are created in an ES.

- The **service-carving mode manual** command allows the user to manually configure the **evi** identifiers for which the PE is primary, using the commands:  
**service-carving>mode manual** and  
**service-carving>manual evi start [to to] primary**
  - The system will be the primary PE, forwarding or multicasting traffic for the **evi** identifiers included in the configuration. The PE will be secondary (non-DF) for the non-specified EVIs.
  - If a range is configured but the **service-carving** mode is not **manual**, the range has no effect.
  - Only two PEs are supported when **service-carving mode manual** is configured. If a third PE is configured with **service-carving mode manual** for an ESI, the two non-primary PEs remain non-DF regardless of the primary status.
  - For example, as shown in [Figure 164](#), if PE1 is configured with **service-carving manual evi 1 to 100** and PE2 with **service-carving manual evi 101 to 200**, then PE1 will be the primary PE and PE2 will be the secondary PE.
- When **service-carving** is disabled, the lowest originator IP address will win the election for a specified service and ESI. The following command disables service carving:  
**config>service>system>bgp-evpn>ethernet-segment>service-carving mode off**

The following **show** command displays the Ethernet segment configuration and DF status for all EVIs configured in the Ethernet segment.

### Step 3 – DF and Non-DF Service Behavior

Based on the result of the DF election or the manual service carving, the control plane on the non-DF (PE1) instructs the data path to remove the LAG SAP associated with the ESI from the default flooding list for broadcast and multicast (BM) traffic. Unknown unicast traffic may still be sent if the EVI label is a unicast label and the source MAC address is not associated with the ESI.

On PE1 and PE2, both LAG SAPs learn the same MAC address (coming from the CE). For example, in the following **show** commands, 00:ca:ca:ba:ce:03 is learned on both the PE1 and PE2 access LAG (on ESI-1). However, PE1 learns the MAC address as “Learned” whereas PE2 learns it as “Evpn”. This is due to CE2 switching the traffic for that source MAC address to PE1. PE2 learns the MAC address through EVPN but it associates the MAC address with the ESI SAP because the MAC address belongs to the ESI.

```

Aliasing

Following the example in [Figure 164](#), if the service configuration on PE3 has ECMP > 1, then PE3 adds PE1 and PE2 to the list of next hops for ESI-1. As soon as PE3 receives a MAC address for ESI-1, it starts load balancing the flows, per service, between PE1 and PE2 to the remote ESI CE. The following command shows the FDB in PE3.

**Note:** MAC address 00:ca:ca:ba:ce:03 is associated with the Ethernet segment eES:01:00:00:00:00:71:00:00:00:01 (**esi esi** configured on PE1 and PE2 for ESI-1).

### Network Failures and Convergence for All-Active Multihoming

[Figure 165](#) shows the behavior on the remote PE (PE3) when there is an Ethernet segment failure.

**Figure 165 All-Active Multihoming ES Failure**

28726

The unicast traffic behavior on PE3 is as follows.

1. PE3 can only forward MAC DA = CE2 to both PE1 and PE2 when the MAC advertisement route from PE1 or PE2 and the set of Ethernet AD per-ES routes and Ethernet AD per-EVI routes from PE1 and PE2 are active at PE3.
2. If there is a failure between CE2 and PE2, PE2 withdraws its set of Ethernet AD and ES routes, then PE3 forwards traffic destined for CE2 to PE1 only. PE3 does not need to wait for the withdrawal of the individual MAC address.
3. The same behavior would be followed if the failure had been at PE1.
4. If after (2), PE2 withdraws its MAC advertisement route, PE3 treats traffic to MAC DA = CE2 as unknown unicast, unless the MAC address had been previously advertised by PE1.

For BMU traffic, the following events trigger a DF election on a PE and only the DF forwards BMU traffic after the **esi-activation-timer** expiration (if there was a transition from non-DF to DF):

- reception of ES route update (local ES **shutdown/no shutdown** or remote route)
- new AD-ES route update or withdrawal
- new AD-EVI route update or withdrawal
- local ES port or SAP or service shutdown

- service-carving range change (affecting the **evi**)
- multihoming mode change (single-active to all-active or all-active to single-active)

### Logical Failures on Ethernet Segments and Black Holes

Figure 166 shows a black hole caused by a SAP or service shutdown.

**Figure 166 Black Hole Caused by SAP or Service Shutdown**

28728

If an individual VPLS service is **shutdown** in PE1 (the example is also valid for PE2), the corresponding LAG SAP goes operationally down. This event triggers the withdrawal of the AD per-EVI route for that particular SAP. PE3 removes PE1 from its list of aliased next hops and PE2 takes over as DF (if it was not the DF already). However, this does not prevent the network from blackholing the traffic that CE2 switches to the link to PE1. Traffic sent from CE2 to PE2 or traffic from the rest of the CEs to CE2 is unaffected, so this situation is not easily detected on the CE.

The same result occurs if the ES SAP is administratively **shutdown** instead of the service.

**Note:** When `bgp-evpn>mpls shutdown` is executed, the SAP associated with the ES is brought operationally down (**StandbyforMHprotocol**) and so is the entire service if there are no other SAPs or SDP bindings in the service. However, if there are other SAPs or SDP bindings, the service remains operationally up.

### Transient Issues Due to MAC Route Delays

Some situations may cause transient issues to occur, such as a transient packet duplication and a transient black hole. These are shown in [Figure 167](#) and explained below.

**Figure 167 Transient Issues Caused by Slow MAC Learning**

28735

- **Transient packet duplication caused by delay in PE3 to learn MAC1:**

This scenario is illustrated by the diagram at the top in [Figure 167](#).

In an all-active multihoming scenario, if a specified MAC address (for example, MAC1), is not learned yet in a remote PE (for example, PE3) but it is known in the two PEs of the ES (for example, PE1 and PE2), the latter PEs might send duplicated packets to the CE.

This issue is solved by the use of the **ingress-replication-bum-label** command in PE1 and PE2. If the command is configured, PE1 and PE2 will know that the received packet is an unknown unicast packet; therefore, the non-DF (PE1) will not send the packets to the CE and there will not be duplication.

Even if the **ingress-replication-bum-label** command is not used, this is only a transient situation that is solved as soon as MAC1 is learned in PE3.

- **Transient black hole caused by delay in PE1 to learn MAC1:**

This scenario is illustrated by the diagram at the bottom in [Figure 167](#).

In an all-active multihoming scenario, MAC1 is known in PE3 and aliasing is applied to MAC1. However, MAC1 is not known yet in PE1, the non-DF for the ES. If PE3 hashing picks up PE1 as the destination for the aliased MAC1, the packets will be blackholed. This case is solved on the non-DF by not blocking unknown unicast traffic that arrives with a unicast label, which is possible if PE1 and PE2 are configured using **ingress-replication-bum-label**.

As soon as PE1 learns MAC1, the black hole is resolved even if **ingress-replication-bum-label** is not used.

#### 10.2.2.4.2 EVPN Single-Active Multihoming

This section provides information on the following topics:

- single-active multihoming service model
- ES and DF Election Procedures (single-active multihoming)
- backup PE function
- network failures and convergence for single-active multihoming

The 7705 SAR supports single-active multihoming on access SAPs, LAG SAPs, and spoke SDPs for a specified VPLS service. For LAG SAPs, the CE is configured with a different LAG to each PE in the Ethernet segment (as opposed to a single LAG in all-active multihoming).

The following procedures support EVPN single-active multihoming for a specified Ethernet segment:

- DF election

As in all-active multihoming, DF election in single-active multihoming determines the forwarding for BMU traffic from the EVPN network to the Ethernet segment CE. Also, in single-active multihoming, DF election determines the forwarding of any traffic (unicast and BMU) in any direction (to or from the CE).

- backup PE

In single-active multihoming, the remote PEs do not perform aliasing to the PEs in the Ethernet segment. The remote PEs identify the DF based on the MAC routes and send the unicast flows for the Ethernet segment to the PE in the DF and program a backup PE as an alternative next hop for the remote ESI in case of failure, as shown in [Figure 168](#) for PE3.

**Figure 168 Backup PE**

28727

## Single-Active Multihoming Service Model

The following is an example of PE1 configuration that provides single-active multihoming to CE2, as shown in [Figure 168](#).

```

In single-active multihoming, the non-DF PEs for a specified ESI block unicast and BMU traffic in both directions (upstream and downstream) on the object associated with the ESI. Single-active multihoming is similar to all-active multihoming with the following differences.

- The Ethernet segment is configured for single-active: **service>system>bgp-evpn>ethernet-segment>multi-homing single-active**.
- The advertisement of the ESI label in an AD per-ESI route is optional for **single-active** Ethernet segments. By default, the ESI label is used for single-active Ethernet segments. The user can control the **no advertisement** of the ESI label by using the following command: **service>system>bgp-evpn>ethernet-segment>multi-homing single-active no-esi-label**.

- For single-active multihoming, the Ethernet segment can be associated with a port, SDP, or LAG ID, as shown in [Figure 168](#), where:
  - a port is used for single-active SAP redundancy without the need for a LAG
  - an SDP is used for single-active spoke SDP redundancy
  - a LAG ID is used for single-active LAG redundancy

**Note:** In the last case (LAG ID for single-active LAG redundancy), the *admin-key*, *system-id*, and *system-priority* values must be different on the PEs that are part of the Ethernet segment.

- For single-active multihoming, when the PE is non-DF for the service, the SAPs and spoke SDPs on the Ethernet segment are operationally down and show **StandByForMHPProtocol** as the reason.
- From a service perspective, single-active multihoming can provide redundancy to CEs (multihomed devices (MHD)) or networks (multihomed networks (MHN)) with the following setup:
  - **LAG with or without LACP**  
In this case, the multihomed ports on the CE are part of different LAGs (one LAG per multihomed PE is used in the CE).
  - **regular Ethernet 802.1q/ad ports**  
In this case, the multihomed ports on the CE or network are not part of any LAG.
  - **active-standby PWs**  
In this case, the multihomed CE or network is connected to the PEs through an MPLS network and an active/standby spoke SDP per service. The non-DF PE for each service uses the LDP PW status bits to signal that the spoke SDP is operationally down on the PE side.

### ES and DF Election Procedures (single-active multihoming)

In all-active multihoming, the non-DF keeps the SAP operationally up, although it removes the SAP from the default flooding list. See the [ES Discovery and DF Election Procedures \(all-active multihoming\)](#) for more information. In the single-active multihoming implementation, the non-DF brings the SAP or SDP binding operationally down.

The following **show** commands display the status of the single-active Ethernet segment (ESI-7413) in the non-DF. The associated spoke SDP is operationally down and it signals PW status standby to the multihomed CE.

## Backup PE Function

A remote PE (PE3 in [Figure 168](#)) imports the AD routes per ESI, where the single-active flag is set. PE3 interprets the Ethernet segment as single-active if at least one PE sends an AD per-ESI route with the single-active flag set. MAC addresses for a specified service and ESI are learned from a single PE, that is, the DF for that ESI-EVI pair (per ESI, per EVI).

The remote PE installs both a single EVPN-MPLS destination (TEP, label) for a received MAC address and a backup next hop to the PE for which the AD per-ESI and per-EVI routes are received. For example, in the following **show** command output, 00:ca:ca:ba:ca:06 is associated with the remote Ethernet segment **eES 01:74:13:00:74:13:00:00:74:13**. That eES resolves to PE 192.0.2.73, which is the DF on the Ethernet segment.

If PE3 sees only two single-active PEs in the same ESI, the second PE is the backup PE. Upon receiving an AD per-ES or per-EVI route withdrawal for the ESI from the primary PE, PE3 starts sending the unicast traffic to the backup PE immediately.

If PE3 receives AD routes for the same ESI and EVI from more than two PEs, the PE does not install any backup route in the data path. Upon receiving an AD per-ES or per-EVI route withdrawal for the ESI, the PE flushes the MAC addresses associated with the ESI.

### Network Failures and Convergence for Single-Active Multihoming

[Figure 169](#) shows the remote PE (PE3) behavior when there is an Ethernet segment failure.

**Figure 169 Single-Active Multihoming ES Failure**

28736

The PE3 behavior for unicast traffic is as follows.

1. PE3 forwards MAC DA = CE2 to PE2 when the MAC advertisement route came from PE2 and the set of Ethernet AD per-ES routes and Ethernet AD per-EVI routes from PE1 and PE2 are active at PE3.
2. If there is a failure between CE2 and PE2, PE2 withdraws its set of Ethernet AD and ES routes, then PE3 immediately forwards the traffic destined for CE2 to PE1 only (the backup PE). PE3 does not need to wait for the withdrawal of the individual MAC address.
3. After PE2 withdraws its MAC advertisement route, PE3 treats traffic to MAC DA = CE2 as unknown unicast, unless the MAC has been previously advertised by PE1.

Also, a DF election on PE1 is triggered. In general, a DF election is triggered by the same events as for all-active multihoming. In this case, the DF forwards traffic to CE2 when the **esi-activation-timer** expiration occurs (the timer activates when there is a transition from non-DF to DF).

### 10.2.3 EVPN-VPWS for MPLS Tunnels

This section contains information about EVPN-VPWS for MPLS tunnels.

- [BGP-EVPN Control Plane for EVPN-VPWS](#)
- [EVPN for MPLS Tunnels in Epipe Services](#)
- [Using A/S PW and MC-LAG with EVPN-VPWS Epipes](#)
- [EVPN Multihoming for EVPN-VPWS Services](#)

#### 10.2.3.1 BGP-EVPN Control Plane for EVPN-VPWS

EVPN-VPWS uses route type 1 and route type 4; it does not use route types 2 or 3. [Figure 170](#) shows the encoding of the required extensions for the Ethernet AD per-EVI routes. The encoding follows the guidelines described in *draft-ietf-bess-evpn-vpws*.

**Figure 170** EVPN-VPWS BGP Extensions

28738

If the advertising PE has an access SAP-SDP or spoke SDP that is not part of an Ethernet segment (ES), the PE populates the fields of the AD per-EVI route with the following values.

- Ethernet tag ID field is encoded with the value configured by the user in the **service>epipe>bgp-evpn>local-ac-name>eth-tag** *value* command.
- RD and MPLS label values are encoded as specified in RFC 7432.
- ESI is 0.
- The route is sent along an EVPN Layer 2 attributes extended community, as specified in IETF *draft-ietf-bess-evpn-vpws*, where:
  - type and subtype are 0x06 and 0x04, as allocated by IANA
  - flag C is set if **control-word** is configured in the service
  - P- and B-flags are zero
  - Layer 2 MTU is encoded with **service-mtu** configured in the Epipe service

If the advertising PE has an access SAP-SDP or spoke SDP that is part of an ES, the AD per-EVI route is sent with the information described in the preceding list, with the following minor differences.

- The ESI encodes the corresponding non-zero value.
  - The P- and B-flags are set in the following cases:
    - all-active multihoming
      - All PEs that are part of the ES always set the P-flag.
      - The B-flag is never set in the all-active multihoming ES case.
    - single-active multihoming
      - Only the DF PE sets the P-flag for an EVI and the remaining PEs send it as P=0.
      - Only the backup DF PE sets the B-flag.
- If more than two PEs are present in the same single-active ES, the backup PE is the winner of a second DF election (excluding the DF). The remaining non-DF PEs send B=0.

Also, ES and AD per-ES routes are advertised and processed for the Ethernet segment, as described in RFC 7432. The ESI label sent with the AD per-ES route is used by BMU traffic on VPLS services; it is not used for Epipe traffic.

### 10.2.3.2 EVPN for MPLS Tunnels in Epipe Services

BGP-EVPN can be enabled in Epipe services with either SAPs or spoke SDPs at the access, as shown in [Figure 171](#).

**Figure 171 EVPN-MPLS in Epipe Services**

28740

EVPN-VPWS is supported in MPLS networks that also run EVPN-MPLS in VPLS services. From a control plane perspective, EVPN-VPWS is a simplified point-to-point version of RFC 7432 for E-Line services for the following reasons.

- EVPN-VPWS does not use inclusive multicast or MAC/IP routes.
- Ethernet AD per-EVI routes are used to advertise the local attachment circuit identifiers at each side of the VPWS instance. The attachment circuit identifiers are configured as local and remote Ethernet tags. When an AD per-EVI route is imported and the Ethernet tag matches the configured remote Ethernet tag, an EVPN-MPLS destination is created for the Epipe.

In the following configuration example, Epipe 2 is an EVPN-VPWS service between PE2 and PE4 (as shown in [Figure 171](#)):

```
PE2>config>service>epipe(2)#

 bgp-evpn
 evi 2
 mpls
 auto-bind-tunnel resolution any
 ecmp 2
 no shutdown
 local-ac-name "AC-1"
 eth-tag 100
 remote-ac-name "AC-2"
 eth-tag 200
 sap 1/1/1:1 create
```

```
PE4>config>service>epipe(2)#

 bgp-evpn
 evi 2
 mpls
 auto-bind-tunnel resolution any
 no shutdown
 local-ac-name "AC-2"
 eth-tag 200
 remote-ac-name "AC-1"
 eth-tag 100
 spoke-sdp 1:1
```

The following considerations apply to the configuration.

- The **evi** value is used to auto-derive the route target or route distinguisher of the service. The **evi** values must be unique in the system regardless of the type of service they are assigned (Epipe or VPLS).
- Support for the following **bgp-evpn** commands in Epipe services is the same as in VPLS services:
  - **mpls>auto-bind-tunnel**
  - **mpls>control-word**
  - **mpls>entropy-label**
  - **mpls>force-vlan-vc-forwarding**
  - **mpls>shutdown**

- The following **bgp-evpn** commands identify the local and remote attachment circuits, with the configured **eth-tag** values encoded in the advertised and received AD Ethernet per-EVI routes:

- **local-ac-name** *ac-name*
- **local-ac-name** *ac-name* **eth-tag** *tag-value*, where *tag-value* is 1 to 16777215
- **remote-ac-name** *ac-name*
- **remote-ac-name** *ac-name* **eth-tag** *tag-value*, where *tag-value* is 1 to 16777215

Changes to the remote **eth-tag** value is allowed without shutting down **bgp-evpn>mpls** or the Epipe service. The local **eth-tag** value cannot be changed without using the **bgp-evpn>mpls>shutdown** command.

Both local and remote **eth-tag** values are mandatory to bring up the Epipe service.

EVPN-VPWS Epipes can also be configured with the following characteristics.

- Access attachment circuits can be SAPs or spoke SDPs. Only manually configured spoke SDPs are supported; BGP-VPWS and **endpoints** are not supported. The **vc-switching** configuration is not supported on **bgp-evpn** enabled Epipes.
- EVPN-VPWS Epipes support **control-word** and **entropy-label**.

When the **bgp-evpn>mpls>control-word** command is configured, the PE sets the C-bit in its AD per-EVI advertisement and sends the control word in the data path. In this case, the PE also expects the control word to be received. If there is a mismatch between the received control word and the configured control word, the system will not set up the EVPN destination. As a result, the service will not come up.

- EVPN-VPWS Epipes can advertise the Layer 2 (service) MTU and check its consistency as follows.
  - The advertised MTU value is taken from the configured **service-mtu** in the Epipe service.
  - The received Layer 2 MTU is checked and compared with the local value. In case of a mismatch between the received MTU and the configured **service-mtu**, the system does not set up the EVPN destination. As a result, the service does not come up.
  - The system does not check the network port MTU value.
  - If the received Layer 2 MTU value is 0, the MTU is ignored.

### 10.2.3.3 Using A/S PW and MC-LAG with EVPN-VPWS Epipe

The use of active/standby (A/S) PW (for access spoke SDPs) and MC-LAG (for access SAPs) provides an alternative redundant solution for EVPN-VPWS that does not use the EVPN multihoming procedures described in IETF *draft-ietf-bess-evpn-vpws*. Figure 172 shows the use of both mechanisms in a single Epipe.

**Figure 172 A/S PW and MC-LAG Support on EVPN-VPWS**

28739

In Figure 172, an A/S PW connects the CE to PE1 and PE2 (left-hand side of the diagram), and an MC-LAG connects the CE to PE3 and PE4 (right-hand side of the diagram). Because EVPN multihoming is not used, there are no AD per-ES routes or ES routes in this example. The redundancy is handled as follows.

- PE1 and PE2 are configured with Epipe 1, where a spoke SDP connects the service in each PE to the access CE. The **local-ac-name eth-tag** is 1 and the **remote-ac-name eth-tag** is 2.
- PE3 and PE4 are configured with Epipe 1, where each PE has a LAG SAP that belongs to a previously configured MC-LAG construct. The **local-ac-name eth-tag** is 2 and the **remote-ac-name eth-tag** is 1.
- An endpoint and A/S PW is configured on the CE on the left-hand side of the diagram. PE1 and PE2 are able to advertise **eth-tag 1** based on the operational status or the forwarding status of the spoke SDP.

For example, if PE1 receives a standby PW status indication from the CE and the previous status was forward, PE1 withdraws the AD EVI route for **eth-tag 1**. If PE2 receives a forward PW status indication and the previous status was standby or down, PE2 advertises the AD EVI route for **eth-tag 1**.

- The user can configure MC-LAG for access SAPs using the configuration of PE3 and PE4 shown in [Figure 172](#). In this case, the MC-LAG determines which of the two chassis is active or standby.

If PE4 becomes the standby chassis, the entire LAG port is brought down. As a result, the SAP goes operationally down and PE4 withdraws any previous AD EVI route for **eth-tag 2**.

If PE3 becomes the active chassis, the LAG port becomes operationally up. As a result, the SAP and PE3 advertise the AD per-EVI route for **eth-tag 2**.

#### 10.2.3.4 EVPN Multihoming for EVPN-VPWS Services

EVPN multihoming is supported for EVPN-VPWS Epipe services with the following considerations.

- Single-active and all-active multihoming is supported for SAPs and spoke SDPs.
- Ethernet segments (ESs) can be shared between the Epipe and VPLS services for LAGs, ports, and SDPs.
- A split-horizon function is not required because there is no traffic between the DF and the non-DF for Epipe services. As a result, the ESI label is never used. For this reason, the **ethernet-segment >multi-homing single-active no-esi-label** command does not affect Epipe services.
- The local Ethernet tag values must match on all PEs that are part of the same ES, regardless of the multihoming mode. The PEs in the ES use the AD per-EVI routes from the peer PEs to validate the PEs as DF election candidates for a specific EVI.

The DF election for Epipes that is defined in an all-active multihoming ES is not relevant because all PEs in the ES behave in the same way.

- All PEs send P=1 on the AD per-EVI routes.
- All PEs can send upstream and downstream traffic, regardless of whether traffic is unicast, multicast, or broadcast (all traffic is treated as unicast in the Epipe services).

Therefore, the following **tools** command output shows “N/A” when all-active multihoming is configured.

```
*A:PE-2# tools dump service system bgp-evpn ethernet-segment "ESI-12" evi 6000 df
[03/18/2016 20:31:35] All Active VPWS - DF N/A
```

Aliasing is supported for traffic sent to an Ethernet segment destination. If ECMP is enabled on the ingress PE, per-service load balancing is performed to all PEs that advertise P=1. The PEs that advertise P=0 are not considered as next hops for an ES destination.

Although DF election is not relevant for Epipes in an all-active multihoming ES, it is essential for the following forwarding and backup functions in a single-active multihoming ES.

- The PE elected as DF is the primary PE for the Ethernet segment in the Epipe. The primary PE unblocks the SAP or spoke SDP for upstream and downstream traffic. The remaining PEs in the ES bring their ES SAPs or spoke SDPs operationally down.
- The DF candidate list is built from the PEs sending ES routes for the same ES and is pruned for a specific service, depending on the availability of the AD per-ES and per-EVI routes.
- When the SAP or spoke SDPs (part of the ES) come up, the AD per-EVI routes are sent with P=B=0. The remote PEs do not send traffic at this stage. The remote PEs do not start sending traffic until the DF election process is completed, the **es-activation-timer** has expired, and the PEs advertise AD per-EVI routes with P- and B-bits different from 0.
- The backup PE function is supported as defined in IETF *draft-ietf-bess-evpn-vpws*. The primary PE, backup, or none status is signaled by the PEs (part of the same single-active multihoming ES) in the P- or B-flags of the EVPN Layer 2 attributes extended community. [Figure 173](#) shows the advertisement and use of the primary, backup, or none indication by the PEs in the ES.

**Figure 173** EVPN-VPWS Single-active Multihoming

28741

As specified in RFC 7432, the remote PEs in VPLS services have knowledge of the primary PE in the remote single-active ES, based on the advertisement of the MAC/IP routes (because only the DF learns and advertises MAC/IP routes).

Because there are no MAC or IP routes in EVPN-VPWS, the remote PEs can forward the traffic based on the P- and B-bits. The process is described in the following list (see the example in [Figure 173](#)).

- The DF PE for an EVI (PE2 in [Figure 173](#)) sends P=1 and B=0.
- For each ES or EVI, a second DF election is run among the PEs in the backup candidate list to elect the backup PE. The backup PE (PE3 in [Figure 173](#)) sends P=0 and B=1.
- All remaining multihoming PEs (PE4 and PE5) send P=B=0.
- At the remote PEs (PE1 in [Figure 173](#)), the P- and B-flags are used to identify the primary and backup PEs within the ES destination. The traffic is then sent to the primary PE, provided that it is active.
  - When a remote PE receives the withdrawal of an Ethernet AD per-ES (or EVI) route from the primary PE, the remote PE immediately switches the traffic to the backup PE for the affected EVIs.
  - The backup PE takes over immediately without waiting for the ES activation timer to expire and bring up its SAP or spoke SDP.

- The **bgp-evpn mpls ecmp** setting also governs the forwarding in single-active multihoming, regardless of the single-active multihoming bit in the AD per-ES route received at the remote PE (PE1 in [Figure 173](#)).
  - PE1 always sends the traffic to the primary remote PE (the owner of the P=1 bit). If there are multiple primary PEs and ECMP > 1, PE1 will load-balance the traffic to all the primary PEs, regardless of the multihoming mode.
  - If the last primary PE withdraws its AD per-EVI or ES route, PE1 sends the traffic to the backup PE or PEs. If there are multiple backup PEs and ECMP > 1, PE1 load-balances the traffic to the backup PEs.

## 10.2.4 EVPN for MPLS Tunnels in r-VPLS Services

EVPN-MPLS and IP prefix advertisement (enabled by the **ip-route-advertisement** command) are fully supported in routed VPLS services. The following capabilities are supported in a service where **bgp-evpn mpls** is enabled:

- r-VPLS with VRRP support on VPRN interfaces
- r-VPLS support including **ip-route-advertisement** with regular interfaces

This includes the advertisement and process of IP prefix routes defined in IETF *draft-ietf-bess-evpn-prefix-advertisement* with the appropriate encoding for EVPN-MPLS.
- r-VPLS support including **ip-route-advertisement** with **evpn-tunnel** interfaces
- r-VPLS with IPv6 support on the VPRN IP interface

### 10.2.4.1 Overview

EVPN and MPLS can be enabled on VPLS or r-VPLS services on the 7705 SAR. While the [EVPN-VPLS for MPLS Tunnels](#) section focuses on the use of EVPN-MPLS Layer 2 services (that is, how EVPN-MPLS is configured in VPLS services), this section describes how EVPN-MPLS can be used to provide inter-subnet forwarding in r-VPLS and VPRN services. Although inter-subnet forwarding can be provided by regular r-VPLS and VPRN services, EVPN provides an efficient and unified way to populate forwarding databases (FDBs), address resolution protocol (ARP) tables, and routing tables using a single BGP address family. Inter-subnet forwarding in overlay networks would otherwise require data plane learning and the use of routing protocols on a per-VPRN basis.

The 7705 SAR solution for inter-subnet forwarding using EVPN is based on building blocks described in *draft-sajassi-l2vpn-evpn-inter-subnet-forwarding* and the use of the EVPN IP prefix routes (route type 5) as explained in *draft-rabadan-l2vpn-evpnprefix-advertisement*.

The IRB interface refers to an r-VPLS service bound to a VPRN IP interface.

### 10.2.4.2 EVPN-MPLS Multihoming and Passive VRRP

SAP-based and spoke SDP-based Ethernet segments are supported on r-VPLS services where **bgp-evpn mpls** is enabled.

Figure 174 shows an example of EVPN-MPLS multi-homing in r-VPLS services, with the following assumptions.

- There are two subnets for a specific customer (for example, EVI1 and EVI2 in Figure 174), and a VPRN is instantiated in all the PEs for efficient inter-subnet forwarding.
- A backhaul r-VPLS with **evpn-tunnel** mode enabled is used in the core to interconnect all the VPRNs. EVPN IP prefix routes are used to exchange the prefixes corresponding to the two subnets.
- An all-active ES is configured for EVI1 on PE1 and PE2.
- A single-active ES is configured for EVI2 on PE3 and PE4.

**Figure 174 EVPN-MPLS Multi-Homing in r-VPLS Services**

28913

In [Figure 174](#), the hosts connected to CE1 and CE4 could use regular VRRP for default gateway redundancy; however, this may not be the most efficient way to provide upstream routing.

For example, if PE1 and PE2 are using regular VRRP, the upstream traffic from CE1 may be hashed to the backup IRB VRRP interface instead of being hashed to the master interface. The same thing may occur for single-active multi-homing and regular VRRP for PE3 and PE4. The traffic from CE4 will be sent to PE3 although PE4 may be the VRRP master. In that case, PE3 will have to send the traffic to PE4 instead of routing it directly.

In both cases, unnecessary bandwidth between the PEs is used to get to the master IRB interface. In addition, VRRP scaling is limited if aggressive keepalive timers are used.

Because of these issues, passive VRRP is recommended as the best method when EVPN-MPLS multi-homing is used in combination with r-VPLS redundant interfaces.

Passive VRRP is a VRRP setting in which the transmission and reception of keepalive messages is completely suppressed, and therefore the VPRN interface always behaves as the master. Passive VRRP is enabled by adding the **passive** keyword to the VRRP instance at creation time (passive mode cannot be enabled or disabled while the protocol is running), as shown in the following examples:

```
config service vprn interface vrrp virtual-router-id passive
```

```
config service vprn interface ipv6 vrrp virtual-router-id passive
```

For example, if PE1, PE2, and PE5 in [Figure 174](#) use passive VRRP, then even if each individual r-VPLS interface has a different MAC/IP address, because they share the same VRRP instance 1 and the same backup IP, the three PEs will own the same virtual MAC and virtual IP address (for example, 00-00-5E-00-00-01 and 10.0.0.254). The virtual MAC is auto-derived from 00-00-5E-00-00-VRID, as per RFC 3768. The following is the expected behavior when passive VRRP is used in this example.

- All r-VPLS IRB interfaces for EVI1 have their own physical MAC/IP address; they also own the same default gateway virtual MAC and IP address.
- All EVI1 hosts have a unique configured default gateway; for example, 10.0.0.254.
- When CE1 or CE2 sends upstream traffic to a remote subnet, the packets are routed by the closest PE because the virtual MAC is always local to the PE.

For example, the packets from CE1 hashed to PE1 are routed at PE1. The packets from CE1 hashed to PE2 are routed directly at PE2.

- Downstream packets (for example, packets from CE3 to CE1), are routed directly by the PE to CE1, regardless of the PE to which PE5 routed the packets. For example, the packets from CE3 sent to PE1 are routed to CE1 at PE1. The packets from CE3 sent to PE2 are routed to CE1 at PE2.
- In case of ES failure in one of the PEs, the traffic will be forwarded by the available PE.  
For example, if the packets routed by PE5 arrive at PE1 and the link to CE1 is down, PE1 will send the packets to PE2. PE2 will forward the packets to CE1 even if the MAC source address of the packets matches the virtual MAC address of PE2. Virtual MAC addresses bypass the r-VPLS interface MAC protection.

The following list summarizes the advantages of using passive VRRP mode versus regular VRRP for EVPN-MPLS multi-homing in r-VPLS services.

- Passive VRRP does not require multiple VRRP instances to achieve default gateway load balancing. Only one instance per r-VPLS—hence only one default gateway—is needed for all the hosts.
- The convergence time for link or node failures is not impacted by the VRRP convergence because all the nodes in the VRRP instance are master routers.
- Passive VRRP scales better than VRRP because it does not use keepalive or BFD messages to detect failures and allow the backup to take over.

## 10.2.5 MPLS Entropy Label

The router supports the MPLS entropy label (RFC 6790), allowing LSR nodes in a network to load-balance labeled packets in a much more granular fashion than allowed by simply hashing on the standard label stack. The entropy label can be enabled on BGP-EVPN services (VPLS and Epipe). Refer to the “MPLS Entropy Labels” section in the 7705 SAR MPLS Guide for more information.

---

## 10.3 General EVPN Topics

This section provides information on general topics related to EVPN.

- [BGP-EVPN MAC Mobility](#)
- [BGP-EVPN MAC Duplication](#)
- [Conditional Static MAC and Protection](#)
- [Blackhole MAC](#)
- [CFM Interaction with EVPN Services](#)
- [BGP and EVPN Route Selection for EVPN Routes](#)
- [Interaction of EVPN and Other Features](#)

### 10.3.1 BGP-EVPN MAC Mobility

EVPN defines a mechanism to allow the smooth mobility of MAC addresses. The 7705 SAR supports the MAC mobility extended community in MAC advertisement routes as follows.

- The router honors and generates the SEQ (sequence) number in the MAC mobility extended community for MAC moves.
- When a MAC address is EVPN-learned and there is an attempt for it to be learned locally, a BGP update is sent with the SEQ number changed to previous\_SEQ+1, except when the MAC duplication *num-moves* value is reached.
- If the sequence number is 0 or if the extended community received in the type 2 MAC/IP advertisement route is not included, then the sequence number is interpreted as 0.
- For MAC mobility, the following MAC address selection procedure is followed.
  - If a PE has two or more active remote EVPN routes for the same MAC address, the highest SEQ number is selected. The tiebreaker is the lowest IP address (BGP next-hop IP address).
  - If a PE has two or more active EVPN routes and the PE is the originator of one of the routes, the highest SEQ number is selected. The tiebreaker is the lowest IP address (BGP next-hop IP address of the remote route is compared to the local system address).

**Note:** When EVPN multihoming is used in EVPN-MPLS, the ESI is examined to determine whether a MAC address received from two different PEs must be processed within the context of MAC mobility or multihoming. Two MAC routes that are associated with the same remote or local ESI but different PEs are considered reachable through all the PEs. Mobility procedures are not triggered as long as the MAC route still belongs to the same ESI.

## 10.3.2 BGP-EVPN MAC Duplication

EVPN defines a mechanism to protect the EVPN service from control plane churn as a result of loops or accidental duplicated MAC addresses. The 7705 SAR supports an enhanced version of this procedure as described in this section.

A situation may arise where the same MAC address is learned by different PEs in the same VPLS because of two or more hosts being incorrectly configured with the same (duplicate) MAC address. In this situation, the traffic originating from these hosts triggers continuous MAC moves among the PEs attached to these hosts. It is important to recognize this situation and avoid incrementing the sequence number in the MAC mobility attribute to infinity.

To remedy the above situation, a router that detects a MAC mobility event by way of local learning starts a **window minutes** timer (default value is 3 minutes). and if the router detects **num-moves value** before the timer expires (default value is 5 moves), the router concludes that a duplicate MAC situation has occurred. The router then alerts the operator with a trap message. The offending MAC address can be viewed using the **show>service>id n >bgp-evpn** command:

```
10 2018/01/14 01:00:22.91 UTC MINOR: SVCNMR #2331 Base
"VPLS Service 1 has MAC(s)detected as duplicates by EVPN mac-duplication detection."

show service id 1 bgp-evpn
=====
BGP EVPN Table
=====
MAC Advertisement : Enabled Unknown MAC Route : Disabled
VXLAN Admin Status : Disabled Creation Origin : manual
MAC Dup Detn Moves : 5 MAC Dup Detn Window : 3
MAC Dup Detn Retry : 9 Number of Dup MACs : 1

Detected Duplicate MAC Addresses Time Detected

00:00:00:00:00:12 01/14/2014 01:00:23

=====
```

After detecting the duplicate address, the router stops sending and processing any BGP MAC advertisement routes for that MAC address until one of the following occurs:

- the MAC address is flushed due to a local event (such as a SAP or SDP binding associated with the MAC address failing) or the reception of a remote update with a higher SEQ number (due to a MAC address flush at the remote router)
- the **retry** *minutes* timer expires, which flushes the MAC address and restarts the process

**Note:** The other routers in the VPLS instance will forward the traffic for the duplicate MAC address to the router advertising the best route for the MAC address.

The **num-moves** and **window** values are configurable to allow for the required flexibility in different environments. In scenarios where **bgp>rapid-update evpn** is configured, the operator might want to configure a shorter window timer than in scenarios where BGP updates are sent every default **min-route-advertisement** interval.

The MAC duplication parameters can be configured per VPLS service under the **bgp-evpn>mac-duplication** context, as shown in the following example:

```
*A:DGW1>config>service>vpls>bgp-evpn# info

mac-advertisement
mac-duplication
 detect num-moves 5 window 3
 retry 9
exit
```

### 10.3.3 Conditional Static MAC and Protection

RFC 7432 defines the use of the sticky bit in the MAC mobility extended community to signal static MAC addresses. These addresses must be protected in case there is an attempt to dynamically learn them from a different source.

On the 7705 SAR, any conditional static MAC address is advertised by BGP-EVPN as a static address—that is, with the sticky bit set. An example of the configuration of a conditional static MAC address is shown below:

```
*A:PE63>config>service>vpls# info

...
 sap 1/1/1:1000 create
exit
```

```

static-mac

```

Local static MAC addresses or remote MAC addresses with sticky bit are considered to be protected. A packet entering a SAP or SDP binding is discarded if its source MAC address matches one of the protected MAC addresses.

## 10.3.4 Blackhole MAC

A blackhole MAC is a local FDB record. It is similar to a conditional static MAC; it is associated with a black hole—similar to a VPRN blackhole static route in VPRNs—instead of a SAP or SDP binding. A blackhole MAC can be added by using the following CLI command:

**config>service>vpls>static-mac>mac *ieee-address* [create] black-hole**

The static blackhole MAC can have security applications for certain MAC addresses (for example, replacement of MAC filters).

**Note:** A static MAC can only be created as a blackhole MAC if BGP-EVPN is configured first. It is not supported for regular VPLS service, only for an EVPN VPLS service.

For example, when a specified blackhole MAC is added to a service (**static-mac mac 00:00:ca:fe:ca:fe create black-hole**), the following behavior occurs.

- The configured MAC address is created as a static MAC address with a “black-hole” source identifier.

```

=====
```

- After the blackhole MAC has been successfully added to the FDB, it is treated like any other protected MAC. The blackhole MAC is added as protected (CStatic:P) and advertised in EVPN as static.
- After the blackhole MAC has been successfully added to the FDB, any frame arriving at any SAP, SDP binding, or EVPN endpoint with a MAC DA that is equal to the blackhole MAC is discarded.

---

## 10.3.5 CFM Interaction with EVPN Services

Ethernet connectivity and fault management (ETH-CFM) allows the operator to validate and measure Ethernet Layer 2 services using standard IEEE 802.1ag and ITU-T Y.1731 protocols. Each tool performs a unique function and adheres to that tool's specific PDU and frame format and the associated rules governing the transmission, interception, and process of the PDU. For more information, refer to the "ETH OAM Capabilities" section in the 7705 SAR OAM and Diagnostics Guide.

EVPN provides powerful solution architectures. ETH-CFM is supported in various Layer 2 EVPN architectures. Because the destination Layer 2 MAC address (unicast or multicast) is ETH-CFM tool-dependent (that is, ETH-CC is sent as a Layer 2 multicast and ETH-DM is sent as a Layer 2 unicast), the ETH-CFM function is allowed to multicast and broadcast to the virtual EVPN connections. The Maintenance Endpoint (MEP) does not populate the local Layer 2 MAC address forwarding database (FDB) with the MAC address related to the MEP. This means that the 48-bit IEEE MAC address is not exchanged with peers and all ETH-CFM frames are broadcast across all virtual connections. To prevent the flooding of unicast packets and allow the remote forwarding databases to learn the remote MEP Layer 2 MAC addresses, the command **cfm-mac-advertisement** must be configured under the **config>service>vpls>bgp-evpn** context. This allows the MEP Layer 2 IEEE MAC addresses to be exchanged with peers. This command tracks configuration changes and sends the required updates via the EVPN notification process related to a change.

Up MEP and Down MEP creation is supported on SAP connections in the EVPN service. There is no support for the creation of ETH-CFM MEPs on the virtual connection.

When MEPs are used in combination with EVPN multihoming, the following must be considered:

- Behavior of operationally down MEPs on SAPs with EVPN multihoming:
  - **all-active multi-homing**: in this case, no ETH-CFM is expected to be used because the SAPs on the PEs are operationally up and active. However, the CE has a single LAG and responds as though it is connected to a single system. In addition, **cfm-mac-advertisement** can lead to traffic loops in all-active multihoming.
  - **single-active multi-homing**: operationally down MEPs defined on single-active Ethernet segment SAPs do not send any CCMs when the PE is a non-DF for the Ethernet segment and fault-propagation is configured.

- Behavior of operationally up MEPs on Ethernet segment SAPs with EVPN multihoming:
  - **all-active multi-homing**: operationally up MEPs defined on non-DF Ethernet segment SAPs can send CFM packets. However, they cannot receive CCMs (the SAP is removed from the default multicast list) or unicast CFM packets (because the MEP MAC address is not installed locally in the FDB, unicast CFM packets are treated as unknown and are not sent to the non-DF SAP MEP).
  - **single-active multi-homing**: operationally up MEPs are able to send or receive CFM packets normally.

Due to the above considerations, the use of ETH-CFM in EVPN multihomed SAPs is only recommended on operationally down MEPs and single-active multihoming. ETH-CFM is used in this case to notify the CE of the DF or non-DF status.

## 10.3.6 BGP and EVPN Route Selection for EVPN Routes

When two or more EVPN routes are received at a PE, BGP route selection typically takes place when the route key or the routes are equal. When the route key is different but the PE must make a selection (for instance, the same MAC address is advertised in two routes with different RDs), BGP hands over the routes to EVPN and the EVPN application performs the selection.

EVPN and BGP selection criteria are described below.

- **EVPN route selection for MAC routes**

When two or more routes with the same **mac-length** and **mac** but different route key are received, BGP hands the routes over to EVPN. EVPN selects the route based on the following tiebreaking order:

1. Conditional static MAC addresses (local protected MAC addresses)
2. EVPN static MAC addresses (remote protected MAC addresses)
3. Data plane learned MAC addresses (regular learning on SAPs and SDP bindings)
4. EVPN MAC addresses with higher SEQ number
5. Lowest IP address (next-hop IP address of the EVPN NLRI)
6. Lowest Ethernet tag (the tag will be 0 for MPLS)
7. Lowest RD

- **BGP route selection:**

The regular BGP route selection is followed.

**Note:** If BGP runs a route selection operation and a specified—but otherwise valid—EVPN route loses a tiebreaker to another EVPN route, the nonselected route can be displayed, along with a tiebreaker reason, using the **show>router>bgp>routes>evpn evpn-type** command.

## 10.3.7 Interaction of EVPN and Other Features

This section contains information on the following topics:

- [Interaction of EVPN-MPLS with Existing VPLS Features](#)
- [Routing Policies for BGP-EVPN IP Prefixes](#)

### 10.3.7.1 Interaction of EVPN-MPLS with Existing VPLS Features

When enabling existing VPLS features in an EVPN-MPLS service, the following must be considered.

- EVPN-MPLS is only supported in regular VPLS. Other VPLS types, such as management VPLS (mVPLS), are not supported with EVPN-MPLS.
- In general, no router-generated control packets are sent to the EVPN destination bindings, except for ETH-CFM for EVPN-MPLS.
- STP and mVPLS services:
  - STP can be configured in BGP-EVPN services. BPDUs are not sent over the EVPN bindings.
  - The **bgp-evpn** command is blocked in mVPLS services; however, a separate mVPLS service can manage a SAP or spoke SDP in a BGP-EVPN service.
- The **mac-move** command can be used in BGP-EVPN VPLS services for SAPs and SDP bindings; however, the MAC addresses being learned through BGP-EVPN will not be considered.

**Note:** The MAC duplication function already provides protection against MAC moves between EVPN and SAPs and SDP bindings.

- The **disable-learning** command and other FDB-related tools only work for data-plane learned MAC addresses.

- The **mac-protect** command cannot be used in conjunction with EVPN.

**Note:** EVPN provides its own protection mechanism for static MAC addresses.

- MAC OAM tools are not supported for BGP-EVPN services, including the following commands: **mac-ping**, **mac-trace**, **mac-populate**, **mac-purge**, and **cpe-ping**.
- SAPs and SDP bindings that belong to a specified ES but are configured on non-BGP-EVPN MPLS-enabled VPLS or Epipe services are kept operationally down with the **StandByForMHPProtocol** flag.
- CPE ping is not supported for EVPN services. CPE ping packets are not sent over EVPN destinations.
- Other functions not supported in conjunction with the **bgp-evpn** command include:
  - endpoints and attributes
  - MLD snooping and attributes
  - BPDU translation
  - MAC pinning

### 10.3.7.2 Routing Policies for BGP-EVPN IP Prefixes

BGP routing policies are supported for IP prefixes imported or exported through BGP-EVPN.

When applying routing policies to control the distribution of prefixes between EVPN and IP-VPN, the user must consider that both families are separate as far as BGP is concerned, and when prefixes are imported in the VPRN routing table, the BGP attributes are lost to the other family. The use of route tags allows the controlled distribution of prefixes across the two families.

[Figure 175](#) shows an example of how VPN-IPv4 routes are imported into the routing table manager (RTM) and then passed to EVPN for processing.

**Note:** VPN-IPv4 routes can be tagged at ingress, and that tag is preserved throughout the RTM and EVPN processing so that the tag can be matched at the egress BGP routing policy.

**Figure 175 IP-VPN Import and EVPN Export BGP Workflow**

28723

Policy tags can be used to match EVPN IP prefixes that were learned not only from BGP VPN-IPv4 but also from other routing protocols. The tag range supported for each protocol is different:

```

<tag> : accepts in decimal or hex
[0x1..0xFFFFFFFF]H (for OSPF and IS-IS)
[0x1..0xFFFF]H (for RIP)
[0x1..0xFF]H (for BGP)

```

Figure 176 shows an example of the reverse workflow: routes imported from EVPN and exported from RTM to BGP VPN-IPv4.

**Figure 176 EVPN Import and IP-VPN Export BGP Workflow**

28724

The policy behavior for EVPN IP prefixes is summarized in the following statements:

- for EVPN prefix routes received and imported in RTM:
  - policy entries can match on communities and add tags. This works at the peer level or at the vsi-import level.
  - policy entries can match on **family evpn**
- for exporting RTM to EVPN prefix routes:
  - policy entries can match on tags and based on that, add communities, accept, or reject. This works at the peer level or the virtual switch instance (VSI) export level.

Policy entries can add tags for static routes, RIP, OSPF, IS-IS, and BGP that can then be matched on the BGP peer export policy or VSI export policy for EVPN prefix routes.

## 10.4 Configuring an EVPN Service With CLI

This section provides examples for configuring EVPN multihoming for VPLS services using the command line interface:

- [EVPN All-Active Multihoming Configuration Example](#)
- [EVPN Single-Active Multihoming Configuration Example](#)
- [EVPN-MPLS r-VPLS Configuration Examples](#)

### 10.4.1 EVPN All-Active Multihoming Configuration Example

This section shows a configuration example for three 7705 SAR PEs, with the following assumptions.

- PE-1 and PE-2 are multihomed to CE-12, which uses a LAG to connect to the network. CE-12 is connected to LAG SAPs configured in an all-active multihoming Ethernet segment.
- PE-3 is a remote PE that performs aliasing for traffic destined for the CE-12.

The following configuration excerpt applies to a VPLS-1 on PE-1 and PE-2 and includes the corresponding **ethernet-segment** and **lag** commands.

```

```

## 10.4.2 EVPN Single-Active Multihoming Configuration Example

To use single-active multihoming on PE-1 and PE-2 instead of all-active multihoming, make the following modifications to the configuration of the [EVPN All-Active Multihoming Configuration Example](#):

- change the LAG configuration to **single-active**  
CE-12 will now be configured with two different LAGs; therefore, the *admin-key*, *system-id*, and *system-priority* must be different on PE-1 and PE-2.
- change the Ethernet segment configuration to **single-active**

No changes are needed at the service level on any of the three PEs.

The differences between single-active and all-active multihoming are highlighted in **bold** in the following configuration excerpts:

```
A:PE1# configure lag 1
A:PE1>config>lag# info

mode access
encap-type dot1q
port 1/1/2

### 10.4.3 EVPN-MPLS r-VPLS Configuration Examples

This section contains the following configuration examples:

- [EVPN-MPLS r-VPLS Without Multihoming](#)
- [EVPN-MPLS r-VPLS With All-Active Multihoming](#)
- [EVPN-MPLS r-VPLS With Single-Active Multihoming](#)

EVPN can be used as the unified control plane VPN technology, not only for providing Layer 2 connectivity, but also for Layer 3 (inter-subnet forwarding). EVPN for MPLS tunnels, along with multihoming and passive VRRP, provides efficient Layer-2 or Layer-3 connectivity to distributed hosts and routers.

#### 10.4.3.1 EVPN-MPLS r-VPLS Without Multihoming

The first scenario describes r-VPLS support including IP route advertisement (BGP-EVPN route type 5) with EVPN tunnel interfaces without multihoming. VPLS 101 does not have a connected host, but the linked VPRN has SAP 1/2/1:10. [Figure 177](#) shows an example of topology used for r-VPLS with an EVPN tunnel but without multihoming. IP prefixes are advertised.

**Figure 177 r-VPLS With EVPN Tunnel, Without Multihoming**

26851

The initial configuration includes the following:

- cards, MDAs, ports
- router interface between PE-2 and PE-3
- IS-IS (or OSPF)
- LDP enabled on the router interface between PE-2 and PE-3

BGP is configured for address family EVPN on PE-2 and PE-3. The BGP configuration on PE-2 is as follows. The BGP configuration on PE-3 is similar.

```
on PE-2:
configure
router
 autonomous-system 64500
 bgp
 family evpn
 vpn-apply-import
 vpn-apply-export
 enable-peer-tracking
 rapid-withdrawal
 rapid-update evpn
 group "internal"
 peer-as 64500
 neighbor 192.0.2.3
 exit
 exit
 exit
```

The CEs are connected to SAP 1/2/1:10 in VPRN 10. r-VPLS 101 is bound to VPRN 10 and VPRN 10 has a dedicated interface “int-evi-101” for the EVPN tunnel. In general, if only one route target (RT) is used for import and export in the EVPN-VPLS, it is best to add the EVI and have the route distinguisher (RD) and RT auto-derived from the EVI; this simplifies the configuration and reduces the chance of errors. The service configuration on PE-2 is as follows:

```
on PE-2:
configure
```

```

service
 vprn 10 name "VPRN 10" customer 1 create
 route-distinguisher 192.0.2.2:10
 vrf-target target:64500:10
 interface "int-PE-2-CE-20" create
 address 172.16.2.1/24
 sap 1/2/1:10 create
 exit
 exit
 interface "int-evi-101" create
 vpls "evi-101"
 evpn-tunnel
 exit
 exit
 no shutdown
exit
vpls 101 name "evi-101" customer 1 create
 allow-ip-int-bind
 exit
 bgp // RD and RT are not manually configured in BGP context
 exit
 bgp-evpn
 ip-route-advertisement
 evi 101 // RD and RT will be auto-derived from the EVI
 mpls bgp 1
 auto-bind-tunnel
 resolution any
 exit
 no shutdown
 exit
 exit
 no shutdown
exit

```

In the preceding configuration:

- the **allow-ip-int-binding** command is required so that r-VPLS 101 can be bound to VPRN 10
- the service name is required and the configured name “evi-101” must match the name in the VPRN 10 VPLS interface. The service name is configured at service creation time.
- the VPRN 10 VPLS interface is configured with the keyword **evpn-tunnel**. This configuration has the advantage of not having to allocate IP addresses to the r-VPLS interfaces; however, it cannot be used when the r-VPLS interface has local SAPs.

The configuration is similar on PE-3. The RD must be different on PE-2 and PE-3; this is automatically the case when the RD is auto-derived from the configured EVI, as in the example. The RD on PE-2 is 192.0.2.2:101; on PE-3, the RD is 192.0.2.3:101.

PE-3 receives the following BGP-EVPN IP prefix route for prefix 172.16.2.0/24 from PE-2:

```

34 2019/09/27 12:21:38.100 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2

 bgp-tunnel-encap:MPLS
"

```

GW IP 0.0.0.0 is an indication that an EVPN tunnel is in use. With EVPN tunnels, no IRB IP address needs to be configured in the VPRN. EVPN tunnels make provisioning easier to automate and save IP addresses from the tenant IP space.

The BGP tunnel encapsulation is MPLS, but the MPLS label in the debug message is not the same as in the service, because the router strips the extra four lowest bits to get the 20-bit MPLS label. In the debug message, the label is 8388464. This is because the debug message is shown before the router can parse the label field and see if it corresponds to an MPLS label (20 bits). The MPLS label is calculated by dividing the label value by 24 (16), as follows:  $8388464/16 = 524279$ .

The MAC next-hop extended community 04:0b:ff:ff:ff:a2 is the MAC address of the interface “int-evi-101” in VPRN 10 on PE-2, as follows:

```

*A:PE-2# show service id 10 interface "int-evi-101" detail | match MAC
MACSec : N/A
MAC Address : 04:0b:ff:ff:ff:a2 Mac Accounting : Disabled

```

The routing table for VPRN 10 on PE-3 contains the route for prefix 172.16.2.0/24 as the BGP-EVPN route with next-hop “int-evi-101” and interface name “ET-04:0b:ff:ff:ff:a2” (ET stands for EVPN Tunnel), as follows:

```

*A:PE-3# show router 10 route-table

```

When the CEs have IPv6 addresses, the VPRN configuration is similar on the PEs, but the **ipv6** context must be enabled on the EVPN tunnel interface so that the router can advertise and process BGP-EVPN type 5 routes with IPv6 prefixes. The configuration of VPLS is identical for IPv4 and IPv6.

```

on PE-2:
configure
 service
 vprn 16 name "VPRN 16" customer 1 create
 route-distinguisher 192.0.2.2:16

 auto-bind-tunnel
 resolution any
 exit
 no shutdown
 exit
exit
no shutdown
exit

```

When advertising IPv6 prefixes, the GW IP field for route type 5 is always populated with the IPv6 address of the r-VPLS interface. In this example, because no specific IPv6 global address is configured, the GW IP will be populated with the auto-created link local address. The following BGP update is received by PE-3 for IPv6 prefix 2001:db8:16::2:0/120:

```

on PE-3:
36 2019/09/27 12:21:38.123 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2

10.4.3.2    EVPN-MPLS r-VPLS With All-Active Multihoming

Figure 178 shows an example of the topology with all-active multihoming Ethernet segment (ES) “ESI-23”.

Figure 178    EVPN-MPLS r-VPLS With All-Active Multihoming ES

26852

BGP is configured between PE-2, PE-3, and PE-4 for address family EVPN. The configuration on PE-2 is as follows:

```
on PE-2:
configure
```

```

router
 autonomous-system 64500
 bgp
 family evpn
 vpn-apply-import
 vpn-apply-export
 enable-peer-tracking
 rapid-withdrawal
 rapid-update evpn
 group "internal"
 peer-as 64500
 neighbor 192.0.2.3
 exit
 neighbor 192.0.2.4
 exit
 exit
 exit
exit

```

All-active multihoming Ethernet segment “ESI-23” is configured on PE-2 and PE-3 as follows:

```

configure
 service
 system
 bgp-evpn
 ethernet-segment "ESI-23" create
 esi 01:00:00:00:00:23:00:00:00:01
 es-activation-timer 3
 service-carving
 mode auto
 exit
 multi-homing all-active
 lag 1
 no shutdown
 exit
 exit
 exit

```

The following services are configured on the PEs:

- VPRN 20 has interfaces bound to VPLS 200 and VPLS 202. On PE-4, VPRN 20 also has an interface bound to VPLS 203.
- VPLS 200 is configured as an EVPN tunnel that connects the PEs.
- VPLS 202 and VPLS 203 have attachment circuits to CEs.

The services are configured on PE-2 as follows. The configuration on PE-3 and PE-4 is similar.

```

on PE-2:
configure
 service
 vprn 20 name "VPRN 20" customer 1 create
 route-distinguisher 192.0.2.2:20
 vrf-target target:64500:20

```

The IPv6 VRRP backup address is in the same subnet as the link local address of the interface “int-evi-202”. The IPv6 address can be set as preferred. Also for IPv6, router advertisement must be enabled and configured to use the virtual MAC address.

### 10.4.3.2.1 Passive VRRP

EVI 202 is configured as an r-VPLS interface with passive VRRP. A passive VRRP VRID instance suppresses the transmission and reception of keepalive messages. All PEs configured with passive VRRP become VRRP masters and take ownership of the virtual IP and MAC addresses.

Each individual r-VPLS interface has a different MAC/IP address on each PE. The MAC/IP addresses for “int-evi-202” on PE-2 are MAC 00:ca:fe:00:02:02 and IP 172.16.20.2/24 for IPv4 and the same MAC address with IPv6 2001:db8:16::20:2 and fe80::16:20:2. However, the r-VPLS interfaces on all PEs share the same VRID 1 and backup IP address 172.16.20.254, so the same vMAC/vIP 00:00:5e:00:01:01/172.16.20.254 and vMAC/vIP 00:00:5e:00:02:01/ fe80::16:20:fe are advertised by all PEs. PE-2 advertises the following EVPN MAC routes:

```

 mac-nh:04:0f:ff:00:00:05
 bgp-tunnel-encap:MPLS
"

```

The IP prefixes are advertised with the next hop equal to the EVPN-tunnel GW MAC “int-evi-200”, as follows:

```

*A:PE-4# show router 20 interface "int-evi-200" detail | match MAC
MACSec : N/A
MAC Address : 04:0f:ff:00:00:05 Mac Accounting : Disabled

```

The routing table for VPRN 20 on PE-2 contains IP prefix 172.16.23.0/24 with next hop 04:0f:ff:00:00:05, as follows:

```

*A:PE-2# show router 20 route-table

=====
Route Table (Service: 20)
=====
Dest Prefix[Flags] Type Proto Age Pref
Next Hop[Interface Name] Metric

172.16.20.0/24 Local Local 00h01m07s 0
 int-evi-202 0
172.16.23.0/24 Remote BGP EVPN 00h00m48s 169
 int-evi-200 (ET-04:0f:ff:00:00:05) 0

No. of Routes: 2

```

The following IPv6 routing table for VPRN 20 on PE-2 contains prefix 2001:db8:16::23:0/120, which has also been advertised by PE-4. The next hop is again “int-evi-200”, only this time the link local IPv6 address is displayed (GW IP) instead of the MAC address. The next hop is the GW IP value for route type 5, as long as it is a non-zero value. When the GW IP address is 0, route type 5 is expected to contain a **mac-nh** extended community. The MAC encoded in the extended community is used as the next hop in that case.

```

*A:PE-2# show router 20 route-table ipv6

### 10.4.3.2.2 Operation

On PE-4, VPRN 20 has one interface bound to VPLS 202 and another interface bound to VPLS 203. CE-41 is attached to VPLS 202 and CE-43 is attached to VPLS 203. When ping messages are sent from CE-41 to CE-43, or vice versa, the messages go via VPRN 20, which has routes to both CEs, as follows:

```

*A:PE-4# show router 20 route-table

=====
Route Table (Service: 20)
=====
Dest Prefix[Flags] Type Proto Age Pref
Next Hop[Interface Name] Metric

172.16.20.0/24 Local Local 04h25m52s 0
int-evi-202 0
172.16.23.0/24 Local Local 04h25m51s 0

```

```

int-evi-203
0

No. of Routes: 2

*A:PE-4# show router 20 route-table ipv6

=====
IPv6 Route Table (Service: 20)
=====

### 10.4.3.3 EVPN-MPLS r-VPLS With Single-Active Multihoming

Figure 179 shows an example of topology with single-active multihoming ES “ESI-23”. The difference between this figure and Figure 178 is that in Figure 179 the ES is single-active and SDPs are used instead of a LAG.

**Figure 179 EVPN-MPLS r-VPLS With Single-Active Multihoming**

26853

The configuration is modified as follows:

- LAG 1 is removed from MTU-1, PE-2, and PE-3
- network interfaces are configured between MTU-1 and PE-2/PE-3 with IS-IS and LDP enabled
- SDPs are configured
- ES “ESI-23” is redefined as single-active multihoming. The SDP is associated with this ES.

- VPLS 202 on PE-2 and PE-3 no longer has a SAP, but has a spoke-SDP instead
- no changes are required on VPRN 20 or VPLS 200

The service configuration on PE-2 is as follows. The configuration on PE-3 is similar. No changes are required on PE-4.

```
*A:PE-2# configure service
*A:PE-2>config>service# info

---

When the SDP between MTU-1 and DF PE-2 goes down, traffic from CE-41 to CE-11 is forwarded by PE-4 to DF PE-2. PE-2 cannot forward the packets to CE-11 directly and will forward the packets to its ES peer PE-3. PE-3 will forward to CE-11 even if the MAC SA matches its own vMAC. Virtual MACs bypass the r-VPLS interface protection, so traffic can be forwarded between the PEs without being dropped.

10.5.2.1 EVPN Configuration Commands

10.5.2.1.1 BGP Commands

bgp

Syntax	[no] bgp
Context	config>service>epipe config>service>vpls
Description	This command enables the context to configure the BGP-related parameters for a BGP Epipe or VPLS. The no version of the command removes the BGP instance.

route-distinguisher

Syntax	route-distinguisher rd no route-distinguisher
Context	config>service>epipe>bgp config>service>vpls>bgp
Description	This command configures the route distinguisher (RD) component that is signaled in the MP-BGP NLRI for Layer 2 VPN and EVPN families. This value is used for the BGP Epipe NLRI and BGP VPLS NLRI when this command is configured. Alternatively, for BGP-EVPN-enabled Epipe and VPLS services, the route-distinguisher value can be auto-derived from the evi evi value (config>service>epipe>bgp-evpn>evi or config>service>vpls>bgp-evpn>evi) if this command is not configured.
Default	no route-distinguisher
Parameters	rd — specifies the route distinguisher address
Values	ip-addr:comm-val 2byte-asnumber:ext-comm-val 4byte-asnumber:comm-val
	ip-addr: a.b.c.d
	comm-val: 0 to 65535
	2byte-asnumber: 1 to 65535
	ext-comm-val: 0 to 4294967295
	4byte-asnumber: 1 to 4294967295

route-target

Syntax	For Epipe: route-target {<i>ext-community</i> export <i>ext-community</i> import <i>ext-community</i>} no route-target For VPLS: route-target <i>ext-community</i> route-target export <i>ext-community</i> [import <i>ext-community</i>] route-target import <i>ext-community</i> no route-target										
Context	config>service>epipe>bgp config>service>vpls>bgp										
Description	This command configures the route target (RT) component that is signaled in the related MP-BGP attribute that is used for the BGP Epipe, BGP VPLS, and EVPN when this command is configured in this Epipe or VPLS service. If this command is not used, the RT is formed automatically using the Epipe or VPLS ID. The extended community can have the same two formats as the Epipe or VPLS ID, that is, a two-octet AS-specific extended community or an IPv4-specific extended community. The extended community can also have a four-octet AS-specific community format. For BGP-EVPN-enabled Epipe and VPLS services, the route target can also be auto-derived from the evi value (config>service>vpls>bgp-evpn>evi or config>service>epipe>bgp-evpn>evi) if this command is not configured.										
Default	no route-target										
Parameters	export <i>ext-community</i> — specifies extended communities allowed to be sent to remote PE neighbors import <i>ext-community</i> — specifies extended communities allowed to be accepted from remote PE neighbors <i>ext-community</i> — specifies the extended community										
Values	target:{<i>ip-addr:comm-val</i> <i>2byte-asnumber:ext-comm-val</i> <i>4byte-asnumber:comm-val</i>} <table><tr><td><i>ip-addr:</i></td><td>a.b.c.d</td></tr><tr><td><i>comm-val:</i></td><td>0 to 65535</td></tr><tr><td><i>2byte-asnumber:</i></td><td>1 to 65535</td></tr><tr><td><i>ext-comm-val:</i></td><td>0 to 4294967295</td></tr><tr><td><i>4byte-asnumber:</i></td><td>1 to 4294967295</td></tr></table>	<i>ip-addr:</i>	a.b.c.d	<i>comm-val:</i>	0 to 65535	<i>2byte-asnumber:</i>	1 to 65535	<i>ext-comm-val:</i>	0 to 4294967295	<i>4byte-asnumber:</i>	1 to 4294967295
<i>ip-addr:</i>	a.b.c.d										
<i>comm-val:</i>	0 to 65535										
<i>2byte-asnumber:</i>	1 to 65535										
<i>ext-comm-val:</i>	0 to 4294967295										
<i>4byte-asnumber:</i>	1 to 4294967295										

vsi-export

Syntax	vsi-export <i>policy-name</i> [<i>policy-name</i> ... (up to 5 max)] no vsi-export
Context	config>service>vpls>bgp
Description	This command specifies the name of the virtual switch instance (VSI) export policies to be used for BGP VPLS when this command is configured in this VPLS service. If multiple policy names are configured, the policies are evaluated in the order in which they are specified. The first policy that matches is applied. The policy name list is handled by the SNMP agent as a single entity.
Default	no vsi-export
Parameters	<i>policy-name</i> — specifies a VSI export policy (32 characters maximum)

vsi-import

Syntax	vsi-import <i>policy-name</i> [<i>policy-name</i> ... (up to 5 max)] no vsi-import
Context	config>service>vpls>bgp
Description	This command specifies the name of the virtual switch instance (VSI) import policies to be used for BGP VPLS when this command is configured in this VPLS service. If multiple policy names are configured, the policies are evaluated in the order in which they are specified. The first policy that matches is applied. The policy name list is handled by the SNMP agent as a single entity.
Default	no vsi-import
Parameters	<i>policy-name</i> — specifies a VSI import policy (32 characters maximum)

10.5.2.1.2 BGP-EVPN Commands

bgp-evpn

Syntax	[no] bgp-evpn
Context	config>service>epipe config>service>vpls
Description	This command enables the context to configure the BGP-EVPN parameters in the specified service.

cfm-mac-advertisement

Syntax	[no] cfm-mac-advertisement
Context	config>service>vpls>bgp-evpn
Description	This command enables the advertisement and withdrawal, as appropriate, of the IEEE MAC address associated with the MEP created on a SAP in an EVPN service. The update occurs each time a MEP is added or deleted or an IEEE MAC address is changed for an MEP on a SAP within the service. The size of the update depends on the number of MEPs in the service affected by the modification. Only enable this functionality for services that require a resident MAC address to properly forward unicast traffic and that do not perform Layer 2 MAC learning as part of the data plane. Local MEP IEEE MAC addresses are not stored in the local FDB and therefore cannot be advertised through a control plane to a peer without this command. The no version of the command disables the functionality and withdraws all previously advertised MEP IEEE MAC addresses.
Default	no cfm-mac-advertisement

evi

Syntax	evi value [no] evi
Context	config>service>epipe>bgp-evpn config>service>vpls>bgp-evpn
Description	This command specifies a 2-byte EVPN instance (EVI) that is unique in the system. It is used for the service-carving algorithm for multihoming and for auto-deriving route targets and route distinguishers.

If not specified, the **evi** value is 0 and there are no route distinguishers or route targets auto-derived from the value. If the **evi** value is specified and no other route distinguishers or route targets are configured in the service, the following rules apply:

- the route distinguisher is derived from *system-ip:evi* value
- the route target is derived from *autonomous-system:evi* value

If VSI import and VSI export policies are configured, the route target must be configured in the policies and the policy values take preference over the auto-derived route targets. The operational route target for a service is shown using the **show>service>id>bgp** command.

The **no** version of the command sets the **evi** value back to 0.

Default	no evi
Parameters	<i>value</i> — specifies the EVPN instance
Values	1 to 65535

incl-mcast-orig-ip

Syntax	incl-mcast-orig-ip <i>ip-address</i> no incl-mcast-orig-ip
Context	config>service>vpls>bgp-evpn
Description	This command specifies that the IP address configured with the command is encoded in the originating-ip field of EVPN Inclusive Multicast Routes with tunnel type Ingress Replication (IR) (value 6). The configured address does not need to be reachable in the base router or have an interface in the base router. The originating IP address is used solely for BGP route-key selection. The no version of the command withdraws the affected Inclusive Multicast Routes and readvertises the routes with the default system IP address in the originating IP field.
Default	system IP address
Parameters	<i>ip-address</i> — specifies the IPv4 address value
Values	a.b.c.d

ingress-repl-inc-mcast-advertisement

Syntax	[no] ingress-repl-inc-mcast-advertisement
Context	config>service>vpls>bgp-evpn
Description	This command enables the advertisement of the inclusive multicast Ethernet tag route with tunnel type ingress-replication in the PMSI tunnel attribute.
Default	ingress-repl-inc-mcast-advertisement

ip-route-advertisement

Syntax	ip-route-advertisement [incl-host] no ip-route-advertisement
Context	config>service>vpls>bgp-evpn
Description	This command enables or disables the advertisement of IP prefixes in EVPN. When enabled, any active route in the r-VPLS VPRN route table will be advertised in EVPN using the VPLS BGP configuration. The interface host addresses are not advertised in EVPN unless the incl-host parameter is specified.
Default	no ip-route-advertisement
Parameters	incl-host — specifies to advertise the interface host addresses in EVPN

local-ac-name

Syntax	local-ac-name ac-name no local-ac-name
Context	config>service>epipe>bgp-evpn
Description	This command enables the context and specifies the attachment circuit name in which the local Ethernet tag value is configured.
Default	no local-ac-name
Parameters	ac-name — specifies the name of the local attachment circuit

eth-tag

Syntax	eth-tag <i>tag-value</i> no eth-tag
Context	config>service>epipe>bgp-evpn>local-ac-name config>service>epipe>bgp-evpn>remote-ac-name
Description	This command configures the Ethernet tag value. When configured in the local-ac-name context, the system uses the value in the advertised AD per-EVI route sent for the attachment circuit. When configured in the remote-ac-name context , the system compares that value with the eth-tag tag-value of the imported AD per-EVI routes for the service. If there is a match, the system creates an EVPN-MPLS destination for the Epipe.
Default	none
Parameters	<i>tag-value</i> — specifies the Ethernet tag value of the attachment circuit Values 1 to 16777215

mac-advertisement

Syntax	[no] mac-advertisement
Context	config>service>vpls>bgp-evpn
Description	This command enables the advertisement in BGP of the learned MAC addresses on SAPs and SDP bindings. When the mac-advertisement command is disabled, the local MAC addresses are withdrawn in BGP.
Default	mac-advertisement

mac-duplication

Syntax	mac-duplication
Context	config>service>vpls>bgp-evpn
Description	This command enables the context to configure the BGP-EVPN MAC duplication parameters.

detect

Syntax	detect num-moves <i>num-moves</i> window <i>minutes</i>								
Context	config>service>vpls>bgp-evpn>mac-duplication								
Description	This command modifies the default behavior of the mac-duplication command. The mac-duplication feature is always enabled by default and monitors the number of moves of a MAC address for a period of time (window).								
Default	num-moves 5 window 3								
Parameters	<i>num-moves</i> — specifies the number of MAC moves in a VPLS service. The counter is incremented when a specified MAC is locally relearned in the FDB or flushed from the FDB due to the reception of a better remote EVPN route for that MAC. <table><tr><td>Values</td><td>3 to 10</td></tr><tr><td>Default</td><td>3</td></tr></table> <i>minutes</i> — specifies the duration of the window <table><tr><td>Values</td><td>1 to 15</td></tr><tr><td>Default</td><td>3</td></tr></table>	Values	3 to 10	Default	3	Values	1 to 15	Default	3
Values	3 to 10								
Default	3								
Values	1 to 15								
Default	3								

retry

Syntax	retry <i>minutes</i> no retry		
Context	config>service>vpls>bgp-evpn>mac-duplication		
Description	This command specifies the timer after which the MAC in hold-down state is automatically flushed and the MAC duplication process starts again. This value is expected to be equal to or greater than two times that of the window <i>minutes</i> . The no form of the command implies that when MAC duplication is detected, MAC updates for that MAC will be held down until the user intervenes or a network event that flushes the MAC occurs.		
Default	9		
Parameters	<i>minutes</i> — specifies the BGP EVPN MAC duplication retry <table><tr><td>Values</td><td>2 to 60</td></tr></table>	Values	2 to 60
Values	2 to 60		

mpls

Syntax	mpls
Context	config>service>epipe>bgp-evpn config>service>vpls>bgp-evpn
Description	This command enables the context to configure the BGP-EVPN MPLS parameters.

auto-bind-tunnel

Syntax	auto-bind-tunnel
Context	config>service>epipe>bgp-evpn>mpls config>service>vpls>bgp-evpn>mpls
Description	This command enables the context to configure automatic binding of a BGP-EVPN MPLS service to tunnels to MP-BGP peers.

resolution

Syntax	resolution {disabled any filter}
Context	config>service>epipe>bgp-evpn>mpls>auto-bind-tunnel config>service>vpls>bgp-evpn>mpls>auto-bind-tunnel
Description	This command configures the resolution mode in the automatic binding of a BGP-EVPN MPLS service to tunnels to MP-BGP peers. The user must configure the resolution command to enable auto-bind resolution to tunnels in the tunnel table manager (TTM). The following options are available: • disabled (explicitly set): auto-binding to the tunnel is removed • any: any supported tunnel type in the EVPN context will be selected according to TTM preference • filter: when filter and one or more tunnel types are explicitly specified under the resolution-filter command, only those tunnel types are selected according to TTM preference The user must set the resolution command to filter in order to activate the list of tunnel types configured under the resolution-filter command.
Default	disabled
Parameters	any — enables the binding to any supported tunnel type in a BGP-EVPN MPLS context following TTM preference

disabled — disables the automatic binding of a BGP-EVPN MPLS service to tunnels to MP-BGP peers

filter — enables the binding to the subset of tunnel types configured under **resolution-filter**

resolution-filter

Syntax	resolution-filter
Context	config>service>epipe>bgp-evpn>mpls>auto-bind-tunnel config>service>vpls>bgp-evpn>mpls>auto-bind-tunnel
Description	This command enables the context that allows the configuration of the subset of tunnel types that can be used in the resolution of BGP-EVPN routes within the automatic binding of BGP-EVPN MPLS service to tunnels to MP-BGP peers. The user must set the resolution command to filter in order to activate the list of tunnel types configured under the resolution-filter command. The following tunnel types are supported in a BGP-EVPN MPLS context in order of preference: RSVP, SR-TE, LDP, SR-ISIS, SR-OSPF, and BGP.

bgp

Syntax	[no] bgp
Context	config>service>epipe>bgp-evpn>mpls>auto-bind-tunnel>resolution-filter config>service>vpls>bgp-evpn>mpls>auto-bind-tunnel>resolution-filter
Description	This command selects the BGP tunnel type. The bgp command instructs BGP-EVPN to search for a BGP LSP to the address of the BGP next hop. If the user does not enable the BGP tunnel type, inter-area or inter-as prefixes will not be resolved.

ldp

Syntax	[no] ldp
Context	config>service>vpls>bgp-evpn>mpls>auto-bind-tunnel>resolution-filter config>service>epipe>bgp-evpn>mpls>auto-bind-tunnel>resolution-filter
Description	This command selects the LDP tunnel type. The ldp command instructs BGP to search for an LDP LSP with a FEC prefix corresponding to the address of the BGP next hop.

rsvp

Syntax	[no] rsvp
Context	config>service>vpls>bgp-evpn>mpls>auto-bind-tunnel>resolution-filter config>service>epipe>bgp-evpn>mpls>auto-bind-tunnel>resolution-filter
Description	This command selects the RSVP-TE tunnel type. The rsvp command instructs BGP to search for the best metric RSVP-TE LSP to the address of the BGP next hop. This address can correspond to the system interface or to another loopback address used by the BGP instance on the remote node. The LSP metric is provided by MPLS in the tunnel table. If there are multiple RSVP-TE LSPs with the same lowest metric, BGP selects the LSP with the lowest tunnel ID.

sr-isis

Syntax	[no] sr-isis
Context	config>service>vpls>bgp-evpn>mpls>auto-bind-tunnel>resolution-filter config>service>epipe>bgp-evpn>mpls>auto-bind-tunnel>resolution-filter
Description	This command selects the segment routing (SR) tunnel type programed by an IS-IS instance in the TTM. When the sr-isis or sr-ospf command is enabled, a segment routing (SR) tunnel to the BGP next hop is selected in the TTM from the lowest numbered IS-IS or OSPF instance.

sr-ospf

Syntax	[no] sr-ospf
Context	config>service>vpls>bgp-evpn>mpls>auto-bind-tunnel>resolution-filter config>service>epipe>bgp-evpn>mpls>auto-bind-tunnel>resolution-filter
Description	This command selects the segment routing (SR) tunnel type programed by an OSPF instance in the TTM. When the sr-isis or sr-ospf command is enabled, a segment routing (SR) tunnel to the BGP next hop is selected in the TTM from the lowest numbered IS-IS or OSPF instance.

sr-te

Syntax	[no] sr-te
Context	config>service>vpls>bgp-evpn>mpls>auto-bind-tunnel>resolution-filter config>service>epipe>bgp-evpn>mpls>auto-bind-tunnel>resolution-filter

Description	This command selects the segment routing traffic engineered LSP programmed in the TTM. The sr-te command instructs the code to search for the best metric SR-TE LSP to the address of the BGP next hop. The LSP metric is provided by MPLS in the tunnel table. If there are multiple SR-TE LSPs with the same lowest metric, BGP selects the LSP with the lowest tunnel ID.

control-word

Syntax	[no] control-word
Context	<pre>config>service>epipe>bgp-evpn>mpls config>service>vpls>bgp-evpn>mpls</pre>
Description	This command enables the transmission and reception of the control word. As defined in RFC 7432, the use of the control word helps avoid frame disordering. The control-word command is enabled or disabled for all EVPN-MPLS destinations at the same time.
Default	no control-word

ecmp

Syntax	ecmp <i>max-ecmp-routes</i>
Context	<pre>config>service>epipe>bgp-evpn>mpls config>service>vpls>bgp-evpn>mpls</pre>
Description	This command controls the number of paths allowed to reach a specified MAC address when that MAC in the FDB is associated with a remote all-active multihomed Ethernet segment. The configuration of two or more ECMP paths to a specified MAC enables the aliasing function described in RFC 7432.
Default	0
Parameters	<i>max-ecmp-routes</i> — specifies the number of paths allowed to the same multihomed MAC address, assuming the MAC is located in an all-active multihomed Ethernet segment Values 0 to 8

entropy-label

Syntax	[no] entropy-label

Context	config>service>vpls>bgp-evpn>mpls config>service>epipe>bgp-evpn>mpls
Description	This command inserts the entropy label (EL) and entropy label indicator (ELI) in packets for which at least one LSP in the stack for the far end of the tunnel used by the service has advertised entropy-label capability. If the tunnel is the rsvp type, entropy-label can also be controlled under the config>router>mpls or config>router>mpls>lsp context.
Default	no entropy-label

force-vlan-vc-forwarding

Syntax	[no] force-vlan-vc-forwarding
Context	config>service>epipe>bgp-evpn>mpls config>service>vpls>bgp-evpn>mpls
Description	This command allows the system to preserve the VLAN ID and 802.1p bits of the service-delimiting qtag in a new tag added in the customer frame before sending it to the EVPN-MPLS destinations. This command may be used in conjunction with the sap ingress vlan-translation command. If it is used, the configured translated VLAN ID will be the VLAN ID sent to the EVPN-MPLS destinations as opposed to the service-delimiting tag VLAN ID. If the ingress SAP or SDP binding is null-encapsulated, the output VLAN ID and P-bits will be 0.
Default	no force-vlan-vc-forwarding

ingress-replication-bum-label

Syntax	[no] ingress-replication-bum-label
Context	config>service>vpls>bgp-evpn>mpls
Description	This command allows the user to configure the system so that a separate label is sent for BMU (broadcast, multicast, and unknown unicast) traffic in a specified service. By default, the same label is used for unicast and flooded BMU packets when forwarding traffic to remote PEs. When saving label space, this might cause transient packet duplication for all-active multihoming. By enabling ingress-replication-bum-label, the system will advertise two labels per EVPN VPLS instance, one for unicast and one for BMU traffic. The ingress PE will use the BMU label for flooded traffic to the advertising egress PE so that the egress PE can determine if the unicast traffic has been flooded by the ingress PE. Depending on the scale required in the network, the user may choose between saving label space or avoiding transient packet duplication sent to an all-active multihomed CE for certain MAC addresses.
Default	no ingress-replication-bum-label

shutdown

Syntax	[no] shutdown
Context	config>service>epipe>bgp-evpn>mpls config>service>vpls>bgp-evpn>mpls
Description	This command controls the administrative state of EVPN-MPLS in the service.

split-horizon-group

Syntax	split-horizon-group <i>name</i> no split-horizon-group
Context	config>service>vpls>bgp-evpn>mpls
Description	This command allows the user to configure an explicit split horizon group for all BGP-EVPN MPLS destinations that can be shared by other SAPs and spoke SDPs. The use of explicit split horizon groups for EVPN-MPLS and spoke SDPs allows the integration of VPLS and EVPN-MPLS networks. If the split-horizon-group command under bgp-evpn>mpls is not used, the default split horizon group that contains all the EVPN destinations is still used, but it is not possible to refer to it on SAPs or spoke SDPs. Split horizon groups can be configured within the service context. The same group name can be associated with SAPs, spoke SDPs, and EVPN-MPLS destinations. The configuration of bgp-evpn>mpls>split-horizon-group will only be allowed if bgp-evpn>mpls is shutdown; no changes are allowed when bgp-evpn>mpls is no shutdown. When the SAPs or spoke SDPs are configured within the same split horizon group as the EVPN-MPLS endpoints, MAC addresses are still learned on them but they are not advertised in BGP-EVPN.
Default	no split-horizon-group
Parameters	<i>name</i> — specifies the split horizon group name

remote-ac-name

Syntax	remote-ac-name <i>ac-name</i> no remote-ac-name
Context	config>service>epipe>bgp-evpn
Description	This command enables the context and specifies the attachment circuit name in which the remote Ethernet tag value is configured.
Default	no remote-ac-name

Parameters *ac-name* — specifies the name of the remote attachment circuit

static-mac

Syntax **static-mac**

Context config>service>vpls

Description This command enables the context that allows the assignment of a set of conditional static MAC addresses to a SAP, spoke SDP, or **black-hole**. In the FDB, the static MAC address is then associated with the active SAP or spoke SDP.

A set of conditional static MAC addresses can be created within a VPLS supporting BGP-EVPN. Unless they are configured as **black-hole**, conditional static MAC addresses are dependent on the SAP or SDP state.

Static MAC addresses configured in a BGP-EVPN service are advertised as protected (EVPN signals the MAC address as protected).

mac

Syntax **mac** *ieee-address* [**create**] **black-hole**
mac *ieee-address* [**create**] **sap** *sap-id* **monitor** {**fwd-status**}
mac *ieee-address* [**create**] **spoke-sdp** *sdp-id:vc-id* **monitor** {**fwd-status**}
no mac *ieee-address*

Context config>service>vpls>static-mac

Description This command assigns a conditional static MAC address entry to an EVPN VPLS SAP, spoke SDP, or a black hole on the 7705 SAR.

Parameters *ieee-address* — specifies the static MAC address to SAP, SDP binding, or black hole

Values 6-byte MAC address (xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx); cannot be all zeros

sap-id — specifies the SAP ID

sdp-id — specifies the SDP ID

vc-id — specifies the virtual circuit ID

create — mandatory keyword while creating a static MAC

black-hole — creates a static FDB entry for the MAC address to blackhole traffic

fwd-status — specifies that this static MAC address will be installed in the FDB based on the forwarding status of the SAP or spoke SDP

10.5.2.2 Routed VPLS EVPN Commands

evpn-tunnel

Syntax	[no] evpn-tunnel
Context	config>service>vpn>if>vpls
Description	This command enables or disables EVPN tunnel mode for the attached r-VPLS interface. When enabled, no IP address is required for the interface. The no version of the command disables EVPN tunnel mode.
Default	no evpn-tunnel

10.5.2.3 EVPN Service System Commands

bgp-evpn

Syntax	[no] bgp-evpn
Context	config>service>system
Description	This command enables the context to configure the BGP-EVPN parameters in the base instance.

ad-per-es-route-target

Syntax	ad-per-es-route-target evi-rt ad-per-es-route-target evi-rt-set route-distinguisher <i>ip-address</i>
Context	config>service>system>bgp-evpn
Description	This command controls how Ethernet auto-discovery (AD) per-ES routes are generated. The system can send either a separate Ethernet AD per-ES route per service or several Ethernet AD per-ES routes aggregating the route targets for multiple services. While the two methods can interoperate, RFC 7432 states that the EVPN AD per-ES route must be sent with a set of route targets corresponding to all the EVIs defined on the Ethernet segment. Either method can be enabled using the evi-rt and evi-rt-set options. The default option, evi-rt, configures the system to send a separate Ethernet AD per-ES route per service. The evi-rt-set option, when enabled, allows the aggregation of routes; that is, a single AD per-ES route with the associated RD (<i>ip-address:1</i>) and a set of EVI route targets are advertised (to a maximum of 128 route targets). If the number of EVIs defined in the Ethernet segment is significantly large for the packet size, the system will send more than one route. For example: • AD per-ES route for EVI-route-set 1 is sent with RD <i>ip-address:1</i> • AD per-ES route for EVI-route-set 2 is sent with RD <i>ip-address:2</i>
Default	ad-per-es-route-target evi-rt
Parameters	evi-rt — specifies the option to advertise a separate AD per-ES route per service evi-rt-set — specifies the option to advertise a set of AD per-ES routes aggregating the route targets for all the services in the Ethernet segment <i>ip-address</i> — specifies the IP address part of the route distinguisher (RD) being used in the evi-rt-set option

ethernet-segment

Syntax	ethernet-segment <i>name</i> [create] no ethernet-segment <i>name</i>
Context	config>service>system>bgp-evpn
Description	This command configures an Ethernet segment instance and its corresponding name. When a port or LAG is added, the type and encap-type values are checked. If the encap-type is dot1q , only the dot1q node can be configured; the qinq context is not allowed. If the encap-type is qinq , only the QinQ node is allowed. A dot1q , qinq , or vc-id range is required for a virtual ES to be operationally active.
Default	None
Parameters	<i>name</i> — specifies the ES name (28 characters maximum) create — mandatory keyword for creating an ES

es-activation-timer

Syntax	es-activation-timer <i>seconds</i> no es-activation-timer				
Context	config>service>system>bgp-evpn>ethernet-segment				
Description	This command configures the activation timer for a specified Ethernet segment. This timer delays the activation of the Ethernet segment on a specified PE that has been elected as the designated forwarder (DF). Only when the timer has expired can the SAP associated with an Ethernet segment be activated (for single-active multihoming) or added to the default multicast list (for all-active multihoming). If this command is not configured, the system uses the value configured in the config>redundancy>bgp-evpn-multi-homing>es-activation-timer context, if it has been configured. Otherwise, the system uses the default value of 3 seconds.				
Default	no es-activation-timer				
Parameters	<i>seconds</i> — specifies the delay time for the ES activation timer <table> <tr> <td>Values</td><td>0 to 100</td></tr> <tr> <td>Default</td><td>3</td></tr> </table>	Values	0 to 100	Default	3
Values	0 to 100				
Default	3				

esi

Syntax	esi <i>esi</i> no esi
Context	config>service>system>bgp-evpn>ethernet-segment
Description	This command configures the 10-byte Ethernet segment identifier (ESI) associated with the Ethernet segment that is signaled in the BGP-EVPN routes. The <i>esi</i> value cannot be changed unless the Ethernet segment is shutdown . Reserved <i>esi</i> values (ESI-0 and ESI-MAX) are not allowed.
Default	no esi
Parameters	<i>esi</i> — specifies the 10-byte ESI Values <i>xx-xx-xx-xx-xx-xx-xx-xx-xx-xx</i> , where <i>xx</i> is a hexadecimal number (00 to ff) and the separator is a dash ("-"), colon (":"), or space (" ") For example, 00-11-22-33-44-55-66-77-88-99

lag

Syntax	lag <i>lag-id</i> no lag
Context	config>service>system>bgp-evpn>ethernet-segment
Description	This command configures a LAG ID associated with the Ethernet segment. If the Ethernet segment is configured as all-active , only a LAG can be associated with the Ethernet segment. If the Ethernet segment is configured as single-active , a LAG, port, or SDP can be associated with the Ethernet segment. A specified LAG can be part of only one Ethernet segment.
Default	no lag
Parameters	<i>lag-id</i> — specifies the LAG ID associated with the Ethernet segment Values 1 to 800

multi-homing

Syntax	multi-homing single-active [no-esi-label] multi-homing all-active no multi-homing
Context	config>service>system>bgp-evpn>ethernet-segment

Description	This command configures the multihoming mode for the Ethernet segment as single-active or all-active multihoming, as defined in RFC 7432. By default, the use of an ESI label is enabled for all-active and single-active as defined in RFC 7432 (for single-active multihoming, the ESI label is used to avoid transient loops). When single-active no-esi-label is specified, the system does not allocate a label for the ESI and advertises ESI label 0 to peers. Even if the ESI is configured not to send the ESI label, upon receiving an ESI label from a peer, the PE always sends traffic to that peer using the received ESI label.
Default	no multi-homing
Parameters	single-active — configures single-active mode for the Ethernet segment all-active — configures single-active mode for the Ethernet segment no-esi-label — configures single-active mode without adding an ESI label for the Ethernet segment

port

Syntax	port <i>port-id</i> no port												
Context	config>service>system>bgp-evpn>ethernet-segment												
Description	This command configures a port ID associated with the Ethernet segment. If the Ethernet segment is configured as all-active , only a LAG can be associated with the Ethernet segment. If the Ethernet segment is configured as single-active , a LAG, port, or SDP can be associated with the Ethernet segment. A specified port can be part of only one Ethernet segment. Only Ethernet ports can be added to an Ethernet segment.												
Default	no port												
Parameters	<i>port-id</i> — specifies the port ID associated with the Ethernet segment <table><tr><td><i>port-id</i></td><td><i>slot/mda/port</i></td><td></td><td></td></tr><tr><td></td><td><i>mw-link-id</i></td><td><i>mw-link-link-num</i></td><td></td></tr><tr><td></td><td></td><td><i>link-num</i></td><td>1 to 24</td></tr></table>	<i>port-id</i>	<i>slot/mda/port</i>				<i>mw-link-id</i>	<i>mw-link-link-num</i>				<i>link-num</i>	1 to 24
<i>port-id</i>	<i>slot/mda/port</i>												
	<i>mw-link-id</i>	<i>mw-link-link-num</i>											
		<i>link-num</i>	1 to 24										

sdp

Syntax	sdp <i>sdp-id</i> no sdp
Context	config>service>system>bgp-evpn>ethernet-segment

Description	This command configures an SDP ID associated with the Ethernet segment. If the Ethernet segment is configured as all-active , only a LAG can be associated with the Ethernet segment. If the Ethernet segment is configured as single-active , a LAG, port, or SDP can be associated with the Ethernet segment. A specified SDP can be part of only one Ethernet segment. Only user-configured SDPs can be added to an Ethernet segment.
Default	no sdp
Parameters	<i>sdp-id</i> — specifies the SDP identifier
Values	1 to 17407

service-carving

Syntax	service-carving
Context	config>service>system>bgp-evpn>ethernet-segment
Description	This command enables the context to configure service carving in the Ethernet segment. The service-carving algorithm determines which PE is the DF in a specified Ethernet segment and for a specific service.

manual

Syntax	manual
Context	config>service>system>bgp-evpn>ethernet-segment>service-carving
Description	This command enables the context to manually configure the service-carving algorithm, that is, to configure the EVIs for which the PE is the DF.

evi

Syntax	evi start [to to] primary no evi start
Context	config>service>system>bgp-evpn>ethernet-segment>service-carving>manual
Description	This command configures the EVI values and ranges for which the PE is primary.

Note: Multiple individual **evi** values and ranges are allowed. Each value and range requires a separate use of the **evi** command.

Default	none

Parameters	<i>start</i> — specifies the initial evi value of the range Values 1 to 65535 <i>to</i> — specifies the end evi value of the range. If not configured, only the individual start value is considered. Values 1 to 65535 primary — mandatory keyword to specify that the PEs are primary EVIs

mode

Syntax	mode { manual auto off }
Context	config>service>system>bgp-evpn>ethernet-segment>service-carving
Description	This command configures the service-carving mode. This determines how the DF is elected for a specified Ethernet segment and service.
Default	mode auto
Parameters	auto — specifies that the service-carving algorithm is as defined in RFC 7432. The DF for the service is calculated based on the modulo function of the service (identified by the evi value) and the number of PEs. manual — specifies that the DF is elected based on the configuration of the manual command in the service-carving>manual context off — specifies that all the services elect the same DF PE, assuming that the same PEs are active for all the configured services. The PE with the lowest IP address is elected as DF for the Ethernet segment.

shutdown

Syntax	[no] shutdown
Context	config>service>system>bgp-evpn>ethernet-segment
Description	This command changes the administrative status of the Ethernet segment. The user can configure no shutdown only when the esi, multi-homing, and lag, port, or sdp commands are configured. If the Ethernet segment or the corresponding lag, port, or sdp is shutdown, the Ethernet segment route and the AD per-ES routes will be withdrawn. No changes are allowed when the Ethernet segment is no shutdown.
Default	shutdown

route-distinguisher

Syntax	route-distinguisher <i>rd</i> no route-distinguisher
Context	config>service>system>bgp-evpn
Description	This command configures the route distinguisher (RD) component that is signaled in the MP-BGP NLRI for EVPN corresponding to the base EVPN instance (route type 4, Ethernet Segment routes). If the route distinguisher component is not configured, the system uses the system IP address as the default route distinguisher for the IP address portion of the RD.
Default	system-ip:0
Parameters	<i>rd</i> — specifies the IP address Values <i>ip-addr</i> : a.b.c.d <i>comm-val</i> : 0 to 65535

10.5.2.4 EVPN Redundancy Commands

redundancy

Syntax	redundancy
Context	config
Description	This command enables the context to configure the global redundancy parameters.

bgp-evpn-multi-homing

Syntax	bgp-evpn-multi-homing
Context	config>redundancy
Description	This command enables the context to configure the BGP-EVPN global timers.

boot-timer

Syntax	boot-timer <i>seconds</i>
Context	config>redundancy>bgp-evpn-multihoming
Description	This command allows the necessary time during PE boot-up for the control plane protocols to come up before bringing up the Ethernet segments and running the DF algorithm. The following considerations apply to the functionality. • The configured boot-timer value must provide enough time to allow the IOM and BGP sessions to come up before exchanging ES routes and running the DF election for each EVI. • The boot timer is synchronized across CSMs and is relative to the system up time; therefore, it is not subject to change or reset upon CSM switchover. • The boot timer is never interrupted. However, the es-activation-timer can be interrupted if a new event triggers the DF election. • The boot timer runs per EVI on the ESs in the system. While the timer is running, the system does not run the DF election for any EVI. When the boot timer expires, the DF election for the EVI is run, and if the system is elected DF for the EVI, the es-activation-timer activates. • The system does not advertise ES routes until the boot timer has expired. This guarantees that the peer ES PEs do not run the DF election until the PE is ready to become the DF, if required.
Default	boot-timer 10

Parameters	<i>seconds</i> — specifies the delay time used for the boot timer
Values	0 to 600

es-activation-timer

Syntax	es-activation-timer <i>seconds</i>
Context	config>redundancy>bgp-evpn-multi-homing
Description	This command configures the global Ethernet segment activation timer. The timer delays the activation of an Ethernet segment on a specified PE that has been elected as DF. Only when the es-activation-timer has expired can the SAP or SDP binding associated with an Ethernet segment be activated (for single-active multihoming) or added to the default multicast list (for all-active multihoming). The es-activation-timer configured at the ethernet-segment level supersedes this global es-activation-timer.
Default	es-activation-timer 3
Parameters	<i>seconds</i> — specifies the delay time for the ES activation timer
	Values 0 to 100

10.5.2.5 Show Commands

evpn-mpls

Syntax	evpn-mpls [<i>tep-ip-address</i>]
Context	show>service
Description	This command displays the remote EVPN-MPLS tunnel endpoints in the system.
Parameters	<i>tep-ip-address</i> — specifies the IP address of a tunnel endpoint
	Values a.b.c.d
Output	The following output is an example of EVPN-MPLS tunnel endpoint information, and Table 200 describes the fields.

Output Example

```
*A:PE70(4)# show service evpn-mpls

bgp-evpn

Syntax **bgp-evpn**

Context show>service>id

Description This command displays the BGP-EVPN parameters configured for a specified service, including the configuration of the **mac-advertisement** command, as well as the **mac-duplication** parameters. The command shows the duplicate MAC addresses that **mac-duplication** has detected.

This command also shows whether the **ip-route-advertisement** command (and the **incl-host** parameter) is enabled. If the service is BGP-EVPN MPLS, the command also shows the parameters corresponding to EVPN-MPLS.

Output The following output is an example of service BGP-EVPN information, and [Table 202](#) describes the fields.

Output Example

```
*A:DutA# show service id 1 bgp-evpn

Table 202 Service BGP-EVPN Field Descriptions

Label	Description
BGP EVPN Table	
MAC Advertisement	The state of MAC advertising for the service
Unknown MAC Route	Not applicable
CFM MAC Advertise	The state of the IEEE MAC address associated with the MEP created on a SAP in an EVPN service
VXLAN Admin Status	Not applicable
Creation Origin	Indicates whether the route creation was manual or automatic
MAC Dup Detn Moves	The number of detected moves of a MAC address for the period of time defined by the window parameter
MAC Dup Detn Window	The period of time defined by the window parameter for MAC duplication detection

Table 202 Service BGP-EVPN Field Descriptions (Continued)

Label	Description
MAC Dup Detn Retry	The period of time after which the MAC in hold-down state is automatically flushed and the MAC duplication process starts again
Number of Dup MACs	The number of duplicate MAC addresses detected
IP Route Advertise*	Not applicable
EVI	The EVPN instance
Ing Rep Inc McastAd	The state of the advertisement of the inclusive multicast Ethernet tag route with tunnel type ingress-replication in the PMSI tunnel attribute
Detected Duplicate MAC Addresses	The MAC address of detected duplicate MACs
Time Detected	The time that the duplicated MAC address was detected
BGP EVPN MPLS Information	
Admin Status	The administrative status of the transport tunnel
Force Vlan Fwding	Indicates whether forced VLAN forwarding is enabled or disabled
Control Word	Indicates whether the control word for the service is enabled or disabled
Split Horizon Group	The name of the split horizon group for all BGP-EVPN MPLS destinations that can be shared by other SAPs and spoke SDPs
Ingress Rep BUM Lbl	Indicates whether sending a separate label for BMU (broadcast, multicast, and unknown unicast) traffic in a specified service—in addition to a label for unicast traffic—is enabled or disabled
Max Ecmp Routes	The number of paths allowed to reach a specified MAC address when that MAC address in the FDB is associated with a remote all-active multihomed Ethernet segment
Ingress Ucast Lbl	The number of ingress unicast labels received
Ingress Mcast Lbl	The number of ingress multicast labels received
Entropy Label	Indicates whether the insertion of the entropy label (EL) and entropy label indicator (ELI) in packets for which at least one LSP in the stack for the far end of the tunnel used by the service has advertised entropy-label capability is enabled or disabled

Table 202 Service BGP-EVPN Field Descriptions (Continued)

Label	Description
BGP EVPN MPLS Auto Bind Tunnel Information	
Resolution	The configuration of the auto-bind-tunnel command (disabled, any, or filter)
Filter Tunnel Types	The tunnel types that can be used in the resolution of BGP-EVPN routes within the automatic binding of BGP-EVPN MPLS service to tunnels to MP-BGP peers

ethernet-segment

Syntax	ethernet-segment [<i>ethernet-segment-name</i>]
Context	show>service>id
Description	This command displays the SAP and SDP Ethernet segment information.
Parameters	<i>ethernet-segment-name</i> — specifies the name of the Ethernet segment for which the information is displayed
Output	The following output is an example of service Ethernet segment information, and Table 203 describes the fields.

Output Example

Eth-Seg	The Ethernet segment name associated with the specified SDP

evpn-mpls

Syntax **evpn-mpls**
evpn-mpls esi esi

Context show>service>id

Description This command displays the existing EVPN-MPLS destinations for a specified service and all related information. The command allows filtering based on the **esi esi** value (for EVPN multihoming) to display the EVPN-MPLS destinations associated with an ESI.

Parameters *esi* — specifies a 10-byte Ethernet segment identifier (ESI) by which to filter the displayed information

Values ESI-0, ESI-MAX, or xx-xx-xx-xx-xx-xx-xx-xx-xx, where xx is a hexadecimal number (00 to ff) and the separator is a dash ("-"), colon (":"), or space (" ")
 For example, 00-11-22-33-44-55-66-77-88-99

ieee-address — specifies a 48-bit MAC address by which to filter information. The parameter is entered in the form xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx, where xx is a hexadecimal number.

Output The following output is an example of service EVPN-MPLS information, and [Table 204](#) describes the fields.

Output Example

```

Table 204 Service ID EVPN-MPLS Field Descriptions

Label	Description
BGP EVPN-MPLS Dest	
TEP Address	The tunnel endpoint address
Egr Label	The egress label for the tunnel endpoint
Transport	The type of transport tunnel for the tunnel endpoint
Num. MACs	The number of MAC addresses associated with the transport tunnel
Mcast	Indicates whether multicast is used
Last Change	The time of the last change to the transport tunnel
BGP EVPN-MPLS Ethernet Segment Dest	
Eth SegId	The Ethernet segment ID of the tunnel endpoint
Num. Macs	The number of MAC addresses associated with the transport endpoint
Last Change	The time of the last change to the transport endpoint
BGP EVPN-MPLS ES BMAC Dest	
vBmacAddr	Not applicable
Num. Macs	Not applicable
Last Change	Not applicable

system

Syntax **system**

Context show>service

Description This command enables the context to display the service system parameters.

bgp-evpn

Syntax	bgp-evpn bgp-evpn ethernet-segment bgp-evpn ethernet-segment name <i>name</i> [all] bgp-evpn ethernet-segment name <i>name</i> evi [<i>evi</i>]
Context	show>service>system
Description	This command shows all the information related to the base EVPN instance, including the base RD used for ES routes, Ethernet segments, or individual Ethernet segment information.
Parameters	ethernet-segment — displays information for BGP-EVPN Ethernet segments <i>name</i> — specifies the name of an Ethernet segment for which to show information all — displays all available information for the specified Ethernet segment <i>evi</i> — displays information for the specified EVI Values 1 to 65535
Output	The following outputs are examples of service system BGP-EVPN information: • service system BGP-EVPN (Output Example, Table 205) • service system BGP-EVPN Ethernet segment name all (Output Example, Table 206) • service system BGP-EVPN Ethernet segment name (Output Example, Table 207)

Output Example

```

Table 207 Service System BGP Route Distinguisher Field Descriptions

Label	Description
Service Route Distinguishers	
Svc Id	The service ID
Type	The service type
Oper Route-Distinguisher	The operational route distinguisher
Route-Distinguisher	The type of route distinguisher
Service System BGP Route Distinguisher Information	
Oper Route Distinguisher	The operational route distinguisher for the BGP route distinguisher for the service system
Type	The type of BGP route distinguisher for the service system
BGP EVPN Ethernet Segment AD EVI RT Set Route Distinguishers	
Eth Seg	The Ethernet segment name for the AD EVI RT set
EVI	The EVI ID for the AD EVI RT set
Svc ID	The service ID associated with the AD EVI RT set
Route Distinguisher	The route distinguisher for the AD EVI RT set

redundancy

Syntax	redundancy
Context	show
Description	This command enables the context for the display of global redundancy parameters.

bgp-evpn-multi-homing

Syntax	bgp-evpn-multi-homing
Context	show>redundancy
Description	This command shows the information related to the EVPN global timers.
Output	The following output is an example of BGP-EVPN multihoming information, and Table 208 describes the fields.

Output Example

```

*A:PE2# show redundancy bgp-evpn-multi-homing
=====
Redundancy BGP EVPN Multi-homing Information
=====
Boot-Timer           : 10 secs
Boot-Timer Remaining : 0 secs

```

Table 208 Redundancy BGP-EVPN Multihoming Field Descriptions

Label	Description
Redundancy BGP EVPN Multi-homing Information	
Boot-Timer	The value of the BGP EVPN boot timer
Boot-Timer Remaining	The time remaining on the BGP EVPN boot timer
ES Activation Timer	The value of the Ethernet segment activation timer

11 List of Acronyms

Table 209 **Acronyms**

Acronym	Expansion
2G	second generation wireless telephone technology
3DES	triple DES (data encryption standard)
3G	third generation mobile telephone technology
6VPE	IPv6 on Virtual Private Edge Router
7705 SAR	7705 Service Aggregation Router
7750 SR	7750 Service Router
8 PSK	eight phase shift keying
16 QAM	16-state quadrature amplitude modulation
32 QAM	32-state quadrature amplitude modulation
64 QAM	64-state quadrature amplitude modulation
128 QAM	128-state quadrature amplitude modulation
256 QAM	256-state quadrature amplitude modulation
ABR	area border router available bit rate
AC	alternating current attachment circuit
ACK	acknowledge
ACL	access control list
ACR	adaptive clock recovery
AD	auto-discovery
ADM	add/drop multiplexer
ADP	automatic discovery protocol
AES	advanced encryption standard
AFI	authority and format identifier
AIGP	accumulated IGP
AIS	alarm indication signal

Table 209 Acronyms (Continued)

Acronym	Expansion
ALG	application level gateway
ANSI	American National Standards Institute
Apipe	ATM VLL
APS	automatic protection switching
ARP	address resolution protocol
A/S	active/standby
AS	autonomous system
ASAP	any service, any port
ASBR	autonomous system boundary router
ASM	any-source multicast autonomous system message
ASN	autonomous system number
ATM	asynchronous transfer mode
ATM PVC	ATM permanent virtual circuit
AU	administrative unit
AUG	administrative unit group
B3ZS	bipolar with three-zero substitution
Batt A	battery A
B-bit	beginning bit (first packet of a fragment)
BBE	background block errors
Bc	committed burst size
Be	excess burst size
BECN	backward explicit congestion notification
Bellcore	Bell Communications Research
BFD	bidirectional forwarding detection
BGP	border gateway protocol
BGP-LS	border gateway protocol link state
BGP-LU	border gateway protocol labeled unicast

Table 209 Acronyms (Continued)

Acronym	Expansion
BITS	building integrated timing supply
BMCA	best master clock algorithm
BMU	broadcast, multicast, and unknown traffic Traffic that is not unicast. Any nature of multipoint traffic: • broadcast (that is, all 1s as the destination IP to represent all destinations within the subnet) • multicast (that is, traffic typically identified by the destination address, uses special destination address); for IP, the destination must be 224.0.0.0 to 239.255.255.255 • unknown (that is, the destination is typically a valid unicast address but the destination port/interface is not yet known; therefore, traffic needs to be forwarded to all destinations; unknown traffic is treated as broadcast)
BNM	bandwidth notification message
BOF	boot options file
BoS	bottom of stack
BPDU	bridge protocol data unit
BRAS	Broadband Remote Access Server
BSC	Base Station Controller
BSM	bootstrap message
BSR	bootstrap router
BSTA	Broadband Service Termination Architecture
BTS	base transceiver station
CA	certificate authority
CAS	channel associated signaling
CBN	common bonding networks
CBS	committed buffer space
CC	continuity check control channel
CCM	continuity check message
CCTV	closed-circuit television

Table 209 Acronyms (Continued)

Acronym	Expansion
CE	circuit emulation customer edge
CEM	circuit emulation
CES	circuit emulation services
CESoPSN	circuit emulation services over packet switched network
CFM	connectivity fault management
cHDLC	Cisco high-level data link control protocol
CIDR	classless inter-domain routing
CIR	committed information rate
CLI	command line interface
CLP	cell loss priority
CMP	certificate management protocol
C-multicast	customer multicast
CoS	class of service
CPE	customer premises equipment
Cpipe	circuit emulation (or TDM) VLL
CPM	Control and Processing Module (CPM is used instead of CSM when referring to CSM filtering to align with CLI syntax used with other SR products). CSM management ports are referred to as CPM management ports in the CLI.
CPROTO	C prototype
CPU	central processing unit
C/R	command/response
CRC	cyclic redundancy check
CRC-32	32-bit cyclic redundancy check
CRL	certificate revocation list
CRON	a time-based scheduling service (from chronos = time)
CRP	candidate RP
CSM	Control and Switching Module

Table 209 Acronyms (Continued)

Acronym	Expansion
CSNP	complete sequence number PDU
CSPF	constrained shortest path first
C-TAG	customer VLAN tag
CV	connection verification customer VLAN (tag)
CW	control word
CWDM	coarse wavelength-division multiplexing
DA/FAN	distribution automation and field area network
DC	direct current
DC-C	DC return - common
DCE	data communications equipment
DC-I	DC return - isolated
DCO	digitally controlled oscillator
DCR	differential clock recovery
DDoS	distributed DoS
DE	discard eligibility
DER	distinguished encoding rules
DES	data encryption standard
DF	do not fragment designated forwarder
DH	Diffie-Hellman
DHB	decimal, hexadecimal, or binary
DHCP	dynamic host configuration protocol
DHCPv6	dynamic host configuration protocol for IPv6
DIS	designated intermediate system
DLCI	data link connection identifier
DLCMI	data link connection management interface
DM	delay measurement

Table 209 Acronyms (Continued)

Acronym	Expansion
DNS	domain name server
DNU	do not use
DoS	denial of service
dot1p	IEEE 802.1p bits, in Ethernet or VLAN ingress packet headers, used to map traffic to up to eight forwarding classes
dot1q	IEEE 802.1q encapsulation for Ethernet interfaces
DPD	dead peer detection
DPI	deep packet inspection
DPLL	digital phase locked loop
DR	designated router
DSA	digital signal algorithm
DSCP	differentiated services code point
DSL	digital subscriber line
DSLAM	digital subscriber line access multiplexer
DTE	data termination equipment
DU	downstream unsolicited
DUID	DHCP unique identifier
DUS	do not use for synchronization
DV	delay variation
DVMRP	distance vector multicast routing protocol
e911	enhanced 911 service
EAP	Extensible Authentication Protocol
EAPOL	EAP over LAN
E-bit	ending bit (last packet of a fragment)
E-BSR	elected BSR
ECMP	equal cost multipath
EE	end entity
EFM	Ethernet in the first mile

Table 209 Acronyms (Continued)

Acronym	Expansion
EGP	exterior gateway protocol
EIA/TIA-232	Electronic Industries Alliance/Telecommunications Industry Association Standard 232 (also known as RS-232)
EIR	excess information rate
EJBCA	Enterprise Java Bean Certificate Authority
E-LAN	Ethernet local area network
E-Line	Ethernet virtual private line
EL	entropy label
eLER	egress label edge router
ELI	entropy label indicator
E&M	ear and mouth earth and magneto exchange and multiplexer
eMBMS	evolved MBMS
EOP	end of packet
EPC	evolved packet core
EPD	early packet discard
Epipe	Ethernet VLL
EPL	Ethernet private line
EPON	Ethernet Passive Optical Network
EPS	equipment protection switching
ERO	explicit route object
ES	Ethernet segment errored seconds
ESD	electrostatic discharge
ESI	Ethernet segment identifier
ESMC	Ethernet synchronization message channel
ESN	extended sequence number
ESP	encapsulating security payload

Table 209 Acronyms (Continued)

Acronym	Expansion
ESPI	encapsulating security payload identifier
ETE	end-to-end
ETH-BN	Ethernet bandwidth notification
ETH-CFM	Ethernet connectivity fault management (IEEE 802.1ag)
EVC	Ethernet virtual connection
EVDO	evolution - data optimized
EVI	EVPN instance
EVPL	Ethernet virtual private link
EVPN	Ethernet virtual private network
EXP bits	experimental bits (currently known as TC)
FC	forwarding class
FCS	frame check sequence
FD	frequency diversity
FDB	forwarding database
FDL	facilities data link
FEAC	far-end alarm and control
FEC	forwarding equivalence class
FECN	forward explicit congestion notification
FeGW	far-end gateway
FEP	front-end processor
FF	fixed filter
FFD	fast fault detection
FIB	forwarding information base
FIFO	first in, first out
FIPS-140-2	Federal Information Processing Standard publication 140-2
FNG	fault notification generator
FOM	figure of merit

Table 209 Acronyms (Continued)

Acronym	Expansion
Fpipe	frame relay VLL
FQDN	fully qualified domain name
FR	frame relay
FRG bit	fragmentation bit
FRR	fast reroute
FTN	FEC-to-NHLFE
FTP	file transfer protocol
FXO	foreign exchange office
FXS	foreign exchange subscriber
GFP	generic framing procedure
GigE	Gigabit Ethernet
GLONASS	Global Navigation Satellite System (Russia)
GNSS	global navigation satellite system (generic)
GPON	Gigabit Passive Optical Network
GPRS	general packet radio service
GPS	Global Positioning System
GRE	generic routing encapsulation
GRT	global routing table
GSM	Global System for Mobile Communications (2G)
GTP-U	GPRS tunneling protocol user plane
GW	gateway
HA	high availability
HCM	high capacity multiplexing
HDB3	high density bipolar of order 3
HDLC	high-level data link control protocol
HEC	header error control
HMAC	hash message authentication code

Table 209 Acronyms (Continued)

Acronym	Expansion
Hpipe	HDLC VLL
H-QoS	hierarchical quality of service
HSB	hot standby
HSDPA	high-speed downlink packet access
HSPA	high-speed packet access
H-VPLS	hierarchical virtual private line service
IANA	internet assigned numbers authority
IBN	isolated bonding networks
ICB	inter-chassis backup
ICMP	Internet control message protocol
ICMPv6	Internet control message protocol for IPv6
ICP	IMA control protocol cells
IDS	intrusion detection system
IDU	indoor unit
IED	intelligent end device
IEEE	Institute of Electrical and Electronics Engineers
IEEE 1588v2	Institute of Electrical and Electronics Engineers standard 1588-2008
IES	Internet Enhanced Service
IETF	Internet Engineering Task Force
IGMP	Internet group management protocol
IGP	interior gateway protocol
IID	instance ID
IKE	Internet key exchange
iLER	ingress label edge router
ILM	incoming label map
IMA	inverse multiplexing over ATM
IMET-IR	inclusive multicast Ethernet tag—ingress replication

Table 209 Acronyms (Continued)

Acronym	Expansion
INVARP	inverse address resolution protocol
IOM	input/output module
IP	Internet Protocol
IPCP	Internet Protocol Control Protocol
IPIP	IP in IP
Ipipe	IP interworking VLL
I-PMSI	inclusive PMSI
IPoATM	IP over ATM
IPS	intrusion prevention system
IPSec	Internet Protocol security
IR	ingress replication
IRB	integrated routing and bridging
ISA	integrated services adapter
ISAKMP	Internet security association and key management protocol
IS-IS	Intermediate System-to-Intermediate System
IS-IS-TE	IS-IS-traffic engineering (extensions)
ISO	International Organization for Standardization
IW	interworking
JP	join prune
KG	key group
LB	loopback
lbf-in	pound force inch
LBM	loopback message
LBO	line buildout
LBR	loopback reply
LCP	link control protocol
LDP	label distribution protocol

Table 209 Acronyms (Continued)

Acronym	Expansion
LER	label edge router
LFA	loop-free alternate
LFIB	label forwarding information base
LIB	label information base
LLDP	link layer discovery protocol
LLDPDU	link layer discovery protocol data unit
LLF	link loss forwarding
LLID	loopback location ID
LM	loss measurement
LMI	local management interface
LOS	line-of-sight loss of signal
LSA	link-state advertisement
LSDB	link-state database
LSP	label switched path link-state PDU (for IS-IS)
LSPA	LSP attributes
LSR	label switch router link-state request
LSU	link-state update
LT	linktrace
LTE	long term evolution line termination equipment
LTM	linktrace message
LTN	LSP ID to NHLFE
LTR	link trace reply
MA	maintenance association
MAC	media access control
MA-ID	maintenance association identifier

Table 209 Acronyms (Continued)

Acronym	Expansion
MBB	make-before-break
MBGP	multicast BGP multiprotocol BGP multiprotocol extensions for BGP
MBMS	multimedia broadcast multicast service
MBS	maximum buffer space maximum burst size media buffer space
MBSP	mobile backhaul service provider
MCAC	multicast connection admission control
MC-APS	multi-chassis automatic protection switching
MC-MLPPP	multi-class multilink point-to-point protocol
MCS	multicast server multi-chassis synchronization
MCT	MPT craft terminal
MD	maintenance domain
MD5	message digest version 5 (algorithm)
MDA	media dependent adapter
MDDDB	multidrop data bridge
MDL	maintenance data link
MDT	multicast distribution tree
ME	maintenance entity
MED	multi-exit discriminator
MEF	Metro Ethernet Forum
MEG	maintenance entity group
MEG-ID	maintenance entity group identifier
MEN	Metro Ethernet network
MEP	maintenance association end point
MFC	multi-field classification

Table 209 Acronyms (Continued)

Acronym	Expansion
MHD	multi-homed device
MHF	MIP half function
MHN	multi-homed network
MIB	management information base
MI-IS-IS	multi-instance IS-IS
MIR	minimum information rate
MLD	multicast listener discovery
mLDP	multicast LDP
MLPPP	multilink point-to-point protocol
mLSP	multicast LSP
MoFRR	multicast-only fast reroute
MP	merge point multilink protocol multipoint
MP-BGP	multiprotocol border gateway protocol
MPLS	multiprotocol label switching
MPLSCP	multiprotocol label switching control protocol
MPP	MPT protection protocol
MPR	see Wavence
MPR-e	Microwave Packet Radio (standalone mode)
MPT-HC V2/9558HC	Microwave Packet Transport, High Capacity version 2
MPT-HLC	Microwave Packet Transport, High-Capacity Long-Haul Cubic (ANSI)
MPT-HQAM	Microwave Packet Transport, High Capacity (MPT-HC-QAM) or Extended Power (MPT-XP-QAM) with 512/1024 QAM
MPT-MC	Microwave Packet Transport, Medium Capacity
MPT-XP	Microwave Packet Transport, High Capacity (very high power version of MPT-HC V2/9558HC)
MRAI	minimum route advertisement interval

Table 209 Acronyms (Continued)

Acronym	Expansion
MRRU	maximum received reconstructed unit
MRU	maximum receive unit
MSDP	Multicast Source Discovery Protocol
MSDU	MAC Service Data Unit
MSO	multi-system operator
MS-PW	multi-segment pseudowire
MSS	maximum segment size Microwave Service Switch
MTIE	maximum time interval error
MTSO	mobile trunk switching office
MTU	maximum transmission unit multi-tenant unit
M-VPLS	management virtual private line service
MVPN	multicast VPN
MVR	multicast VPLS registration
MW	microwave
MWA	microwave awareness
N·m	newton meter
NAT	network address translation
NAT-T	network address translation traversal
NBMA	non-broadcast multiple access (network)
ND	neighbor discovery
NE	network element
NET	network entity title
NFM-P	Network Functions Manager - Packet (formerly 5620 SAM)
NGE	network group encryption
NG-MVPN	next generation MVPN
NH	next hop

Table 209 Acronyms (Continued)

Acronym	Expansion
NHLFE	next hop label forwarding entry
NHOP	next-hop
NLOS	non-line-of-sight
NLPID	network level protocol identifier
NLRI	network layer reachability information
NNHOP	next next-hop
NNI	network-to-network interface
Node B	similar to BTS but used in 3G networks — term is used in UMTS (3G systems) while BTS is used in GSM (2G systems)
NPAT	network port address translation
NRC-F	Network Resource Controller - Flow
NRC-P	Network Resource Controller - Packet
NRC-T	Network Resource Controller - Transport
NRC-X	Network Resource Controller - Cross Domain
NSAP	network service access point
NSD	Network Services Director
NSP	native service processing Network Services Platform
NSSA	not-so-stubby area
NTP	network time protocol
NTR	network timing reference
OADM	optical add/drop multiplexer
OAM	operations, administration, and maintenance
OAMPDU	OAM protocol data units
OC3	optical carrier level 3
OCSP	online certificate status protocol
ODU	outdoor unit
OIF	outgoing interface

Table 209 Acronyms (Continued)

Acronym	Expansion
OLT	optical line termination
OMC	optical management console
ONT	optical network terminal
OOB	out-of-band
OPX	off premises extension
ORF	outbound route filtering
OS	operating system
OSI	Open Systems Interconnection (reference model)
OSINLCP	OSI Network Layer Control Protocol
OSPF	open shortest path first
OSPF-TE	OSPF-traffic engineering (extensions)
OSS	operations support system
OSSP	organization specific slow protocol
OTP	one time password
OWAMP	one-way active measurement protocol
P2MP	point to multipoint
PADI	PPPoE active discovery initiation
PADR	PPPoE active discovery request
PAE	port authentication entities
PSB	path state block
PBO	packet byte offset
PBR	policy-based routing
PBX	private branch exchange
PCAP	packet capture
PCC	Path Computation Element Client
PCE	Path Computation Element
PCEP	Path Computation Element Protocol

Table 209 Acronyms (Continued)

Acronym	Expansion
PCM	pulse code modulation
PCP	priority code point
PCR	proprietary clock recovery
PDU	power distribution unit protocol data units
PDV	packet delay variation
PDVT	packet delay variation tolerance
PE	provider edge router
PEAPv0	protected extensible authentication protocol version 0
PEM	privacy enhanced mail
PFoE	power feed over Ethernet
PFS	perfect forward secrecy
PHB	per-hop behavior
PHP	penultimate hop popping
PHY	physical layer
PIC	prefix independent convergence
PID	protocol ID
PIM SSM	protocol independent multicast—source-specific multicast
PIR	peak information rate
PKCS	public key cryptography standards
PKI	public key infrastructure
PLAR	private line automatic ringdown
PLCP	Physical Layer Convergence Protocol
PLR	point of local repair
PLSP	path LSP
PMSI	P-multicast service interface
P-multicast	provider multicast
PoE	power over Ethernet

Table 209 Acronyms (Continued)

Acronym	Expansion
PoE+	power over Ethernet plus
POH	path overhead
POI	purge originator identification
PoP	point of presence
POS	packet over SONET
PPP	point-to-point protocol
PPPoE	point-to-point protocol over Ethernet
PPS	pulses per second
PRC	primary reference clock
PRS	primary reference source
PRTC	primary reference time clock
PSE	power sourcing equipment
PSK	pre-shared key
PSN	packet switched network
PSNP	partial sequence number PDU
PTA	PMSI tunnel attribute
PTM	packet transfer mode
PTP	performance transparency protocol precision time protocol
PuTTY	an open-source terminal emulator, serial console, and network file transfer application
PVC	permanent virtual circuit
PVCC	permanent virtual channel connection
PW	pseudowire
PWE	pseudowire emulation
PWE3	pseudowire emulation edge-to-edge
Q.922	ITU-T Q-series Specification 922
QL	quality level

Table 209 Acronyms (Continued)

Acronym	Expansion
QoS	quality of service
QPSK	quadrature phase shift keying
RADIUS	Remote Authentication Dial In User Service
RAN	Radio Access Network
RBS	robbed bit signaling
RD	route distinguisher
RDI	remote defect indication
RED	random early discard
RESV	reservation
RIB	routing information base
RIP	routing information protocol
RJ-45	registered jack 45
RMON	remote network monitoring
RNC	Radio Network Controller
RP	rendezvous point
RPF RTM	reverse path forwarding RTM
RPS	radio protection switching
RPT	rendezvous-point tree
RR	route reflector
RRO	record route object
RS-232	Recommended Standard 232 (also known as EIA/TIA-232)
RSA	Rivest, Shamir, and Adleman (authors of the RSA encryption algorithm)
RSHG	residential split horizon group
RSTP	rapid spanning tree protocol
RSVP-TE	resource reservation protocol - traffic engineering
RT	receive/transmit
RTC	route target constraint

Table 209 Acronyms (Continued)

Acronym	Expansion
RTM	routing table manager
RTN	battery return
RTP	real-time protocol
R&TTE	Radio and Telecommunications Terminal Equipment
RTU	remote terminal unit
RU	rack unit
r-VPLS	routed virtual private LAN service
SA	security association source-active
SAA	service assurance agent
SAFI	subsequent address family identifier
SAP	service access point
SAR-8	7705 Service Aggregation Router – 8-slot chassis
SAR-18	7705 Service Aggregation Router – 18-slot chassis
SAR-A	7705 Service Aggregation Router – two variants: • passively cooled chassis with 12 Ethernet ports and 8 T1/E1 ports • passively cooled chassis with 12 Ethernet ports and no T1/E1 ports
SAR-Ax	7705 Service Aggregation Router: • passively cooled • DC-powered with a dual-feed DC input that can be connected to a +24/-48/-60 VDC power source • equipped with 12 Ethernet ports (ports 1 to 4 are XOR ports and 5 to 12 are 100/1000 Ethernet SFP ports) • equipped with a factory-installed GPS receiver and GNSS RF faceplate connector
SAR-H	7705 Service Aggregation Router – temperature- and EMC-hardened to the following specifications: IEEE 1613 and IEC 61850-3
SAR-Hc	7705 Service Aggregation Router – compact version of 7705 SAR-H

Table 209 Acronyms (Continued)

Acronym	Expansion
SAR-M	7705 Service Aggregation Router – four variants: • actively cooled chassis with 16 T1/E1 ports, 7 Ethernet ports, and 1 hot-insertable module slot • actively cooled chassis with 0 T1/E1 ports, 7 Ethernet ports, and 1 hot-insertable module slot • passively cooled chassis with 16 T1/E1 ports, 7 Ethernet ports, and 0 module slots • passively cooled chassis with 0 T1/E1 ports, 7 Ethernet ports, and 0 module slots
SAR-O	7705 Service Aggregation Router passive CWDM device – three variants: • 2-wavelength CWDM dual-fiber • 4-wavelength CWDM dual-fiber • 8-wavelength CWDM single-fiber Each variant has different models that are used to add and drop different wavelengths
SAR-W	7705 Service Aggregation Router – passively cooled, universal AC and DC powered unit, equipped with five Gigabit Ethernet ports (three SFP ports and two RJ-45 Power over Ethernet (PoE) ports)

Table 209 Acronyms (Continued)

Acronym	Expansion
SAR-Wx	7705 Service Aggregation Router – passively cooled, universal AC powered unit; there are six variants: • a unit that is equipped with an AC power input connector, five Gigabit Ethernet data ports (three SFP ports and two RJ-45 Ethernet ports), and an RJ-45 alarm input connector • a unit that is equipped with an AC power input connector, five Gigabit Ethernet data ports (three SFP ports and two RJ-45 Ethernet ports), a GPS receiver, and an RJ-45 alarm input connector • a unit that is equipped with an AC power input connector, five Gigabit Ethernet data ports (three SFP ports, one RJ-45 Ethernet port, and one RJ-45 PoE+ port), and an RJ-45 alarm input connector • a unit that is equipped with an AC power input connector, five Gigabit Ethernet data ports (three SFP ports, one RJ-45 Ethernet port, and one RJ-45 PoE+ port), a GPS receiver, and an RJ-45 alarm input connector • a unit that is equipped with an AC power input connector, four Gigabit Ethernet data ports (three SFP ports and one RJ-45 port), one RJ-45 4-pair xDSL port, and an RJ-45 alarm input connector • a unit that is equipped with an AC power input connector, four Gigabit Ethernet data ports (three SFP ports and one RJ-45 port), one RJ-45 4-pair xDSL port, a GPS receiver, and an RJ-45 alarm input connector
SAR-X	7705 Service Aggregation Router – fan-cooled, rack-mountable, IP20 design, available in two variants: • AC-powered variant with a single-feed AC input that can be connected to a 100 to 240 VAC, 50/60 Hz power source • DC-powered variant with a dual-feed DC input that can be connected to a +24/-48/-60 VDC power source
SAToP	structure-agnostic TDM over packet
SCADA	surveillance, control and data acquisition
SC-APS	single-chassis automatic protection switching
SCP	secure copy
SCTP	Stream Control Transmission Protocol

Table 209 Acronyms (Continued)

Acronym	Expansion
SD	signal degrade space diversity
SDH	synchronous digital hierarchy
SDI	serial data interface
SDN	software defined network
SDP	service destination point
SE	shared explicit
SeGW	secure gateway
SES	severely errored seconds
SETS	synchronous equipment timing source
SF	signal fail
SFP	small form-factor pluggable (transceiver)
SFTP	SSH file transfer protocol
(S,G)	(source, group)
SGT	self-generated traffic
SHA-1	secure hash algorithm
SHG	split horizon group
SIR	sustained information rate
SLA	Service Level Agreement
SLARP	serial line address resolution protocol
SLID	subscriber location identifier of a GPON module
SLM	synthetic loss measurement
SNMP	Simple Network Management Protocol
SNPA	subnetwork point of attachment
SNR	signal to noise ratio
SNTP	simple network time protocol
SONET	synchronous optical networking
S-PE	switching provider edge router

Table 209 Acronyms (Continued)

Acronym	Expansion
SPF	shortest path first
SPI	security parameter index
S-PMSI	selective PMSI
SPT	shortest path tree
SR	service router (7750 SR) segment routing
SRLG	shared risk link group
SRP	stateful request parameter
SRRP	subscriber routed redundancy protocol
SR-ISIS	segment routing IS-IS
SR-OSPF	segment routing OSPF
SR-TE	segment routing traffic engineering
SSH	secure shell
SSM	source-specific multicast synchronization status messaging
SSU	system synchronization unit
S-TAG	service VLAN tag
STM	synchronous transport module
STM1	synchronous transport module, level 1
STP	spanning tree protocol
STS	synchronous transport signal
SVC	switched virtual circuit
SVEC	synchronization vector
SYN	synchronize
TACACS+	Terminal Access Controller Access-Control System Plus
TC	traffic class (formerly known as EXP bits)
TCP	transmission control protocol
TDA	transmit diversity antenna

Table 209 Acronyms (Continued)

Acronym	Expansion
TDEV	time deviation
TDM	time division multiplexing
TE	traffic engineering
TEDB	traffic engineering database
TEID	tunnel endpoint identifier
TEP	tunnel endpoint
TFTP	trivial file transfer protocol
T-LDP	targeted LDP
TLS	transport layer security
TLV	type length value
TM	traffic management
ToD	time of day
ToS	type of service
T-PE	terminating provider edge router
TPID	tag protocol identifier
TPIF	IEEE C37.94 teleprotection interface
TPMR	two-port MAC relay
TPS	transmission protection switching
TSoP	Transparent SDH/SONET over Packet
TTL	time to live
TTLS	tunneled transport layer security
TTM	tunnel table manager
TU	tributary unit
TUG	tributary unit group
TWAMP	two-way active measurement protocol
U-APS	unidirectional automatic protection switching
UAS	unavailable seconds

Table 209 Acronyms (Continued)

Acronym	Expansion
UBR	unspecified bit rate
UDP	user datagram protocol
UFD	unidirectional forwarding detection
UMH	upstream multicast hop
UMTS	Universal Mobile Telecommunications System (3G)
UNI	user-to-network interface
uRPF	unicast reverse path forwarding
V.11	ITU-T V-series Recommendation 11
V.24	ITU-T V-series Recommendation 24
V.35	ITU-T V-series Recommendation 35
VC	virtual circuit
VCB	voice conference bridge
VCC	virtual channel connection
VCCV	virtual circuit connectivity verification
VCI	virtual circuit identifier
VID	VLAN ID
VLAN	virtual LAN
VLL	virtual leased line
VM	virtual machine
VoIP	voice over IP
Vp	peak voltage
VP	virtual path
VPC	virtual path connection
VPI	virtual path identifier
VPLS	virtual private LAN service
VPN	virtual private network
VPRN	virtual private routed network

Table 209 Acronyms (Continued)

Acronym	Expansion
VRF	virtual routing and forwarding table
VRRP	virtual router redundancy protocol
VSE	vendor-specific extension
VSI	virtual switch instance
VSO	vendor-specific option
VT	virtual trunk virtual tributary
VTG	virtual tributary group
Wavence	formerly 9500 MPR (Microwave Packet Radio)
WCDMA	wideband code division multiple access (transmission protocol used in UMTS networks)
WRED	weighted random early discard
WTR	wait to restore
X.21	ITU-T X-series Recommendation 21
XOR	exclusive-OR
XRO	exclude route object

12 Standards and Protocol Support

This chapter lists the 7705 SAR compliance with EMC, environmental, and safety standards, telecom standards, and supported protocols:

- [EMC Industrial Standards Compliance](#)
- [EMC Regulatory and Customer Standards Compliance](#)
- [Environmental Standards Compliance](#)
- [Safety Standards Compliance](#)
- [Telecom Interface Compliance](#)
- [Directives, Regional Approvals and Certifications Compliance](#)
- [Security Standards](#)
- [Telecom Standards](#)
- [Protocol Support](#)
- [Proprietary MIBs](#)

Table 210 EMC Industrial Standards Compliance

Standard	Title	Platform									
		SAR-X	SAR-A	SAR-Ax	SAR-M	SAR-8	SAR-18	SAR-H	SAR-Hc	SAR-W	SAR-Wx
IEEE 1613:2009 + A1:2011	IEEE Standard Environmental and Testing Requirements for Communications Networking Devices Installed in Electric Power Substations	✓ ¹		✓ ¹		✓ ²	✓ ¹	✓ ³	✓ ³		
IEEE 1613.1-2013	IEEE Standard Environmental and Testing Requirements for Communications Networking Devices Installed in Transmission and Distribution Facilities	✓ ⁴		✓ ⁴		✓ ⁵	✓ ⁶	✓ ⁷	✓ ⁷		
IEEE Std C37.90	IEEE Standard for relays and relay systems associated with Electric Power Apparatus	✓		✓		✓	✓	✓	✓		
IEEE Std C37.90.1	Surge Withstand Capability (SWC) Tests	✓		✓		✓	✓	✓	✓		
IEEE Std C37.90.2	Withstand Capability of Relay Systems to Radiated Electromagnetic Interference from Transceivers	✓		✓		✓	✓	✓	✓		
IEEE Std C37.90.3	IEEE Standard Electrostatic Discharge Tests for Protective Relays	✓		✓		✓	✓	✓	✓		
EN 50121-4	Electromagnetic Compatibility – Part 4: Emission and Immunity of the Signalling and Telecommunications Apparatus	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓
IEC 62236-4	Electromagnetic Compatibility – Part 4: Emission and Immunity of the Signalling and Telecommunications Apparatus	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓
IEC 61000-6-2	Generic standards – Immunity for industrial environments	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓
IEC 61000-6-4	Generic standards – Emissions standard for industrial environments	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓
IEC 61000-6-5	Generic standards – immunity for equipment used in power station and substation environment	✓		✓		✓	✓	✓	✓		
IEC 61850-3	Communication networks and systems for power utility automation - Part 3: General requirements	✓		✓		✓	✓ ⁸	✓	✓		
IEC/AS 60870.2.1	Telecontrol equipment and systems. Operating conditions. Power supply and electromagnetic compatibility	✓		✓		✓	✓	✓	✓		

Notes:

1. Performance Class 1
2. Performance Class 1 (Class 2 with Optics interfaces only)
3. Performance Class 2
4. Zone A; Performance Class 1
5. Zone A; Performance Class 1 (Class 2 with Optics interfaces only)
6. Zone B; Performance Class 1
7. Zone A; Performance Class 2
8. With the exception of DC surges

ITU-T G.707—Network node interface for the Synchronous Digital Hierarchy (SDH)

ITU-T G.826—End-to-end error performance parameters and objectives for international, constant bit-rate digital paths and connections

ITU-T G.8032 — Ethernet Ring Protection Switching

ITU-T G.984.1—Gigabit-capable passive optical networks (GPON): general characteristics

ITU-T Y.1564—Ethernet service activation test methodology

ITU-T Y.1731—OAM functions and mechanisms for Ethernet-based networks

Protocol Support

ATM

AF-PHY-0086.001—Inverse Multiplexing for ATM (IMA)
af-tm-0121.000—Traffic Management Specification Version 4.1, March 1999
GR-1113-CORE—Bellcore, Asynchronous Transfer Mode (ATM) and ATM Adaptation Layer (AAL) Protocols Generic Requirements, Issue 1, July 1994
GR-1248-CORE—Generic Requirements for Operations of ATM Network Elements (NEs). Issue 3 June 1996
ITU-T Recommendation I.432.1—B-ISDN user-network interface - Physical layer specification: General characteristics
ITU-T Recommendation I.610—B-ISDN Operation and Maintenance Principles and Functions version 11/95
RFC 2514—Definitions of Textual Conventions and OBJECT_IDENTITIES for ATM Management, February 1999
RFC 2515—Definition of Managed Objects for ATM Management, February 1999
RFC 2684—Multiprotocol Encapsulation over ATM Adaptation Layer 5

BFD

draft-ietf-bfd-mib-00.txt—Bidirectional Forwarding Detection Management Information Base
draft-ietf-bfd-base-o5.txt—Bidirectional Forwarding Detection
draft-ietf-bfd-v4v6-1hop-06.txt—BFD IPv4 and IPv6 (Single Hop)
draft-ietf-bfd-multihop-06.txt—BFD for Multi-hop Paths

BGP

RFC 1397—BGP Default Route Advertisement
RFC 1997—BGP Communities Attribute
RFC 2385—Protection of BGP Sessions via the TCP MD5 Signature Option
RFC 2439—BGP Route Flap Dampening
RFC 2545—Use of BGP-4 Multiprotocol Extensions for IPv6 Inter-Domain Routing
RFC 2918—Route Refresh Capability for BGP-4
RFC 3107—Carrying Label Information in BGP-4
RFC 3392—Capabilities Advertisement with BGP-4
RFC 4271—BGP-4 (previously RFC 1771)
RFC 4360—BGP Extended Communities Attribute
RFC 4364—BGP/MPLS IP Virtual Private Networks (VPNs) (previously RFC 2574bis BGP/MPLS VPNs)
RFC 4456—BGP Route Reflection: Alternative to Full-mesh IBGP (previously RFC 1966 and RFC 2796)

RFC 4486—Subcodes for BGP Cease Notification Message
RFC 4684—Constrained Route Distribution for Border Gateway Protocol/
MultiProtocol Label Switching (BGP/MPLS) Internet Protocol (IP) Virtual
Private Networks (VPNs)
RFC 4724—Graceful Restart Mechanism for BGP - GR Helper
RFC 4760—Multi-protocol Extensions for BGP (previously RFC 2858)
RFC 4893—BGP Support for Four-octet AS Number Space
RFC 6513—Multicast in MPLS/BGP IP VPNs
RFC 6514—BGP Encodings and Procedures for Multicast in MPLS/BGP IP VPNs
draft-ietf-idr-add-paths-04.txt—Advertisement of Multiple Paths in BGP
draft-ietf-idr-add-paths-guidelines-00.txt—Best Practices for Advertisement of
Multiple Paths in BGP

DHCP/DHCPv6

RFC 1534—Interoperation between DHCP and BOOTP
RFC 2131—Dynamic Host Configuration Protocol (REV)
RFC 2132—DHCP Options and BOOTP Vendor Extensions
RFC 3046—DHCP Relay Agent Information Option (Option 82)
RFC 3315—Dynamic Host Configuration Protocol for IPv6
RFC 3736—Stateless Dynamic Host Configuration Protocol (DHCP) Service for IPv6

Differentiated Services

RFC 2474—Definition of the DS Field in the IPv4 and IPv6 Headers
RFC 2597—Assured Forwarding PHB Group
RFC 2598—An Expedited Forwarding PHB
RFC 3140—Per-Hop Behavior Identification Codes

Digital Data Network Management

V.35
RS-232 (also known as EIA/TIA-232)
X.21

DSL Modules

IEEE 802.2 LLC/SNAP bridged encapsulation while operating in ATM bonded mode
ITU-T G.991.2 Annex A, B, F and ITU-T G.991.2 Amendment 2 Annex G—SHDSL
standards compliance
ITU-T G.991.2 Appendix F and G—Support for up to 5696 Kb/s per pair
ITU-T G.992.1 (ADSL)
ITU-T G.992.3 (G.dmt.bis), Annex A, B, J, M
ITU-T G.992.3 Annex K.2 (ADSL2)

ITU-T G.992.5, Annex A, B, J, M
ITU-T G.992.5 Annex K (ADSL2+)
ITU-T G.993.2 Amendment 1—Seamless Rate Adaptation
ITU-T G.993.2 Annex A and Annex B—xDSL Standards Compliance (ADSL2/2+ and VDSL2)
ITU-T G.993.2 Annex K.3—Supported Transport Protocol Specific Transmission Convergence functions
ITU G.994.1 (2/07) Amendment 1 and 2—G.hs Handshake
ITU-T G.998.2—SHDSL 4-pair EFM bonding
ITU-T G.998.4 G.inp—Physical layer retransmission
ITU-T Y.1564 Ethernet service activation test methodology
TR-060—SHDSL rate and reach
TR112 (U-R2 Deutsche Telekom AG) Version 7.0 and report of Self-Test-Result (ATU-T Register#3)

ECMP

RFC 2992—Analysis of an Equal-Cost Multi-Path Algorithm

Ethernet VPN (EVPN)

RFC 7432—BGP MPLS-Based Ethernet VPN
draft-ietf-bess-evpn-vpls-seamless-integ—(PBB-)EVPN Seamless Integration with (PBB-)VPLS
draft-ietf-bess-evpn-vpws—Virtual Private Wire Service support in Ethernet VPN

Frame Relay

ANSI T1.617 Annex D—Signalling Specification For Frame Relay Bearer Service
ITU-T Q.922 Annex A—Digital Subscriber Signalling System No. 1 (DSS1) data link layer - ISDN data link layer specification for frame mode bearer services
FRF.1.2—PVC User-to-Network Interface (UNI) Implementation Agreement
FRF.12—Frame Relay Fragmentation Implementation Agreement
RFC 2427—Multiprotocol Interconnect over Frame Relay

GRE

RFC 2784—Generic Routing Encapsulation (GRE)

IPSec

ITU-T X.690 (2002)—ASN.1 encoding rules: Specification of Basic Encoding Rules (BER), Canonical Encoding Rules (CER) and Distinguished Encoding Rules (DER)
PKCS #12 Personal Information Exchange Syntax Standard
RFC 2315—PKCS #7: Cryptographic Message Syntax

RFC 2401—Security Architecture for the Internet Protocol
RFC 2409—The Internet Key Exchange (IKE)
RFC 2986—PKCS #10: Certification Request Syntax Specification
RFC 3706—A Traffic-Based Method of Detecting Dead Internet Key Exchange (IKE) Peers
RFC 3947—Negotiation of NAT-Traversal in the IKE
RFC 3948—UDP Encapsulation of IPsec ESP Packets
RFC 4303—IP Encapsulating Security Payload (ESP)
RFC 4210—Internet X.509 Public Key Infrastructure Certificate Management Protocol (CMP)
RFC 4211—Internet X.509 Public Key Infrastructure Certificate Request Message Format (CRMF)
RFC 4945—The Internet IP Security PKI Profile of IKEv1/ISAKMP, IKEv2, and PKIX
RFC 5280—Internet X.509 Public Key Infrastructure Certificate and Certificate Revocation List (CRL) Profile
RFC 5996—Internet Key Exchange Protocol Version 2 (IKEv2)
RFC 7383—Internet Key Exchange Protocol Version 2 (IKEv2) Message Fragmentation

IPv6

RFC 2460—Internet Protocol, Version 6 (IPv6) Specification
RFC 2462—IPv6 Stateless Address Autoconfiguration
RFC 2464—Transmission of IPv6 Packets over Ethernet Networks
RFC 3587—IPv6 Global Unicast Address Format
RFC 3595—Textual Conventions for IPv6 Flow Label
RFC 4007—IPv6 Scoped Address Architecture
RFC 4193—Unique Local IPv6 Unicast Addresses
RFC 4291—IPv6 Addressing Architecture
RFC 4443—Internet Control Message Protocol (ICMPv6) for the Internet Protocol Version 6 Specification
RFC 4649—DHCPv6 Relay Agent Remote-ID Option
RFC 4861—Neighbor Discovery for IP version 6 (IPv6)
RFC 5095—Deprecation of Type 0 Routing Headers in IPv6
RFC 5952—A Recommendation for IPv6 Address Text Representation

IS-IS

RFC 1142—OSI IS-IS Intra-domain Routing Protocol (ISO 10589)
RFC 1195—Use of OSI IS-IS for routing in TCP/IP & dual environments
RFC 2763—Dynamic Hostname Exchange for IS-IS

RFC 2966—Domain-wide Prefix Distribution with Two-Level IS-IS
RFC 2973—IS-IS Mesh Groups
RFC 3373—Three-Way Handshake for Intermediate System to Intermediate System (IS-IS) Point-to-Point Adjacencies
RFC 3567—Intermediate System to Intermediate System (IS-IS) Cryptographic Authentication
RFC 3719—Recommendations for Interoperable Networks using IS-IS
RFC 3784—Intermediate System to Intermediate System (IS-IS) Extensions for Traffic Engineering (TE)
RFC 3787—Recommendations for Interoperable IP Networks
RFC 4205 for Shared Risk Link Group (SRLG) TLV
RFC 4971—Intermediate System to Intermediate System (IS-IS) Extensions for Advertising Router Information
RFC 5304—IS-IS Cryptographic Authentication
RFC 5305—IS-IS Extensions for Traffic Engineering
RFC 5308—Routing IPv6 with IS-IS
RFC 5309—Point-to-Point Operation over LAN in Link State Routing Protocols
RFC 5310—IS-IS Generic Cryptographic Authentication
RFC 6232—Purge Originator Identification TLV for IS-IS

LDP

RFC 5036—LDP Specification
RFC 5283—LDP Extension for Inter-Area Label Switched Paths
RFC 5350—IANA Considerations for the IPv4 and IPv6 Router Alert Options
RFC 5443—LDP IGP Synchronization
RFC 5561—LDP Capabilities
RFC 6388—Label Distribution Protocol Extensions for Point-to-Multipoint and Multipoint-to-Multipoint Label Switched Paths
RFC 6512—Using Multipoint LDP When the Backbone Has No Route to the Root
RFC 6829—Label Switched Path (LSP) Ping for Pseudowire Forwarding Equivalence Classes (FECs) Advertised over IPv6
RFC 7552—Updates to LDP for IPv6
draft-ietf-mpls-ldp-ip-pw-capability—Controlling State Advertisements Of Non-negotiated LDP Applications
draft-ietf-mpls-oam-ipv6-rao—IPv6 Router Alert Option for MPLS OAM
draft-pdutta-mpls-ldp-adj-capability-00—LDP Adjacency Capabilities
draft-pdutta-mpls-ldp-v2-00—LDP Version 2
draft-pdutta-mpls-mldp-up-redundancy-00.txt—Upstream LSR Redundancy for Multi-point LDP Tunnels

LDP and IP FRR

RFC 5286—Basic Specification for IP Fast Reroute: Loop-Free Alternates

RFC 7490—Remote Loop-Free Alternate (LFA) Fast Reroute (FRR)

MPLS

RFC 3031—MPLS Architecture

RFC 3032—MPLS Label Stack Encoding

RFC 3815—Definitions of Managed Objects for the Multiprotocol Label Switching (MPLS), Label Distribution Protocol (LDP)

RFC 6790—The Use of Entropy Labels in MPLS Forwarding

MPLS – OAM

RFC 4379—Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures

RFC 6424— Mechanism for Performing Label Switched Path Ping (LSP Ping) over MPLS Tunnels

Multicast

RFC 3956—Embedding the Rendezvous Point (RP) Address in an IPv6 Multicast Address

RFC 3973—Protocol Independent Multicast - Dense Mode (PIM-DM): Protocol Specification (Revised)

RFC 4610—Anycast-RP Using Protocol Independent Multicast (PIM), which is similar to RFC 3446—Anycast Rendezvous Point (RP) mechanism using Protocol Independent Multicast (PIM) and Multicast Source Discovery Protocol (MSDP)

RFC 6514—BGP Encodings and Procedures for Multicast in MPLS/IP VPNs

cisco-ipmulticast/pim-autorp-spec—Auto-RP: Automatic discovery of Group-to-RP mappings for IP multicast, which is similar to RFC 5059—Bootstrap Router (BSR) Mechanism for Protocol Independent Multicast (PIM)

draft-ietf-l2vpn-vpls-pim-snooping-07—Protocol Independent Multicast (PIM) over Virtual Private LAN Service (VPLS)

draft-ietf-mboned-msdp-deploy-nn.txt—Multicast Source Discovery Protocol (MSDP) Deployment Scenarios

Network Management

IANA-IFTtype-MIB

ITU-T X.721—Information technology- OSI-Structure of Management Information

ITU-T X.734—Information technology- OSI-Systems Management: Event Report Management Function

TMF 509/613—Network Connectivity Model

OSPF

RFC 1765—OSPF Database Overflow

RFC 2328—OSPF Version 2

RFC 2370—Opaque LSA Support

RFC 2740—OSPF for IPv6

RFC 3101—OSPF NSSA Option

RFC 3137—OSPF Stub Router Advertisement

RFC 3509—Alternative Implementations of OSPF Area Border Routers

RFC 3623—Graceful OSPF Restart (support for Helper mode)

RFC 3630—Traffic Engineering (TE) Extensions to OSPF

RFC 4203 for Shared Risk Link Group (SRLG) sub-TLV

RFC 4577—OSPF as the Provider/Customer Edge Protocol for BGP/MPLS IP
Virtual Private Networks (VPNs) (support for basic OSPF at PE-CE links)

RFC 4915—Multi-Topology (MT) Routing in OSPF

RFC 4970—Extensions to OSPF for Advertising Optional Router Capabilities

RFC 5185—OSPF Multi-Area Adjacency

OSPFv3

RFC 4552—Authentication/Confidentiality for OSPFv3

PPP

RFC 1332—PPP Internet Protocol Control Protocol (IPCP)

RFC 1570—PPP LCP Extensions

RFC 1619—PPP over SONET/SDH

RFC 1661—The Point-to-Point Protocol (PPP)

RFC 1662—PPP in HDLC-like Framing

RFC 1989—PPP Link Quality Monitoring

RFC 1990—The PPP Multilink Protocol (MP)

RFC 2686—The Multi-Class Extension to Multi-Link PPP

Pseudowires

Metro Ethernet Forum—Implementation Agreement for the Emulation of PDH
Circuits over Metro Ethernet Networks

RFC 3550—RTP: A Transport Protocol for Real-Time Applications

RFC 3985—Pseudo Wire Emulation Edge-to-Edge (PWE3) Architecture

RFC 4385—Pseudowire Emulation Edge-to-Edge (PWE3) Control Word for Use over an MPLS PSN

RFC 4446—IANA Allocation for PWE3

RFC 4447—Pseudowire Setup and Maintenance Using the Label Distribution Protocol (LDP)

RFC 4448—Encapsulation Methods for Transport of Ethernet over MPLS Networks

RFC 4553—Structure-Agnostic Time Division Multiplexing (TDM) over Packet (SAToP)

RFC 4717—Encapsulation Methods for Transport of Asynchronous Transfer Mode (ATM) over MPLS Networks

RFC 4618—Encapsulation Methods for Transport of PPP/High-Level Data Link Control (HDLC) over MPLS Networks

RFC 4619—Encapsulation Methods for Transport of Frame Relay over Multiprotocol Label Switching (MPLS) Networks

RFC 4816—Pseudowire Emulation Edge-to-Edge (PWE3) Asynchronous Transfer Mode (ATM) Transparent Cell Transport Service

RFC 5085—Pseudowire Virtual Circuit Connectivity Verification (VCCV): A Control Channel for Pseudowires

RFC 5086—Structure-Aware Time Division Multiplexed (TDM) Circuit Emulation Service over Packet Switched Network (CESoPSN)

draft-ietf-pwe3-redundancy-02.txt—Pseudowire (PW) Redundancy

RIP

RFC 1058—Routing Information Protocol

RFC 2453—RIP Version 2

RADIUS

RFC 2865—Remote Authentication Dial In User Service

RFC 2866—RADIUS Accounting

RSVP-TE and FRR

RFC 2430—A Provider Architecture for DiffServ & TE

RFC 2702—Requirements for Traffic Engineering over MPLS

RFC 2747—RSVP Cryptographic Authentication

RFC 2961—RSVP Refresh Overhead Reduction Extensions

RFC 3097—RSVP Cryptographic Authentication - Updated Message Type Value

RFC 3209—Extensions to RSVP for LSP Tunnels

RFC 3210—Applicability Statement for Extensions to RSVP for LSP Tunnels

RFC 3477—Signalling Unnumbered Links in Resource ReSerVation Protocol - Traffic Engineering (RSVP-TE)

RFC 4090—Fast Reroute Extensions to RSVP-TE for LSP Tunnels
RFC 5440—Path Computation Element (PCE) Communication Protocol (PCEP)
draft-ietf-pce-stateful-pce—PCEP Extensions for Stateful PCE
draft-ietf-pce-segment-routing—PCEP Extensions for Segment Routing
draft-alvarez-pce-path-profiles—PCE Path Profiles

Segment Routing (SR)

draft-francois-rtgwg-segment-routing-ti-lfa-04—Topology Independent Fast Reroute using Segment Routing
draft-gredler-idr-bgp-ls-segment-routing-ext-03—BGP Link-State extensions for Segment Routing
draft-ietf-isis-segment-routing-extensions-04—IS-IS Extensions for Segment Routing
draft-ietf-mpls-spring-lsp-ping-02—Label Switched Path (LSP) Ping/Trace for Segment Routing Networks Using MPLS Dataplane
draft-ietf-ospf-segment-routing-extensions-04—OSPF Extensions for Segment Routing

SONET/SDH

GR-253-CORE—SONET Transport Systems: Common Generic Criteria. Issue 3, September 2000
ITU-T Recommendation G.841—Telecommunication Standardization Section of ITU, Types and Characteristics of SDH Networks Protection Architecture, issued in October 1998 and as augmented by Corrigendum1 issued in July 2002

SSH

draft-ietf-secsh-architecture.txt—SSH Protocol Architecture
draft-ietf-secsh-userauth.txt—SSH Authentication Protocol
draft-ietf-secsh-transport.txt—SSH Transport Layer Protocol
draft-ietf-secsh-connection.txt—SSH Connection Protocol
draft-ietf-secsh-newmodes.txt—SSH Transport Layer Encryption Modes
draft-ietf-secsh-filexfer-13.txt—SSH File Transfer Protocol

Synchronization

G.781—Synchronization layer functions, 2001/09/17
G.803—Architecture of transport networks based on the synchronous digital hierarchy (SDH)
G.813—Timing characteristics of SDH equipment slave clocks (SEC)
G.823—The control of jitter and wander within digital networks which are based on the 2048 kbit/s hierarchy, 2003/03/16

- G.824—The control of jitter and wander within digital networks which are based on the 1544 kbit/s hierarchy, 2003/03/16
- G.8261—Timing and synchronization aspects in packet networks
- G.8262—Timing characteristics of synchronous Ethernet equipment slave clock
- GR 1244 CORE—Clocks for the Synchronized Network: Common Generic Criteria
- IEEE Std 1588-2008—IEEE Standard for a Precision Clock Synchronization Protocol for Networked Measurement and Control Systems
- IEEE Std 1588-2008—IEEE Standard for a Precision Clock Synchronization Protocol for Networked Measurement and Control Systems, Annex E – Transport of PTP over User Datagram Protocol over Internet Protocol Version 6
- ITU-T G.8264—Telecommunication Standardization Section of ITU, Distribution of timing information through packet networks, issued 10/2008
- ITU-T G.8265.1—Telecommunication Standardization Section of ITU, Precision time protocol telecom profile for frequency synchronization, issued 10/2010
- ITU-T G.8275.1—Telecommunication Standardization Section of ITU, Precision time protocol telecom profile for phase/time synchronization with full timing support from the network, issued 07/2014
- ITU-T G.8275.2—Telecommunication Standardization Section of ITU, Precision time protocol telecom profile for time/phase synchronization with partial timing support from the network, issued 06/2016
- RFC 5905—Network Time Protocol Version 4: Protocol and Algorithms Specification

TACACS+

- IETF draft-grant-tacacs-02.txt—The TACACS+ Protocol

TCP/IP

- RFC 768—User Datagram Protocol
- RFC 791—Internet Protocol
- RFC 792—Internet Control Message Protocol
- RFC 793—Transmission Control Protocol
- RFC 826—Ethernet Address Resolution Protocol
