Table of Contents

1	Preface	33
1.1	About This Guide	33
1.1.1	Audience	33
1.1.2	Technical Support	34
2	7705 SAR Services Configuration Process	35
3	Services Overview	37
3.1	Introduction to Services on the 7705 SAR	38
3.1.1	Overview	38
3.1.2	Service Types	40
3.1.3	Service Policies	42
3.2	Nokia Service Model	43
3.3	Service Entities	44
3.3.1	Customers	45
3.3.2	Service Types	45
3.3.2.1	Service Names	45
3.3.3	Service Access Points (SAPs)	46
3.3.3.1	SAP Encapsulation Types and Identifiers	47
3.3.3.2	SAP Configuration Considerations	51
3.3.4	Service Destination Points (SDPs)	52
3.3.4.1	SDP Binding	53
3.3.4.2	Spoke and Mesh SDPs	54
3.3.4.3	SDPs and BGP Route Tunnels	55
3.3.4.4	SDP Encapsulation Types	55
3.3.4.5	Spoke SDP Terminations	63
3.3.4.6	SDP Ping	63
3.3.4.7	SDP Keepalives	64
3.3.4.8	Mixed-LSP SDPs	65
3.3.4.9	Multiple Load-balancing LSPs Under a Single SDP	66
3.4	Mobile Solutions	68
3.4.1	HSDPA Offload	68
3.4.1.1	Failure Detection	71
3.4.2	Pure DSL Backhaul	72
3.4.2.1	DSL Channel Bonding	74
3.5	ETH-CFM (802.1ag and Y.1731)	75
3.5.1	802.1ag and Y.1731 Terminology	76
3.5.1.1	MDs, MD Levels, MAs, and MEPs (802.1ag)	77
3.5.1.2	MEG Levels, MEGs, and MEPs (Y.1731)	79
3.5.2	ETH-CFM Frame Format	79
3.5.2.1	ETH-CFM OAMPDU	81
3.5.2.2	CFM Frame Processing	82
3.5.2.3	MEG-ID and ICC-Based Format	83
3.5.3	ETH-CFM Functions and Tests	84
3.5.3.1	ETH-CFM Ethernet OAM Tests	85

3.5.4	MEP Support (802.1ag and Y.1731)	91
3.5.4.1	802.1ag MEP Support on Ethernet SAPs.....	92
3.5.4.2	802.1ag MEP Support on Ethernet Spoke and Mesh SDPs	93
3.5.4.3	Y.1731 MEP Support on Ethernet SAPs	95
3.5.5	Priority Mapping (802.1ag and Y.1731).....	96
3.5.5.1	Priority Mapping for SAP Up MEPs.....	96
3.5.5.2	Priority Mapping for SAP Down MEPs	98
3.6	G.8032 Ethernet Ring Protection Switching	99
3.6.1	Overview of G.8032 Operation	101
3.6.2	Ethernet Ring Sub-Rings.....	107
3.6.2.1	Virtual and Non-Virtual Channel	108
3.6.2.2	OAM Considerations	113
3.6.2.3	Support Service and Solution Combinations	114
3.7	QinQ Support.....	115
3.7.1	Overview of QinQ	115
3.7.2	QinQ Support with Forced C-Tag Forwarding (VPLS only).....	117
3.7.2.1	Example 1: General QinQ Implementation.....	118
3.7.2.2	Example 2: QinQ using VPLS with Ethernet SAPs	118
3.7.2.3	Example 3: QinQ Using VPLS with ATM SAPs.....	119
3.7.3	QinQ Support on Ethernet Ports.....	120
3.7.3.1	Special QinQ SAP Identifiers.....	120
3.7.3.2	QinQ Dot1p Match Behavior.....	121
3.7.3.3	QinQ Top-Only Mark Option.....	122
3.7.3.4	Maximum Number of VLAN Tags.....	122
3.7.4	QinQ Configuration Overview	122
3.8	Raw Socket IP Transport Service.....	123
3.8.1	Remote Host Manual TCP Connection Check	129
3.8.2	QoS Requirements for IP Transport	130
3.9	Service Creation Overview	131
3.10	Port and SAP CLI Identifiers.....	133
3.10.1	Reference Sources.....	133
3.11	Configuring Global Service Entities with CLI	135
3.12	Service Model Entities	136
3.13	Basic Configuration	137
3.14	Common Configuration Tasks	139
3.14.1	Configuring Customer Accounts.....	139
3.14.2	Configuring SDPs	140
3.14.2.1	Enabling IP Fragmentation for GRE SDPs.....	144
3.14.3	Configuring Service Names.....	144
3.15	ETH-CFM (802.1ag and Y.1731) Tasks	145
3.15.1	Configuring ETH-CFM Parameters (802.1ag and Y.1731).....	145
3.15.2	Applying ETH-CFM Parameters	148
3.16	Service Management Tasks	150
3.16.1	Modifying Customer Accounts.....	150
3.16.2	Deleting Customers	151
3.16.3	Modifying SDPs.....	151
3.16.4	Deleting SDPs	152
3.16.5	Deleting LSP Associations	152
3.17	Global Service Command Reference	153

3.17.1	Command Hierarchies	153
3.17.1.1	Global Service Configuration Commands	154
3.17.1.2	Show Commands	157
3.17.2	Command Descriptions	158
3.17.2.1	Global Service Configuration Commands	159
3.17.2.2	Show Commands	186
4	VLL Services	201
4.1	ATM VLL (Apipe) Services	202
4.1.1	ATM VLL for End-to-End ATM Service.....	202
4.1.2	ATM Virtual Trunk Over an IP/MPLS Packet-Switched Network.....	203
4.1.3	ATM SAP-to-SAP Service	205
4.1.4	ATM Traffic Management Support	205
4.1.4.1	Network Ingress Classification	205
4.1.4.2	ATM Access Egress Queuing and Shaping	206
4.1.5	Control Word	206
4.2	Circuit Emulation VLL (Cpipe) Services	207
4.2.1	Cpipe Service Overview	207
4.2.2	TDM SAP-to-SAP Service	208
4.2.3	Cpipe Service Modes	208
4.2.3.1	Unstructured Mode (SAToP)	209
4.2.3.2	SAToP Serial	209
4.2.3.3	Structured Mode (CESoPSN).....	212
4.2.4	TDM PW Encapsulation	216
4.2.5	Circuit Emulation Parameters and Options	219
4.2.5.1	Unstructured	222
4.2.5.2	Structured DS1/E1 CES without CAS	222
4.2.5.3	Structured T1/E1 CES with CAS	226
4.2.5.4	Packet Payload Size.....	228
4.2.5.5	Jitter Buffer	229
4.2.5.6	Asymmetric Delay Control	230
4.2.5.7	RTP Header.....	233
4.2.5.8	Control Word	233
4.2.6	Transparent SDH/SONET Over Packet (TSoP)	234
4.2.7	Error Situations.....	235
4.3	Ethernet VLL (Epipe) Services	236
4.3.1	Epipe Service Overview	236
4.3.2	Ethernet Access Egress Queuing and Scheduling.....	238
4.3.3	Ethernet SAP-to-SAP	238
4.3.4	Epipe with ATM SAPs	239
4.3.5	MEF 8.....	240
4.3.5.1	Epipe Service Modes.....	243
4.3.6	Ethernet OAM.....	245
4.3.7	Control Word	245
4.3.8	MTU	246
4.3.9	Raw and Tagged Modes	246
4.3.9.1	Raw Mode	247
4.3.9.2	Tagged Mode	247
4.3.9.3	VLAN Translation	247

4.3.9.4	Tagging Rules for Epipe	248
4.3.10	IP Filters (Epipe).....	254
4.3.11	MPLS Entropy Label.....	255
4.4	Frame Relay VLL (Fpipe) Services	256
4.4.1	Fpipe Service Overview.....	256
4.4.2	Frame Relay SAP-to-SAP Service	258
4.4.3	Frame Relay Traffic Management.....	258
4.4.3.1	Ingress SAP Classification and Marking.....	258
4.4.4	Frame Relay Encapsulation	258
4.4.4.1	Frame Relay PW Control Word	259
4.4.5	Status Signaling and OAM Propagation	260
4.5	HDLC VLL (Hpipe) Services.....	261
4.5.1	Hpipe Service Overview	261
4.5.2	HDLC VLL for End-to-End HDLC Service	262
4.5.3	HDLC SAP-to-SAP Service	263
4.5.4	HDLC Encapsulation	263
4.5.4.1	HDLC PW Control Word and Payload Size.....	264
4.5.5	Status Signaling.....	266
4.5.5.1	OAM Propagation	266
4.6	IP Interworking VLL (Ipipe) Services	267
4.6.1	Ipipe Service Overview.....	268
4.6.2	IP Interworking VLL Datapath.....	269
4.6.3	CE IP Address Discovery and Distribution	270
4.6.3.1	Manual IP Configuration	270
4.6.3.2	CE IP Address Discovery Using ARP	271
4.6.3.3	CE IP Address Discovery for Frame Relay	271
4.6.3.4	CE IP Address Discovery for cHDLC	271
4.6.3.5	CE IP Address Discovery for PPP/MLPPP	272
4.6.3.6	CE IP Address Distribution to Remote PE Nodes	272
4.6.4	IP SAP-to-SAP Service	272
4.6.5	Hardware Support for Interworking IP PWs	272
4.6.6	Control Word	275
4.6.7	Termination at Access	275
4.6.7.1	PPP and MLPPP Termination	275
4.6.7.2	FR Termination.....	275
4.6.7.3	cHDLC Termination	276
4.6.7.4	PPP and MLPPP Termination on 2-port OC3/STM1 Channelized Adapter Cards	277
4.6.8	Traffic Management.....	279
4.6.8.1	Traffic Management for FR IW SAPs	279
4.6.9	Status Signaling.....	279
4.6.9.1	FR LMI	279
4.6.10	IP Filters (Ipipe)	280
4.7	Pseudowire Switching	282
4.7.1	Overview.....	282
4.7.2	Pseudowire Switching with Pseudowire Redundancy	285
4.7.3	Pseudowire Switching Behavior	286
4.7.3.1	Pseudowire Switching With IP Tunnels	288
4.7.4	Pseudowire Switching TLV.....	288

4.8	VLL Service Considerations	290
4.8.1	Service Support.....	290
4.8.2	SDPs	294
4.8.2.1	SDP Statistics for VLL Services	294
4.8.3	SAP Encapsulations and Pseudowire Types	294
4.8.4	ATM PWE3 N-to-1 Cell Mode Encapsulation	297
4.8.4.1	N-to-1 Cell Mode Encapsulation (N = 1).....	298
4.8.4.2	N-to-1 Cell Mode Encapsulation (N > 1).....	300
4.8.5	SAP Aggregation Groups	304
4.8.5.1	Configuration	304
4.8.5.2	QoS and Traffic Descriptor Profiles (N > 1).....	306
4.8.5.3	Statistics and Counters.....	306
4.8.5.4	Fault Management	307
4.8.6	QoS Policies	308
4.8.7	IP Filter Policies.....	308
4.8.8	MTU Settings.....	309
4.8.8.1	Targeted LDP and MTU	315
4.8.9	QinQ (VLL Service)	316
4.8.10	Pseudowire Control Word.....	316
4.8.11	Pseudowire Redundancy.....	317
4.8.11.1	PW Redundancy Operation.....	318
4.8.11.2	Selecting the Active Spoke SDP for PW Redundancy Configuration	320
4.8.11.3	PW Redundancy and Inter-Chassis Backup	321
4.8.11.4	AIS Fault Propagation	323
4.8.12	Active/Standby Mode for Pseudowire Redundancy (Standby Signaling).....	324
4.8.12.1	PW Status Signaling Label Withdrawal Option.....	327
4.8.12.2	Pseudowire Redundancy on Serial Data Interface Ports	329
4.9	Configuring a VLL Service with CLI.....	331
4.10	Common Configuration Tasks	332
4.11	Configuring VLL Components	333
4.11.1	Creating an Apipe Service.....	334
4.11.1.1	Configuring Apipe SAP Parameters	335
4.11.1.2	Configuring Apipe SDP Bindings.....	337
4.11.1.3	Configuring Apipe SAP Aggregation Groups.....	338
4.11.1.4	Configuring Apipe SAPs as Aggregation Group Members.....	339
4.11.2	Creating a Cpipe Service.....	341
4.11.2.1	Configuring Cpipe SAP Parameters	342
4.11.2.2	Configuring Cpipe SDP Bindings.....	344
4.11.3	Creating an Epipe Service.....	345
4.11.3.1	Configuring Epipe SAP Parameters	346
4.11.3.2	Configuring Epipe with ATM SAP.....	348
4.11.3.3	Configuring Epipe SAP MEF 8 Parameters.....	350
4.11.3.4	Configuring Epipe SAP Microwave Link Parameters for Interworking with TDM2Ethernet.....	353
4.11.3.5	Configuring ATM Encapsulation Under Epipe Service (7705 SAR-M only).....	354
4.11.3.6	Configuring Epipe Spoke SDP Bindings.....	356

4.11.4	Creating an Fpipe Service	359
4.11.4.1	Configuring Fpipe SAP Parameters	360
4.11.4.2	Configuring Fpipe SDP Bindings	362
4.11.5	Creating an Hpipe Service	363
4.11.5.1	Configuring Hpipe SAP Parameters	364
4.11.5.2	Configuring Hpipe SDP Bindings	366
4.11.6	Creating an Lpipe Service	367
4.11.6.1	Configuring Lpipe SAP Parameters	367
4.11.6.2	Configuring Lpipe SDP Bindings	369
4.11.7	Configuring PW Switching	369
4.11.8	Configuring Ingress and Egress SAP Parameters	372
4.11.9	Using the Control Word	373
4.11.10	Configuring PW Redundancy	374
4.11.10.1	Configuring PW Redundancy—Standby Signaling	375
4.11.10.2	Configuring PW Redundancy—ICB	376
4.12	Service Management Tasks	380
4.12.1	Modifying Service Parameters	380
4.12.2	Disabling a Service	382
4.12.3	Re-enabling a Service	384
4.12.4	Deleting a Service	384
4.13	VLL Services Command Reference	387
4.13.1	Command Hierarchies	387
4.13.1.1	VLL Services Configuration Commands	388
4.13.1.2	Show Commands	398
4.13.1.3	Clear Commands	399
4.13.2	Command Descriptions	400
4.13.2.1	VLL Service Configuration Commands	401
4.13.2.2	Show Commands	458
4.13.2.3	Clear Commands	553
5	VPLS	557
5.1	VPLS Overview	558
5.1.1	VPLS Packet Walkthrough	561
5.1.2	Bridged Mobile Backhaul	565
5.1.3	Multi-Tenant Unit (MTU) Termination	567
5.2	VPLS Features	569
5.2.1	VPLS Enhancements	569
5.2.2	Fabric Mode	571
5.2.3	Subscriber VLAN	571
5.2.4	ATM Encapsulated Residential SAP	572
5.2.5	VPLS over MPLS	572
5.2.6	VPLS MAC Learning and Packet Forwarding	573
5.2.7	Pseudowire Control Word	573
5.2.8	Agent Circuit ID Insertion	573
5.2.9	MAC Filters	575
5.2.10	FDB Table Management	575
5.2.10.1	FDB Size	576
5.2.10.2	FDB Size Alarms	576
5.2.10.3	Local and Remote Aging Timers	576

5.2.10.4	Unknown MAC Discard	577
5.2.11	VPLS and Rate Limiting Via QoS Policy	578
5.2.12	MAC Move.....	578
5.2.13	Split Horizon Groups (SAP and Spoke SDP)	579
5.2.13.1	Residential Split Horizon Groups.....	580
5.2.14	Multicast for VPLS and Routed VPLS (IGMP and MLD Snooping).....	580
5.2.14.1	Application Examples	581
5.2.14.2	Group and Addressing Support.....	583
5.2.14.3	IP Multicast in r-VPLS.....	584
5.2.14.4	Multicast Router Ports	586
5.2.14.5	Tagged Access Traffic.....	586
5.2.14.6	Hardware Support	587
5.2.15	PIM Snooping for VPLS.....	587
5.2.15.1	Snooping versus Proxy Mode.....	589
5.2.16	MPLS Entropy Label.....	589
5.2.17	Ethernet OAM	589
5.3	Routed VPLS	590
5.3.1	IES or VPRN IP Interface Binding	590
5.3.1.1	Assigning a Service Name to a VPLS Service	591
5.3.1.2	Binding a Service Name to an IP Interface.....	591
5.3.1.3	Removing a Bound VPLS Service or Service Name	592
5.3.1.4	IP Interface and VPLS Operational State Coordination.....	592
5.3.2	IP Interface MTU and Fragmentation	592
5.3.3	ARP/ND and VPLS FIB Interactions.....	593
5.3.3.1	Routed VPLS Specific ARP/ND Cache Behavior	594
5.3.4	The allow-ip-int-binding VPLS Flag	595
5.3.4.1	VPLS Feature Restrictions (due to allow-ip-int-binding).....	596
5.3.5	DSCP Marking.....	596
5.3.6	VPLS Ingress IP Filter Override	596
5.3.7	Routed VPLS Supported Routing-Related Protocols	597
5.4	VPLS and Spanning Tree Protocol.....	598
5.4.1	VPLS Redundancy	598
5.4.1.1	Spoke SDP Redundancy for Metro Interconnection.....	599
5.4.1.2	Spoke SDP-Based Redundant Access	600
5.4.2	VPLS Access Redundancy.....	600
5.4.2.1	STP-Based Redundant Access to VPLS	601
5.4.3	MAC Flush Message Processing	601
5.4.3.1	Dual Homing to a VPLS Service.....	603
5.5	ATM PVC Access and Termination on a VPLS Service.....	605
5.6	VPLS Service Considerations	607
5.6.1	SAP Encapsulations	607
5.6.2	VLAN Processing	607
5.6.2.1	Tagging Rules for VPLS	608
5.6.3	QinQ (VPLS).....	608
5.7	Configuration Notes.....	609
5.7.1	Reference Sources.....	609
5.8	Configuring a VPLS Service with CLI	611
5.9	Basic Configuration	612
5.10	Common Configuration Tasks	614

5.11	Configuring VPLS Components.....	615
5.11.1	Creating a VPLS Service.....	615
5.11.2	Creating a Split Horizon Group.....	616
5.11.3	Enabling MAC Move.....	616
5.11.4	Configuring STP Bridge Parameters in a VPLS	618
5.11.4.1	Bridge STP Admin State.....	618
5.11.4.2	Mode.....	619
5.11.4.3	Bridge Priority	619
5.11.4.4	Hello Time	619
5.11.4.5	Hold Count.....	620
5.12	Configuring a VPLS SAP	621
5.12.1	Local VPLS SAPs.....	621
5.12.2	Distributed VPLS SAPs	622
5.12.3	Configuring SAP-Specific STP Parameters.....	623
5.12.3.1	SAP STP Administrative State	623
5.12.3.2	SAP Virtual Port Number	624
5.12.3.3	SAP Priority	624
5.12.3.4	SAP Path Cost.....	625
5.12.3.5	SAP Edge Port	625
5.12.3.6	SAP Auto Edge.....	626
5.12.3.7	SAP Link Type.....	626
5.12.4	STP SAP Operational States.....	627
5.12.4.1	Operationally Disabled	627
5.12.4.2	Operationally Discarding	627
5.12.4.3	Operationally Learning	628
5.12.4.4	Operationally Forwarding	628
5.12.5	Configuring VPLS SAPs with Split Horizon	628
5.13	Configuring SDP Bindings.....	629
5.13.1	Configuring Mesh SDP Bindings	630
5.13.2	Configuring Spoke SDPs.....	631
5.13.2.1	Configuring Spoke SDP Bindings.....	631
5.13.2.2	Configuring Spoke SDP-Specific STP Parameters	632
5.13.3	Configuring VPLS Spoke SDPs with Split Horizon.....	636
5.13.4	Configuring Selective MAC Flush.....	637
5.14	Configuring Routed VPLS	638
5.15	Configuring IP Multicast in VPLS.....	639
5.16	Configuring IP Multicast in r-VPLS	640
5.17	Configuring Multicast Parameters for VPLS and r-VPLS	642
5.18	Configuring a Static Multicast Group	644
5.19	Configuring PIM Snooping for VPLS	645
5.20	Service Management Tasks.....	646
5.20.1	Modifying VPLS Service Parameters	646
5.20.2	Modifying Management VPLS Parameters	647
5.20.3	Deleting a Management VPLS	647
5.20.4	Disabling a Management VPLS.....	647
5.20.5	Deleting a VPLS Service	648
5.20.6	Disabling a VPLS Service.....	648
5.20.7	Re-enabling a VPLS Service	648
5.21	VPLS Command Reference	649

5.21.1	Command Hierarchies	649
5.21.1.1	VPLS Service Configuration Commands	650
5.21.1.2	Show Commands	659
5.21.1.3	Clear Commands	661
5.21.1.4	Debug Commands	662
5.21.2	Command Descriptions	663
5.21.2.1	VPLS Service Configuration Commands	664
5.21.2.2	Routed VPLS Configuration Commands	736
5.21.2.3	VPLS Show Commands	738
5.21.2.4	VPLS Clear Commands	833
5.21.2.5	VPLS Debug Commands	841
6	Internet Enhanced Service	849
6.1	IES for In-band Management	850
6.1.1	Setting Up Connections Between the NSP NFM-P and the 7705 SAR	851
6.1.2	Encapsulation	852
6.1.3	Layer 2 and Layer 3 Traffic Management	852
6.1.4	Troubleshooting and Fault Detection Services	852
6.1.5	IP ECMP Load Balancing	853
6.2	IES for Customer Traffic	854
6.2.1	DHCP Relay and DHCPv6 Relay	857
6.2.1.1	DHCP Relay	858
6.2.1.2	DHCPv6 Relay	859
6.2.2	IPCP	860
6.2.3	IPSec Support	860
6.2.4	Security Zones and IES	861
6.2.5	Proxy ARP	862
6.2.6	Configurable ARP Retry Timer	862
6.2.7	Unnumbered Interfaces	863

1 Preface

1.1 About This Guide

This guide describes subscriber services support provided by the 7705 Service Aggregation Router (7705 SAR) and presents examples to configure and implement various protocols and services.

This document is organized into functional chapters and provides concepts and descriptions of the implementation flow, as well as Command Line Interface (CLI) syntax and command usage.

Note: This manual generically covers Release 20.x content and may contain some content that will be released in later maintenance loads. Please refer to the 7705 SAR 20.x.Rx Software Release Notes, part number 3HE16192000xTQZZA, for information on features supported in each load of the Release 20.x software.

Note:

As of Release 7.0, support for the following hardware has been deprecated:

- CSMv1
- 7705 SAR-F
- 8-port Ethernet Adapter card, version 1
- 16-port T1/E1 ASAP Adapter card, version 1

These components are no longer recognized in the release.

1.1.1 Audience

This guide is intended for network administrators who are responsible for configuring the 7705 SAR routers. It is assumed that the network administrators have an understanding of networking principles and configurations. Concepts described in this guide include the following:

- CLI concepts
- subscriber services

1.1.2 Technical Support

If you purchased a service agreement for your 7705 SAR router and related products from a distributor or authorized reseller, contact the technical support staff for that distributor or reseller for assistance. If you purchased a Nokia service agreement, follow this link to contact a Nokia support representative and to access product manuals and documentation updates:

[Product Support Portal](#)

2 7705 SAR Services Configuration Process

[Table 1](#) lists the tasks that are required to configure subscriber services.

This guide is presented in an overall logical configuration flow. Each section describes a software area and provides CLI syntax and command usage to configure parameters for a functional area.

Table 1 Configuration Process

Area	Task/Description	Reference
Global entities	Configure global entities	Configuring Global Service Entities with CLI
VLL services	Apipe service	ATM VLL (Apipe) Services
	Cpipe service	Circuit Emulation VLL (Cpipe) Services
	Epipe service	Ethernet VLL (Epipe) Services
	Fpipe service	Frame Relay VLL (Fpipe) Services
	Hpipe service	HDLC VLL (Hpipe) Services
	Ipipe service	IP Interworking VLL (Ipipe) Services
VPLS service	Configure VPLS service	VPLS
Internet Enhanced Service	Configure a routed-IP connectivity or Internet access service and configure in-band management of the 7705 SAR over ATM links	Internet Enhanced Service
VPRN	Configure a Layer 3 multipoint-to-multipoint VPN service as defined in RFC 2547bis	VPRN Services
IPSec	Configure IPSec service	IPSec
Network group encryption	Configure network group encryption	Network Group Encryption
Reference	List of IEEE, IETF, and other proprietary entities	Standards and Protocol Support

3 Services Overview

This chapter provides an overview of the 7705 SAR subscriber services, service model, and service entities. Additional details on the individual subscriber services are found in subsequent chapters.

Topics in this chapter include:

- [Introduction to Services on the 7705 SAR](#)
- [Nokia Service Model](#)
- [Service Entities](#)
- [Mobile Solutions](#)
- [ETH-CFM \(802.1ag and Y.1731\)](#)
- [G.8032 Ethernet Ring Protection Switching](#)
- [QinQ Support](#)
- [Raw Socket IP Transport Service](#)
- [Service Creation Overview](#)
- [Port and SAP CLI Identifiers](#)
- [Configuring Global Service Entities with CLI](#)
- [Global Service Command Reference](#)

3.1 Introduction to Services on the 7705 SAR

Topics in this section include:

- [Overview](#)
- [Service Types](#)
- [Service Policies](#)

3.1.1 Overview

A service is a type of telecommunications connection from one place to another. These telecommunications connections have the particular attributes and characteristics that are needed to provide a specific communications link through which an information flow or exchange can occur. The 7705 Service Access Router (7705 SAR) offers VLL services, Layer 2 multipoint VPN services (VPLS), Layer 3 MPLS VPN services (VPRN), and Layer 3 routed/IP services.

The 7705 SAR service model uses (logical) service entities to construct a service. These logical entities provide a uniform, service-centric configuration, management, and billing model for service provisioning (see [Nokia Service Model](#) for more information). Many services can be created on the same 7705 SAR at the same time, and each service is uniquely identified by a service ID.

The 7705 SAR offers Virtual Leased Line (VLL) services (also referred to as pseudowire (PW) services or pipes), which emulate a Layer 1/2 entity, such as a wire or a leased line. These emulated services provide connectivity between a service access point (SAP) on one 7705 SAR and on another SAP on the same router, or on a remote 7705 SAR, 7710 SR, or 7750 SR. VLL services offer SAP logical entities—such as a VLAN or a virtual connection—Layer 2 visibility or processing (IMA termination). A SAP is the point where customer traffic enters and exits the service.

A connection between two SAPs on the same router is known as a local service. A connection between SAPs on a local and a remote router is known as a distributed service. SAP-to-SAP connections are supported for ATM, Ethernet, FR, HDLC, and TDM VLLs.

The 7705 SAR also supports the aggregation of multiple ATM VCC SAPs into a single aggregation group within a service. Aggregation groups enable service providers to make more efficient use of the ATM VCC VLL services that are deployed in a network.

Distributed services use service destination points (SDPs) to direct traffic from a local router to a remote router through a service tunnel. An SDP is created on the local router and identifies the endpoint of a logical unidirectional service tunnel. Traffic enters the tunnel at the SDP on the local router and exits the tunnel at the remote router. Hence, a service tunnel provides a path from a 7705 SAR to another service router, such as another 7705 SAR, a 7710 SR, or a 7750 SR. Because an SDP is unidirectional, two service tunnels are needed for bidirectional communication between two service routers (one SDP on each router).

SDPs are configured on each participating 7705 SAR or service router, specifying the address of the source router (the 7705 SAR participating in the service communication) and the address of the destination router, such as another 7705 SAR or service router. After SDPs are created, they are bound to a specific service. The binding process is needed to associate the far-end devices to the service; otherwise, far-end devices are not able to participate in the service.

The 7705 SAR also offers IES, VPLS, and VPRN services.

IES provides IP connectivity between customer access points. From the customer's perspective, IES provides direct IP connectivity. The customer is assigned an IP interface and a SAP designates the customer access point where the customer IP device is connected—one SAP binding per IP interface. Supported SAP encapsulations are MC-MLPPP, PPP/MLPPP and null/dot1q/qinq Ethernet. SDP binding is not required because traffic is routed rather than being encapsulated in a tunnel.

A Virtual Private Routed Network (VPRN) consists of a set of customer sites connected to one or more PE routers. VPRNs are based on RFC 2547bis, which details a method of distributing routing information and forwarding data to provide a Layer 3 Virtual Private Network (VPN) service to end customers. VPRN traffic is transported over LDP and RSVP-TE tunnels, as well as static LSPs.

A Virtual Private LAN Service (VPLS) enables Layer 2 multipoint connections within an enterprise infrastructure. Supported SAP encapsulations are null/dot1q/qinq Ethernet (on the 8-port Ethernet Adapter card, 6-port Ethernet 10Gbps Adapter card, 7705 SAR-X, 8-port Gigabit Ethernet Adapter card, and the 10-port 1GigE/1-port 10GigE X-Adapter card) and ATM (on the 4-port OC3/STM1 Clear Channel Adapter card).

Note: The 10-port 1GigE/1-port 10GigE X-Adapter card supports qinq only when it is in 10-port 1GigE mode.

VPLS traffic can also be transported over existing tunnel types like GRE tunnels, LDP tunnels, RSVP-TE tunnels, and static LSPs using SDPs. For the ATM SAPs, the Layer 2 Ethernet frames are encapsulated in Ilc-snap bridged PDUs, as per RFC 2684, widely referred to with the obsoleted RFC 1483.

3.1.2 Service Types

Services are commonly called customer or subscriber services. The 7705 SAR offers the following types of services, which are described in more detail in the referenced chapters:

- Virtual Leased Line (VLL) services
 - ATM VLL (Apipe)—a pseudowire emulation edge-to-edge (PWE3) ATM service over MPLS, GRE, or IP tunnels on 7705 SAR nodes. See [ATM VLL \(Apipe\) Services](#).
 - Circuit emulation VLL (Cpipe)—a PWE3 circuit emulation service over MPLS or GRE tunnels on 7705 SAR nodes. See [Circuit Emulation VLL \(Cpipe\) Services](#).
 - Ethernet VLL (Epipe)—a PWE3 Ethernet service over MPLS or GRE tunnels for Ethernet frames on 7705 SAR nodes. See [Ethernet VLL \(Epipe\) Services](#).
 - FR VLL (Fpipe)—a PWE3 FR service over MPLS or GRE tunnels for FR frames on 7705 SAR nodes. See [Frame Relay VLL \(Fpipe\) Services](#).
 - HDLC VLL (Hpipe)—a PWE3 HDLC service over MPLS or GRE tunnels for HDLC frames on 7705 SAR nodes. See [HDLC VLL \(Hpipe\) Services](#).
 - IP interworking VLL (Ipipe)—a PWE3 IP service between two hosts connected by any combination of point-to-point access circuits. IP interworking VLLs can operate over MPLS or GRE networks. Some typical examples are Ethernet SAP to Ethernet SAP, Ethernet SAP to MLPPP SAP, Ethernet SAP to LAG SAP, FR SAP to Ethernet SAP, or cHDLC SAP to Ethernet SAP. See [IP Interworking VLL \(Ipipe\) Services](#).
- Internet Enhanced Service (IES)
 - IES is used both as a direct Internet access service where the customer is assigned an IP interface for routed connectivity and for in-band management of the 7705 SAR. See [Internet Enhanced Service](#).

- Virtual Private LAN Service (VPLS)
 - VPLS provides a Layer 2 multipoint VPN service to end customers. VPLS includes Hierarchical VPLS (H-VPLS), which is an enhancement of VPLS that extends pseudowire-style signaled or static virtual circuit labeling outside the fully meshed VPLS core. The 7705 SAR can participate in hierarchical VPLS. In addition, the 7705 SAR supports management VPLS (mVPLS) via Rapid Spanning Tree Protocol (RSTP). See [VPLS](#).
- Virtual Private Routed Network Service (VPRN)
 - VPRN provides a Layer 3 VPN service to end customers. VPRN services provide MP-BGP peering with other PEs, configurable QoS policy and filtering, VRF import and export policies, and SGT-QoS marking. See [VPRN Services](#).

[Table 2](#) lists the supported pseudowire (PW) service types. The values are as defined in RFC 4446.

Table 2 Pseudowire Service Types

PW Service Type (Ethertype)	Value
IP Layer 2 transport	0x000B
Ethernet tagged mode	0x0004
Ethernet raw	0x0005
HDLC	0x0006
ATM N-to-one VCC cell mode ¹	0x0009
ATM N-to-one VPC cell mode	0x000A
ATM transparent cell transport mode	0x0003
SAToP E1	0x0011
SAToP T1	0x0012
CESoPSN basic mode	0x0015
CESoPSN TDM with CAS	0x0017
FR DLCI	0x0019

Note:

1. “N-to-one” is expressed as “N-to-1” throughout this guide.

3.1.3 Service Policies

Common to all 7705 SAR connectivity services are policies that are assigned to the service. Policies are defined at the global level, then applied to a service on the router. Policies are used to define 7705 SAR service enhancements.

The types of policies that are common to all 7705 SAR connectivity services are SAP Quality of Service (QoS) policies and accounting policies. Filter policies are supported on network interfaces, Epipe and Lpipe SAPs, VPLS SAPs and SDPs (mesh and spoke), VPRN SAPs and spoke SDPs, IES SAPs and spoke SDPs, and IES in-band management SAPs.

- SAP Quality of Service (QoS) policies allow for different classes of traffic within a service at SAP ingress and SAP egress.

QoS ingress and egress policies determine the QoS characteristics for a SAP. A QoS policy applied to a SAP specifies the number of queues, queue characteristics (such as forwarding class, committed information rates, and peak information rates) and the mapping of traffic to a forwarding class. A QoS policy must be created before it can be applied to a SAP. A single ingress and a single egress QoS policy can be associated with a SAP.

QoS ingress and egress policies also apply to SAP aggregation groups.

- Accounting policies define how to count the traffic usage for a service for billing purposes.

The 7705 SAR routers provide a comprehensive set of service-related counters. Accounting data can be collected on a per-service, per-forwarding class basis, which enables network operators to accurately measure network usage and bill each customer for each individual service using any of a number of different billing models.

- Filter policies, also referred to as access control lists (ACLs), allow selective blocking or forwarding of traffic that matches criteria that is set in the policy. The resulting action (block or forward) is applied to that traffic.

Filter policies control the traffic allowed into a SAP or SDP, and are based on IP or MAC match criteria. The ability to configure and apply a filter depends on the combination of service, traffic type and direction, and entity type (SAP or SDP). Assigning a filter policy to a SAP or SDP is optional. Filter policies are identified by a unique filter policy ID. A filter policy must be created before it can be applied. A single ingress and a single egress filter policy can be assigned to a SAP (if supported), and a single ingress filter policy can be assigned to an SDP (if supported).

For more information on provisioning QoS policies, including queuing behaviors, refer to the 7705 SAR Quality of Service Guide. For information on configuring IP and MAC filter policies, refer to the 7705 SAR Router Configuration Guide.

3.2 Nokia Service Model

The 7705 SAR routers are deployed at the provider edge (PE). Services are provisioned on the 7705 SAR and other network equipment in order to facilitate the transport of telecommunications data across an IP/MPLS provider's core network. The data is formatted so that it can be transported in encapsulation tunnels created using generic routing encapsulation (GRE), IP encapsulation, or MPLS label switched paths (LSPs).

The service model has four main logical components, referred to as (logical) service entities. The entities are: customers, service types, service access points (SAPs), and service destination points (SDPs) (see [Service Entities](#)). In accordance with the service model, the operator uses the (logical) service entities to construct an end-to-end service. The service entities are designed to provide a uniform, service-centric model for service provisioning. This service-centric design implies the following characteristics.

- Many services can be bound to a single customer.
- Many services can be bound to a single tunnel.
- Tunnel configurations are independent of the services they carry.
- Changes are made to a single service entity rather than to multiple ports on multiple devices. It is easier to change one tunnel rather than several services.
- The operational integrity of a service entity (such as a service tunnel or service endpoint) can be verified by one operation rather than through the verification of dozens of parameters, thereby simplifying management operations, network scalability, and performance.
- A failure in the network core can be correlated to specific subscribers and services.
- The following policies are applied to various services:
 - QoS policies
 - accounting policies
 - filter policies (IP and MAC)

Additional properties can be configured for bandwidth assignments, class of service, and accounting and billing on the appropriate entity.

3.3 Service Entities

The basic (logical) service entities in the service model used to construct an end-to-end service are:

- [Customers](#)
- [Service Types](#)
- [Service Access Points \(SAPs\)](#)
- [Service Destination Points \(SDPs\)](#)

[Figure 1](#) shows an example of how the service entities relate to the service model. A subscriber (or customer) attachment circuit connects to a SAP. SDPs define the entrance and exit points of unidirectional service tunnels, which carry one-way traffic between the two routers (ALU-A and ALU-B). After SDPs have been configured, they are bound to a service, which is the final step in making the end-to-end service connection. In [Figure 1](#), the entrance point is labeled SDP and the exit point is labeled Exit.

Traffic encapsulation occurs at the SAP and SDP. The SAP encapsulation types are SONET/SDH, Ethernet, and TDM. The SDP encapsulation types are MPLS, GRE, and IP. For information on SAP encapsulation types, see [SAP Encapsulation Types and Identifiers](#). For information on SDP encapsulation types, see [SDP Encapsulation Types](#).

Figure 1 Service Entities and the Service Model

19686

3.3.1 Customers

The terms customers and subscribers are used synonymously. Every customer account must have a customer ID, which is assigned when the customer account is created. To provision a service, a customer ID must be associated with the service at the time of service creation.

3.3.2 Service Types

Service types provide the traffic adaptation needed by customer attachment circuits (ACs). This (logical) service entity adapts customer traffic to service tunnel requirements. The 7705 SAR provides six types of VLL service (that is, point-to-point MPLS-based emulation service, also called Virtual Private Wire Service (VPWS)):

- ATM VLL (Apipe)
- circuit emulation VLL (Cpipe)
- Ethernet VLL (Epipe)
- Frame relay VLL (Fpipe)
- HDLC VLL (Hpipe)
- IP interworking VLL (Ipipe)

The 7705 SAR also provides Ethernet layer (MAC-based) VPLS service (including management VPLS), as well as IP layer VPRN and IES services, that offer any-to-any connectivity within a Virtual Routing Domain or Generic Routing Domain, respectively.

3.3.2.1 Service Names

A service ID number must be associated with a service at the time of service creation. Once the service is created, an optional service name can be assigned to the service for use by commands that reference the service.

3.3.3 Service Access Points (SAPs)

A service access point (SAP) is the point at which a service begins (ingress) or ends (egress) and represents the access point associated with a service. A SAP may be a physical port or a logical entity within a physical port. For example, a SAP may be a channel group within a DS1 or E1 frame, an ATM endpoint, an Ethernet port, or a VLAN that is identified by an Ethernet port and a VLAN tag. Each subscriber service connection on the 7705 SAR is configured to use only one SAP.

A SAP identifies the customer interface point for a service on a 7705 SAR router. [Figure 2](#) shows one customer connected to two services via two SAPs. The SAP identifiers are 1/1/5 and 1/1/6, which represent the physical ports associated with these SAPs. The physical port information should be configured prior to provisioning a service. Refer to the 7705 SAR Interface Configuration Guide for more information about configuring a port. See [Port and SAP CLI Identifiers](#) for more information about identifiers.

The 7705 SAR supports the following services types: ATM pseudowires (Apipe), TDM pseudowires (Cpipe), IP pseudowires (Ipipe), Ethernet pseudowires (Epipe), FR pseudowires (Fpipe), HDLC pseudowires (Hpipe), IES, VPLS, and VPRN services. Customer access to these services is provided via SAPs. For each service type, the SAP has slightly different parameters.

In general, SAPs are logical endpoints that are local to the 7705 SAR and are uniquely identified by:

- the physical Ethernet port, SONET/SDH port, or TDM channel group
- the encapsulation type for the service (for example, ATM)
- the encapsulation identifier (ID), which is, for example, the optional VLAN ID for Epipes, or the channel group ID for Cpipes

Depending on the encapsulation, a physical port or channel can have more than one SAP associated with it (for example, a port may have several circuit groups, where each group has an associated SAP). SAPs can only be created on ports or channels designated as “access” in the physical port configuration.

SAPs cannot be created on ports designated as core-facing “network” ports because these ports have a different set of features enabled in software.

Figure 2 Service Access Point (SAP)

19479

3.3.3.1 SAP Encapsulation Types and Identifiers

The SAP encapsulation type is an access property of the Ethernet port, SONET/SDH port, or TDM channel group used for the service. It identifies the protocol that is used to provide the service.

The 7705 SAR supports three SAP encapsulation types:

- [Ethernet Encapsulations](#)
- [SONET/SDH Encapsulations](#)
- [TDM and Serial \(TDM\) Encapsulations](#)
- [Service Types and SAP Encapsulations—Summary](#)

Encapsulation types may have more than one option to choose from. For example, the options for TDM encapsulation type include “cem” (for circuit emulation service) and “atm” (for ATM service), among others.

In the case of SAPs configured on the 16-port T1/E1 ASAP Adapter card version 2, the 32-port T1/E1 ASAP Adapter card, and the 4-port DS3/E3 Adapter card, the cards must be configured to support the appropriate encapsulation methods before the encapsulation type can be configured. This is done using the **mda-mode** command. Refer to the 7705 SAR Interface Configuration Guide for more information.

The encapsulation ID is an optional suffix that is appended to a *port-id* to specify a logical sub-element for a SAP. For example, *port-id:qtag1* represents a port that can be tagged to use IEEE 802.1Q encapsulation (referred to as dot1q), where each individual tag can identify with an individual service. Similarly, *port-id.channel-group:vpi/vci* represents the encapsulation ID for an ATM SAP, which is a special case because it requires that a channel group identifier (which always uses the value 1) precede the VPI/VCI value.

**Note:**

- Throughout this guide, the term “channel group” is often simplified to “channel”.
- Do not confuse the term “encapsulation ID” (described here) with the term “Encapsulation ID”, which is used with the SNMP and MIBs for the 7705 SAR.

3.3.3.1.1 Ethernet Encapsulations

The following encapsulation service options are available on Ethernet ports:

- null—supports a single service on the port; for example, where a single customer with a single service customer edge (CE) device is attached to the port.
- dot1q—supports multiple services for one customer or services for multiple customers (see [Figure 3](#)). An example of dot1q use might be the case where the Ethernet port is connected to a multi-tenant unit device with multiple downstream customers. The encapsulation ID used to distinguish an individual service is the VLAN ID in the IEEE 802.1Q header.
- qinq— supports multiple services for one customer or services for multiple customers. The encapsulation IDs used to distinguish an individual service are the QinQ VLAN IDs in the IEEE 802.1ad header, producing a double-tagged frame. For more information on QinQ, see [QinQ Support](#).

Figure 3 Multiple SAPs on a Single Port/Channel

19480

Default SAP on a Dot1q and QinQ Port

The 7705 SAR supports default SAP functionality on dot1q- and qinq-encapsulated ports. On dot1q- and qinq-encapsulated ports where a default SAP is configured, all packets with Q-tags not matching any other explicitly defined SAPs are assigned to the default SAP for transport.

A default SAP is identified in the CLI by the use of the character “*” as a Q-tag, where the “*” means “all”. For example, *port-id:vlan-x.** and *port-id:.** are default SAPs. The former case (vlan-x.*) is a specific example of the latter case (.*), where the outer tag (vlan-x) matches an existing SAP VLAN ID. See [Special QinQ SAP Identifiers](#) for more information.

Note: On the 7705 SAR, the *.* notation for QinQ behaves in the same way as the * notation for dot1q. This behavior is different from the 7750 SR implementation. On the 7750 SR, the “*.*” notation is used only for VPLS service as a capture SAP.

One of the applications where the default SAP feature can be used is for an access connection of a customer who uses the whole port to access Layer 2 services. The internal VLAN tags are transparent to the service provider. This (the use of a whole port) can be provided by a null-encapsulated port. A dedicated VLAN (not used by the user) can be used to provide CPE management.

In this type of environment, two SAPs logically exist, a management SAP and a service SAP. The management SAP can be created by specifying a VLAN tag that is reserved to manage the CPE. The service SAP covers all other VLANs and behaves as a SAP on a null-encapsulated port.

There are a few constraints related to the use of a default SAP on a dot1q- or a qinq-encapsulated port:

- The default SAP is supported only on VPLS and Epipe services and cannot be created in IES and VPRN services because IES and VPRN services cannot preserve VLAN tag markings.
- For VPLS SAPs with STP enabled, STP listens to untagged and null-tagged BPDUs only. All other tagged BPDUs are forwarded like other customer packets. This is the same behavior as null-encapsulated ports.
- IGMP snooping is not supported on a default SAP. By not allowing IGMP snooping of a default SAP, all IGMP packets will be transparently forwarded.
- The default SAP and the SAP defined by explicit null encapsulation are mutually exclusive (for example, 1/1/1:* and 1/1/1:0 are mutually exclusive, and 1/1/2:1.* and 1/1/2:1.0 are mutually exclusive). This avoids conflict as to which SAP untagged frames should be associated with.

3.3.3.1.2 SONET/SDH Encapsulations

The following service encapsulation option is available on SONET/SDH ports:

- atm—supports multiple service instances for one customer, as well as bridged llc-snap encapsulated ATM SAP termination to VPLS

3.3.3.1.3 TDM and Serial (TDM) Encapsulations

The following service encapsulation options are available on TDM and SDI ports:

- atm—supports multiple services for one customer (TDM ports only)
- cem—supports multiple services for one customer. Structured cem service (circuit emulation service over packet switched network (CESoPSN ($n \times DS0$)) and unstructured cem service (structure-agnostic TDM over packet (SAToP)) are supported. (TDM and SDI ports)
- ipcp—supports a single IP service per TDM channel group on channelized interfaces. This is typically used for router interconnection using the point-to-point protocol (PPP). (TDM ports, and SDI V.35 and X.21 ports at super-rate speeds)
- frame-relay (TDM port0s, and SDI V.35 and X.21 ports at super-rate speeds)
- cisco-hdlc (TDM on DS1/E1 ports, and SDI V.35 and X.21 ports at super-rate speeds)
- hdlc (TDM on DS1/E1 ports, and SDI V.35 and X.21 ports at super-rate speeds)

3.3.3.1.4 Service Types and SAP Encapsulations—Summary

[Table 3](#) lists the SAP encapsulations available to 7705 SAR service types. These encapsulations apply to access-facing ports. The service (port) type and encapsulations are configured at the port level. See the 7705 SAR Interface Configuration Guide for more information about the cards and ports that support each of the service types.

Table 3 Service Types and SAP Encapsulations

Service (Port) Type	Encapsulation Option
Ethernet	null
Ethernet	dot1q
Ethernet	qinq

Table 3 Service Types and SAP Encapsulations (Continued)

Service (Port) Type	Encapsulation Option
SONET/SDH	atm
TDM	cem
TDM	atm
TDM	ipcp
TDM	frame-relay
TDM	cisco-hdlc
TDM	hdlc

3.3.3.2 SAP Configuration Considerations

In addition to being an entry or exit point for service traffic, a SAP has to be configured for a service and, therefore, has properties. When configuring a SAP, consider the following.

- A SAP is a local entity and is only locally unique to a given device. The same SAP ID value can be used on another 7705 SAR.
- There are no default SAPs. All subscriber service SAPs must be created.
- The default administrative state for a SAP at creation time is administratively enabled.
- When a SAP is deleted, all configuration parameters for the SAP are also deleted.
- A SAP is owned by and associated with the service in which it is created.
- An Ethernet port or channel with a dot1q encapsulation type means that the traffic for the SAP is identified based on a specific IEEE 802.1Q VLAN ID value. The VLAN ID is stripped off at SAP ingress and the appropriate VLAN ID is placed on at SAP egress. As a result, VLAN IDs only have local significance, so the VLAN IDs for the SAPs for a service need not be the same at each SAP. QinQ encapsulation means that the SAP is identified based on specific IEEE 802.1ad VLAN ID values.
- A TDM circuit emulation service (for example, CESoPSN) requires a channel group. The channel group must be created before it can be assigned to a SAP.

- An ATM service (for example, ATM N-to-1 VCC cell transport) on a 16-port T1/E1 ASAP Adapter card, 2-port OC3/STM1 Channelized Adapter card, or a 4-port OC3/STM1 / 1-port OC12/STM4 Adapter card requires a channel group. For this case, the channel group requires the assignment of all 24 timeslots (T1) or 30 timeslots (E1). The timeslot assignments are made automatically after a channel group is configured for ATM encapsulation.
- If a port or channel is administratively shut down, all SAPs on that port or channel will be operationally out of service.
- A SAP cannot be deleted until it has been administratively disabled (shut down).
- Each SAP can have one of the following policies assigned to it:
 - Ingress QoS policy
 - Egress QoS policy
 - Accounting policy
 - Ingress filter policy (for Epipe SAPs, Ipipe SAPs, VPLS SAPs, VPRN SAPs, IES SAPs, and IES in-band management SAPs)
 - Egress filter policy (for VPRN and IES SAPs, and for VPLS SAPs (Ethernet SAPs only))

3.3.4 Service Destination Points (SDPs)

An SDP identifies the endpoint of a logical unidirectional service tunnel. The service tunnel provides a path from one 7705 SAR to another network device, such as another 7705 SAR, a 7710 SR, or a 7750 SR.

In more general terms, SDP refers to the service tunnel itself. The SDP terminates at the far-end router, which is responsible for directing the flow of packets to the correct service egress SAPs on that device.

Note: In this document and in command line interface (CLI) usage, SDP is defined as Service Destination Point. However, it is not uncommon to find the term SDP defined in several different ways, as in the following list. All variations of SDP have the same meaning:

- Service Destination Point
- Service Distribution Point
- Service Destination Path
- Service Distribution Path
- Service Delivery Path

When an SDP is bound to a service, the service is referred to as a distributed service. A distributed service consists of a configuration with at least one SAP on a local node, one SAP on a remote node, and an SDP binding that binds the service to the service tunnel.

An SDP has the following characteristics.

- An SDP is locally unique to a participating 7705 SAR. The same SDP ID can appear on other 7705 SAR routers.
- An SDP uses the system IP address of the far-end edge router to locate its destination.
- An SDP is not specific to any one service or to any type of service. Once an SDP is created, services are bound to the SDP. An SDP can also have more than one service type associated with it.
- All services bound to an SDP use the same SDP (transport) encapsulation type defined for the SDP (GRE, IP, or MPLS).
- An SDP is a service entity used for service management. Even though the SDP configuration and the services carried within it are independent, they are related objects. Operations on the SDP affect all the services associated with the SDP. For example, the operational and administrative state of an SDP controls the state of services bound to the SDP.
- An SDP tunnel from the local device (typically, a 7705 SAR) to the far-end device (router) requires a return SDP tunnel from the far end back to the local device. Each device must have an SDP defined for every remote router to which it wants to provide service. The SDP must be created before a distributed service can be configured.
- An SDP can be used to provide PW redundancy, where up to four spoke SDPs can be assigned to a service endpoint that acts as the managing entity to ensure service connection. See [Pseudowire Redundancy](#).

3.3.4.1 SDP Binding

To configure a distributed service pointing from ALU-A to ALU-B, the SDP ID on the ALU-A side (see [Figure 4](#)) must be specified during service creation in order to bind the service to the tunnel (the SDP). Otherwise, service traffic is not directed to a far-end point and the far-end 7705 SAR devices cannot participate in the service (there is no service). To configure a distributed service pointing from ALU-B to ALU-A, the SDP ID on the ALU-B side must be specified.

Figure 4 SDP Tunnel Pointing from ALU-A to ALU-B

19687

3.3.4.2 Spoke and Mesh SDPs

There are two types of SDPs: spoke and mesh. The type of SDP defines how flooded traffic (or broadcast traffic, such as an ARP request) is propagated. For point-to-point PW/VLL services, spoke SDPs are the only way to bind services to the far-end router. For VPLS, mesh and spoke SDP bindings are allowed.

A spoke SDP that is bound to a service operates like a traditional bridge port. Flooded traffic that is received on the spoke SDP is transmitted to all the spoke SDPs, mesh SDPs, and SAPs to which it is connected. Flooded traffic is not transmitted back toward the port from which it was received.

In contrast, a mesh SDP that is bound to a service operates like a single bridge port. Flooded traffic received on a mesh SDP is transmitted to all spoke SDPs and SAPs to which it is connected. Flooded traffic is not transmitted to any other mesh SDPs or back toward the port from which it was received. This property of mesh SDPs is important for multi-node networks; mesh SDPs are used to prevent the creation of routing loops.

3.3.4.3 SDPs and BGP Route Tunnels

SDP can use BGP route tunnels to extend inter-AS support for Layer 2 and Layer 3 VPN services as defined in RFC 3107. An SDP can be configured based on service transport method (for example, GRE or MPLS tunnel). MPLS SDP support is enhanced to allow a BGP route tunnel to reach the far-end PE.

A single method of tunneling is allowed per SDP (for example, LDP LSP, RSVP-TE LSP or BGP route tunnel). This restriction is relaxed for some combinations of the transport methods when the mixed-LSP mode option is enabled on the SDP. See [Mixed-LSP SDPs](#) for more information.

For an inter-AS far-end PE, the next hop for the BGP route tunnel must be one of the local ASBRs. The LSP type selected to reach the local ASBR (BGP-labeled route next hop) must be configured under the BGP global context. LDP/RSVP must be supported to provide a transport LSP to reach the BGP route tunnel next hop.

Only BGP route labels can be used to transition from an ASBR to the next-hop ASBR. The global BGP route tunnel transport configuration option must be configured to select an LSP to reach the PE node from the ASBR.

For more information on BGP route tunnels, refer to the 7705 SAR Routing Protocols Guide, “BGP Route Tunnels”.

3.3.4.4 SDP Encapsulation Types

The Nokia service model uses encapsulation tunnels (also referred to as service tunnels) through the core to interconnect 7705 SAR and SR routers. An SDP is a logical way of referencing the entrance to an encapsulation tunnel.

The following encapsulation types are supported:

- Layer 2 within multiprotocol label switching ([MPLS Encapsulation](#))
- Layer 2 or Layer 3 within generic routing encapsulation ([GRE Encapsulation](#))
- Layer 2 within IP ([IP Encapsulation](#))

Each SDP service tunnel has an entrance and an exit point for the pseudowires contained within it.

3.3.4.4.1 MPLS Encapsulation

Multiprotocol label switching (MPLS) encapsulation has the following characteristics.

- An MPLS 7705 SAR router supports both signaled and non-signaled LSPs through the network.
- Non-signaled paths are defined at each hop through the network.

An SDP has an implicit Maximum Transmission Unit (MTU) value because services are carried in encapsulation tunnels and an SDP is an entrance to the tunnel. The MTU is configurable (in octets), where the transmitted frame can be no larger than the MTU.

With MPLS, the MTU for the network port permits the addition of labels for transmission across the MPLS network. Ethernet frames that are sent out of a network port toward the MPLS core network (or a P router) are allowed to be oversized in order to include the MPLS labels without the need to fragment large frames. See [MTU Settings](#) for more information.

The following ways of configuring an MPLS tunnel are supported:

- LDP signaled
- RSVP-TE signaled
- user-configured (static LSP)

3.3.4.4.2 GRE Encapsulation

Generic routing encapsulation (GRE) is one of the most common tunneling techniques in the industry. GRE tunnels are used to transport various network layer packets and are especially useful for facilitating pseudowires over IP networks. Since MPLS is a Layer 2.5 protocol, MPLS packets cannot be natively transported over a Layer 3 (IP) network. Therefore, GRE is the ideal alternative for applications where traffic must travel over a Layer 3 network; for example, in DSL applications.

For the HSDPA offload application (see [HSDPA Offload](#)), ATM pseudowires are transported over IP using GRE tunneling. For other applications, Ethernet and TDM pseudowires over GRE are also supported.

GRE SDPs are supported on all network interfaces.

GRE Format

In accordance with RFC 2784, a GRE encapsulated packet has the following format:

- delivery header
- GRE header
- payload packet

Delivery Header

The delivery header is always an IP header.

GRE Header

The GRE header format is shown in [Figure 5](#) and described in [Table 4](#).

Figure 5 GRE Header

19874

Table 4 GRE Header Descriptions

Field	Description
C	Specifies whether there is a checksum in the header If set to 1, both the checksum and reserved1 fields must be present On the 7705 SAR, in the network egress (transmit) direction, the C bit is always set to 0; therefore, the checksum and reserved1 fields are omitted from the header. The GRE header is therefore always 4 bytes (32 bits) in the network egress direction. In the network ingress direction, the C bit validity is checked. If it is set to a non-zero value, the GRE packet is discarded and the IP discards counter is increased.
Reserved0	Indicates whether the header contains optional fields Not applicable to the 7705 SAR—first 5 bits of the field are always set to 0 and bits 6 to 12 are reserved for future use and also set to 0 by the 7705 SAR

Table 4 GRE Header Descriptions (Continued)

Field	Description
Ver	Always set to 000 for GRE At network ingress, if a GRE packet is received with the version field set to any value other than 000, the packet is discarded and the IP discards counter is increased
Protocol Type	Specifies the protocol type of the original payload packet—identical to Ethertype with the only supported option being MPLS unicast (0x8847)
Checksum (optional)	Not applicable
Reserved1 (optional)	Not applicable

Payload Packet

The payload encapsulation format for pseudowires over GRE is shown in [Figure 6](#) and described in [Table 5](#).

Figure 6 GRE Pseudowire Payload Packet over Ethernet

19873

Table 5 GRE Pseudowire Payload Packet Descriptions

Field	Description
Eth	The Layer 2 transport header The only Layer 2 protocol supported is Ethernet MTU size depends on the encapsulation type (14 bytes for null encapsulation, 18 bytes for dot1q encapsulation, and 22 bytes for qinq encapsulation)
IP	Indicates the transport protocol The Ethertype is always set to IP (0x800), and in case of a mismatch, the unexpected or illegal Ethertype counters are increased ¹

Table 5 GRE Pseudowire Payload Packet Descriptions (Continued)

Field	Description
GRE	Indicates the encapsulation protocol
PW header	The pseudowire header identifies a service within the GRE tunnel
CW (optional)	The pseudowire control word (CW) is a 32-bit (4-byte) field that is inserted between the VC label and the Layer 2 frame For more information on the control word, see Pseudowire Control Word
PW payload	The PW payload is the payload of the service being encapsulated (Ethernet, ATM, or TDM)

Note:

1. The only exception to the Ethertype is if the packets are address resolution protocol (ARP) packets. For information on ARP, refer to the 7705 SAR Router Configuration Guide.

At the network egress of the 7705 SAR, the source address of the IP header is always set to the system IP address. The destination IP address is set to the system IP address of the service router on which the GRE SDP is configured, the far-end interface address, or the loopback address. Using the system IP addresses to bring up the GRE session ensures that any IP link between the two routers can be used to transport GRE/IP packets. It might therefore be necessary to use static IP address configuration over DSL networks to ensure connectivity between the routers (especially if the DSL modem is in bridge mode).

GRE Fragmentation

IP fragmentation can be enabled for GRE tunnels. Services for which fragmentation is typically not available can make use of IP fragmentation performed at the IP layer of the GRE tunnel. The IP fragmentation feature can be enabled at the GRE tunnel ingress by enabling the **allow-fragmentation** command on the SDP. The IP fragmentation size limits are derived from the MTU of the network port used by the GRE tunnel.

At the GRE tunnel egress, IP reassembly can be performed as specified by a reassembly profile assigned to the network interfaces on which the GRE packets are expected to arrive. The IP reassembly function is performed on the IP fragments received at the GRE tunnel egress before any underlying service label is processed. A reassembly profile is used to specify the amount of buffer space allocated for the IP reassembly function and to configure a reassembly timeout. These parameters are configured for each forwarding class to isolate different types of GRE traffic.

When **allow-fragmentation** is enabled on an SDP, the current MTU algorithm is overwritten with the configured path MTU. The administrative MTU and operational MTU both show the specified MTU value. If the path MTU is not configured or available, the operational MTU is set to 2000 bytes, and the administrative MTU displays a value of 0. When **allow-fragmentation** is disabled, the operational MTU reverts to the previous value.

Fragmentation is supported on the following types of GRE SDPs:

- VPLS
- Layer 3 spoke SDP
- Epipe

IP packets that are transported over a Layer 3 spoke SDP using a fragmentation-enabled GRE tunnel are handled differently depending on the DF bit setting and the size of the packet.

- If the packet DF bit setting is 0 (Fragment), the GRE fragment size is determined by the network port MTU value.
- If the packet DF bit setting is 1 (Do not fragment), and the packet size is smaller or equal to the smaller value of either the operational MTU of the spoke SDP or the Layer 3 spoke SDP interface MTU (if configured), the packet is sent through the GRE tunnel and the fragment size is determined by either the network port MTU value or the Layer 3 spoke interface MTU value, whichever is smaller.
- If the packet DF bit setting is 1 (Do not fragment), and the packet size is larger than the smaller value of either the operational MTU of the spoke SDP or the Layer 3 spoke SDP interface MTU (if configured), the packet is discarded and an ICMP message “Fragmentation Needed and Don’t Fragment was Set” is sent back to the source IP address.

IP reassembly profiles are required to ensure that all packet fragments are received within an expected time frame for each forwarding class. When the reassembly profile timers expire, all fragments of the corresponding incomplete frame are dropped and a “Fragment Reassembly Time Exceeded” ICMP error message is sent to the source node.

Note: The system checks the reassembly queues every 64 ms in a constant loop, which may cause a maximum of 63 ms variation between the user-configured value and the actual detection time. For example, using the default configuration of 2000 ms, the system may check the reassembly queue timer at 1999 ms, in which case the timeout would not occur during that cycle and would instead take place during the next cycle at 2063 ms.

Traffic ingressing a GRE tunnel can use different forwarding classes and different queues. If multiple queues are transmitting fragments, a higher-priority queue could interrupt the transmission of fragments of a frame in a lower-priority queue by interleaving fragments of another frame. If the fragments from the different frames have similar IP identifiers, they could be reassembled incorrectly into one frame at the tunnel egress. To prevent this incorrect reassembly of frames, the 7705 SAR that is performing the IP fragmentation uses 4 bits of the 16-bit IP identifier to indicate the transmitting queue at the tunnel ingress. The IP identifier is part of the IP reassembly tuple, which also contains the protocol, source address, and destination address. Using the IP reassembly tuple, fragments of frames from different queues are always differentiated. However, reserving 4 bits in the IP identifier field leaves only 12 bits to act as a sequence number, which causes a shorter identifier wraparound. The time required for the IP identifier to wrap around is a function of the traffic rate on a given queue at the GRE tunnel ingress.

If fragments are dropped along the GRE tunnel due to congestion or bit errors, the 7705 SAR that is performing the IP reassembly at the tunnel egress normally drops partially reassembled packets due to expiration of the reassembly timeout interval. If fragment loss occurs in the network along with an IP identifier wraparound due to a high packet rate, the IP reassembly block may incorrectly insert fragments of a new frame into a frame of older fragments that are waiting for timeout. When configuring the timeout interval, it is therefore important to factor in the pre-fragmentation frame rate for forwarding classes on a GRE tunnel. As a guideline, higher-priority packets should have shorter timeout intervals than other packets because their queue interruption at the ingress GRE tunnel is minimal, and the timeout intervals should be shorter than the transmission time of 4096 packets for that forwarding class.

When the last fragment of a frame is received before the middle fragments, all fragments of the corresponding incomplete frame are dropped.

The 7705 SAR does not support double fragmentation.

3.3.4.4.3 IP Encapsulation

IP encapsulation is added to the 7705 SAR in response to a growing demand for more pseudowire-based solutions in mobile backhaul. IP encapsulation is similar to GRE encapsulation but allows pseudowires to be transported natively over IP packets. Only static pseudowires are supported for IP SDPs because there is no label path to define except for the endpoints. The path is an IP routed path.

The 7705 SAR supports the transport of pseudowires over IP tunnels. [Figure 7](#) shows an example of an application using Apipes over IP over Ethernet.

Payload Packet

A typical payload encapsulation format for pseudowires over IP is shown in [Figure 7](#) and described in [Table 6](#).

Figure 7 IP Example of Pseudowire Payload Packet over Ethernet

20695

Table 6 IP Pseudowire Payload Packet Descriptions

Field	Description
Eth	The Layer 2 transport header The only Layer 2 protocol supported is Ethernet MTU size depends on the encapsulation type (14 bytes for null encapsulation, 18 bytes for dot1q encapsulation, and 22 bytes for qinq encapsulation)
IP	Indicates the transport protocol The only supported option is MPLS in IP (0x89) The Ethertype is always set to IP (0x0800), and in case of a mismatch, the unexpected or illegal Ethertype counters are increased ¹
PW header	The pseudowire header identifies a service within the IP tunnel. The pseudowire header is like an MPLS header that has context only to the encapsulating and decapsulating LERs. This means that the IP transport network has no knowledge about the pseudowires that it carries. Only the edge LERs are aware of the pseudowire because the IPv4 Protocol Number field is set to 137 (0x89), indicating an MPLS unicast packet.
CW (optional)	The pseudowire control word (CW) is a 32-bit (4-byte) field that is inserted between the VC label and the Layer 2 frame For more information on control word, see Pseudowire Control Word
ATM Cell #1 to ATM Cell #N	Indicates the payload of the service being encapsulated (ATM)

Note:

1. The only exception to the Ethertype is if the packets are address resolution protocol (ARP) packets. For information on ARP, refer to the 7705 SAR Router Configuration Guide.

3.3.4.5 Spoke SDP Terminations

The 7705 SAR supports spoke SDP as termination points for IES and VPRN services. [Table 7](#) shows which service interfaces and spoke SDPs can be connected to each other. For example, an Epipe spoke SDP can connect to an IES or VPRN interface. See [Spoke SDP Termination to IES](#) and [Spoke SDP Termination to VPRN](#) for more information.

Table 7 Spoke SDP Termination Support

	Epipe Spoke SDP	Epipe Spoke SDP Redundancy (standby-signal-master enabled)	IES Interface	VPRN Interface	VPLS Spoke SDP	VPLS Spoke SDP Redundancy (suppress-standby-signaling disabled)
Epipe Spoke SDP	✓	✓	✓	✓	✓	✓
Epipe Spoke SDP Redundancy (standby-signal-master enabled)	✓	✓	✓	✓	✓	✓
IES Interface	✓	✓	✓	✓	✓	✓
VPRN Interface	✓	✓	✓	✓	✓	✓
VPLS Spoke SDP	✓	✓	✓	✓	✓	✓
VPLS Spoke SDP Redundancy (suppress-standby-signaling disabled)	✓	✓	✓	✓	✓	✓

3.3.4.6 SDP Ping

Ping is an application that allows a user to test whether a particular host is reachable. SDP Ping is an application that allows a user to test whether a particular SDP endpoint is reachable.

SDP ping uses the SDP identifier that is stored in the 7705 SAR that originates the ping request. SDP ping responses can be configured to return through the corresponding return tunnel as a round-trip ping, or out-of band when unidirectional pings are requested. Refer to the 7705 SAR OAM and Diagnostics Guide, “SDP Ping”, for more information.

3.3.4.7 SDP Keepalives

The SDP keepalive application allows a system operator to actively monitor the SDP operational state using periodic Nokia SDP Echo Request and Echo Reply messages. Automatic SDP keepalives work in a manner that is similar to a manual SDP ping command. The SDP Echo Request and Echo Reply messages provide a mechanism for exchanging far-end SDP statuses.

SDP keepalive Echo Request messages are only sent after the SDP has been completely configured and is administratively up and the SDP keepalives are administratively up. If the SDP is administratively down, keepalives for the SDP are disabled.

SDP keepalive Echo Request messages are sent out periodically based on the configured Hello Time. An optional message length for the Echo Request can be configured.

The SDP is immediately brought operationally down when:

- the Max Drop Count Echo Request messages do not receive an Echo Reply
- a keepalive response is received that indicates an error condition

After a response is received that indicates the error has cleared and the Hold Down Time interval has expired, the SDP is eligible to be put into the operationally up state. If no other condition prevents the operational change, the SDP enters the operational state.

Configuring SDP keepalives on a given SDP is optional. SDP keepalives have the following configurable keepalive parameters:

- Hello Time
- Message Length
- Max Drop Count
- Hold Down Time
- Timeout

For information about configuring keepalive parameters, see [Configuring SDPs](#).

3.3.4.8 Mixed-LSP SDPs

If mixed-LSP SDP mode is enabled on an SDP, a maximum of two LSP types can be configured on the SDP: a primary LSP and a secondary (backup) LSP. Two combinations are possible:

- an RSVP-TE primary LSP backed up by an LDP LSP
- an LDP primary LSP backed up by a BGP LSP

The **config>service>sdp mpls>mixed-lsp-mode** command is used to configure a mixed-LSP SDP.

Note: Mixed-LSP SDPs do not support static LSPs on either the primary or backup.

Mixed-LSP Mode of Operation

The service manager programs only one type of LSP in the line card, which activates it to forward service packets. The LSPs are programmed in the following priority order:

1. RSVP-TE LSP type

This is the highest-priority LSP type. Up to eight RSVP-TE LSPs can be entered by the user and programmed by the service manager in the ingress line card to load-balance service packets.

2. LDP LSP type

One LDP FEC is programmed by the service manager, but the ingress line card can use up to eight LDP ECMP paths for the FEC to load-balance service packets when ECMP is enabled on the node.

3. BGP LSP type

One RFC 3107-labeled BGP prefix is programmed by the service manager. The ingress line card can use more than one next hop for the prefix.

For an RSVP-TE/LDP SDP, the service manager programs the NHLFEs for the active LSP type, preferring the RSVP-TE LSP type over the LDP LSP type. If no RSVP-TE LSP is configured, or if all of the configured RSVP-TE LSPs go down, the service manager reprograms the line card with the LDP LSP, if available. If no LDP LSP is available, the SDP goes operationally down.

For LDP/BGP SDPs, the service manager prefers the LDP LSP type over the BGP LSP type. If no LDP LSP is configured or all configured LDP LSPs go down, the service manager reprograms the line card with the BGP LSP if it is available; otherwise, the SDP goes operationally down.

An LDP/BGP SDP differs from an RSVP/LDP SDP in the number of routes available. For any given /32 prefix, only a single route exists in the routing table: the IGP route or the BGP route. Therefore, only the LDP FEC or the BGP label route is active at any given time. The impact of this is that the tunnel table must be reprogrammed each time a route is deactivated and the other route is activated. In this scenario, the SDP **revert-time** command cannot be used because there is no situation where both LSP types are active for the same /32 prefix.

When a higher-priority LSP type becomes available, the service manager resets the SDP configuration to this LSP type when the revert timer expires or when the current active LSP fails, whichever occurs first. The length of time that the service manager must wait can be configured with the **config>service>sdp mpls>mixed-lsp-mode>revert-time** command. After the SDP has reverted to the higher-priority LSP, the service manager reprograms the line card accordingly. If the revert timer is configured with the **infinite** parameter, the service manager never resets the SDP to the highest-priority LSP type unless the current active LSP fails.

If the value of the revert time timer is changed, it takes effect when the timer is next activated. Any timer that is currently active when the value is changed is restarted with the new value.

Note: LDP uses a tunnel-down-damp timer that is set to 3 seconds by default. If the LDP LSP fails, the SDP reverts to the RSVP-TE LSP type after the expiry of this timer. For an immediate switchover, this timer must be set to 0 with the **config>router>ldp>tunnel-down-damp-time** command.

3.3.4.9 Multiple Load-balancing LSPs Under a Single SDP

Configuring multiple LSPs under a single SDP allows load distribution among multiple LSPs to the same destination. This load distribution is handled by the node without the need for any operator intervention. LSP additions or deletions result in automatic rehashing of services onto remaining LSPs, making it transparent to the operator. No new hashing algorithms are required; existing hashing algorithms are extended to select an LSP from multiple LSPs under an SDP.

Up to eight RSVP-TE or SR-TE LSPs can be configured under a single SDP. However, a mix of RSVP-TE and SR-TE LSPs is not supported. When the first LSP is configured under the SDP, all other LSPs configured under that SDP must be of the same type.

Multiple LSPs are only supported for SDPs configured for MPLS encapsulation.

3.4 Mobile Solutions

Topics in this section include:

- [HSDPA Offload](#)
- [Pure DSL Backhaul](#)

The Mobile Radio Access Network (RAN) is rapidly growing to meet the increased demand in mobile services. This in turn increases demands on carriers to provide high-bandwidth, mobile broadband services. Today, at a typical cell site, 2G and 3G base stations are connected to high-cost, T1/E1 leased lines that are used to backhaul both voice and data traffic to the MTSO. For mission-critical, delay-sensitive, and low-bandwidth traffic such as voice, signaling, and synchronization traffic, it is vital that the high availability of these leased lines is ensured. SLA agreements also promise a high level of availability for customers.

Currently, however, best-effort traffic such as high-speed downlink packet access (HSDPA) is also switched over these SLA-enabled leased lines. HSDPA is a 3G mobile telephony communications service that allows UMTS networks to have higher data transfer speeds and capacity, allowing the mobile customer (end user) to browse the Internet or to use the mobile device. The increasing use of HSDPA is having a dramatic impact on the ability of the T1/E1 leased lines to scale with the traffic growth as well as on the operating costs of these lines.

Similar issues confront CDMA EVDO networks today.

Nokia provides a solution that enables mobile operators to keep their existing infrastructure (circuit-based leased lines), while gradually migrating to a packet-based infrastructure that will allow scalability, decrease costs, and ease the transition to the next-generation, all-IP network solutions.

3.4.1 HSDPA Offload

The Nokia solution is to make use of widely available DSL networks and split the traffic being backhauled. Mission-critical traffic (voice, signaling, synchronization) remains on the T1/E1 leased line circuits, while the best-effort, bandwidth-hungry HSDPA traffic is off-loaded to DSL networks.

The 7705 SAR-A and the 7705 SAR-M with DSL modules are ideal candidates for this scenario. They are small-scale versions of the 7705 SAR product family, optimized for use in standalone small or midsized sites where traffic aggregation from multiple cell sites is not needed. For more information on the 7705 SAR-A and the 7705 SAR-M, refer to the 7705 SAR-A Chassis Installation Guide and the 7705 SAR-M Chassis Installation Guide.

Figure 8 shows an example of HSDPA offload with the 7705 SAR-A.

Figure 8 7705 SAR-A HSDPA Offload Example

19872

A 3G Node B is connected to a 7705 SAR-A over an ATM/IMA access port (SAP endpoint). An ATM SAP-to-SAP connection is set up in the 7705 SAR-A and a pseudowire is configured between the two endpoints to emulate local ATM switching. Traffic from the Node B enters an ATM/IMA port, the VCs transporting mission-critical traffic are locally switched (SAP-to-SAP) to another ATM/IMA port (SAP endpoint), and then switched over the leased lines to the MTSO.

Note: ATM SAP-to-SAP connections are supported between any T1/E1 ASAP port that is in access mode with ATM/IMA encapsulation and another port with the same encapsulation configuration. One endpoint of a SAP connection can be an IMA group, while the other endpoint can be on a single ATM port. ATM SAP-to-SAP connections are also supported between any two OC3/STM1 ports and between any T1/E1 ASAP port and OC3/STM1 port, as long as both SAPs support ATM.

For non-mission-critical traffic, for example, HSDPA traffic, an Ethernet interface on the 7705 SAR is connected to an external DSL modem. HSDPA traffic is interworked to ATM pseudowires and transported over the DSL network to the BRAS, then forwarded to the service router at the MTSO.

Figure 9 shows an example of HSDPA offload with the 7705 SAR-M using an 8-port xDSL module. Figure 10 shows an example of HSDPA offload with the 7705 SAR-M using a 6-port DSL Combination module.

Figure 9 7705 SAR-M With 8-port xDSL Module for HSDPA Offload

22346

Figure 10 7705 SAR-M With 6-port DSL Combination Module for HSDPA Offload

22347

On a 7705 SAR-M with an 8-port xDSL module, non-real-time UMTS traffic is backhauled over the xDSL connection and all voice traffic remains on the existing attached TDM network. For this type of network, timing recovery via DSL is typically not required as synchronization can be derived from the attached TDM network.

On a 7705 SAR-M with a 6-port DSL Combination module, non-real-time UMTS traffic is backhauled over the xDSL connection and all voice traffic is backhauled over the SHDSL interface. Using SHDSL rather than existing ATM or TDM networks as the primary means to backhaul voice and signaling is an additional step toward improving the economies of backhaul. With this functionality, all voice, signaling, and HSDPA offload can be backhauled over a low-cost DSL network. The network characteristics of SHDSL are based on the design considerations for T1/E1 lines and are subject to lower latency and delay compared with xDSL. Clock recovery with NTR is supported over both SHDSL and xDSL interfaces on the 6-port DSL Combination module and over any xDSL interface on the 8-port xDSL module.

3.4.1.1 Failure Detection

Failure of the GRE SDP or the IP network it rides over can be detected by OAM tools as well as by BFD. With SAA, OAM tools can be configured to run periodically in order to facilitate faster failure detection. If a failure occurs, the ATM SAPs must be rerouted by the NSP NFM-P to the ATM ports used for backhauling the traffic. The mission-critical traffic is still serviced before the best-effort HSDPA traffic.

For information on OAM and SAA tools, refer to the 7705 SAR OAM and Diagnostics Guide. For information on BFD, refer to the 7705 SAR Router Configuration Guide.

3.4.2 Pure DSL Backhaul

There are two applications for pure backhaul over DSL:

- wholesale mobile backhaul aggregation or business services provided via DSL
- cell site aggregation from one or more base stations

Timing and/or synchronization are typically not requirements for deployments of the first application since mobile operators have their own cell site aggregator for timing recovery. [Figure 11](#) shows a typical network using pure DSL backhaul with a 7705 SAR-M. Pure DSL backhaul is also supported on networks with distributed MPLS services.

Figure 11 Pure DSL Backhaul Network Example

Figure 12 shows a breakdown of the traffic on this network.

Figure 12 DSL Network Traffic

22350

In the case of pure backhaul via DSL for a mobile operator, legacy 2G and 3G traffic is aggregated at the 7705 SAR-M then fed upstream to a connected ISAM. Services remain terminated on a 7750 SR as shown in Figure 11, but without the north ATM path. Timing recovery is provided by a local GPS at the cell site, by NTR, or by 1588 for frequency synchronization.

Note: Using 1588 for timing recovery over DSL requires careful consideration of the end-to-end network characteristics for 1588v2 PTP delivery, and for the underlying PDV characteristics of the DSL used to transport the PTP packets.

Pure DSL backhaul maximizes savings for mobile operators since leased lines are not used at all. SHDSL can also be more expensive to deploy and operate because it is generally not deployed for residential broadband services. Additionally, when mobile backhaul services are combined with triple-play services reusing the same broadband platform (in this case the ISAM), the pure DSL backhaul architecture offers a compelling, cost-effective solution across a wide range of scenarios.

The pure DSL backhaul deployment model may be Layer 2-based with the use of a local Epipe on the 7705 SAR-M as shown in [Figure 11](#). The SAP facing the ISAM must support an Epipe SAP and an IES SAP for in-band management. Alternatively, distributed services via MPLS or GRE tunnels can be used with pure DSL backhaul to offer distributed VPLS, VPRN, IES, or VLL services.

3.4.2.1 DSL Channel Bonding

DSL channel bonding provides an ideal mix of features, including higher bandwidth for all users and the ability to extend the distance that can be reached at certain bandwidths. DSL bonding distributes traffic over a bundle of copper pairs instead of just a single copper pair. For example, to achieve an effective bandwidth of 12 Mb/s, three DSL lines of 4 Mb/s are bundled with a channel bonding processor at each of the Central Office and CPE devices.

In order to meet the growing needs of mobile backhaul and business services in areas where fiber connectivity is not available, DSL access solutions can be used as a viable alternative through the use of channel bonding for increased rate and reach. For more information about DSL bonding and DSL modules, see the 7705 SAR Interface Configuration Guide and the 7705 SAR-M Chassis Installation Guide.

3.5 ETH-CFM (802.1ag and Y.1731)

Topics in this section include:

- [802.1ag and Y.1731 Terminology](#)
- [ETH-CFM Frame Format](#)
- [ETH-CFM Functions and Tests](#)
- [MEP Support \(802.1ag and Y.1731\)](#)
- [Priority Mapping \(802.1ag and Y.1731\)](#)

Ethernet Connectivity Fault Management (ETH-CFM) is defined in two complementary standards: IEEE 802.1ag (dot1ag) and ITU-T Y.1731. Both standards specify protocols, procedures, and managed objects in support of transport fault management, including discovery and verification of the path, and detection and isolation of a connectivity fault for each Ethernet service instance.

Dot1ag and Y.1731 provide fault management (FM) functions for loopback, linktrace, and connectivity checks, as well as Up and Down MEP support for Ethernet SAPs (Epipe and VPLS), Down MEP support for Epipe and VPLS spoke SDPs and VPLS mesh SDPs (dot1ag only), and facility MEP support for network interfaces.

Y.1731 fault management (Y.1731 FM) extends dot1ag CFM by providing functions for alarm indication signal (AIS) and ETH-Test testing. Furthermore, Y.1731 provides performance monitoring (Y.1731 PM) functions for delay and loss measurements. For more information on Y.1731 PM, refer to the “ITU-T Y.1731 Performance Monitoring (PM)” section in the 7705 SAR OAM and Diagnostics Guide.

For information on running Ethernet OAM tests, refer to the “ETH-CFM (802.1ag and Y.1731)” section in the 7705 SAR OAM and Diagnostics Guide.

The information in this section is specific to Ethernet SAPs and spoke and mesh SDPs, although most of it also applies to Ethernet network interfaces. For information on ETH-CFM support specific to network interfaces, refer to the 7705 SAR Router Configuration Guide, “ETH-CFM Support”.

CFM uses Ethernet frames that are distinguished by their Ethertype value and special Ethernet multicast address. For more information on the Ethernet frame, and the Ethertype and Ethernet multicast address values, see [ETH-CFM Frame Format](#).

Using CFM, interoperability can be achieved between different vendor equipment in the service provider network, up to and including customer premises bridges.

Note: In the 7705 SAR CLI command hierarchy, commands for 802.1ag and Y.1731 are found under the **eth-cfm** context that appears at the following levels:

- global (**config>eth-cfm**)
- Epipe SAPs (**config>service>epipe>sap>eth-cfm**)
- Epipe spoke SDPs (**config>service>epipe>spoke-sdp>eth-cfm**)
- VPLS SAPs (**config>service>vpls>sap>eth-cfm**)
- VPLS spoke SDPs (**config>service>vpls>spoke-sdp>eth-cfm**)
- VPLS mesh SDPs (**config>service>vpls>mesh-sdp>eth-cfm**)
- network interface (**config>router>if>eth-cfm**)
- show (**show>eth-cfm**)
- oam (**oam>eth-cfm**)

3.5.1 802.1ag and Y.1731 Terminology

[Table 8](#) defines 802.1ag terms. [Table 9](#) illustrates the similarities and differences between Y.1731 and 802.1ag terms.

Table 8 802.1ag Terminology

Term	Expansion	Definition
MA	Maintenance Association	A grouping of maintenance entities (MEs) that need to be managed as part of a service
MA-ID	Maintenance Association Identifier	A unique combination of MD index (<i>md-index</i>), MD level (<i>level</i>), and MA index (<i>ma-index</i>), where <i>md-index</i> , <i>level</i> , and <i>ma-index</i> are user-configured values An MA is identified by its MA-ID
MD	Maintenance Domain	A set of Ethernet network elements or ports that are controlled by an operator, where boundaries are set by MEPs
MD level	Maintenance Domain level	A user-configured value of 0 to 7 representing a level of hierarchy within a CFM architecture. The value 7 is the highest MD level and 0 is the lowest. The MD level is transmitted as part of the Ethernet CFM frame. A CFM message is said to have a higher MD level when its MD level value is higher than the MD value configured on the receiving MEP 7705 SAR. Higher-level CFM messages are relayed as data frames by MEPs and ignored by the MEP entity.
ME	Maintenance Entity	An Ethernet port or endpoint that is managed as part of dot1ag OAM An endpoint can be a SAP, spoke SDP, or mesh SDP (VPLS only)

Table 8 802.1ag Terminology (Continued)

Term	Expansion	Definition
MEP	Maintenance Association End Point	An (edge) endpoint that can terminate, respond to, or initiate the OAM messages for a configured MD-MA combination
MEP-ID	Maintenance Association End Point Identifier	A MEP is identified by its MEP-ID, which is a unique combination of MD index (<i>md-index</i>) and MA index (<i>ma-index</i>), where <i>md-index</i> and <i>ma-index</i> are user-configured values
MIP	Maintenance Association Intermediate Point	An intermediate point that can respond to OAM messages initiated by MEPs in the same MD. Connectivity fault management (CFM) messages destined for other MIPs or the destination MEP are transparent to MIPs. MIPs are not supported on the 7705 SAR

Table 9 Y.1731 Terminology

Term	Expansion	Definition
MEG	Maintenance Entity Group	Same as MA but applies to Y.1731
MEG-ID	Maintenance Entity Group Identifier	Same as MA-ID but applies to Y.1731
MEG level	Maintenance Entity Group Level	Same as MD level but applies to Y.1731 Although MEG level and MD level are equivalent terms, there is no Y.1731 equivalent to an MD
MEP	Maintenance Association End Point	Same as MEP for 802.1ag

3.5.1.1 MDs, MD Levels, MAs, and MEPs (802.1ag)

Maintenance domains (MDs) and maintenance associations (MAs) are configured at the global level. Maintenance association endpoints (MEPs) are configured at the service level.

An MD is a set of network elements that have a common CFM OAM purpose. MDs are identified by their MD index and can be given an MD name. An MD is assigned a maintenance domain level (MD level). There are eight MD levels. MD levels are used to set up a messaging hierarchy for the CFM architecture.

An MA consists of up to eight MEPs (one local and up to seven remote) for Up MEPs on Epipe and VPLS services and two MEPs (one local and one remote) for Down MEPs on Epipe and VPLS services. The MA and the service are associated by configuring the MA bridge identifier parameter to have the same value as the service ID of the service that supports the MEPs. MAs are identified by their MA index and can be given an MA name. The MA is used to verify the integrity of a single service instance.

A MEP is configured as part of an Ethernet SAP, spoke SDP, or mesh SDP (VPLS only). MEPs can generate or terminate CFM OAM messages. MEPs only communicate within the same MD level, where the value of the MD level (0 to 7) is carried in a CFM OAMPDU. MEPs are identified by their MEP identifier and MA-ID. The MA-ID is configured at the global level.

Figure 13 shows a high-level view of MEPs in a CFM-enabled network. Two MAs are shown. The endpoints of MA 1 are MEPs 1 and 2, while MEPs 3 and 4 are the endpoints for MA 2.

For more information on MEP support, see [Ethernet OAM](#).

Figure 13 **MEPs and MAs**

20497

3.5.1.2 MEG Levels, MEGs, and MEPs (Y.1731)

On the 7705 SAR, the implementation of Y.1731 Fault Management (FM) is similar to that of dot1ag CFM, except that Y.1731 does not have a maintenance domain (MD). For Y.1731 and 802.1ag, the following terms are equivalent:

- MEG level is equivalent to MD level
- MEG is equivalent to MA
- a Y.1731 MEP is equivalent to a dot1ag MEP

To access Y.1731 functions, including Y.1731 Performance Monitoring (PM) functions, configure a MEP to have the domain format set to **none** and the association format set to **icc-based** or **string** (the **string** keyword enables the Y.1731 MEP to interoperate with a dot1ag MEP).

3.5.2 ETH-CFM Frame Format

ETH-CFM OAMPDU messages for 802.1ag and Y.1731 use a standard Ethernet frame (see [Figure 14](#)). The parts of the frame are described below.

Figure 14 ETH-CFM Frame Format

Destination MAC
Source MAC
T = 8100
Vlan / Dot1p
T = 8902
ETH-CFM OAMPDU
FCS

20472

Destination and Source Addresses

The destination and source MAC addresses of the CFM message must match at the send and the receive routers. For example, a 7705 SAR-initiated ETH-CFM message would use the spoke SDP MAC address of the 7705 SAR as the source MAC address and the spoke SDP MAC address of the far-end router as the destination MAC address. At the far end, the source and destination MAC addresses would be the reverse of the near end.

An exception to the matching source-destination MAC address requirement occurs for linktrace and continuity messages, where the destination MAC address is set to a multicast group address. The designated multicast group address for linktrace and CCM is 01-80-C2-00-00-3x; where x represents the maintenance domain (MD) level (for 802.1ag) or the MEG level (for Y.1731). For example, a dot1ag CCM message destined for 01-80-C2-00-00-31 corresponds to MD level 1.

CCM packets using source-destination multicast MAC addresses are for user-initiated messages only (loopbacks).

Ethertype (T)

If dot1q or qinq encapsulation is not configured, the Ethertype value is 0x8902 and there are no VLAN tags. If dot1q or qinq encapsulation is configured, the VLAN tag (Ethertype value 0x8100) is present and is followed by the Ethertype value of 0x8902, which indicates ETH-CFM messages. The Ethertype is not hard-coded to 0x8100 and can be changed via the port configuration command.

VLAN/dot1p

The Vlan/Dot1p tag is the VLAN/dot1p identifier. If null encapsulation is configured (for Ethernet SAPs or spoke or mesh SDP bindings to a VC-type, **ether** or **vlan**), the frame is tagged with NULL.

ETH-CFM OAMPDU

The contents of the Ethernet OAMPDU depend on whether dot1ag or Y.1731 standards are being used. For information on the dot1ag or Y.1731 OAMPDU, see [ETH-CFM OAMPDU](#).

FCS

The FCS is the frame check sequence field.

3.5.2.1 ETH-CFM OAMPDU

As shown in [Figure 15](#), each ETH-CFM OAMPDU message contains the following fields:

- MD level or MEG level: user-configured value, 0 to 7
- version: current version is 0
- opcodes: as defined in IEEE 802.1ag and Y.1731 standards, for messages such as:
 - Continuity Check Message (CCM)
 - Loopback Message (LBM)
 - Loopback Reply (LBR)
 - Linktrace Message (LTM)
 - Linktrace Reply (LTR)
- flags: as defined in IEEE 802.1ag and Y.1731 standards
- one or more TLVs, which include:
 - End TLV
 - Data TLV
 - Reply Ingress TLV
 - Reply Egress TLV
 - LTM egress identifier TLV
 - LTR egress identifier TLV
 - Test TLV

Figure 15 ETH-CFM OAMPDU Message

20847

3.5.2.2 CFM Frame Processing

Table 10 shows whether a CFM frame received by various MEP types is processed. Frames that are processed are extracted from the datapath for CFM processing; unprocessed frames are treated as user traffic and follow the user traffic rules.

Table 10 CFM Frame Processing

MEP Details				Received CFM Frame Treatment	
MEP Type	Direction	VC-Type	Port	Untagged	Tagged ¹
Spoke SDP	Down	Raw	Any	Processed	Not processed
		VLAN	Any	Not processed	Processed
Mesh SDP	Down	Raw	Any	Processed	Not processed
		VLAN	Any	Not processed	Processed
SAP	Down	Any	Dot1q or QinQ	Not processed ²	Processed
		Any	Null	Processed	Not processed
	Up	Any	Dot1q or QinQ	Not processed	Processed
		Any	Null	Processed	Not processed

Notes:

1. Tagged frames are single-tagged frames (dot1q) or double-tagged frames (qinq).
2. Untagged frames received on a dot1q-encapsulated port are processed by the Epipe or VPLS pseudowire configured to handle untagged frames. The SAP identifier uses VLAN ID 0, also referred to as SAP 0 (for example, 1/1/2:0). Untagged frames are also processed on the *.* QinQ SAP, and on a vlan-x.0 QinQ SAP only if the outer tag matches.

3.5.2.2.1 Processing SAP 0 and SAP 0.* OAM Packets

The following points describe the processing of OAM packets on SAP 0 (dot1q) and SAP 0.* (qinq). SAP 0.0 is not supported on OAM packets.

- the 7705 SAR transmits untagged OAM frames on SAP 0 and SAP 0.*
- the 7705 SAR does not process OAM frames tagged with VLAN ID 0 or VLAN ID 0.* on a port configured with null encapsulation
- the 7705 SAR processes double-tagged or triple-tagged OAM frames under the following configuration scenario: there is a SAP Up MEP on a dot1q- or qinq-encapsulated port, using SAP 0 or 0.*, and having VC-type VLAN

In this case, the top VLAN tag is removed and the bottom VLAN tag is assumed to be SAP 0 or 0.*. If the bottom VLAN tag is not SAP 0 or 0.*, the VLAN ID is changed to 0. If the frame is an OAM frame, double-tagged (or triple-tagged), the frame is extracted from the SAP Up MEP and the reply is with a single-tagged frame with its VLAN ID set to 0.

- on a SAP Down MEP (dot1q or qinq), untagged frames are processed on SAP 0 or 0.*

3.5.2.3 MEG-ID and ICC-Based Format

Similar to an 802.1ag MA-ID, a Y.1731 MEG-ID uniquely identifies a group of MEs that are associated at the same MEG level in one administrative domain. The features of MEG-IDs are:

- each MEG-ID must be globally unique
- if the MEG may be required for path setup across interoperator boundaries, then the MEG-ID must be available to other network operators
- the MEG-ID should not change while the MEG remains in existence
- the MEG-ID should be able to identify the network operator that is responsible for the MEG

The 7705 SAR supports the ITU Carrier Code (ICC-based) MEG-ID format (TLV value 32). The generic and ICC-based MEG-ID formats are defined in the ITU-T Y.1731 standard. [Figure 16](#) shows the ICC-based MEG-ID format.

The MEG-ID value has exactly 13 characters and consists of two subfields, the ITU Carrier Code (ICC) followed by a Unique MEG-ID Code (UMC). The ITU Carrier Code consists of between 1 and 6 left-justified characters (alphabetic or leading alphabetic with trailing numeric). The UMC code immediately follows the ICC and consists of between 7 and 12 characters, with trailing NULLs (if necessary to complete the 13 characters).

The UMC is the responsibility of the organization to which the ICC has been assigned, provided that uniqueness is guaranteed.

Figure 16 ICC-based MEG-ID Format

20848

3.5.3 ETH-CFM Functions and Tests

The following list of ETH-CFM functions applies to both dot1ag and Y.1731 Ethernet OAM:

- ETH-CFM—ETH-CFM can be enabled or disabled on a SAP, spoke SDP, or mesh SDP (VPLS only)
- MD levels—eight MD levels can be assigned
- MD name—the following MD name formats are supported:
 - none (no MD name; used for specifying a Y.1731 functionality)
 - DNS name
 - MAC address and 2-octet integer
 - character string
- MAs—MAs for each MD level can be configured, modified, or deleted
 - each MA is defined by a unique combination of MD index, MD level, and MA index. This unique combination of values is called the MA identifier (MA-ID).
 - the following MA name formats are supported:
 - primary VLAN ID (VID)
 - character string (when used with MD name format none, specifies Y.1731 interoperability with 802.1ag)

- 2-octet integer
- RFC 2685, Virtual Private Networks Identifier
- ICC-based (used for specifying a Y.1731 functionality)
- when a VID is used as the MA name, CFM will not support VLAN translation because the unique MA-ID must match all the MEPs
- the default format for an MA name is a 2-octet integer; integer value 0 means that the MA is not attached to a VID.
- MEPs—Up and Down MEPs on a SAP, and Down MEPs on a spoke or mesh SDP
 - MEPs can be configured, modified, or deleted for each MD level (both associations for the Up or Down MEP are with the same bridge port as described in Section 19.2.1 of IEEE Standard 802.1ag-2007)
 - each MEP is uniquely identified by its MEP identifier and MA-ID combination
- MEP creation—MEP creation on a SAP is allowed only for Ethernet ports (with null, dot1q, or qinq encapsulations)

3.5.3.1 ETH-CFM Ethernet OAM Tests

This section describes Ethernet OAM tests for ETH-CFM on the 7705 SAR, including:

- loopbacks
- linktrace
- throughput measurement
- continuity check
- remote defect indication
- alarm indication signal
- Ethernet (signal) test

Note: The 7705 SAR also supports Ethernet Bandwidth Notification (ETH-BN) on the client side. For information, refer to the 7705 SAR OAM and Diagnostics Guide, “ITU-T Y.1731 Ethernet Bandwidth Notification (ETH-BN)”.

3.5.3.1.1 Loopback

The loopback (LB) function is supported by 802.1ag and Y.1731 on the 7705 SAR. A Loopback Message (LBM) is generated by a MEP to its peer MEP. Both dot1ag and dot3ah loopbacks are supported. The loopback function is similar to IP or MPLS ping in that it verifies Ethernet connectivity between the nodes on a per-request basis. That is, it is non-periodic and is only initiated by a user request.

In [Figure 17](#), the line labeled LB represents the dot1ag loopback message between the 7750 SR (source) and 7705 SAR (target). The 7750 SR-generated LBM is switched to the 7705 SAR, where the LBM is processed. Once the 7705 SAR generates the Loopback Reply message (LBR), the LBR is switched over the PW to the 7750 SR.

The following loopback-related functions are supported:

- loopback message functionality on a MEP can be enabled or disabled
- MEP—supports generating loopback messages and responding to loopback messages with loopback reply messages
- displays the loopback test results on the originating MEP

Figure 17 Dot1ag Loopback Test

20480

3.5.3.1.2 Linktrace

The linktrace (LT) function is supported by 802.1ag and Y.1731 on the 7705 SAR. A Linktrace Message (LTM) is originated by a MEP and targeted to a peer MEP in the same MA and within the same MD level. Its function is similar to IP traceroute. The peer MEP responds with a Linktrace Reply (LTR) message after successful inspection of the LTM.

The following linktrace related functions are supported:

- enables/disables LT functions on a MEP
- MEP—supports generating LTMs and responding with LTR messages
- displays linktrace test results on the originating MEP

3.5.3.1.3 Throughput Measurement

Throughput measurement is performed by sending frames to the far end at an increasing rate (up to wire speed) and measuring the percentage of frames received back. In general, the rate is dependent on frame size; the larger the frame size, the lower the rate.

The Y.1731 specification recommends the use of unicast ETH-LB and ETH-Test frames to measure throughput.

On the 7705 SAR, LBM processing and LBR generation are enhanced and occur on the datapath, allowing the 7705 SAR to respond to loopback messages at wire speed and making in-service throughput tests possible. Therefore, if the 7705 SAR receives LBMs at up to wire speed, it can generate up to an equal number of LBRs.

In order to process LBMs at wire speed, there must be either no TLVs or a single TLV (which is a data TLV) in the LBM frame. The End TLV field (0) must be present and the frame can be padded with data after the End TLV field in order to increase the size of the frame. Note, however, that the MAC address cannot be a multicast MAC address; it must be the MEP MAC destination address (DA).

Datapath processing of LBMs is supported for the following MEPs:

- dot1ag
 - SAP Up MEP
 - SAP Down MEP
 - spoke SDP Down MEP
 - mesh SDP Down MEP (VPLS only)

- Y.1731
 - SAP Up MEP
 - SAP Down MEP

For spoke or mesh SDP Down MEPs, fastpath (datapath) LBM processing requires that both interfaces—the LBM receiver and the LBR transmitter—reside on the same adapter card. For example, if the 7705 SAR must perform a reroute operation and needs to move the next-hop interface to another adapter card (that is, LBMs are received on one card and LBRs are transmitted on another), the fastpath processing of LBMs is terminated and LBM processing continues via the CSM.

3.5.3.1.4 Continuity Check

The continuity check (CC) function is supported by 802.1ag and Y.1731 on the 7705 SAR. A Continuity Check Message (CCM) is a multicast frame that is generated by a MEP and sent to its remote MEPs in the same MA. The CCM does not require a reply message. To identify faults, the receiving MEP maintains a MEP database with the MAC addresses of the remote MEPs with which it expects to maintain connectivity checking. The MEP database can be provisioned manually. If there is no CCM from a monitored remote MEP in a preconfigured period, the local MEP raises an alarm.

The following CC capabilities are supported:

- enable and disable CC for a MEP
- automatically put local MEPs into the database when they are created
- manually configure and delete the MEP entries in the CC MEP monitoring database. The only local provisioning required to identify a remote MEP is the remote MEP identifier (using the **remote-mepid** *mep-id* command).
- CCM transmit interval: 10ms, 100ms, 1s, 10s, 1m, 10m (default: 10s)
- transmit interval: 10ms, 100ms, 1s, 10s, 1m, 10m (default: 10s)
- CCM declares a fault when it:
 - stops hearing from one of the remote MEPs for a period of 3.5 times the CC interval
 - hears from a MEP with a lower MD level
 - hears from a MEP that is not in the same MA
 - hears from a MEP that is in the same MA but is not in the configured MEP list
 - hears from a MEP that is in the same MA with the same MEP ID as the receiving MEP

- recognizes that the CC interval of the remote MEP does not match the local configured CC interval
 - recognizes that the remote MEP declares a fault
- An alarm is raised and a trap is sent if the defect is greater than or equal to the configured low-priority-defect value.
- CC must be enabled in order for RDI information to be carried in the CCM OAMPDU

3.5.3.1.5 Remote Defect Indication

The Ethernet Remote Defect Indication (ETH-RDI) function is used by a MEP to communicate to its peer MEPs that a defect condition has been encountered. Defect conditions such as signal failure and AIS may result in the transmission of frames with ETH-RDI information. ETH-RDI is used only when ETH-CC transmission is enabled and it is enabled automatically.

ETH-RDI has the following two applications:

- single-ended fault management—the receiving MEP detects an RDI defect condition, which gets correlated with other defect conditions in this MEP and may become a fault cause. The absence of received ETH-RDI information in a single MEP indicates the absence of defects in the entire MEG.
- contribution to far-end performance monitoring—the transmitting MEP reflects that there was a defect at the far end, which is used as an input to the performance monitoring process

A MEP that is in a defect condition transmits frames with ETH-RDI information. A MEP, upon receiving frames with ETH-RDI information, determines that its peer MEP has encountered a defect condition.

The specific configuration information required by a MEP to support the ETH-RDI function is as follows:

- MEG level—the MEG level at which the MEP exists
- ETH-RDI transmission period—application-dependent and is the same value as the ETH-CC transmission period
- priority—the priority of frames containing ETH-RDI information and is the same value as the ETH-CC priority

The PDU used to carry ETH-RDI information is the CCM.

3.5.3.1.6 Alarm Indication Signal

The Ethernet Alarm Indication Signal (ETH-AIS) function is a Y.1731 CFM enhancement used to suppress alarms at the client (sub) layer following detection of defect conditions at the server (sub) layer.

Transmission of frames with ETH-AIS information can be enabled or disabled on a Y.1731 MEP.

Frames with ETH-AIS information can be issued at the client MEG level by a MEP, including a server MEP, upon detecting the following conditions:

- signal failure conditions in the case where ETH-CC is enabled
- AIS condition in the case where ETH-CC is disabled

For a point-to-point Ethernet connection at the client (sub) layer, a client layer MEP can determine that the server (sub) layer entity providing connectivity to its peer MEP has encountered a defect condition upon receiving a frame with ETH-AIS information. Alarm suppression is simplified by the fact that a MEP is expected to suppress only those defect conditions associated with its peer MEP.

Only a MEP, including a server MEP, is configured to issue frames with ETH-AIS information. Upon detecting a defect condition, the MEP can immediately start transmitting periodic frames with ETH-AIS information at a configured client MEG level. A MEP continues to transmit periodic frames with ETH-AIS information until the defect condition is removed. Upon receiving a frame with ETH-AIS information from its server (sub) layer, a client (sub) layer MEP detects the AIS condition and suppresses alarms associated with all its peer MEPs. Once the AIS condition is cleared, a MEP resumes alarm generation upon detecting defect conditions.

The following specific configuration information is required by a MEP to support ETH-AIS:

- client MEG level—the MEG level at which the most immediate client layer MEPs exist
- ETH-AIS transmission period—the transmission period of frames with ETH-AIS information
- priority—the priority of frames with ETH-AIS information

3.5.3.1.7 Ethernet Test

The Ethernet Test (ETH-Test) signal function is a Y.1731 CFM enhancement used to perform one-way, on-demand, in-service diagnostics tests, which include verifying frame loss, bit errors, and so on.

Note: The out-of-service diagnostics test is not supported on the 7705 SAR.

When configured to perform such tests, a MEP inserts frames with ETH-Test information such as frame size and transmission patterns.

When an in-service ETH-Test function is performed, data traffic is not disrupted and the frames with ETH-Test information are transmitted.

To support ETH-Test, a Y.1731 MEP requires the following configuration information:

- MEG level—the MEG level at which the MEP exists
- unicast MAC address—the unicast MAC address of the peer MEP for which ETH-Test is intended
- data—an optional element with which to configure data length and contents for the MEP. The contents can be a test pattern and an optional checksum.

Examples of test patterns include all 0s or all 1s. At the transmitting MEP, this configuration information is required for a test signal generator that is associated with the MEP. At the receiving MEP, this configuration is required for a test signal detector that is associated with the MEP.

- priority—the priority of frames with ETH-Test information

A MEP inserts frames with ETH-Test information towards a targeted peer MEP. The receiving MEP detects the frames with ETH-Test information and performs the requested measurements.

3.5.4 MEP Support (802.1ag and Y.1731)

The 7705 SAR supports Up and Down MEPs on Ethernet (Epipe and VPLS) SAPs for both 802.1ag and Y.1731. It also supports Down MEPs on Ethernet (Epipe and VPLS) spoke SDPs and mesh SDPs (VPLS only) for 802.1ag only.

3.5.4.1 802.1ag MEP Support on Ethernet SAPs

The 7705 SAR supports Up and Down MEPs on Ethernet SAPs. [Figure 18](#) shows that the 7705 SAR can terminate and respond to CFM messages received from connected devices, such as base stations, when port B is a Down MEP on a SAP. A CFM message coming from port A would be terminated on port B of the 7705 SAR. As well, port B on the 7705 SAR can generate and send a CFM message towards port A.

Figure 18 MEP on Ethernet Access

20474

[Figure 19](#) shows how a Down MEP on an Ethernet SAP might be used. In this example, an Ethernet network connects to an access Ethernet port on the 7705 SAR and there are multiple SAPs on that port (that is, multiple endpoints). Since CFM offers OAM capabilities on a per-service basis, which in this case means per SAP (or endpoint), each service can run CFM. If BSC end devices were directly connected to the 7705 SAR (and a VLAN was not used to separate services from each other), EFM would offer capabilities similar to CFM for Ethernet OAM.

In the example shown in [Figure 19](#), separate dot1ag instances initiated on the Wavence nodes can be used to ensure Ethernet layer connectivity on a per-base-station basis. All the traffic from these base stations is aggregated and switched to a single port on the 7705 SAR. Each base station is recognized through a different VLAN, where the VLANs are bound to different services. CFM with traffic in the Down MEP OAMPDU direction at the Ethernet SAP offers the flexibility to run OAM tests on a per-base-station basis.

Figure 19 Down MEP at Ethernet SAP

28769

3.5.4.2 802.1ag MEP Support on Ethernet Spoke and Mesh SDPs

The 7705 SAR supports Down MEPs on Ethernet spoke SDP endpoints (Epipe and VPLS) and mesh SDP endpoints (VPLS only). [Figure 20](#) illustrates a Down MEP on an Ethernet spoke SDP.

CFM messages can be generated and switched across an Ethernet PW. CFM messages that are received and have an MD that matches the value configured on the 7705 SAR are extracted and processed. Any received CFM messages with an MD level that does not match the configured value are not terminated and are switched transparently to the Ethernet SAP.

Down MEPs on Ethernet spoke and mesh SDPs on the 7705 SAR support the following:

- termination of the CFM messages destined for the MEP-ID of the 7705 SAR
- termination of CFM messages at the user-configured domain only
- discarding of OAMPDUs at a lower MD level than the configured one (an alarm message is raised)
- transparent pass-through of upper-layer CFM messages
 - MD of the CFM messages that are higher than the one configured on the 7705 SAR

MIP functionality (that is, forwarding of CFM messages with the same MD level) is not supported. Only Down MEP functionality is supported on Ethernet spoke or mesh SDPs (that is, termination of CFM messages that are ingress from the Ethernet PW, or generation of CFM packets that are destined for the 7750 SR spoke or mesh SDP MEP-ID).

Figure 20 Dot1ag Down MEPs on Spoke SDPs

20476

In [Figure 20](#), assuming that the MEP is enabled both on the SR and the 7705 SAR spoke SDP endpoints, the 7705 SAR can generate CFM messages and can terminate any received CFM messages that are destined for the 7705 SAR MEP-ID and have a matching configured domain. Any 7705 SAR-generated CFM packets would traverse the Ethernet PW and would be processed first by the SR node. The Ethernet PW running between the 7705 SAR and the SR generates a pipe-like connectivity; therefore, no intermediate Ethernet node can process the CFM messages. All the CFM messages are transported over Ethernet PWs, and PW termination only takes place on SR and 7705 SAR endpoints.

3.5.4.3 Y.1731 MEP Support on Ethernet SAPs

As shown in [Figure 21](#), the 7705 SAR supports Y.1731 Up and Down MEPs on Ethernet SAPs that are bound to an Ethernet PW service.

[Figure 21](#) also shows an 802.1ag Down MEP on an Ethernet spoke SDP in order to illustrate that when performing CFM tests on the 7705 SAR, a Y.1731 Up MEP on an Ethernet SAP should be used instead of an 802.1ag Down MEP on an Ethernet spoke or mesh SDP. Using a Y.1731 SAP Up MEP means that CFM packets verify the switching fabric and SAP status before the packet is processed, because the SAP is on the access side of the 7705 SAR whereas a spoke or mesh SDP is on the network side. If a spoke or mesh SDP Down MEP is used, packets are terminated and extracted on the network side without being switched through the switching fabric.

Figure 21 Y.1731 MEP Support on the 7705 SAR

20849

3.5.5 Priority Mapping (802.1ag and Y.1731)

Operators often run OAM tests over a single, specific forwarding class (FC). For example, an operator might be mapping OAM traffic to FC2 (AF – Assured Forwarding) and, in order to examine the delay, jitter, or loss qualities of the OAM traffic, would need to run OAM tests using FC2. To provide operators with the ability to control which FC the OAM packets will follow, the **priority** *priority* command is included in several OAM test commands.

When the 7705 SAR generates an Ethernet OAM frame, it uses the priority as per the user's configuration of the **priority** keyword and then sends the frame through the datapath. Therefore, the OAM frame follows the entire datapath and receives the same treatment as any other user frame before it is switched over the port.

For example, a CCM frame generated by a SAP Up MEP with a priority value of 7 will receive the following treatment.

- First, the CCM frame is classified as per the access ingress and QoS policy settings. For example, the CCM frame can be mapped to the BE forwarding class if the assigned QoS policy has its priority 7 mapped to BE.
- Then, the OAM packet is mapped to the associated queue (the queue hosting the BE forwarding class) and follows ingress scheduling like any other datapath frame.
- Next, the CCM frame is switched through the fabric and reclassified to the network egress queues, as per the assigned QoS policy classifiers.
- Finally, the CCM frame is scheduled again, as per the queue type and profile state of the queue.

This implementation replicates the user experience since the OAM packet follows the same path as the data packets.

3.5.5.1 Priority Mapping for SAP Up MEPs

For Up MEPs on a SAP, priority mapping operates as described in the following list, which indicates how the messages or replies generated on ingress have their FC and VLAN tag priority set.

The resulting frames (CCM, LMM, DMM, 1DM, LBM, LMR, DMR, or LBR) are inserted in the access ingress datapath and are processed in the same way as any other frame. That is, they are classified based on the SAP ingress policy.

- Continuity Check Messages (CCMs) generated on ingress are based on the setting of the **ccm-ltm-prio** command for the MEP (that is, the VLAN tag priority is set according to the **ccm-ltm-prio** command for the MEP).
- Loss Measurement Messages (LMMs), two-way Delay Measurement Messages (DMMs), one-way Delay Measurement Messages (1DMs), and Loopback Messages (LBMs) generated on ingress are based on the priority specified during the LMM, DMM, 1DM, or LBM test (that is, the VLAN tag priority is set according to the priority specified during the test).
- Loss Measurement Replies (LMRs), two-way Delay Measurement Replies (DMRs), and Loopback Replies (LBRs) generated on ingress keep the VLAN tag priority of their corresponding LMM or DMM frame.

[Table 11](#) summarizes the 7705 SAR FC and VLAN priority mappings for SAP Up and Down MEPs based on the frame type.

Table 11 FC and VLAN Priority Mappings for Up and Down MEPs as per Frame Type

MEP Type	Frame Type (Tx)	FC	VLAN priority
SAP Up MEP	CCM	derived from vlan-prio after classification	ccm-ltm-prio
	LMM, DMM, 1DM, LBM	derived from vlan-prio after classification	user-specified
	LMR, DMR, LBR	derived from vlan-prio after classification	preserve incoming query priority
SAP Down MEP	CCM	ccm-ltm-prio	ccm-ltm-prio
	LMM, DMM, 1DM, LBM	user-specified	user-specified
	LMR, DMR, LBR	ccm-ltm-prio	incoming tag priority

3.5.5.2 Priority Mapping for SAP Down MEPs

For SAP Down MEPs, priority mapping operates as described in the following list, which indicates how the messages or replies generated on egress have their FC and VLAN tag priority set.

- CCMs generated on egress are based on **ccm-ltm-prio** of the MEP (that is, FC and VLAN tag priority are set according to the **ccm-ltm-prio** of the MEP).
- LMM, DMM and 1DM generated on egress are based on the priority specified during the test (that is, FC and VLAN tag priority are set according to the priority specified during the test).
- LMR, DMR, and LBR generated on egress use the **ccm-ltm-prio** of the MEP as FC. The VLAN tag priority is not replaced (that is, the VLAN tag priority of LMM and DMM are kept).

3.6 G.8032 Ethernet Ring Protection Switching

This section contains the following topics:

- [Overview of G.8032 Operation](#)
- [Ethernet Ring Sub-Rings](#)

The 7705 SAR supports Ethernet ring protection switching in accordance with ITU-T G.8032 to achieve resiliency for Ethernet Layer 2 networks. A G.8032 Ethernet ring is built on Ethernet OAM and is also referred to as Ring Automatic Protection Switching (RAPS).

Ethernet rings are supported on VPLS SAPs. VPLS services supporting Ethernet rings can connect to other rings and Ethernet services using VPLS and R-VPLS SAPs. Ethernet rings provide rings for core network or access network resiliency. A single point of interconnection to other services is supported. The Ethernet-ring service is a VLAN service providing protection for ring topologies and the ability to interact with other protection mechanisms for overall service protection. This combined service protection ensures that higher layers are isolated from failures because there will only be a RAPS switchover when the lower layer cannot recover.

Rings are preferred in data networks where the native connectivity is laid out in a ring or where there is a requirement for simple resilient LAN services. Due to the symmetry and the simple topology, rings are considered a good solution for access and core networks where resilient LANS are required. The 7705 SAR implementation can be used for interconnecting access rings and to provide traffic engineered backbone rings.

Even though 7705 SAR nodes are often connected via IP/MPLS links to each other or to higher hierarchies, the first level of connected aggregation nodes can significantly benefit from G.8032 protection switching. [Figure 22](#) shows a common example where standalone microwave nodes are deployed in a ring that are connected to a 7705 SAR node acting as the head-end of the ring. Providing G.8032 Ethernet ring protection switching would provide significantly better reconvergence times in the ring and ensure minimal service disruption in case of failure.

Figure 22 Ethernet Protection Switching

28787

Ethernet rings use one VLAN ID per control per ring instance and use one or sometimes multiple VLAN IDs for data instances per control instance. A dedicated control VLAN (ERP VLAN) is used to run the protocol on the control VLAN ID. G.8032 controls the active state for the data VLANs (ring data instances) associated with a control instance. Multiple control instances allow logically separate rings on the same topology.

The 7705 SAR supports dot1q and qinq encapsulation for data ring instances. The control channel supports dot1q and qinq encapsulation. The control channel can support dot1q while the data channels use qinq if the global **new-qinq-untagged-sap** command is enabled.

3.6.1 Overview of G.8032 Operation

RAPS messages that carry the G.8032 protocol are sent on a dedicated protocol VLAN called the Ethernet Ring Protection (ERP) instance. Revertive and non-revertive behaviors are supported. In revertive mode, the G.8032 protocol ensures that one Ring Protection Link (RPL) owner blocks the RPL. RAPS messages are periodically sent around the ring to inform other nodes in the ring about the blocked port in the RPL owner node. In non-revertive mode, any link may be the RPL.

Y.1731 Ethernet OAM CC is the basis of the RAPS messages. Nodes in the ring typically use Y.1731 CC messages to monitor the health of each link in the ring in both directions. CC messages are not mandatory. Other link layer mechanisms could be used, for example, Loss of Signal (LOS) for instances when the nodes are directly connected.

Initially each ring node blocks one of its links and notifies other nodes in the ring about the blocked link. Once a ring node in the ring learns that another link is blocked, the node unblocks its blocked link possibly causing an FDB flush of all links in the ring for the affected service VLANs controlled by the ring control instance. This results in unblocking all links except one so that the ring is in the normal, or idle, state. In revertive mode, the link that is blocked when all other links are operable after the revert time has expired becomes the RPL. In non-revertive mode the RPL is no different than other ring links. Revertive mode offers predictability, especially when there are multiple ring instances and the operator can control which links are blocked on each instance. When there is a topology change that affects reachability, the nodes may flush the FDB and MAC learning occurs for the affected service VLANs, which allows packet forwarding to continue. [Figure 23](#) depicts this operational state.

Figure 23 G.8032 Ring in the Idle State

28779

When a ring failure occurs, any node that detects the failure (by using Y.1731 OAM CC monitoring) sends RAPS message in both directions. After receiving a failure notification, the nodes at both ends of the failed link block forwarding to the failed link to prevent it from becoming active.

When a ring failure occurs in revertive mode, the RPL owner unblocks the previously blocked RPL and triggers an FDB flush for all nodes for the affected service instances. The ring is now in the protecting state and full ring connectivity is restored. MAC learning occurs, which allows Layer 2 packet forwarding on the ring. [Figure 24](#) depicts a G.8032 ring in the protecting state.

Figure 24 G.8032 Ring in the Protecting State

28780

Once the failed link recovers, the nodes that blocked the link send RAPS messages indicating no failure. This triggers the RPL owner to block the RPL link and indicate the blocked link in its own RAPS message. When the nodes at the recovered link receive the RPL RAPS message, they unblock the specified link, restore connectivity, and all nodes in the ring perform an FBD flush. MAC learning takes place and the ring returns to the normal, or idle, state.

Each path uses Y.1731 Maintenance Entity Groups (MEGs) and Maintenance Endpoints (MEPs) to exchange RAPS-specific information to co-ordinate switchovers. As well Y.1731 MEGs and MEPs optionally use fast Continuity Check Messages (CCM), which provide an inherent fault detection mechanism as part of the protocol. When a ring path failure is detected, the protection links are activated. During a failure, reconvergence times depend on the failure detection mechanisms being used. For Y.1731, the CCM transmit interval determines the response time. The router supports message timers as low as 10 ms, providing restoration times comparable to SONET/SDH. Alternatively, 802.3ah (Ethernet in the First Mile) or simple LOS can act as a trigger for a protection switch where appropriate. Where nodes are directly connected there is no need to use Ethernet CC messaging for liveness detection.

G.8032 supports multiple data channels (VLAN IDs) or instances per ring control instance (RAPS tag). G.8032 also supports multiple control instances such that each instance can support RPLs on different links, providing load balancing capability. However, once services have been assigned to one instance the rest of the services that need to be interconnected to them must be on the same instance. In other words, each data instance is a separate data VLAN on the same physical topology. If there is a single link or node failure in the ring, G.8032 protocols are capable of restoring traffic between all remaining nodes in these data instances.

Ethernet RAPS can be configured on any port configured for access mode by using dot1q or QinQ encapsulation, enabling support for Ethernet RAPS protected services on the service edge towards the customer site or within the Ethernet backbone.

The Ethernet ring is built from a VPLS service on each node with VPLS SAPs that provide ring paths with SAPs. As a result, most of the VPLS SAP features are also available on Ethernet rings resulting in a feature-rich ring service.

The control tag defined under each Ethernet ring is used for encapsulating and forwarding the CCMs and the G.8032 messages used for the protection function. If a failure of a link or node affects an active Ethernet ring segment, the services will fail to receive the CCMs exchanged on that segment or will receive a fault indication from the link layer OAM module. CCMs are optional but MEPs are always configured to provide G.8032 control. The forwarding of CCMs and G.8032 RAPS messages continues in the control VPLS even if the service or its SAPs are administratively shut down. The Ethernet ring instance can be shut down to stop the operation of the ring on a node.

For fault detection using CCMs, three CC messages and a configurable hold-off timer must be missed for a fault to be declared on the associated path. The hold-off timer is required in order to support an additional 50 ms resiliency mechanism in the optical layer. After receiving the fault indication, the protection module declares the associated ring link down and the G.8032 state machine sends the appropriate messages to open the RPL and flush the learned addresses.

Flushing is triggered by the G.8032 state machine and the router implementation allows flooding of traffic during the flushing interval to expedite traffic recovery.

[Figure 25](#) illustrates a resilient Ring Service. In the example, a ring (solid line) with that usage dot1q VLAN ID 100 carries service VID 500. The RPL for the ring is between A and B, where B is the RPL owner. Also illustrated is a QinQ service on the (dotted line) ring that uses dot1q VLAN ID 600 for the ring to connect service VLAN 100.50. The two rings have RPLs on different nodes, which allows a form of load balancing.

Figure 25 illustrates that service encapsulations and ring encapsulation can be mixed in various combinations. Neither of the rings is a closed loop. When any one node or link fails, a ring can restore connectivity to all remaining nodes within the 50 ms transfer time (the signaling time after detection).

    no shutdown
exit
```

3.6.2 Ethernet Ring Sub-Rings

Ethernet sub-rings offer a dual redundancy with interconnected rings. The router supports sub-rings connected to major rings and a sub-ring connected to an LDP-based VPLS for access ring support in VPLS networks. Figure 26 and Figure 27 illustrates a major ring and sub-ring scenario. In this scenario, any link can fail in either ring (ERP1 or ERP2) and each ring is protected. The sub-ring (ERP2) relies on the major ring (ERP1) as part of its protection for traffic from nodes C and D, which are configured as interconnection nodes.

Figure 26 G.8032 Sub-Ring

28783

Sub-rings and major rings run similar state machines for the ring logic, however there are some differences. When sub-rings protect a link, the flush messages are propagated to the major ring. A special configuration allows control of this option on the router. When major rings change topology, the flush is propagated around the major ring but does not continue to any sub-rings. The reason for this is that major rings are completely connected but sub-rings are dependent on another ring or network for full connectivity. The topology changes usually need to be propagated to the other ring or network. Sub-rings offer the same capabilities as major rings in terms of control and data so that all link resources may be utilized.

3.6.2.1 Virtual and Non-Virtual Channel

The 7705 SAR supports sub-ring control communication using either a virtual channel or non-virtual channel. In the virtual channel mode, a dedicated VLAN ID, other than the major ring RAPS control channel is configured as a data instance on the major ring. This allows the sub-ring control messages and state machine logic to behave similar to a major ring. In the non-virtual channel mode, the sub-ring is only connected by the RAPS control channels on the sub-ring itself. This mode offers slightly less redundancy in the RAPS messaging than the virtual channel mode since sub-ring RAPS messages are not propagated across the major ring. When a non-virtual link is configured, the protocol allows RPL messages over the sub-ring blocked link. [Figure 27](#) shows a sub-ring configuration using virtual and non-virtual channels.

Figure 27 Sub-Ring Configuration Example

28784

Sub-ring configuration is similar to major ring configuration and consists of three parts:

- Ethernet ring instance configuration
- control VPLS configuration
- data VPLS configuration (data instance or data channel)

The Ethernet ring configuration of a sub-ring is tied to a major ring and only one path is allowed. A split horizon group is mandatory to ensure that sub-ring control messages from the major ring are only passed to the sub-ring control.

As with a major ring, CCMs and RAPS messages continue to be forwarded in the control VPLS even if the service or its SAPs are administratively shut down. The Ethernet ring instance can be shut down to stop the operation of the ring on a node.

The data VPLS can be configured on the major ring and shares the same VLAN ID (SAP encapsulation) on both the major ring and the sub-ring to keep data on the same VLAN ID everywhere. See the configuration example shown below. Like other services in the router, the encapsulation VLAN ID is controlled by SAP configuration and the association to the controlling ring is by the Ethernet ring ID.

The following CLI output is an example of a sub-ring configuration on Node C shown in [Figure 27](#):

```
eth-ring 2
  description "Ethernet Sub Ring on Ring 1"
  sub-ring virtual-link // Using a virtual link
    interconnect ring-id 1 // Link to Major Ring 1
    propagate-topology-change
  exit
exit
path a 1/1/3 raps-tag 100 // Ring control uses VLAN ID 100
  eth-cfm
    mep 9 domain 1 association 4
    ccm-enable
    control-mep
    no shutdown
  exit
exit
no shutdown
exit
no shutdown
exit
```

If the sub-ring had been configured as a non-virtual-link, the sub-ring configuration above and on all the other sub-ring nodes for this sub-ring would instead be:

```
sub-ring non-virtual-link // Not using a virtual link
```

```
# Control Channel for the Major Ring ERP1 illustrates that Major ring
# control is still separate from Sub-ring control
vpls 10 customer 1 create
    description "Control VLAN ID 10 for Ring 1 Major Ring"
    stp shutdown
    sap 1/1/1:10 eth-ring 1 create

    exit
    sap 1/1/4:100 split-horizon-group "s1" eth-ring 1 create
        stp shutdown
    exit
    sap 1/1/3:100 eth-ring 2 create
        stp shutdown
    exit
    no shutdown
exit
```

The 7705 SAR supports a special configuration of the non-virtual link sub-ring that can be homed to a VPLS service as illustrated in [Figure 28](#). This is an economical way to have a redundant ring connection to a VPLS service. This is currently supported only for dot1q and qinq sub-rings and only on LDP-based VPLS. The primary application for this is access rings that require resiliency. This example in [Figure 28](#) shows a sub-ring at an interconnection node without a virtual channel and interconnected to a VPLS. A VPLS service 1 is used to terminate the ring control. The Ethernet ring data SAP appears in the associated LDP-based VPLS service 5.

Figure 28 Sub-Ring Homed to VPLS

    exit
    mesh-sdp 5005:5 create
    exit
    mesh-sdp 5006:5 create
    exit
    no shutdown
exit

```

Ethernet rings and sub-rings offer a way to build a scalable and resilient Ethernet transport network. [Figure 29](#) illustrates a hierarchical ring network where dual-homed services are connected to an Ethernet ring network.

Figure 29 Multi-Ring Hierarchy

28786

Major rings are connected by sub-rings to the top level major ring. These sub-rings require a virtual channel and will not work with non-virtual channels. Ring flushing is contained to major rings or in the case of a sub-ring link failure or node failure, to the sub-ring and any directly attached major rings.

3.6.2.1.1 LAG Support

Ethernet rings support LAG on Ethernet ring SAPS. However, using LAG impacts the resiliency response time. In many cases, operators may achieve better resiliency response time and QoS by using multiple ring instances, each on a single link, instead of LAG on Ethernet rings. If a response time of less than 100 ms is not required, LAG is an acceptable option for Ethernet rings.

3.6.2.2 OAM Considerations

Ethernet CFM is enabled by configuring MEPs on each individual path under an Ethernet ring. Only down MEPs can be configured on each path. CCM sessions can also be enabled to monitor the liveness of the path using an interval of 10 ms or 100 ms. Different CCM intervals can be supported on path A and path B in an Ethernet ring. CFM is optional if the node supports LOS, which is controlled by configuring **no-ccm-enable**.

Up MEPs on service SAPs that multicast into the service and monitor the active path may be used to monitor services.

When an Ethernet ring is configured on two ports located on different cards, the SAP queues and virtual schedulers are created with the actual parameters on each card.

Ethernet ring CC messages that are transmitted over the SAP queues using the default egress QoS policy use network class (NC) as a forwarding class. If user traffic is assigned to the NC forwarding class, it will compete for bandwidth resources with the Ethernet CCMs and cause congested queues. This congestion can result in CCM loss that could lead to unnecessary switching of the Ethernet ring. To avoid potential congestion, configure different QoS policies that will control the amount of traffic assigned into the corresponding queue.

3.6.2.3 Support Service and Solution Combinations

Ethernet rings are supported on VPLS and R-VPLS instances. The following considerations apply.

- Only ports in access or hybrid mode can be configured as Ethernet ring paths. The ring ports can be located on the same or different media adapter cards.
- Dot1q and qinq ports are supported as Ethernet ring path members.
- A mix of regular and multiple Ethernet ring SAPs and pseudowires can be configured in the same services.

3.7 QinQ Support

This section contains the following topics:

- [Overview of QinQ](#)
- [QinQ Support with Forced C-Tag Forwarding \(VPLS only\)](#)
- [QinQ Support on Ethernet Ports](#)
- [QinQ Configuration Overview](#)

3.7.1 Overview of QinQ

On the 7705 SAR, QinQ (also referred to as VLAN stacking) is based on the IEEE 802.1ad specification. QinQ allows a service provider to use a single VLAN for customers needing multiple VLANs by adding a second VLAN tag to an Ethernet frame, as shown in [Figure 30](#). QinQ encapsulation can be thought of as a dot1q within a dot1q encapsulation.

QinQ operates from end-to-end by receiving customer frames on an ingress SAP, transporting the frames over a service tunnel, and receiving them at the far-end router, where they are unpacked and sent through the egress SAP to the customer.

Figure 30 **QinQ Frame**

23834

On the 7705 SAR, QinQ ports and QinQ SAPs offer the same feature set as dot1q ports and dot1q SAPs for the following features:

- OAM
- redundancy
- synchronization
- QoS
- card and node limits

QinQ is supported on the following service SAPs (including SAP-to-SAP configurations):

- VLL services (Epipe and Ipipe)
- VPLS
- VPRN
- IES

QinQ is supported on the following adapter cards, modules, and nodes:

- 8-port Ethernet Adapter card, version 2
- 6-port Ethernet 10Gbps Adapter card
- 8-port Gigabit Ethernet Adapter card (all versions)
- 10-port 1GigE/1-port 10GigE X-Adapter card (10-port 1GigE mode)
- Packet Microwave Adapter card
- 4-port SAR-H Fast Ethernet module
- 6-port SAR-M Ethernet module
- 7705 SAR-M
- 7705 SAR-A
- 7705 SAR-Ax
- 7705 SAR-W
- 7705 SAR-Wx (Ethernet ports and DSL ports)
- 7705 SAR-H
- 7705 SAR-Hc
- 7705 SAR-X

Note: QinQ is not supported by DSL and GPON modules on the 7705 SAR-M.

Figure 31 shows an example of QinQ tagging, where three customer sites each use the same service provider PE router to transport multiple VLANs across an MPLS network. Customer 1 sends an Ethernet frame without a VLAN tag (null encapsulation) and the provider uses MPLS label 25. Customer 2 sends dot1q frames (VLAN ID 20) and the provider uses MPLS label 35. Lastly, customer 3 sends a qinq frame (VLAN ID 10:300) and the provider uses MPLS label 45.

For details on VLAN translation in an Ethernet frame from ingress SAP to egress SAP, see [Raw and Tagged Modes](#).

Figure 31 QinQ Tagging Example

24021

3.7.2 QinQ Support with Forced C-Tag Forwarding (VPLS only)

For VPLS, **force-c-vlan-forwarding** can be user-configured as enabled or disabled. When **force-c-vlan-forwarding** is enabled at the ingress and egress SAPs, the VLAN tag transmitted at the far-end egress SAP is the same as the VLAN tag received at the near-end ingress SAP.

The following examples illustrate the QinQ implementation. Example 1 is a general example. Examples 2 and 3 are examples where the 7705 SAR parses a single frame that has three VLAN tags. For examples 2 and 3, the innermost VLAN Ethertype is always set to 0x8100.

3.7.2.1 Example 1: General QinQ Implementation

When a service has multiple SAPs configured that can match an incoming frame, the SAP with the most explicit match transmits the frame. For this example, assume that the following SAPs are configured on a port and that the port is in QinQ mode:

- SAP_1 identifier is *port-id:vlan-x.vlan-y*
- SAP_2 identifier is *port-id:vlan-x.**
- SAP_3 identifier is *port-id:.**

For an incoming frame with VLAN tags *vlan-x.vlan-y*, SAP_1 processes the frame because it is the most explicit match. Although SAP_2 and SAP_3 also match the frame, the most explicit SAP prevails.

3.7.2.2 Example 2: QinQ using VPLS with Ethernet SAPs

In this example, assume that the 7705 SAR parses a single frame that has three VLAN tags (innermost VLAN Ethertype is always set to 0x8100). This might occur in the scenario shown in [Figure 32](#), where VPLS QinQ SAPs with **force-c-vlan-forwarding** enabled connect Customer 1 and Customer 2 and preserve the ingress VLAN tag.

Figure 32 QinQ Using VPLS Ethernet SAPs

24017

In [Figure 32](#), the following events occur.

- At Node_1, an ingress QinQ SAP with **force-c-vlan-forwarding** enabled receives a frame and ensures that the bottom (inner) tag is preserved. The frame is then sent to an egress qinq-encapsulated SAP, where the top (outer) tag is swapped and an additional (third) tag is pushed on top.
- At Node_2, the frame with three tags is received on a qinq-encapsulated SAP. The frame is then sent to an egress QinQ SAP with **force-c-vlan-forwarding** enabled, where the egress qinq-encapsulation SAP:
 - removes the first (top) tag
 - replaces the second (middle) tag
 - replaces only the Ethertype of the third (bottom/innermost) tag (that is, the VLAN ID is not replaced)

3.7.2.3 Example 3: QinQ Using VPLS with ATM SAPs

A second example of triple-tag behavior is shown in [Figure 33](#), where customers are connected using ATM SAPs with **subscriber-vlan** enabled.

Figure 33 QinQ Using VPLS ATM SAPs

24018

In this example, the ATM SAP with **subscriber-vlan** enabled pushes a tag on the frame at ingress. The frame is then sent toward a qinq-encapsulated SAP on egress, which pushes two more tags onto the frame. At the far end, the frame (with three tags) is received on a qinq-encapsulated SAP and sent toward the egress ATM SAP with **subscriber-vlan** enabled. In this case, the egress ATM-encapsulated SAP must be able to remove the three tags.

3.7.3 QinQ Support on Ethernet Ports

This section contains the following topics:

- [Special QinQ SAP Identifiers](#)
- [QinQ Dot1p Match Behavior](#)
- [QinQ Top-Only Mark Option](#)
- [Maximum Number of VLAN Tags](#)

QinQ requires that the **encap-type** for the associated port be set for **qinq**, and that the *sap-id* include two Q-tags (VLAN IDs). An ingress QinQ SAP can be configured so that dot1p bits for packet QoS classification can come from the top or the bottom Q-tag. At egress, if dot1p re-marking is configured, both Q-tags are re-marked. However, you can use **qinq-mark-top-only** to re-mark only the top Q-tag.

3.7.3.1 Special QinQ SAP Identifiers

[Table 12](#) describes the special SAP identifiers used on the 7705 SAR. In [Table 12](#), a *qtag* value represents a VLAN ID. The * (asterisk) represents a reserved VLAN that is used to carry traffic from any unused VLAN on the port. An unused VLAN is a VLAN that is not explicitly defined on the port.

Table 12 Special QinQ SAP Identifiers

QinQ SAP Type	SAP Identifier	Example	Notes
Explicit (specified)	<i>port-id:qtag1.qtag2</i> ¹	1/1/1:20.2000	<i>qtag1</i> and <i>qtag2</i> range: 0 to 4094, and *
Null	<i>port-id</i> <i>port-id:0</i> <i>port-id:0.*</i> <i>port-id:qtag1.0</i> ³	1/1/1 1/1/1:0 1/1/1:0.*	No suffix means no VLANs 0 suffix means SAP 0 0.* suffix means SAP 0 and any unused VLAN on the port
Default	<i>port-id:*</i> <i>port-id:.*</i> <i>port-id:qtag1.*</i>	1/1/1:.* 1/1/1:.*.* 1/1/1:40.*	*.* means any unused VLAN on the port ²

Notes:

1. *qtag1* is the top (outer) tag. *qtag2* is the bottom (inner) tag.
2. The behavior of the *.* SAP on the 7705 SAR is different from the *.* SAP behavior on the 7750 SR. On the 7750 SR, *.* represents a capture SAP.

3. This configuration becomes available when the **new-qinq-untagged-sap** command is enabled.

Note: The following default SAPs are not supported on the 7705 SAR:

- *port-id:*.0*
- *port-id:*.vlan-y*

The following list describes how the SAP types in [Table 12](#) process frames. Packet breakdowns are described in [Raw and Tagged Modes](#).

- default SAP (*port-id:qtag1.**)
 - receives all frames with an explicit outer tag value of *qtag1*, regardless of the inner tag
 - the outer tag is stripped and the inner tag is passed transparently
 - example: SAP 1/1/1:10.* only matches a top Q tag of VLAN 10. The SAP may have any bottom tag or no bottom tag at all.
- null SAP (*port-id:0.**)
 - receives all untagged frames and/or any frames with a VLAN tag of 0
 - example: SAP 1/1/1:0.* allows any untagged frames and/or frames with an outer tag of “0” only

If the outer tag is 10, then the frame is dropped. If the outer tag is 0 and the inner tag is any valid VLAN ID, then the frame is not dropped.
- null inner SAP (*port-id:qtag1.0*)
 - receives all frames with explicit outer tag value *qtag1*, and may have an inner tag of 0 or no inner tag at all
 - example: SAP 1/1/1:10.0 or SAP 1/1/1:10 will only match “10” as the outer tag, and may have a bottom tag of 0 or no bottom tag at all. The SAP 1/1/1:1/10 will be dropped because its outer tag is not “10”.
- invalid SAPs (not supported) (*port-id:*.qtag2* and *port-id:*.0*)

3.7.3.2 QinQ Dot1p Match Behavior

Since a qinq-encapsulated packet has top and bottom Q-tags, you can specify which qtag position provides the dot1p bits (P-bits) when QoS evaluates the P-bits in an ingress packet for a classification match. This is done with the **sap>ingress>match-qinq-dot1p** command. The default setting is to use the P-bits from the inner (bottom) Q-tag, or if the ingress packet has no Q-tags or has null encapsulation, then no match filtering is done.

3.7.3.3 QinQ Top-Only Mark Option

By default, if dot1p re-marking is configured at SAP egress on a QinQ SAP, the dot1p bits for both the top and bottom tags are re-marked. However, re-marking can be configured such that only the top Q-tag P-bits get remarked by enabling the **sap>egress>qinq-mark-top-only** command. The DEI bit is ignored.

3.7.3.4 Maximum Number of VLAN Tags

The maximum number of VLAN tags allowed in a packet depends on whether the service requires Layer 3 packet parsing (for example, to access to the IP header), as follows.

- For services that do not require access to the Layer 3 IP header, such as Ethernet PWs and VPLS, there is no limit on the number of VLAN tags in the packet. Any packet with any number of VLAN tags is accepted.
- For services that require access to the Layer 3 IP header, such as IP PWs, IES, and VPRN, there is a limit of three or fewer VLAN tags. When a packet is received that has four VLAN tags, the data following the third VLAN tag is considered as an IP packet. As a result, packets with four VLAN tags will be dropped by these services due to the inability to decode the IP header.

3.7.4 QinQ Configuration Overview

The basic steps to configure QinQ are as follows.

1. Configure the port **encap-type** for qinq and (optionally) set the Ethertype (**qinq-etype**).
2. Create one or more SAPs for the service.
3. Configure the SAP ingress dot1p re-marking behavior (match the top or bottom tag).
4. Enable the SAP egress **qinq-mark-top-only** command.
5. Configure the spoke SDP **vc-type** (ether or vlan).

3.8 Raw Socket IP Transport Service

Serial data transport using raw sockets over IP transport services is a method of transporting serial data, in character form, over an IP network using Layer 3-based services. This feature can help transport Supervisory Control and Data Acquisition (SCADA) data from Remote Terminal Units (RTUs) to Front-End Processors (FEPs), or SCADA masters.

The functionality provided by the IP transport service feature for serial raw sockets is summarized as follows:

- IP transport local host (server) function, to listen to and open raw socket sessions from remote hosts
- IP transport remote host (client) function, to initiate and open new raw socket sessions to remote hosts
- both local host and remote host functions support for either TCP or UDP IP transport services
- IP transport over an IES or VPRN service
- enhanced QoS and queuing of sessions to ensure that collisions between sessions do not cause serial data to impact RTUs and end-user equipment

[Figure 34](#) illustrates a detailed view of the local host (server) and remote host (client) functionality that enables multiple communication streams to and from a serial port using raw socket IP transport.

The figure shows a three-node network: a 7705 SAR-H/7705 SAR-Hc (left), a 7705 SAR-8/7705 SAR-18 (top right) and a 7705 SAR-H/7705 SAR-Hc node, 7705 SAR-8/7705 SAR-18 node, or 7750 SR/VSF node (bottom right). There are two devices, RTU (1) and RTU (2) connected to the serial ports on the 7705 SAR-H/7705 SAR-Hc. FEP server [A] can reach the RTUs via the socket sessions that originate from the 12-port Serial Data Interface card on the 7705 SAR-8/7705 SAR-18 node. The bottom-right 7705 SAR or 7750 SR/VSF node is connected to FEP server [B] directly using Ethernet. This FEP server reaches the RTUs via a Layer 3 IP/MPLS service where raw socket sessions are processed directly on the FEP servers.

Through local host and remote host configurations on the 7705 SAR-H/7705 SAR-Hc or 7705 SAR-8/7705 SAR-18, serial raw socket IP transport sessions are established to carry serial data over a wireless IP/MPLS network. The source and destination IP addresses and port numbers for these sessions are derived directly from the local/remote host configurations associated with each serial port or master head-end server.

Figure 34 IP Transport Service

The 7705 SAR-H/7705 SAR-Hc supports the ability to configure a raw socket IP transport interface for each serial port. This allows the raw socket IP transport to receive TCP or UDP session packets from multiple remote hosts when operating as a local host (server), or to create new multiple sessions to remote hosts to send and receive serial data when operating as a client.

There are two main configurations required for a serial raw socket IP transport service to be operational and to support the sending and receiving of serial data:

- **port-level configuration**

This includes configuring rudimentary serial link parameters such as baud rate, start/stop values, and bits. Socket-level configuration is also required, such as configuring end-of-packet checking parameters (idle-time, length, special character) and the inter-sessions delay for transmitting sessions data out the serial link. For information on the required port-level configuration, refer to the 7705 SAR Interface Configuration Guide, Configuration Command Reference chapter, “Serial Commands”.

- **IP transport service-level configuration**

This includes creating an IP transport subservice to associate the serial port within a Layer 3 IES/VP RN service, so that TCP/UDP encapsulated serial data can be routed within the corresponding Layer 3 service. The IP transport subservice ID is modeled and created in the same way that the SAP IDs are created under the same service types. IP transport configuration includes configuring IP transport local host items and remote host items, such as setting TCP timers and sessions controls. See [IES Command Reference](#) and [VP RN Services Command Reference](#) for the required commands.

The 7705 SAR-H/7705 SAR-Hc supports the configuration of a raw socket IP transport service for each serial port. This allows each serial port’s local host to listen to and open raw socket sessions from remote hosts that need to communicate over the serial port, and for each serial port’s local host to initiate and open raw socket sessions to remote hosts when serial data needs to be sent to those remote hosts. The local and remote host functions support TCP or UDP sessions (but not both concurrently) over the IES/VP RN service.

The serial data is received as characters that represent bytes in a packet. These bytes are packetized into Layer 3 TCP/UDP packets that are then transported or forwarded across the IP/MPLS network using the node’s Layer 3 IES/VP RN service constructs for routing. [Figure 35](#) illustrates how serial data is encapsulated into TCP/UDP packets and transported over IP/MPLS.

Figure 35 TCP/UDP Packet Transport Over IP/MPLS

For raw socket packets to be routed within an IES/VPRN service, an IP transport subservice must be configured within an IES/VPRN context. The IP transport subservice context is where users configure local host and remote host information, such as IP addresses and ports for establishing TCP/UDP sessions, and other per-session parameters. TCP/UDP encapsulated serial data is routed within the corresponding Layer 3 IES/VPRN service. [Figure 36](#) illustrates this concept.

Figure 36 IES/VRN IP Transport Service

To create an IP transport subservice, the **ip-transport** command is used with the corresponding serial port as the *ipt-id* to bind the serial port SAP to the IP transport subservice. After the IP transport service is created, local host and remote host configurations can proceed. A local host must be configured before remote hosts can be configured.

Each local host uses a local address (from a loopback or local interface configured under the IES/VRN service context) as the local host IP address of the IP transport subservice associated with the serial port. The local host IP address is the source IP address in the raw socket packets leaving the node within the IES/VRN service. The local host is used to terminate TCP/UDP sessions from remote hosts. The local host can select either the TCP or UDP protocol for raw socket sessions but not both concurrently.

Multiple remote hosts can be configured under the IP transport subservice associated with the serial port so that each remote host receives the serial data that is received on the serial port. Each remote host has its own remote destination IP address and port value for establishing sessions. The configured remote hosts use the TCP or UDP protocol configured for the IP transport subservice.

Note: It is not necessary to configure remote hosts when the IP transport service is not originating sessions. If sessions are only established toward the IP transport local host (for example, remote servers polling the local host), the remote host configuration is not necessary. Remote host configurations may still be desirable when using the **filter-unknown-host** command.

IP transport processing of TCP/UDP packets occurs on the CSM of the 7705 SAR-H/ 7705 SAR-Hc. Filters configured for protecting the CSM must take into account the raw socket IP transport packets and ensure that the filter is not blocking associated IP transport sessions. For example, operators must ensure that interface IP addresses and ports configured on the node are not blocked and that remote host IP/port combinations are not blocked.

For IES/VPNRN IP transport services, all tunnel types supported by the IES/VPNRN service are also supported for the IP transport service. This includes all types of MPLS tunnels (such as RSVP-TE, LDP, auto-bind, static LSP) and GRE tunnels.

Note: IP transport-to-IP transport raw socket data on the same node is not supported. If serial-to-serial communication is needed on the same node, then customers must use Cpipes.

The 7705 SAR supports the concurrent operation of raw sockets and Cpipes on the 12-port Serial Data Interface card, version 2. See [Figure 37](#).

Figure 37 Raw Socket and Cpipe Support on the 7705 SAR

26507

3.8.1 Remote Host Manual TCP Connection Check

A manual TCP connection check can be performed for each remote host configured for a raw socket IP transport subservice. When executed by an operator, the TCP connection check attempts to establish a TCP session towards the configured remote host. Only one TCP connection check attempt is made, with a fixed timeout of 5 s. If the attempt is successful, the session is torn down immediately without data being sent.

The TCP connection check is initiated in the CLI using the **tools>perform>service>id>ip-transport>remote-host>check-tcp** command. The result is displayed in the CLI using the **tools>dump>service>id>ip-transport>remote-host>check-tcp** command. Equivalent management is available via SNMP.

If a TCP connection to a remote host already exists due to serial traffic being transmitted, the check returns “successful” without impacting the existing TCP connection.

3.8.2 QoS Requirements for IP Transport

Serial raw socket data that is transported using an IP transport service can be DSCP marked and FC classified at the source node. This allows the source node (local host) of the traffic to mark packets correctly so that downstream nodes prioritize them as needed, and to queue local traffic in the right egress queue based on the classification assigned to the IP transport service.

Additionally, the DSCP setting is assigned per IP transport subservice for all traffic from the local host and all traffic destined for each remote host. The DSCP setting is not set per remote host.

See the **dscp** and **fc** commands under [IES Raw Socket IP Transport Configuration Commands](#) and [VPRN Raw Socket IP Transport Configuration Commands](#) for more information on configuring the QoS settings for an IES or VPRN IP transport subservice.

3.9 Service Creation Overview

[Figure 38](#) shows a flowchart that provides an overview of the process to create a service. Service creation can be separated into two main functional areas—core services tasks and subscriber services tasks. Core services tasks are performed prior to subscriber services tasks.

Before starting the process shown in [Figure 38](#), ensure that the 7705 SAR system has been configured with an IP address and (for the 7705 SAR-8 or 7705 SAR-18) has the appropriate adapter cards installed and activated.

Core services tasks include the following items:

- create customer accounts
- create template QoS and accounting policies
- create LSPs
- create SDPs

Subscriber services tasks include the following items:

- create VLL (Apipe, Cpipe, Epipe, Fpipe, Hpipe, or Ipipe), IES, VPLS, or VPRN services
- configure SAPs
- bind SDPs
- create exclusive QoS policies
- (optionally) assign IP filter policies to Epipe SAPs, Ipipe SAPs, VPLS SAPs, VPRN interface SAPs, IES interface SAPs, and IES Management interface SAPs. IP filter policies can also be applied to VPLS SDPs (ingress mesh and spoke), and VPRN and IES interface ingress spoke SDPs.
- (optionally) assign MAC ingress filter policies to VPLS SAPs and VPLS SDPs (mesh and spoke)

Figure 38 Service Creation and Implementation Flowchart

21829

3.10 Port and SAP CLI Identifiers

When typing text in the command line interface (CLI), *port-id* is often displayed to indicate that a port identifier may need to be typed in the command line. Similarly, to identify a SAP, the *port-id* is used, but additional information may need to be appended to indicate a logical sub-element of the port.

On the CLI, a *port-id* is defined using the format *slot/mda/port*, where *slot* identifies the IOM card slot (always 1), *mda* identifies the physical slot in the chassis for the adapter card, and *port* identifies the physical port on the adapter card.

The value that can be appended to a SAP has the format *[:ID]*, *[.ID]*, *[:ID/ID]*, or *[:ID.ID]*. The colon or dot and following ID identify a sub-element of the port (if applicable), such as a TDM channel group for a Cpipe, a VPI/VCI value for an Apipe, or a dot1q or qinq VLAN ID for an Epipe.

For example, a SAP associated with a TDM channel group on port 12 of an 16-port T1/E1 ASAP Adapter card in MDA slot 3 is identified as <1/3/12.3>, where “.3” is the appended value and identifies that for this SAP the channel group begins in timeslot 3.

3.10.1 Reference Sources

For information on standards and supported MIBs, refer to [Standards and Protocol Support](#).

3.11 Configuring Global Service Entities with CLI

This section provides information to create subscriber (customer) accounts and to configure service destination points (SDPs) using the command line interface.

Topics in this section include:

- [Service Model Entities](#)
- [Basic Configuration](#)
- [Common Configuration Tasks](#)
- [ETH-CFM \(802.1ag and Y.1731\) Tasks](#)
- [Service Management Tasks](#)

3.12 Service Model Entities

The Nokia service model uses (logical) service entities to construct a service. Each entity within the model has properties that describe it and influence its behavior. The service model has four main entities to configure a service. The entities are:

- Customers
 - [Configuring Customer Accounts](#)
- Service Destination Points (SDPs)
 - [Configuring SDPs](#)
- Service Types
 - [ATM VLL \(Apipe\) Services](#)
 - [Circuit Emulation VLL \(Cpipe\) Services](#)
 - [Ethernet VLL \(Epipe\) Services](#)
 - [Frame Relay VLL \(Fpipe\) Services](#)
 - [HDLC VLL \(Hpipe\) Services](#)
 - [IP Interworking VLL \(Ipipe\) Services](#)
 - [VPLS](#)
 - [Internet Enhanced Service](#)
 - [VPRN Services](#)
- Service Access Points (SAPs)
 - [Configuring Apipe SAP Parameters](#)
 - [Configuring Cpipe SAP Parameters](#)
 - [Configuring Epipe SAP Parameters](#)
 - [Configuring Fpipe SAP Parameters](#)
 - [Configuring Hpipe SAP Parameters](#)
 - [Configuring Ipipe SAP Parameters](#)
 - [Configuring a VPLS SAP](#)
 - [Configuring IES SAP Parameters](#)
 - [Configuring VPRN Interface SAP Parameters](#)

3.13 Basic Configuration

Before configuring a subscriber service, the QoS, logs, and MPLS LSPs (if applicable) must be configured. Refer to the following guides for more information:

- 7705 SAR Quality of Service Guide
- 7705 SAR Router Configuration Guide
- 7705 SAR System Management Guide
- 7705 SAR MPLS Guide

A basic service configuration must have the following items configured:

- a customer ID
- a service type
- a service ID (a *service-id* number is mandatory and a *service-name* is optional)
- a SAP identifying a port and encapsulation value
- an interface (where required) identifying an IP address, IP subnet, and broadcast address
- an associated SDP (for distributed services)

The following example shows an Epipe service configuration displaying the SDP and Epipe service entities. SDP ID 2 was created with the far-end node 10.10.10.104. Epipe ID 6000 was created for customer ID 6, which uses the SDP ID 2.

3.14 Common Configuration Tasks

This section provides a brief overview of the following common configuration tasks that must be performed to configure a customer account and an SDP:

- [Configuring Customer Accounts](#)
- [Configuring SDPs](#)
- [Configuring Service Names](#)

3.14.1 Configuring Customer Accounts

Use the **customer** command to configure customer information. Every customer account must have a customer ID. Optional parameters include:

- description
- contact name
- telephone number

If special characters are included in the customer description string, such as spaces, #, or ?, the entire string must be enclosed in double quotes.

Use the following CLI syntax to create and input customer information.

CLI Syntax:

```
config>service# customer customer-id create
                        contact contact-information
                        description description-string
                        phone phone-number
```

Example:

```
config>service# customer 5 create
config>service>cust# contact "Technical Support"
config>service>cust$ description "Nokia Customer"
config>service>cust# phone "650 555-5100"
config>service>cust# exit
```

The following example displays the customer account configuration output.

```
A:ALU-12>config>service# info
-----
customer 5 create
    contact "Technical Support"
    description "Nokia Customer"
    phone "650 555-5100"
exit
```

3.14.2 Configuring SDPs

When configuring an SDP, consider the following points.

- SDPs can be configured for MPLS, GRE, or IP encapsulation.
- If you do not specify an encapsulation type, the default is MPLS.
- An SDP can have more than one service bound to it. That is, an SDP is not specific or exclusive to any one service or any type of service.
- By default, SDPs are not associated with services. After an SDP is created, services can be associated with that SDP.
- A distributed service must be bound to an SDP.
- When configuring a distributed service, you must identify an SDP ID and the far-end IP address. Use the **show>service>sdp** command to display a list of qualifying SDPs.
- If an SDP configuration does not include the IP address of the associated far-end router, VLL and VPLS services to the far-end router cannot be provided.
- Up to eight RSVP-TE or SR-TE LSPs can be configured under a single MPLS-encapsulated SDP. However, a mix of RSVP-TE and SR-TE LSPs is not supported. RSVP-TE LSPs are configured using the **config>service>sdp>lsp** command and SR-TE LSPs are configured using the **config>service>sdp>sr-te-lsp** command.
- For MPLS-encapsulated SDPs, LSPs must be configured before the LSP-to-SDP associations can be assigned. The LSP-to-SDP associations must be created explicitly.
- LSPs are configured in the **config>router>mpls** context. Refer to the 7705 SAR MPLS Guide for configuration and command information.
- The destination address of the LSPs must match the far-end IP address of the SDP.
- The far-end SDP IP address can be the system IP address of a 7705 SAR or an SR-series router, or loopback or network interface of the far-end router.
- When configuring MPLS SDP parameters, you can either specify up to eight RSVP-TE LSPs using the **config>service>sdp>lsp** command or enable LDP using the **config>service>sdp>ldp** command. There cannot be two methods of transport in a single SDP unless the **mixed-lsp-mode** option is selected (the **lsp** and **ldp** commands are mutually exclusive).

If **mixed-lsp-mode** is enabled and an LSP is specified, RSVP-TE is used for dynamic signaling in the LSP.
- Automatic ingress and egress labeling (targeted LDP) is enabled by default. Ingress and egress VC labels are signaled over a targeted LDP connection between two 7705 SAR routers.

Note: If signaling is disabled for an SDP, ingress and egress vc-labels for the services using that SDP must be configured manually.

For a basic SDP configuration, perform the following steps:

1. Create an SDP ID.
2. Specify an encapsulation type.
3. Specify a far-end node.

The following examples show the CLI syntax for a basic MPLS SDP configuration. The first two show the syntax for configuring the SDP without **mixed-lsp-mode** enabled; one shows an RSVP-TE LSP configuration and the other shows an LDP configuration. The third example shows the syntax for configuring the SDP with **mixed-lsp-mode** enabled, with both an RSVP-TE LSP and LDP configured.

CLI Syntax:

```
config>service>sdp sdp-id mpls create
    far-end ip-addr
    lsp lsp-name
    keep-alive
    shutdown
no shutdown
```

Example:

```
config>service# sdp 100 mpls create
config>service>sdp# far-end 10.10.10.10
config>service>sdp# lsp "LSP1"
config>service>sdp# no shutdown
config>service>sdp# exit
```

The following example displays a basic SDP LSP configuration output.

```
*A:Sar18 Dut-B>config>service# info
-----
.....
    sdp 100 create
        no shutdown
        far-end 10.10.10.10
        lsp "LSP1"
        keep-alive
        shutdown
    exit
exit
.....
-----
```

CLI Syntax:

```
config>service>sdp sdp-id mpls create
                        far-end ip-addr
                        ldp
                        keep-alive
                        shutdown
                        no shutdown
```

Example:

```
config>service# sdp 300 mpls create
config>service>sdp# far-end 10.10.10.10
config>service>sdp# ldp
config>service>sdp# no shutdown
config>service>sdp# exit
```

The following example displays a basic SDP LDP configuration output.

```
*A:Sar18 Dut-B>config>service# info
-----
.....
      sdp 300 create
      far-end 10.10.10.10
      ldp
      keep-alive
      shutdown
      exit
      no shutdown
      exit
.....
-----
```

CLI Syntax:

```
config>service>sdp sdp-id mpls create
                        description description-string
                        far-end ip-addr
                        mixed-lsp-mode
                        exit
                        ldp
                        lsp lsp-name
                        keep-alive
                        shutdown
                        no shutdown
```

Example:

```
config>service# sdp 1 mpls create
config>service>sdp# description "SDI4"
config>service>sdp# far-end 10.10.10.10
config>service>sdp# mixed-lsp-mode
config>service>sdp# exit
config>service>sdp# ldp
config>service>sdp# lsp "LSP1"
config>service>sdp# no shutdown
config>service>sdp# exit
```

The following example displays a basic SDP **mixed-lsp-mode** configuration output.

```
A:Sar18 Dut-B>config>service# info
-----
.....
      sdp 1 create
        description "SDI4"
        far-end 10.10.10.10
        mixed-lsp-mode
        exit
        ldp
        lsp "LSP1"
        keep-alive
        shutdown
        exit
        no shutdown
      exit
.....
-----
```

The following examples show the CLI syntax for a basic GRE SDP configuration.

CLI Syntax:

```
config>service>sdp sdp-id gre create
      description description-string
      far-end ip-addr
      keep-alive
      shutdown
      no shutdown
```

Example:

```
config>service# sdp 2 gre create
config>service>sdp# description "GRE-10.10.10.10"
config>service>sdp# far-end 10.10.10.10
config>service>sdp# no shutdown
config>service>sdp# exit
```

The following example displays a basic GRE SDP configuration output.

```
A:ALU-12>config>service# info
-----
.....
      sdp 2 create
        description "GRE-10.10.10.104"
        far-end 10.10.10.104
        keep-alive
        shutdown
        exit
        no shutdown
      exit
.....
-----
A:ALU-12>config>service#
```

3.14.2.1 Enabling IP Fragmentation for GRE SDPs

Use the following CLI syntax to enable fragmentation of IP packets for GRE SDPs.

CLI Syntax: `config>service>sdp sdp-id gre [create]
 allow-fragmentation`

Example: `config>service# sdp 2 gre create
config>service>sdp# allow-fragmentation`

Note: Fragmented IP packets require a reassembly profile in order to ensure that packets that cannot be reassembled are disposed of in a timely manner. See the 7705 SAR Router Configuration Guide for configuration and command information.

3.14.3 Configuring Service Names

After a service has been created, it can be assigned a service name.

Use the following CLI syntax to assign a service name to a service. The syntax example is for an Epipe.

CLI Syntax: `config>service>epipe# service-name service-name`

Example: `config>service# epipe 1 customer 1 create
config>service>epipe# service-name "Epipe_1"`

The following example displays the service name configuration output.

```
A:ALU-12>config>service>epipe# info
-----
...
      shutdown
      service-name "Epipe_1"
      sdp 2 create
          description "GRE-10.10.10.104"
          far-end 10.10.10.104
          keep-alive
              shutdown
          exit
          no shutdown
      exit
...
-----
A:ALU-12>config>service#
```

3.15 ETH-CFM (802.1ag and Y.1731) Tasks

This section provides a brief overview of the following ETH-CFM tasks:

- [Configuring ETH-CFM Parameters \(802.1ag and Y.1731\)](#)
- [Applying ETH-CFM Parameters](#)

3.15.1 Configuring ETH-CFM Parameters (802.1ag and Y.1731)

Configuration commands for both the 802.1ag and the Y.1731 functions are entered in an **eth-cfm** context (global or Epipe or VPLS service). For information on Ethernet OAM commands for 802.1ag and Y.1731 OAM, refer to the “Ethernet OAM Capabilities” section in the 7705 SAR OAM and Diagnostics Guide.

An 802.1ag MEP and a Y.1731 MEP are similar in function. Configure a MEP to be a Y.1731 MEP by choosing the **format none** keywords in the global **domain** command, and the **format icc-based** keywords in the **global association** command. Configure a MEP to be a Y.1731 MEP that can interoperate with a 802.1ag MEP by choosing the **format none** keywords in the global **domain** command, and the **format string** keywords in the **global association** command.

802.1ag Configuration

The first set of commands occurs at the global level. The second set occurs at the Epipe or VPLS service level.

```
*A:ALU-1>config>eth-cfm# info
-----
    domain 1 name "kanata_MD" level 5
      association 1 format string name "kanata_MA"
        bridge-identifier 2
        exit
        ccm-interval 60
        remote-mepid 125
      exit
    exit
-----

*A:ALU-1>config>service>epipe 2 customer 1 create
*A:ALU-1>config>service>epipe# info
-----
    shutdown
    sap 1/5/1 create
    eth-cfm
```

```

        mep 1 domain 1 association 1 direction down
        shutdown
    exit
exit
spoke-sdp 1:11 create
eth-cfm
    mep 2 domain 1 association 1 direction down
    shutdown
    exit
exit
exit
exit
-----

*A:ALU-1>config>service>vpls 2 customer 1 create
*A:ALU-1>config>service>vpls# info
-----
    shutdown
    sap 1/2/1:0 create
    eth-cfm
        mep 1 domain 1 association 1 direction down
        shutdown
        exit
    exit
exit
mesh-sdp 7:2 create
eth-cfm
    mep 2 domain 1 association 1 direction down
    shutdown
    exit
    exit
exit
exit
-----

```

Note: RDI information is carried in the CCM OAMPDU. To be able to transmit and also receive RDI information, a MEP must have CCM enabled. See [Applying ETH-CFM Parameters](#).

Y.1731 Configuration

The following example displays a Y.1731 configuration. The first set of commands occurs at the global level. The second set occurs at the Epipe or VPLS service level.

```

*A:ALU-1>config>eth-cfm# info
-----
    domain 1 format none level 1
        association 1 format icc-based name "1234567890123"
            bridge-identifier 100
            exit
            ccm-interval 1
        exit
    exit
exit
-----

```

```

*A:ALU-1>config>service>epipe# info
-----
shutdown
sap 2/2/1:40 create
  eth-cfm
    mep 1 domain 1 association 1 direction up
      ais-enable
        priority 2
        interval 60
      exit
      eth-test-enable
        test-pattern all-ones crc-enable
      exit
      no shutdown
    exit
  exit
exit
no shutdown
...
-----

*A:ALU-1>config>service>vpls# info
-----
shutdown
sap 1/2/1:0 create
  eth-cfm
    mep 1 domain 1 association 1 direction up
      ais-enable
        interval 60
        priority 2
      exit
      eth-test-enable
        test-pattern all-ones crc-enable
      exit
      no shutdown
    exit
  exit
exit
no shutdown
...
-----

```

Note: To be able to transmit and also receive AIS PDUs, a Y.1731 MEP must have **ais-enable** set. To be able to transmit and also receive ETH-Test PDUs, a Y.1731 MEP must have **eth-test-enable** set.

3.15.2 Applying ETH-CFM Parameters

Apply ETH-CFM parameters to the following entities, as shown in the CLI syntax examples below:

- Epipe SAP
- Epipe spoke SDP
- VPLS SAP
- VPLS spoke or mesh SDP
- OAM tests (loopback, linktrace, Ethernet test, delay measurement, loss measurement, synthetic loss measurement)

The MAC address for a MEP on an Epipe SAP or on an Epipe or VPLS SDP cannot be changed. For a MEP on an Epipe SAP, the MAC address is the port MAC address. For a MEP on an Epipe or VPLS SDP, the MAC address is the system MAC address. The MAC address for a MEP on a VPLS SAP can be changed; the default is the port MAC address.

The 7705 SAR supports the following MEPs:

- 802.1ag
 - SAP Up MEP
 - SAP Down MEP
 - spoke SDP Down MEP
 - mesh SDP Down MEP (VPLS only)
- Y.1731
 - SAP Up MEP
 - SAP Down MEP

The following two syntax examples are for an Epipe service. Configuration for VPLS is the same except that the **hold-mep-up-on-failure** and **dual-ended-loss-test-enable** parameters are not supported on VPLS SAPs.

The third syntax shows the OAM tests that can be applied to MEPs.

CLI Syntax:

```
config>service>epipe>sap
eth-cfm
    hold-mep-up-on-failure
    mep mep-id domain md-index association ma-index
        [direction {up | down}]
        ais-enable
        ccm-enable
        ccm-ltm-priority priority
```

```

dual-ended-loss-test-enable
eth-test-enable
low-priority-defect {allDef|macRemErrXcon|
    remErrXcon|errXcon|xcon|noXcon}
one-way-delay-threshold seconds
[no] shutdown

```

CLI Syntax: `config>service>epipe>spoke-sdp`
`eth-cfm`
`mep mep-id domain md-index association ma-index`
`[direction {up | down}]`
`ccm-enable`
`ccm-ltm-priority priority`
`low-priority-defect {allDef|macRemErrXcon|`
`remErrXcon|errXcon|xcon|noXcon}`
`[no] shutdown`

CLI Syntax: `oam`
`eth-cfm eth-test mac-address mep mep-id domain`
`md-index association ma-index [priority priority]`
`[data-length data-length]`
`eth-cfm linktrace mac-address mep mep-id domain`
`md-index association ma-index [ttl ttl-value]`
`eth-cfm loopback mac-address mep mep-id domain`
`md-index association ma-index [send-count`
`send-count] [size data-size] [priority priority]`
`eth-cfm one-way-delay-test mac-address mep mep-id`
`domain md-index association ma-index [priority`
`priority]`
`eth-cfm two-way-delay-test mac-address mep mep-id`
`domain md-index association ma-index [priority`
`priority]`
`eth-cfm single-ended-loss-test mac-address mep`
`mep-id domain md-index association ma-index`
`[priority priority] [interval interval]`
`[send-count send-count]`
`eth-cfm two-way-slm-test mac-address mep mep-id`
`domain md-index association ma-index [priority`
`priority] [send-count send-count] [size data-`
`size] [timeout timeout] [interval interval]`

3.16 Service Management Tasks

This section provides a brief overview of the following service management tasks:

- [Modifying Customer Accounts](#)
- [Deleting Customers](#)
- [Modifying SDPs](#)
- [Deleting SDPs](#)
- [Deleting LSP Associations](#)

3.16.1 Modifying Customer Accounts

Use the **show>service>customer** command to display a list of customer IDs.

To modify a customer account:

1. Access the specific account by specifying the customer ID.
2. Enter the parameter to modify (**description**, **contact**, **phone**) and then enter the new information.

CLI Syntax:

```
config>service# customer customer-id create
                        [no] contact contact-information
                        [no] description description-string
                        [no] phone phone-number
```

Example:

```
config>service# customer 27 create
config>service>customer$ description "Western Division"
config>service>customer# contact "John Dough"
config>service>customer# no phone "(650) 237-5102"
```

3.16.2 Deleting Customers

The **no** form of the **customer** command typically removes a customer ID and all associated information; however, all service references to the customer must be shut down and deleted before a customer account can be deleted.

CLI Syntax: `config>service# no customer customer-id`

Example:

```
config>service# epipe 5 customer 27 shutdown
config>service# epipe 9 customer 27 shutdown
config>service# no epipe 5
config>service# no epipe 9
config>service# no customer 27
```

3.16.3 Modifying SDPs

Use the **show>service>sdp** command to display a list of SDP IDs.

To modify an SDP:

1. Access the specific SDP by specifying the SDP ID.
2. Enter the parameter to modify, such as **description**, **far-end**, or **lsp**, and then enter the new information.

Note: Once the SDP is created, you cannot modify the SDP encapsulation type.

CLI Syntax: `config>service# sdp sdp-id`

Example:

```
config>service# sdp 79
config>service>sdp# description "Path-to-107"
config>service>sdp# shutdown
config>service>sdp# far-end "10.10.10.107"
config>service>sdp# path-mtu 1503
config>service>sdp# no shutdown
```

3.16.4 Deleting SDPs

The **no** form of the **sdp** command typically removes an SDP ID and all associated information; however, before an SDP can be deleted, the SDP must be shut down and removed (unbound) from all customer services where it is applied.

CLI Syntax: `config>service# no sdp 79`

Example: `config>service# epipe 5 spoke-sdp 79:5
config>service>epipe>spoke-sdp# shutdown
config>service>epipe>spoke-sdp# exit
config>service>epipe 5 no spoke-sdp 79:5
config>service>epipe# exit
config>service# no sdp 79`

3.16.5 Deleting LSP Associations

The **no** form of the **lsp** command removes an LSP ID and all associated information; however, before an LSP can be deleted, it must be removed from all SDP associations.

CLI Syntax: `config>service# sdp sdp-id
[no] lsp lsp-name`

Example: `config>service# sdp 79
config>service>sdp# no lsp 123
config>service>sdp# exit all`

3.17 Global Service Command Reference

3.17.1 Command Hierarchies

- [Global Service Configuration Commands](#)
 - [Customer Commands](#)
 - [SDP Commands](#)
 - [SAP Commands](#)
 - [Ethernet Ring Commands](#)
 - [ETH-CFM Commands](#)
- [Show Commands](#)

3.17.1.1 Global Service Configuration Commands

3.17.1.1.1 Customer Commands

```

config
  — service
    — customer customer-id [create]
    — no customer customer-id
      — customer contact-information
      — no customer
      — description description-string
      — no description
      — customer phone-number
      — [no] customer

```

3.17.1.1.2 SDP Commands

```

config
  — service
    — sdp sdp-id [gre | mpls | ip] [create]
    — no sdp sdp-id
      — [no] adv-mtu-override
      — [no] allow-fragmentation
      — [no] bgp-tunnel
      — description description-string
      — no description
      — encryption-keygroup keygroup-id direction {inbound | outbound}
      — no encryption-keygroup direction {inbound | outbound}
      — far-end [ip-address | ipv6-address]
      — no far-end
      — keep-alive
        — hello-time seconds
        — no hello-time
        — hold-down-time seconds
        — no hold-down-time
        — max-drop-count count
        — no max-drop-count
        — message-length octets
        — no message-length
        — [no] shutdown
        — timeout timeout
        — no timeout
      — [no] ldp
      — [no] lsp lsp-name
      — metric metric
      — no metric
      — [no] mixed-lsp-mode
        — revert-time {revert-time | infinite}

```

- **no revert-time**
- **path-mtu** *bytes*
- **no path-mtu**
- **[no] shutdown**
- **signaling** {**off** | **tldp**}
- **[no] sr-isis**
- **[no] sr-ospf**
- **[no] sr-te-lsp** *lsp-name*
- **vlan-vc-etype** *0x0600..0xffff*
- **no vlan-vc-etype** [*0x0600..0xffff*]

3.17.1.1.3 SAP Commands

- ```

config
 — service
 — apipe
 — sap sap-id [create]
 — no sap sap-id
 — cpipe
 — sap sap-id [create]
 — no sap sap-id
 — epipe
 — sap sap-id [create]
 — no sap sap-id
 — fpipe
 — sap sap-id [create]
 — no sap sap-id
 — hpipe
 — sap sap-id [create]
 — no sap sap-id
 — ipipe
 — sap sap-id [create]
 — no sap sap-id
 — ies
 — interface ip-int-name [create]
 — sap sap-id [create]
 — no sap sap-id
 — vpn
 — interface ip-int-name [create]
 — sap sap-id [create]
 — no sap sap-id
 — vpls
 — sap sap-id [create]
 — no sap sap-id
 — system
 — ethernet
 — [no] new-qinq-untagged-sap

```

### 3.17.1.1.4 Ethernet Ring Commands

```

config
— [no] eth-ring ring-index
 — ccm-hold-time [down down-timeout] [up up-timeout]
 — no ccm-hold-time
 — compatible-version version
 — no compatible-version
 — description description-string
 — no description
 — guard-time time
 — no guard-time
 — node-id xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx
 — no node-id
 — path {a | b} [{port-id | lag-id | mw-link-id} raps-tag qtag1 [qtag2]]
 — no path {a | b}
 — description description-string
 — no description
 — eth-cfm
 — [no] mep mep-id domain md-index association ma-index
 — [no] ccm-enable
 — ccm-ltm-priority priority
 — no ccm-ltm-priority
 — [no] control-mep
 — description description-string
 — no description
 — no eth-test-enable
 — bit-error-threshold bit-errors
 — test-pattern {all-zeros | all-ones} [crc-enable]
 — no test-pattern
 — low-priority-defect {allDef | macRemErrXcon | remErrXcon | errXcon | xcon | noXcon}
 — one-way-delay-threshold seconds
 — [no] shutdown
 — [no] rpl-end
 — [no] shutdown
 — revert-time time
 — no revert-time
 — rpl-node {owner | nbr}
 — no rpl-node
 — [no] shutdown
 — [no] sub-ring {virtual-link | non-virtual-link}
 — interconnect ring-id ring-index
 — interconnect vpls
 — [no] interconnect
 — [no] propagate-topology-change

```

### 3.17.1.1.5 ETH-CFM Commands

```

config
 — eth-cfm
 — domain md-index [format {dns | mac | none | string}] name md-name level level
 — domain md-index
 — no domain md-index
 — association ma-index [format {icc-based | integer | string | vid | vpn-id}]
 name ma-name
 — association ma-index
 — no association ma-index
 — [no] bridge-identifier bridge-id
 — vlan vlan-id
 — no vlan
 — ccm-interval {10ms | 100ms | 1 | 10 | 60 | 600}
 — no ccm-interval
 — [no] remote-mepid mep-id
 — slm
 — inactivity-timer timeout
 — no inactivity-timer

```

**Note:** For information on configuring ETH-CFM commands, refer to the 7705 SAR OAM and Diagnostics Guide.

### 3.17.1.2 Show Commands

```

show
 — eth-ring [status]
 — eth-ring [ring-index] hierarchy
 — eth-ring ring-index [path {a | b}]
 — service
 — customer customer-id

#### description

|                    |                                                                                                                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>description</b> <i>description-string</i><br><b>no description</b>                                                                                                                                                                                                                         |
| <b>Context</b>     | config>service>customer<br>config>service>sdp<br>config>eth-ring<br>config>eth-ring>path<br>config>eth-ring>path>eth-cfm>mep                                                                                                                                                                  |
| <b>Description</b> | This command creates a text description stored in the configuration file for a configuration context.<br><br>The <b>no</b> form of this command removes the string from the context.                                                                                                          |
| <b>Default</b>     | No description is associated with the configuration context.                                                                                                                                                                                                                                  |
| <b>Parameters</b>  | <i>description-string</i> — the description character string. Allowed values are any string up to 80 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes. |

#### shutdown

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] shutdown</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Context</b>     | config>service>sdp<br>config>service>sdp>keep-alive                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b> | The <b>shutdown</b> command administratively disables an entity. The operational state of the entity is disabled as well as the operational state of any entities contained within. When disabled, an entity does not change, reset, or remove any configuration settings or statistics. Many objects must be shut down before they may be deleted. Many entities must be explicitly enabled using the <b>no shutdown</b> command.<br><br>The <b>no</b> form of this command places the entity into an administratively enabled state.<br><br>Services are created in the administratively down state ( <b>shutdown</b> ). When a <b>no shutdown</b> command is entered, the service becomes administratively up and then tries to enter the operationally up state. Default administrative states for services and service entities are described in the following Special Cases. |

- 
- Special Cases**
- Service Admin State** — bindings to an SDP within the service will be put into the out-of-service state when the service is shut down. While the service is shut down, all customer packets are dropped and counted as discards for billing and debugging purposes.
  - SDP (global)** — when an SDP is shut down at the global service level, all bindings to that SDP are put into the out-of-service state and the SDP itself is put into the administratively and operationally down states. Packets that would normally be transmitted using this SDP binding will be discarded and counted as dropped packets.
  - SDP (service level)** — shutting down an SDP within a service only affects traffic on that service from entering or being received from the SDP. The SDP itself may still be operationally up for other services.
  - SDP Keepalives** — enables SDP connectivity monitoring keepalive messages for the SDP ID. Default state is disabled (shutdown), in which case the operational state of the SDP-ID is not affected by the keepalive message state.

## new-qinq-untagged-sap

- Syntax** `[no] new-qinq-untagged-sap`
- Context** `config>system>ethernet`
- Description**

This command controls the behavior of qinq SAP y.0 (for example, 1/1/1:3000.0). If this command is enabled, the y.0 SAP maps all ingress frames tagged with outer tag VLAN ID of y (qinq Ethertype) and no inner tag, or with an inner tag VLAN ID of zero (0). This behavior applies to all existing and future y.0 SAPs.

The **no** form of this command disables qinq untagged SAP, and the y.0 SAP will work like a y.\* SAP (for example, 1/1/1:3000.\*); all frames tagged with outer VLAN y and no inner VLANs, or inner VLAN x, where inner VLAN x is not specified in a SAP y.x configured on the same port (for example, 1/1/1:3000.10).
- Default** `no new-qinq-untagged-sap`. This setting ensures that there will be no disruption for existing usage of this SAP type.

### 3.17.2.1.2 Customer Commands

#### customer

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>customer</b> <i>customer-id</i> [ <b>create</b> ]<br><b>no customer</b> <i>customer-id</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Context</b>     | config>service                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | <p>This command creates a customer ID and customer context used to associate information with a particular customer. Services can later be associated with this customer at the service level.</p> <p>Each <i>customer-id</i> must be unique and the <b>create</b> keyword must follow each new <b>customer</b> <i>customer-id</i> entry.</p> <p>To edit a customer's parameters, enter the existing <b>customer</b> <i>customer-id</i> without the <b>create</b> keyword.</p> <p>Default <b>customer 1</b> always exists on the system and cannot be deleted.</p> <p>The <b>no</b> form of this command removes a <i>customer-id</i> and all associated information. Before removing a <i>customer-id</i>, all references to that customer in all services must be deleted or changed to a different customer ID.</p> |
| <b>Parameters</b>  | <p><i>customer-id</i> — specifies the ID number to be associated with the customer, expressed as an integer</p> <p><b>Values</b> 1 to 2147483647</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Description</b> | <p>This command allows you to configure contact information for a customer. Include any customer-related contact information such as a technician's name or account contract name.</p> <p>The <b>no</b> form of this command removes the contact information from the customer ID.</p>                                              |
| <b>Default</b>     | No contact information is associated with the <i>customer-id</i> .                                                                                                                                                                                                                                                                  |
| <b>Parameters</b>  | <i>contact-information</i> — the customer contact information entered as an ASCII character string. Allowed values are any string up to 80 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes. |

| <b>Description</b> | <p>This command creates or edits an SDP. SDPs must be explicitly configured.</p> <p>An SDP is a (logical) service entity that is created on the local router. An SDP identifies the endpoint of a logical, unidirectional service tunnel. Traffic enters the tunnel at the SDP on the local router and exits the tunnel at the remote router. Thus, it is not necessary to specifically define far-end SAPs.</p> <p>The 7705 SAR supports generic routing encapsulation (GRE) tunnels, multiprotocol label switching (MPLS) tunnels, and IP tunnels.</p> <p>For MPLS, the 7705 SAR supports both signaled and non-signaled label switched paths (LSPs) through the network. Non-signaled paths are defined at each hop through the network. Signaled LSPs are established in LDP-DU (downstream unsolicited) mode. Segment routing (SR) is another MPLS tunnel type and is used to allow service binding to an SR tunnel programmed in the tunnel table manager (TTM) by OSPF or IS-IS. An SDP of type <b>sr-isis</b> or <b>sr-ospf</b> can be used with the far-end option.</p> <p>SDPs are created and then bound to services. Many services may be bound to a single SDP. The operational and administrative state of the SDP controls the state of the SDP binding to the service.</p> <p>If <i>sdp-id</i> does not exist, a new SDP is created. SDPs are created in the admin down state (<b>shutdown</b>). Once all relevant parameters are defined, the <b>no shutdown</b> command must be executed before the SDP can be used.</p> <p>If <i>sdp-id</i> exists, the current CLI context is changed to that SDP for editing and modification. If editing an existing SDP, the <b>gre</b>, <b>mpls</b>, or <b>ip</b> keyword is not specified. If a keyword is specified for an existing <i>sdp-id</i>, an error is generated and the context of the CLI is not changed to the specified <i>sdp-id</i>.</p> <p>The <b>no</b> form of this command deletes the specified SDP. Before an SDP can be deleted, it must be administratively down (<b>shutdown</b>) and not bound to any services. If the specified SDP is bound to a service, the <b>no sdp</b> command fails, generating an error message specifying the first bound service found during the deletion process. If the specified <i>sdp-id</i> does not exist, an error is generated.</p> |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

**gre** — specifies that the SDP will use GRE encapsulation tunnels. Only one GRE SDP is supported to a given destination 7705 SAR or 7710/7750 SR.

**mpls** — specifies that the SDP will use MPLS encapsulation and one or more LSP tunnels to reach the far-end 7705 SAR or 7710/7750 SR. Multiple MPLS SDPs are supported to a given destination service router. Multiple MPLS SDPs to a single destination service router are helpful when they use divergent paths.

**ip** — specifies that the SDP will use IP encapsulation tunnels. Only one IP SDP is supported to a given destination 7705 SAR because the SDP is tied to the system address of the destination LER.

| <b>Context</b>     | config>service>sdp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | <p>This command enables GRE-encapsulated packets transmitted from the SDP to be fragmented if their size exceeds the configured network port MTU.</p> <p>When <b>allow-fragmentation</b> is enabled, GRE-encapsulated packets that are larger than the network port MTU are fragmented and the DF bit is set to 0 by the router. Packets that are smaller than the port MTU are left unfragmented, the DF bit is set to 1 by the router, and the identification number of the packet is set to 0.</p> |

**Note:** The **allow-fragmentation** command cannot be enabled for an SDP that has NGE (**encryption-keygroup**) enabled. Attempting to enable both commands will result in an error message.

The **no** form of the command disables fragmentation of oversize GRE-encapsulated packets transmitted from the SDP.

---

**Default** no allow-fragmentation

## bgp-tunnel

**Syntax** [no] bgp-tunnel

**Context** config>service>sdp

**Description** This command allows the use of BGP route tunnels available in the tunnel table to reach SDP far-end nodes. BGP route tunnels are only available with MPLS SDPs. Only one transport method is allowed per SDP: LDP, RSVP-LSP, BGP-tunnel, SR-ISIS, SR-OSPF, or SR-TE-LSP. This restriction is relaxed for some combinations of the transport methods when the mixed-LSP mode option is enabled on the SDP.

The **no** form of the command disables the use of BGP route tunnels for the SDP far end.

**Default** no bgp-tunnel

## encryption-keygroup

**Syntax** encryption-keygroup *keygroup-id* direction {inbound | outbound}  
no encryption-keygroup direction {inbound | outbound}

**Context** config>service>sdp

**Description** This command is used to bind a key group to an SDP for inbound or outbound packet processing. When configured in the outbound direction, packets egressing the node use the **active-outbound-sa** associated with the key group configured. When configured in the inbound direction, received packets must be encrypted using one of the valid security associations configured for the key group. Services using the SDP will be encrypted.

Encryption is enabled once the outbound direction is configured.

The **no** form of the command removes the key group from the SDP in the specified direction (inbound or outbound).

**Default** n/a

**Parameters** *keygroup-id* — the number of the key group being configured

**Values** 1 to 15 or *keygroup-name* (up to 64 characters)

**direction {inbound | outbound}** — mandatory keywords when binding a key group to a service for a particular direction

far-end

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                     |  |

| <b>Description</b> | <p>This command configures the system IP address of the far-end destination 7705 SAR, 7710 SR, 7750 SR, or other router ID platform for the SDP that is the termination point for a service.</p> <p>The far-end IP address must be explicitly configured. The destination IP address must be a 7705 SAR, 7710 SR, 7750 SR, or other router ID platform system IP address.</p> <p>If the SDP uses GRE or IP for the destination encapsulation, the local 7705 SAR might not know that the <i>ip-address</i> is actually a system IP interface address on the far-end service router.</p> <p>If the SDP uses MPLS encapsulation, the <b>far-end</b> <i>ip-address</i> is used to check LSP names when added to the SDP. If the “to IP address” defined within the LSP configuration does not exactly match the SDP <b>far-end</b> <i>ip-address</i>, the LSP will not be added to the SDP and an error message will be generated.</p> <p>An SDP cannot be administratively enabled until a <b>far-end</b> <i>ip-address</i> is defined. The SDP is operational when it is administratively enabled (<b>no shutdown</b>).</p> <p>The <b>no</b> form of this command removes the currently configured destination IP address for the SDP. The <i>ip-address</i> and <i>ipv6-address</i> parameters are not specified and will generate an error message if used in the <b>no far-end</b> command. The SDP must be administratively disabled using the <b>config&gt;service&gt;sdp&gt;shutdown</b> command before the <b>no far-end</b> command can be executed. Removing the far-end IP address will cause all <i>lsp-name</i> associations with the SDP to be removed.</p> |                                     |  |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                     |  |
| <b>Parameters</b>  | <i>ip-address</i> — the IPv4 address of the far-end destination router for the SDP                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                     |  |

| <b>Description</b> | <p>This command enables LDP-signaled LSPs on MPLS-encapsulated SDPs.</p> <p>In MPLS SDP configurations, up to eight RSVP-TE LSPs can be specified or LDP can be enabled. The SDP <b>ldp</b> and <b>lsp</b> commands are mutually exclusive unless mixed-LSP SDP is enabled with the <a href="#">mixed-lsp-mode</a> command.</p> <p>If mixed-LSP SDP is not enabled and an LSP is specified on an MPLS SDP, LDP cannot be enabled on the SDP. To enable LDP on the SDP when an LSP is already specified, the LSP must be removed from the configuration using the <b>no lsp lsp-name</b> command.</p> |

| <b>Context</b>     | config>service>sdp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | <p>This command creates an association between an LSP and an MPLS SDP. This command is implemented only on MPLS-encapsulated SDPs. Up to eight RSVP-TE LSPs can be associated with a single SDP. The LSPs must have already been created in the <b>config&gt;router&gt;mpls</b> context with a valid far-end IP address. Refer to the 7705 SAR MPLS Guide for CLI syntax and command usage.</p> <p>In MPLS SDP configurations, LSPs can be specified or LDP can be enabled. The SDP <b>ldp</b> and <b>lsp</b> commands are mutually exclusive unless mixed-LSP SDP is enabled with the <a href="#">mixed-lsp-mode</a> command.</p> <p>If mixed-LSP SDP is not enabled and LDP is already enabled on an MPLS SDP, an LSP cannot be specified on the SDP. To specify an LSP on the SDP, LDP must be disabled.</p> <p>If no LSP is associated with an MPLS SDP, the SDP cannot enter the operationally up state. The SDP can be administratively enabled (<b>no shutdown</b>) with no LSP associations. The <i>lsp-name</i> can be shut down, causing the association with the SDP to be operationally down (the LSP will not be used by the SDP).</p> <p>LSP SDPs also require that the T-LDP signaling be specified and that the SDP keepalive parameter be enabled and not timed out.</p> <p>The <b>no</b> form of this command deletes an LSP association from an SDP. If the <i>lsp-name</i> does not exist as an association or as a configured LSP, no error is returned. An <i>lsp-name</i> must be removed from all SDP associations before the <i>lsp-name</i> can be deleted from the system. The SDP must be administratively disabled (<b>shutdown</b>) before the last <i>lsp-name</i> association with the SDP is deleted.</p> |

| <b>Context</b>     | config>service>sdp                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b> | This command enables the mixed-LSP mode of operation on an SDP, which allows a primary LSP type and a backup LSP type in the same SDP configuration. For example, RSVP-TE LSPs and LDP LSPs can be configured on an SDP with the <b>lsp</b> and <b>ldp</b> commands. If mixed-LSP mode is not enabled, these commands are mutually exclusive. |

Two combinations of mixed LSPs are possible:

- an RSVP-TE primary LSP backed up by an LDP LSP
- an LDP primary LSP backed up by a BGP LSP

**Note:** Mixed-LSP SDPs do not support static LSPs on either the primary or backup.

The **no** form of this command disables mixed-LSP; however you must remove one of the LSP types from the SDP configuration first or the command will fail.

| <b>Context</b>     | config>service>sdp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Description</b> | <p>This command specifies the signaling protocol used to obtain the ingress and egress labels in frames transmitted and received on the SDP. When signaling is <b>off</b>, then labels are manually configured when the SDP is bound to a service. The signaling value can only be changed while the administrative status of the SDP is down.</p> <p>The <b>no</b> form of this command is not applicable. To modify the signaling configuration, the SDP must be administratively shut down and then the signaling parameter can be modified and re-enabled.</p> |
| <b>Default</b>     | tldp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <p><b>off</b> — ingress and egress signal auto-labeling is not enabled. If this parameter is selected, then each service using the specified SDP must manually configure VPN labels. This configuration is independent of the SDP transport type, MPLS (LDP).</p> <p><b>tldp</b> — ingress and egress signaling auto-labeling is enabled</p>                                                                                                                                                                                                                       |

| <b>Context</b>     | config>service>sdp                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b> | <p>This command configures the VLAN VC Ethertype. The <b>no</b> form of this command returns the value to the default. The etype value populates the Ethertype field in the Ethernet frame. It is used to indicate which protocol is being transported in the Ethernet frame. The default value indicates that the payload is an IEEE 802.1q-tagged frame.</p> |
| <b>Default</b>     | no vlan-vc-etype ( <i>0x8100</i> )                                                                                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <i>0x0600..0xffff</i> — specifies a valid VLAN etype identifier                                                                                                                                                                                                                                                                                                |

### 3.17.2.1.4 SDP Keepalive Commands

#### keep-alive

|                    |                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>keep-alive</b>                                                                                          |
| <b>Context</b>     | config>service>sdp                                                                                         |
| <b>Description</b> | This command is the context for configuring SDP connectivity monitoring keepalive messages for the SDP-ID. |

SDP-ID keepalive messages use SDP Echo Request and Reply messages to monitor SDP connectivity. The operating state of the SDP is affected by the keepalive state on the SDP-ID. SDP Echo Request messages are only sent when the SDP-ID is completely configured and administratively up. If the SDP-ID is administratively down, keepalives for that SDP-ID are disabled. SDP Echo Requests, when sent for keepalive messages, are always sent with the *originator-sdp-id*. All SDP-ID keepalive SDP Echo Replies are sent using generic IP OAM encapsulation.

When a keepalive response is received that indicates an error condition, the SDP ID will immediately be brought operationally down. Once a response is received that indicates the error has cleared and the **hold-down-time** interval has expired, the SDP ID will be eligible to be put into the operationally up state. If no other condition prevents the operational change, the SDP ID will enter the operational state.

A set of event counters track the number of keepalive requests sent, the size of the message sent, non-error replies received and error replies received. A keepalive state value is kept, indicating the last response event. A keepalive state timestamp value is kept, indicating the time of the last event. With each keepalive event change, a log message is generated, indicating the event type and the timestamp value.

[Table 13](#) describes keepalive interpretation of SDP Echo Reply response conditions and the effect on the SDP ID operational status.

**Table 13 SDP Echo Reply Response Conditions**

| Result of Request                                                              | Stored Response State          | Operational State |
|--------------------------------------------------------------------------------|--------------------------------|-------------------|
| keepalive request timeout without reply                                        | Request Timeout                | Down              |
| keepalive request not sent due to non-existent <i>orig-sdp-id</i> <sup>1</sup> | Orig-SDP Non-Existent          | Down              |
| keepalive request not sent due to administratively down <i>orig-sdp-id</i>     | Orig-SDP Admin-Down            | Down              |
| keepalive reply received, invalid origination-id                               | Far End: Originator-ID Invalid | Down              |

**Table 13** SDP Echo Reply Response Conditions (Continued)

| Result of Request                              | Stored Response State       | Operational State                   |
|------------------------------------------------|-----------------------------|-------------------------------------|
| keepalive reply received, invalid responder-id | Far End: Responder-ID Error | Down                                |
| keepalive reply received, No Error             | Success                     | Up (if no other condition prevents) |

**Note:**

1. This condition should not occur.

## hello-time

|                    |                                                                                                                                                                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>hello-time</b> <i>seconds</i><br><b>no hello-time</b>                                                                                                                                                                                               |
| <b>Context</b>     | config>service>sdp>keep-alive                                                                                                                                                                                                                          |
| <b>Description</b> | This command configures the time period between SDP keepalive messages on the SDP-ID for the SDP connectivity monitoring messages.<br><br>The <b>no</b> form of this command resets the <b>hello-time</b> <i>seconds</i> value to the default setting. |
| <b>Parameters</b>  | <i>seconds</i> — the time period in seconds between SDP keepalive messages, expressed as a decimal integer<br><br><b>Values</b> 1 to 3600<br><b>Default</b> 10                                                                                         |

## hold-down-time

|                    |                                                                                                                                                                                                                                                                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>hold-down-time</b> <i>seconds</i><br><b>no hold-down-time</b>                                                                                                                                                                                                                                                                                     |
| <b>Context</b>     | config>service>sdp>keep-alive                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | This command configures the minimum time period the SDP will remain in the operationally down state in response to SDP keepalive monitoring.<br><br>This parameter can be used to prevent the SDP operational state from “flapping” by rapidly transitioning between the operationally up and operationally down states based on keepalive messages. |

When an SDP keepalive response is received that indicates an error condition or the **max-drop-count** keepalive messages receive no reply, the *sdp-id* will immediately be brought operationally down. If a keepalive response is received that indicates the error has cleared, the *sdp-id* will be eligible to be put into the operationally up state only after the **hold-down-time** interval has expired.

The **no** form of this command resets the **hold-down-time** *seconds* value to the default setting.

|                   |                                                                                                                                                                                                                                                                                                                       |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>seconds</i> — the time in seconds, expressed as a decimal integer, the <i>sdp-id</i> will remain in the operationally down state after an SDP keepalive error before it is eligible to enter the operationally up state. A value of 0 indicates that no <b>hold-down-time</b> will be enforced for <i>sdp-id</i> . |
| <b>Values</b>     | 0 to 3600                                                                                                                                                                                                                                                                                                             |
| <b>Default</b>    | 10                                                                                                                                                                                                                                                                                                                    |

## max-drop-count

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>max-drop-count</b> <i>count</i><br><b>no max-drop-count</b>                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Context</b>     | config>service>sdp>keep-alive                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b> | <p>This command configures the number of consecutive SDP keepalive failed request attempts or remote replies that can be missed after which the SDP is operationally downed.</p> <p>If the <b>max-drop-count</b> consecutive keepalive request messages cannot be sent or no replies are received, the SDP-ID will be brought operationally down by the keepalive SDP monitoring.</p> <p>The <b>no</b> form of this command resets the <b>max-drop-count</b> <i>count</i> value to the default settings.</p> |
| <b>Parameters</b>  | <p><i>count</i> — the number of consecutive SDP keepalive requests that can fail to be sent or replies missed before the SDP is brought down, expressed as a decimal integer</p> <p><b>Values</b> 1 to 5</p> <p><b>Default</b> 3</p>                                                                                                                                                                                                                                                                         |

## message-length

|                    |                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>message-length</b> <i>octets</i><br><b>no message-length</b>                                       |
| <b>Context</b>     | config>service>sdp>keep-alive                                                                         |
| <b>Description</b> | This command configures the size of SDP monitoring keepalive request messages transmitted on the SDP. |

The **no** form of this command resets the **message-length** *octets* value to the default setting.

**Parameters**    *octets* — the size of keepalive request messages in octets, expressed as a decimal integer. The **size** keyword overrides the default keepalive message size.  
The message length should be equal to the SDP operating path MTU as configured in the [path-mtu](#) command.  
If the default size is overridden, the actual size used will be the smaller of the operational SDP-ID path MTU and the size specified.

**Values**        72 to 1500

**Default**       0

timeout

**Syntax**        **timeout** *timeout*  
                 **no timeout**

**Context**       config>service>sdp>keep-alive

**Description**   This command configures the time interval that the SDP waits before tearing down the session.

**Parameters**    *timeout* — the timeout in seconds, expressed as a decimal integer

**Values**        1 to 10

**Default**       5

---

### 3.17.2.1.5 Ethernet Ring Commands

#### eth-ring

|                    |                                                                                                                                                                                                                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] eth-ring</b> <i>ring-index</i>                                                                                                                                                                                                                                                                 |
| <b>Context</b>     | config                                                                                                                                                                                                                                                                                                 |
| <b>Description</b> | <p>This command configures a G.8032 Ethernet ring. Ethernet rings may be configured as major rings with two paths (A and B), as sub-rings with two paths, or in the case of an interconnection node, a single path.</p> <p>The <b>no</b> form of this command deletes the specified Ethernet ring.</p> |
| <b>Default</b>     | no eth-ring                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <i>ring-index</i> — specifies the Ethernet ring ID                                                                                                                                                                                                                                                     |
| <b>Values</b>      | 1 to 128                                                                                                                                                                                                                                                                                               |

#### ccm-hold-time

|                    |                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ccm-hold-time</b> [ <b>down</b> <i>down-timeout</i> ] [ <b>up</b> <i>up-timeout</i> ]<br><b>no ccm-hold-time</b>                                        |
| <b>Context</b>     | config>eth-ring                                                                                                                                            |
| <b>Description</b> | <p>This command configures Ethernet ring dampening timers.</p> <p>The <b>no</b> form of the command sets the up and down timers to the default values.</p> |
| <b>Default</b>     | down 0<br>up 20                                                                                                                                            |
| <b>Parameters</b>  | <i>down-timeout</i> — specifies the down timeout, in centiseconds                                                                                          |
| <b>Values</b>      | 0 to 5000                                                                                                                                                  |
| <b>Default</b>     | 0                                                                                                                                                          |
|                    | <i>up-timeout</i> — specifies the hold-time for reporting the recovery, in deciseconds                                                                     |
| <b>Values</b>      | 0 to 5000                                                                                                                                                  |
| <b>Default</b>     | 20                                                                                                                                                         |

---

## compatible-version

|                    |                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>compatible-version</b> <i>version</i><br><b>no compatible-version</b>                                                                                                                                                                                                                                                                                                      |
| <b>Context</b>     | config>eth-ring                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | <p>This command configures Ethernet ring compatibility version for the G.8032 state machine and messages. The default is version 2 and all router switches use version 2. The version can be changed if there is a need to interwork with third party devices that only support version 1.</p> <p>The <b>no</b> form of this command sets the compatibility version to 2.</p> |
| <b>Default</b>     | 2                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <i>version</i> — specifies the version of the G.8032 state machine                                                                                                                                                                                                                                                                                                            |
| <b>Values</b>      | 1 or 2                                                                                                                                                                                                                                                                                                                                                                        |

## guard-time

|                    |                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>guard-time</b> <i>time</i><br><b>no guard-time</b>                                                                                          |
| <b>Context</b>     | config>eth-ring                                                                                                                                |
| <b>Description</b> | <p>This command configures the guard time for an Ethernet ring.</p> <p>The <b>no</b> form of this command restores the default guard time.</p> |
| <b>Default</b>     | 5                                                                                                                                              |
| <b>Parameters</b>  | <i>value</i> — specifies the guard time, in deciseconds                                                                                        |
| <b>Values</b>      | 1 to 20                                                                                                                                        |
| <b>Default</b>     | 5                                                                                                                                              |

## node-id

|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>node-id</b> <i>xx:xx:xx:xx:xx:xx</i> or <i>xx-xx-xx-xx-xx-xx</i><br><b>no node-id</b>                                                                                                                                     |
| <b>Context</b>     | config>eth-ring                                                                                                                                                                                                              |
| <b>Description</b> | This optional command configures the MAC address of the RPL link. The default is to use the chassis MAC address for the ring control. This command allows the chassis MAC address to be overridden with another MAC address. |

The **no** form of the command removes the RPL link.

|                   |                                                                                  |
|-------------------|----------------------------------------------------------------------------------|
| <b>Default</b>    | no node-id                                                                       |

| <b>Description</b> | <p>This command enables Ethernet test functionality on the MEP. For the test to work, operators need to configure Ethernet test parameters on both the sender and receiver nodes. The Ethernet test can be performed using the <b>oam&gt;eth-cfm&gt;eth-test</b> command.</p> <p>A check is done for both the provisioning and the test to ensure the MEP is a Y.1731 MEP, provisioned with domain format <b>none</b> and associated with format <b>icc-based</b>. If they are not, the command fails and an error message is generated in the CLI and SNMP indicating the problem.</p> |
| <b>Default</b>     | no eth-test-enable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Context</b>     | config>eth-ring>path                                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | <p>This command configures the G.8032 path as a ring protection link (RPL) end. The ring must be declared as either an RPL owner or an RPL neighbor in order for this command to be valid. Only a path configured as A or B can be configured as an RPL end.</p> <p>The <b>no</b> form of this command reverts to the default.</p> |
| <b>Default</b>     | no rpl-end                                                                                                                                                                                                                                                                                                                         |

## revert-time

|                    |                                                                                                                                                                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>revert-time <i>time</i></b><br><b>no revert-time</b>                                                                                                                                                                                                                 |
| <b>Context</b>     | config>eth-ring                                                                                                                                                                                                                                                         |
| <b>Description</b> | <p>This command configures the revert time for an Ethernet ring. It ranges from 60 s to 720 s.</p> <p>The <b>no</b> form of this command means that the Ethernet ring is in non-revertive mode and the revert time is essentially 0. The revert timers are not set.</p> |
| <b>Default</b>     | 300                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <i>time</i> — specifies the revert time, in seconds                                                                                                                                                                                                                     |
| <b>Values</b>      | 60 to 720                                                                                                                                                                                                                                                               |

## rpl-node

|                |                                                     |
|----------------|-----------------------------------------------------|
| <b>Syntax</b>  | <b>rpl-node {owner   nbr}</b><br><b>no rpl-node</b> |
| <b>Context</b> | config>eth-ring                                     |

**Description** This command configures the G.8032 ring protection link type as either owner or neighbor. The **no** form of the command means this node is not connected to an RPL link. When an RPL owner or neighbor is specified, either the A or B path must be configured with the [rpl-end](#) command. An owner is responsible for operation of the RPL link. The link can be left with no RPL type configured, but if this command is used the **nbr** parameter is mandatory.

On a sub-ring without a virtual channel, it is mandatory to configure a sub-ring non-virtual-link on all nodes on the sub-ring to propagate the RAPS messages around the sub-ring.

The **no** form of this command removes the RPL link.

**Default** no rpl-node

## sub-ring

**Syntax** **[no] sub-ring {virtual-link | non-virtual-link}**

**Context** config>eth-ring

**Description** This command defines an Ethernet ring as a sub-ring as defined in G.8032. A sub-ring can have only one valid path connecting it to a major ring or to a VPLS instance. The **virtual-link** parameter indicates that a sub-ring is connected to another ring and that control messages can be sent over the attached ring to the other side of the sub-ring. The **non-virtual-link** channel parameter indicates that a sub-ring may be connected to a another ring or to a VPLS instance but that control messages from the sub-ring can not use the attached ring or VPLS instance. The non-virtual channel behavior is standard G.8032 capability.

The **no** form of this command deletes the sub-ring and its virtual channel associations.

**Default** no sub-ring

**Parameters** **virtual-link** — specifies that the interconnection is to a ring and a virtual link will be used  
**non-virtual-link** — specifies that the interconnection is to a ring or a VPLS instance and a virtual link will not be used

## interconnect

**Syntax** **interconnect ring-id** *ring-index*  
**interconnect vpls**  
**no interconnect**

**Context** config>eth-ring>sub-ring

---

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command links the G.8032 sub-ring to a ring instance or to a VPLS instance. The ring instance must be a complete ring with two paths but may itself be a sub-ring or a major ring, as declared by its configuration on another node. When the interconnection is to another node, the sub-ring may have a virtual link or a non-virtual-link. When the sub-ring has been configured with a non-virtual link, the sub-ring may be alternatively be connected to a VPLS service. This command is only valid on the interconnection node where a single sub-ring port connects to a major ring or terminates on a VPLS service.</p> <p>The <b>no</b> form of this command removes the interconnect node.</p> |
| <b>Default</b>     | no interconnect                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <p><i>ring-index</i> — specifies the identifier for the ring instance of the connection ring for this sub-ring on this node</p> <p><b>Values</b>      0 to 128</p> <p><b>vpls</b> — specifies that the sub-ring is connected to the VPLS instance that contains the sub-ring SAP</p>                                                                                                                                                                                                                                                                                                                                                                                                                              |

## propagate-topology-change

**Table 14 Ethernet Ring Command Field Descriptions**

| Label       | Description                                                                                                                 |
|-------------|-----------------------------------------------------------------------------------------------------------------------------|
| Ring ID     | Displays the Ethernet ring ID number                                                                                        |
| Admin State | Up – the Ethernet ring or path is administratively enabled<br>Down – the Ethernet ring or path is administratively disabled |
| Oper State  | Up – the Ethernet ring or path is operationally enabled<br>Down – the Ethernet ring or path is operationally disabled       |
| Path        | Displays the configured Ethernet ring path                                                                                  |

**Table 14 Ethernet Ring Command Field Descriptions (Continued)**

| Label            | Description                                                                  |
|------------------|------------------------------------------------------------------------------|
| Tag              | Displays the APS tag                                                         |
| Ctrl-MEP         | Indicates whether the MEP is configured as a control MEP                     |
| CC-Intvl         | Displays the configured CCM interval value                                   |
| Defects          | Displays any Ethernet tunnel MEP defects                                     |
| Int ID           | Displays the interface ID                                                    |
| Path States      | Displays the state of Ethernet ring paths<br>B – Blocked<br>U – Unblocked    |
| Description      | Displays the Ethernet ring path description                                  |
| Fwd State        | Displays the forwarding state of the path                                    |
| Fwd State Change | Displays the date and time of the last change to the path's forwarding state |

## customer

**Syntax** **customer** *customer-id*

**Context** show>service

**Description** This command displays service customer information.

**Parameters** *customer-id* — displays only information for the specified customer ID

**Values** 1 to 2147483647

**Default** all customer IDs display

**Output** The following output is an example of customer information, and [Table 15](#) describes the fields.

### Output Example

```
*A:ALU-12# show service customer
=====
Customers
=====
Customer-ID : 1
Contact : Manager
Description : Default customer
Phone : (123) 555-1212
```

**Table 15 Customer Command Field Descriptions**

| Label           | Description                                                                     |
|-----------------|---------------------------------------------------------------------------------|
| Customer-ID     | Displays the unique customer identification number                              |
| Contact         | Displays the name of the primary contact person                                 |
| Description     | Displays generic information about the customer                                 |
| Phone           | Displays the telephone or pager number used to reach the primary contact person |
| Total Customers | Displays the total number of customers configured                               |

## sdp

**Syntax** **sdp** *sdp-id* **keep-alive-history**  
**sdp** [*sdp-id*] [**detail**]  
**sdp far-end** *ip-addr* **keep-alive-history**  
**sdp far-end** *ip-addr* [**detail**]

**Context** show>service

**Description** This command displays SDP information.

If no optional parameters are specified, a summary SDP output for all SDPs is displayed.

**Parameters** *sdp-id* — the SDP ID for which to display information

**Values** 1 to 17407

**Default** all SDPs

*ip-address* — displays only SDPs matching with the specified far-end IP address

**Default** SDPs with any far-end IP address

**detail** — displays detailed SDP information

**keep-alive-history** — displays the last fifty SDP keepalive events for the SDP

**Output** The following output is an example of service SDP information, and [Table 16](#) describes the fields.

### Output Example

```
*A:Sar18 Dut-B>show>service# sdp

**Table 16** Service SDP Field Descriptions

| Label                  | Description                                                                                                                 |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| SDP Id                 | Identifies the SDP                                                                                                          |
| Description            | Identifies the SDP by the text description stored in its configuration file                                                 |
| SDP Source             | Specifies the SDP source type                                                                                               |
| Adm MTU (Adm Path MTU) | Specifies the desired largest service frame size (in octets) that can be transmitted through this SDP to the far-end router |
| Opr MTU (Opr Path MTU) | Specifies the actual largest service frame size (in octets) that can be transmitted through this SDP to the far-end router  |

**Table 16 Service SDP Field Descriptions (Continued)**

| Label                              | Description                                                                                                                                         |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| Delivery                           | Specifies the delivery routing protocol                                                                                                             |
| Far End                            | Specifies the IP address of the remote end of the GRE or MPLS tunnel defined by this SDP                                                            |
| Tunnel Far End                     | On the 7705 SAR, tunnel far end is the same as the SDP far end and is not configurable                                                              |
| LSP Types                          | Specifies the supported LSP types: R = RSVP, L = LDP, B = BGP, I = SR-ISIS, O = SR-OSPF, T = SR-TE, and n/a = Not Applicable                        |
| Adm (Admin State)                  | Specifies the desired state of the SDP                                                                                                              |
| Opr (Oper State)                   | Specifies the operating state of the SDP                                                                                                            |
| Del (Delivery)                     | Specifies the type of delivery used by the SDP: MPLS, GRE, or IP                                                                                    |
| Sig (Signaling)                    | Specifies the signaling protocol used to obtain the ingress and egress labels used in frames transmitted and received on the SDP                    |
| Metric                             | Specifies the value used as a tiebreaker by the tunnel table manager to select a route                                                              |
| Last Status Change                 | Specifies the time of the most recent operating status change to this SDP                                                                           |
| Last Mgmt Change                   | Specifies the time of the most recent management-initiated change to this SDP                                                                       |
| Adv. MTU Over                      | Specifies the state of the advertised VC-type MTU override command                                                                                  |
| VLAN VC Etype                      | Specifies the VLAN VC Ethertype for the SDP                                                                                                         |
| Flags                              | Specifies all the conditions that affect the operating status of this SDP                                                                           |
| Number of SDPs                     | Specifies the total number of SDPs displayed according to the criteria specified                                                                    |
| <b>Mixed LSP Mode Information:</b> |                                                                                                                                                     |
| Mixed LSP Mode                     | Indicates whether mixed-LSP mode is configured on the SDP                                                                                           |
| Active LSP Type                    | Indicates the active LSP type on the mixed-LSP SDP: RSVP or LDP                                                                                     |
| Revert Time                        | The number of seconds the service manager must wait before it resets the SDP configuration to a higher priority LSP type when one becomes available |

**Table 16 Service SDP Field Descriptions (Continued)**

| Label                         | Description                                                                                                                                    |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Keepalive Information:</b> |                                                                                                                                                |
| Admin State                   | Specifies the desired keepalive state                                                                                                          |
| Oper State                    | Specifies the operating keepalive state                                                                                                        |
| Hello Time                    | Specifies how often the SDP Echo Request messages are transmitted on this SDP                                                                  |
| Hello Msg Len                 | Specifies the length of the SDP Echo Request messages transmitted on this SDP                                                                  |
| Hello Timeout                 | Specifies the number of seconds to wait for an SDP echo response message before declaring a timeout                                            |
| Unmatched Replies             | Specifies the number of SDP unmatched message replies timer expired                                                                            |
| Max Drop Count                | Specifies the maximum number of consecutive SDP Echo Request messages that can be unacknowledged before the keepalive protocol reports a fault |
| Hold Down Time                | Specifies the amount of time to wait before the keepalive operating status is eligible to enter the alive state                                |
| TX Hello Msgs                 | Specifies the number of SDP echo request messages transmitted since the keepalive was administratively enabled or the counter was cleared      |
| Rx Hello Msgs                 | Specifies the number of SDP echo request messages received since the keepalive was administratively enabled or the counter was cleared         |
| Collect Stats.                | Specifies that the collection of accounting and statistical data for the SDP is enabled or disabled                                            |
| <b>Keepalive History:</b>     |                                                                                                                                                |
| Time of Probe Report          | Indicates the date and time of the report                                                                                                      |
| RTT (ms)                      | Indicates round-trip time (RTT), in milliseconds.                                                                                              |
| Size                          | Indicates the size of the packet, in bytes                                                                                                     |
| Status                        | Indicates the status of the response                                                                                                           |
| <b>LDP Information:</b>       |                                                                                                                                                |
| LDP LSP Id                    | Indicates the LDP LSP identifier                                                                                                               |

**Table 16 Service SDP Field Descriptions (Continued)**

| Label                    | Description                                                                                                                                                                                                                                                                                               |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RSVP/Static LSPs:</b> |                                                                                                                                                                                                                                                                                                           |
| Associated LSP List      | Lists the associated LSPs<br>If the SDP type is MPLS, a list of LSPs used to reach the far-end router displays. All the LSPs in the list must terminate at the IP address specified in the far-end field<br>If the SDP type is GRE, the following message displays:<br>SDP Delivery Mechanism is not MPLS |
| Lsp Name                 | For MPLS: identifies the name of the static LSP                                                                                                                                                                                                                                                           |
| Time since Last Trans*   | For MPLS: specifies the time that the associated static LSP has been in service                                                                                                                                                                                                                           |
| <b>Segment Routing</b>   |                                                                                                                                                                                                                                                                                                           |
| ISIS                     | Indicates the state of IS-IS segment routing: enabled or disabled                                                                                                                                                                                                                                         |
| OSPF                     | Indicates the state of OSPF segment routing: enabled or disabled                                                                                                                                                                                                                                          |
| TE-LSP                   | Indicates the state of TE-LSP segment routing: enabled or disabled                                                                                                                                                                                                                                        |
| <b>Group Encryption</b>  |                                                                                                                                                                                                                                                                                                           |
| Inbound Keygroup Id      | Indicates the key group used to decrypt inbound traffic for the service                                                                                                                                                                                                                                   |
| Outbound Keygroup Id     | Indicates the key group used to encrypt outbound traffic for the service                                                                                                                                                                                                                                  |

## sdp-using

**Syntax** **sdp-using** [*sdp-id[:vc-id]* | **far-end** *ip-address*]

**Context** show>service

**Description** This command displays services using SDP or far-end address options.

**Parameters** *sdp-id* — displays only services bound to the specified SDP ID

**Values** 1 to 17407

*vc-id* — the virtual circuit identifier

**Values** 1 to 4294967295

*ip-address* — displays only services matching with the specified far-end IP address

**Default** services with any far-end IP address

**Output** The following output is an example of service SDP-using information, and [Table 17](#) describes the fields.

### Output Example

```
*A:ALU-1# show service sdp-using 300
=====
Service Destination Point (Sdp Id : 300)
=====
SvcId SdpId Type Far End Opr State I.Label E.Label

1 300:1 Spok 10.0.0.13 Up 131071 131071
2 300:2 Spok 10.0.0.13 Up 131070 131070
100 300:100 Spok 10.0.0.13 Up 131069 131069
101 300:101 Spok 10.0.0.13 Up 131068 131068

**Table 17** Service SDP-Using Field Descriptions

| Label     | Description                                                                                                      |
|-----------|------------------------------------------------------------------------------------------------------------------|
| SvcId     | Identifies the service                                                                                           |
| SdpId     | Identifies the SDP                                                                                               |
| Type      | Indicates the type of SDP (mesh or spoke)                                                                        |
| Far End   | Displays the far-end address of the SDP                                                                          |
| Opr State | Displays the operational state of the service                                                                    |
| I. Label  | Displays the ingress label used by the far-end device to send packets to this device in this service by this SDP |
| E. Label  | Displays the egress label used by this device to send packets to the far-end device in this service by this SDP  |

## service-using

- Syntax** `service-using [epipe] [fpipe] [hpipe] [ies] [vpls] [vprn] [mirror] [apipe] [ipipe] [cpipe] [sdp sdp-id] [customer customer-id]`
- Context** `show>service`
- Description** This command displays the services matching certain usage properties.
- If no optional parameters are specified, all services defined on the system are displayed.

- Parameters**
- epipe** — displays matching Epipe services
  - ies** — displays matching IES services
  - vpls** — displays matching VPLS services
  - vprn** — displays matching VPRN services
  - mirror** — displays matching mirror services
  - apipe** — displays matching Apipe services
  - cpipe** — displays matching Cpipe services
  - fpipe** — displays matching Fpipe services
  - hpipe** — displays matching Hpipe services
  - sdp-id** — displays only services bound to the specified SDP ID
    - Values** 1 to 17407
    - Default** services bound to any SDP ID
  - customer-id** — displays services only associated with the specified customer ID
    - Values** 1 to 2147483647
    - Default** services associated with a customer

**Output** The following outputs are examples of service-using information, and [Table 18](#) describes the fields.

#### Output Example – all services used in system

```
*A:ALU-12# show service service-using

## 4 VLL Services

This chapter provides information about Virtual Leased Line (VLL) services and implementation notes.

Topics in this chapter include:

- [ATM VLL \(Apipe\) Services](#)
- [Circuit Emulation VLL \(Cpipe\) Services](#)
- [Ethernet VLL \(Epipe\) Services](#)
- [Frame Relay VLL \(Fpipe\) Services](#)
- [HDLC VLL \(Hpipe\) Services](#)
- [IP Interworking VLL \(Ipipe\) Services](#)
- [Pseudowire Switching](#)
- [VLL Service Considerations](#)
- [Configuring a VLL Service with CLI](#)
- [VLL Services Command Reference](#)

---

## 4.1 ATM VLL (Apipe) Services

This section provides information about the Apipe service. Topics in this section include:

- [ATM VLL for End-to-End ATM Service](#)
- [ATM Virtual Trunk Over an IP/MPLS Packet-Switched Network](#)
- [ATM SAP-to-SAP Service](#)
- [ATM Traffic Management Support](#)
- [Control Word](#)

Apipe configuration information is found under the following topics:

- [Common Configuration Tasks](#)
- [Configuring VLL Components](#)
- [Service Management Tasks](#)

See [Service Support](#) for information on the adapter cards and chassis that support ATM VLL services.

### 4.1.1 ATM VLL for End-to-End ATM Service

ATM VLLs (Apipe) provide a point-to-point ATM service between users connected to 7705 SAR nodes or other SR routers over an IP/MPLS network (see [Figure 39](#)). User ATM traffic is connected to a 7705 SAR either directly or through an ATM access network. In both cases, an ATM PVC—for example, a virtual channel (VC) or a virtual path (VP)—is configured on the 7705 SAR. VPI/VCI translation is supported in the ATM VLL.

The ATM pseudowire (PW) is initiated using targeted LDP signaling as specified in RFC 4447, *Pseudowire Setup and Maintenance using LDP*; alternatively, it can be configured manually. The 7705 SAR supports MPLS, GRE, and IP as the tunneling technologies for transporting ATM PWs.

The 7705 SAR receives standard UNI/NNI cells on the ATM SAP, or on a number of SAPs belonging to a SAP aggregation group, which are then encapsulated into a pseudowire packet using N-to-1 cell mode encapsulation in accordance with RFC 4717. See [ATM PWE3 N-to-1 Cell Mode Encapsulation](#) for more information about N-to-1 cell mode encapsulation.

In addition to supporting N-to-1 cell mode encapsulation, ATM VLL service supports cell concatenation, control word (CW), SAP-to-SAP (local service), and SAP-to-SDP binding (distributed service). See [SAP Encapsulations and Pseudowire Types](#) for more information. ATM SAP-to-SAP service is not supported when  $N > 1$ ; see [ATM SAP-to-SAP Service](#) for information about ATM SAP-to-SAP services.

ATM VLL optimizes the ATM cell from a 53-byte cell to a 52-byte packet by removing the header error control (HEC) byte at the near end. The far end regenerates the HEC before switching ATM traffic to the attached circuit.

**Figure 39 ATM VLL for End-to-End ATM Service**

19482

### 4.1.2 ATM Virtual Trunk Over an IP/MPLS Packet-Switched Network

ATM virtual trunks (VT), also known as ATM transparent cell transport in RFC 4446, provide a transparent trunking function for user and control traffic between two ATM switches over an ATM pseudowire. ATM control traffic includes PNNI signaling and routing traffic, ILMI traffic, and F4/F5 OAM traffic. [Figure 40](#) shows two switches labeled ATM 2 and ATM 4 that appears to be directly connected over an ATM link because the virtual trunk emulates a direct connection between the ATM switches.

Virtual trunks are supported on 7705 SAR 4-port OC3/STM1 Clear Channel Adapter cards with ports configured for OC3 or STM1 and 4-port DS3/E3 Adapter cards with ports configured for DS3 and E3.

All cells arriving on a port configured for virtual trunking on the 7705 SAR are fed to a single ATM pseudowire. The VPI range cannot be configured. No VPI/VCI translation is performed on ingress or egress. Cell order is maintained within a VT. SAP to SAP service is supported. The two ATM ports can therefore be on the same PE node.

By carrying all cells from all VPIs making up the VT in one pseudowire, a transport solution is provided that is both robust and operationally efficient since the entire VT can be managed as a single entity from the NSP NFM-P (single point for configuration, status, alarms, statistics).

ATM virtual trunks use PWE3 N:1 ATM cell mode encapsulation to provide cell-mode transport, supporting all AAL types, over the MPLS network. Cell concatenation on a pseudowire packet is supported. The SDP type can be MPLS or GRE.

The ATM pseudowire is initiated using targeted LDP (T-LDP) signaling (defined in draft-ietf-pwe3-control-protocol-xx.txt, *Pseudowire Setup and Maintenance using LDP*). In this application, there is no ATM signaling on the 7705 SAR gateway nodes since both endpoints of the MPLS network are configured by the network operator. ATM signaling between the ATM nodes is passed transparently over the VT (along with user traffic) from one ATM port on a 7705 SAR PE to another ATM port on a remote (or the same) 7705 SAR PE.

OAM signaling behaves in the same way as user traffic in that OAM cells are transported transparently and no special action is taken when F4 or F5 OAM cells are received at the SAP ingress or egress. As well, all ILMI messages are transported transparently between two endpoints. In the case of a pseudowire failure (for example, label withdrawal, loss of reachability, loss of tunnel to the eLER), the virtual trunk service SAP port is not taken down.

**Figure 40 ATM Virtual Trunk Over IP/ MPLS Packet-Switched Network**

22322

### 4.1.3 ATM SAP-to-SAP Service

ATM VLLs can be configured with both endpoints (SAPs) on the same 7705 SAR. This is referred to as an ATM SAP-to-SAP or local ATM service. An ATM SAP-to-SAP service emulates local ATM switching between two ATM endpoints on the 7705 SAR. Both ingress and egress traffic is legacy ATM traffic. The two SAPs can be any combination of supported ATM encapsulation ports, channel-groups, or IMA bundles.

**Note:** ATM SAP-to-SAP connections are supported on any combination of the following:

- IMA group
- T1/E1 ASAP port
- E3/DS3 port
- OC3/STM1 port. The OC3 port can be configured for clear channel or channelized service.

**Note:** ATM SAP-to-SAP connections are not supported for pseudowire packets using N-to-1 cell mode encapsulation where  $N > 1$ .

### 4.1.4 ATM Traffic Management Support

The 7705 SAR supports the ATM Forum Traffic Management Specification Version 4.1.

Topics in this section include:

- [Network Ingress Classification](#)
- [ATM Access Egress Queuing and Shaping](#)

#### 4.1.4.1 Network Ingress Classification

Classification is based on the EXP value of the pseudowire label and EXP-to-FC mapping is determined by the network ingress QoS policy.

The ingress MPLS packets are mapped to forwarding classes based on EXP bits that are part of the headers in the MPLS packets. The EXP bits are used to ensure an end-to-end QoS application. For PW services, there are two labels: one for the MPLS tunnel and one for the pseudowire itself. Mapping is done according to the outer tunnel EXP bit settings. This ensures that if the EXP bit settings are altered along the path by the intermediate LSR nodes, the newly requested FC selection is carried out properly.

Ingress GRE and IP packets are mapped to forwarding classes based on DSCP bit settings of the IP header.

#### 4.1.4.2 ATM Access Egress Queuing and Shaping

The 7705 SAR provides a per-SAP queuing architecture on the 16-port T1/E1 ASAP Adapter card, 32-port T1/E1 ASAP Adapter card, 4-port DS3/E3 Adapter card, and 4-port OC3/STM1 Clear Channel Adapter card. After the ATM pseudowire is terminated at the access egress point, all the ATM cells are mapped to default queue 1, and queuing is performed on a per-SAP basis.

Access ingress and access egress traffic management features are identical for SAP-to-SAP and SAP-to-SDP applications.

**Note:** The ATM access egress shaping configuration in a SAP egress QoS policy is ignored when that policy is assigned to an ATM SAP. The shaping of the egress cell stream is controlled by the **atm-td-profile** command. If the **atm-td-profile** is not configured, the default **atm-td-profile** is in effect.

For more information on ATM access egress queuing and scheduling, refer to the 7705 SAR Quality of Service Guide.

#### 4.1.5 Control Word

ATM VLLs support an optional control word. The control word contains protocol control information and can be enabled to guarantee ordered cell delivery for ATM (Apipe) pseudowire service. See [Pseudowire Control Word](#) for more information.

---

## 4.2 Circuit Emulation VLL (Cpipe) Services

This section provides information about the Cpipe service.

Topics in this section include:

- [Cpipe Service Overview](#)
- [TDM SAP-to-SAP Service](#)
- [Cpipe Service Modes](#)
- [TDM PW Encapsulation](#)
- [Circuit Emulation Parameters and Options](#)
- [Transparent SDH/SONET Over Packet \(TSoP\)](#)
- [Error Situations](#)

Cpipe configuration information is found under the following topics:

- [Common Configuration Tasks](#)
- [Configuring VLL Components](#)
- [Service Management Tasks](#)

See [Service Support](#) for information on the adapter cards and chassis that support circuit emulation VLL services.

### 4.2.1 Cpipe Service Overview

Cpipe service is the Nokia implementation of TDM PW VLL as defined in the IETF PWE3 working group.

The 7705 SAR can support TDM circuit applications that are able to transport delay-sensitive TDM traffic over a packet network. For example, in the case of cell site aggregation, Cpipe services provide transport service for 2G connectivity between the base transceiver station and the base station controller, and for 3G backhaul applications (for example, EVDO traffic from T1/E1 ports with MLPPP). Cpipe services over MPLS or GRE tunnels are supported.

The 2G traffic is transported encapsulated in a TDM VLL over the packet switched network (PSN). The entire T1/E1 frame or part of a frame ( $n \times 64$  kb/s) is carried as a TDM VLL over the PSN. At the far end, the transport layer frame structure is regenerated when structured circuit emulation is used, or simply forwarded as part of the payload when unstructured circuit emulation is used. The 3G UMTS R99 traffic uses ATM/IMA as the transport protocol. The IMA sessions are terminated at the site by the 7705 SAR and the 3G ATM traffic is transported across the PSN through the use of ATM VLLs (PWE3).

## 4.2.2 TDM SAP-to-SAP Service

TDM VLLs can be configured with both endpoints (SAPs) on the same 7705 SAR. This is referred to as TDM SAP-to-SAP or local TDM service. TDM SAP-to-SAP emulates a TDM multiplexing and switching function on the 7705 SAR.

A TDM SAP-to-SAP connection is set up in the 7705 SAR and a pseudowire is configured between the two endpoints.

**Note:** TDM SAP-to-SAP connections are supported between any T1/E1 port or channel that is configured for access mode and circuit emulation service and another port or channel with the same configuration (endpoint type, bit rate [number of DS0s in a channel group], payload size, CAS enabled/disabled, and RTP enabled/disabled).

## 4.2.3 Cpipe Service Modes

Cpipe services support unstructured circuit emulation mode (SAToP) for DS3, E3, DS1, and E1 circuits as per RFC 4553 and structured circuit emulation mode (CESoPSN) for  $n \times 64$  kb/s timeslots in DS1 and E1 circuits as per RFC 5086.

The 7705 SAR supports MEF 8, which allows both structured and unstructured emulation of TDM services across Epipes, also known as Circuit Emulation Services over Ethernet (CESoETH). See [MEF 8](#) for more information about CESoETH.

Topics in this section include:

- [Unstructured Mode \(SAToP\)](#)
- [SAToP Serial](#)
- [Structured Mode \(CESoPSN\)](#)

### 4.2.3.1 Unstructured Mode (SAToP)

Structure-agnostic TDM over Packet (SAToP) is an unstructured circuit emulation mode used for the transport of unstructured TDM or structured TDM (where the structure is ignored).

**Note:** The word “agnostic” is used in RFC 4553, but it is not used in the literal sense. The meaning of agnostic in this case is “unaware or independent”; therefore, structure-agnostic is used to mean structure-unaware or structure-independent.

As a structure-unaware or structure-independent service, SAToP service does not align to any framing; the framing mode for the port is set to unframed. For structured TDM, SAToP disregards the bit sequence and TDM structure in order to transport the entire signal over a PSN as a pseudowire.

### 4.2.3.2 SAToP Serial

A **satop-serial** virtual channel (vc) type can be configured on the 12-port Serial Data Interface card, version 3, in order to encapsulate serial traffic (subrate or super-rate) directly in the Cpipe without using High Capacity Multiplexing (HCM). This capability allows the transport of serial control leads directly in the pseudowire instead of in HCM and allows the signaling to be transported with any line speed, not just subrate. It also extends support for TDM rates up to 16 Mb/s for the RS-530 interface. For subrate speeds, it can also use less bandwidth than the current HCM implementation, which occupies a full 64 kb/s timeslot.

The SAToP serial capability is supported on RS-530 and RS-232 interfaces.

#### 4.2.3.2.1 SAToP Serial Payload Size

The payload size for SAToP serial is configurable using the **payload-size** command as an integer number of octets and a multiple of 2 (instead of 32 for normal SAToP). This size affects the packet efficiency (that is, the payload-to-header ratio), packetization delay, and packets/s rate. The range is 2 to 1496 octets (instead of 1514 as for other Cpipes). See [Cpipe Service Configuration Commands](#) for more information.

[Table 19](#) shows the payload size minimum values and the defaults. Serial rates of 4800 b/s and lower only support a payload size of 2 bytes.

The minimum payload size is set so that the lowest bit rates can achieve the lowest delays possible and all rates do not exceed 4000 packets/s. The maximum payload size is set so that the packetization delay does not exceed 64 ms.

For rates of 600 and 1200 b/s, the system oversamples to 2400 b/s. This results in the same packet size and packets/s as for 2400 b/s. Therefore, a 2-byte payload size is equivalent to 8 bits at 1200 b/s and 4 bits at 600 b/s of “real” serial data.

Mismatched rate configurations between the two endpoints may not be identified when baud rates are 600, 1200 or 2400 b/s.

**Table 19 SAToP Serial Payload Size Minimums and Defaults**

| Serial rate (kb/s) | Minimum Payload Size (bytes) | Minimum Packetization Delay | Minimum Packets/s | Default Payload Size (bytes) | Default Packetization Delay | Default Packets/s | Default Jitter Buffer (ms) |
|--------------------|------------------------------|-----------------------------|-------------------|------------------------------|-----------------------------|-------------------|----------------------------|
| 0.6                | 2 <sup>1</sup>               | —                           | 150               | 2 <sup>1</sup>               | —                           | 150               | 32                         |
| 1.2                | 2 <sup>1</sup>               | —                           | 150               | 2 <sup>1</sup>               | —                           | 150               | 32                         |
| 2.4                | 2                            | 6.67                        | 150               | 2                            | 6.67                        | 150               | 32                         |
| 4.8                | 2                            | 333                         | 300               | 2                            | 3.33                        | 300               | 32                         |
| 9.6                | 2                            | 1.7                         | 600               | 8                            | 6.67                        | 150               | 32                         |
| 1.44               | 2                            | 1.11                        | 900               | 8                            | 4.44                        | 225               | 32                         |
| 16                 | 2                            | 1.0                         | 1000              | 8                            | 4.00                        | 250               | 32                         |
| 19.2               | 2                            | 0.83                        | 1200              | 8                            | 3.33                        | 300               | 32                         |
| 38.4               | 2                            | 0.42                        | 2400              | 8                            | 1.67                        | 600               | 32                         |
| 56                 | 2                            | 0.29                        | 3500              | 8                            | 1.14                        | 875               | 32                         |
| 57.6               | 2                            | 0.28                        | 3600              | 8                            | 1.11                        | 900               | 32                         |

**Note:**

1. 600 and 1200 b/s are oversampled to 2400 b/s.

#### 4.2.3.2.2 SAToP Serial Jitter Buffer

For each circuit, the maximum receive jitter buffer is configurable using the **jitter-buffer** command. See [Cpipe Service Configuration Commands](#) for more information. Playout from this buffer must start when the buffer is 50% full to give an operational packet delay variance (PDV) equal to half the maximum buffer size. The supported range is 12 to 250 ms in increments of 1 ms. The buffer size must be set to at least three times the packetization delay and not more than 32 times the packetization delay.

The default jitter buffer values are shown in [Table 19](#).

Jitter buffer overrun and underrun counters are available via statistics and may be optionally alarmed while the circuit is up. On overruns, excess packets are discarded and counted. On underruns, all ones are sent for unstructured circuits.

The circuit status is tracked to show a status of either up, loss of packets, or administratively down. Statistics are available for the number of in-service seconds and the number of out-of-service seconds when the circuit is administratively up.

#### 4.2.3.3 Structured Mode (CESoPSN)

Structure-aware circuit emulation is used for the transport of structured TDM, taking at least some level of the structure into account. By selecting only the necessary  $n \times 64$  kb/s timeslots to transport, bandwidth usage is reduced or optimized (compared to a full DS1 or E1). Full DS1s or E1s can be transported by selecting all the timeslots in the DS1 or E1 circuit. Framing bits (DS1) or FAS (E1) are terminated at the near end and reproduced at the far end.

The 7705 SAR supports CESoPSN with and without Channel Associated Signaling (CAS) for DS1 and E1.

When CESoPSN with CAS is selected, the ABCD bits are coded into the T1 or E1 multiframe packets, transported within the TDM PW, and reconstructed in the T1 or E1 multiframe at the far end for each timeslot.

CAS includes four signaling bits (A, B, C, and D) in the messages sent over a voice trunk. These messages provide information such as the dialed digits and the call state (whether on-hook or off-hook).

The mechanism for E1 CAS is described in ITU-T G.732. When configured for E1 CAS, timeslot 17 carries the signaling information for the timeslots used for voice trunking. Each channel requires four signaling bits, so grouping 16 E1 frames into a multiframe allows the signaling bits for all 30 channels to be trunked.

As shown in Figure 41, timeslot 1 of all frames within the E1 multiframe is reserved for alignment, alarm indication, and CRC. For Frame 0, timeslot 17 is reserved for multiframe alignment bits. For the remaining 15 frames, timeslot 17 contains ABCD bits for two channels.

**Note:** For E1 CAS, timeslots are numbered 1 to 32 on the 7705 SAR.

**Figure 41 E1 Framing for CAS Support in an E1 Multiframe**

For T1 CAS, the signaling bits are transferred using Robbed Bit Signaling (RBS), where the least significant bit in the channel is used periodically to transport these bits instead of voice data. T1 CAS is supported when extended superframe format (ESF) or superframe format (SF) framing is configured. ESF framing uses a 24-frame multiframe and transfers all four signaling bits (ABCD). SF framing uses a 12-frame multiframe and transfers only the AB bits. The signaling bits are carried in the least significant bit of the following frames:

- A bit in frame 6
- B bit in frame 12
- C bit in frame 18
- D bit in frame 24

When CESoPSN with CAS is selected, the ABCD bits are decoded from the incoming E1/T1 multiframe, transferred within the TDM PW, and reconstructed in the E1/T1 multiframe at the far end for every DS0 channel. CAS can be configured on a per-T1/E1 basis or on a per-DS0/64 kb/s channel basis.

In previous releases, when a Cpipe was configured for CESoPSN with CAS, the T1 ports at each end of the Cpipe had to be configured for the same framing format: either ESF or SF. If the framing formats did not match, a SapParamMismatch alarm was raised.

The 7705 SAR now supports mixed framing formats for the T1 ports on a Cpipe configured for CESoPSN with CAS; that is, one port can be configured for ESF framing and the other port for SF framing.

If the ingress port is an ESF-framed T1 port, when the packets arrive at the egress port, the ABCD bits from the ingress ESF SAP are sent out as AB bits in two consecutive superframes on the egress SF SAP. The CD bits from the ingress ESF SAP are mapped as AB bits in the second SF frame.

If the ingress port is an SF-framed T1 port, when the packets arrive at the egress port, the AB bits from every second SF frame from the ingress SF SAP are repeated twice as the ABCD bits of an egress ESF frame. The AB bits from the interlacing SF frames are dropped.

ESF and SF framing interoperability is supported on DS1 (T1) ports or channels on the following hardware:

- 16-port T1/E1 ASAP Adapter card, version 2
- 32-port T1/E1 ASAP Adapter card
- 2-port OC3/STM1 Channelized Adapter card
- 4-port DS3/E3 Adapter card

- 4-port OC3/STM1 / 1-port OC12/STM4 Adapter card
- 4-port T1/E1 and RS-232 Combination module (supported on the 7705 SAR-H)
- 7705 SAR-A (variant with T1/E1 ports)
- 7705 SAR-M (variants with T1/E1 ports)
- 7705 SAR-X

Table 20 shows the structure of a T1 ESF multiframe that uses RBS. The structure of a T1 SF multiframe is based on 12 frames and only the A and B bits are available.

**Table 20 T1 Framing for CAS (RBS) Support in a T1 ESF Multiframe**

| Frame Number | F Bit                        |                  |                 |                  | Bit Numbers in Each Channel Timeslot |                            | Signaling Channel Designation <sup>4</sup> |
|--------------|------------------------------|------------------|-----------------|------------------|--------------------------------------|----------------------------|--------------------------------------------|
|              | Bit Number within Multiframe | Assignments      |                 |                  |                                      |                            |                                            |
|              |                              | FAS <sup>1</sup> | DL <sup>2</sup> | CRC <sup>3</sup> | For Character Signal <sup>4</sup>    | For Signaling <sup>4</sup> |                                            |
| 1            | 1                            | —                | m               | —                | 1-8                                  | —                          | —                                          |
| 2            | 194                          | —                | —               | e1               | 1-8                                  | —                          | —                                          |

| 21           | 3861                         | —                | m               | —                | 1-8                                  | —                          | —                                          |
| 22           | 4054                         | —                | —               | e6               | 1-8                                  | —                          | —                                          |
| 23           | 4247                         | —                | m               | —                | 1-8                                  | —                          | —                                          |
| 24           | 4440                         | 1                | —               | —                | 1-7                                  | 8                          | D                                          |

**Notes:**

1. FAS = frame alignment signal (...001011....)
2. DL = 4 kb/s data link (m represents message bits)
3. CRC = CRC-6 block check field (e1 to e6 represent check bits)
4. Only applicable for CAS

## 4.2.4 TDM PW Encapsulation

TDM circuits are MPLS-encapsulated as per RFC 4553 (SAToP) and RFC 5086 (CESoPSN). (see [Figure 42](#) and [Figure 43](#)).

For GRE tunnels, the same encapsulations shown in [Figure 43](#) are used, but GRE tunnel headers are used instead of MPLS tunnel headers.

Figure 42 SAToP MPLS Encapsulation

21830

Figure 43 CESoPSN MPLS Encapsulation

21831

Figure 44 shows the format of the CESoPSN TDM payload (with and without CAS) for packets carrying trunk-specific  $n \times 64$  kb/s service.

**Figure 44 CESoPSN Packet Payload Format for Trunk-Specific  $n \times 64$  kb/s (With and Without CAS Transport)**

21832

For CESoPSN without CAS, select the packet size so that an integer number of frames are transported. That is, if  $n$  timeslots per frame are to be encapsulated in a TDM PW, then the packet size must be a multiple of  $n$  (where  $n$  is not equal to 1). For example, if  $n = 4$  timeslots, then the packet size can be 8, 12, 16, and so on. If only one timeslot per frame is being transported, the packet size must be an even number.

For CESoPSN with CAS, the packet size is an integer number of frames. A single T1/E1 port can have a mix of CAS and non-CAS traffic in each DS0/64 kb/s channel. You must configure the relevant T1/E1 port or channel group for CAS signal mode before provisioning the TDM PW with CAS or the system will disallow the signal mode configuration. The extra bytes for ABCD (CAS) signaling bits are not included when setting the packet size.

For a single T1/E1 port that contains a mix of CAS and non-CAS signaling, all the non-CAS channel Cpipes inherit the CAS channel restriction concerning 24/16 frames for payload size. For a T1 port, the payload size is equal to the number of CAS and/or non-CAS timeslots  $\times$  24 frames/multiframe  $\times$   $n$  multiframe, where  $n = 1$  to 8. For an E1 port, the payload size is equal to the number of CAS and/or non-CAS timeslots  $\times$  16 frames/multiframe  $\times$   $n$  multiframe, where  $n = 1$  to 8.

**Note:** The extra bytes for CAS signaling bits must be included when setting the **service-mtu** size. See [Structured T1/E1 CES with CAS](#) for more information.

## 4.2.5 Circuit Emulation Parameters and Options

Cpipe services support unstructured circuit emulation mode (SAToP) for DS3, E3, DS1, and E1 circuits as per RFC 4553, and structured circuit emulation mode (CESoPSN) for  $n \times 64$  kb/s timeslots in DS1 and E1 circuits as per RFC 5086.

[Table 21](#) lists the adapter cards, modules, and chassis that support SAToP and CESoPSN.

**Table 21 SAToP and CESoPSN Support on the 7705 SAR**

| Card/Module/Chassis                       |                                                   | SAToP | CESoPSN |
|-------------------------------------------|---------------------------------------------------|-------|---------|

**Notes:**

1. No support for E3
2. No support for E1/64K channel groups
3. The Integrated Services card acts as a Cpipe bridge/multicaster. There are no physical ports on the Integrated Services card.

See [Service Support](#) for further information on circuit emulation VLL services.

The following parameters and options are described in this section:

- [Unstructured](#)
- [Structured DS1/E1 CES without CAS](#)
- [Structured T1/E1 CES with CAS](#)
- [Packet Payload Size](#)
- [Jitter Buffer](#)
- [Asymmetric Delay Control](#)
- [RTP Header](#)
- [Control Word](#)

### 4.2.5.1 Unstructured

Unstructured CES is configured by choosing **satop-t1**, **satop-e1**, **satop-t3**, or **satop-e3** as the **vc-type** when creating a Cpipe service. For DS1 and E1 unstructured circuit emulation, the framing parameter of the port must be set to **ds1-unframed** and **e1-unframed** (respectively) because SAToP service ignores the underlying framing. Additionally, channel group 1 must contain all 24 or 32 timeslots, which is configured automatically when channel group 1 is created.

For DS1, E1, DS3, and E3 circuit emulation, the payload packet size is configurable and must be an integer value between 64 and 1514 octets and must be a multiple of 32. The payload packet size affects the packet efficiency and packetization delay. [Table 22](#) shows the default values for packet size and packetization delay. See [Packet Payload Size](#) for more information.

**Note:** When using SAToP to transport DS1 traffic, the framing bit (bit 193) in the DS1 overhead is included and packed in the payload and sent over the PSN. If the underlying framing is ESF, then the Facility Data Link (FDL) channel is transported over the Cpipe as part of the SAToP service. No matter the case, the framing parameter of the port must be set to unframed.

**Table 22 Unstructured Payload Defaults**

| Circuit | Payload Size (Octets) | Packetization Delay (ms) |
|---------|-----------------------|--------------------------|
| DS1     | 192                   | 1.00                     |
| E1      | 256                   | 1.00                     |
| DS3     | 1024                  | 0.183                    |
| E3      | 1024                  | 0.238                    |

### 4.2.5.2 Structured DS1/E1 CES without CAS

Structured CES without CAS is configured by choosing **cesopsn** as the **vc-type** when creating a Cpipe service. For  $n \times 64$  kb/s structured circuit emulation operation, the framing parameter of the port must be set to a framed setting (such as ESF for DS1). Each channel group contains  $n$  DS0s (timeslots), where  $n$  is between 1 and 24 timeslots for DS1 and between 1 and 31 timeslots for E1.

The packet payload size is configurable (in octets) and must be an integer multiple of the number of timeslots in the channel group. The minimum payload packet size is 2 octets (based on two frames per packet and one timeslot per frame). See [Table 23](#) for default and minimum payload size values. The maximum payload packet size is 1514 octets.

If a port on a 16-port T1/E1 ASAP Adapter card, version 2, or 32-port T1/E1 ASAP Adapter card is configured for DCR, the port timing is associated with the service clock of the Cpipe of channel group 1. For a framed T1 port, there is a restriction on the Cpipe payload size of channel group 1:

- for DCR with a timestamp frequency of 77.76 MHz, the payload size =  $2 \times I \times$  (number of timeslots), where  $I = 1$  to 20
- for DCR with a timestamp frequency of 19.44 MHz, the payload size =  $8 \times I \times$  (number of timeslots), where  $I = 1$  to 5

This restriction does not apply to framed E1 ports or unframed T1/E1 ports.

Each DS1 or E1 frame contributes a number of octets to the packet payload. That number is equal to the number of timeslots configured in the channel group. Thus, a channel group with four timeslots contributes 4 octets to the payload. The timeslots do not need to be contiguous.

A smaller packet size results in a lower packetization delay; however, it increases the packet overhead (when expressed as a percentage of the traffic).

### Calculation of Payload Size

The payload size (S), in octets, can be calculated using the following formula:

$$S = N \times F$$

where:

N = the number of octets (timeslots) collected per received frame (DS1 or E1)  
 F = the number of received frames (DS1 or E1) that are accumulated in each CESoPSN packet

For example, assume the packet collects 16 frames (F) and the channel group contains 4 octets (timeslots) (N). Then the packet payload size (S) is:

$$\begin{aligned} S &= 4 \text{ octets/frame} \times 16 \text{ frames} \\ &= 64 \text{ octets} \end{aligned}$$

### Calculation of Packetization Delay

Packetization delay is the time needed to collect the payload for a CESoPSN packet. DS1 and E1 frames arrive at a rate of 8000 frames per second. Therefore, the received frame arrival period is 125  $\mu$ s.

In the previous example, 16 frames were accumulated in the CESoPSN packet. In this case, the packetization delay (D) can be calculated as follows:

$$D = 125 \mu\text{s/frame} \times 16 \text{ frames} \\ = 2.000 \text{ ms}$$

Table 23 shows the default and minimum values for frames per packet, payload size, and packetization delay as they apply to the number of timeslots (N) that contribute to the packet payload. The default values are set by the operating system as follows:

- for  $N = 1$ , the default is 64 frames/packet
- for  $2 \leq N \leq 4$ , the default is 32 frames/packet
- for  $5 \leq N \leq 15$ , the default is 16 frames/packet
- for  $N \geq 16$ , the default is 8 frames/packet

**Table 23** Default and Minimum Payload Size for CESoPSN without CAS

| Number of Timeslots (N) | Default Values        |                           |                              | Minimum Values        |                           |                              |
|-------------------------|-----------------------|---------------------------|------------------------------|-----------------------|---------------------------|------------------------------|
|                         | Frames per Packet (F) | Payload Size (Octets) (S) | Packetization Delay (ms) (D) | Frames per Packet (F) | Payload Size (Octets) (S) | Packetization Delay (ms) (D) |
| 1                       | 64                    | 64                        | 8.000                        | 2                     | 2                         | 0.250                        |

### 4.2.5.3 Structured T1/E1 CES with CAS

Structured circuit emulation with CAS is supported for T1 and E1 circuits.

Structured CES with CAS service is configured by choosing **cesopsn-cas** as the **vc-type** when creating a Cpipe service. The DS1 or E1 service on the port associated with the Cpipe SAP should be configured to support CAS (via the **signal-mode {cas}** command) before configuring the Cpipe service to support DS1 or E1 with CAS. Refer to the 7705 SAR Interface Configuration Guide for information on configuring signal mode.

For  $n \times$  DS0 and  $n \times$  64 kb/s structured circuit emulation with CAS, the implementation is almost identical to that of CES without CAS. When CAS operation is enabled, timeslot 16 (channel 17) cannot be included in the channel group on E1 carriers. Since the CAS in-band method is used, separate PW support for CAS is not provided.

When CAS is enabled, the packet size is based on the number of multiframes per packet and whether the circuit is configured for E1 or T1. Payload size is user-configurable to correspond to the desired integer number of multiframes. The 7705 SAR supports up to 8 multiframes, where a multiframe contains 24 frames for T1 and 16 frames for E1. Therefore, the payload size = number of timeslots  $\times$  24 (T1) or 16 (E1) frames per multiframe  $\times$  number of multiframes. For example, the payload size for a T1 line (24 frames) using 2 timeslots and 8 multiframes is 384 bytes ( $384 = (2 \times 24) \times 8$ ).

Multiple multiframes are supported on the following cards and platforms:

- 6-port E&M Adapter card (see note below)
- 16-port T1/E1 ASAP Adapter card
- 32-port T1/E1 ASAP Adapter card
- 7705 SAR-A (variant with T1/E1 ports)
- 7705 SAR-M (variants with T1/E1 ports)
- 7705 SAR-X

**Note:** If the 6-port E&M Adapter card is configured for A-Law companding, the E&M ports support 16 (E1) frames per multiframe. If the card is configured for Mu-Law companding, the ports support 24 (T1) frames per multiframe.

Table 24 shows the default payload sizes based on the number of timeslots.

For CAS, the signaling portion adds  $(n/2)$  bytes ( $n$  is an even integer) or  $((n+1)/2)$  bytes ( $n$  is odd) to the packet, where  $n$  is the number of timeslots in the channel group. You do not include the additional signaling bytes when setting the TDM payload size. However, the operating system includes the additional bytes in the total packet payload, and the total payload must be accounted for when setting the **service-mtu** size. Continuing the example above, since  $n = 4$ , the total payload is 64 octets plus  $(4/2 = 2)$  CAS octets, or 66 octets. Refer to [Figure 44](#) to see the structure of the CES with CAS payload.

CES fragmentation is not supported.

**Note:** If you configure the **service-mtu** size to be smaller than the total payload size (payload plus CAS bytes), then the Cpipe will not become operational. This must be considered if you change the **service-mtu** from its default value.

**Table 24** Default Values for the Payload Size for T1 and E1 CESoPSN with CAS

| Number of Timeslots | T1                          |                       |                          | E1                          |                       |                          |
|---------------------|-----------------------------|-----------------------|--------------------------|-----------------------------|-----------------------|--------------------------|
|                     | Number of Frames per Packet | Payload Size (Octets) | Packetization Delay (ms) | Number of Frames per Packet | Payload Size (Octets) | Packetization Delay (ms) |
| 1                   | 24                          | 24                    | 3.00                     | 16                          | 16                    | 2.00                     |
| 2                   | 24                          | 48                    | 3.00                     | 16                          | 32                    | 2.00                     |
| 3                   | 24                          | 72                    | 3.00                     | 16                          | 48                    | 2.00                     |
| 4                   | 24                          | 96                    | 3.00                     | 16                          | 64                    | 2.00                     |

#### 4.2.5.4 Packet Payload Size

The packet payload size defines the number of octets contained in the payload of a TDM PW packet when the packet is transmitted. Each DS0 (timeslot) in a DS1 or E1 frame contributes 1 octet to the payload, and the total number of octets contributed per frame depends on the number of timeslots in the channel group (for example, 10 timeslots contribute 10 octets per frame).

### 4.2.5.5 Jitter Buffer

A circuit emulation service uses a jitter buffer to ensure that received packets are tolerant to packet delay variation (PDV). The selection of jitter buffer size must take into account the size of the TDM-encapsulated packets (payload size). A properly configured jitter buffer provides continuous play-out, thereby avoiding discards due to overruns and underruns (packets arriving too early or too late). The maximum receive jitter buffer size is configurable for each SAP configured for circuit emulation. The range of values is from 1 to 250 ms in increments of 1 ms.

#### 4.2.5.5.1 Configuration and Design Considerations

Determining the best configuration value for the jitter buffer may require some adjustments to account for the requirements of your network, which can change PDV as nodes are added or removed.

For each circuit, the maximum receive jitter buffer is configurable. Play-out from this buffer must start when the buffer is 50% full, in order to give an operational PDV equal to half the maximum buffer size. The supported range is 1 to 250 ms in increments of 1 ms. The buffer size must be set to at least 3 times the packetization delay and no greater than 32 times the packetization delay. Use a buffer size (in ms) that is equal to or greater than the peak-to-peak PDV expected in the network used by circuit emulation service. For example, for a PDV of  $\pm 5$  ms, configure the jitter buffer to be at least 10 ms.

**Note:**

- The jitter buffer setting and payload size (packetization delay) interact such that it may be necessary for the operating system to adjust the jitter buffer setting in order to ensure no loss of packets. Thus, the configured jitter buffer value may not be the value used by the system. Use the **show>service>id service-id>all** command to show the effective PDVT (packet delay variation tolerance).
- If asymmetric delay control is enabled (**asym-delay-control**), it must be enabled on both ends of the Cpipe and the jitter buffer size must match on both ends of the Cpipe; otherwise, a service parameter mismatch state occurs and the service is brought down.

The following values are the default jitter buffer times for structured circuits without CAS, where N is the number of timeslots:

- for  $N = 1$ , the default is 32 ms
- for  $2 \leq N \leq 4$ , the default is 16 ms
- for  $5 \leq N \leq 15$ , the default is 8 ms

- for  $N \geq 16$ , the default is 5 ms

For CESoPSN with CAS, the default jitter buffer is 12 ms for T1 and 8 ms for E1.

Jitter buffer overrun and underrun counters are available for statistics and can raise an alarm (optional) while the circuit is operational. For overruns, excess packets are discarded and counted. For underruns, an all-ones pattern is sent for unstructured circuits and an all-ones or a user-defined pattern is sent for structured circuits (based on configuration).

The circuit status and statistics can be displayed using the **show** command.

#### 4.2.5.6 Asymmetric Delay Control

If there is high jitter in the network, the last packet for initialization of the circuit emulation service may arrive early or late, resulting in a jitter buffer latency that is different from the expected configured jitter buffer setting (time associated with 50% jitter buffer size). The latency difference between each direction of the TDM PW is known as asymmetric latency, and because some applications (for example, power industry networks) require a very low latency difference, it must be controlled.

Asymmetric Delay Control (ADC) is used to control the asymmetric latency contributed by the jitter buffer. When the **asym-delay-control** command is enabled, a special startup sequence is triggered when the TDM PW is initially started or is restarted after being brought down (due to faults such as packet overflow, packet underflow, or the port going down).

Upon startup, a configurable number of TDM PW packets are analyzed. During this analysis period, the access port transmits an all-ones pattern (for the 8-port Voice & Teleprotection card or 8-port C37.94 Teleprotection card) or the configured **idle-payload-fill** value (for the other port types). Refer to the 7705 SAR Interface Configuration Guide for information on the **idle-payload-fill** command. The service is considered to be down during this period.

If any packet loss is detected during the analysis period, the analysis is restarted. If no packet loss is detected, the average jitter buffer latency is computed. Based on the difference between the average latency and the expected latency of the jitter buffer size, the network processor will either:

- drop a number of octets based on the difference (if the measured average is higher than expected)
- add a number of dummy octets based on the difference (if the measured average is lower than expected); the dummy octets are based on the **idle-payload-fill** value of the channel or port

**Note:**

- ADC can only reduce asymmetry in the jitter buffer. It does not reduce any asymmetry that may exist in the network path.
- Because of this, the network must be engineered to maintain symmetrical latency:
  - use explicit-path LSPs with strict hops
  - do not use MPLS FRR because it may change the latency characteristics of a single direction without changing the other direction
  - ensure that both directions of the TDM PW traverse the same path end to end
- With ADC, care must be taken when designing the network to prevent a situation where an error recovery mechanism would result in different MPLS paths in the two directions of the Cpipe, between the two SAPs across the network. If different paths are used, latencies may be different, causing asymmetry. To avoid this situation, the 7705 SAR supports path redundancy for ADC. See [ADC for Redundant Paths](#).

Optionally, the ADC analysis can be set to repeat at configured time intervals after the service is up. This analysis is done with live traffic (that is, not with all-ones or the **idle-payload-fill** value). If the difference between the calculated average latency and the expected latency is greater than the **threshold-repeat** value, octets are added or dropped as necessary.

On-demand ADC allows users to initiate a one-time ADC analysis and correction on a live service using the **tools>perform>service>id>sap** command. Similar to the ADC repeat function, ADC uses the **threshold-repeat** value to determine if octets need to be added or dropped.

If ADC is enabled, it must be enabled on both ends of the Cpipe; otherwise, a service parameter mismatch state occurs and the service is brought down. Jitter buffer size is also included in the set of parameters that will cause a service parameter mismatch if the value is not the same at both ends of the Cpipe. This prevents the operator from changing the jitter buffer size, which would immediately change the latency symmetry of the Cpipe service.

As well, Cpipes using ADC must have the same card and port type on both ends of the Cpipe. Mismatched card/port configuration is not blocked in the CLI or in SNMP but must be avoided; otherwise, differential delay will be introduced caused by different framer delays on the cards/ports.

ADC can only be enabled for Cpipes configured as CESoPSN without CAS (no SAToP). If ADC is enabled, ACR, DCR, and RTP cannot be enabled on the port.

The following adapter cards, modules, and platforms support ADC:

- 4-port T1/E1 and RS-232 Combination module (RS-232 channels) on the 7705 SAR-H

- 8-port Voice & Teleprotection card (G.703 (codir) and C37.94 (TPIF) channels) on the 7705 SAR-8 and 7705 SAR-18
- 8-port C37.94 Teleprotection card (C37.94 (TPIF) channels) on the 7705 SAR-8 and 7705 SAR-18
- 12-port Serial Data Interface cards (RS-232, X.21, and V.35 on all 12-port Serial Data Interface card versions, and RS-530 on 12-port Serial Data Interface card version 3) on the 7705 SAR-8 and 7705 SAR-18
- 7705 SAR-Hc (RS-232 channels)
- T1/E1 ports on the 16-port T1/E1 ASAP Adapter card version 2 and 32-port T1/E1 ASAP Adapter card on the 7705 SAR-8 and 7705 SAR-18
- T1/E1 ports on the 7705 SAR-A, 7705 SAR-M, 7705 SAR-X, and 7705 SAR-H

#### 4.2.5.6.1 ADC for Redundant Paths

When two paths are created between Cpipe endpoint routers, there is no guarantee that the latency of the two paths is exactly the same. Each path may be a different distance and have different numbers or types of switches or routers, and path failures may occur in a single direction. Automatic path switchover in these cases will result in asymmetry of traffic latency. This is problematic for networks that require high availability, such as power industry networks that use teleprotection. To overcome this problem, the 7705 SAR supports ADC over redundant network paths.

To enable ADC over redundant network paths in a Cpipe service, each router in the service must be configured with one SAP and two SDPs, where:

- one router is configured as the standby-signaling master and the other is configured as the standby-signaling slave
- the two SDPs on each router provide two different paths between the routers. In order to keep the service symmetric, both the master endpoint router and the slave endpoint router must use the same SDP and therefore the same path at any one time.
- each path is made up of two unidirectional LSPs with strict hop-by-hop routing over the two routers

If the active path becomes unavailable, as detected through LOS, BFD failure, LSP down, or spoke SDP down, the standby-signaling master and the standby-signaling slave routers both switch over to the available path.

After each path switchover, ADC automatically executes its analysis and resets the jitter buffer latency to the engineered value. This occurs because the switchover process may leave the path in a state that is susceptible to asymmetry.

In addition, TDM PWs enabled with ADC receive data only from the active path. Normally, incoming traffic is accepted from both active and inactive paths. However, because in-transit traffic may cause symmetry issues after a path switchover, only traffic on the active path is accepted.

4.2.5.7 RTP Header

For all circuit emulation channels, the RTP in the header is optional (as per RFC 5086). When enabled for absolute mode operation, an RTP header is inserted in the MPLS frame upon transmit. Absolute mode is defined in RFC 5086 and means that the ingress PE will set timestamps using the clock recovered from the incoming TDM circuit. When an MPLS frame is received, the RTP header is ignored. The RTP header mode is for TDM PW interoperability purposes only and should be enabled when the other device requires an RTP header.

RTP cannot be enabled if asymmetric delay control is enabled.

4.2.5.8 Control Word

The control word is mandatory for SAToP and CESoPSN. The bit structure is shown in [Figure 45](#). [Table 25](#) describes the bit fields. See [Pseudowire Control Word](#) for more information.

Figure 45 Control Word Bit Structure

21833

Table 25 Control Word Bit Descriptions

| Bit                      | Description                                                                                                                                                                                                                           |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bits 0 to 3              | The use of bits 0 to 3 is described in RFC 4385. These bits are set to 0 unless they are being used to indicate the start of an Associated Channel Header (ACH) for the purposes of VCCV.                                             |
| L<br>(Local TDM Failure) | The L bit is set to 1 if an abnormal condition of the attachment circuit such as LOS, LOF, or AIS has been detected and the TDM data carried in the payload is invalid. The L bit is cleared (set back to 0) when fault is rectified. |

**Table 25 Control Word Bit Descriptions (Continued)**

| Bit                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| R<br>(Remote Loss of Frames indication) | The R bit is set to 1 if the local CE-bound interworking function (IWF) is in the packet loss state and cleared (reset to 0) after the local CE-bound IWF is no longer in the packet loss state.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| M<br>(Modifier)                         | <p>The M bits are a 2-bit modifier field. For SAToP, M is set to 00 as per RFC 4553. For CESoPSN, M is set according to RFC 5086, summarized as follows:</p> <ul style="list-style-type: none"> <li>When L bit = 0, and <ul style="list-style-type: none"> <li>M = 00—Normal conditions</li> <li>M = 01—Reserved for future use</li> <li>M = 10—RDI condition for the attachment circuit (AC)</li> <li>M = 11—Reserved for CESoPSN</li> </ul> </li> <li>When L bit = 1, and <ul style="list-style-type: none"> <li>M = 00—TDM data is invalid</li> <li>M = 01—Reserved for future use</li> <li>M = 10—Reserved for future use</li> <li>M = 11—Reserved for future use</li> </ul> </li> </ul> |
| FRG                                     | The FRG bits in the CESoPSN control word are set to 00.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| LEN                                     | The LEN bits (bits 10 to 15) carry the length of the CESoPSN packet (defined as the size of the CESoPSN header plus the payload size) if it is less than 64 bytes, and set to 0 otherwise.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Sequence number                         | The sequence number is used to provide the common PW sequencing function as well as detection of lost packets.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## 4.2.6 Transparent SDH/SONET Over Packet (TSoP)

Transparent SDH/SONET over Packet (TSoP) is a method for transporting clear channel OC3/STM1 or clear channel OC12/STM4 traffic over a packet network using OC3/STM1 TSoP SFPs and OC12/STM4 TSoP SFPs. With TSoP, the entire signal is encapsulated in a pseudowire and transported over the network to a single destination, which simplifies operation. TSoP is modeled after the SAToP method for pseudowire transport of DS1, E1, DS3, or E3 circuits (RFC 4553).

TSoP SFPs are inserted into Ethernet SFP ports, and the 7705 SAR treats them as standard Ethernet SFPs. To set up the TSoP service, an Epipe must be created across the network connecting two OC3/STM1 TSoP SFPs or two OC12/STM4 TSoP SFPs. The TSoP SFPs implement DCR for service clock delivery. Both nodes must be synchronized against a common clock for DCR.

---

TSoP SFPs are supported on the 7705 SAR-8 and 7705 SAR-18 on the following adapter cards:

- 8-port Gigabit Ethernet Adapter card
- 6-port Ethernet 10Gbps Adapter card
- 10-port 1GigE/1-port 10GigE X-Adapter card (7705 SAR-18 only)

Each adapter card supports two OC3/STM1 or OC12/STM4 TSoP SFPs. A maximum of 16 TSoP SFPs are supported on the 7705 SAR-8 or 7705 SAR-18.

**Note:** For a 7705 SAR-8 with a maximum ambient temperature of 131°F (55°C), a maximum of eight TSoP SFPs are supported per adapter card.

## 4.2.7 Error Situations

The CE-bound interworking function (IWF) uses the sequence numbers in the control word to detect lost and incorrectly ordered packets. Incorrectly ordered packets that cannot be reordered are discarded.

For unstructured CES, the payload of received packets with the L bit set is replaced with an all-ones pattern. For structured CES, the payload of received packets with the L bit set is replaced with an all-ones or a user-configurable bit pattern. This is configured using the **idle-payload-fill** command. For structured CES with CAS, the signaling bits are replaced with an all-ones or a user-configurable bit pattern. This is configured using the **idle-signal-fill** command. Refer to the 7705 SAR Interface Configuration Guide for more information.

All circuit emulation services can have a status of up, loss of packets (LOP) or admin down, and any jitter buffer overruns or underruns are logged.

---

## 4.3 Ethernet VLL (Epipe) Services

This section provides information about the Epipe service.

Topics in this section include:

- [Epipe Service Overview](#)
- [Ethernet Access Egress Queuing and Scheduling](#)
- [Ethernet SAP-to-SAP](#)
- [Epipe with ATM SAPs](#)
- [MEF 8](#)
- [Ethernet OAM](#)
- [Control Word](#)
- [MTU](#)
- [Raw and Tagged Modes](#)
- [IP Filters \(Epipe\)](#)
- [MPLS Entropy Label](#)

Epipe configuration information is found under the following topics:

- [Common Configuration Tasks](#)
- [Configuring VLL Components](#)
- [Service Management Tasks](#)

See [Service Support](#) for information on the adapter cards and chassis that support Ethernet VLL services.

### 4.3.1 Epipe Service Overview

An Ethernet pseudowire (PW) is used to carry Ethernet/802.3 protocol data units (PDUs) over an MPLS or IP network, allowing service providers to offer emulated Ethernet services over existing MPLS or IP networks. For the 7705 SAR, Ethernet emulation is a point-to-point service.

The 7705 SAR uses Ethernet VLLs to carry Ethernet traffic from various sources at a site, including traffic such as e911 locators, power supply probes, and HSPA-dedicated interfaces. Native Ethernet bridging is not supported.

An MPLS Epipe service is the Nokia implementation of an Ethernet VLL based on the IETF RFC 4448, *Encapsulation Methods for Transport of Ethernet over MPLS Networks*.

Figure 46 shows a typical Ethernet VLL frame together with its MPLS tunnel encapsulation.

**Figure 46 Ethernet VLL Frame with MPLS Encapsulation**

19767

An Epipe service is a Layer 2 point-to-point service where the customer data is encapsulated and transported across a service provider's MPLS or IP network. Figure 47 shows a typical Epipe service. An Epipe service is completely transparent to the subscriber's data and protocols. Like other PW VLL services, Epipe service behaves like a non-learning Ethernet bridge. A distributed Epipe service consists of a SAP and an SDP pair, where one SDP is on same router as the SAP, and the second SDP is on the far-end router.

Each SAP configuration includes a specific port on which service traffic enters the 7705 SAR from the customer side (also called the access side). Each port is configured with an encapsulation type (SAP encapsulation). Thus, a whole Ethernet port can be bound to a single service (that is, the whole Ethernet port is configured as a SAP), or if a port is configured for IEEE 802.1Q or 802.1ad encapsulation (referred to as dot1q or qinq, respectively), then a unique encapsulation value (ID) must be specified.

**Figure 47 Epipe Service**

19483

### 4.3.2 Ethernet Access Egress Queuing and Scheduling

Ethernet access egress queuing and scheduling is very similar to the Ethernet access ingress behavior. Once the Ethernet pseudowire is terminated, traffic is mapped to up to eight different forwarding classes per SAP. Mapping traffic to different forwarding classes is performed based on the EXP bit settings of the received Ethernet pseudowire.

For more information on Ethernet access egress queuing and scheduling, refer to the 7705 SAR Quality of Service Guide.

### 4.3.3 Ethernet SAP-to-SAP

Ethernet VLLs can be configured with both endpoints (SAPs) on the same 7705 SAR. This is referred to as Ethernet SAP-to-SAP or local Ethernet service. Ethernet SAP-to-SAP provides local Ethernet switching between two Ethernet endpoints on the 7705 SAR.

An Ethernet SAP-to-SAP connection is set up on the 7705 SAR and a pseudowire is configured between the two endpoints.

When the port encapsulation is null, there is no change to the VLAN tags on the ingress and egress frame headers, if VLAN tags are present.

When the port encapsulation is dot1q, the VLAN tag is removed from the ingress frame header and a new VLAN tag is inserted into the egress frame header. No VLAN tag is inserted into the egress frame header if the SAP has a VLAN ID of 0.

When the port encapsulation is qinq, the VLAN tags are removed from the ingress frame header and a new set of outer and inner VLAN tags are inserted in the egress frame header. No VLAN tags are inserted in the egress frame if the SAP has a VLAN ID of 0 or VLAN IDs of 0.\*. SAP 0.0 is not a valid combination.

In addition, the 7705 SAR-M can use a SAP-to-SAP Ethernet PW to provide an Ethernet-to-ATM interworking service. This is done by having one SAP on an Ethernet port and the other SAP on an ATM port or IMA bundle. Encapsulation options are specified in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*. The Ethernet-to-ATM interworking service can be used to support:

- interworking of legacy bridged ATM traffic to Ethernet
- transport of Ethernet traffic over an existing ATM network

See [Configuring ATM Encapsulation Under Epipe Service \(7705 SAR-M only\)](#) for more information.

### 4.3.4 Epipe with ATM SAPs

The 7705 SAR supports Epipe with ATM SAPs over an Ethernet SDP; this feature is available on the 7705 SAR-8 or 7705 SAR-18. IP interworking is between an OC3 clear channel ATM over a 10-Gigabit or Gigabit Ethernet connection through an MPLS network. The SAP connection is from an ATM VC configured on a 4-port OC3/STM1 Clear Channel Adapter card. The Ethernet SDP connection is from a 6-port Ethernet 10Gbps Adapter card. The ATM SAP format can only be UNI. BPDU with LLC/SNAP is used as specified in RFC 2684.

[Figure 48](#) shows an example of an Epipe network configuration with an ATM SAP on a 7705 SAR-8. For a CLI configuration example, see [Configuring Epipe with ATM SAP](#).

**Figure 48 Epipe Network Configuration with ATM SAP**

### 4.3.5 MEF 8

The 7705 SAR supports MEF 8 as defined in the Implementation Agreement for the Emulation of PDH Circuits over Metro Ethernet Networks. Support for the MEF 8 standard allows both structured and unstructured emulation of TDM services across Epipes, also known as Circuit Emulation Services over Ethernet (CESoETH). The MEF 8 feature enables the 7705 SAR to interoperate with equipment that does not support MPLS-based Cpipes but does support MEF 8 Epipes.

Figure 49 shows an Ethernet-encapsulated TDM circuit. See [TDM PW Encapsulation](#) for complete information about TDM PW encapsulation.

**Figure 49 CESoETH Encapsulation**

23173

The 7705 SAR supports the following MEF 8 configuration scenarios:

- TDM SAP to Ethernet SAP (see [Figure 50](#))  
A GPON ONT or other MEF 8-only device is used to encapsulate TDM over a GPON or Ethernet network, and the 7705 SAR is used to terminate the MEF 8.
- TDM SAP to Ethernet SAP via 7705 SAR-M GPON module (see [Figure 51](#))  
The 7705 SAR-M is the GPON ONT and is used to interoperate with a MEF 8-only device. The 7705 SAR-M terminates the MEF 8.
- TDM SAP to spoke SDP (see [Figure 52](#))  
A GPON ONT or other MEF 8-only device is used to encapsulate TDM over an MPLS network, and the 7705 SAR is used to terminate both the LSP and MEF 8.

**Figure 50 TDM SAP to Ethernet SAP**

**Figure 51 TDM SAP to Ethernet SAP via 7705 SAR-M GPON Module**

**Figure 52 TDM SAP to Spoke SDP**

Table 26 shows the platforms, adapter cards, and modules that support MEF 8.

**Table 26 MEF 8 Support on the 7705 SAR**

**Notes:**

1. Supported on n x DS0 channels with or without CAS
2. Supported on DS1/E1 ports
3. Supported on DS1/E1 channels and DS3/E3 channels
4. Supported on DS1/E1 channels and DS3/E3 ports
5. Supported on DS1/E1 channels

### 4.3.5.1 Epipe Service Modes

Epipe services support structured circuit emulation mode for nxDS0 and structured or unstructured circuit emulation mode for DS1, E1, DS3, and E3 as defined in the MEF 8 specification.

There are two methods for using MEF 8 to emulate TDM circuits over Ethernet using an Epipe:

- TDM SAP-to-Ethernet SAP
- TDM SAP-to-spoke SDP

Defining one TDM SAP and one Ethernet SAP is known as Circuit Emulation Services over Ethernet (CESoETH). The TDM SAP configured in the Epipe must include a local and remote Emulated Circuit Identifier (ECID) and a far-end destination MAC address. The TDM port's MAC address is used as the source MAC address for the circuit.

TDM can also be encapsulated into Ethernet which is then encapsulated in MPLS (or GRE). This method is known as Circuit Emulation Services over Ethernet over MPLS (CESoETHoMPLS). CESoETHoMPLS is configured with an Epipe with a TDM SAP and a spoke SDP. The TDM SAP configured in the Epipe must include a local and remote ECID and a far-end destination MAC address. The TDM port's MAC address is used as the source MAC address for the circuit.

The 7705 SAR supports unicast MAC addresses and non-IEEE-reserved group multicast MAC addresses.

**Note:** Users should exercise caution when using multicast MAC addresses, as Ethernet frames with a multicast destination address could be flooded when traversing an Ethernet broadcast domain.

The TDM SAP's framing and CAS settings determine the MEF 8 circuit emulation mode. If the TDM port is framed, MEF 8 is in structured mode. If the TDM port is unframed, MEF 8 is in unstructured mode. If the TDM SAP is configured with CAS enabled, MEF 8 is in structured mode with CAS. See [Unstructured](#), [Structured DS1/E1 CES without CAS](#), and [Structured T1/E1 CES with CAS](#) for more information about circuit emulation modes.

Adaptive clock recovery (ACR) is supported for MEF 8 in structured or unstructured mode on the following platforms and adapter cards:

- 7705 SAR-M (variants with T1/E1 ports)
- 7705 SAR-A (variants with T1/E1 ports)
- 7705 SAR-X (T1/E1 ports)
- 16-port T1/E1 ASAP Adapter card
- 32-port T1/E1 ASAP Adapter card

For more information on ACR, refer to the 7705 SAR Basic System Configuration Guide, "Adaptive Clock Recovery (ACR)".

Differential clock recovery (DCR) is supported for MEF 8 in structured or unstructured mode on the following platforms, adapter cards, and modules:

- 7705 SAR-M (variants with T1/E1 ports)
- 7705 SAR-A (variant with T1/E1 ports)
- 7705 SAR-X (T1/E1 ports)
- 16-port T1/E1 ASAP Adapter card, version 2
- 32-port T1/E1 ASAP Adapter card
- 4-port OC3/STM1 / 1-port OC12/STM4 Adapter card (DS1/E1 channels)
- 4-port DS3/E3 Adapter card (clear channel DS3/E3 ports and DS1/E1 channels on channelized DS3 ports (E3 ports cannot be channelized)); DCR on DS1/E1 channels is supported only on the first three ports of the card
- T1/E1 ports of the 4-port T1/E1 and RS-232 Combination module

To enable DCR, the network must have a common clock between the two terminating SAPs or SAP/spoke SDP using MEF 8. In each direction, the service clock is compared to the common clock and the difference is encoded into the RTP header in the TDM PW overhead. At the other end of the network, the original service clock is reproduced by comparing the common clock to the frequency difference in the RTP header.

**Note:** DCR is not supported on DS1 or E1 channels that have CAS signaling enabled.

For more information on DCR, refer to the 7705 SAR Basic System Configuration Guide, “Differential Clock Recovery (DCR)”.

### 4.3.6 Ethernet OAM

Ethernet VLL service supports Ethernet OAM functions for ETH-CFM according to the 802.1ag and Y.1731 standards, for Y.1731 Performance Monitoring, and for EFM OAM according to the 802.3ah standard. For more information, see [ETH-CFM \(802.1ag and Y.1731\)](#), and refer to the “Ethernet OAM” section in the 7705 SAR Interface Configuration Guide, and the “Ethernet OAM Capabilities” section in the 7705 SAR OAM and Diagnostics Guide.

Ethernet ports in access or network mode also support CFM loopback message (LBM) frames for Layer 1 and Layer 2 OAM tests on unlabeled ports. For more information, refer to the “Ethernet OAM” section in the 7705 SAR Interface Configuration Guide.

### 4.3.7 Control Word

Ethernet (Epipe) services support an optional control word, with the exception of MEF 8 (CESoETH) services for which the control word is mandatory (for information on the MEF 8 service control word, see the [Control Word](#) section in [Circuit Emulation Parameters and Options](#)).

If the Epipe service control word is enabled, it is set to all zeros and ignored on egress.

See [Pseudowire Control Word](#) for more information.

## 4.3.8 MTU

Network-facing Ethernet ports must support a larger MTU than access-facing Ethernet ports in order to account for the pseudowire headers that are added to the access Ethernet frames.

As an example, the following list gives the worst-case MTU sizes for Ethernet VLLs over Ethernet ports under various configurations, where the worst case is the largest MTU size required in order to carry a standard payload (1500 bytes):

- Access, null mode: 1514 bytes
- Access, dot1q mode: 1518 bytes
- Access, qinq mode: 1522 bytes
- Network, null mode: 1572 bytes
- Network, dot1q mode: 1572 bytes

**Note:** Since it is not practical to split a Layer 2 Ethernet frame into smaller frames, the access port (SAP) MTU must be smaller than the service and network port MTU. If the access port MTU is larger than the tunnel MTU, the Ethernet VLL does not come into service and remains in the inoperative state. See [MTU Settings](#) for information on MTU for VLL service.

## 4.3.9 Raw and Tagged Modes

An Ethernet PW operates in one of two modes: raw or tagged. Raw and tagged modes relate to the way the router handles VLAN tags embedded in the header of an Ethernet frame. Both modes are supported by the 7705 SAR.

Raw and tagged modes are configured using the **vc-type {ether | vlan}** parameter under the **spoke-sdp** command. To configure raw mode, choose the **ether** option; to configure tagged mode, choose **vlan**.

VLAN tags can provide service-delimiting information about a frame. Service-delimiting means that information in the tag affects the forwarding decisions that are made to route the packet. The port connected to the attachment circuit (AC) can be configured for null, dot1q, or qinq operation. When the port is configured for null, the 7705 SAR treats any attached tag received at the SAP (from the AC) as not service-delimiting; when configured for dot1q or qinq, received tags are service-delimiting.

---

### 4.3.9.1 Raw Mode

In raw mode, VLAN tags are not service-delimiting (that is, the port is set to null and the tags do not affect frame forwarding decisions) and are forwarded over the Epipe as part of the payload.

If a service-delimiting tag arrives from the ingress AC (that is, the port is set to dot1q or qinq and a tag is received), the tags are removed (popped) from the payload before the Ethernet frame gets switched over the PSN via the Epipe.

In raw mode, all traffic from the ingress port gets switched to the same endpoint. However, if the MTU (or configured size) of the tunnel is exceeded then service is affected because the frame is dropped.

In raw mode, when the 7705 SAR detects a failure on the Ethernet ingress port or the port is administratively disabled, the 7705 SAR sends a PW status notification message to the remote router.

### 4.3.9.2 Tagged Mode

In tagged mode, every frame sent on the Ethernet PW has a service-delimiting VLAN tag. If the frame received by the 7705 SAR from the attachment circuit (AC) does not have a service-delimiting VLAN tag, then the 7705 SAR inserts (pushes) a VLAN tag into the frame header before sending the frame to the SDP and the PW. If the frame received from the AC has a service-delimiting VLAN tag, the tag is replaced.

In tagged mode, when the 7705 SAR detects a failure on the Ethernet physical port or the port is administratively disabled, the 7705 SAR sends a PW status notification message for all PWs associated with the port.

### 4.3.9.3 VLAN Translation

VLAN ID translation is supported, as appropriate. [Table 29](#) (see [Tagging Rules for Epipe](#)) shows the VLAN ID translation operation for the various packet types. The payload part of the packet is shown in parentheses.

The operations to add, strip (remove), or forward the VLAN headers are performed based on the encapsulation type at the ingress of the attachment circuit (the SAP), in the network, and at the egress circuit.

### 4.3.9.4 Tagging Rules for Epipe

Table 27 and Table 28 show the general tagging rules for combinations of interface port type (null, dot1q, or qinq) and Epipe type (Ethernet or VLAN) for SAP ingress and SAP egress directions.

An AC (attachment circuit, ingress or egress) can be configured for one of the following encapsulation types:

- null
- dot1q
- qinq

**Note:**

- Single-tagged Ethernet packets with VLAN ID set to 0 are handled in the same way as other tagged packets.
- For Ethernet VLL SAP-to-SAP with a VLAN SAP, the dot1p header is not popped at ingress. Instead, it is preserved across the ingress and egress ports to ensure dot1p transparency. Dot1q bits are overwritten with configured VLAN information at egress. If there is a matching non-default QoS policy applied at egress, the dot1p bits are re-marked accordingly.

**Table 27 Ingress SAP Tagging Rules**

| Ingress SAP Type <sup>1</sup> | VC Type (Epipe) |                                               |
|-------------------------------|-----------------|-----------------------------------------------|
|                               | Raw (Ethernet)  | Tagged (VLAN)                                 |
| Null                          | No operation    | Push (VC tag)                                 |
| Dot1q                         | Pop (outer tag) | Pop (outer tag)<br>Push (VC tag) <sup>2</sup> |
| QinQ                          | Pop (outer tag) | Pop (outer tag)<br>Push (VC tag)              |

**Notes:**

1. Ingress SAP type is configured at the port level.
2. If the VC tag is not set, then the original tag is preserved. The VC tag is set on the spoke SDP, using the **vlan-vc-tag** command.

**Table 28 Egress SAP Tagging Rules**

| Egress SAP Type <sup>1</sup> | VC Type (Epipe)             |                                             |
|------------------------------|-----------------------------|---------------------------------------------|
|                              | Raw (Ethernet)              | Tagged (VLAN)                               |
| Null                         | No operation                | Pop (VC tag)                                |
| Dot1q                        | Push (SAP tag) <sup>2</sup> | Pop (VC tag)<br>Push (SAP tag) <sup>3</sup> |
| QinQ                         | Push (SAP tags)             | Pop (VC tag)<br>Push (SAP tags)             |

**Notes:**

1. Egress SAP type is configured at the port level.
2. If the SAP tag is 0, then no VLAN tag is pushed.
3. If the SAP tag is 0, then only the pop operation is performed.

**Table 29** shows several examples of how VLAN tags are translated as they flow from ingress to egress. The ingress or egress point can be a SAP or an SDP. For a SAP, encapsulation can be null, dot1q, or qinq; for an SDP, encapsulation (vc-type) can be ether raw or VLAN (tagged). When the SAP encapsulation is dot1q or qinq, outer and inner tags are used.

**Note:** When the SAP type is dot1q or qinq:

- the SAP VLAN tag always delimits the ingress traffic, regardless of the Ethernet VLL type (raw or tagged)
- untagged frames are dropped at the SAP ingress. That is, only the frames with an outer VLAN tag that matches the SAP VLAN tag are forwarded. The exception to this case occurs when the VLAN tag = 0. When a SAP is configured with VLAN ID = 0, any received untagged packets are processed.

**Table 29** VLAN Tagging Examples (Epipe)

| Example | Configuration Settings                                                                                                                      |             |        |              |       |  |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------|-------------|--------|--------------|-------|--|
|         | Rx (Ing)/<br>Tx (Egr)                                                                                                                       | SAP/<br>SDP | Encap. | SAP VLAN Tag |       |  |
|         |                                                                                                                                             |             |        | Outer        | Inner |  |
| 1       | Rx                                                                                                                                          | SAP         | Null   | N/A          | N/A   |  |
|         | Tx                                                                                                                                          | SAP         | Null   | N/A          | N/A   |  |
|         | <b>Result:</b> Untagged, single-, and double-tagged frames are accepted. On egress, all frames are transmitted untouched.                   |             |        |              |       |  |
| 2       | Rx                                                                                                                                          | SAP         | Dot1q  | 252          | N/A   |  |
|         | Tx                                                                                                                                          | SAP         | Null   | N/A          | N/A   |  |
|         | <b>Result:</b> Single- and double-tagged frames are accepted if the outermost VLAN ID matches. On egress, the outermost VLAN tag is popped. |             |        |              |       |  |

## 4.3.10 IP Filters (Epipe)

IP filters are applied to Epipe SAPs in the ingress direction, as described below. For a full list of entities to which IP filters can be applied, see [IP Filter Policies](#).

Ethernet pseudowires are generally used to transparently switch traffic across an MPLS network to the far end. However, in some cases, the traffic that is switched over the network, consuming valuable bandwidth, is just discarded at the other end of the pseudowire. As well, with the 7705 SAR expanding into areas such as vertical markets, and with local area networks being connected to the 7705 SAR Ethernet ports, an increasing amount of traffic must stay local and not pass through the MPLS network to the far end. By using IP filters at the access ingress, operators can determine what traffic is passed through the pseudowire and therefore use the network links more efficiently.

IP filters can also be used for security purposes, by allowing access only to designated services (for example, allowing e-mail and FTP services while disallowing Telnet services) at the origin of the traffic.

IP filter policies specify either a forward or a drop action for packets, based on information specified in the match criteria. Within each filter policy, you can create entries that define matching criteria.

The same IP filter policy can be assigned to any entity (network interfaces, IP pseudowires, Ethernet pseudowires, IES, and VPRN services), all of which can be configured on the same adapter card. For example, a filter policy defined as “filter-5” can be assigned to multiple Epipe SAPs and, simultaneously, to network interfaces on the same adapter card.

A filter policy assigned to an entity on one adapter card can also be assigned to any entity on another adapter card. For example, a filter policy defined as “filter-2” can be assigned to an Epipe on an Ethernet Adapter card and to a network interface on another Ethernet Adapter card.

Assigning the same filter policy to different entities on a card counts as using one filter policy.

Configuration and assignment of filter policies is similar for network interfaces, IES management SAPs, Ethernet and IP pseudowire SAPs, VPRN and IES SAPs and spoke SDPs, and VPLS SAPs and SDPs (spoke and mesh). This guide describes the assignment of filter policies to SAPs and SDPs. Refer to the 7705 SAR Router Configuration Guide, “Filter Policies”, for information on configuring filter policies and assigning them to network interfaces.

---

### 4.3.11 MPLS Entropy Label

For Cpipes, Epipes, and Ipipes, the router supports MPLS entropy labels as per RFC 6790. The entropy label provides greater granularity for load balancing on an LSR where load balancing is typically based on the MPLS label stack.

For more information, refer to the “MPLS Entropy Labels” section in the 7705 SAR MPLS Guide and to the “LAG and ECMP Hashing” section in the 7705 SAR Interface Configuration Guide.

---

## 4.4 Frame Relay VLL (Fpipe) Services

This section provides information about the Fpipe service. Topics in this section include:

- [Fpipe Service Overview](#)
- [Frame Relay SAP-to-SAP Service](#)
- [Frame Relay Traffic Management](#)
- [Frame Relay Encapsulation](#)
- [Status Signaling and OAM Propagation](#)

Fpipe configuration information is treated under the following topics:

- [Common Configuration Tasks](#)
- [Configuring VLL Components](#)
- [Service Management Tasks](#)

See [Service Support](#) for information on the adapter cards and chassis that support frame relay VLL services.

### 4.4.1 Fpipe Service Overview

The frame relay VLL (Fpipe) provides a point-to-point frame relay service between users connected to 7705 SAR nodes or other SR routers over an IP/MPLS network. Users are connected to the 7705 SAR nodes using frame relay PVCs. The 7705 SAR receives a standard Q.922 core frame on the frame relay SAP and encapsulates it into a pseudowire packet according to the one-to-one frame relay encapsulation mode in RFC 4619 *Encapsulation Methods for Transport of Frame Relay over Multiprotocol Label Switching (MPLS) Networks*.

The MPLS tunnel label is used by MPLS LSRs to forward a PW packet from one PE to the other. The PW label identifies one PW (that is, one LSP) assigned to an FR VC in one direction. Together the MPLS tunnel label and PW label form an MPLS label stack, as described in RFC 3032.

The control word contains protocol control information and must be used for any frame relay (Fpipe) pseudowire service in one-to-one mapping mode; see [Frame Relay PW Control Word](#) for more information. The payload field corresponds to X.36/X.76 FR frame information field with the following components removed: bit/byte stuffing, FR header, and FCS. The maximum length of the payload field must be agreed on by the two PEs; this agreement can be achieved by using the MTU interface parameter when the PW is established (RFC 4447).

[Figure 53](#) shows an example of the frame relay VLL end-to-end service.

**Figure 53** FR VLL for End-to-End FR Service

21995

Fpipe SAPs are supported on the following:

- 16-port T1/E1 ASAP Adapter card, version 2
- 32-port T1/E1 ASAP Adapter card
- 4-port DS3/E3 Adapter card
- 12-port Serial Data Interface card
- T1/E1 ports on the 7705 SAR-M (variants with T1/E1 ports)

Before an Fpipe can be configured on an MDA that supports multiple MDA modes, namely the 16-port T1/E1 ASAP Adapter card, version 2, the 32-port T1/E1 ASAP Adapter card, and the 4-port DS3/E3 Adapter card, the **mda-mode** command must be set to **cem-fr-hdlc-ppp**. Likewise, the AC port that is bound to the Fpipe SAP must have the **encap-type** command set to **frame-relay**. Refer to the 7705 SAR Interface Configuration Guide for more information about how to set the **mda-mode** command at the card level and the **encap-type** command at the port/channel level. See [Service Support](#) for more information about the supported chassis and the port- and channel-level configuration requirements.

### 4.4.2 Frame Relay SAP-to-SAP Service

FR VLLs can be configured with both endpoints (SAPs) on the same 7705 SAR, which is referred to as an FR SAP-to-SAP or local FR service. FR SAP-to-SAP emulates local FR switching between two FR endpoints on the same 7705 SAR node.

### 4.4.3 Frame Relay Traffic Management

Traffic management of frame relay VLLs is achieved through the application of ingress and egress QoS policies to SAPs.

#### 4.4.3.1 Ingress SAP Classification and Marking

If the **de-1-out-profile** is configured, DE=1 frames are classified as out-of-profile and are not subject to the CIR marking. All received DE=0 frames that exceed the CIR are marked as out-of-profile and have the DE set to 1 regardless of whether the **de-1-out-profile** command is enabled or disabled. Refer to the 7705 SAR Quality of Service Guide for more information about the **de-1-out-profile** command.

### 4.4.4 Frame Relay Encapsulation

Figure 54 shows the standard FR frame.

Figure 54 FR Frame

21991

Figure 55 shows the one-to-one mapping mode for FR encapsulation over an MPLS network according to RFC 4619. The FR service payload can be *n* octets.

Figure 55 FR PW 1-to-1 MPLS PSN Encapsulation

21992

The native FR PDU is processed as follows:

- Flag—The FR flags are removed during encapsulation.
- FCS—The FCS can use a 2-byte CRC-CCITT or a 4-byte CRC-32. The CRC is configurable. The FCS is removed during encapsulation.
- Frame header—A 2-byte DLCI frame header is supported. The header is removed during encapsulation.
- The F, B, D, and C control bits are copied into the control word as described in [Frame Relay PW Control Word](#).

4.4.4.1 Frame Relay PW Control Word

The control word is required for FR one-to-one mode. Figure 56 shows the FR PW control word.

Figure 56 FR PW Control Word

21993

Table 30 describes the bits used in the FR PW control word.

**Table 30 Control Word Bit Descriptions**

| Bit             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bits 0 to 3     | 4 bits. Bits 0 to 3 are always set to 0 to indicate the presence of the PW.                                                                                                                                                                                                                                                                                                                                                                             |
| F               | Bit 4; FR FECN bit. The F bit is copied from the FR frame.                                                                                                                                                                                                                                                                                                                                                                                              |
| B               | Bit 5; FR BECN bit. The B bit is copied from the FR frame.                                                                                                                                                                                                                                                                                                                                                                                              |
| D               | Bit 6; FR DE bit. The D bit is copied from the FR frame, but can be reset as a result of the ingress frame policy, as described in <a href="#">Frame Relay Traffic Management</a> .                                                                                                                                                                                                                                                                     |
| C               | Bit 7; FR frame C/R bit. The C bit is copied unchanged from the FR frame.                                                                                                                                                                                                                                                                                                                                                                               |
| FRG             | 2 bits (bits 8 and 9).<br>FRG bits are not supported. The bits must be set to 0.                                                                                                                                                                                                                                                                                                                                                                        |
| Length          | 6 bits (bits 10 to 15). If the frame length (defined as the length of the FR Layer 2 payload plus the length of the control word) is less than 64 octets, the length field must be set to the PW payload length. Otherwise, the length field must be set to zero. The value of the length field, if non-zero, is used to remove the padding characters by the egress PE. See the <a href="#">control-word</a> command description for more information. |
| Sequence Number | A 16-bit, unsigned circular space. Sequence numbers provide a mechanism to ensure the ordered delivery of PW packets.<br>The sequence number field is not supported. The sequence number value 0 indicates that the sequence number check algorithm is not used.                                                                                                                                                                                        |

### 4.4.5 Status Signaling and OAM Propagation

The 7705 SAR supports the mapping and notification of defect states between an FR PW and an ACs in accordance with *Pseudowire (PW) OAM Message Mapping draft-ietf-pwe3-oam-msg-map-14.txt*, Section 10. Failures in the network are propagated to the customer edge using LMI messages. LMI and AC failures are propagated to the network using PW status signaling.

---

## 4.5 HDLC VLL (Hpipe) Services

This section provides information about the Hpipe service. Topics in this section include:

- [Hpipe Service Overview](#)
- [HDLC VLL for End-to-End HDLC Service](#)
- [HDLC SAP-to-SAP Service](#)
- [HDLC Encapsulation](#)
- [Status Signaling](#)

Hpipe configuration information is found under the following topics:

- [Common Configuration Tasks](#)
- [Configuring VLL Components](#)
- [Service Management Tasks](#)

See [Service Support](#) for information on the adapter cards and chassis that support HDLC VLL services.

### 4.5.1 Hpipe Service Overview

An HDLC PW is used to carry HDLC PDUs over an MPLS network. HDLC PWs enable service providers to offer emulated HDLC services over existing MPLS networks.

HDLC mode provides port-to-port transport of HDLC-encapsulated traffic. The HDLC PDU is transported in its entirety, including the HDLC address and control fields, but the HDLC flags and the FCS are excluded. If the optional control word is used, the flag bits in the control word are not used and must be set to 0 for transmitting and must be ignored upon receipt.

HDLC PWs are implemented in accordance with RFC 4618.

Hpipe SAPs are supported on the following:

- 16-port T1/E1 ASAP Adapter card, version 2
- 32-port T1/E1 ASAP Adapter card
- 12-port Serial Data Interface card
- T1/E1 ports on the 7705 SAR-M (variants with T1/E1 ports)

Before HDLC SAPs can be configured on the 16-port T1/E1 ASAP Adapter card, version 2, and the 32-port T1/E1 ASAP Adapter card, the **mda-mode** command must be set to **cem-fr-hdlc-ppp** at the card level. Refer to the 7705 SAR Interface Configuration Guide for more information about how to set the **mda-mode** command. See [Service Support](#) for more information about the supported chassis and the port- and channel-level configuration requirements.

Only ports that are configured with HDLC encapsulation can be mapped to an Hpipe SAP. HDLC encapsulating ports do not terminate the HDLC. The ports pass the HDLC frames through the Hpipe. HDLC encapsulated ports can pass through any HDLC-framed traffic, such as Cisco-HDLC, FR, PPP, and so on.

HDLC encapsulation can be used on a port to transmit Cisco-HDLC frames over an H-pipe. To transport Cisco-HDLC traffic over an Hpipe, the attachment circuit (AC) port that is bound to the Hpipe SAP must have the **encap-type** command set to **hdlc**, not **cisco-hdlc**. Refer to the 7705 SAR Interface Configuration Guide for more information about how to set the **encap-type** command.

**Note:** A Cisco-HDLC encapsulating port cannot be bound to an Hpipe SAP. A Cisco-HDLC encapsulating port can only be bound to an Ipipe SAP. See [IP Interworking VLL \(Ipipe\) Services](#) for more information.

## 4.5.2 HDLC VLL for End-to-End HDLC Service

[Figure 57](#) shows an example of how a mobile operator can deploy end-to-end HDLC services over an MPLS network.

**Figure 57** HDLC VLL for End-to-End HDLC Service

21994

In [Figure 57](#), the CE (an ATM switch) transmits HDLC PDUs and receives HDLC PDUs over the physical layer between the CE and a 7705 SAR (PE1). The native service processing (NSP) function in PE1 performs the packet processing, such as bit stuffing, PW-PW bridging, L2 encapsulation, shaping, and policing, for the HDLC packets that are forwarded to the PW termination point in PE1. The PW, which terminates at a logical port in the PE1, delivers the unaltered HDLC packets that are received across the MPLS network to the corresponding logical port on PE2 at the other end of the PW.

The PW termination points on each PE represent the operations that establish and maintain the PW and that encapsulate and decapsulate the HDLC packets. For more information, refer to the PW reference diagram packet processing that supports the HDLC PW as described in RFC 4618.

### 4.5.3 HDLC SAP-to-SAP Service

HDLC VLLs can be configured with both endpoints (SAPs) on the same 7705 SAR, which is referred to as an HDLC SAP-to-SAP or local HDLC service. HDLC SAP-to-SAP emulates local HDLC switching between two endpoints on the same 7705 SAR node.

#### 4.5.4 HDLC Encapsulation

Figure 58 shows a typical HDLC VLL frame.

**Figure 58 HDLC VLL Frame**

21988

Figure 59 shows a typical HDLC VLL frame together with its MPLS tunnel encapsulation.

**Figure 59 HDLC VLL Frame with MPLS Encapsulation**

21989

The native HDLC PDU is processed as follows:

- Flag—the HDLC flags are removed during encapsulation
- FCS—the FCS can use a 2-byte CRC-CCITT or a 4-byte CRC-32. The CRC is configurable. The default value is 2-byte. The FCS is removed during encapsulation.
- Address—HDLC address is retained
- Control—HDLC control is retained

The MPLS tunnel is used to transport the encapsulated HDLC across the PSN and the PW header is appended to the modified HDLC PDU as described in RFC 4618. The HDLC control word is inserted in the frame before the HDLC payload. See [HDLC PW Control Word and Payload Size](#) for information.

#### 4.5.4.1 HDLC PW Control Word and Payload Size

HDLC VLLs support an optional control word (CW). The control word must be used for any HDLC (Hpipe) pseudowire service that transports packets that are less than 64 bytes.

To switch frames through the 7705 SAR switch fabric, the frame size must be 64 bytes or larger. If the HDLC frames received at the SAP are not 64 bytes or larger, the 7705 SAR pads the HDLC payload at the access ingress to ensure that the HDLC payload can be passed through the switch fabric and transported properly across the network. When padding occurs, the size of the original payload must be indicated in the length field of the control word so that at the termination of the HDLC PW, the far-end device can correctly determine the actual size of the HDLC payload, remove the padding, and forward the original, non-padded HDLC payload to the access egress. See RFC 4618, section 4.1 part-2. [Figure 60](#) shows the HDLC PW control word.

Figure 60 HDLC PW Control Word

21990

Table 31 describes the bits used in the HDLC PW control word.

Table 31 Control Word Bit Descriptions

| Bit             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bits 0 to 3     | The use of bits 0 to 3 is described in RFC 4385. The bits are always set to 0 to indicate the presence of the CW.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Flags           | 4 bits (bits 4 to 7). No flags are defined for the HDLC PW. The bits must be set to 0 and must be ignored by the PE.                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| FRG             | 2 bits (bits 8 and 9). FRG bits are not supported. The bits must be set to 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Length          | 6 bits (bits 10 to 15). The length represents the combined size of the CW and the HDLC payload. If the combined size is less than 64 bytes, this field must be populated to indicate the actual size of the HDLC payload that is received at the access ingress. At the access egress, this field is used to strip bytes that are appended for padding purposes. If the combined size of the CW and the HDLC payload exceeds 64 bytes, all bits in this field must be set to 0. See the <a href="#">control-word</a> command description for more information. |
| Sequence Number | The sequence number is used to provide the common PW sequencing function as well as detection of lost packets. The sequence number field is not supported on the 7705 SAR.                                                                                                                                                                                                                                                                                                                                                                                     |

See [Pseudowire Control Word](#) for more information.

---

## 4.5.5 Status Signaling

The HDLC PW supports status signaling in accordance with RFC 4618, section 5.1. When the PE detects a status change in the attachment circuit (AC) status, such as an AC physical link failure, or if the AC is administratively disabled, the PE sends the appropriate PW status notification message that corresponds to the HDLC AC status. The local PW status is also reflected in a PW status notification message, as described in RFC 4447, section 5.4.

### 4.5.5.1 OAM Propagation

The 7705 SAR supports OAM propagation between AC SAPs and the PW and vice-versa. For example, if no viable tunnel exists from the AC to the eLER, the status of the local SAP is set to the down state. Likewise, when a local SAP fails, the 7705 SAR sends a PW status message informing the far end of an AC ingress/egress fault. The far-end eLER then sets the status of the service and the SAP to the down state.

---

## 4.6 IP Interworking VLL (Ipipe) Services

This section provides information about the Ipipe service.

Topics in this section include:

- [Ipipe Service Overview](#)
- [IP Interworking VLL Datapath](#)
- [CE IP Address Discovery and Distribution](#)
- [IP SAP-to-SAP Service](#)
- [Hardware Support for Interworking IP PWs](#)
- [Control Word](#)
- [Termination at Access](#)
- [Traffic Management](#)
- [Status Signaling](#)
- [IP Filters \(Ipipe\)](#)

Ipipe configuration information is found under the following topics:

- [Common Configuration Tasks](#)
- [Configuring VLL Components](#)
- [Service Management Tasks](#)

See [Service Support](#) for information on the adapter cards and chassis that support IP interworking VLL services.

## 4.6.1 Ipipe Service Overview

An Ipipe pseudowire (IP PW) enables service interworking between different link layer technologies and network interworking between connections with the same link layer technologies. IP PWs provide an efficient means to connect Layer 3 IP traffic to the IP/MPLS network, even without access to VLANs.

An Ipipe is a point-to-point Layer 2 service where the customer data is encapsulated and transported across an MPLS or IP network. An Ipipe service transparently forwards all packets received on one SAP to the other SAP. No native IP routing of customer packets occurs.

IP interworking allows connections to be created with any combination of PPP, MLPPP, Ethernet, LAG, FR, and Cisco HDLC (cHDLC) SAPs, but the payload must always be IP. Ipipes can be used to transport IP payloads more efficiently than Epipes because an Ipipe service does not need to forward the Ethernet header information.

Figure 61 shows an example of IP connectivity between a host attached to a point-to-point access circuit (FR, cHDLC, and PPP) with routed PDU IPv4 encapsulation and a host attached to an Ethernet interface. Both hosts are on the same LAN segment.

**Figure 61 IP Pseudowires Between SAR Nodes**

21996

A frame relay SAP makes use of RFC 2427, *Multiprotocol Interconnect over Frame Relay, routed PDU encapsulation of an IPv4 packet*. A PPP interface makes use of RFC 1332, *The PPP Internet Protocol Control Protocol (IPCP)*, for PPP IPCP encapsulation of an IPv4 packet. A Cisco HDLC SAP uses the routed IPv4 encapsulation. The PW uses the IP Layer 2 transport pseudowire encapsulation type.

## 4.6.2 IP Interworking VLL Datapath

In order to be able to forward IP packets between CE 1 and CE 3 in [Figure 61](#), PE 2 is configured with both CE 1 and CE 3 IP addresses. These are host addresses and are entered in the /32 format.

**Note:** Addresses can be configured manually or by using CE Address discovery.

PE 2 maintains an ARP cache context for each IP interworking VLL and responds to ARP request messages received on the Ethernet SAP. PE 2 responds with the Ethernet SAP configured MAC address as a proxy for any ARP request for the CE 1 IP address. PE 2 silently discards any ARP request messages received on the Ethernet SAP for addresses other than CE 1. Likewise, PE 2 silently discards any ARP request messages with source IP addresses other than CE 3. In all cases, PE 2 keeps track of the association of IP to MAC addresses for ARP requests it receives over the Ethernet SAP. All entries are subject to aging.

In order to forward unicast frames destined for CE 3, PE 2 needs to know the MAC address of CE 3. If there is no entry in the ARP cache, PE 2 sends an ARP request message for the CE 3 MAC address over the Ethernet SAP.

IP broadcast and IP multicast packets are sent on the Ethernet SAP using the broadcast or direct-mapped multicast MAC address.

In order to forward unicast frames destined for CE 1, PE 2 validates the MAC destination address of the received Ethernet frame. It should match that of the Ethernet SAP. PE 2 then removes the Ethernet header and encapsulates the IP packet directly into a pseudowire with or without the optional control word. PE 1 removes the pseudowire encapsulation and forwards the IP packet over the SAP using PPP encapsulation.

When a packet reaches the access egress and the configured SAP is over a VLAN, the node pushes (inserts) the appropriate VLAN tag into the Ethernet frame header before forwarding the Ethernet frame out of the port. Ethernet frames at the access egress can also be marked with appropriate dot1 priority bits if the dot1 priority QoS profile is assigned to the forwarding class configuration.

Ethernet frames mapped to an lpipe service can have a maximum of two VLAN tags. Frames with more than two VLAN tags are dropped at the lpipe access ingress SAP.

At access ingress, PE 1 performs proxy PPP negotiation and provides the IP address of the remote CE 3 device to CE 1 during IPCP negotiation using the IP-Address option.

A PE does not flush the ARP cache unless the SAP goes administratively or operationally down. The PE with the Ethernet SAP sends unsolicited ARP requests to refresh the ARP cache according to the refresh interval. ARP requests are staggered at an increasing rate if no reply is received to the first unsolicited ARP request. The refresh interval is configurable using the **mac-refresh** CLI command.

### 4.6.3 CE IP Address Discovery and Distribution

The following subsections describe the customer edge (CE) IP address discovery methods and how the CE IP address is distributed to remote PE nodes. Topics include:

- [Manual IP Configuration](#)
- [CE IP Address Discovery Using ARP](#)
- [CE IP Address Discovery for Frame Relay](#)
- [CE IP Address Discovery for cHDLc](#)
- [CE IP Address Discovery for PPP/MLPPP](#)
- [CE IP Address Distribution to Remote PE Nodes](#)

#### 4.6.3.1 Manual IP Configuration

Manually configured IP addresses are supported for all attachment circuit types. No further mechanisms for detecting the local or remote CE IP address are required. The PE responds to all ARP requests arriving on Ethernet attachment circuits by replying with the local interface MAC address and the remote CE IP address.

---

### 4.6.3.2 CE IP Address Discovery Using ARP

Ethernet attachment circuits can be configured to use ARP messages that are received from the CE device to determine the local CE IP address. The PE waits for an ARP request from the CE in order to learn the IP address that is associated with the MAC address of the CE. When a valid ARP request is received by the PE from the CE, the ARP cache on the PE is populated with the CE IP/MAC entry. The PE accepts any ARP request message that it receives over the Ethernet SAP and updates the ARP cache entries with no further check. The PE does not validate the source IP address of the ARP request message nor does it try to match the IP address in the ARP request with the programmed IP address.

The 7705 SAR always replies to an ARP request message that is received over the Ethernet SAP. The 7705 SAR replies with the SAP MAC address and a source IP address of the IP address being ARPed without any further check of the latter.

If the SAP status changes to operationally down or if an operator manually clears the ARP cache, the system flushes the ARP cache and the CE address discovered on the SAP is cleared. When the SAP comes into service initially or after a failure, an unsolicited ARP request is not sent over the Ethernet SAP. In the case where multiple ARP messages are received from different CE devices, the last received message prevails and the ARP cache is populated with the newly received information.

An SNMP trap is generated whenever an ARP entry or IPv4 CE address entry is discovered or changed for an lpipe service.

Prior to Release 7.0, lpipe IPv4 ARP packets were transmitted by bypassing the service SAPs. These packets are now sent using the service SAP. This enables normal service SAP functions such as QoS, statistics, and filtering to apply to these packets.

### 4.6.3.3 CE IP Address Discovery for Frame Relay

Frame relay access circuits use INVARP to learn a local CE address and to propagate the remote CE address.

### 4.6.3.4 CE IP Address Discovery for cHDLc

The cHDLc access circuits do not need to discover the IP address of the local and remote CE for point-to-point interfaces. The IP addresses remain 0.0.0.0.

---

### 4.6.3.5 CE IP Address Discovery for PPP/MLPPP

The address of a locally attached CE device can be learned via IPCP. If the lpipe uses a spoke SDP, when the 7705 SAR sends the label mapping message, this learned address is not included in the address list TLV in the interface parameters field of the pseudowire FEC TLV.

### 4.6.3.6 CE IP Address Distribution to Remote PE Nodes

The PE includes an IP address list TLV in the label mapping message of the PW FEC in order to communicate the local CE IP address to the remote PE. If the IP address is set to 0.0.0.0, it is assumed that the connected CE IP address is unknown. For point-to-point connections such as frame relay and cHDLC, an IP address of 0.0.0.0 does not affect the PW status or stop the flow of IP traffic through the lpipe. Broadcast interfaces such as Ethernet must learn the local CE IP address and MAC relationship before unicast traffic can be sent, but the remote PE IP address can remain as 0.0.0.0. The value of the remote PE IP address is always 0.0.0.0 when the remote PE access circuit is PPP/MLPPP (IPCP) or cHDLC.

If the CE IP address changes, an LDP notification message is sent to the remote PE with the new IP address of the CE.

## 4.6.4 IP SAP-to-SAP Service

IP VLLs can be configured with both endpoints (SAPs) on the same 7705 SAR, which is referred to as an IP SAP-to-SAP or local IP service. IP SAP-to-SAP emulates local IP switching between two endpoints on the same 7705 SAR node.

## 4.6.5 Hardware Support for Interworking IP PWs

[Table 32](#) lists the hardware that supports interworking IP PWs.

**Table 32**      **Hardware Support for Interworking PWs**

| MDA Type                                   | Interworking PWs |              |                |                   |             |                |              |
|--------------------------------------------|------------------|--------------|----------------|-------------------|-------------|----------------|--------------|
|                                            | Eth to IP PW     | PPP to IP PW | MLPPP to IP PW | MC-MLPPP to IP PW | FR to IP PW | cHDLC to IP PW | ATM to IP PW |

## 4.6.6 Control Word

IP interworking VLLs support an optional control word. The control word may be required to interoperate with devices at the far end. If the control word is enabled, it is set to all zeros and ignored on egress.

See [Pseudowire Control Word](#) for more information.

## 4.6.7 Termination at Access

The following sections describe the termination requirements and features for interworking pseudowires. Topics include:

- [PPP and MLPPP Termination](#)
- [FR Termination](#)
- [cHDLCL Termination](#)
- [PPP and MLPPP Termination on 2-port OC3/STM1 Channelized Adapter Cards](#)

### 4.6.7.1 PPP and MLPPP Termination

For PPP termination, ports must be configured in access mode with IPCP encapsulation. Access ports on the 12-port Serial Data Interface card or 2-port OC3/STM1 Channelized Adapter card must be configured with IPCP encapsulation to support PPP/MLPPP termination for an interworking pseudowire. The ppp-auto encapsulation type applies only to network-side terminations.

### 4.6.7.2 FR Termination

The following features are supported for FR termination:

- ports must be configured for access mode according to Q.922 Annex A frame format
- RFC 2427, *Multiprotocol Interconnect over Frame Relay, routed PDU encapsulation of an IPv4 packet*
- UNI DCE and DTE
- NLPID (0xCC) IPv4 encapsulation
- LMI (see [FR LMI](#))

- configurable service MTU of 1 to 2048 bytes. When encapsulated in the IPv4 PDU, the FR flags, FCS, and FR header are removed. The resulting data is the lpipe payload represented in the IP Datagram field in [Figure 62](#).

**Figure 62** FR Header with NLPID Support for IP Interworking PW

21997

4.6.7.3 cHDLC Termination

The following features are supported for cHDLC termination:

- ports must be configured for access mode according to the cHDLC frame format. Refer to the 7705 SAR Interface Configuration Guide for information about how to configure the **encap-type** command to **cisco-hdlc**.
- IP encapsulation (0x0800). [Figure 63](#) shows the cHDLC header frame.
- keepalive support using SLARP (0x8035). [Figure 64](#) shows the SLARP keepalive frame.
- configurable service MTU of 1 to 2048 bytes. When encapsulated in the IPv4 PDU, the cHDLC packet shown in [Figure 63](#) is modified to remove the flag, address, control, protocol ID, and FCS.

**Figure 63** cHDLC Header Frame

21998

**Note:** cHDLC encapsulation cannot be used to transmit HDLC frames into an Ipipe.

**Figure 64 SLARP Keepalive Frame**

21999

Refer to the 7705 SAR Interface Configuration Guide for more information about how to configure access ports for interworking IP PWs.

**4.6.7.4 PPP and MLPPP Termination on 2-port OC3/STM1 Channelized Adapter Cards**

One use for PPP and MLPPP termination to IP pseudowires is in fixed backhaul networks with customers connected to the network via DS1/E1 or *n* x DS1/E1 rates.

Figure 65 shows an example of a network using PPP and MLPPP encapsulation to IP PWs on a 2-port OC3/STM1 Channelized Adapter card.

**Figure 65 PPP and MLPPP to IP PWs on 2-port OC3/STM1 Channelized Adapter Cards**

22349

Customer traffic aggregation remains on the available SONET/SDH infrastructure and is sent to a 2-port OC3/STM1 Channelized Adapter card on the 7705 SAR, where the PPP/MLPPP encapsulation termination takes place. Using an IP PW with PPP/MLPPP encapsulation from a SAP-to-VLAN SAP, the 7705 SAR passes the data to a 7750 SR. The 7750 SR offers the necessary scale of IP services, such as IES or VPRN, needed to handle the large amount of traffic coming from each OC3/STM1 port.

After terminating PPP/MLPPP encapsulated traffic on a channelized OC3/STM1 port, the 7705 SAR switches the IP traffic, without performing any IP lookup, to another SAP over an Ipipe. IP traffic is then passed on to the 7750 SR with a unique VLAN identifier on a per-connection basis.

Refer to the 7705 SAR Interface Configuration Guide for more information about how to configure 2-port OC3/STM1 Channelized Adapter card ports for interworking IP PWs and PPP/MLPPP termination.

## 4.6.8 Traffic Management

### 4.6.8.1 Traffic Management for FR IW SAPs

Traffic management of interworking SAPs is achieved by applying ingress and egress QOS policies to SAPs. Access ingress forwarding classes are determined by inspecting the DSCP marking of the IP packets to determine the queuing and the EXP bit setting of packets. If all traffic for a DLCI must be classified as a single forwarding class, you can define a policy to classify all DSCP values from the IP header to one forwarding class.

## 4.6.9 Status Signaling

### 4.6.9.1 FR LMI

LMI enables the exchange of information between the CE and the LER about the status of the link, device, and logical circuit. The frame relay CE device (the DTE) begins an LMI exchange by sending a Status Enquiry message. DTE status enquiry message supports link integrity verification requests. The frame relay network (the DCE) completes the exchange by responding with a Status message.

The DCE status messages support the following response types:

- full status
- link integrity verification
- single PVC status

The LMI protocol operates over a dedicated PVC of a frame relay link. Since LMI occupies its own PVC, its link signaling cannot congest or interfere with traffic on the PVCs that carry subscriber data.

The following standards are supported:

- ANSI T.617 Annex D
- ITU-T Q.922 Annex A
- Cisco Rev.1

---

## 4.6.10 IP Filters (Ipipe)

IP filters are applied to Ipipe SAPs in the ingress direction, as described below. For a full list of entities to which IP filters can be applied, see [IP Filter Policies](#).

IP pseudowires are generally used to transparently switch traffic across an MPLS network to the far end. However, in some cases, the traffic that is switched over the network, consuming valuable bandwidth, is just discarded at the other end of the pseudowire. As well, with the 7705 SAR expanding into areas such as vertical markets, and with local area networks being connected to the 7705 SAR Ethernet ports, an increasing amount of traffic must stay local and not pass through the MPLS network to the far end. By using IP filters at the access ingress, operators can determine what traffic is passed through the pseudowire and therefore use the network links more efficiently.

Another use for IP filters is in cases where a customer router is connected to an access port on the 7705 SAR with PPP/MLPPP encapsulation. The service provider may want to filter incoming traffic from the customer at the boundaries of the network.

IP filters can also be used for security purposes, by allowing access only to designated services (for example, allowing e-mail and FTP services while disallowing Telnet services) at the origin of the traffic.

IP filter policies specify either a forward or a drop action for packets, based on information specified in the match criteria. Within each filter policy, you can create entries that define matching criteria.

The same IP filter policy can be assigned to any entity (network interfaces, IP pseudowires, Ethernet pseudowires, IES, and VPRN services), all of which can be configured on the same adapter card. For example, a filter policy defined as “filter-5” can be assigned to multiple Ipipe SAPs and, simultaneously, to network interfaces on the same adapter card.

A filter policy assigned to an entity on one adapter card can also be assigned to any entity on another adapter card. For example, a filter policy defined as “filter-2” can be assigned to an Ipipe on an Ethernet Adapter card and to a network interface on another Ethernet Adapter card.

Assigning the same filter policy to different entities on a card counts as using one filter policy.

---

Configuration and assignment of filter policies is similar for network interfaces, IES management SAPs, Ethernet and IP pseudowire SAPs, VPRN and IES SAPs and spoke SDPs, and VPLS SAPs and SDPs (spoke and mesh). This guide describes the assignment of filter policies to SAPs and SDPs. Refer to the 7705 SAR Router Configuration Guide, “Filter Policies”, for information on configuring filter policies and assigning them to network interfaces.

---

## 4.7 Pseudowire Switching

Topics in this section include:

- [Overview](#)
- [Pseudowire Switching with Pseudowire Redundancy](#)
- [Pseudowire Switching Behavior](#)
- [Pseudowire Switching TLV](#)

### 4.7.1 Overview

The pseudowire switching feature provides the user with the ability to create a VLL service by cross-connecting two spoke SDPs.

Services with one SAP and one spoke SDP are created normally on the PE; however, when a pseudowire originates at customer equipment and not the 7705 SAR, the target destination of the SDP is the 7705 SAR pseudowire switching node instead of the remote PE. In such cases, the user must configure a VLL service on the pseudowire switching node (the 7705 SAR, in this case) using the two SDPs and no SAP. This creates a VLL service that travels over two different types of tunnels. The first pseudowire segment connects the Node B to the 7705 SAR, and the second segment connects the 7705 SAR to a 7750 SR node. [Figure 66](#) shows an example of a VLL pseudowire switching service.

For the 7750 SR node, there is no implementation change required. The pseudowire segment is treated as a 7705 SAR-initiated dynamic ATM pseudowire. The 7705 SAR signals for the ATM pseudowire and negotiates all required parameters, including the pseudowire label, control word, and VCCV type.

The pseudowire switching node acts in a passive role with respect to signaling of the pseudowires. The node waits until one or both of the PEs send the label mapping message before relaying it to the other PE. This is because it needs to pass the interface parameters of each PE to the other. For example, the 7705 SAR assumes the pseudowire payload from the Node B, then signals for the ATM pseudowire to the far end and negotiates all required parameters, including the pseudowire label, control word, and VCCV type.

The switching pseudowire inserts a pseudowire switching point TLV indicating the system address in the label mapping message. This TLV is useful because it allows for troubleshooting of the path of the pseudowire, especially if multiple pseudowire switching points exist between the two PEs. The TLV also helps in loop detection of T-LDP signaling messages, where a switching point receives a label mapping message that it already relayed. The switching point TLV is inserted in pseudowire status notification messages when they are sent end-to-end or from a pseudowire switching node towards a destination PE. See [Pseudowire Switching TLV](#) for more information.

Pseudowire OAM is supported for dynamic switching pseudowires and allows the 7705 SAR pseudowire switching node to relay end-to-end pseudowire status notification messages between the two PEs. The 7705 SAR can generate a pseudowire status and send it to one, or both, of the PEs by including its system address in the pseudowire switching point TLV. This allows a 7705 SAR PE to identify the origin of the pseudowire status notification message.

The pseudowire segment between the 7705 SAR and the 7750 SR supports OAM tools as well as BFD; however, since Node Bs are not dual-homed, OAM tools operating on this pseudowire segment can only provide informative messages. The 7705 SAR responds to Node B-initiated ping packets if the destination IP address is the system IP or interface IP address of the 7705 SAR. If the IP packet does not contain a SAR destination IP address, the 7705 SAR does not respond, and instead, forwards the packet.

[Figure 66](#) shows an example of static-simplex to dynamic-simplex pseudowire switching. This service consists of a SAP and a spoke SDP. However, the target destination of the SDP is not the remote PE but the pseudowire switching node. In addition, the user configures a VLL service on the pseudowire switching node using the two SDPs.

**Figure 66 Simplex to Simplex Pseudowire Switching**

20772

Configuration examples can be found in [Configuring PW Switching](#).

[Table 33](#) shows the pseudowire switching options supported on the 7705 SAR.

**Table 33 Supported Pseudowire Switching Options**

| PW Segment 1                             |                     | PW Segment 2                             |                                               |        |        |        |        |        |          |             |
|------------------------------------------|---------------------|------------------------------------------|-----------------------------------------------|--------|--------|--------|--------|--------|----------|-------------|
| Tunnel                                   | PW                  | Tunnel                                   | PW                                            | E-pipe | F-pipe | H-pipe | I-pipe | A-pipe | Cpipe-cs | Cpipe-satop |
| RSVP-TE, LDP, Static MPLS, IP, or GRE/IP | Static              | RSVP-TE, LDP, Static MPLS, IP, or GRE/IP | T-LDP (with or without pseudowire redundancy) | ✓      | ✓      | ✓      | ✓      | ✓      | ✓        | ✓           |
| RSVP-TE, LDP, Static MPLS, IP, or GRE/IP | T-LDP               | RSVP-TE, LDP, Static MPLS, IP, or GRE/IP | T-LDP                                         | ✓      | ✓      | ✓      | ✓      | ✓      | ✓        | ✓           |
| IP                                       | Static <sup>1</sup> | MPLS-Static                              | Static <sup>1</sup>                           | ✓      | ✓      | ✓      | ✓      | ✓      | ✓        | ✓           |

**Note:**

1. A static- to-static pseudowire switching service will fail if there is more than one S-PE node between the T-PE nodes.

The 7705 SAR supports use of an optional control word on both pseudowire segments. Use of a control word is negotiated by the 7705 SAR and 7750 SR during the signaling phase. The 7705 SAR and 7750 SR negotiate during the signaling phase even if a control word is not used. If a control word is used, the 7705 SAR generates it and configures it with all 0s.

When the 7705 SAR appends or strips the control word to support VCCV ping type 1, the TTL value of the switched pseudowire is reset to 255. If the control word is present on the ingress pseudowire packet and it is not removed because it is on an end-to-end service, the 7705 SAR reduces the pseudowire TTL by 1 at the time of pseudowire switching.

## 4.7.2 Pseudowire Switching with Pseudowire Redundancy

Pseudowire switching with pseudowire redundancy supports one redundant pseudowire with up to four redundant spoke SDPs. [Figure 67](#) shows an example of a network with simplex to redundant pseudowire switching.

**Figure 67** Simplex to Redundant Pseudowire Switching

20773

To enable pseudowire redundancy, the first pseudowire segment must be a static pseudowire (that is, T-LDP disabled). The second pseudowire segment can then be configured with up to four redundant spoke SDPs. See [Pseudowire Redundancy](#) for instructions on configuring redundancy. Pseudowire switching with pseudowire redundancy also supports standby signaling. See [Active/Standby Mode for Pseudowire Redundancy \(Standby Signaling\)](#) for more information.

### 4.7.3 Pseudowire Switching Behavior

In the network in [Figure 68](#), T-PE nodes act as masters and pseudowire switching nodes (S-PE nodes) act as slaves for the purpose of pseudowire signaling. Switching nodes need to pass the SAP interface parameters of each PE to the other PE. T-PE1 sends a label mapping message for the Layer 2 FEC to the peer pseudowire switching node; for example, S-PE1. It includes the SAP interface parameters, such as MTU, in the label mapping message. S-PE1 checks the FEC against the local information, and if a match exists, it appends the optional pseudowire switching point TLV to the FEC TLV in which it records its system address. T-PE1 then relays the label mapping message to S-PE2. S-PE2 performs a similar operation and forwards a label mapping message to T-PE2.

**Figure 68 Pseudowire Switching Network**

20905

The same procedures are followed for the label mapping message in the reverse direction; for example, from T-PE2 to T-PE1. S-PE1 and S-PE2 will affect the spoke SDP cross-connect only when both directions of the pseudowire have been signaled and matched.

Pseudowire status notification messages can be generated by the T-PE nodes and/or the S-PE nodes. Pseudowire status notification messages received by a switching node are processed and then passed on to the next hop. An S-PE node appends the optional pseudowire switching TLV, with its system address added to it, to the FEC in the pseudowire status notification message only if it originated the message or the message was received with the TLV in it. If the S-PE node is not the originator or if there is no TLV with the system address in the message, this means that the message was originated by a T-PE node. In this case, the S-PE processes and passes the message without changes except for the VC ID value in the FEC TLV.

The merging of the received T-LDP status notification message and the local status for the spoke SDPs from the service manager at a 7705 SAR PE complies with the following rules.

- When the local status for both spokes is up, the S-PE passes any received SAP or SDP-binding generated status notification message unchanged. For example, the status notification TLV is unchanged but the VC-ID in the FEC TLV is set to the value of the pseudowire segment to the next hop.
- When the local operational status for any of the spokes is down, the S-PE always sends SDP-binding down status bits regardless if the received status bits from the remote node indicated SAP up or down or SDP-binding up or down.

When one segment of the pseudowire cross-connect at the S-PE is static while the other is signaled using T-LDP, the S-PE operates much like a T-PE from a signaling perspective and as an S-PE from a data plane perspective. The S-PE signals a label mapping message as soon as the local configuration is complete. The control word C-bit field in the pseudowire FEC is set to the value configured on the static spoke SDP.

When the label mapping for the egress direction is also received from the T-LDP peer, and the information in the FEC matches that of the local configuration, the static-to-dynamic cross-connect is established.

In a static-to-dynamic pseudowire switching service, it is possible for the end nodes of the static pseudowire segment to be misconfigured. In this case, an S-PE or T-PE node may receive packets with the wrong encapsulation. If this happens, an invalid payload might be forwarded over the pseudowire or the SAP respectively.

Furthermore, if the S-PE or T-PE node is expecting the control word in the packet encapsulation, and the received packet arrives with no control word but the first nibble below the label stack is 0x0001, the packet may be mistaken for a VCCV OAM packet and may be forwarded to the CSM. In that case, the CSM will perform a check of the IP header fields. If any of the fields fail the check, the VCCV packet will be discarded.

### 4.7.3.1 Pseudowire Switching With IP Tunnels

You cannot enable T-LDP dynamic pseudowire establishment on pseudowire switching segments using IP tunnels if the second pseudowire segment is configured for pseudowire redundancy. The pseudowire label, control word, VCCV type, and so on, must be configured manually.

On the first pseudowire segment, ATM pseudowires are natively transported over IP using GRE encapsulation with the IP type set to 0x8847, or IP encapsulation. The destination IP address of pseudowire packets received from the Node B must be set to the system IP or interface IP address of the 7705 SAR. Similarly, the destination IP address of pseudowire packets received from the 7750 SR must be set to the system IP or interface IP address of the Node B. Node B management traffic is transported over the same Ethernet link between the 7705 SAR and the Node B. The 7705 SAR forwards the management IP traffic to its destination based on longest prefix match.

On the second pseudowire segment, ATM pseudowires are transported over MPLS tunnels. The MPLS tunnels can also be used to transport additional cell site traffic, such as BTS traffic using TDM pseudowires, or LTE base station traffic using IP or Ethernet pseudowires.

## 4.7.4 Pseudowire Switching TLV

[Figure 69](#) shows the format of the pseudowire switching TLV and [Table 34](#) describes the fields.

Figure 69 Pseudowire Switching TLV

21834

Table 34 Pseudowire Switching TLV Field Descriptions

| Field            | Description                                                                                             |
|------------------|---------------------------------------------------------------------------------------------------------|
| PW sw TLV Length | Specifies the total length of all the following pseudowire switching point TLV fields in octets         |
| Type             | Encodes how the Value field is to be interpreted                                                        |
| Length           | Specifies the length of the Value field in octets                                                       |
| Value            | Octet string of Length octets that encodes information to be interpreted as specified by the Type field |

The following list describes details specific to pseudowire switching point sub-TLVs:

- pseudowire ID of last pseudowire segment traversed
- pseudowire switching point description string—an optional description string of text up to 80 characters long
- IP address of pseudowire switching point—an optional sub-TLV containing the IPv4 address of the pseudowire switching point
- MH VCCV capability indication

---

## 4.8 VLL Service Considerations

This section describes the general 7705 SAR service features and any special capabilities or considerations as they relate to VLL services.

Topics in this section include:

- [Service Support](#)
- [SDPs](#)
- [SAP Encapsulations and Pseudowire Types](#)
- [ATM PWE3 N-to-1 Cell Mode Encapsulation](#)
- [SAP Aggregation Groups](#)
- [QoS Policies](#)
- [IP Filter Policies](#)
- [MTU Settings](#)
- [QinQ \(VLL Service\)](#)
- [Pseudowire Control Word](#)
- [Pseudowire Redundancy](#)
- [Active/Standby Mode for Pseudowire Redundancy \(Standby Signaling\)](#)

### 4.8.1 Service Support

The section describes hardware support for the following VLL services:

- ATM
- Ethernet
- Frame relay
- TDM
- HDLC
- IP interworking

**ATM**

ATM VLL service is supported on the following:

- T1/E1 ports on the 2-port OC3/STM1 Channelized Adapter card (when the port is configured for ATM or IMA)
- T1/E1 ports on the 4-port DS3/E3 Adapter card (when the port is configured for ATM or IMA)
- 4-port OC3/STM1 Clear Channel Adapter card (when the port is configured for ATM)
- 16-port T1/E1 ASAP Adapter card (when the port is configured for ATM or IMA)
- 32-port T1/E1 ASAP Adapter card (when the port is configured for ATM or IMA)
- T1/E1 ports on the 7705 SAR-M (variants with T1/E1 ports)

**Ethernet**

Ethernet VLL service is supported on the following:

- 6-port Ethernet 10Gbps Adapter card
- 8-port Ethernet Adapter card
- 8-port Gigabit Ethernet Adapter card
- 10-port 1GigE/1-port 10GigE X-Adapter card
- Ethernet ports on the 7705 SAR-A (both variants)
- Ethernet ports on the 7705 SAR-Ax
- Ethernet ports on the 7705 SAR-H
- Ethernet ports on the 7705 SAR-Hc
- Ethernet ports on the 7705 SAR-M (all variants)
- 7705 SAR-W
- Ethernet ports on the 7705 SAR-Wx (all variants)
- Ethernet ports on the 7705 SAR-X
- 6-port DSL Combination module
- 8-port xDSL module
- GPON module
- 4-port SAR-H Fast Ethernet module
- 6-port SAR-M Ethernet module

---

### **Frame Relay**

Frame relay VLL service is supported on the following:

- DS3/E3 clear channel or channelized DS1/E1 ports on the 4-port DS3/E3 Adapter card
- V.35 and X.21 serial ports on the 12-port Serial Data Interface card
- 16-port T1/E1 ASAP Adapter card, version 2
- 32-port T1/E1 ASAP Adapter card
- T1/E1 ports on the 7705 SAR-M (variants with T1/E1 ports)

### **TDM**

TDM VLL service is supported on the following:

- T1/E1 ports and DS3 channels on the 2-port OC3/STM1 Channelized Adapter card
- T1/E1 ports (DS3 ports only) and DS3/E3 ports on the 4-port DS3/E3 Adapter card
- T1/E1 ports on the 4-port OC3/STM1 / 1-port OC12/STM4 Adapter card
- 6-port E&M Adapter card (when the port is configured for cem encapsulation)
- 8-port Voice & Teleprotection card
- 8-port C37.94 Teleprotection card
- 12-port Serial Data Interface card
- 16-port T1/E1 ASAP Adapter card
- 32-port T1/E1 ASAP Adapter card
- 4-port T1/E1 and RS-232 Combination module
- T1/E1 ports on the 7705 SAR-A (variant with T1/E1 ports)
- RS-232 serial ports on the 7705 SAR-Hc
- T1/E1 ports on the 7705 SAR-M (variants with T1/E1 ports)
- T1/E1 ports on the 7705 SAR-X

### **HDLC**

HDLC VLL service is supported on the following:

- V.35 and X.21 serial ports (super-rate speeds only) on the 12-port Serial Data Interface card

- 16-port T1/E1 ASAP Adapter card, version 2
- 32-port T1/E1 ASAP Adapter card
- T1/E1 ports on the 7705 SAR-M (variants with T1/E1 ports)

### IP Interworking

IP interworking VLL service is supported on the following:

- 2-port OC3/STM1 Channelized Adapter card (when the payload is configured as vt1.5/vc12)
- DS3/E3 clear channel ports on the 4-port DS3/E3 Adapter card (when the port is configured for frame-relay encapsulation)
- 6-port Ethernet 10Gbps Adapter card
- 8-port Ethernet Adapter card
- 8-port Gigabit Ethernet Adapter card
- 10-port 1GigE/1-port 10GigE X-Adapter card
- V.35 and X.21 serial ports (super-rate speeds only) on the 12-port Serial Data Interface card (when the port is configured for ipcp, frame-relay, or cisco-hdlc encapsulation)
- 16-port T1/E1 ASAP Adapter card (on PPP/MLPPP connections)
- 32-port T1/E1 ASAP Adapter card (on PPP/MLPPP connections)
- all ports on the 7705 SAR-A (on PPP/MLPPP connections on the T1/E1 ports)
- 7705 SAR-H
- Ethernet ports on the 7705 SAR-Ax
- Ethernet ports on the 7705 SAR-Hc
- all ports on the 7705 SAR-M (on PPP/MLPPP connections on the T1/E1 ports; variants with T1/E1 ports also support frame relay and HDLC SAPs on the T1/E1 ports)
- 7705 SAR-W
- Ethernet ports on the 7705 SAR-Wx (all variants)
- 7705 SAR-X
- 4-port SAR-H Fast Ethernet module
- 6-port SAR-M Ethernet module

**Note:** MPLS and VLL service over MPLS are not supported on access ports.

## 4.8.2 SDPs

The most basic SDPs must have the following characteristics:

- a locally unique SDP identification (ID) number and a VC-ID
- the system IP address of the far-end 7705 SAR routers
- an SDP encapsulation type—GRE, IP, or MPLS

### 4.8.2.1 SDP Statistics for VLL Services

The 7705 SAR supports local CLI-based and SNMP-based statistics collection for each VC used in the SDPs. This allows for traffic management of tunnel usage by the different services and, with aggregation, the total tunnel usage.

## 4.8.3 SAP Encapsulations and Pseudowire Types

The section describes encapsulations and PW types for the following VLL services:

- Apipe
- Cpipe
- Epipe
- Fpipe
- Hpipe
- Lpipe

### Apipe

ATM VLLs can be configured with both endpoints (SAPs) on the same router or with the two endpoints on different routers. In the latter case, Pseudowire Emulation Edge-to-Edge (PWE3) signaling can be used to establish a pseudowire between the devices, allowing ATM traffic to be tunneled through an MPLS or IP network.

**Note:** ATM SAP-to-SAP connections are not supported for pseudowire packets using N-to-1 cell mode encapsulation where  $N > 1$ .

As an alternative to signaled pseudowires, manual configuration of pseudowires is also supported.

The Apipe service supports virtual trunking, VP connections, and VC connections, which are identified by specifying the **vc-type** when provisioning the Apipe. When **vc-type** is **atm-cell**, ATM transparent cell transport mode is used for VT connections. The N-to-1 cell transport mode is supported for VC and VP services (see [ATM PWE3 N-to-1 Cell Mode Encapsulation](#)). For VCCs, the value of N can be 1 ( $N = 1$ ) or greater than 1 ( $N > 1$ ). The value of N is always 1 for VPCs.

The supported PW service types are 0x0009 (for ATM N-to-1 VCC cell mode, where  $N \geq 1$ ), 0x000A (for ATM N-to-1 VPC cell mode, where  $N = 1$ ) and 0x0003 (for ATM transparent cell transport mode). Refer to RFC 4717 and RFC 4446 for more information.

### Cpipe

Cpipe service supports CESoPSN and SAToP encapsulation over MPLS or GRE tunnels to connect to the far-end circuit. Cpipes support SAP-to-SAP and SAP-to-spoke SDP binding with a default service MTU of 1514 bytes.

The supported PW service types are 0x0011 (SAToP E1), 0x0012 (SAToP T1), 0x0013 (SAToP E3), 0x0014 (SAToP T3), 0x0015 (CESoPSN basic mode), and 0x0017 (CESoPSN TDM with CAS).

### Epipe

Epipe service is designed to carry Ethernet frame payloads, so it can provide connectivity between any two SAPs on different nodes that pass Ethernet frames. The following SAP encapsulations are supported on the 7705 SAR Epipe service:

- Ethernet null
- Ethernet dot1q
- Ethernet qinq

While different encapsulation types can be used at either end, encapsulation mismatching can occur if the encapsulation behavior is not understood by connecting devices and if those devices are unable to send and receive the expected traffic. For example, if the encapsulation type on one side of the Epipe is dot1q and the other is null, tagged traffic received on the null SAP will be double-tagged when it is transmitted out of the dot1q SAP.

The supported PW service types are 0x0004 (Ethernet tagged mode), and 0x0005 (Ethernet raw).

---

**Fpipe**

Fpipe service supports frame relay services over an MPLS PSN. MPLS label switched paths—also referred to as MPLS tunnels—are used to forward PW packets between two PEs.

The 7705 SAR supports one-to-one mapping of FR VCs to PWs. An MPLS tunnel can contain several PWs, but each PW encapsulates the traffic of one FR VC.

Fpipes support SAP-to-SAP and SAP-to-spoke SDP binding.

Fpipe service supports the 0x0019 (frame relay DLCI) PW service type.

**Hpipe**

The 7705 SAR supports many-to-one mapping of HDLC PDUs to PWs, which is also known as port mode encapsulation. The Hpipe provides port-to-port transport of HDLC-encapsulated traffic. The HDLC PDU is transported from PE port to PE port in its entirety, including the HDLC address and control fields, but excluding HDLC flags and the FCS.

Hpipes support SAP-to-SAP and SAP-to-spoke SDP binding.

Hpipe service supports the 0x0006 (HDLC) PW service type.

**Ipipe**

Ipipe service supports Ethernet null, Ethernet dot1q, Ethernet qinq, IPCP, PPP/MLPPP, FR, and cHDLC SAP encapsulation over IP or MPLS. Ipipes support SAP-to-SAP and SAP-to-spoke SDP binding with a default service MTU of 1500 bytes.

Ipipe service supports 0x000B (IP Layer 2 Transport) PW service type.

### 4.8.4 ATM PWE3 N-to-1 Cell Mode Encapsulation

The 7705 SAR supports N-to-1 cell mode encapsulation for ATM VPCs and VCCs (per RFC 4717), where N represents the number of VCs or VPs that can be multiplexed onto a single ATM VLL.

For VCCs, N is a configurable value where N can be greater than or equal to 1 ( $N \geq 1$ ). VCC cell mode supports the 0x0009 (ATM N-to-1 VCC Cell Mode) PW service type. The  $N > 1$  cell mode encapsulation enables service providers to multiplex multiple ATM VCs onto a single VLL to optimize the use of PWs in the network, to reduce the associated overhead of maintaining the PWs, and to increase the bandwidth available to transport user data.  $N > 1$  cell mode encapsulation is implemented on the 7705 SAR using SAP aggregation groups. See [SAP Aggregation Groups](#) for more information about how to configure a SAP aggregation group.

For VPCs, N is not user-configurable and must be equal to 1 ( $N = 1$ ). VPC cell mode supports the 0x000A (ATM N-to-1 VPC Cell Mode) PW service type.

In N-to-1 mode, OAM cells are transported through the VLL in the same way as any other cell.

An optional control word (CW) is supported for ATM VLLs. See [Pseudowire Control Word](#) for more information.

Figure 70 shows the structure of an N-to-1 cell mode frame.

Figure 70 N-to-1 Cell Mode Encapsulation

---

### 4.8.4.1 N-to-1 Cell Mode Encapsulation (N = 1)

The following sections describe ATM cell mode encapsulation where N = 1.

#### 4.8.4.1.1 Deployment Scenario for N = 1 Cell Mode Encapsulation

In a typical network multiple cell sites are aggregated to individual 7705 SAR nodes. Each cell site has one or more Node Bs. The Node Bs are typically from the same vendor and deployed on a regional basis, and it is common for carriers to simplify provisioning by using the same VPI and VCI values for specific types of traffic handled at different cell sites.

Such a scenario applies, for example, to a service provider that deploys multiple Node Bs in a specific region to support voice, low-speed, and high-speed packet data. In this case, the 7705 SAR grooms the three traffic types from each of the node Bs onto the network. Each traffic type is transported over a dedicated VC as follows:

- circuit-switched VC for voice services
- packet-switched VC for low-bandwidth data services
- HSxPA VC for high-bandwidth data services

In this N-to-1 scenario where N = 1, three VCs and three ATM PWs are required for each Node B.

#### 4.8.4.1.2 VPI/VCI Translation (N = 1)

Before traffic from different cell sites can be switched to an RNC, VPI and VCI translation may be required in order to uniquely identify the site and the far-end equipment. If overlapping VPI/VCI values, as described in [Deployment Scenario for N = 1 Cell Mode Encapsulation](#), are not used, VPI/VCI translation is not necessary.

The endpoints of a PWE3 N-to-1 cell mode ATM VLL can be:

- ATM VCs—VPI/VCI translation is supported  
In this case, when the VPI/VCI used at the endpoints (NodeB endpoint and RNC endpoint) are different, the VPI/VCI value can be modified at the endpoint of the far-end PE node, before the cells are switched to the ATM interface.
- ATM VPs—VPI translation is supported (the VPI at each endpoint need not be the same, but the original VCI will be maintained)

In this case, when the VPI and VCI used at the endpoints are different, only the VPI can be modified at the endpoint (VPI can only be changed by the far-end PE node, before the cells are switched to the ATM interface).

See [VPI/VCI Translation for SAP Aggregation Group Members \(N>1\)](#) for information about how VPI/VCI translation functions with N > 1 mode.

#### 4.8.4.1.3 Cell Concatenation (N = 1)

The 7705 SAR supports the concatenation of ATM VP and VC cells into a pseudowire packet payload. Cells are packed on ingress to the VLL and unpacked on egress.

The number of cells in the payload of a single VLL packet is user-configurable, which ensures proper transport of traffic sensitive to delay and jitter. For example, for voice traffic in 3G/WCDMA, delay is a crucial factor and the time spent for concatenation should be minimized. The payload is extremely delay-sensitive and should be transported with only a small amount of bandwidth optimization.

In all cases, the number of cells in a VLL packet must be less than the MTU size, where the MTU maximum is 1514 bytes and the maximum N-to-1 mode payload is 29 cells (52 ATM bytes per cell (no HEC byte)).

While cells are being packed, the concatenation process may be terminated and the packet sent by any one of the following conditions. Each condition has a configurable attribute associated with it:

- reaching a maximum number of cells per packet
- expiring of a timer
- changing of the cell loss priority (CLP) bit

The CLP bits are untouched, even if VPI/VCI translation occurs at egress.

**Note:** Configuring the attributes that provide the best compromise between minimizing delay (low number of cells concatenated) and maximizing bandwidth (high number of cells concatenated) requires careful planning.

#### 4.8.4.1.4 QoS and Traffic Descriptor Profiles (N = 1)

QoS is configured on individual SAPs at ingress and egress using the SAP configuration hierarchy.

---

Individual SAPs support VC-based characteristics that include ingress and egress ATM (Layer 2) traffic descriptor profiles. Apipe rate-limiting on egress is controlled by the traffic-descriptor profile, not the QoS policy queue rates.

#### **4.8.4.1.5 OAM (N = 1)**

The ATM PW N-to-1 mode supports OAM operations in non-terminating mode for N = 1 services. The far-end PE node translates the incoming VPI/VCI values of the ATM OAM cells in the same way as the user data cells.

### **4.8.4.2 N-to-1 Cell Mode Encapsulation (N > 1)**

The following sections describe ATM cell mode encapsulation where N > 1.

#### **4.8.4.2.1 Deployment Scenario for N > 1 Cell Mode Encapsulation**

N-to-1 mode where N > 1 can be used by wireless service providers to optimize the PWs that are deployed in a network. By multiplexing the VCs of the same type that derive from different ATM base stations (Node Bs), the number of PWs can be decreased to one PW per service type.

With N-to-1 cell mode encapsulation where N > 1 traffic with the same characteristics and QoS requirements (such as delay, jitter, and loss) can be carried over the payload of a single ATM PW.

[Figure 71](#) shows a typical network where N > 1 is deployed.

Figure 71 VCC Cell Mode Encapsulation with N > 1

22321

4.8.4.2.2 PW Optimization (N > 1)

A network that uses a single PW for each type of traffic significantly reduces the number of ATM PWs that need to be configured to groom the traffic from multiple Node Bs. The result is a more efficient network backhaul configuration and traffic management strategy.

#### 4.8.4.2.3 Overhead Optimization ( $N > 1$ )

A VC carrying signaling information between a Node B and an RNC must be configured with minimal packetization delay. N-to-1 cell mode encapsulation where  $N > 1$  can be employed to:

- optimize the overhead associated with ATM PW headers because one PW packet header is used to transport multiple cells
- improve performance for delay and throughput efficiency

Typically, operators configure packetization delay to be 1 ms. Every 1 ms, an ATM PW packet is required to switch the signaling information from the 7705 SAR to the 7750 SR—regardless of the number of ATM cells that are received to transport signaling information. In most cases, the ATM PW packet carries very few ATM cells.

When signaling VCs from multiple Node Bs are mapped to the same ATM PW in N-to-1 fashion, the number of ATM cells that are received every 1 ms potentially increases. For example, if signaling from five Node Bs is aggregated for each ATM PW, a much larger number of ATM cells can be transported per ATM PW header.

#### 4.8.4.2.4 Cell Concatenation ( $N > 1$ )

The maximum N-to-1 mode payload is 29 cells for N-to-1 cell mode where  $N > 1$ . This value applies to all of the SAPs that are members of the same SAP aggregation group. When the cell concatenation is configured for a specified number of cells, the 7705 SAR counts the cells it has received from all of the SAPs in the same SAP aggregation group and transmits the ATM PW packet when the limit is reached.

For example, for an ATM  $N > 1$  VCC service with four SAPs bound to the same SAP aggregation group, where the maximum number of cells for cell concatenation is set to 10, SAP1 might have 2 cells, SAP2 might have 5 cells, SAP3 might have 0 cells, and SAP4 might have 3 cells.

In all cases, the number of cells in a VLL packet must be less than the MTU size, where the MTU maximum is 1514 bytes and the maximum N-to-1 mode payload is 29 cells (52 ATM bytes per cell (no HEC byte)).

The **max-delay** configuration also applies at the SAP aggregation group level.

**Note:** CLP change-based termination of payload concatenation is not supported for  $N > 1$  cell mode.

#### 4.8.4.2.5 OAM (N > 1)

The ATM PW N-to-1 mode supports OAM operations in non-terminating mode for N > 1 services. The 7705 SAR forwards the Layer 2 AIS cells that it receives from the SAP aggregation group SAPs over the PW. The 7705 SAR translates the incoming VPI/VCI values of the AIS cells in the same way as any other type of traffic.

#### 4.8.4.2.6 Hardware Support for N > 1 Cell Mode Encapsulation

The following hardware supports N > 1 cell mode encapsulation:

- 16-port T1/E1 ASAP Adapter card
- 32-port T1/E1 ASAP Adapter card
- 7705 SAR-M (variants with T1/E1 ports)

#### 4.8.4.2.7 SAP Support for N > 1

The SAP aggregation group can include SAPs on:

- different ATM ports
- different IMA ports
- a combination of ATM and IMA ports

**Note:** All SAPs that are bound to the same N > 1 ATM PW must be configured on the same adapter card. An N > 1 ATM PW cannot span multiple adapter cards.

---

## 4.8.5 SAP Aggregation Groups

N > 1 cell mode encapsulation is implemented on the 7705 SAR using SAP aggregation groups. The following sections describe how to configure and manage SAP aggregation groups:

- [Configuration](#)
- [QoS and Traffic Descriptor Profiles \(N > 1\)](#)
- [Statistics and Counters](#)
- [Fault Management](#)

**Note:** An Apipe can have either regular SAPs or SAPs that belong to SAP aggregation groups, but not both.

See [Apipe Service with SAP Aggregation Configuration Commands](#) for more information about the commands and parameters that are required to configure a SAP aggregation group.

### 4.8.5.1 Configuration

The following section describes the objects required to configure a SAP aggregation group and group members. See [VLL Services Configuration Commands](#) for more information.

#### 4.8.5.1.1 Sap-aggregation-group Keyword

The **sap-aggregation-group** keyword is used to associate multiple SAPs with a single ATM VCC Apipe service. The SAP aggregation group is a high-level object under which general features are defined. These features include accounting, statistics, and the packet layer QoS profile. All common access parameters are configured under the **sap-aggregation-group**.

#### 4.8.5.1.2 Sap-aggregation-group Group Identifier

The **sap-aggregation-group** *group-id* is used for two purposes:

- to identify a SAP aggregation group. The *group-id* is an alphanumeric identifier. For example:

**sap-aggregation-group group\_id\_1**

- to identify a SAP as a member of an aggregation group. SAPs that are to be bound to the same ATM PW payload must be tagged with the same

**sap-aggregation-group** *group-id*. For example:

**sap 1/2/3.1:3/300 sap-aggregation-group group\_id\_1**

The **sap-aggregation-group** *group-id* can be up to 32 alphanumeric characters.

#### 4.8.5.1.3 VPI/VCI Translation for SAP Aggregation Group Members (N>1)

The **vcid-translation** *vpi/vci* keyword is an optional configuration item that is used only for SAPs that are members of a SAP aggregation group. The **vcid-translation** *vpi/vci* keyword translates the VPI and VCI values of the incoming ATM cells before the cells are mapped to an ATM PW payload. That is, at ingress, the VPI/VCI values for a SAP that is a member of a SAP aggregation group are rewritten by the VPI/VCI values of the **vcid-translation** keyword.

In the reverse direction, when the 7705 SAR receives the cells with translated VPI/VCI values from its peer (such as a 7750 SR), another translation to SAP-configured VPI/VCI values is required before cells are sent to the SAP.

The **vcid-translation** keyword applies to user and OAM cells. When the **vcid-translation** keyword is configured, all cells are translated.

If the **vcid-translation** keyword is not configured for any ATM SAP aggregation group, the ingress VPI/VCI values are retained.

**Note:** The 7705 SAR performs a check to ensure the uniqueness of the translated VPI/VCI values for all of the SAPs of the same ATM PW service, that is, within the same SAP aggregation group. If there are duplicate VC identifiers, the status of the VCs are set to operationally down and flagged as **ApipeSapVcidNotUnique**. It is the sole responsibility of the user to ensure uniqueness of VPI/VCI values after translation.

### 4.8.5.2 QoS and Traffic Descriptor Profiles (N > 1)

Packet layer, N > 1 ATM PW QoS functions are configured using the SAP aggregation group hierarchy. The QoS profiles for ingress and egress are configurable for each N > 1 service. Any existing QoS profile can be applied to an N > 1 service. The QoS policy determines the QoS offering, including the classification and queuing for the whole PW, irrespective of the number of SAPs that are bound to the aggregated service.

Although a single SAP egress policy is configured for a SAP aggregation group, a separate egress queue is created for each SAP. The MBS and CBS values for each of these egress SAP queues are set to equal the MBS and CBS values configured in the SAP egress QoS policy for the SAP aggregation group. The SAP egress QoS policy causes  $n$  times the values of the CBS buffers to be committed, where  $n$  is the number of SAPs in the SAP aggregation group. Refer to the 7705 SAR Quality of Service Guide for more information.

**Note:** ATM layer policing on individual SAPs within a SAP aggregation group is not supported. You cannot apply ATM QoS traffic descriptor profiles on ingress to a SAP in a SAP aggregation group; the profile is set to the default (1).

Rate-limiting on egress for aggregated SAPs is controlled by the ATM traffic-descriptor profile, not the QoS policy queue rates. Each SAP that is a member of a SAP aggregation group has its own egress Layer 2 traffic descriptors. These descriptors are used for shaping and scheduling priority at egress.

### 4.8.5.3 Statistics and Counters

The statistics for aggregation groups are maintained on a per-group basis. Statistics for SAP aggregation groups are available using the following commands:

- **show service id *n* sap-aggregation-group *group-id* stats**
- **show service id *n* sap-aggregation-group *group-id* group-stats**

The **stats** keyword shows statistics for the aggregation group on a per-queue basis. The **group-stats** keyword shows the SAPs that are members of a specified group and the corresponding SAP-level statistics, including aggregated queue statistics. See [Show Commands](#) for more information.

Because SAP aggregation groups can span multiple ports, the 7705 SAR does not support port-level packet and discard counters for  $N > 1$  SAPs. When only  $N > 1$  services are configured on an adapter card, the 7705 SAR shows a value of 0 for port packet and discard statistics.

Octet counters are available under each SAP group member. The port and bundle ATM PVC statistics are recorded for the SAPs in a SAP aggregation group. These statistics are helpful for debugging an individual SAP.

A statistics counter tracks all unconfigured or unknown VPI/VCI values that are received in an ATM PW payload from the network. The received VPI/VCI values are compared to the **vcid-translation vpi/vci** keyword values, and if a value is detected that does not match, the counter for unknown VPIs/VCIs is incremented. The values appear in the Dropped Egress Cells (unconfigured vpi/vci) field and are available using the **show service id n all** and **show service id n sap-aggregation-group group-id detail** commands. See [Show Commands](#) for more information.

The **monitor service id n sap-aggregation-group group-id** command provides user-configurable controls for the interval and rate of statistics collection. Refer to the 7705 SAR Basic System Configuration Guide for more information.

Statistics are cleared using the **clear service statistics sap sap-id** and **clear service statistics sap-aggregation-group group-id** commands. The **sap sap-id** clears ATM Layer 2 counters; QoS counters are not applicable for SAPs that are members of an aggregation group. The **sap-aggregation-group group-id** clears network Layer 3 QoS queue statistics. See [Clear Commands](#) for more information.

#### 4.8.5.4 Fault Management

A PW failure results in the transmission of a pw-status TLV message to the far-end node. If the 7705 SAR receives a pw-status TLV message, the 7705 SAR sends an AIS to all of the ATM SAPs.

If an individual SAP in a SAP aggregation group of an  $N > 1$  service fails or is disabled, the 7705 SAR inserts OAM cells into the PW for the failing VC, using the translated VPI/VCIs. If all SAPs in a SAP aggregation group fail or are shut down, the 7705 SAR generates a pw-status TLV message that designates the SAP as sap-down.

In the case of a card failure for  $N = 1$  and  $N > 1$  services, if all the SAPs of the same service fail or if the service is shut down, the 7705 SAR transmits a pw-status TLV message to the far-end node. If the 7705 SAR receives a pw-status TLV from the far-end node (that is, a lacIngressFault or lacEgressFault), AIS messages are generated and sent to all of the SAPs that are part of the SAP aggregation group.

If a port fails, the 7705 SAR sends AIS cells over the ATM PW to the far-end node.

For end-to-end resiliency, an  $N > 1$  ATM PW service supports PW redundancy.

## 4.8.6 QoS Policies

When applied to 7705 SAR Apipe, Cpipe, Epipe, and Lpipe services, service ingress QoS policies only create the unicast queues defined in the policy.

With Apipe, Cpipe, Epipe, and Lpipe services, egress QoS policies function as with other services where the class-based queues are created as defined in the policy.

Both Layer 2 and Layer 3 criteria can be used in the QoS policies for traffic classification in a Cpipe, Epipe, or Lpipe service. QoS policies on Apipes cannot perform any classification.

## 4.8.7 IP Filter Policies

The 7705 SAR supports IPv4 and IPv6 filter policies on the following entities:

- IPv4 ingress
  - network interfaces
  - Ethernet SAPs on all services
  - ATM SAPs on a 4-port OC3/STM1 Clear Channel Adapter card in conjunction with bridged llc-snap ATM SAP to VPLS
  - ATM SAPs on a 16- or 32-port T1/E1 ASAP Adapter card in conjunction with routed VC-Mux ATM SAP to IES
  - FR and cHDLC SAPs on a 16- or 32-port T1/E1 ASAP Adapter card in conjunction with IP PWs
  - FR SAPs on a 4-port DS3/E3 Adapter card in DS3, clear channel mode in conjunction with IP PWs
  - V.35 and X.21 cHDLC SAPs on a 12-port Serial Data Interface card in conjunction with IP PWs
  - spoke SDPs on VPLS, VPRN interfaces, and IES interfaces
  - mesh SDPs on VPLS
- IPv4 egress
  - network interfaces
  - Ethernet SAPs on VPRN and IES interfaces

- Ethernet SAPs on VPLS
- IPv6 ingress and egress
  - Ethernet network interfaces (with null or dot1q encapsulation)
  - network interfaces on the 4-port OC3/STM1 Clear Channel Adapter card (with POS encapsulation)
  - Ethernet SAPs on IES

Configuration and assignment of IP filter policies is similar for network interfaces, IES management SAPs, Ethernet and IP pseudowire SAPs, VPRN and IES SAPs and spoke SDPs, and VPLS SAPs and SDPs (spoke and mesh). Refer to the 7705 SAR Router Configuration Guide, “Filter Policies”, for information on configuring IP filters.

## 4.8.8 MTU Settings

There are several MTU values that must be set properly for a VLL service (Apipe, Cpipe, Epipe, Fpipe, Hpipe, or Lpipe) to work from end to end. [Figure 72](#) locates the MTU point for each value. [Table 35](#) describes the MTU points. The MTU points are:

- access port MTU
- SAP MTU
- service MTU
- path MTU
- network port MTU

In order for a VLL service to be declared “up” without any MTU-related error messages, the following rule must be true:

$$\text{SAP MTU} \geq \text{Service MTU} \leq \text{Path MTU}$$

**Figure 72 MTU Points on the 7705 SAR**

19688

**Table 35 MTU Points and Descriptions**

| MTU Point         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Command                                                                                                                                 |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| 1 Access port MTU | <p>The access port MTU value is a configurable value that accounts for the Layer 2 header and the payload. The default access port MTU value for the following Fast Ethernet port SAP encapsulations is:</p> <ul style="list-style-type: none"> <li>• <b>null</b>: 1514 bytes (payload = 1500 bytes, L2 header = 14 bytes)</li> <li>• <b>dot1q</b>: 1518 bytes (payload = 1500 bytes, L2 header = 18 bytes)</li> <li>• <b>qinq</b>: 1522 bytes (payload = 1500 bytes, L2 header = 22 bytes)</li> </ul>  | <b>mtu</b> , under the <b>config&gt;port</b> context, where the port type can be Ethernet, DSL, GPON, TDM, serial, or SONET/SDH         |
| 2 SAP MTU         | The SAP MTU value is not a configurable value. It is set at the SAP by the 7705 SAR operating system. It defines the service payload capability of the service and is automatically set to be the same value as the access port MTU.                                                                                                                                                                                                                                                                    | Not user-configurable                                                                                                                   |
| 3 Service MTU     | <p>The service MTU value is a configurable value and is the same size as the VLL payload. The service MTU is sometimes called the VC-type MTU in the 7705 SAR documentation set. In <a href="#">Figure 72</a>, NP stands for network processor.</p> <p>For CESoPSN with CAS service, ensure that the service MTU is set to a value large enough to account for the extra bytes appended to the packet payload for CAS bits. See <a href="#">Structured T1/E1 CES with CAS</a> for more information.</p> | <b>service-mtu</b> , under the <b>config&gt;port</b> context, where the port type can be Ethernet, DSL, GPON, TDM, serial, or SONET/SDH |
|                   | IP MTU is specific to Layer 3 spoke-SDP termination. Layer 3 spoke-SDP termination can be configured for interfaces under IES and VPRN services. IP MTU is used to signal the service MTU of Layer 3-spoke SDP termination to a peer PE node.                                                                                                                                                                                                                                                           | <b>ip-mtu</b> , under the <b>config&gt;service&gt;vprn</b> or <b>ies</b> context for an interface                                       |

**Table 35 MTU Points and Descriptions (Continued)**

|   | MTU Point        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Command                                                              |
|---|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------|
| 4 | Path MTU         | <p>The path MTU is configured at the SDP. It is the maximum that the SDP can transmit without rejecting and discarding the packet. The path MTU value is derived from the network port MTU value by subtracting the Layer 2 and Layer 2.5 overhead values (for MPLS) and the Layer 2 and Layer 3 overhead values (for GRE).</p> <p>If the network port SDP binding is Ethernet, then the following equations hold:</p> <ul style="list-style-type: none"> <li>For MPLS:<br/> <b>Path MTU = Port MTU - (Ethernet header [14 bytes or 18 bytes or 22 bytes] + Tunnel header + PW header)</b> </li> <li>For GRE:<br/> <b>Path MTU = Port MTU - (Ethernet header [14 bytes or 18 bytes or 22 bytes] + IP header [20 bytes] + Tunnel header [4 bytes] + PW header [4 bytes])</b> </li> </ul> | <b>path-mtu</b> , under the <b>config&gt; service&gt;sdp</b> context |
| 5 | Network port MTU | The network port MTU is a configurable value equal to the payload plus all headers (L2, IP (for GRE), tunnel and PW), up to the maximum supported value (hardware limit) of 9728 bytes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Same as access port MTU (above)                                      |

[Table 36](#) displays the default, minimum, and maximum service MTU values for Ethernet ports. These values are dependent upon the port type, mode, encapsulation type, and service type.

[Table 37](#) and [Table 38](#) aid in calculating MTU values for various configurations and operating scenarios.

**Table 36**      **Service MTU Default and Maximum Values**

| Port Type                    | Mode   | Encap Type                     | Service Type | Service MTU (bytes) |         |                      |                      |
|------------------------------|--------|--------------------------------|--------------|---------------------|---------|----------------------|----------------------|
|                              |        |                                |              | Default             | Minimum | Maximum (SAP to SDP) | Maximum (SAP to SAP) |
| 10/100 Ethernet <sup>1</sup> | Access | null, dot1q, qinq <sup>3</sup> | Epipe, VPLS  | 1514                | 1       | 9670 <sup>2</sup>    | 9724 <sup>2</sup>    |
|                              |        |                                | lpipe        | 1500                |         |                      |                      |
| GigE SFP <sup>1</sup>        | Access | null, dot1q, qinq <sup>3</sup> | Epipe, VPLS  | 1514                | 1       | 9670 <sup>2</sup>    | 9724 <sup>2</sup>    |
|                              |        |                                | lpipe        | 1500                |         |                      |                      |

**Notes:**

1. The maximum MTU value is supported only on cards that have buffer chaining enabled; therefore, it is not supported on the 8-port Ethernet Adapter card, version 1.
2. On the Packet Microwave Adapter card, the MWA ports support 4 bytes less than the Ethernet ports. Thus, MWA ports support a maximum MTU of 9720 bytes (null) or 9724 bytes (dot1q). MWA ports do not support QinQ.
3. QinQ is supported only on access ports.

For more information on port MTU, refer to “MTU Configuration Guidelines” in the 7705 SAR Interface Configuration Guide.

**Table 37 MTU Calculator—Service Creation (Worst Case) Access Ports and SAPs**

| Service Creation                                                      |                       |                            |      |             |             |             |             |             |             |

|                                                        | Eth-DA             |                          |         | 6        | 6         |            |                       | 6                     | 6          |
|                                                        | TDM/ATM            |                          |         |          |           |            |                       |                       |            |
|                                                        | PPP Protocol       | 2                        | 2       |          |           |            | 2                     |                       |            |
|                                                        | ML Sequence        |                          | 3       |          |           |            |                       |                       |            |
|                                                        | ML Preamble        |                          | 1       |          |           |            |                       |                       |            |
|                                                        | Total              | 2                        | 6       | 14       | 26        |            | 50                    | 2110                  | 2114       |

**Note:**

- In order to accommodate current and future services (including overhead), the MTU values for Gigabit Ethernet and PPP/MLPPP ports have the default value set to 1572 bytes. For 10/100 Ethernet ports, the MTU value is set to 1514 or 1518 or 1522 bytes, depending on the encapsulation setting (null or dot1q or qinq).
- The default service MTU value is 1514 bytes; the maximum value is 1522 bytes.

### 4.8.8.1 Targeted LDP and MTU

The extended discovery mechanism for Label Distribution Protocol (LDP) sends LDP Targeted Hello messages to a specific address. This is known as targeted LDP or T-LDP. Refer to RFC 5036 for detailed information about the extended discovery mechanism.

During the VLL service creation process (that is, using targeted LDP signaling), the MTU or payload size of a service is signaled to the far-end peer. MTU settings at both ends (near and far peers) must match in order for the VLL service to operate.

[Table 39](#) shows the values that are expected to match.

**Table 39 Matching MTU or Payload Values for Signaled VLL Services**

|                             | Apipe | Cpipe | Epipe | Fpipe | Hpipe | Ipipe |
|-----------------------------|-------|-------|-------|-------|-------|-------|
| Payload size (bytes)        |       | Yes   |       |       |       |       |
| Bit rate                    |       | Yes   |       |       |       |       |
| Maximum number of ATM cells | Yes   |       |       |       |       |       |
| Service MTU                 |       |       | Yes   | Yes   | Yes   | Yes   |
| Must match at both ends     | Yes   | Yes   | Yes   | Yes   | Yes   | Yes   |

---

## 4.8.9 QinQ (VLL Service)

Epipe and Lpipe VLL services support QinQ functionality. For details, see [QinQ Support](#).

## 4.8.10 Pseudowire Control Word

The PW control word (CW) is a 32-bit field that is inserted between the VC label and the Layer 2 frame. The presence of the control word is indicated by the C bit of the FEC element used in LDP signaling. The PW control word is described in RFC 4385.

The PW control word is supported for all implemented PW types:

- Apipes (ATM VLLs)
- Epipes (Ethernet VLLs)
- Cpipes (TDM VLLs in SAToP and CESoPSN circulation emulation mode)
- Fpipes (frame relay VLLs in one-to-one mapping mode)
- Hpipes (HDLC VLLs)
- Lpipes (IP interworking VLLs)

For Apipes, the control word is optional. It can be enabled to guarantee ordered packet/cell delivery.

For Epipes (with the exception of MEF 8 services) and Lpipes, the control word is optional. If it is enabled, it will be set to all zeros and ignored on egress.

For Cpipes, Epipe MEF 8 services, and Fpipes, the control word is mandatory and cannot be configured.

For Hpipes, the control word is optional when transporting packets that are more than 64 bytes but mandatory when transporting packets that are less than 64 bytes.

When the packet length is less than 64 bytes (that is, the length of the Layer 2 payload plus the length of the control word), the length field in the control word is set to the length of the packet. Otherwise, the length field is set to 0. The CE-bound PE uses the length field in the control word to determine the size of the padding that was added by the PSN so that the PE can extract the PW payload from the PW packet. If the control word is not set for packets less than 64 bytes, the PE cannot determine the original length of the packet and will forward the payload, including the padding bits. On reception of the padded packet, the CE will drop the packet.

The following points describe the behavior of the 7705 SAR when it receives a Label Mapping message for a PW. It is assumed that no Label Mapping message for the PW has been sent to the next PW router yet. The 7705 SAR operating system does the following.

- If the received Label Mapping message has  $C = 0$  (where  $C$  refers to the  $C$  bit of the FEC element), a Label Mapping message with  $C = 0$  is sent forward to the next router (or hop). In this case, the control word is not used.
- If the received Label Mapping message has  $C = 1$  and the PW is locally configured such that the use of the control word is mandatory, then the 7705 SAR sends a Label Mapping message with  $C = 1$ . In this case, the control word is used. (Note: SAToP and CESoPSN (Cpipes), Epipe MEF 8 services, and Fpipes always require the control word.)
- If the received Label Mapping message has  $C = 1$  and the PW is locally configured such that the use of the control word is not supported, the 7705 SAR sends a new Label Mapping message in which the  $C$  bit is set to correspond to the locally configured preference for use of the control word (that is,  $C = 0$ ).

## 4.8.11 Pseudowire Redundancy

Pseudowire (PW) redundancy protects a PW and any services on the PW against endpoint failures. This differs from LSP redundancy and FRR, which offer protection against link and node failures within the backhaul network.

As shown in [Figure 73](#), in order to provide redundant PWs, the 7705 SAR must signal PWs to two endpoints at the MTSO (7x50-1 and 7x50-2), which is done using two spoke SDPs on the 7705 SAR. This configuration removes any single point of failure from a given network. If 7x50-1 loses all of its connectivity to the network or to the RNC, the 7705 SAR can reroute the PW traffic to 7x50-2, which switches traffic to the RNC.

For end-to-end protection, PW redundancy is supported in the following scenarios:

- PW redundancy with multi-chassis LAG (MC-LAG), multi-chassis APS (MC-APS), and T1/E1 multi-chassis line card redundancy (MC-LCR)
- PW redundancy with VPLS or PW switching

For more information on MC-LAG, refer to the 7705 SAR Interface Configuration Guide, “Multi-Chassis LAG”. For more information on MC-APS, refer to the 7705 SAR Interface Configuration Guide, “Automatic Protection Switching”. For more information on MC-LCR, refer to the 7705 SAR Interface Configuration Guide, “T1/E1 Line Card Redundancy”.

**Figure 73 Pseudowire Redundancy**

20225

PW redundancy applies to all VLL services available on the 7705 SAR: Apipe, Cpipe, Epipe, Fpipe, Hpipe, and Ipipe.

#### 4.8.11.1 PW Redundancy Operation

PW redundancy on the 7705 SAR is similar to a point-to-multipoint implementation for PWs (in the ingress to the egress direction). A single SAP can be bound to more than one spoke SDP, and traffic from multiple spoke SDPs can all be switched to the same SAP. To implement PW redundancy, a PW service on the 7705 SAR must be able to accommodate more than one spoke SDP on the spoke SDP side. This is achieved using the concept of endpoints.

An endpoint can be thought of as a container for a single SAP, a single spoke SDP, or multiple spoke SDPs. [Figure 74](#) illustrates the model for a redundant VLL service based on the endpoints. Endpoints are implicit or explicit objects.

Implicit endpoints are transparent to the user and are not user-configurable. As shown in [Figure 74a](#), implicit endpoints mean that one endpoint is a SAP and another endpoint is a spoke SDP. Endpoints are considered implicit if the **endpoint** command is not used in the **config>service>xpipe>spoke-sdp** context, where **xpipe** refers to any of the VLL services.

Explicit endpoints are user-configurable and apply when there are multiple spoke SDPs. As shown in [Figure 74b](#), explicit endpoints mean that there can be multiple spoke SDPs associated with the endpoint. An endpoint created explicitly can have up to four spoke SDPs associated with it. The explicit endpoint method is used for PW redundancy. Explicit endpoints are user-configurable.

**Figure 74 Implicit and Explicit Endpoint Objects**

20226

The 7705 SAR supports the following types of endpoint objects:

- SAP—there can be only one SAP per PW endpoint (Endpoint X in [Figure 74a](#))
- Spoke SDP—from the perspective of a 7705 SAR, if there is only one SDP endpoint, then it is a spoke SDP endpoint and it is implicitly defined. In other words, there can be only one implicitly defined spoke SDP per PW endpoint (Endpoint Y in [Figure 74a](#)).
- Primary spoke SDP—there can be only one explicitly defined primary spoke SDP per PW endpoint (one of the spoke SDPs at Endpoint Z in [Figure 74b](#)). If a primary spoke SDP is defined, then there can be up to three secondary spoke SDPs per endpoint and the service can be revertive.
- Secondary spoke SDP—there can be up to four explicitly defined secondary spoke SDPs per endpoint if no primary spoke SDP is defined; otherwise, there can be up to three. Secondary spoke SDPs are assigned a precedence value that is used by the 7705 SAR to determine which secondary PW becomes active when the currently active PW fails (see [Selecting the Active Spoke SDP for PW Redundancy Configuration](#)).

Multiple spoke SDPs can be established between a 7705 SAR and any SR platform. For example, multiple spoke SDPs on a 7705 SAR can connect to a 7750 SR. In this case, the 7750 SR must be configured to use multi-chassis backup in conjunction with multi-segment PWs; that is, the 7750 SR nodes at the far end must support multi-chassis redundancy.

A PW service endpoint can only use a single active spoke SDP for transmission at any given time. A PW SAP can receive traffic from any of the endpoint spoke SDPs assigned to the service.

7705 SAR nodes support user-initiated manual switchover of the VLL path to the primary path or any of the secondary paths using the **force-switchover** command under the **tools>perform>service-id** context. A manual switchover is useful during planned outages such as node upgrade procedures.

#### 4.8.11.2 Selecting the Active Spoke SDP for PW Redundancy Configuration

There are two main scenarios for configuring PW redundancy. One scenario uses a primary spoke SDP and provides revertive behavior. The other scenario uses only secondary spoke SDPs for non-revertive behavior.

**Note:** Non-revertive behavior is not supported on Cpipes.

##### 4.8.11.2.1 Primary and Secondary Spoke SDPs

If a primary spoke SDP is defined, up to three secondary spoke SDPs can also be defined. The VLL service always uses the primary endpoint PW and only switches to a secondary PW when the primary PW is down. The PW service switches the path back to the primary PW when the primary PW is back up. The user can configure a timer to delay reverting to the primary path or to never revert to the primary path. When the primary PW goes down, the 7705 SAR selects the secondary spoke SDP that is operationally up and has the highest precedence setting.

##### 4.8.11.2.2 Secondary Spoke SDPs Only

If a primary spoke SDP is not defined, up to four secondary spoke SDPs can be defined. The user can configure the precedence of each secondary PW to indicate the order in which secondary PWs are activated. The secondary PW with the highest precedence is selected first. If two or more secondary spoke SDPs are assigned the same precedence, the 7705 SAR selects the secondary path that is operationally up and has the lowest spoke SDP identifier. There is no revertive behavior between secondary paths, which means that a secondary path will not switch to another secondary path of higher precedence if one becomes available.

The use of four secondary spoke SDPs is illustrated in [Figure 75](#), where:

- spoke SDP-1 goes over S-PE-1 to T-PE1 (red path) (S-PE is a switching PE and T-PE is a terminating PE)
- spoke SDP-2 goes over S-PE-1 to T-PE2 (green path)
- spoke SDP-3 goes over S-PE-2 to T-PE1 (violet path)
- spoke SDP-4 goes over S-PE-2 to T-PE2 (orange path)

**Figure 75 Pseudowire Redundancy with Four Spoke SDPs**

20227

#### 4.8.11.3 PW Redundancy and Inter-Chassis Backup

Inter-Chassis Backup (ICB) spoke SDPs are supported for use with Cpipe services in an MC-APS or MC-LCR configuration and with Epipe services in an MC-LAG configuration. ICB improves switch times, provides additional protection in case of network failures, and reduces packet loss when an active endpoint is switched from a failed MC-APS, MC-LCR, or MC-LAG node to a protection node.

A failure on the access side triggers an access side MC-APS, MC-LCR, or MC-LAG switchover and a network-side pseudowire switchover. A failure on the network side triggers a pseudowire switchover but does not trigger an MC-APS, MC-LCR, or MC-LAG switchover.

Figure 76 shows a network experiencing an access side failure in an MC-LAG scenario.

**Figure 76 Access Side Failure with ICB Protection**

23496

If the active access link of an MC-APS, MC-LCR, or MC-LAG group fails, the MC-APS, MC-LCR, or MC-LAG protocol causes the access side to switch to the protection (standby) link. If ICB is configured, the in-flight packets coming from the network side will be sent over the ICB to the newly active access link. Shortly after the access-side switchover, pseudowire redundancy causes the network side to switch as well. In this scenario, ICB reduces the switch time by carrying the in-flight packets during the access and network switchovers.

Figure 77 shows a network experiencing a network side failure in an MC-LAG scenario.

**Figure 77 Network Side Failure with ICB Protection**

23497

If the active network link of an MC-APS, MC-LCR, or MC-LAG group fails, pseudowire redundancy causes the network side to switch to the standby pseudowire. This does not trigger an MC-APS, MC-LCR, or MC-LAG switchover. If there is no ICB, the end-to-end transmission will be lost because the access link never switches. If ICB is configured, the packets coming in from the newly active network link are sent across the ICB to the active access side and vice versa. In this scenario, ICB provides protection against network failures.

An endpoint can have only one ICB spoke SDP, which must be identified as ICB in the **spoke-sdp** command. If an ICB spoke SDP is added to an endpoint, a SAP can be added only if it is part of an MC-LAG, MC-APS, or MC-LCR group. Similarly, if an MC-LAG, MC-APS, or MC-LCR SAP is added to an endpoint, the only other possible addition to that endpoint is an ICB spoke SDP.

#### 4.8.11.4 AIS Fault Propagation

When the 7705 SAR is operating in an MPLS network with TDM pseudowires using PW redundancy, it can interoperate with SDH networks that use subnetwork connection protection (SNCP). SNCP is a path-based protection mechanism for T1/E1 services. When the 7705 SAR interoperates with SDH networks that use SNCP, it can make PW redundancy switching decisions based on SDH signaling, which keeps the active data paths in the SDH and the MPLS networks synchronized.

This functionality is only available on unframed E1 channels and unframed DS1 channels on the following cards:

- 2-port OC3/STM1 Channelized Adapter card
- 4-port OC3/STM1 / 1-port OC12/STM4 Adapter card

If SNCP-protected equipment detects a failure in an SDH network, it inserts an AIS into the TU-12 overhead of the SDH frame so that the appropriate activity switch can occur in the SDH network. When the 7705 SAR detects a TU12-AIS for a specific VC-12 path in an SDH network and AIS propagation is enabled using the command **config>card>mda>ais-propagation**, the 7705 SAR generates a TU12-AIS for the corresponding VC-12 at the other end of the Cpipe. If the VC-12 path is involved in PW redundancy, a PW activity switch occurs, which signals the SDH node to do an SNCP switch.

#### 4.8.12 Active/Standby Mode for Pseudowire Redundancy (Standby Signaling)

Pseudowire redundancy as described in the previous section operates in active/active mode; that is, the primary pseudowire is up and ready to transmit and receive traffic, and the secondary pseudowire is up and ready to receive traffic. In [Figure 78](#), if both pseudowires were active, this mode of operation would offer seamless redundancy in most cases. However, this mode could also potentially stress the IGP; for example, in active/active mode the number of routes advertised is greater than in active/standby mode. Another example is the duplication of Ethernet control frames to the 7705 SAR from a VPLS or VPRN service on an SR node through both primary and secondary VLLs.

**Figure 78 Active/Standby Mode for Redundant Pseudowires**

20694

Active/standby mode is introduced to address these issues. Active/standby mode is also referred to as standby signaling. Standby signaling is supported on all VLLs: Apipes, Cpipes, Epipes, Lpipes, Fpipes, and Hpipes.

Standby signaling has two components: standby-signaling master and standby-signaling slave. [Figure 79](#) shows an example where **standby-signaling-master** has been enabled on the 7705\_MTU node. A Cpipe has been configured between the 7705\_MTU and the 7705\_A node and between the 7705\_MTU and the 7705\_B node. The spoke SDP towards 7705\_A is the active PW (precedence primary), while the spoke SDP towards 7705\_B is the standby PW (precedence 1).

An example of the CLI syntax to configure the 7705\_MTU is:

**CLI Syntax:**

```
config>service# cpipe 555 customer 1 vc-type cesopsn
create
 endpoint "stdbyMaster" create
 standby-signaling-master
 exit
 spoke-sdp 5:555 endpoint "stdbyMaster" create
 precedence 1
 exit
 spoke-sdp 131:555 endpoint "stdbyMaster" create
 precedence primary
 exit
```

**Figure 79** Standby-signaling-master Enabled

22796

**Note:** Standby-signaling-master should be enabled on only one endpoint of the pseudowire; otherwise, the pseudowire could bounce.

Traffic passes over the active PW. If the status of the active PW changes, the standby PW becomes active and starts passing traffic.

Because the 7705\_MTU is configured for **standby-signaling-master**, the standby PW sends its status to the far end by sending a standby bit over T-LDP. However, the receiving end (in [Figure 79](#), 7705\_B) ignores the bit and continues to transmit data towards the 7705\_MTU as long as the PW is up; therefore, pseudowire redundancy does not work.

In order to stop data from being transmitted along standby spoke SDPs, the far-end endpoints must be enabled for **standby-signaling-slave**. [Figure 80](#) shows a scenario where 7705\_A and 7705\_B have been enabled for **standby-signaling-slave**.

An example of the CLI syntax to configure the 7705\_A and 7705\_B nodes is:

**CLI Syntax:**

```
config>service# cpipe 555 customer 1 vc-type cesopsn
create
 endpoint "FarendA" create
 standby-signaling-slave
 exit
 spoke-sdp 130:555 endpoint "FarendA" create
 precedence primary
 exit
```

**CLI Syntax:**

```
config>service# cpipe 555 customer 1 vc-type cesopsn
create
 endpoint "FarendB" create
 standby-signaling-slave
 exit
 spoke-sdp 130:555 endpoint "FarendB" create
 precedence primary
 exit
```

**Figure 80 Standby-signaling-slave Enabled**

22797

With **standby-signaling-slave** enabled, when the standby PW sends the standby bit to the far end over T-LDP, the SDP flags bit is set to block traffic being transmitted back to the 7705\_MTU (flags bit is set to StandbySigSlaveTxDown). The spoke SDP remains up. If the standby PW becomes active, the flags bit is reset and traffic resumes on the PW.

**Note:** Standby-signaling-master and standby-signaling slave cannot be enabled at the same time on the same endpoint.

### 4.8.12.1 PW Status Signaling Label Withdrawal Option

The 7705 SAR supports PW status signaling or label withdrawal for signaling PW status.

Signaling PW status based on label withdrawal requires the PW label to be released, whereas PW status signaling can mark the PW as unusable based on local-end and far-end status and on status messages exchanged between endpoints.

As indicated in RFC 4447, *Pseudowire Setup and Maintenance Using the Label Distribution Protocol*, PW status signaling is the preferred method for exchanging state information between two endpoints and should be used as long as both endpoints support it.

However, the PW label withdrawal method for exchanging PW status can be configured even if the far end supports PW status signaling and the PW status TLV for designating the operational (forwarding) state of a PW.

This configuration option allows the PEs at both ends of the spoke SDP to use PW label withdrawal rather than the PW status TLV. This is necessary when a 7705 SAR must interoperate with PEs that do not support the PW forwarding standby bit, or when multiple remote PEs are connected to an r-VPLS instance via spoke-SDP termination.

---

#### 4.8.12.1.1 Interoperation with PEs that do not Support the PW Forwarding Standby Bit

Not all PEs support the PW forwarding standby bit as part of pseudowire status signaling. If **standby-signaling-master** is enabled on the 7705 SAR, then it signals standby on all but one of the PWs, and blocks the transmit direction for all standby PWs. However, if a PE does not support processing of that bit, it will not block its end of the PW and will forward traffic onto that PW. As a result, traffic received on a standby PW at the 7705 SAR end is forwarded to the associated SAP. Master-slave PW redundancy prevents this from occurring only if all of the PEs support PW active/standby mode in a master-slave configuration and block their transmit directions for the standby PW. Previously, the 7705 SAR only used the PW label withdrawal method if a PE did not support the PW status signaling bit.

In order to allow PW redundancy on the 7705 SAR to interoperate with third party PEs that do not support the PW forwarding standby bit, an option to disable PW status signaling is provided. This will ensure that forwarding on a standby PW will be bidirectionally blocked in order to prevent PWs in standby mode from transmitting traffic via label withdrawal.

#### 4.8.12.1.2 Multiple Remote PEs Connected to an r-VPLS Instance Via Spoke-SDP Termination

When multiple remote PEs are hooked up to an r-VPLS instance via spoke-SDP termination, label withdrawal can be used to control the operational status of the associated IP interface at the r-VPLS.

If all of the spoke SDPs of an r-VPLS enter the forwarding standby state, the spoke SDP is locally blocked if the **no ignore-standby-signaling** option is configured. In its default mode of operation, the 7705 SAR automatically negotiates the use of PW status signaling on the spoke SDP. This means that a standby spoke SDP will not go operationally down at the endpoint. As a result, there is no change in the operational status of the VPLS to which the spoke SDPs are bound, and consequently, no change to the operational status of the r-VPLS or the IP interface.

The ability to disable PW status signaling makes it possible to configure the use of PW label withdrawal on a node, rather than allowing the automatic negotiation of PW status signaling. When pseudowire status signaling is disabled, a 7705 SAR does not include the PW status TLV in the initial label mapping message of the pseudowire that is used for a spoke SDP. This forces both 7705 SAR nodes to use the pseudowire label withdrawal method for exchanging pseudowire status. When the remote endpoint determines that a particular PW should be in standby mode, it will withdraw the PW label. This causes VPLS to go operationally down if the label is withdrawn for all PWs on a VPLS. The IP interface associated with r-VPLS goes down as a result.

#### 4.8.12.2 Pseudowire Redundancy on Serial Data Interface Ports

Pseudowire redundancy is only supported on serial data interface ports when there is a Cpipe on a standby-signaling master with a single SAP and a endpoint with up to two spoke SDPs. The far-end slaves (standby-signaling slaves) each have a single SAP and a single spoke SDP back to the master.

Subrate speeds (< 64 kb/s) on RS-232 and X.21 ports are supported using HCM. HCM cannot determine signal quality until a circuit is established (that is, both endpoints of the circuit are connected); therefore, when **standby-signaling-slave** is enabled on subrate circuits, HCM framing will always be down on the inactive slave. The normal behavior is for the slave to send the port status to the master using the pseudowire status bit, indicating local attachment circuit (LAC) Tx/Rx faults. Because the slave cannot clear these faults, this prevents the master from switching back to the primary pseudowire as soon as possible (pseudowire redundancy reversion).

To enable pseudowire redundancy reversion in this case, the sending of LAC Tx/Rx fault messages from the slaves to the master is suppressed on RS-232 and X.21 ports configured for subrate speeds. The master is therefore not aware that the far-end port is down due to HCM being down and will switch back to the primary pseudowire as soon as other types of alarms are cleared.

These limitations apply to:

- RS-232 and X.21 ports on the 12-port Serial Data Interface card
- RS-232 ports on the 4-port T1/E1 and RS-232 Combination module (on the 7705 SAR-H)
- RS-232 ports on the 7705 SAR-Hc

---

## 4.9 Configuring a VLL Service with CLI

This section provides the information required to configure Virtual Leased Line (VLL) services using the command line interface.

Topics in this section include:

- [Common Configuration Tasks](#)
- [Configuring VLL Components](#)
- [Service Management Tasks](#)

---

## 4.10 Common Configuration Tasks

The following list provides a brief overview of the tasks that must be performed to configure a VLL service.

- Associate the service with a customer ID.
- Define SAP parameters.
  - Optional—select egress and ingress QoS policies (configured in the **config>qos** context)
  - Optional—select ingress IP filter policies (for Epipes and Ipipes only)
- Define spoke SDP parameters.
  - Optional—select egress and ingress vc label parameters
  - Optional—explicitly assign spoke SDP endpoints for pseudowire (PW) redundancy applications
- Enable the service.

---

## 4.11 Configuring VLL Components

This section provides configuration examples for components of VLL services. Each component includes some or all of the following: introductory information, CLI syntax, a specific CLI example, and an example of the CLI display output. Included are the following VLL components:

- [Creating an Apipe Service](#)
- [Creating a Cpipe Service](#)
- [Creating an Epipe Service](#)
- [Creating an Fpipe Service](#)
- [Creating an Hpipe Service](#)
- [Creating an Ipipe Service](#)
- [Configuring PW Switching](#)
- [Configuring Ingress and Egress SAP Parameters](#)
- [Using the Control Word](#)
- [Configuring PW Redundancy](#)

## 4.11.1 Creating an Apipe Service

This section describes how to create an Apipe service. Additional topics in this section include:

- [Configuring Apipe SAP Parameters](#)
- [Configuring Apipe SDP Bindings](#)
- [Configuring Apipe SAP Aggregation Groups](#)
- [Configuring Apipe SAPs as Aggregation Group Members](#)

Use the following CLI syntax to create an Apipe service.

**CLI Syntax:**

```
config>service# apipe service-id [customer customer-id]
[create] [vpn vpn-id] [vc-type {atm-vcc | atm-vpc |
atm-cell}] [vc-switching]
description description-string
service-mtu octets
no shutdown
```

PE router 1 (A:ALU-41):

**Example:**

```
A:ALU-41>config>service# apipe 5 customer 1 create
A:ALU-41config>service>apipe# description "apipe test"
A:ALU-41config>service>apipe# service-mtu 1400
A:ALU-41config>service>apipe# no shutdown
```

PE router 2 (A:ALU-42):

**Example:**

```
A:ALU-42>config>service# apipe 5 customer 1 create
A:ALU-42>config>service>apipe# description "apipe test"
A:ALU-42>config>service>apipe# service-mtu 1400
A:ALU-42>config>service>apipe# no shutdown
```

The following example shows the Apipe service creation output.

PE Router 1 (ALU-41):

```
A:ALU-41>config>service# info

...
 apipe 5 customer 1 create
 description "apipe test"
 service-mtu 1400
 no shutdown
 exit
...

A:ALU-41>config>service#
```

## PE Router 2 (ALU-42):

```
A:ALU-42>config>service# info

...
 apipe 5 customer 1 create
 description "apipe test"
 service-mtu 1400
 no shutdown
 exit

A:ALU-42>config>service#
```

### 4.11.1.1 Configuring Apipe SAP Parameters

Use the following CLI syntax to configure Apipe SAP parameters. For ingress and egress configuration information, see [Configuring Ingress and Egress SAP Parameters](#).

**CLI Syntax:**

```
config>service# apipe service-id [customer customer-id]
[create] [vpn vpn-id] [vc-type {atm-vcc | atm-vpc |
atm-cell}] [vc-switching]
 sap sap-id [create]
 accounting-policy acct-policy-id
 atm
 egress
 traffic-desc traffic-desc-profile-id
 ingress
 traffic-desc traffic-desc-profile-id
 oam
 alarm-cells
 collect-stats
 description description-string
 egress
 qos policy-id
 ingress
 qos policy-id
 no shutdown
```

**Example:**

```
A:ALU-41>config>service# apipe 5
A:ALU-41>config>service>apipe# sap 1/1/1.1:0/32 create
A:ALU-41>config>service>apipe>sap# ingress
A:ALU-41>config>service>apipe>sap>ingress# qos 102
A:ALU-41>config>service>apipe>sap>ingress# exit
A:ALU-41>config>service>apipe>sap# egress
A:ALU-41>config>service>apipe>sap>egress# qos 103
A:ALU-41>config>service>apipe>sap>egress# exit
A:ALU-41>config>service>apipe>sap# no shutdown
```

```
A:ALU-41>config>service>apipe>sap# exit
```

The following example shows Apipe SAP configuration output for PE Router 1 (ALU-41).

```
A:ALU-41>config>service# info

...
 apipe 5 customer 1 create
 description "apipe test"
 service-mtu 1400
 sap 1/1/1.1:0/32 create
 ingress
 qos 102
 exit
 egress
 qos 103
 exit
 exit
 no shutdown
 exit

```

To configure a basic local Apipe service (SAP-to-SAP), enter the **sap sap-id** command twice with different port IDs in the same service configuration.

The following example shows an ATM SAP-to-SAP configuration:

```
A:ALU-4>config>service# info

...
 apipe 5 customer 1 create
 description "ATM sap2sap"
 service-mtu 1514
 sap 1/1/1.1:0/32
 sap 1/2/1.1:0/100
 no shutdown
 exit

```

The following example shows an Apipe SAP configuration for a virtual trunk service:

```
A:ALU-4>config>service# info

...
 apipe 5 customer 1 vc-type atm-cell create
 description "port VT apipe"
 service-mtu 1500
 sap 1/1/10 create
 ingress
 qos 102
 exit
 egress
 qos 103
 exit

```

```

 exit
 no shutdown
 exit

```

#### 4.11.1.2 Configuring Apipe SDP Bindings

Use the following CLI syntax to create a spoke SDP binding with an Apipe service (for distributed service). For SDP configuration information, see [Configuring SDPs](#).

**CLI Syntax:**

```

config>service# apipe service-id [customer customer-id]
[create] [vpn vpn-id] [vc-type {atm-vcc | atm-vpc |
atm-cell}] [vc-switching]
 spoke-sdp sdp-id:vc-id [create]
 cell-concatenation
 clp-change
 max-cells cell-count
 max-delay delay-time
 egress
 vc-label egress-vc-label
 ingress
 vc-label ingress-vc-label
 no shutdown

```

**Example:**

```

A:ALU-41>config>service# apipe 5
A:ALU-41>config>service>apipse# spoke-sdp 1:5 create
A:ALU-41>config>service>apipse>spoke-sdp# no shutdown
A:ALU-41>config>service>apipse>spoke-sdp# exit

```

The following example shows the Apipe spoke SDP configuration output for PE Router 1 (ALU-41).

```

A:ALU-41>config>service# info

...
 apipse 5 customer 1 create
 description "apipse test"
 service-mtu 1400
 sap 1/1/1.1:0/32 create
 ingress
 qos 102
 exit
 egress
 qos 103
 exit
 exit
 spoke-sdp 1:5 create
 exit
 no shutdown
 exit

```

```
...

A:ALU-41>config>service#
```

### 4.11.1.3 Configuring Apipe SAP Aggregation Groups

Use the following CLI syntax to configure the parameters for an Apipe SAP aggregation group. The **vc-type** parameter must be set to **atm-vcc**. For ingress and egress configuration information, see [Configuring Ingress and Egress SAP Parameters](#).

**CLI Syntax:**

```
config>service# apipe service-id [customer customer-id]
[create] [vpn vpn-id] [vc-type {atm-vcc | atm-vpc |
atm-cell}] [vc-switching]
 sap-aggregation-group group-id [create]
 accounting-policy acct-policy-id
 collect-stats
 description description-string
 egress
 qos policy-id
 ingress
 qos policy-id
 no shutdown
 no shutdown
```

**Example:**

```
A-ALU-1>config>service# apipe 3 customer 1 vc-type
atm-vcc create
A-ALU-1>config>service>apipe# sap-aggregation-group
GroupName1 create
A-ALU-1>config>service>apipe>sap-aggregation-group#
ingress
A-ALU-1>config>service>apipe>sap-aggregation-
group>ingress# qos 102
A-ALU-1>config>service>apipe>sap-aggregation-
group>ingress# exit
A-ALU-1>config>service>apipe>sap-aggregation-group#
egress
A-ALU-1>config>service>apipe>sap-aggregation-group#
egress qos 103
A-ALU-1>config>service>apipe>sap-aggregation-
group>egress# exit
A-ALU-1>config>service>apipe>sap-aggregation-group# no
shutdown
A-ALU-1>config>service>apipe>sap-aggregation-group#
exit
A-ALU-1>config>service>apipe#
```

The following example shows an Apipe SAP aggregation group configuration output.

```
A-ALU-1>config>service# info

...
 apipe 3 customer 1 vc-type atm-vcc create
 description "SAP aggregation group 1"
 sap-aggregation-group GroupName1 create
 ingress
 qos 102
 exit
 egress
 qos 103
 exit
 exit
 no shutdown
 exit
...

```

#### 4.11.1.4 Configuring Apipe SAPs as Aggregation Group Members

Use the following CLI syntax to configure an Apipe SAP as a member of a SAP aggregation group. To add a SAP as a member of a SAP aggregation group, enter the **sap-aggregation-group** *group-id* command after the **sap** *sap-id* command. A SAP aggregation group can have up to 16 SAP members.

ATM attributes for aggregation group members can also be configured, including:

- vcid-translation
- traffic descriptor profiles for egress

**Note:** You cannot apply ATM QoS traffic descriptor profiles on ingress to a SAP in a SAP aggregation group; the profile is set to the default (1). Attempting to change the ingress traffic descriptor will cause an error message to be displayed.

- OAM alarm notifications

For ingress and egress configuration information, see [Configuring Apipe SAP Parameters](#).

**CLI Syntax:**

```
config>service# apipe service-id [customer customer-id]
 [create] [vpn vpn-id] [vc-type {atm-vcc | atm-vpc |
 atm-cell}] [vc-switching]
 sap sap-id sap-aggregation-group group-id
 atm
 vcid-translation vpi/vci
```

```

 egress
 traffic-desc traffic-desc-
 profile-id
 ingress
 traffic-desc traffic-desc-
 profile-id
 oam
 alarm-cells
 description description-string
 no shutdown
 no shutdown

```

**Example:**

```

A-ALU-1>config>service# apipe 3 customer 1 create
A-ALU-1>config>service>apipe# sap 1/2/2.1:10/10
 sap-aggregation-group GroupName1
A-ALU-1>config>service>apipe>sap# exit
A-ALU-1>config>service>apipe# sap 1/2/2.1:20/20
 sap-aggregation-group GroupName1
A-ALU-1>config>service>apipe>sap# exit
A-ALU-1>config>service>apipe# sap 1/2/2.1:30/30
 sap-aggregation-group GroupName1
A-ALU-1>config>service>apipe>sap# exit
A-ALU-1>config>service>apipe#

```

The following example shows the output for an Apipe service with a SAP aggregation group containing three SAPs as aggregation group members.

```

A:ALU-41>config>service# info

...
 apipe 3 customer 1 create
 sap-aggregation-group "GroupName1" create
 exit
 sap 1/2/2.1:10/10 sap-aggregation-group "GroupName1" create
 exit
 sap 1/2/2.1:20/20 sap-aggregation-group "GroupName1" create
 exit
 sap 1/2/2.1:30/30 sap-aggregation-group "GroupName1" create
 exit
 exit
...

```

## 4.11.2 Creating a Cpipe Service

This section describes how to create a Cpipe service. Additional topics in this section include:

- [Configuring Cpipe SAP Parameters](#)
- [Configuring Cpipe SDP Bindings](#)

Use the following CLI syntax to create a Cpipe service.

**CLI Syntax:**

```
config>service# cpipe service-id [customer customer-id]
[create] [vpn vpn-id] [vc-type {satop-e1 | satop-t1 |
satop-e3 | satop-t3 | cesopsn | cesopsn-cas}] [vc-
switching]
description description-string
service-mtu octets
no shutdown
```

**Example:**

```
config>service# cpipe 234 customer 123 create vc-type
cesopsn
config>service>cpipe# description "cpipe test"
config>service>cpipe# service-mtu 1400
config>service>cpipe# no shutdown
config>service>cpipe#
```

The following example shows the Cpipe service creation output for PE Router 1 (ALU-41).

```
A:ALU-41>config>service# info

...
 cpipe 234 customer 123 create
 description "cpipe test"
 service-mtu 1400
 no shutdown
 exit
...

A:ALU-41>config>service#
```

### 4.11.2.1 Configuring Cpipe SAP Parameters

Use the following CLI syntax to configure Cpipe SAP parameters. For ingress and egress configuration information, see [Configuring Ingress and Egress SAP Parameters](#).

**CLI Syntax:**

```
config>service# cpipe service-id [customer customer-id]
[create] [vpn vpn-id] [vc-type {satop-e1 | satop-t1 |
satop-e3 | satop-t3 | cesopsn | cesopsn-cas}] [vc-
switching]
 sap sap-id [create]
 cem
 [no] packet
 asym-delay-control [samples {ksamples}]
 [min-repeat minutes] [threshold-repeat
 uSecs]
 jitter-buffer value | payload-size
 size
 payload-size size
 [no] report-alarm [stray] [malformed]
 [pktloss]
 [overrun] [underrun] [rpktloss]
 [rfault] [rrdi]
 [no] rtp-header
 [no] collect-stats
 description description-string
 no description
 egress
 qos policy-id
 no qos
 ingress
 qos policy-id
 no qos
 [no] shutdown
```

**Example:**

```
A:ALU-41>config>service# cpipe 5 cesopsn
A:ALU-41>config>service>cpipe# sap 1/1/1.1 create
A:ALU-41>config>service>cpipe>sap# ingress
A:ALU-41>config>service>cpipe>sap>ingress# qos 102
A:ALU-41>config>service>cpipe>sap>ingress# exit
A:ALU-41>config>service>cpipe>sap# egress
A:ALU-41>config>service>cpipe>sap>egress# qos 103
A:ALU-41>config>service>cpipe>sap>egress# exit
A:ALU-41>config>service>cpipe>sap# no shutdown
A:ALU-41>config>service>cpipe>sap# exit
A:ALU-41>config>service>cpipe#
```

The following example shows the Cpipe SAP configuration output for PE Router 1 (ALU-41).

```
A:ALU-41>config>service# info

...
 cpipe 5 customer 1 create
 description "cpipe test"
 service-mtu 1400
 sap 1/1/1.1 create
 ingress
 qos 102
 exit
 egress
 qos 103
 exit
 exit
 no shutdown
 exit
...

```

To configure a basic local Cpipe service (SAP-to-SAP), enter the **sap sap-id** command twice with different port IDs in the same service configuration.

The following example shows a TDM SAP-to-SAP configuration:

```
A:ALU-41>config>service# info

...
 cpipe 5 customer 1 create
 description "TDM sap2sap"
 service-mtu 1400
 sap 1/1/1.1
 sap 1/2/1.1
 no shutdown
 exit
...

```

Use the following CLI syntax to configure a Cpipe SAP used by a Surveillance, Control, and Data Acquisition Support (SCADA) bridge. In this instance, the *sap-id* variable is in the format *slot/mda/bridge-id.branch-id*, where *bridge-id* represents an existing bridge number with a value of 1 to 16 and *branch-id* represents an existing branch number with a value of 1 to 32. Refer to the 7705 SAR Interface Configuration Guide, “Configuration Command Reference”, for information on how to configure bridges and branches for a SCADA application.

**CLI Syntax:**

```
config>service# cpipe service-id [customer customer-id]
[create] vc-type cesopsn
 sap sap-id [create]
 description description-string
 no description
```

[no] shutdown

**Example:**

```
A:ALU-41>config>service# cpipe 8 customer 1 create
vc-type cesopsn
A:ALU-41>config>service>cpipe# sap 1/5/16.10 create
A:ALU-41>config>service>cpipe>sap# description "sap
branch 10"
A:ALU-41>config>service>cpipe>sap# no shutdown
A:ALU-41>config>service>cpipe>sap# exit
A:ALU-41>config>service>cpipe#
```

The following example shows a SCADA bridge Cpipe SAP configuration:

```
A:ALU-41>config>service# info

...
 cpipe 8 customer 1 vc-type cesopsn
 sap 1/5/16.10
 description "sap branch 10"
 no shutdown
 exit
```

### 4.11.2.2 Configuring Cpipe SDP Bindings

Use the following CLI syntax to create a spoke SDP binding with a Cpipe service. For SDP configuration information, see [Configuring SDPs](#).

**CLI Syntax:**

```
config>service# cpipe service-id [customer customer-id]
[create] [vpn vpn-id] [vc-type {satop-e1 | satop-t1 |
satop-e3 | satop-t3 | cesopsn | cesopsn-cas}]
[vc-switching]
 spoke-sdp sdp-id:vc-id [create]
 egress
 vc-label egress-vc-label
 ingress
 vc-label ingress-vc-label
 [no] shutdown
```

**Example:**

```
A:ALU-41>config>service# cpipe 5
A:ALU-41>config>service>cpipe# spoke-sdp 1:5 create
A:ALU-41>config>service>cpipe>spoke-sdp# no shutdown
A:ALU-41>config>service>cpipe>spoke-sdp# exit
```

The following example shows the Cpipe spoke SDP configuration output for PE Router 1 (ALU-41).

```
A:ALU-41>config>service# info

...
 cpipe 5 customer 1 create
 description "cpipe test"
 service-mtu 1400
 sap 1/1/1.1 create
 ingress
 qos 102
 exit
 egress
 qos 103
 exit
 exit
 spoke-sdp 1:5 create
 exit
 no shutdown
 exit
...

A:ALU-41>config>service#
```

### 4.11.3 Creating an Epipe Service

This section describes how to create an Epipe service. Additional topics in this section include:

- [Configuring Epipe SAP Parameters](#)
- [Configuring Epipe with ATM SAP](#)
- [Configuring Epipe SAP MEF 8 Parameters](#)
- [Configuring Epipe SAP Microwave Link Parameters for Interworking with TDM2Ethernet](#)
- [Configuring ATM Encapsulation Under Epipe Service \(7705 SAR-M only\)](#)
- [Configuring Epipe Spoke SDP Bindings](#)

Use the following CLI syntax to create an Epipe service.

**CLI Syntax:**

```
config>service# epipe service-id [customer customer-id]
[create] [vpn vpn-id] [vc-switching]
 description description-string
 no shutdown
```

**Example:**

```
config>service# epipe 500 customer 5 create
config>service>epipe$ description "Local epipe service"
```

```
config>service>epipe# no shutdown
```

The following example shows the Epipe service creation output.

```
ALU-1>config>service# info

 epipe 500 customer 5 vpn 500 create
 description "Local epipe service"
 no shutdown
 exit

```

### 4.11.3.1 Configuring Epipe SAP Parameters

The 7705 SAR supports distributed Epipe service and local (SAP-to-SAP) Epipe service. A distributed Epipe consists of two SAPs on different nodes. A local Epipe consists of both SAPs on the same 7705 SAR. To configure a distributed Epipe service, you must configure service entities on the originating and far-end nodes.

Use the following CLI syntax to create distributed Epipe SAPs. For ingress and egress configuration information, see [Configuring Ingress and Egress SAP Parameters](#). For information on configuring ETH-CFM parameters on an Epipe SAP, see [ETH-CFM \(802.1ag and Y.1731\) Tasks](#).

**CLI Syntax:**

```
config>service# epipe service-id [customer customer-id]
[create] [vc-switching]
 sap sap-id [create]
 accounting-policy policy-id
 collect-stats
 description description-string
 no shutdown
 egress
 qos policy-id
 eth-cfm
 ingress
 filter [ip ip-filter-id]
 qos policy-id
```

**Example:**

```
ALU-1>epipe 5500 customer 5 create
config>service>epipe$ description "Distributed epipe
service to east coast"
config>service>epipe# sap 1/1/3:21 create
config>service>epipe>sap# ingress
config>service>epipe>sap>ingress# filter ip 1
config>service>epipe>sap>ingress# qos 555
config>service>epipe>sap>ingress# exit
config>service>epipe>sap# egress
```

```

config>service>epipe>sap>egress# qos 627
config>service>epipe>sap>egress# exit
config>service>epipe>sap# no shutdown
config>service>epipe>sap# exit
config>service>epipe#

ALU-2>config>service# epipe 5500 customer 5 create
config>service>epipe$ description "Distributed epipe
 service to west coast"
config>service>epipe# sap 1/1/4:550 create
config>service>epipe>sap# ingress
config>service>epipe>sap>ingress# qos 654
config>service>epipe>sap>ingress# exit
config>service>epipe>sap# egress
config>service>epipe>sap>egress# qos 432
config>service>epipe>sap>egress# exit
config>service>epipe>sap# no shutdown
config>service>epipe#

```

The following example shows the SAP configuration output for ALU-1 and ALU-2.

```

ALU-1>config>service# info

...
 epipe 5500 customer 5 vpn 5500 create
 description "Distributed epipe service to east coast"
 sap 1/1/3:21 create
 ingress
 filter ip 1
 qos 555
 exit
 egress
 qos 627
 exit
 exit
 exit
...

ALU-1>config>service#

ALU-2>config>service# info

...
 epipe 5500 customer 5 vpn 5500 create
 description "Distributed epipe service to west coast"
 sap 1/1/4:550 create
 ingress
 qos 654
 exit
 egress
 qos 432
 exit
 exit
 exit
...

```

```

ALU-2>config>service#
```

To configure a basic local Epipe service (SAP-to-SAP), enter the **sap sap-id** command twice with different port IDs in the same service configuration.

The following example shows an Ethernet SAP-to-SAP configuration:

```
A:ALU-4>config>service# info

...
 epipe 2 customer 1 create
 description "Ethernet sap2sap"
 sap 1/1/1:1000
 sap 1/2/1:50
 no shutdown
 exit
...

```

### 4.11.3.2 Configuring Epipe with ATM SAP

Use the following CLI syntax to configure an Epipe with ATM SAP. An OC3 clear channel ATM path is configured and then the Epipe SAP is configured.

**CLI Syntax:**

```
configure port port-id
 description description
 sonet-sdh
 path
 atm
 cell-format uni
 mtu mtu
 no shutdown
 no shutdown
```

The following example shows an OC3 clear channel ATM path configuration and output.

**Example:**

```
*A:Sar8 Dut-B# configure port 1/2/3
config>port# description "1/OC03/KAN"
config>port# sonet-sdh
config>port>sonet-sdh# path
config>port>sonet-sdh>path# atm
config>port>sonet-sdh>path>atm# cell-format uni
config>port>sonet-sdh>path>atm# exit
config>port>sonet-sdh>path# mtu 2090
config>port>sonet-sdh>path# no shutdown
config>port>sonet-sdh>path# exit
```

```
config>port>sonet-sdh# exit
```

```
*A: Sar8 Dut-B>config>port# info
```

```

description "1/OC03/KAN"
sonet-sdh
 path
 atm
 cell-format uni
 mtu 2090
 exit
 no shutdown
 exit
exit
no shutdown
```

**CLI Syntax:**

```
config>service# epipe service-id [customer customer-id]
create
 description description-string
 sap sap-id create
 description description-string
 egress
 qos policy-id
 no shutdown
 ingress
 qos policy-id
 service-mtu octets
 service-name service-name
 spoke-sdp sdp-id:vc-id create
 no shutdown
 no shutdown
```

The following example shows an Epipe SAP configuration and output.

**Example:**

```
*A: Sar8 Dut-B# configure service epipe 202165 customer 1
create
config>service>epipe$ description "00/ARDU/902/863/2949"
config>service>epipe$ sap 1/2/3:0/49 create
config>service>epipe>sap$ description "00/ARDU/902/863/
2949"
config>service>epipe>sap$ egress
config>service>epipe>sap>egress$ qos 1421
config>service>epipe>sap>egress$ exit
config>service>epipe>sap$ no shutdown
config>service>epipe>sap$ ingress
config>service>epipe>sap>ingress$ qos 1421
config>service>epipe>sap>ingress$ exit
config>service>epipe>sap$ exit
config>service>epipe$ service-mtu 1622
config>service>epipe$ service-name "EPIPE 202165"
config>service>epipe$ spoke-sdp 3080:202165 create
```

```

config>service>epipe>spoke-sdp$ no shutdown
config>service>epipe>spoke-sdp$ exit
config>service>epipe$ no shutdown
config>service>epipe$ exit

*A: Sar8 Dut-B>config>service>epipe$ info

description "00/ARDU/902/863/2949"
 service-mtu 1622
 service-name "EPIPE 202165"
 sap 1/2/3:0/49 create
 description "00/ARDU/902/863/2949"
 egress
 qos 1421
 exit
 ingress
 qos 1421
 exit
 no shutdown
 exit
 spoke-sdp 3080:202165 create
 description "00/ARDU/902/863/2949"
 no shutdown
 exit
 no shutdown
exit

```

### 4.11.3.3 Configuring Epipe SAP MEF 8 Parameters

MEF 8 allows TDM services to be encapsulated across Epipes. To configure MEF 8, define one TDM SAP and one Ethernet SAP on the Epipe; see [Configuring Epipe SAP Parameters](#) for information on configuring an Ethernet SAP. The TDM SAP for the Epipe must include a local and remote ECID and a far-end destination MAC address. The TDM port's MAC address is used as the source MAC address for the circuit.

TDM can also be encapsulated into Ethernet, which is then encapsulated in MPLS (or GRE) by configuring an Epipe with a TDM SAP and a spoke SDP. See [Configuring SDPs](#) for information on configuring a spoke SDP. The TDM SAP configured in the Epipe must include a local and remote ECID and a far-end destination MAC address. The TDM port's MAC address is used as the source MAC address for the circuit.

Use the following CLI syntax to configure MEF 8 parameters:

**CLI Syntax:**

```

config>service# epipe service-id [customer customer-id]
[create] [vpn vpn-id] [vc-switching]
description description-string
sap sap-id [create]
accounting-policy policy-id
cem
 packet
 jitter-buffer value | payload-size
 size
 payload-size size
 local-ecid value
 no local-ecid
 remote-ecid value
 no remote-ecid
 remote-mac ieee-mac-addr
 no remote-mac
 report-alarm [stray] [malformed]
 [pktloss] [overrun] [underrun]
 [rpktloss] [rfault] [rrdi]
description description-string

```

The following example shows a TDM SAP-to-Ethernet SAP MEF 8 configuration and output.

**Example:**

```

ALU-1>epipe 1
config>service>epipe# description "Test Epipe for
service ID 1"
config>service>epipe# sap 1/2/4:1 create
config>service>epipe>sap# description "test SAP for
service ID 1"
config>service>epipe>sap# exit
config>service>epipe# sap 1/1/1.1 create
config>service>epipe>sap# description "test SAP2 for
service ID 1"
config>service>epipe>sap# cem
config>service>epipe>sap>cem# report alarm rpktloss
rfault rrdi
config>service>epipe>sap>cem# local-ecid 1
config>service>epipe>sap>cem# remote-ecid 1
config>service>epipe>sap>cem# remote-mac
10:00:50:00:00:02
config>service>epipe>sap>cem# exit
config>service>epipe>sap# exit
config>service>epipe# no shutdown

```

```
*A:7705:Dut-A>config>service>epipe# info
```

```

```

```

description "Default epipe description for service id 1"
sap 1/2/4:1 create
 description "Test SAP for service ID 1"
exit
sap 1/1/1.1 create
 description "Test SAP2 for service ID 1"
 cem
 report-alarm rpktloss rfault rrdi
 local-ecid 1
 remote-ecid 1
 remote-mac 10:00:50:00:00:02
 exit
exit
no shutdown

*A:7705:Dut-A>config>service>epipe# back

```

The following example shows a TDM SAP-to-spoke SDP MEF 8 configuration and output. See [Configuring SDPs](#) for more information about SDPs.

**Example:**

```

config>service>epipe 2
config>service>epipe# description "Test Epipe for
 service ID 2"
config>service>epipe# sap 1/1/1.2 create
config>service>epipe>sap# description "test SAP for
 service ID 2"
config>service>epipe>sap# exit
config>service>epipe# exit
config>service# sdp 2 mpls create
config>service>sdp# description "MPLS-10.10.10.104"
config>service>sdp# far-end "10.10.10.104"
config>service>sdp# no shutdown
config>service>sdp# exit
config>service# epipe 2 sap
config>service>epipe>sap# cem
config>service>epipe>sap>cem# report alarm rpktloss
 rfault rrdi
config>service>epipe>sap>cem# local-ecid 2
config>service>epipe>sap>cem# remote-ecid 2
config>service>epipe>sap>cem# remote-mac
 10:00:50:00:00:02
config>service>epipe>sap>cem# exit
config>service>epipe>sap# exit
config>service>epipe# no shutdown

```

```

*A:7705:Dut-A>config>service# epipe 2
*A:7705:Dut-A>config>service>epipe# info

description "Default epipe description for service id 2"
sap 1/1/1.2 create
description "Default sap description for service id 2"
cem
 report-alarm rpktloss rfault rrdi
 local-ecid 2
 remote-ecid 2
 remote-mac 10:00:50:00:00:02
exit
exit
spoke-sdp 2:2 create
exit
no shutdown

*A:7705:Dut-A>config>service>epipe#

```

#### 4.11.3.4 Configuring Epipe SAP Microwave Link Parameters for Interworking with TDM2Ethernet

In a Microwave Awareness environment, a mixed microwave link scenario may exist where an access link site has an MPR-e radio connected to a 7705 SAR-8 or 7705 SAR-18 as a standalone network element as well as an MPR-e radio connected to a 9500 MSS as an indoor unit, as shown in [Figure 81](#).

When TDM2Ethernet transport is required, the 9500 MSS packetizes the TDM2Ethernet stream using a MEF 8 frame format; the 7705 SAR-8 or 7705 SAR-18 acts as the MEF 8 endpoint. From a packet flow perspective, the TDM2Ethernet MEF 8 stream is a VLAN flow that can be handled by a VLAN SAP into an Epipe service going into the 7705 SAR-8 or 7705 SAR-18. To optimize the microwave bandwidth for the TDM2Ethernet MEF 8 transport, the packet header is compressed at the ingress MPR-e radio (connected to the 9500 MSS) and restored at the egress MPR-e radio (connected to the 7705 SAR-8 or 7705 SAR-18). In order for the egress MPR-e radio to perform this function, the parameters listed below are configured for an Epipe SAP on a 7705 SAR-8 or 7705 SAR-18; see [Epipe Service Configuration Commands](#) for more information:

- TDM2Ethernet compression on the Epipe
- Real-time Transport Protocol (RTP) header, if required (see [RTP Header](#) for a description of how an RTP header is applied)
- source 9500 MSS MAC address and destination 7705 SAR-8 or 7705 SAR-18 MAC address

**Figure 81 Mixed Microwave Link Scenario**

Apply Epipe SAP microwave link parameters for interworking with TDM2Ethernet as shown in the CLI syntax example below:

**CLI Syntax:**

```
config>service>epipe epipe-id customer customer-id
create
sap sap-id create
mw
compression source-mac destination-mac
[rtp]
```

#### 4.11.3.5 Configuring ATM Encapsulation Under Epipe Service (7705 SAR-M only)

The 7705 SAR-M can provide the transport of Ethernet traffic over an ATM network through the configuration of a SAP-to-SAP Ethernet PW. For example, as shown in [Figure 82](#), the 7705 SAR-M provides radio access of Ethernet traffic into an existing ATM network.

The SAP facing the eNodeB is configured as a null- or dot1q-encapsulated Ethernet SAP. The SAP facing the ATM network is ATM/IMA-encapsulated.

ATM/IMA is configured on E1 ports of the 7705 SAR-M. The uplink port must be in access mode in order to host the ATM/IMA SAP. The 7705 SAR-M supports IMA groups with 1 to 16 member links as well as ATM encapsulation on a single E1 port.

The following exceptions on ATM encapsulation under an Epipe service apply:

- ATM SAPs are allowed on E1 and E1 IMA ports only
- ETH-CFM OAM on an Ethernet SAP is not supported
- ACL filtering is not supported
- QinQ encapsulated Ethernet SAP interworking to an ATM SAP is not supported
- ATM policing on an ATM SAP is not supported

**Note:** In addition to supporting ATM-encapsulated SAPs under an Epipe service, the 7705 SAR-M also supports:

- the termination of ATM-encapsulated SAPs to IES for node management purposes. If the only transport uplink for a site is ATM, it is necessary to offer in-band management over the existing ATM network.
- VC-mux routed PDU encapsulated SAPs for node management. The SAP must be attached to an IES service. No IP forwarding is supported on this management SAP.

For the application described in this section, an ATM-encapsulated SAP to IES is used for managing the 7705 SAR-M at the cell site. See [IES for In-band Management](#) for details.

**Figure 82 Ethernet-to-ATM Interworking on the 7705 SAR-M**

26463

The following examples show the Epipe SAP-to-SAP configurations for Ethernet-to-ATM interworking. The first example shows the ATM SAP configuration (ATM VPI/VCI is 30/80), and the second example shows the IMA configuration (IMA bundle). In both examples, SAP 1/1/2:2 is the Ethernet SAP facing the eNodeB.

**Example:**

```

epipe 105 customer 1 create
 sap 1/1/2:2 create
 exit
 sap 1/2/3.1:30/80 create
 exit
 no shutdown
exit

```

**Example:**

```

epipe 105 customer 1 create
 sap 1/1/2:2 create
 exit
 sap bundle-ima-1/2.1:20/200 create
 atm
 exit
exit
no shutdown
exit

```

When ATM encapsulation under an Epipe service is used, the AAL-5 encapsulation type for the ATM SAP is “aal5mux-bridged-eth-nof\*”, as shown in the following **show>service>id service-id>sap sap-id detail** screen.

```

ATM SAP Configuration Information

Ingress TD Profile : 1 Egress TD Profile : 1
Ingress TD Ovr : N/A Egress TD Ovr : N/A
Alarm Cell Handling: Enabled
OAM Termination : Disabled Periodic Loopback : Disabled
AAL-5 Encap : aal5mux-bridged-eth-nof*

```

### 4.11.3.6 Configuring Epipe Spoke SDP Bindings

[Figure 83](#) shows an example of a distributed Epipe service configuration between two routers, identifying the service and customer IDs and the unidirectional SDPs required to communicate to the far-end routers. The **spoke-sdp sdp-id:vc-id** must match on both sides.

**Figure 83 SDPs—Unidirectional Tunnels**

19484

An SDP must exist before it can be used with a spoke SDP. For SDP configuration information, see [Configuring SDPs](#).

For information on configuring ETH-CFM parameters on a spoke SDP, see [ETH-CFM \(802.1ag and Y.1731\) Tasks](#).

Use the following CLI syntax to create a spoke SDP binding with an Epipe service.

**CLI Syntax:**

```
config>service# epipe service-id [customer customer-id]
[create] [vc-switching]
 spoke-sdp sdp-id:vc-id [vc-type {ether|vlan}]
 [create] vlan-vc-tag 0..4094
 egress
 vc-label egress-vc-label
 eth-cfm
 ingress
 vc-label ingress-vc-label
 no shutdown
```

**Example:**

```
ALU-1>config>service# epipe 5500
config>service>epipe# spoke-sdp 2:123
config>service>epipe>spoke-sdp# egress
config>service>epipe>spoke-sdp>egress# vc-label 5500
config>service>epipe>spoke-sdp>egress# exit
config>service>epipe>spoke-sdp# ingress
config>service>epipe>spoke-sdp>ingress# vc-label 6600
config>service>epipe>spoke-sdp>ingress# exit
config>service>epipe>spoke-sdp# no shutdown
```

```

ALU-2>config>service# epipe 5500
config>service>epipe# spoke-sdp 2:123
config>service>epipe>spoke-sdp# egress
config>service>epipe>spoke-sdp>egress# vc-label 6600
config>service>epipe>spoke-sdp>egress# exit
config>service>epipe>spoke-sdp# ingress
config>service>epipe>spoke-sdp>ingress# vc-label 5500
config>service>epipe>spoke-sdp>ingress# exit
config>service>epipe>spoke-sdp# no shutdown

```

The following example shows the configuration output for binding an Epipe service between ALU-1 and ALU-2. This example assumes the SAPs have already been configured (see [Configuring Epipe SAP Parameters](#)).

```

ALU-1>config>service# info

...
 epipe 5500 customer 5 vpn 5500 create
 description "Distributed epipe service to east coast"
 sap 1/1/3:21 create
 ingress
 filter ip 1
 qos 555
 exit
 egress
 qos 627
 exit
 exit
 spoke-sdp 2:123 create
 ingress
 vc-label 6600
 exit
 egress
 vc-label 5500
 exit
 exit
 no shutdown
 exit
...

ALU-1>config>service#

```

```

ALU-2>config>service# info

...
 epipe 5500 customer 5 vpn 5500 create
 description "Distributed epipe service to west coast"
 sap 1/1/4:550 create
 ingress
 qos 654
 exit
 egress
 qos 432

```

```

 exit
 exit
 spoke-sdp 2:123 create
 ingress
 vc-label 5500
 exit
 egress
 vc-label 6600
 exit
 exit
 no shutdown
 exit
...

```

## 4.11.4 Creating an Fpipe Service

This section describes how to create an Fpipe service. Additional topics in this section include:

- [Configuring Fpipe SAP Parameters](#)
- [Configuring Fpipe SDP Bindings](#)

Use the following CLI syntax to create an Fpipe service.

**CLI Syntax:**

```

config>service# fpipe service-id [customer customer-id]
[create] [vpn vpn-id] [vc-type {fr-dlci}]
[vc-switching]
 description description-string
 service-mtu octets
 no shutdown

```

PE router 1 (A:ALU-41):

**Example:**

```

A:ALU-41>config>service# fpipe 1 customer 1 create
A:ALU-41>config>service>fpipe# description "fpipe test"
A:ALU-41>config>service>fpipe# service-mtu 1400
A:ALU-41>config>service>fpipe# no shutdown
A:ALU-41>config>service>fpipe#

```

PE router 2 (A:ALU-42):

**Example:**

```

A:ALU-42>config>service# fpipe 1 customer 1 create
A:ALU-42>config>service>fpipe# description "fpipe test"
A:ALU-42>config>service>fpipe# service-mtu 1400
A:ALU-42>config>service>fpipe# no shutdown
A:ALU-42>config>service>fpipe#

```

The following example shows the Fpipe service creation output.

PE Router 1 (ALU-41):

```
A:ALU-41>config>service# info

...
 fpipe 1 customer 1 create
 description "fpipe test"
 service-mtu 1400
 no shutdown
 exit
...

A:ALU-41>config>service#
```

PE Router 2 (ALU-42):

```
A:ALU-42>config>service# info

...
 fpipe 1 customer 1 create
 description "fpipe test"
 service-mtu 1400
 no shutdown
 exit

A:ALU-42>config>service#
```

#### 4.11.4.1 Configuring Fpipe SAP Parameters

Use the following CLI syntax to configure Fpipe SAP parameters.

For ingress and egress configuration information, see [Configuring Ingress and Egress SAP Parameters](#).

**CLI Syntax:**

```
config>service# fpipe service-id [customer customer-id]
[create] [vpn vpn-id] [vc-type {fr-dlci}]
[vc-switching]
 sap sap-id [create]
 accounting-policy acct-policy-id
 collect-stats
 description description-string
 egress
 qos policy-id
 ingress
 qos policy-id [shared-queuing]
 no shutdown
```

**Example:**

```

A:ALU-41>config>service# fpipe 1
A:ALU-41>config>service>fpipe# sap 1/2/1:16 create
A:ALU-41>config>service>fpipe>sap# ingress
A:ALU-41>config>service>fpipe>sap>ingress# qos 101
A:ALU-41>config>service>fpipe>sap>ingress# exit
A:ALU-41>config>service>fpipe>sap# egress
A:ALU-41>config>service>fpipe>sap>egress# qos 1020
A:ALU-41>config>service>fpipe>sap>egress# exit
A:ALU-41>config>service>fpipe>sap# no shutdown
A:ALU-41>config>service>fpipe>sap# exit
A:ALU-41>config>service>fpipe#

```

The following example shows the Fpipe SAP configuration output for PE Router 1 (ALU-41).

```

A:ALU-41>config>service# info

...
 fpipe 1 customer 1 create
 description "fpipe test"
 service-mtu 1400
 sap 1/2/1:16 create
 ingress
 qos 101
 exit
 egress
 qos 1020
 exit
 exit
 no shutdown
 exit
...

```

To configure a basic local Fpipe service (SAP-to-SAP), enter the **sap sap-id** command twice with different port IDs in the same service configuration.

The following example shows an FR SAP-to-SAP configuration:

```

A:ALU-41>config>service# info

...
 fpipe 1 customer 1 create
 description "FR sap2sap"
 service-mtu 1400
 sap 1/2/1:16
 sap 1/3/1:20
 no shutdown
 exit
...

```

#### 4.11.4.2 Configuring Fpipe SDP Bindings

Use the following CLI syntax to create a spoke SDP binding with an Fpipe service (for distributed service). For SDP configuration information, see [Configuring SDPs](#).

**CLI Syntax:**

```
config>service# fpipe service-id [customer customer-id]
[create] [vpn vpn-id] [vc-type {fr-dlci}]
[vc-switching]
 spoke-sdp sdp-id:vc-id [create]
 egress
 vc-label egress-vc-label
 ingress
 vc-label ingress-vc-label
 no shutdown
```

**Example:**

```
A:ALU-41>config>service# fpipe 1
A:ALU-41>config>service>fpipe# spoke-sdp 1:1 create
A:ALU-41>config>service>fpipe>spoke-sdp# no shutdown
A:ALU-41>config>service>fpipe>spoke-sdp# exit
```

The following example shows the Fpipe spoke SDP configuration output for PE Router 1 (ALU-41).

```
A:ALU-41>config>service# info

...
 fpipe 1 customer 1 create
 description "fpipe test"
 service-mtu 1400
 sap 1/2/1:16 create
 ingress
 qos 101
 exit
 egress
 qos 1020
 exit
 exit
 spoke-sdp 1:1 create
 exit
 no shutdown
 exit
...

A:ALU-41>config>service#
```

## 4.11.5 Creating an Hpipe Service

This section describes how to create an Hpipe service. Additional topics in this section include:

- [Configuring Hpipe SAP Parameters](#)
- [Configuring Hpipe SDP Bindings](#)

Use the following CLI syntax to create an Hpipe service.

**CLI Syntax:**

```
config>service# hpipe service-id [customer customer-id]
[create] [vpn vpn-id] [vc-type {hdlc}] [vc-switching]
description description-string
service-mtu octets
no shutdown
```

PE router 1 (ALU-41):

**Example:**

```
A:ALU-41>config>service# hpipe 4 customer 1 create
A:ALU-41>config>service>hpipe# description "hpipe test"
A:ALU-41>config>service>hpipe# service-mtu 1400
A:ALU-41>config>service>hpipe# no shutdown
A:ALU-41>config>service>hpipe#
```

PE router 2 (ALU-42):

**Example:**

```
A:ALU-42>config>service# hpipe 4 customer 1 create
A:ALU-42>config>service>hpipe# description "hpipe test"
A:ALU-42>config>service>hpipe# service-mtu 1400
A:ALU-42>config>service>hpipe# no shutdown
A:ALU-42>config>service>hpipe#
```

The following example shows the Hpipe service creation output.

PE Router 1 (ALU-41):

```
A:ALU-41>config>service# info

...
 hpipe 4 customer 1 create
 description "hpipe test"
 service-mtu 1400
 no shutdown
 exit
...

A:ALU-41>config>service#
```

## PE Router 2 (ALU-42):

```
A:ALU-42>config>service# info

...
 hpipe 4 customer 1 create
 description "hpipe test"
 service-mtu 1400
 no shutdown
 exit
```

### 4.11.5.1 Configuring Hpipe SAP Parameters

Use the following CLI syntax to configure Hpipe SAP parameters. For ingress and egress configuration information, see [Configuring Ingress and Egress SAP Parameters](#).

**CLI Syntax:**

```
config>service# hpipe service-id [customer customer-id]
[create] [vpn vpn-id] [vc-type {hdlc}] [vc-switching]
sap sap-id [create]
 accounting-policy acct-policy-id
 collect-stats
 description description-string
 egress
 qos policy-id
 ingress
 qos policy-id [shared queuing]
 no shutdown
```

**Example:**

```
A:ALU-41>config>service# hpipe 4
A:ALU-41>config>service>hpipe# sap 1/4/1.20 create
A:ALU-41>config>service>hpipe>sap# ingress
A:ALU-41>config>service>hpipe>sap>ingress# qos 102
A:ALU-41>config>service>hpipe>sap>ingress# exit
A:ALU-41>config>service>hpipe>sap# egress
A:ALU-41>config>service>hpipe>sap>egress# qos 103
A:ALU-41>config>service>hpipe>sap>egress# exit
A:ALU-41>config>service>hpipe>sap# no shutdown
A:ALU-41>config>service>hpipe>sap# exit
A:ALU-41>config>service>hpipe#
```

The following example shows the Hpipe SAP configuration output for PE Router 1 (ALU-41).

```
A:ALU-41>config>service# info

...
 hpipe 4 customer 1 create
 description "hpipe test"
 service-mtu 1400
 sap 1/4/1.20 create
 ingress
 qos 102
 exit
 egress
 qos 103
 exit
 exit
 no shutdown
 exit
...

```

To configure a basic local Hpipe service (SAP-to-SAP), enter the **sap sap-id** command twice with different port IDs in the same service configuration.

The following example shows an HDLC SAP-to-SAP configuration:

```
A:ALU-41>config>service# info

...
 hpipe 4 customer 1 create
 description "HDLC sap2sap"
 service-mtu 1514
 sap 1/4/1.20
 sap 1/5/1.10
 no shutdown
 exit
...

```

### 4.11.5.2 Configuring Hpipe SDP Bindings

Use the following CLI syntax to create a spoke SDP binding with an Hpipe service (for distributed service). For SDP configuration information, see [Configuring SDPs](#).

**CLI Syntax:**

```
config>service# hpipe service-id [customer customer-id]
[create] [vpn vpn-id] [vc-type {hdlc}] [vc-switching]
spoke-sdp sdp-id:vc-id [create]
egress
 vc-label egress-vc-label
ingress
 vc-label ingress-vc-label
no shutdown
```

**Example:**

```
A:ALU-41>config>service# hpipe 4
A:ALU-41>config>service>hpipe# spoke-sdp 1:4 create
A:ALU-41>config>service>hpipe>spoke-sdp# no shutdown
A:ALU-41>config>service>hpipe>spoke-sdp# exit
```

The following example shows the Hpipe spoke SDP configuration output for PE Router 1 (ALU-41).

```
A:ALU-41>config>service# info

...
 hpipe 4 customer 1 create
 description "hpipe test"
 service-mtu 1400
 sap 1/4/1.20 create
 ingress
 qos 102
 exit
 egress
 qos 103
 exit
 exit
 spoke-sdp 1:4 create
 exit
 no shutdown
 exit
...

A:ALU-41>config>service#
```

---

## 4.11.6 Creating an Ipipe Service

This section describes how to create an Ipipe service. Additional topics in this section include:

- [Configuring Ipipe SAP Parameters](#)
- [Configuring Ipipe SDP Bindings](#)

Use the following CLI syntax to create an Ipipe service.

**CLI Syntax:**    `config>service# ipipe service-id [customer customer-id]  
                  [vpn vpn-id] [vc-switching]  
                  description description-string  
                  no shutdown`

The following example shows an Ipipe configuration:

```
A:ALU-1>config>service# info

...
 ipipe 202 customer 1 create
 description "eth_ipipe"
 no shutdown
 exit

A:ALU-1>config>service#
```

### 4.11.6.1 Configuring Ipipe SAP Parameters

The following example shows an Ipipe SAP configuration:

```
A:ALU-48>config>service# info

...
 ipipe 202 customer 1 create
 sap 1/1/2:444 create
 description "eth_ipipe"
 ce-address 172.16.0.0
 exit
 spoke-sdp 16:516 create
 ce-address 172.16.0.1
 exit
 no shutdown
 exit
...

```

The following shows a PPP to Ethernet local lpipe example:

**Example:**

```

config>service# lpipe 206 customer 1 create
config>service>lpipe$ sap 1/1/2:447 create
config>service>lpipe>sap$ description "eth_ppp_lpipe"
config>service>lpipe>sap$ ce-address 172.16.0.0
config>service>lpipe>sap$ no shutdown
config>service>lpipe>sap$ exit
config>service>lpipe# spoke-sdp 15:516 create
config>service>lpipe>sap>spoke-sdp$ ce-address
172.16.0.1
config>service>lpipe>sap>spoke-sdp$ exit
config>service>lpipe>$ exit
config>service>lpipe# no shutdown
config>service>lpipe# exit
config>service#

```

The following shows the output:

```

A:ALU-48>config>service# info

lpipe 206 customer 1 create
 sap 1/1/2:447 create
 description "eth_ppp_lpipe"
 ce-address 172.16.0.0
 exit
 spoke-sdp 15:516 create
 ce-address 172.16.0.1
 exit
 exit
 no shutdown
 exit
exit

```

The configuration of a Cisco HDLC SAP on an lpipe is similar to the above example, except that the *sap-id* has the form *slot/mda/port.channel-group* (1/2/2.1).

### 4.11.6.2 Configuring Ipipe SDP Bindings

The following shows an Ipipe SDP configuration example:

```
A:ALU-48>config>service# info

...
 sdp 16 mpls create
 far-end 10.4.4.4
 ldp
 path-mtu 1600
 keep-alive
 shutdown
 exit
 no shutdown
exit
...
 ipipe 207 customer 1 create
 shutdown
 sap 1/1/2:449 create
 description "Remote_Ipipe"
 ce-address 172.16.0.10
 exit
 spoke-sdp 16:516 create
 ce-address 172.16.0.11
 exit
```

### 4.11.7 Configuring PW Switching

The **vc-switching** parameter defines a VLL service as a PW switching point, also called an S-PE. This is the point where a VLL service switches from one PW type to another. The **vc-switching** parameter must be specified when the VLL service is created.

Once a VLL service is configured as an S-PE, you cannot add a SAP to the configuration. The following example shows the error message generated by the CLI if you attempt to create a SAP on a VLL PW switching service.

```
Example: *A:ALU>config>service>epipe 2 customer 1 create
 vc-switching
 *A:ALU>config>service>epipe$ sap 1/5/1 create
 MINOR: SVCMGR #1311 SAP is not allowed under PW switching
 service
 *A:ALU>config>service>epipe$
```

Use the following CLI syntax to configure pseudowire switching VLL services.

**CLI Syntax:** `config>service# apipe service-id [customer customer-id]  
[create] [vpn vpn-id] [vc-type {atm-vcc|atm-  
vpc|atm-cell}] [vc-switching]  
description description-string  
spoke-sdp sdp-id:vc-id  
no shutdown`

**CLI Syntax:** `config>service# cpipe service-id [customer customer-id]  
[create] [vpn vpn-id] [vc-type {satop-e1 | satop-t1 |  
satop-e3 | satop-t3 | cesopsn | cesopsn-cas}]  
[vc-switching]  
description description-string  
service-mtu octets  
no shutdown`

**CLI Syntax:** `config>service# epipe service-id [customer customer-id]  
[create] [vpn vpn-id] [vc-switching]  
description description-string  
spoke-sdp sdp-id:vc-id  
no shutdown`

**CLI Syntax:** `config>service# fpipe service-id [customer customer-id]  
[create] [vpn vpn-id] [vc-type {fr-dlci}]  
[vc-switching]  
description description-string  
spoke-sdp sdp-id:vc-id  
no shutdown`

**CLI Syntax:** `config>service# hpipe service-id [customer customer-id]  
[create] [vpn vpn-id] [vc-type {hdlc}] [vc-switching]  
description description-string  
spoke-sdp sdp-id:vc-id  
no shutdown`

**CLI Syntax:** `config>service# ipipe service-id [customer customer-id]  
[vpn vpn-id] [vc-switching]  
description description-string  
spoke-sdp sdp-id:vc-id  
no shutdown`

The following shows an example of the command usage to configure a VLL service as a PW switching service:

**Example:** `ALU-1>config>service# apipe 5 customer 1 vpn 1  
vc-switching create  
config>service>apipe$ description "Default apipe  
description for service id 100"  
config>service>apipe# spoke-sdp 3:1 create  
config>service>apipe>spoke-sdp# exit`

```
config>service>apipe# spoke-sdp 6:200 create
config>service>apipe>spoke-sdp# exit
config>service>apipe# no shutdown
```

The following example shows configurations for each service:

```
*A:ALA-48>config>service# info

apipe 100 customer 1 vpn 1 vc-switching create
description "Default apipe description for service id 100"
spoke-sdp 3:1 create
exit
spoke-sdp 6:200 create
exit
no shutdown
exit
...
cpipe 107 customer 1 vpn 107 vc-switching vc-type satop-e1 create
description "Default cpipe description for service id 107"
spoke-sdp 3:7 create
exit
spoke-sdp 6:207 create
exit
no shutdown
exit
...
epipe 108 customer 1 vpn 108 vc-switching create
description "Default epipe description for service id 108"
spoke-sdp 3:8 create
exit
spoke-sdp 6:208 create
exit
no shutdown
exit
...
fpipe 109 customer 1 vpn 75 vc-switching create
description "Default fpipe description for service id 109"
spoke-sdp 3:9 create
exit
spoke-sdp 6:209 create
exit
no shutdown
exit
...
hpipe 110 customer 1 vpn 76 vc-switching create
description "Default hpipe description for service id 110"
spoke-sdp 3:10 create
exit
spoke-sdp 6:210 create
exit
no shutdown
exit
...
ipipe 111 customer 1 vpn 77 vc-switching create
description "Default ipipe description for service id 111"
spoke-sdp 3:11 create
exit
spoke-sdp 6:211 create
```

```

exit
no shutdown
exit
...

```

## 4.11.8 Configuring Ingress and Egress SAP Parameters

By default, QoS policy ID 1 is applied to ingress and egress service SAPs. Existing QoS policies can be associated with service SAPs on ingress and egress ports.

Ingress and egress QoS SAP parameters can be applied to distributed and local Epipe, Fpipe, Hpipe, and Lpipe service SAPs, and to local Apipe and Cpipe service SAPs.

Ingress and egress QoS parameters can also be applied to SAP aggregation groups for ATM VCC VLL services. QoS parameters cannot be applied to SAPs that are members of the aggregation group.

By default, there are no IP filters associated with interfaces or services. IP filter policies can be applied to ingress Epipe and Lpipe service SAPs.

**Example:**

```

ALU-1>config>service# epipe 5500
config>service>epipe# sap 1/1/3:21
config>service>epipe>sap# ingress
config>service>epipe>sap>ingress# filter ip 1
config>service>epipe>sap>ingress# qos 555
config>service>epipe>sap>ingress# exit
config>service>epipe>sap# egress
config>service>epipe>sap>egress# qos 627
config>service>epipe>sap>egress# exit
config>service>epipe>sap#

```

The following example shows the Epipe SAP ingress and egress configuration output.

```

ALU-1>config>service#

epipe 5500 customer 5 vpn 5500 create
description "Distributed epipe service to east coast"
sap 1/1/3:21 create
 ingress
 filter ip 1
 qos 555
 exit
 egress
 qos 627
 exit
exit

```

```

spoke-sdp 2:123 create
 ingress
 vc-label 6600
 exit
 egress
 vc-label 5500
 exit
exit
no shutdown
exit

```

### 4.11.9 Using the Control Word

The control word is mandatory for Cpipe SAToP and CESoPSN configurations, Epipe MEF 8 configurations, and Fpipe one-to-one mapping configurations.

The control word is optional for Apipe, Epipe (non-MEF 8), Hpipe, and Lpipe services, but must be enabled for Hpipe pseudowire services when transporting packets that are less than 64 bytes. If the control word is enabled for Epipe or Lpipe services, it will be set to all zeros and ignored on egress.

When the control word is enabled, the Admin Control Word is set to Preferred. Both sides of the VLL must be configured with a matching control word, either both enabled or both disabled, for the pipe to be up.

The control word state will be set to True or False depending on what is configured, either enabled (True) or disabled (False).

**Example:**

```

config>service# cpipe 2100 customer 1
config>service>cpipe$ description "Default cpipe
description for service id 2100"
config>service>cpipe$ sap 1/2/7.1:4 create
config>service>cpipe>sap$ description "Default sap
description for service id 2100"
config>service>cpipe>sap$ exit
config>service>cpipe# spoke-sdp 1:2001 create
config>service>cpipe>spoke-sdp$ control-word
config>service>cpipe>spoke-sdp$ exit
config>service>cpipe# no shutdown

```

The following example shows the control word configuration output for a Cpipe service.

```

*A:ALU-Dut-B>config>service>cpipe# info

description "Default cpipe description for service id 2100"
sap 1/2/7.1:4 create

```

```

 description "Default sap description for service id 2100"
 exit
 spoke-sdp 1:2001 create
 control-word
 exit
 no shutdown

*A:ALU-Dut-B>config>service>cpipe#

```

The control word cannot be disabled on Cpipe, Epipe MEF 8, or Fpipe services. To disable the control word option on Apipe, Epipe (non-MEF 8), Hpipe, or Ipipe services, use the **no control-word** command.

**Example:**

```

config>service>apip# spoke-sdp 1:2001 no control-word
config>service>apip>spoke-sdp$ exit

```

## 4.11.10 Configuring PW Redundancy

This section describes configuring PW redundancy. Additional topics in this section include:

- [Configuring PW Redundancy—Standby Signaling](#)
- [Configuring PW Redundancy—ICB](#)

For PW redundancy, create an explicit endpoint and then assign a primary spoke SDP and up to three secondary spoke SDPs, or up to four secondary spoke SDPs with no primary spoke SDP, to that endpoint.

**CLI Syntax:**

```

config>service# cpipe service-id [customer customer-id]
[create]
 endpoint endpoint-name [create]
 spoke-sdp sdp-id:vc-id endpoint endpoint-name
 [create]
 precedence precedence-value
 no shutdown

```

**Example:**

```

config>service# cpipe 2100
config>service>cpipe$ endpoint "Endpoint_Y" create
config>service>cpipe$ spoke-sdp 1:100 endpoint
 "Endpoint_Y" create
config>service>cpipe>spoke-sdp$ precedence primary
config>service>cpipe$ spoke-sdp 2:200 endpoint
 "Endpoint_Y" create
config>service>cpipe>spoke-sdp$ precedence 1
no shutdown

```

The following example shows the PW redundancy configuration output for a Cpipe service.

```
*A:7705:Dut-C>config>service>cpipe# info

 endpoint "Endpoint_Y" create
 exit
 spoke-sdp 1:100 endpoint "Endpoint_Y" create
 precedence primary
 exit
 spoke-sdp 2:200 endpoint "Endpoint_Y" create
 precedence 1
 exit

*A:7705:Dut-C>config>service>cpipe#
```

#### 4.11.10.1 Configuring PW Redundancy—Standby Signaling

For standby signaling, create an endpoint as shown in the preceding section, but specify an SDP as the standby signaling master and the far-end endpoints as standby signaling slaves.

In the following example, precedence primary indicates that the spoke SDP is the active SDP and precedence 1 indicates that the spoke SDP is the standby SDP.

To create a standby signaling master:

**CLI Syntax:**

```
config>service# cpipe service-id [customer customer-id]
[create]
 endpoint endpoint-name [create]
 standby-signaling-master
 exit
 spoke-sdp sdp-id:vc-id endpoint endpoint-name
 [create]
 precedence precedence-value
 no shutdown
```

**Example:**

```
config>service cpipe 555
config>service>cpipe# endpoint "stdbyMaster" create
config>service>cpipe>endpoint# standby-signaling-master
config>service>cpipe>endpoint# exit
config>service>cpipe# spoke-sdp 5:555 endpoint
 "stdbyMaster" create
config>service>cpipe>spoke-sdp$ precedence primary
exit
config>service>cpipe# spoke-sdp 131:555 endpoint
 "stdbyMaster" create
config>service>cpipe>spoke-sdp$ precedence 1
```

```
exit
```

To create the far-end endpoints as standby signaling slaves:

**CLI Syntax:**

```
config>service# cpipe service-id [customer customer-id]
[create]
 endpoint endpoint-name [create]
 standby-signaling-slave
 exit
 spoke-sdp sdp-id:vc-id endpoint endpoint-name
 [create]
 precedence precedence-value
 no shutdown
```

**Example:**

```
config>service cpipe 555
config>service>cpipe# endpoint "FarendA" create
config>service>cpipe>endpoint# standby-signaling-slave
config>service>cpipe>endpoint# exit
config>service>cpipe# spoke-sdp 130:555 endpoint
 "FarendA" create
config>service>cpipe>spoke-sdp$ precedence primary
exit
```

**Example:**

```
config>service cpipe 555
config>service>cpipe# endpoint "FarendB" create
config>service>cpipe>endpoint# standby-signaling-slave
config>service>cpipe>endpoint# exit
config>service>cpipe# spoke-sdp 130:555 endpoint
 "FarendB" create
config>service>cpipe>spoke-sdp$ precedence primary
exit
```

#### 4.11.10.2 Configuring PW Redundancy—ICB

Inter-Chassis Backup (ICB) spoke SDPs are supported for use with Cpipe services in an MC-APS configuration or MC-LCR configuration and with Epipe services in an MC-LAG configuration. ICB improves switch times, provides additional protection in case of network failures, and reduces packet loss when an active endpoint is switched from a failed MC-APS, MC-LCR, or MC-LAG node to a protection node.

To configure ICB, create explicit endpoints on the access and network side on the working node and then assign a primary spoke SDP on the reverse side of the protection node.

---

**CLI Syntax:** `config>service# cpipe service-id [customer customer-id]  
[create]  
    description description-string  
    endpoint endpoint-name [create]  
    service-mtu octets  
    standby-signaling-master  
    exit  
    sap sap-id [create]  
    spoke-sdp sdp-id:vc-id endpoint endpoint-name [icb]  
        [create]  
        precedence precedence-value  
    no shutdown`

The example below shows how to configure ICB on the working node in an MC-APS scenario:

**Example:**

```
config>service cpipe 555
config>service>cpipe# description "Cpipe for service id
1"
config>service>cpipe# service-mtu 1000
config>service>cpipe# endpoint "X" create
config>service>cpipe>endpoint# exit
config>service>cpipe# endpoint "Y" create
config>service>cpipe>endpoint# exit
config>service>cpipe# sap aps-1.1.1.1.1 endpoint "X"
create
config>service>cpipe>sap# description "SAP for service
id 1"
config>service>cpipe>sap# exit
config>service>cpipe# spoke-sdp 2003:1 endpoint
"Y" create
config>service>cpipe>spoke-sdp# exit
config>service>cpipe# spoke-sdp 2004:1001 endpoint
"X" icb create
config>service>cpipe>spoke-sdp# exit
config>service>cpipe# spoke-sdp 2004:1001 endpoint
"Y" icb create
config>service>cpipe>spoke-sdp# exit
config>service>cpipe# no shutdown
exit
```

The example below shows how to configure ICB on the protection node in an MC-APS scenario:

**Example:**

```
config>service cpipe 1 vc-type cesopsn create
config>service>cpipe# service-mtu 1000
config>service>cpipe# endpoint "X" create
config>service>cpipe>endpoint# exit
```

```

config>service>cpipe# endpoint "Y" create
config>service>cpipe>endpoint# exit
config>service>cpipe# sap aps-1.1.1.1 endpoint "X"
create
config>service>cpipe>sap# description "SAP description
for service id 1"
config>service>cpipe>sap# exit
config>service>cpipe# spoke-sdp 4003:1 endpoint
"Y" create
config>service>cpipe>spoke-sdp# exit
config>service>cpipe# spoke-sdp 4002:1001 endpoint
"Y" icb create
config>service>cpipe>spoke-sdp# exit
config>service>cpipe# spoke-sdp 4002:2001 endpoint
"X" icb create
config>service>cpipe>spoke-sdp# exit
config>service>cpipe# no shutdown
exit

```

The CLI output below shows an example of ICB configured on the working node in an MC-LCR scenario:

```

cpipe 1 customer 1 vc-type cesopsn create
description "Default Cpipe description for service id 1"
service-mtu 1000
endpoint "X" create
exit
endpoint "Y" create
exit
sap lcr-1/1.1 endpoint "X" create
description "Default sap description for service id 1"
no shutdown
exit
spoke-sdp 6003:1 endpoint "Y" create
no shutdown
exit
spoke-sdp 6001:1001 endpoint "X" icb create
no shutdown
exit
spoke-sdp 6001:2001 endpoint "Y" icb create
no shutdown
exit
no shutdown
exit

```

The CLI output below shows an example of ICB configured on the protection node in an MC-LCR scenario:

```

cpipe 1 customer 1 vc-type cesopsn create
description "Default Cpipe description for service id 1"
service-mtu 1000
endpoint "X" create
exit

```

```
endpoint "Y" create
exit
sap lcr-1/1.1 endpoint "X" create
 description "Default sap description for service id 1"
 no shutdown
exit
spoke-sdp 1003:1 endpoint "Y" create
 no shutdown
exit
spoke-sdp 1006:1001 endpoint "Y" icb create
 no shutdown
exit
spoke-sdp 1006:2001 endpoint "X" icb create
 no shutdown
exit
no shutdown
exit
```

---

## 4.12 Service Management Tasks

The service management tasks are similar for Apipe, Cpipe, Epipe, and Ipipe services. This section discusses the following service management tasks:

- [Modifying Service Parameters](#)
- [Disabling a Service](#)
- [Re-enabling a Service](#)
- [Deleting a Service](#)

### 4.12.1 Modifying Service Parameters

Use the **show service service-using** command to display a list of configured VLL services.

To modify a VLL service:

1. Access the specific account by specifying the service ID.
2. Enter the service parameter to modify and then enter the new information.

PE router 1 (A:ALU-41):

**Example:**

```
A:ALU-41>config>service# apipe 5
A:ALU-41>config>service>apipe# sap 1/1/1.1:0/32 create
A:ALU-41>config>service>apipe>sap# accounting-policy 2
A:ALU-41>config>service>apipe>sap# exit
A:ALU-41>config>service>apipe# spoke-sdp 1:4
A:ALU-41>config>service>apipe>spoke-sdp# egress
A:ALU-41>config>service>apipe>spoke-sdp>egress# vc-
label 2048
A:ALU-41>config>service>apipe>spoke-sdp>egress# exit
A:ALU-41>config>service>apipe>spoke-sdp# ingress
A:ALU-41>config>service>apipe>spoke-sdp>ingress# vc-
label 18431
A:ALU-41>config>service>apipe>spoke-sdp>ingress# exit
A:ALU-41>config>service>apipe>spoke-sdp# exit
A:ALU-41>config>service>apipe#
```

## PE router 2 (A:ALU-42):

**Example:**

```

A:ALU-42>config>service# apipe 5
A:ALU-42>config>service>apipe# sap 2/2/2.1:0/32 create
A:ALU-42>config>service>apipe>sap# accounting-policy 2
A:ALU-42>config>service>apipe>sap# exit
A:ALU-42>config>service>apipe# spoke-sdp 1:4
A:ALU-42>config>service>apipe>spoke-sdp# egress
A:ALU-42>config>service>apipe>spoke-sdp>egress# vc-
label 18431
A:ALU-42>config>service>apipe>spoke-sdp>egress# exit
A:ALU-41>config>service>apipe>spoke-sdp# ingress
A:ALU-41>config>service>apipe>spoke-sdp>ingress# vc-
label 2043
A:ALU-41>config>service>apipe>spoke-sdp>ingress# exit
A:ALU-42>config>service>apipe>spoke-sdp# exit
A:ALU-42>config>service>apipe#

```

The following example shows the configuration output when adding an accounting-policy to an existing SAP and modifying the spoke SDP parameters on an existing Apipe service for PE Router 1 (ALU-41) and PE Router 2 (ALU-42).

Use a similar syntax to modify Cpipe, Epipe, and Lpipe services.

```

A:ALU-41>config>service# info

...
 apipe 5 customer 1 create
 description "apipe test"
 service-mtu 1400
 sap 1/1/1.1:0/32 create
 accounting-policy 2
 ingress
 qos 102
 exit
 egress
 qos 103
 exit
 exit
 spoke-sdp 1:4 create
 egress
 vc-label 2048
 ingress
 vc-label 18431
 exit
 no shutdown
 exit
...

A:ALU-41>config>service#

```

```

A:ALU-42>config>service# info

...
 apipe 5 customer 1 create
 description "apipe test"
 service-mtu 1400
 sap 2/2/2.1:0/32 create
 accounting-policy 2
 ingress
 qos 102
 exit
 egress
 qos 103
 exit
 exit
 spoke-sdp 1:4 create
 egress
 vc-label 18431
 ingress
 vc-label 2048
 exit
 no shutdown
 exit
...

A:ALU-42>config>service#

```

## 4.12.2 Disabling a Service

A service can be shut down without deleting the service parameters.

Use the **shutdown** command to shut down a VLL service. The following CLI syntax shows the command to shut down an Apipe service. Use a similar syntax to shut down Cpipe, Epipe, Fpipe, Hpipe, and Ipipe services.

**CLI Syntax:**

```

config>service#
 apipe service-id
 shutdown

```

PE router 1 (A:ALU-41):

**Example:**

```

A:ALU-41>config>service# apipe 5
A:ALU-41>config>service>apipe# shutdown
A:ALU-41>config>service>apipe# exit

```

PE router 2 (A:ALU-42):

**Example:**

```

A:ALU-42>config>service# apipe 5
A:ALU-42>config>service>apipe# shutdown
A:ALU-42>config>service>apipe# exit

```

The following example shows the configuration output for deleting an Apipe service on PE Router 1 (ALU-41) and PE Router 2 (ALU-42).

```
A:ALU-41>config>service# info

...
 apipe 5 customer 1 create
 shutdown
 description "apipe test"
 service-mtu 1400
 sap 1/1/1.1:0/32 create
 accounting-policy 2
 ingress
 qos 102
 exit
 egress
 qos 103
 exit
 exit
 spoke-sdp 1:4 create
 egress
 vc-label 16
 exit
 no shutdown
 exit
...

A:ALU-41>config>service#

A:ALU-42>config>service# info

...
 apipe 5 customer 1 create
 shutdown
 description "apipe test"
 service-mtu 1400
 sap 2/2/2.1:0/32 create
 accounting-policy 2
 ingress
 qos 102
 exit
 egress
 qos 103
 exit
 exit
 spoke-sdp 1:4 create
 egress
 vc-label 16
 exit
 exit
...

A:ALU-42>config>service#
```

---

### 4.12.3 Re-enabling a Service

Use the **no shutdown** command to re-enable a previously disabled VLL service. The following CLI syntax shows the command to re-enable an Apipe service. Use a similar syntax to re-enable Cpipe, Epipe, Fpipe, Hpipe, and Ipipe services.

**CLI Syntax:**

```
config>service#
 apipe service-id
 no shutdown
```

PE router 1 (A:ALU-41):

**Example:**

```
A:ALU-41>config>service# apipe 5
A:ALU-41>config>service>apipe# no shutdown
A:ALU-41>config>service>apipe# exit
```

PE router 2 (A:ALU-42):

**Example:**

```
A:ALU-42>config>service# apipe 5
A:ALU-42>config>service>apipe# no shutdown
A:ALU-42>config>service>apipe# exit
```

### 4.12.4 Deleting a Service

Use the **shutdown** command to delete a VLL service. The SAP, and any associated protocols and spoke SDPs, must be deleted from the VLL service before the VLL service can be deleted.

Perform the following steps to delete a service:

1. Shut down the SAP and SDP.
2. Delete the SAP and SDP.
3. Shut down the service.

Use the following syntax to delete Apipe services. Use a similar syntax to delete Cpipe, Epipe, Fpipe, Hpipe, and Ipipe services.

---

**CLI Syntax:**

```
config>service#
 apipe service-id
 sap sap-id
 shutdown
 exit
 no sap sap-id
 spoke-sdp [sdp-id:vc-id]
 shutdown
 exit
 no spoke-sdp [sdp-id:vc-id]
 shutdown
 exit
 no apipe service-id
```

**Example:**

```
A:ALU-41>config>service# apipe 5
A:ALU-41>config>service>apipe# sap 1/1/1.1:0/32
A:ALU-41>config>service>apipe>sap# shutdown
A:ALU-41>config>service>apipe>sap# exit
A:ALU-41>config>service>apipe# no sap 1/1/1.1:0/32
A:ALU-41>config>service>apipe# spoke-sdp 1:4
A:ALU-41>config>service>apipe>spoke-sdp# shutdown
A:ALU-41>config>service>apipe>spoke-sdp# exit
A:ALU-41>config>service>apipe# no spoke-sdp 1:4
A:ALU-41>config>service>apipe# shutdown
A:ALU-41>config>service>apipe# exit
A:ALU-41>config>service# no apipe 5
```

---

## 4.13 VLL Services Command Reference

### 4.13.1 Command Hierarchies

- [VLL Services Configuration Commands](#)
  - [Apipe Service Configuration Commands](#)
  - [Apipe Service with SAP Aggregation Configuration Commands](#)
  - [Cpipe Service Configuration Commands](#)
  - [Epipe Service Configuration Commands](#)
  - [Fpipe Service Configuration Commands](#)
  - [Hpipe Service Configuration Commands](#)
  - [Ipipe Service Configuration Commands](#)

| <b>Description</b> | This command creates a text description stored in the configuration file for a configuration context.<br><br>The <b>no</b> form of this command removes the string from the context.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Default</b>     | No description is associated with the configuration context.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <i>description-string</i> — the description character string. Allowed values are any string up to 80 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.                                                                                                                                                                                                                                                                                                                                                                                                                    |

## shutdown

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Syntax</b>        | <b>[no] shutdown</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Context</b>       | <pre> config&gt;service&gt;apipe config&gt;service&gt;apipe&gt;sap config&gt;service&gt;apipe&gt;spoke-sdp config&gt;service&gt;apipe&gt;sap-aggregation-group config&gt;service&gt;cpipe config&gt;service&gt;cpipe&gt;sap config&gt;service&gt;cpipe&gt;spoke-sdp config&gt;service&gt;epipe config&gt;service&gt;epipe&gt;sap config&gt;service&gt;epipe&gt;spoke-sdp config&gt;service&gt;fpipe config&gt;service&gt;fpipe&gt;sap config&gt;service&gt;fpipe&gt;spoke-sdp config&gt;service&gt;hpipe config&gt;service&gt;hpipe&gt;sap config&gt;service&gt;hpipe&gt;spoke-sdp config&gt;service&gt;ipipe config&gt;service&gt;ipipe&gt;sap config&gt;service&gt;ipipe&gt;spoke-sdp </pre>                                                                                                                                                                                          |
| <b>Description</b>   | <p>The <b>shutdown</b> command administratively disables an entity. The operational state of the entity is disabled as well as the operational state of any entities contained within. When disabled, an entity does not change, reset, or remove any configuration settings or statistics. Many objects must be shut down before they can be deleted. Many entities must be explicitly enabled using the <b>no shutdown</b> command.</p> <p>The <b>no</b> form of this command places the entity into an administratively enabled state.</p> <p>Services are created in the administratively down (<b>shutdown</b>) state. When a <b>no shutdown</b> command is entered, the service becomes administratively up and then tries to enter the operationally up state. Default administrative states for services and service entities are described in the following Special Cases.</p> |
| <b>Special Cases</b> | <p><b>Service Admin State</b> — bindings to an SDP within the service will be put into the out-of-service state when the service is shut down. While the service is shut down, all customer packets are dropped and counted as discards for billing and debugging purposes.</p> <p><b>Service Operational State</b> — a service is considered operational if at least one SAP and one SDP are operational</p> <p><b>SDP (global)</b> — when an SDP is shut down at the global service level, all bindings to that SDP are put into the out-of-service state and the SDP itself is put into the administratively and operationally down states. Packets that would normally be transmitted using this SDP binding will be discarded and counted as dropped packets.</p>                                                                                                                  |

---

**SDP (service level)** — shutting down an SDP within a service only affects traffic on that service from entering or being received from the SDP. The SDP itself may still be operationally up for other services.

| <b>Description</b> | <p>This command configures a point-to-point ATM service. The Apipe service provides a point-to-point Layer 2 VPN connection to a local or remote SAP. An Apipe can connect an ATM endpoint locally (in the same 7705 SAR) or over a PSN to a remote endpoint of the same type.</p> <p>Apipes support SAP aggregation groups in which multiple VCC SAPs can be bound in a single service.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <p><i>service-id</i> — uniquely identifies a service in the service domain. This ID must be unique to this service and may not be used for any other service of any type. The <i>service-id</i> must be the same number or name used for every 7705 SAR on which this service is defined.</p> <p><b>Values</b> 1 to 2147483647 or <i>service-name</i></p> <p><b>create</b> — keyword used to create an Apipe. The <b>create</b> keyword requirement can be enabled/disabled in the <b>environment&gt;create</b> context.</p> <p><i>customer-id</i> — specifies the customer ID number to be associated with the service. This parameter is required on service creation and optional for service editing or deleting.</p> <p><b>Values</b> 1 to 2147483647</p> <p><i>vpn-id</i> — specifies the VPN ID number that allows you to identify virtual private networks (VPNs) by a VPN identification number. If this parameter is not specified, the VPN ID uses the same service ID number.</p> <p><b>Values</b> 1 to 2147483647</p> <p><b>vc-type</b> — specifies a 15-bit value that defines the type of the VC signaled to the peer. Its values are defined in <i>draft-ietf-pwe3-iana-allocation</i> and it defines both the signaled VC type as well as the resulting datapath encapsulation over the Apipe.</p> <p><b>Values</b> atm-vcc, atm-vpc, atm-cell</p> <p><b>Default</b> atm-vcc</p> <p>The <b>vc-type</b> must be set to <b>atm-vcc</b> in order to configure an Apipe for N-to-one cell mode where N &gt; 1.</p> <p>The <b>vc-type</b> must be set to <b>atm-cell</b> in order to configure an Apipe for ATM virtual trunking.</p> <p><b>vc-switching</b> — specifies that pseudowire switching signaling is used for the spoke SDPs configured for this service</p> |

| <b>Description</b> | <p>This command configures a circuit emulation service using MPLS or GRE encapsulation. The <b>vc-type</b> defines the type of unstructured or structured circuit emulation service to be configured. All other parameters (<b>service-id</b>, <b>customer</b>) have common usage with other service types.</p> <p>The <b>no</b> form of the command deletes the configuration for the specified service.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Default</b>     | no cpipe                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <p><i>service-id</i> — uniquely identifies a service in the service domain. This ID must be unique to this service and may not be used for any other service of any type. The <i>service-id</i> must be the same number or name used for every 7705 SAR on which this service is defined.</p> <p><b>Values</b> 1 to 2147483647 or <i>service-name</i></p> <p><i>customer-id</i> — specifies the customer ID number to be associated with the service. This parameter is required on service creation and optional for service editing or deleting.</p> <p><b>Values</b> 1 to 2147483647</p> <p><b>create</b> — keyword used to create a Cpipe. The <b>create</b> keyword requirement can be enabled/disabled in the <b>environment&gt;create</b> context.</p> <p><i>vpn-id</i> — specifies the VPN ID number that allows you to identify virtual private networks (VPNs) by a VPN identification number. ---

**vc-switching** — specifies that pseudowire switching signaling is used for the spoke SDPs configured for this service

## epipe

**Syntax**     **epipe** *service-id* [**customer** *customer-id*] [**create**] [**vpn** *vpn-id*] [**vc-switching**]  
**no epipe** *service-id*

**Context**     config>service

**Description**     This command configures a point-to-point Ethernet service. An Epipe connects two endpoints defined as SAPs. Both SAPs are defined on separate routers (7705 SAR routers or other Nokia service routers) connected over the service provider network. When the endpoint SAPs are separated by the service provider network, the far-end SAP is generalized into an SDP. This SDP describes a destination 7705 SAR and the encapsulation method used to reach it.

No MAC learning or filtering is provided (or needed) on an Epipe.

When a service is created, the **customer** keyword and *customer-id* must be specified, which associates the service with a customer. The *customer-id* must already exist, having been created using the **customer** command in the service context. Once a service has been created with a customer association, it is not possible to edit the customer association. The service must be deleted and recreated with a new customer association.

Once a service is created, the use of the **customer** *customer-id* is optional for navigating into the service configuration context. Attempting to edit a service with the incorrect *customer-id* specified will result in an error.

By default, Epipe services do not exist until they are explicitly created with this command.

The **no** form of this command deletes the Epipe service instance with the specified *service-id*. The service cannot be deleted until the service has been shut down.

**Parameters**     *service-id* — uniquely identifies a service in the service domain. This ID must be unique to this service and may not be used for any other service of any type. The *service-id* must be the same number or name used for every 7705 SAR on which this service is defined.

**Values**     1 to 2147483647 or *service-name*

*customer-id* — specifies the customer ID number to be associated with the service. This parameter is required on service creation and optional for service editing or deleting.

**Values**     1 to 2147483647

**create** — keyword used to create an Epipe. The create keyword requirement can be enabled/disabled in the **environment>create** context

*vpn-id* — specifies the VPN ID number that allows you to identify virtual private networks (VPNs) by a VPN ID. If this parameter is not specified, the VPN ID uses the same service ID number.

**Values** 1 to 2147483647

**vc-switching** — specifies that pseudowire switching signaling is used for the spoke SDPs configured for this service

| <b>Description</b> | This command configures a point-to-point FR service. The Fpipe service provides a point-to-point Layer 2 VPN connection to a local or remote SAP. An Fpipe connects only FR endpoints. Endpoints can be connected locally (in the same 7705 SAR) or remotely over a PSN.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <p><i>service-id</i> — uniquely identifies a service in the service domain. This ID must be unique to this service and may not be used for any other service of any type. The <i>service-id</i> must be the same number or name used for every 7705 SAR on which this service is defined.</p> <p><b>Values</b> 1 to 2147483647 or <i>service-name</i></p> <p><b>create</b> — keyword used to create an Fpipe. The <b>create</b> keyword requirement can be enabled/disabled in the <b>environment&gt;create</b> context.</p> <p><i>customer-id</i> — specifies the customer ID number to be associated with the service. This parameter is required on service creation and is optional for service editing or deleting.</p> <p><b>Values</b> 1 to 2147483647</p> <p><i>vpn-id</i> — specifies the VPN ID number that allows you to identify virtual private networks by a VPN identification number. If this parameter is not specified, the VPN ID uses the service ID number.</p> <p><b>Values</b> 1 to 2147483647</p> <p><b>vc-type</b> — specifies a 15-bit value that defines the type of the VC signaled to the peer. The value is defined in <i>draft-ietf-pwe3-iana-allocation</i> and is used for the signaled VC type and the resulting datapath encapsulation over the Fpipe.</p> <p><b>Values</b> fr-dlci</p> <p><b>vc-switching</b> — specifies that pseudowire switching signaling is used for the spoke SDPs configured for this service</p> |

| <b>Description</b> | This command configures a point-to-point HDLC service.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <p><i>service-id</i> — uniquely identifies a service in the service domain. This ID must be unique to this service and may not be used for any other service of any type. The <i>service-id</i> must be the same number or name used for every 7705 SAR on which this service is defined.</p> <p><b>Values</b> 1 to 2147483647 or <i>service-name</i></p> <p><b>create</b> — keyword used to create an Hpipe. The <b>create</b> keyword requirement can be enabled/disabled in the <b>environment&gt;create</b> context.</p> <p><i>customer-id</i> — specifies the customer ID number to be associated with the service. This parameter is required on service creation and is optional for service editing or deleting.</p> <p><b>Values</b> 1 to 2147483647</p> <p><i>vpn-id</i> — specifies the VPN ID number that allows you to identify virtual private networks by a VPN identification number. If this parameter is not specified, the VPN ID uses the service ID number.</p> <p><b>Values</b> 1 to 2147483647</p> <p><b>vc-type</b> — specifies a 15-bit value that defines the type of the VC signaled to the peer. The value is defined in <i>draft-ietf-pwe3-iana-allocation</i> and is used for the signaled VC type and the resulting datapath encapsulation over the Hpipe.</p> <p><b>Values</b> hdlc</p> <p><b>vc-switching</b> — specifies that pseudowire switching signaling is used for the spoke SDPs configured for this service</p> |

| <b>Description</b> | <p>This command configures an IP interworking service. An Ipipe can be configured as a SAP-to-SAP or SAP-to-SDP service. An Ipipe can connect the following types of SAPs over an MPLS or IP network:</p> <ul style="list-style-type: none"> <li>• Ethernet SAP</li> </ul> |

- LAG SAP
- PPP/MLPPP SAP
- Frame Relay SAP
- cHDLc SAP

**Parameters** *service-id* — uniquely identifies a service in the service domain. This ID must be unique to this service and may not be used for any other service of any type. The *service-id* must be the same number or name used for every 7705 SAR on which this service is defined.

**Values** 1 to 2147483647 or *service-name*

*customer-id* — specifies the customer ID number to be associated with the service. This parameter is required on service creation and optional for service editing or deleting.

**Values** 1 to 2147483647

**create** — keyword used to create an lpipe. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

*vpn-id* — specifies the VPN ID number that allows you to identify virtual private networks (VPNs) by a VPN ID. If this parameter is not specified, the VPN ID uses the same service ID number.

**Values** 1 to 2147483647

**vc-switching** — specifies that pseudowire switching signaling is used for the spoke SDPs configured for this service

## endpoint

**Syntax** [no] **endpoint** *endpoint-name*

**Context** config>service>apipe  
config>service>cpipe  
config>service>epipe  
config>service>fpipe  
config>service>hpipe  
config>service>ipipe

**Description** This command provides access to the service endpoint context.

**Parameters** *endpoint-name* — specifies an endpoint name (up to 32 alphanumeric characters)

## ce-address-discovery

**Syntax** [no] **ce-address-discovery**

**Context** config>service>ipipe

---

|                    |                                                                 |
|--------------------|-----------------------------------------------------------------|
| <b>Description</b> | This command enables CE address discovery for an lpipe service. |
| <b>Default</b>     | no ce-address-discovery                                         |

## load-balancing

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <b>Syntax</b>      | <b>load-balancing</b>                                          |
| <b>Context</b>     | config>service>epipe                                           |
| <b>Description</b> | This command accesses the context to configure load balancing. |

## l4-load-balancing

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Context</b>     | config>service>epipe>load-balancing                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | <p>This command enables or disables Layer 4 load balancing for the Epipe service. When enabled, Layer 4 source and destination port fields of incoming TCP/UDP packets are included in the hashing calculation to randomly determine the distribution of packets.</p> <p>Adding the Layer 4 source and destination port fields to the hashing algorithm generates a higher degree of randomness and a more even distribution of packets across the available LAG ports.</p> <p>You can add additional fields to generate more randomness and more equal distribution of packets with the <a href="#">teid-load-balancing</a> command.</p> <p>Hashing based on the <b>l4-load-balancing</b> and <b>teid-load-balancing</b> commands and hashing based on the <b>per-service-hashing</b> command are mutually exclusive.</p> <p>The <b>no</b> form of the command disables Layer 4 load balancing.</p> |
| <b>Default</b>     | no l4-load-balancing                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## per-service-hashing

|                    |                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] per-service-hashing</b>                                                                                                                                                                                                                                                                                                                   |
| <b>Context</b>     | config>service>epipe>load-balancing                                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | <p>This command enables or disables hashing based on the service ID. The result of the hashing calculation is used to determine the distribution of packets.</p> <p>Hashing based on the <b>per-service-hashing</b> command and hashing based on the <b>l4-load-balancing</b> and <b>teid-load-balancing</b> commands are mutually exclusive.</p> |

**Note:** Prior to Release 8.0.R4 of the 7705 SAR, load balancing for an Epipe service was implicitly defaulted to be enabled (that is, hashing was always on the service ID). Release 8.0.R4 added the **per-service-hashing** command, which is disabled by default. The **per-service-hashing** command must be explicitly enabled if pre-Release 8.0.R4 behavior is needed.

The **no** form of the command disables per-service hashing.

**Default** no per-service-hashing

## teid-load-balancing

**Syntax** **[no] teid-load-balancing**

**Context** config>service>epipe>load-balancing

**Description** This command enables or disables TEID load balancing for the Epipe service. The TEID attribute is included in the header of GTP (general packet radio system tunneling protocol) packets. When TEID load balancing is enabled, the TEID field of incoming TCP/UDP packets is included in the hashing calculation to randomly determine the distribution of packets.

You can add additional fields to generate more randomness and more equal distribution of packets with the [l4-load-balancing](#) command.

Hashing based on the **teid-load-balancing** and **l4-load-balancing** commands and hashing based on the **per-service-hashing** command are mutually exclusive.

The **no** form of the command disables TEID load balancing.

**Default** no teid-load-balancing

## revert-time

**Syntax** **revert-time** [*revert-time* | **infinite**]  
**no revert-time**

**Context** config>service>apipe>endpoint  
config>service>cpipe>endpoint  
config>service>epipe>endpoint  
config>service>fpipe>endpoint  
config>service>hpipe>endpoint  
config>service>ipipe>endpoint

**Description** This command configures the time to wait before reverting to the primary spoke SDP defined on this service endpoint, after having switched over to a backup spoke SDP after a failure of the primary spoke SDP.

**Note:** The **infinite** option (for non-revertive behavior) does not apply to Cpipes.

**Parameters** *revert-time* — specifies the time, in seconds, to wait before reverting to the primary SDP

**Values** 0 to 600

**infinite** — causes the endpoint to be non-revertive

## standby-signaling-master

**Syntax** **[no] standby-signaling-master**

**Context** config>service>apipe>endpoint  
config>service>cpipe>endpoint  
config>service>epipe>endpoint  
config>service>fpipe>endpoint  
config>service>hpipe>endpoint  
config>service>ipipe>endpoint

**Description** This command sends the pseudowire standby bit (value 0x00000020) to the targeted LDP (T-LDP) peer whenever a spoke SDP of the endpoint is selected as a standby (see [precedence](#)). This bit informs the far end that the pseudowire is not currently active.

**Default** no standby-signaling-master

## standby-signaling-slave

**Syntax** **[no] standby-signaling-slave**

**Context** config>service>apipe>endpoint  
config>service>cpipe>endpoint  
config>service>epipe>endpoint  
config>service>fpipe>endpoint  
config>service>hpipe>endpoint  
config>service>ipipe>endpoint

**Description** This command blocks the spoke SDP from transmitting data when the pseudowire standby bit (value 0x00000020) is received from a targeted LDP (T-LDP) peer. In order to have standby-signaling-slave working properly end-to-end, standby-signaling-master must be enabled on the ingress LER (see [standby-signaling-master](#)).

If this command is enabled, the **show service id id all** command output shows the Flags field with a value of “StandbySigSlaveTxDown” and the Peer Pw Bits field with a value of “PwFwdingStandby”, indicating that transmission is blocked but the spoke SDP is still up.

The **no** form of the command disables the blocking of traffic in the transmit direction, and data received via the associated SAP or service continues to be transmitted.

**Default** no standby-signaling-slave

## service-mtu

**Syntax** **service-mtu** *octets*  
**no service-mtu**

**Context** config>service>apipe  
config>service>cpipe  
config>service>epipe  
config>service>fpipe  
config>service>hpipe  
config>service>ipipe

**Description** This command configures the service payload (MTU), in octets, for the service. This MTU value overrides the service-type default MTU.

The **service-mtu** defines the payload capabilities of the service. It is used by the system to validate the SAP and SDP binding's operational state within the service.

The service MTU and a SAP's service delineation encapsulation overhead (4 bytes for a dot1q tag or 8 bytes for qinq tags) is used to derive the required MTU of the physical port or channel on which the SAP was created. If the required payload is larger than the port or channel MTU, the SAP will be placed in an inoperative state. If the required MTU is equal to or less than the port or channel MTU, the SAP will be able to transition to the operative state.

When binding an SDP to a service, the service MTU is compared to the path MTU associated with the SDP. The path MTU can be administratively defined in the context of the SDP. The default or administrative path MTU can be dynamically reduced due to the MTU capabilities discovered by the tunneling mechanism of the SDP or the egress interface MTU capabilities based on the next hop in the tunnel path. If the service MTU is larger than the path MTU, the SDP binding for the service will be placed in an inoperative state. If the service MTU is equal to or less than the path MTU, then the SDP binding will be placed in an operational state.

In the event that a service MTU, port or channel MTU, or path MTU is dynamically or administratively modified, then all associated SAP and SDP binding operational states are automatically re-evaluated.

The **no** form of this command returns the default service-mtu for the indicated service type to the default value.

**Parameters** *octets* — specifies the size of the MTU, expressed as a decimal integer

**Values** 1 to 1514 (apipe, cpipe, fpipe, and hpipe)  
1 to 9670 (epipe and ipipe)

**Default** The default values depend on the PW type:

- apipe: 1508
- cpipe: 1514
- epipe: 1514
- fpipe: 1508
- hpipe: 1514
- ipipe: 1500

[Table 40](#) displays MTU values for specific VC types.

**Table 40 Service MTU Values**

| VC-Type                               | Example of Service MTU | Advertised MTU |
|---------------------------------------|------------------------|----------------|
| Ethernet                              | 1514                   | 1500           |
| Ethernet (with preserved dot1q)       | 1518                   | 1504           |
| Ethernet (with preserved qinq)        | 1522                   | 1508           |
| VLAN (dot1p transparent to MTU value) | 1514                   | 1500           |

## service-name

**Syntax** **service-name** *service-name*  
**no service-name**

**Context** config>service>apipe  
 config>service>cpipe  
 config>service>epipe  
 config>service>fpipes  
 config>service>hpipe  
 config>service>ipipe

**Description** This command configures a service name that can be used for reference in configuration and show commands.

**Parameters** *service-name* — up to 64 characters

### 4.13.2.1.3 VLL SAP Commands

#### sap

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Description</b> | <p>This command creates a SAP within a service. Each SAP must be unique.</p> <p>All SAPs must be explicitly created with the <b>create</b> keyword. If no SAPs are created within a service or an IP interface, a SAP will not exist on that object.</p> <p>To edit SAP parameters, enter an existing SAP without the <b>create</b> keyword.</p> <p>A SAP can only be associated with a single service. The SAP is owned by the service in which it was created. A SAP can only be defined on a port that has been configured as an access port in the <b>config&gt;port</b> <i>port-id</i> context using the <b>mode access</b> command, or on a Surveillance, Control, and Data Acquisition Support (SCADA) bridge that has been configured on an Integrated Services card using the <b>config&gt;scada</b> command. The Integrated Services card is a resource card that does not have any ports; as well, it supports an access functionality only.</p> <p>Fractional TDM ports are always access ports. Refer to the 7705 SAR Interface Configuration Guide.</p> <p>If a port or SCADA bridge is shut down, all SAPs on that port or SCADA bridge become operationally down. When a service is shut down, SAPs for the service are displayed as operationally down and all traffic traversing the service is discarded. The operational state of a SAP is relative to the operational state of the port or SCADA bridge on which the SAP is defined.</p> <p>The following SAP types are supported:</p> <ul style="list-style-type: none"> <li>• ATM VPI/VCI on an ATM port for <b>vc-type atm-vcc</b></li> <li>• ATM VPI on an ATM port for <b>vc-type atm-vpc</b></li> <li>• ATM virtual trunk on an ATM port for <b>vc-type atm-cell</b></li> <li>• Ethernet-Ethernet</li> <li>• SAToP</li> <li>• CESoPSN (with and without CAS)</li> <li>• PPP IPCP encapsulation of an IPv4 packet for lpipe service (RFC 1332)</li> </ul> |

- MLPPP bundle
- LAG
- Ethernet SAPs supporting null, dot1q, and qinq for lpipe service
- FR DLCI
- HDLC
- cHDLC (supported only for lpipe services)

The **no** form of this command deletes the SAP with the specified port or SCADA bridge. When a SAP is deleted, all configuration parameters for the SAP will also be deleted.

SAPs that are configured with this command cannot be bound to a SAP aggregation group. See [SAP Aggregation Group Commands](#) for more information about the sap *sap-id* sap-aggregation-group *group-id* command, which is used to support N-to-one cell mode where  $N > 1$ .

**Default** no sap

**Parameters** *sap-id* — specifies the physical port or SCADA bridge identifier portion of the SAP definition  
The *sap-id* can be configured in one of the formats described in [Table 41](#). The range of values for the parameters follow the table.

**Table 41 SAP ID Configurations**

| Type         | Syntax                                                      | Example                                                                                                                                          |

*port-id* — specifies the physical port ID in the *slot/mda/port* format

If the card in the slot has an adapter card installed, the *port-id* must be in the slot-number/MDA-number/port-number format. For example, 1/2/3 specifies port 3 on MDA 2 in slot 1.

The *port-id* must reference a valid port type. When the *port-id* parameter represents TDM channels, the port ID must include the channel ID. A period “.” separates the physical port from the *channel-id*. The port must be configured as an access port.

*bundle-id* — specifies the multilink bundle identifier. The **bundle** keyword must be entered at the beginning of the parameter. The command syntax must be configured as follows:

```
bundle-id: bundle-type-slot/mda.bundle-num
type: ima, ppp
bundle-num: 1 to 32
```

For example:

```
*A:ALU-12>config# port bundle-ppp-5/1.1
*A:ALU-12>config>port# multilink-bundle
```

*qtag1*, *qtag2* — specifies the encapsulation value used to identify the SAP on the port or sub-port. For dot1q encapsulation, only *qtag1* is used; for qinq encapsulation, both *qtag1* and *qtag2* are used. If *qtag1* or *qtag2* is not specifically defined, the value 0 is used. The “\*” value represents all *qtag* values between 0 and 4094 that are not specifically defined within another SAP context under the same port. In addition, the following *qtag1.qtag2* values are invalid options:

- \*.*qtag2*
- \*.0
- 0.*qtag2*

**Values**      *qtag1*: \*, 0 to 4094

*qtag2*: \*, 0 to 4094

The values depend on the encapsulation type configured for the interface. [Table 42](#) describes the allowed values for the port and encapsulation types.

**Table 42**      **Port and Encapsulation Values**

| Port Type | Encap-Type | Allowed Values | Comments                                                                                                                                                                                                                                                                       |
|-----------|------------|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Ethernet  | Null       | —              | The SAP is identified by the port.                                                                                                                                                                                                                                             |
| Ethernet  | Dot1q      | *, 0 to 4094   | The SAP is identified by the 802.1Q tag on the port. A 0 <i>qtag1</i> value also accepts untagged packets on the dot1q port, and a * <i>qtag1</i> value accepts any VLAN ID that is not specifically configured on the port. <sup>1</sup>                                      |
| Ethernet  | QinQ       | *, 0 to 4094   | The SAP is identified by the two 802.1Q tags on the port. A 0 <i>qtag1</i> or <i>qtag 2</i> value also accepts untagged packets on the qinq port, and a * <i>qtag1</i> or <i>qtag2</i> value accepts any VLAN ID that is not specifically configured on the port. <sup>1</sup> |

**Note:**

1. Traffic matching the \* qtag value uses VLAN 4095 internally.

**create** — keyword used to create a SAP instance. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

| <b>Context</b>     | config>service>epipe>sap                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | <p>This command enables Cflowd to collect traffic flow samples through a SAP for analysis. When Cflowd is enabled on an Epipe service SAP, traffic can be sampled and processed by the system's Cflowd engine and exported to Cflowd version 10 collectors with the <b>I2-ip</b> template enabled.</p> <p>When Cflowd is enabled at the SAP level, all packets forwarded by the interface are subject to analysis according to the Cflowd configuration.</p> <p>For Layer 2 services, only ingress sampling is supported.</p> |
| <b>Default</b>     | no cflowd                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

---

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command specifies the interval between ARP requests sent on an lpipe Ethernet SAP. When the SAP is first enabled, an ARP request will be sent to the attached CE device and the received MAC address will be used in addressing unicast traffic to the CE. Although this MAC address will not expire while the lpipe SAP is enabled and operational, it is verified by sending periodic ARP requests at the specified interval.</p> <p>The <b>no</b> form of this command restores <b>mac-refresh</b> to the default value.</p> |
| <b>Default</b>     | 14400                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <i>refresh-interval</i> — specifies the interval, in seconds, between ARP requests sent on an lpipe Ethernet SAP                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Values</b>      | 0 to 65535                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|                    |                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | This command defines the DNS addresses to be assigned to the far end of the associated PPP/MLPPP link via IPCP extensions. This command is only applicable if the associated SAP or port is a PPP/ MLPPP interface with an IPCP encapsulation.                                                                                                            |
| <b>Default</b>     | no dns                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <p><i>ip-address-1</i> — specifies a unicast IPv4 address for the primary DNS server to be signaled to the far end of the associated PPP/MLPPP link via IPCP extensions</p> <p><i>ip-address-2</i> — specifies a unicast IPv4 address for the secondary DNS server to be signaled to the far end of the associated PPP/MLPPP link via IPCP extensions</p> |

| <b>Context</b>     | config>service>epipe>sap>ethernet                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b> | <p>This command enables Link Loss Forwarding (LLF) on an Ethernet port. LLF can only be enabled on Ethernet ports configured for null encapsulation.</p> <p>LLF provides an end-to-end OAM fault notification for Ethernet VLL service. When LLF is enabled and there is a local fault on the pseudowire or service, or a remote fault on the SAP or pseudowire, the Ethernet port is brought down. Using label withdrawal or T-LDP status bits, LLF signals to connected equipment that the VLL is down. LLF stops signaling when the fault disappears.</p> <p>The <b>no</b> form of the command disables LLF.</p> |

#### 4.13.2.1.4 SAP Aggregation Group Commands

##### sap-aggregation-group

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Description</b> | <p>This command configures a SAP aggregation group on an Apipe. A SAP aggregation group <i>group-id</i> is a unique identifier on each node.</p> <p>To configure an Apipe with a SAP aggregation group, the SAP aggregation group must be configured before any SAPs are bound to the Apipe. SAPs that are to be bound to the same ATM PW payload must be configured with the same SAP aggregation group <i>group-id</i>.</p> <p>All common access configuration parameters, such as accounting, statistics, and packet layer QoS profile can be configured under the sap-aggregation-group.</p> <p>Each sap-aggregation-group SAP has its own ingress and egress Layer 2 traffic descriptors. These descriptors are used for policing at ingress and shaping and scheduling priority at egress.</p> |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Description</b> | <p>This command configures a SAP and associates the SAP as a member of a specified SAP aggregation group. The aggregation group must be configured before the SAP. The SAP must be associated with the aggregation group at the time of configuration. See <a href="#">sap-aggregation-group</a> for more information.</p> <p>Up to 16 SAPs can be bound to a SAP aggregation group.</p> <p>The following restrictions apply to the SAP.</p> <ul style="list-style-type: none"> <li>• An Apipe can either have SAPs that are associated with a SAP aggregation group or regular SAPs (that is, SAPs that are not associated with an aggregation group). An Apipe cannot have both types of SAPs.</li> </ul> |

- The *sap-id* specifies the physical port identifier of the SAP that is to be bound to the aggregation group. The port must be preconfigured for ATM VPI/VCI service with the syntax described in [Table 43](#).

**Table 43** SAP ID Preconfiguration for SAP Aggregation Groups

| Type | Syntax                                 | Example                                            |
|------|----------------------------------------|----------------------------------------------------|
| atm  | <i>slot/mda/port[.channel]:vpi/vci</i> | slot/mda/port[.channel]: 1/1/1.1<br>vpi/vci: 16/26 |

- The SAP can only be defined on a port that has been configured as an access port in the **config>port** *port-id* context using the **mode access** command.
- The Apipe for the SAP must be configured to support **vc-type atm-vcc**.

The **no** form of this command deletes the SAP with the specified port. When a SAP is deleted, all configuration parameters for the SAP are also deleted.

**Default** no sap

**Parameters** *sap-id* — see [Table 43](#). See [Table 41](#) for a full list of SAP IDs.

*group-id* — the name identifying the aggregation group to which the SAP is to be bound. See [sap-aggregation-group](#).

**Values** 1 to 32 alphanumeric characters

| <b>Description</b> | <p>This command enables or disables asymmetric delay control on the Cpipe. When enabled, the TDM PW is analyzed and adjusted for asymmetric delay when the service is initially started or restarted. The service is considered to be down during this period.</p> <p>The optional <b>min-repeat</b> keyword sets the analysis to repeat at configured time intervals after the service is up. The service remains up while the repeated analysis runs.</p> <p>The optional <b>threshold-repeat</b> keyword sets the latency value that will be used by ADC repeat and on-demand ADC to determine if octets need to be added or removed. If the difference between the calculated average latency and the expected latency is greater than the <b>threshold-repeat</b> value, octets are added or dropped as necessary.</p> <p>Asymmetric delay control must be enabled on both ends of the Cpipe; otherwise, a service parameter mismatch state occurs and the service is brought down.</p> |               |                                                                              |                |             |

*minutes* — the interval at which the asymmetric delay control function will repeat after the service is up, in minutes

**Values** 1 to 1440; 0 disables the periodic analysis

**Default** 60

*uSecs* — the threshold used to determine if an octet correction is made after an ADC repeat or on-demand ADC analysis, in microseconds

**Default** 250

**Values** 125 to 4000, in 125- $\mu$ s increments

## packet

**Syntax** [no] packet

**Context** config>service>cpipe>sap>cem  
config>service>epipe>sap>cem

**Description** This command enables the context to configure packet parameters on the SAP.

## jitter-buffer

**Syntax** jitter-buffer *value* [payload-size *size*]

**Context** config>service>cpipe>sap>cem>packet  
config>service>epipe>sap>cem>packet

**Description** This command defines the size of the receive jitter buffer for the circuit emulation service SAP.

If [asym-delay-control](#) is enabled, the jitter buffer size must match on both ends of the Cpipe; otherwise, a service parameter mismatch state occurs and the service is brought down.

**Default** The default value varies depending on the SAP bandwidth, as follows:

- 5 ms, where SAP bandwidth  $\geq$  16 DS0s (1024 kb/s)
- 8 ms, where SAP bandwidth is between 5 and 15 DS0s (between 320 and 960 kb/s)
- 16 ms, where SAP bandwidth is between 2 and 4 DS0s (between 128 and 256 kb/s)
- 32 ms, where SAP bandwidth = 1 DS0 (64 kb/s)

**Parameters** *value* — specifies the size of the receive jitter buffer, expressed in milliseconds. The range of supported values is 1 to 250 ms. Setting the value to 0 sets the default (depends on SAP bandwidth). The buffer size must be set to at least 3 times the value of the packetization delay and no greater than 32 times the value of the packetization delay.

To calculate the size of the buffer (in bytes), multiply the value of the buffer size (in ms) by the SAP TDM bandwidth (in bits per second) and divide by 8. After the initialization of the circuit emulation service, transmission of TDM data begins when the buffer is half full (50%).

*size* — for convenience, the payload size can be configured at the same time as the jitter buffer. This avoids any configuration errors due to interactions between the jitter buffer and payload size settings. See [payload-size](#).

## payload-size

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Description</b> | This command defines the payload size, in bytes, for one circuit emulation service packet.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Default</b>     | For SAToP, see <a href="#">Table 22</a> . For SAToP serial, see <a href="#">Table 19</a> . For CESoPSN without CAS, see <a href="#">Table 23</a> . For CESoPSN with CAS, see <a href="#">Table 24</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <p><i>size</i> — specifies the payload size (in octets) to be encapsulated in one circuit emulation service packet. The range of supported values is 2 to 1514 bytes. If only one timeslot is being transported, the payload size must be an even number. The packetization delay for the circuit emulation service can be calculated by multiplying the payload size (in octets) by 8 (bits/octet), then dividing by the SAP TDM bandwidth (in bits/second).</p> <p>For CESoPSN or CESoETH with CAS, the 7705 SAR supports 1 to 8 multiframes. For T1, 1 multiframe equals 24 frames. For E1, 1 multiframe equals 16 frames. The payload size must correspond to <math>n \times 16</math> E1 frames or <math>n \times 24</math> T1 frames of TDM data, where <math>n</math> is an integer between 1 and 8. The restriction for payload sizes of 1 to 8 multiframes also applies to CESoPSN without CAS if the payload is within a T1/E1 channel that has a mix of CESoPSN with and without CAS.</p> <p>The configured value of the payload size does not need to include the extra bytes for the transport of CAS bits. The configured value of the service MTU size takes the extra CAS bytes into account. See <a href="#">Structured T1/E1 CES with CAS</a> for details.</p> <p>For CESoPSN or CESoETH, if a port on a 16-port T1/E1 ASAP Adapter card, version 2, or 32-port T1/E1 ASAP Adapter card is configured for DCR, the port timing is associated with the service clock of the Cpipe of channel group 1. For a framed T1 port, there is a restriction on the Cpipe payload size of channel group 1:</p> <ul style="list-style-type: none"> <li>• for DCR with a timestamp frequency of 77.76 MHz, the payload size = <math>2 \times l \times</math> (number of timeslots), where <math>l = 1</math> to 20</li> <li>• for DCR with a timestamp frequency of 19.44 MHz, the payload size = <math>8 \times l \times</math> (number of timeslots), where <math>l = 1</math> to 5</li> </ul> <p>This restriction does not apply to framed E1 ports or unframed T1/E1 ports.</p> <p>For CESoPSN or CESoETH, the payload size may be specified as the number of bytes to be included in the packet.</p> |

For SAToP T1, SAToP E1, SAToP T3 and SAToP E3 circuit emulation services, the size must be specified in bytes (with minimum 64 bytes) and the value must be a multiple of 32. The minimum for SAToP T3 and SAToP E3 is 1024 bytes.

For SAToP serial circuit emulation services, the configurable range is 2 to 1496 octets, in multiples of 2. Serial rates of 4800 b/s and lower only support a payload size of 2 bytes.

**Interactions** — The jitter-buffer value must be greater than or equal to twice the payload size to ensure that a frame arrives prior to the start of play-out. Therefore, the payload size may have to be decreased prior to setting the jitter-buffer value. Alternatively, the jitter-buffer value may have to be increased prior to setting the payload-size.

### local-ecid

|                    |                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Context</b>     | config>service>epipe>sap>cem                                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b> | This command defines the Emulated Circuit Identifier to be used for the (local) source end of the MEF 8 Epipe.<br><br>The <b>no</b> form of the command removes the ECID value from the service configuration.                                                                                                                                                     |
| <b>Parameters</b>  | <i>value</i> — specifies the source ECID value for the CES. Upon CES packet reception, the ECID in the packet is compared to the local ECID value. If the local and remote ECID values match, the packet payload is used for the TDM circuit. The remote ECID value is inserted into all MEF 8 CES packets that are transmitted.<br><br><b>Values</b> 0 to 1048575 |

### remote-ecid

|                    |                                                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>remote-ecid</b> <i>value</i><br><b>no remote-ecid</b>                                                                                                                                                              |
| <b>Context</b>     | config>service>epipe>sap>cem                                                                                                                                                                                          |
| <b>Description</b> | This command defines the Emulated Circuit Identifiers to be used for the remote (destination) end of the MEF 8 Epipe.<br><br>The <b>no</b> form of the command removes the ECID value from the service configuration. |

**Parameters** *value* — specifies the destination ECID value for the CES. Upon CES packet reception, the ECID in the packet is compared to the local ECID value specified by the [local-ecid](#) command. If the local and remote ECID values match, the packet payload is used for the TDM circuit. The remote ECID value is inserted into all MEF 8 CES packets that are transmitted.

**Values** 0 to 1048575

## remote-mac

**Syntax** **remote-mac** *ieee-mac-addr*  
**no remote-mac**

**Context** config>service>epipe>sap>cem

**Description** This command defines the destination IEEE MAC address to be used to reach the remote end of the MEF 8 Epipe.

**Default** 00:00:00:00:00:00

**Parameters** *ieee-mac-addr* — specifies the 48-bit MAC address in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff, where aa, bb, cc, dd, ee and ff are hexadecimal numbers. Allowed values are any unicast MAC addresses and non-IEEE-reserved group multicast MAC addresses. Users should exercise caution when using multicast MAC addresses, as Ethernet frames with a multicast destination address could be flooded when traversing an Ethernet broadcast domain.

## report-alarm

**Syntax** [no] **report-alarm** [**stray**] [**malformed**] [**pktloss**] [**overrun**] [**underrun**] [**rpktloss**] [**rfault**] [**rrdi**]

**Context** config>service>cpipe>sap>cem  
 config>service>epipe>sap>cem

**Description** This command enables or disables alarm reporting for CES circuit alarm conditions.

**Default** On: stray, malformed, pktloss, overrun and underline  
 Off: rpktloss, rfault, rrdi

**Parameters** **stray** — reports the reception of packets not destined for this CES circuit  
**malformed** — reports the reception of packets not properly formatted as CES packets  
**pktloss** — reports the lack of reception of CES packets  
**overrun** — reports the reception of too many CES packets resulting in an overrun of the receive jitter buffer. Overrun is supported on Cpipes and MEF 8 Epipes.

**underrun** — reports the reception of too few CES packets resulting in an underrun of the receive jitter buffer. Underrun is supported on Cpipes and MEF 8 Epipes.

**rpktloss** — reports that the remote peer is currently in packet loss status

**rfault** — reports that the remote TDM interface is currently not in service

**rrdi** — reports that the remote TDM interface is currently in RDI status

## rtp-header

|                    |                                                                                                                                                                                                                                                                                        |

| <b>Description</b> | <p>This command sets the aggregate rate limits (PIR and CIR) for the SAP. The <i>agg-rate</i> sets the PIR value. The <i>cir-rate</i> sets the CIR value. When aggregate rate limits are configured on a second-generation (Gen-2) Ethernet adapter card, the scheduler mode must be set to 16-priority. On a third-generation (Gen-3) Ethernet adapter card, the scheduler mode is always 4-priority. For information on adapter card generations, refer to the “Evolution of Ethernet Adapter Cards, Modules, and Platforms” section in the 7705 SAR Interface Configuration Guide.</p> <p>Configuring the <i>cir-rate</i> is optional. If a <i>cir-rate</i> is not entered, then the <i>cir-rate</i> is set to its default value (0 kb/s). If a <i>cir-rate</i> has been set and the <i>agg-rate</i> is changed without re-entering the <i>cir-rate</i>, the <i>cir-rate</i> automatically resets to 0 kb/s. For example, to change the <i>agg-rate</i> from 2000 to 1500 while maintaining a <i>cir-rate</i> of 500, use the command <b>agg-rate-limit 1500 cir 500</b>.</p> <p>If the specified SAP is a LAG SAP, then <i>agg-rate</i> and <i>cir-rate</i> can be configured regardless of the scheduler mode setting on Gen-2 or Gen-3 hardware—it is not configurable if one of the ports configured in the LAG SAP is on Gen-1 hardware. If the active port is on a Gen-3 card or platform, then <i>agg-rate</i> and <i>cir-rate</i> are applicable. If the active port is on a Gen-2 card or platform, then <i>agg-rate</i> and <i>cir-rate</i> apply when the scheduler mode is set to 16-priority. If the active port is on a Gen-1 card, then <i>agg-rate</i> and <i>cir-rate</i> are not applicable. For details on the behavior of a mix-and-match LAG SAP, refer to the “LAG Support on Third-Generation Ethernet Adapter Cards, Ports, and Platforms” and “Network LAG Traffic Management” sections in the 7705 SAR Interface Configuration Guide.</p> <p> <b>Note:</b> Starting with Release 7.0.R6, schedulers on Gen-3 adapter cards and platforms have been updated to better align with the scheduling behavior supported on the other 7705 SAR adapter cards and platforms. The updated scheduler mode is called “4-priority” scheduler-mode throughout the CLI. Prior to Release 7.0.R6, the CLI designation was “4-priority-hqos”. In the updated mode of operation, arbitration among different flows at the second-tier aggregate (per-SAP or per-VLAN) and third-tier aggregate (per-customer (MSS)) levels are carried out in a round-robin manner, scheduling <i>cir-rate</i> first from the shapers, followed by the <i>pir-rate</i>.</p> |

**Caution:** Any Gen-3 adapter card or platform running Release 7.0.R6 or later software uses 4-priority scheduling instead of 4-priority-hqos scheduling, which was supported previously. The migration of scheduler mode is automatic with an upgrade and there is no operator action required. As part of the migration, all CIR values at second-tier (per-SAP and per-VLAN) and third-tier (per-customer (MSS)) aggregate shaper levels are set to zero. Operators must exercise caution when performing an upgrade to Release 7.0.R6 or later from a previous Release 7.0 version, and must adjust the affected CIR values in accordance with the needs of their applications as soon as possible.

The **no** form of the command sets the *agg-rate* to the maximum and the *cir-rate* to 0 kb/s.

**Default** no agg-rate-limit

**Parameters** *agg-rate* — sets the PIR for the aggregate of all the queues on the SAP. The **max** keyword applies the maximum physical port rate possible.

**Values** 1 to 10000000 kb/s, or **max**

**Default** max

*cir-rate* — sets the CIR for the aggregate of all the queues on the SAP

**Values** 0 to 10000000 kb/s, or **max**

**Default** 0 kb/s

filter

**Syntax** **filter ip** *ip-filter-id*  
**no filter** [*ip ip-filter-id*]

**Context** config>service>epipe>sap>ingress  
config>service>ipipe>sap>ingress

**Description** This command associates an IP filter policy with an ingress Epipe or Ipipe SAP.

Filter policies control the forwarding and dropping of packets based on IP matching criteria. Only one filter can be applied to a SAP at a time.

The *ip-filter-id* must already be defined before the **filter** command is executed. If the filter policy does not exist, the operation will fail and an error message will be displayed.

The **no** form of the command removes any configured filter ID association with the SAP. The filter policy cannot be deleted until it is removed from all SAPs where it is applied.

**Default** no filter

**Parameters** *ip-filter-id* — specifies the IP filter policy. The filter ID or filter name must already exist within the created IP filters.

**Values** 1 to 65535 or *filter-name* (up to 64 characters)

## match-qinq-dot1p

**Syntax** **match-qinq-dot1p {top | bottom}**  
**no match-qinq-dot1p**

**Context** config>service>epipe>sap>ingress  
 config>service>ipipe>sap>ingress

**Description** This command specifies which dot1q tag position (top or bottom) in a qinq-encapsulated packet should be used when QoS evaluates dot1p classification.

The **no** form of the command restores the default dot1p evaluation behavior for the SAP, which means that the inner (bottom) tag (second tag) dot1p bits are used for classification.

By default, the dot1p bits from the inner tag service-delineating dot1q tag are used.

Table 44 shows which set of dot1p bits are used for QoS purposes when **match-qinq-dot1p** is configured. To use the table, find the row that represents the settings for **Port/SAP Type** and **Match-QinQ-Dot1p Setting**. Use the **Existing Packet Tags** column to identify which dot1q tags are available in the packet. Then use the **P-bits Used for Match** column to identify which dot1q tag contains the dot1p bits that are used for QoS dot1p classification.

**Default** no match-qinq-dot1p

**Parameters** **top** — the **top** parameter and **bottom** parameter are mutually exclusive. When the **top** parameter is specified, the outer tag's dot1p bits (topmost P-bits) are used (if existing) to match any **dot1p** *dot1p-value* entries.

**bottom** — the **bottom** parameter and **top** parameter are mutually exclusive. When the **bottom** parameter is specified, the bottommost P-bits (second tag's P-bits) are used (if existing) to match any **dot1p** *dot1p-value* entries.

**Table 44 Match-QinQ-Dot1p Matching Behavior**

| Port/ SAP Type | Match-QinQ-Dot1p Setting <sup>1</sup> | Existing Packet Tags | P-bits Used for Match |
|----------------|---------------------------------------|----------------------|-----------------------|
| Null           | n/a                                   | None                 | None                  |
| Null           | n/a                                   | Dot1p (VLAN ID 0)    | None <sup>2</sup>     |
| Null           | n/a                                   | Dot1q                | None <sup>2</sup>     |
| Null           | n/a                                   | TopQ BottomQ         | None <sup>2</sup>     |
| Dot1q          | n/a                                   | None                 | None                  |

**Table 44 Match-QinQ-Dot1p Matching Behavior (Continued)**

| Port/ SAP Type | Match-QinQ-Dot1p Setting <sup>1</sup> | Existing Packet Tags          | P-bits Used for Match |
|----------------|---------------------------------------|-------------------------------|-----------------------|
| Dot1q          | n/a                                   | Dot1p (default SAP VLAN ID 0) | Dot1p P-bits          |
| Dot1q          | n/a                                   | Dot1q                         | Dot1q P-bits          |
| QinQ/ X.Y      | Top                                   | TopQ BottomQ                  | TopQ P-bits           |
| QinQ/ X.Y      | Default or Bottom                     | TopQ BottomQ                  | BottomQ P-bits        |
| QinQ/ X.0      | Top                                   | TopQ                          | TopQ P-bits           |
| QinQ/ X.0      | Default or Bottom                     | TopQ                          | TopQ P-bits           |
| QinQ/ X.0      | Top                                   | TopQ BottomQ                  | TopQ P-bits           |
| QinQ/ X.0      | Default or Bottom                     | TopQ BottomQ                  | BottomQ P-bits        |
| QinQ/ X.*      | Top                                   | TopQ                          | TopQ P-bits           |
| QinQ/ X.*      | Default or Bottom                     | TopQ                          | TopQ P-bits           |
| QinQ/ X.*      | Top                                   | TopQ BottomQ                  | TopQ P-bits           |
| QinQ/ X.*      | Default or Bottom                     | TopQ BottomQ                  | BottomQ P-bits        |
| QinQ/ 0.*      | Top                                   | None                          | None                  |
| QinQ/ 0.*      | Default or Bottom                     | None                          | None                  |
| QinQ/ 0.*      | Top                                   | TopQ                          | TopQ P-bits           |
| QinQ/ 0.*      | Default or Bottom                     | TopQ                          | TopQ P-bits           |
| QinQ/ 0.*      | Top                                   | TopQ BottomQ                  | TopQ P-bits           |
| QinQ/ 0.*      | Default or Bottom                     | TopQ BottomQ                  | BottomQ P-bits        |
| QinQ/ *.*      | Top                                   | None                          | None                  |
| QinQ/ *.*      | Default or Bottom                     | None                          | None                  |
| QinQ/ *.*      | Top                                   | TopQ                          | TopQ P-bits           |
| QinQ/ *.*      | Default or Bottom                     | TopQ                          | TopQ P-bits           |
| QinQ/ *.*      | Top                                   | TopQ BottomQ                  | TopQ P-bits           |
| QinQ/ *.*      | Default or Bottom                     | TopQ BottomQ                  | BottomQ P-bits        |

**Notes:**

1. "Default" in this column refers to the **no** form of the **match-qinq-dot1p** command.
2. For null encapsulation, the 7705 SAR does not process dot1p bits.

## qinq-mark-top-only

|                    |                                                                                                                                                                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] qinq-mark-top-only</b>                                                                                                                                                                                                                                                        |
| <b>Context</b>     | config>service>epipe>sap>egress<br>config>service>ipipe>sap>egress                                                                                                                                                                                                                    |
| <b>Description</b> | When enabled, the <b>qinq-mark-top-only</b> command specifies which P-bits to mark during packet egress. When disabled, both sets of P-bits are marked. When enabled, only the P-bits in the top Q-tag are marked. The <b>no</b> form of the command is the default state (disabled). |

Table 45 shows the dot1p re-marking behavior for different egress port type/SAP type combinations and **qinq-mark-top-only** state, where “False” represents the default (disabled) state.

If a new tag is pushed, the dot1p bits of the new tag will be zero (unless the new tag is re-marked by the egress policy. The dot1p bits are configured using the **dot1p** parameter under the **config>qos** context.

**Table 45 Dot1P Re-marking Behavior for the QinQ-mark-top-only Command**

| Egress Port Type/SAP Type | QinQ-mark-top-only State | Egress P-Bits Marked or Re-marked |
|---------------------------|--------------------------|-----------------------------------|
| Null <sup>1</sup>         | n/a                      | None                              |
| Dot1q/ X <sup>1</sup>     | n/a                      | Outer tag                         |
| Dot1q/ * <sup>2</sup>     | n/a                      | None                              |
| Dot1q/ 0 <sup>1</sup>     | n/a                      | Outer tag                         |
| QinQ/ X.Y <sup>1</sup>    | False                    | Two outer tags <sup>3</sup>       |
|                           | True                     | Outer tag <sup>3</sup>            |
| QinQ/ X.* <sup>1</sup>    | True or False            | Outer tag                         |
| QinQ/ X.0 <sup>1</sup>    | True or False            | Outer tag                         |
| QinQ/ 0.* <sup>1</sup>    | True or False            | None                              |
| QinQ/ *.* <sup>2</sup>    | True or False            | None                              |

**Notes:**

1. This port type/SAP type is supported by the following services: Epipe, Ipipe, VPLS, IES, and VPRN.
2. This port type/SAP type is supported by the following services: Epipe and VPLS.

3. Normally, when a new tag is pushed, the dot1p bits of the new tag will be zero, unless the P-bits are re-marked by the egress policy. However, an exception to this occurs when the egress SAP type is X.Y and only one new outer tag must be pushed. In this case, the new outer tag will have its dot1p bits set to the inner tag's dot1p bits.

**Default** no qinq-mark-top-only (disabled)

## qos

**Syntax** **qos** *policy-id*  
**no qos**

**Context** config>service>apipe>sap>egress  
config>service>apipe>sap>ingress  
config>service>apipe>sap-aggregation-group>egress  
config>service>apipe>sap-aggregation-group>ingress  
config>service>cpipe>sap>egress  
config>service>cpipe>sap>ingress  
config>service>epipe>sap>egress  
config>service>epipe>sap>ingress  
config>service>fpipe>sap>egress  
config>service>fpipe>sap>ingress  
config>service>hpipe>sap>egress  
config>service>hpipe>sap>ingress  
config>service>ipipe>sap>egress  
config>service>ipipe>sap>ingress

**Description** This command associates a QoS policy with an ingress or egress for a SAP or a SAP aggregation group.

QoS ingress and egress policies are important for the enforcement of SLA agreements. The policy ID must be defined prior to associating the policy with a SAP. If the *policy-id* does not exist, an error will be returned.

For SAPs, the **qos** command is used to associate both ingress and egress QoS policies on a per-SAP basis. The **qos** command only allows ingress policies to be associated on the SAP ingress and egress policies on the SAP egress. Attempts to associate a QoS policy of the wrong type returns an error.

For SAP aggregation groups, the **qos** command is used to apply an ingress and egress QoS policy to each N > 1 service. The configuration of a QoS policy on a per-SAP basis is not permitted. Any existing QoS profile can be applied to the N > 1 service. The QoS policy governs the whole PW service at the packet layer, irrespective of the number of SAPs that are bound to the N > 1 service.

For SAPs that are bound to an aggregation group, VC-based QoS using Layer 2 traffic descriptor profiles can be applied at ingress and egress. See the [traffic-desc](#) command for more information.

Only one ingress and one egress QoS policy can be associated with a SAP or a SAP aggregation group at one time.

By default, no specific QoS policy is associated with the SAP or SAP aggregation group for ingress or egress, so the default QoS policy is used.

The **no** form of this command removes the QoS policy association from the SAP or SAP aggregation group, and the QoS policy reverts to the default.

|                   |                                                                                                                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>policy-id</i> — associates the ingress or egress policy ID with the SAP or SAP aggregation group on ingress or egress. The policy ID or name must already exist. The <i>policy-name</i> does not apply to a SAP aggregation group. |
| <b>Values</b>     | 1 to 65535, or <i>policy-name</i> (up to 64 characters)                                                                                                                                                                               |

## scheduler-mode

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Description</b> | <p>This command sets the scheduler mode for the SAP and is part of the hierarchical QoS (H-QoS) feature on the 7705 SAR.</p> <p>If the mode is 4-priority, then the SAP is considered an unshaped 4-priority SAP and the <a href="#">agg-rate-limit</a> cannot be changed from its default values.</p> <p>If the mode is 16-priority and the <b>agg-rate limit</b> parameters are configured to be non-default values, then the SAP is considered a shaped SAP. If the <b>agg-rate limit</b> parameters are left in their default settings, the SAP is considered an unshaped, 16-priority SAP.</p> <p>This command is blocked on third-generation (Gen-3) Ethernet adapter cards and platforms, such as the 6-port Ethernet 10Gbps Adapter card and the 7705 SAR-X, which only support 4-priority scheduling mode.</p> <p>If the specified SAP is a LAG SAP, <b>scheduler-mode</b> can be configured but is not applied to Gen-3 adapter cards and platforms. If one of the ports in the LAG is on a Gen-1 adapter card, then <b>scheduler-mode</b> cannot be configured.</p> |
| <b>Default</b>     | 4-priority                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Description</b> | <p>This command applies a shaper group to a SAP. The shaper group must already be created and must be within the shaper policy assigned to the Ethernet MDA (for ingress) or port (for egress). A shaper group is a dual-rate aggregate shaper used to shape aggregate access ingress or egress SAPs at a shaper group rate. Multiple aggregate shaper groups ensure fair sharing of available bandwidth among different aggregate shapers.</p> <p>The default shaper group cannot be deleted.</p> <p>The <b>no</b> form of this command removes the configured <b>shaper-group</b>.</p> |
| <b>Default</b>     | shaper-group "default"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <p><i>shaper-group-name</i> — the name of the shaper group. To access the default shaper group, enter "default".</p> <p><b>create</b> — keyword used to create a shaper group</p>                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Context</b>     | config>service>apipe>sap<br>config>service>apipe>sap-aggregation-group<br>config>service>cpipe>sap<br>config>service>epipe>sap<br>config>service>fpipe>sap<br>config>service>hpipe>sap<br>config>service>ipipe>sap                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b> | <p>This command creates the accounting policy context that can be applied to a SAP or SAP aggregation group. An accounting policy must be defined before it can be associated with a SAP or SAP aggregation group. If the <i>policy-id</i> does not exist, an error message is generated.</p> <p>A maximum of one accounting policy can be associated with a SAP or SAP aggregation group at one time. Accounting policies are configured in the <b>config&gt;log</b> context.</p> <p>The <b>no</b> form of this command removes the accounting policy association from the SAP or SAP aggregation group, and the accounting policy reverts to the default.</p> |
| <b>Default</b>     | no accounting-policy                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <i>acct-policy-id</i> — the accounting <i>policy-id</i> as configured in the <b>config&gt;log&gt;accounting-policy</b> context                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Values</b>      | 1 to 99                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

##### collect-stats

|                    |                                                                                                                                                                                                                                                    |

| <b>Description</b> | This command enables accounting and statistical data collection for the SAP or SAP aggregation group. When applying accounting policies, the data, by default, is collected in the appropriate records and written to the designated billing file. |

---

When the **no collect-stats** command is issued, the statistics are still accumulated by the CSM. However, the CPU will not obtain the results and write them to the billing file. If a subsequent **collect-stats** command is issued, the counters written to the billing file include all the traffic while the **no collect-stats** command was in effect.

**Default**    collect-stats

| <b>Description</b> | <p>This command binds a service to an existing Service Destination Point (SDP). The syntax for an Epipe spoke SDP has additional parameters. See <a href="#">spoke-sdp</a> for the Epipe syntax.</p> <p>A spoke SDP is treated as the equivalent of a traditional bridge “port” where flooded traffic received on the spoke SDP is replicated on all other “ports” (other spoke SDPs or SAPs) and not transmitted on the port on which it was received.</p> <p>The SDP has an operational state that determines the operational state of the SDP within the service. For example, if the SDP is administratively or operationally down, the SDP for the service will be down.</p> <p>The SDP must already be defined in the <b>config&gt;service&gt;sdp</b> context in order to associate an SDP with a service. If the <b>sdp sdp-id</b> is not already configured, an error message is generated. If the <i>sdp-id</i> does exist, a binding between that <i>sdp-id</i> and the service is created.</p> <p>SDPs must be explicitly associated and bound to a service. If an SDP is not bound to a service, no far-end 7705 SAR devices can participate in the service.</p> <p>The <b>endpoint</b> command allows multiple spoke SDPs to be associated with the endpoint, providing PW redundancy capability. The endpoint must be defined using the <b>create</b> command before multiple spoke SDPs can be associated with the endpoint. The <b>no-endpoint</b> command removes the endpoint and the spoke SDP associations.</p> <p>On Cpipe spoke SDPs, you can configure <b>icb</b> to provide resiliency by reducing packet loss when an active endpoint is switched from a failed node of an MC-APS group to a standby node or from a failed MC-LCR MDA to a protection MDA. For example, if a port on an active MC-APS node fails, the port on the peer becomes active, but traffic continues to route to the previously active MC-APS node until it detects the failure. ICB spoke SDPs ensure that in-flight packets are delivered to the newly active MC-APS node. Two ICB spoke SDPs must be created. The ICB associated with the MC-APS on the first node must be associated with the pseudowire on the second node. Likewise, the ICB associated with the MC-APS on the second node must be associated with the pseudowire on the first node. In an MC-LCR configuration, if the active MDA fails, an MC-LCR switchover occurs which then triggers a pseudowire switchover.</p> |

The **no** form of the **spoke-sdp** command removes the SDP binding from the service. The SDP configuration is not affected; only the binding of the SDP to a service. Once removed, no packets are forwarded to the far-end router.

| <b>Description</b> | <p>This command binds an Epipe service to an existing Service Destination Point (SDP). The syntax for an Apipe, Cpipe, or Ipipe spoke SDP has additional parameters. See <a href="#">spoke-sdp</a> for the Apipe, Cpipe, or Ipipe syntax.</p> <p>A spoke SDP is treated as the equivalent of a traditional bridge “port” where flooded traffic received on the spoke SDP is replicated on all other “ports” (other spoke SDPs or SAPs) and not transmitted on the port on which it was received.</p> <p>The SDP has an operational state that determines the operational state of the SDP within the service. For example, if the SDP is administratively or operationally down, the SDP for the service will be down.</p> <p>The SDP must already be defined in the <b>config&gt;service&gt;sdp</b> context in order to associate an SDP with an Epipe service. If the <b>sdp sdp-id</b> is not already configured, an error message is generated. If the <i>sdp-id</i> does exist, a binding between that <i>sdp-id</i> and the service is created.</p> <p>SDPs must be explicitly associated and bound to a service. If an SDP is not bound to a service, no far-end 7705 SAR devices can participate in the service.</p> <p>The <b>endpoint</b> command allows multiple spoke SDPs to be associated with the endpoint, providing PW redundancy capability. The endpoint must already be defined in the <b>config&gt;service&gt;epipe</b> context in order to associate multiple spoke SDPs with the endpoint.</p> |

The **icb** (inter-chassis backup) spoke SDP provides resiliency by reducing packet loss when an active endpoint is switched from a failed node of an MC-LAG group to a standby node. For example, if a port on an active MC-LAG node fails, the port on the peer becomes active, but traffic continues to route to the previously active MC-LAG node until it detects the failure. ICB spoke SDPs ensure that in-flight packets are delivered to the newly active MC-LAG node. Two ICB spoke SDPs must be created. The ICB associated with the MC-LAG on the first node must be associated with the pseudowire on the second node. Likewise, the ICB associated with the MC-LAG on the second node must be associated with the pseudowire on the first node.

The **no** form of this command removes the SDP binding from the service. The SDP configuration is not affected; only the binding of the SDP to a service. Once removed, no packets are forwarded to the far-end router.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Default</b>    | <code>no sdp-id</code> is bound to a service                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b> | <p><code>sdp-id</code> — uniquely identifies the SDP</p> <p><b>Values</b> 1 to 17407</p> <p><code>vc-id</code> — identifies the virtual circuit</p> <p><b>Values</b> 1 to 4294967295</p> <p><b>vc-type</b> — overrides the default VC type signaled for the spoke binding to the far end of the SDP. The VC type is a 15-bit quantity containing a value that represents the type of VC. The actual signaling of the VC type depends on the signaling parameter defined for the SDP. If signaling is disabled, the <b>vc-type</b> command can still be used to define the dot1q value expected by the far-end provider equipment. A change of the binding's VC type causes the binding to signal the new VC type to the far end when signaling is enabled.</p> <p>VC types are derived according to IETF <i>draft-martini-l2circuit-trans-mpls</i>.</p> <ul style="list-style-type: none"> <li>• The VC type value for Ethernet is 0x0005.</li> <li>• The VC type value for an Ethernet VLAN is 0x0004.</li> </ul> <p><b>Values</b> ether   vlan</p> <p><b>ether</b> — defines the VC type as Ethernet. The <b>ethernet</b> and <b>vlan</b> keywords are mutually exclusive. When the VC type is not defined, then the default is Ethernet for spoke SDP bindings. Defining Ethernet is the same as executing <b>no vc-type</b> and restores the default VC type for the spoke SDP binding.</p> <p><b>vlan</b> — defines the VC type as VLAN. The <b>ethernet</b> and <b>vlan</b> keywords are mutually exclusive. When the VC type is not defined, then the default is Ethernet for spoke SDP bindings. The VLAN VC-type requires at least one dot1q tag within each encapsulated Ethernet packet transmitted to the far end.</p> <p><code>endpoint-name</code> — specifies the name of the service endpoint</p> <p><b>no-endpoint</b> — removes a spoke SDP association</p> <p><b>icb</b> — enables the inter-chassis backup spoke SDP to provide resiliency by reducing packet loss when an active endpoint is switched from a failed node of an MC-LAG group to a standby node.</p> |

| <b>Description</b> | <p>This command enables or disables the use of entropy labels for spoke SDPs.</p> <p>If <b>entropy-label</b> is enabled, the entropy label (EL) and entropy label indicator (ELI) are inserted in packets for which at least one LSP in the stack for the far end of the tunnel used by the service has advertised entropy label capability.</p> <p>If the tunnel is an RSVP-TE type, <b>entropy-label</b> can also be controlled by disabling <b>entropy-label-capability</b> under the <b>config&gt;router&gt;rsvp</b> or <b>config&gt;router&gt;mpls&gt;lsp</b> contexts at the far-end LER.</p> <p>When the <b>entropy-label</b> and <b>entropy-label-capability</b> commands are both enabled, the entropy label value inserted at the iLER is always based on the service ID.</p> |
| <b>Default</b>     | no entropy-label                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Description</b> | <p>This command specifies the precedence of the spoke SDP when there are multiple spoke SDPs associated with one service endpoint. One SDP binding can be assigned to be the primary SDP binding, leaving three bindings for secondary bindings, or, if no primary spoke SDP is defined, up to four secondary spoke SDPs can be configured. When an SDP binding goes down, the next highest precedence SDP binding will begin to forward traffic.</p> <p>The <b>no</b> form of the command returns the precedence value to the default.</p> |
| <b>Default</b>     | 4                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <p><i>precedence-value</i> — specifies the spoke SDP precedence</p> <p><b>Values</b> 1 to 4 (where 1 is the highest precedence)</p> <p><b>primary</b> — makes the specified spoke SDP the primary spoke SDP (primary is indicated on the CLI display as the value 0)</p>                                                                                                                                                                                                                                                                    |

| <b>Description</b> | <p>This command enables pseudowire status signaling for spoke SDPs. The <b>no</b> form of this command disables pseudowire status signaling. When pseudowire status signaling is disabled, a 7705 SAR does not include the PW status TLV in the initial label mapping message of the pseudowire that is used for a spoke SDP. This forces both 7705 SAR PEs to use the pseudowire label withdrawal method for signaling pseudowire status.</p> <p>If pseudowire status signaling is enabled, the 7705 SAR includes the pseudowire status TLV in the initial label mapping message for the pseudowire.</p> |

| <b>Description</b> | This command specifies an explicit dot1q value used when encapsulating to the SDP far end. When signaling is enabled between the near and far end, the configured dot1q tag can be overridden by a received TLV specifying the dot1q value expected by the far end. This signaled value must be stored as the remote signaled dot1q value for the binding. The provisioned local dot1q tag must be stored as the administrative dot1q value for the binding. |

When the dot1q tag is not defined, the default value of zero is stored as the administrative dot1q value. Setting the value to zero is equivalent to not specifying the value.

The **no** form of this command disables the command

|                   |                                                                                  |
|-------------------|----------------------------------------------------------------------------------|
| <b>Default</b>    | no vlan-vc-tag                                                                   |
| <b>Parameters</b> | <i>0..4094</i> — specifies a valid VLAN identifier to bind an 802.1Q VLAN tag ID |

| <b>Description</b> | This command specifies the IP address of the CE device associated with an Ipipe SAP or spoke SDP. In the case of a SAP, it is the address of the CE device directly attached to the SAP. For a spoke SDP, it is the address of the CE device reachable through that spoke SDP (for example, attached to the SAP on the remote node). The address must be a host address (no subnet addresses are accepted) as there must be only one CE device attached to an Ipipe SAP. The CE address specified at one end of an Ipipe will be used in processing ARP messages at the other endpoint, as the router acts as a proxy for ARP messages. |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <i>ip-address</i> — specifies the IP address of the CE device associated with an Ipipe SAP                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Context</b>     | config>service>apipe>spoke-sdp<br>config>service>cpipe>spoke-sdp<br>config>service>epipe>spoke-sdp<br>config>service>hpipe>spoke-sdp<br>config>service>ipipe>spoke-sdp                                                                                                                                |
| <b>Description</b> | This command indicates whether the control word is used. The value of the control word is negotiated with the peer.<br><br>The control word is mandatory for Cpipe SAToP and CESoPSN services, Epipe MEF 8 services, and Fpipe services (in one-to-one mapping configurations) and cannot be changed. |

---

The control word is optional for Apipe services, Epipe non-MEF 8 services, Hpipe services, and Ipipe services, but must be enabled for Hpipe pseudowire services when transporting packets that are less than 64 bytes. If the control word is enabled for Epipe or Ipipe services, it will be set to all zeros and ignored on egress.

For Cpipe services, Epipe MEF 8 services, Fpipe services, and Hpipe services, when the packet length is less than 64 bytes (that is, the length of the Layer 2 payload plus the length of the control word), the length field in the control word is set to the length of the packet. Otherwise, the length field is set to 0. The CE-bound PE uses the length field in the control word to determine the size of the padding that was added by the PSN so that the PE can extract the PW payload from the PW packet.

**Note:** If the control word is not set for packets less than 64 bytes, the PE cannot determine the original length of the packet and will forward the payload, including the padding bits. On reception of the padded packet, the CE will drop the packet. See RFC 4385 for more information.

**Default**    no control-word

#### 4.13.2.1.10 SDP Cell Concatenation Commands

##### cell-concatenation

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>cell-concatenation</b>                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Context</b>     | config>service>apipe>spoke-sdp                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Description</b> | <p>This command enables the context to provide access to the various options that control the termination of ATM cell concatenation into an MPLS frame. Several options can be configured simultaneously. The concatenation process for a given MPLS packet ends when the first concatenation termination condition is met. The concatenation parameters apply only to ATM N-to-1 cell mode VLL.</p> <p>Frame boundaries are not configurable.</p> |

##### clp-change

|                    |                                                                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] clp-change</b>                                                                                                                                                                                                                                                        |
| <b>Context</b>     | config>service>apipe>spoke-sdp>cell-concatenation                                                                                                                                                                                                                             |
| <b>Description</b> | <p>This command enables the configuration of CLP change to be an indication to complete the cell concatenation operation.</p> <p>The <b>no</b> form of the command resets the configuration to ignore the CLP change as an indication to complete the cell concatenation.</p> |

##### max-cells

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Description</b> | <p>This command enables the configuration of the maximum number of ATM cells to accumulate in an MPLS packet. The remote peer will also signal the maximum number of concatenated cells it is willing to accept in an MPLS packet. When the lesser of the configured value and the signaled value is reached, the MPLS packet is queued for transmission onto the pseudowire. It is ensured that the MPLS packet MTU conforms to the configured service MTU.</p> <p>If the max-delay and jitter buffer options are not configured, then the maximum number of cells allowed in a single VLL frame must be less than the configured service-mtu size.</p> <p>The <b>no</b> form of this command sets max-cells to the value "1", indicating that no concatenation will be performed.</p> |

---

|                   |                                                                                                                                                                  |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>cell-count</i> — specifies the maximum number of ATM cells to be accumulated in an MPLS packet before queuing the packet for transmission onto the pseudowire |
| <b>Values</b>     | 1 to 29                                                                                                                                                          |

| <b>Context</b>     | config>service>apipe>spoke-sdp>cell-concatenation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Description</b> | <p>This command enables the configuration of the maximum amount of time to wait while performing ATM cell concatenation into an MPLS packet before transmitting the MPLS packet. This places an upper bound on the amount of delay introduced by the concatenation process. When this amount of time is reached from when the first ATM cell for this MPLS packet was received, the MPLS packet is queued for transmission onto the pseudowire.</p> <p>The <b>no</b> form of this command resets <b>max-delay</b> to its default value.</p> |
| <b>Parameters</b>  | <i>delay-time</i> — specifies the maximum amount of time, in hundreds of microseconds, to wait before transmitting the MPLS packet with whatever ATM cells have been received. For example, a value of 1 equals 100 µs, and a value of 400 equals 40000 µs, or 40 ms.                                                                                                                                                                                                                                                                       |
| <b>Values</b>      | 1 to 400                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Default</b>     | 400                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

#### 4.13.2.1.11 ATM Commands

##### atm

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>atm</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Context</b>     | config>service>apipe>sap<br>config>service>epipe>sap                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b> | <p>This command enables access to the context to configure ATM-related attributes. This command can only be used when a context (for example, a channel or SAP) supports ATM functionality, such as:</p> <ul style="list-style-type: none"> <li>• configuring ATM ports or ATM port-related functionality on T1/E1 ASAP Adapter cards or OC3/STM1 Adapter cards</li> <li>• configuring ATM-related configuration for ATM-based SAPs on T1/E1 ASAP Adapter cards or on OC3/STM1 Adapter cards</li> </ul> <p>If ATM functionality is not supported for a context, the command returns an error.</p> |

##### egress

|                    |                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>egress</b>                                                                                    |
| <b>Context</b>     | config>service>apipe>sap>atm<br>config>service>epipe>sap>atm                                     |
| <b>Description</b> | This command enables access to the context to configure egress ATM traffic policies for the SAP. |

##### encapsulation

|                    |                                                                                                                                                                                                                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>encapsulation</b> <i>atm-encap-type</i>                                                                                                                                                                                                                                                                   |
| <b>Context</b>     | config>service>epipe>sap>atm                                                                                                                                                                                                                                                                                 |
| <b>Description</b> | <p>This command specifies the data encapsulation for an ATM PVCC-delimited SAP. The definition references <i>RFC 2684, Multiprotocol Encapsulation over ATM AAL5</i>, and the ATM Forum LAN Emulation specification.</p> <p>Ingress traffic that does not match the configured encapsulation is dropped.</p> |
| <b>Default</b>     | For VLL SAPs, the default and only option is aal5snap-bridged.                                                                                                                                                                                                                                               |

---

|                   |                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>atm-encap-type</i> — specifies the encapsulation type                                                                            |
| <b>Values</b>     | aal5snap-bridged (bridged encapsulation for LLC encapsulated circuit (LLC/ SNAP precedes protocol datagram) as defined in RFC 2684) |

## ingress

|                    |                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ingress</b>                                                                                    |
| <b>Context</b>     | config>service>apipe>sap>atm<br>config>service>epipe>sap>atm                                      |
| <b>Description</b> | This command enables access to the context to configure ingress ATM traffic policies for the SAP. |

## oam

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>oam</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Context</b>     | config>service>apipe>sap>atm<br>config>service>epipe>sap>atm                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | <p>This command enables the context to configure OAM functionality for a PVCC delimiting a SAP.</p> <p>The T1/E1 ASAP Adapter cards and 4-port OC3/STM1 Clear Channel Adapter card support the generation of F4 (VP) and F5 (VC) AIS cells when the Apipe service is operationally down. When the Apipe or Epipe service is operationally up, OAM cells are transported over the Apipe or Epipe and are transparent to the 7705 SAR. This capability is in accordance with ITU-T Recommendation I.610 - B-ISDN Operation and Maintenance.</p> |

## traffic-desc

|                    |                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Context</b>     | config>service>apipe>sap>atm>egress<br>config>service>epipe>sap>atm>egress<br>config>service>apipe>sap>atm>ingress<br>config>service>epipe>sap>atm>ingress                                                                                                                                                                                                           |
| <b>Description</b> | <p>This command assigns an ATM traffic descriptor profile to a SAP.</p> <p>When configured under the ingress context, the specified traffic descriptor profile defines the traffic contract in the forward direction. When configured under the egress context, the specified traffic descriptor profile defines the traffic contract in the backward direction.</p> |

For SAPs that belong to a SAP aggregation group, the egress traffic descriptor can be changed. The ingress traffic descriptor cannot be changed from the default (1). Attempting to change the ingress traffic descriptor will cause an error message to be displayed.

The **no** form of the command reverts to the default traffic descriptor profile.

|                   |                                                                                                                             |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | The default traffic descriptor (trafficDescProfileId. = 1) is associated with newly created PVCC-delimited SAPs.            |
| <b>Parameters</b> | <i>traffic-desc-profile-id</i> — specifies a defined traffic descriptor profile (see the QoS <b>atm-td-profile</b> command) |
| <b>Values</b>     | 1 to 1000                                                                                                                   |

| <b>Description</b> | <p>This command configures AIS/RDI fault management on a PVCC. Fault management allows PVCC terminations to monitor and report the status of their connection by propagating fault information through the network and by driving the PVCC operational status.</p> <p>Apipes on the 7705 SAR do not support PVCC terminations. They allow OAM cells to be transported transparently end-to-end.</p> <p>When this command is enabled on Apipe SAPs or ATM Epipe SAPs, AIS cells are generated when the Apipe, Epipe, or corresponding SAP is operationally down.</p> <p>The <b>no</b> form of the command disables alarm-cells functionality for the Apipe or Epipe. When alarm-cells functionality is disabled, AIS cells are not generated as a result of the Apipe, Epipe, or corresponding SAP going into the operationally down state.</p> |
| <b>Default</b>     | alarm-cells                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## vcid-translation

|                    |                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>vcid-translation</b> <i>vpi-vci</i><br><b>no vcid-translation</b>                                    |
| <b>Context</b>     | config>service>apipe>sap>atm                                                                            |
| <b>Description</b> | This optional command is used only with SAPs that are configured as members of a SAP aggregation group. |

The **vcid-translation** command is used when traffic arrives on multiple SAPs within the same SAP aggregation group with the same VPI/VCI value. In this case, the VPI/VCI values for incoming ATM cells that are to be aggregated in a single ATM PW must be translated to preserve their individual identification before the cells are mapped to the ATM PW payload.

When vcid-translation is configured for a SAP, ingress cells have their VPI/VCI values translated (rewritten) to the vcid-translation value. On the same node, egressing cells have their VPI/VCI values translated back to the VPI/VCI of the SAP.

If the vcid-translation for any ATM sap-aggregation-group SAP is not configured, the ingress VPI/VCI values are retained.

The 7705 SAR performs a check to ensure the uniqueness of the translated VPI/VCI values for all of the SAPs of the same ATM PW service, that is, within the same SAP aggregation group. If there are duplicate VC identifiers, the status of the VCs are set to operationally down and flagged as **ApipeSapVcidNotUnique**.

It is the responsibility of the user to ensure uniqueness of the VPI and VCI values after translation.

**Default** no vcid-translation

**Parameters** *vpi-vc*i — specifies the VPI and VCI translation values

### 4.13.2.2 Show Commands

**Note:** The following command outputs are examples only; actual displays may differ depending on supported functionality and user configuration.

| Vc Switching                             | Specifies whether the service is configured as a PW switching point                                                                                                        |
| SAP Count                                | Displays the number of SAPs specified for this service                                                                                                                     |
| SDP Bind Count                           | Displays the number of SDPs bound to this service                                                                                                                          |
| <b>Service Destination Points (SDPs)</b> |                                                                                                                                                                            |
| Description                              | Displays generic information about the SDP                                                                                                                                 |
| SDP Id                                   | Identifies the SDP                                                                                                                                                         |
| Type                                     | Identifies the service SDP binding type (for example, spoke)                                                                                                               |
| Split Horiz Grp                          | Not applicable                                                                                                                                                             |
| VC Type                                  | Displays the VC type for the SDP (for example, CESoPSN)                                                                                                                    |
| VC Tag                                   | The explicit dot1q value used when encapsulating to the SDP far end                                                                                                        |
| Admin Path MTU                           | Specifies the desired largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented |
| Oper Path MTU                            | Specifies the actual largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented  |
| Delivery                                 | Specifies the type of delivery used by the SDP (MPLS or GRE)                                                                                                               |
| Far End                                  | Displays the IP address of the remote end of the MPLS or GRE tunnel defined by this SDP                                                                                    |
| Admin State                              | Specifies the administrative state of this SDP                                                                                                                             |
| Oper State                               | Specifies the operational state of this SDP                                                                                                                                |
| Acct. Pol                                | The accounting policy ID assigned to the SAP                                                                                                                               |
| Collect Stats                            | Specifies whether collect stats is enabled                                                                                                                                 |
| Ingress Label                            | Displays the label used by the far-end device to send packets to this device in this service by this SDP                                                                   |

**Table 46 Service-ID All Command Field Descriptions (Continued)**

| Label              | Description                                                                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Egress Label       | Displays the label used by this device to send packets to the far-end device in this service by this SDP                                                                                        |
| Admin ControlWord  | Specifies the administrative state of the control word: Preferred (control word enabled) or Not Preferred (control word disabled)                                                               |
| Oper ControlWord   | Specifies the operational state of the control word: True (control word enabled) or False (control word disabled)                                                                               |
| Last Status Change | Specifies the time of the most recent operating status change to this spoke SDP                                                                                                                 |
| Signaling          | Specifies the signaling protocol used to obtain the ingress and egress labels used in frames transmitted and received on this SDP                                                               |
| Last Mgmt Change   | Specifies the time of the most recent management-initiated change to this spoke SDP                                                                                                             |
| PW Status Sig      | Specifies whether pseudowire status signaling for spoke SDPs is enabled or disabled                                                                                                             |
| Flags              | Displays the conditions that affect the operating status of this spoke SDP. Display output includes PathMTUtooSmall, SdpOperDown, NoIngVCLabel, NoEgrVCLabel, StandbySigSlaveTxDown, and so on. |
| Mac Move           | Indicates the administrative state of the MAC movement feature associated with the service                                                                                                      |
| Local Pw Bits      | Displays the setting of the local pseudowire bits                                                                                                                                               |
| Peer Pw Bits       | Displays the setting of the peer pseudowire bits. Display output includes pwNotforwarding, psnIngressFault, psnEgressFault, lacIngressFault, lacEgressFault, PwFwdingStandby, and so on.        |
| Peer Fault Ip      | N/A                                                                                                                                                                                             |
| Peer Vccv CV Bits  | Displays the setting of the pseudowire peer VCCV control verification bits (lspPing)                                                                                                            |
| Peer Vccv CC Bits  | Displays the setting of the pseudowire peer VCCV control channel bits (pwe3ControlWord and/or mplsRouterAlertLabel)                                                                             |

**Table 46 Service-ID All Command Field Descriptions (Continued)**

| Label                                    | Description                                                                                                                                    |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Keepalive Information</b>             |                                                                                                                                                |
| Admin State                              | Specifies the administrative state of the keepalive protocol                                                                                   |
| Oper State                               | Specifies the operational state of the keepalive protocol                                                                                      |
| Hello Time                               | Specifies how often the SDP Echo Request messages are transmitted on this SDP                                                                  |
| Hello Msg Len                            | Specifies the length of the SDP Echo Request messages transmitted on this SDP                                                                  |
| Max Drop Count                           | Specifies the maximum number of consecutive SDP Echo Request messages that can be unacknowledged before the keepalive protocol reports a fault |
| Hold Down Time                           | Specifies the amount of time to wait before the keepalive operating status is eligible to enter the alive state                                |
| <b>Statistics</b>                        |                                                                                                                                                |
| I. Fwd. Pkts.                            | Specifies the number of forwarded ingress packets                                                                                              |
| I. Dro. Pkts.                            | Specifies the number of dropped ingress packets                                                                                                |
| I. Fwd. Octs.                            | Specifies the number of forwarded ingress octets                                                                                               |
| I. Dro. Octs.                            | Specifies the number of dropped ingress octets                                                                                                 |
| E. Fwd. Pkts.                            | Specifies the number of forwarded egress packets                                                                                               |
| E. Fwd. Octets                           | Specifies the number of forwarded egress octets                                                                                                |
| <b>Eth-Cfm Configuration Information</b> |                                                                                                                                                |
| Md-index                                 | Displays the value of the MD index                                                                                                             |
| Direction                                | Displays the direction of the MEP                                                                                                              |
| Ma-index                                 | Displays the value of the MA index                                                                                                             |
| Admin                                    | Displays the administrative state of the MEP (enabled or disabled)                                                                             |
| MepId                                    | Displays the MEP-ID                                                                                                                            |
| CCM-Enable                               | Displays the status of the Continuity Check Message (CCM)                                                                                      |
| LowestDefectPri                          | Displays a configured value that defects are evaluated against                                                                                 |

**Table 46 Service-ID All Command Field Descriptions (Continued)**

| Label               | Description                                                                                                                 |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------|
| HighestDefect       | Displays the highest defect                                                                                                 |
| Defect Flags        | Indicates the defect flags                                                                                                  |
| Mac Address         | Displays the MAC address (the MAC address for a spoke SDP is the system MAC address; for a SAP, it is the port MAC address) |
| CcmLtmPriority      | Displays the priority of the CCM Linktrace Message (LTM)                                                                    |
| CcmTx               | Displays the number of CCM transmissions                                                                                    |
| CcmSequenceErr      | Displays the number of CCM sequence errors                                                                                  |
| DmrRepliesTx        | Displays the number of delay measurement replies transmitted                                                                |
| LmrRepliesTx        | Displays the number of loss measurement replies transmitted                                                                 |
| Dual-Loss Test      | Displays the status of the dual-ended loss measurement test (enabled or disabled)                                           |
| Dual-Loss Thresh    | Displays the frame error threshold beyond which an alarm will be raised. The threshold is expressed as a percentage.        |
| Eth-Ais             | Displays the status of the ETH-AIS test (enabled or disabled)                                                               |
| Eth-Ais Rx Ais      | Indicates whether any ETH-AIS messages have been received                                                                   |
| Eth-Ais Tx Priorit* | Displays the priority value of a transmitted ETH-AIS frame                                                                  |
| Eth-Ais Rx Interv*  | Indicates the interval of a received ETH-AIS frame                                                                          |
| Eth-Ais Tx Interva* | Displays the interval of a transmitted ETH-AIS frame                                                                        |
| Eth-Ais Tx Counte*  | Displays the number of ETH-AIS frames that have been sent                                                                   |
| Eth-Ais Tx Levels   | Indicates the MD level of transmitted ETH-AIS frames                                                                        |
| Eth-Tst             | Indicates the status of the ETH-Test (enabled or disabled)                                                                  |
| LbRxReply           | Displays the number of received loopback (LB) replies                                                                       |
| LbRxBadOrder        | Displays the number of LB replies that have been received in the wrong order                                                |

**Table 46 Service-ID All Command Field Descriptions (Continued)**

| Label                                            | Description                                                                                                                                                                                                                                                                               |
|--------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LbRxBadMsdu                                      | Displays the number of LB replies that have been received with the wrong destination MAC address (MSDU = MAC Service Data Unit)                                                                                                                                                           |
| LbTxReply (Total)                                | Displays the total number of LBRs (loopback replies) transmitted from this MEP                                                                                                                                                                                                            |
| LbTxReplyNoTLV                                   | Displays the number of LBRs (loopback replies) transmitted from this MEP with no TLV<br>Because only LBMs with no TLVs are used for throughput testing, the LbTxReply (Total), LbTxReplyNoTLV, and LbTxReplyWithTLV counters can help debug problems if throughput testing is not working |
| LbTxReplyWithTLV                                 | Displays the number of LBRs (loopback replies) transmitted from this MEP with TLV                                                                                                                                                                                                         |
| LbNextSequence                                   | Displays the sequence number of the next LB transmission                                                                                                                                                                                                                                  |
| LtNextSequence                                   | Displays the sequence number of the next Linktrace (LT) message transmitted                                                                                                                                                                                                               |
| LtRxUnexplained                                  | Displays the number of the unexplained Linktrace (LT) messages                                                                                                                                                                                                                            |
| <b>Associated LSP LIST</b>                       |                                                                                                                                                                                                                                                                                           |
| Lsp Name                                         | Specifies the name of the static LSP                                                                                                                                                                                                                                                      |
| Admin State                                      | Specifies the administrative state of the associated LSP                                                                                                                                                                                                                                  |
| Oper State                                       | Specifies the operational state of the associated LSP                                                                                                                                                                                                                                     |
| Time Since Last Tr*                              | Specifies the time that the associated static LSP has been in service                                                                                                                                                                                                                     |
| <b>APIPE Service Destination Point specifics</b> |                                                                                                                                                                                                                                                                                           |
| Admin Concat Limit                               | Specifies the administrative (configured) value for the maximum number of cells for cell concatenation, as defined via the <b>max-cells</b> command                                                                                                                                       |
| Oper Concat Limit                                | Specifies the operational value for the maximum number of cells for cell concatenation                                                                                                                                                                                                    |
| Peer Concat Limit                                | Specifies the far-end value for the maximum number of cells for cell concatenation                                                                                                                                                                                                        |

**Table 46 Service-ID All Command Field Descriptions (Continued)**

| Label                                            | Description                                                                                                             |
|--------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| Max Concat Delay                                 | Specifies the amount of time to wait while cell concatenation is occurring, as defined via the <b>max-delay</b> command |
| <b>CPIPE Service Destination Point specifics</b> |                                                                                                                         |
| Local Bit-rate                                   | Specifies the number of DS0s used by the local SDP                                                                      |
| Peer Bit-rate                                    | Specifies the number of DS0s used by the far-end SDP                                                                    |
| Local Payload Size                               | Specifies the local payload size, in bytes, used by the local SDP                                                       |
| Peer Payload Size                                | Specifies the peer payload size, in bytes, used by the far-end SDP                                                      |
| Local Jitter Buffer                              | Specifies the jitter buffer size, in milliseconds, used by the local SDP                                                |
| Peer Jitter Buffer                               | Specifies the jitter buffer size, in milliseconds, used by the far-end SDP                                              |
| Local Asym Delay                                 | Specifies whether asymmetric delay control is enabled on the local SDP                                                  |
| Peer Asym Delay                                  | Specifies whether asymmetric delay control is enabled on the far-end SDP                                                |
| Local Sig Pkts                                   | Specifies the type of signaling packets used by the local SDP                                                           |
| Peer Sig Pkts                                    | Specifies the type of signaling packets used by the far-end SDP                                                         |
| Local CAS Framing                                | Specifies the type of CAS framing used by the local SDP                                                                 |
| Peer CAS Framing                                 | Specifies the type of CAS framing used by the far-end SDP                                                               |
| Local RTP Header                                 | Specifies whether the local router inserts the RTP header                                                               |
| Peer RTP Header                                  | Specifies whether the peer router inserts the RTP header                                                                |
| Number of SDPs                                   | Specifies the number of SDPs bound to the service                                                                       |
| <b>FPIPE Service Destination Point specifics</b> |                                                                                                                         |
| Split Horiz Grp                                  | Not applicable                                                                                                          |
| Endpoint                                         | Not applicable                                                                                                          |
| Precedence                                       | Specifies the precedence level of the SDP binding                                                                       |

**Table 46 Service-ID All Command Field Descriptions (Continued)**

| Label                                            | Description                                                                                                                                                                |
|--------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Class Fwding State                               | Specifies the admin state of class-based forwarding on this SDP                                                                                                            |
| <b>IPIPE Service Destination Point specifics</b> |                                                                                                                                                                            |
| Precedence                                       | Specifies the precedence level of the SDP binding                                                                                                                          |
| IpipeSdpBindCelpAd*                              | Specifies the IP address of the Ipipe spoke-sdp                                                                                                                            |
| <b>Service Access Points</b>                     |                                                                                                                                                                            |
| Service Id                                       | Identifies the service                                                                                                                                                     |
| SAP                                              | Specifies the ID of the access port where this SAP is defined                                                                                                              |
| Encap                                            | Specifies the encapsulation type for this SAP on the access port                                                                                                           |
| Admin State                                      | Specifies the desired state of the SAP                                                                                                                                     |
| Oper State                                       | Specifies the operating state of the SAP                                                                                                                                   |
| Flags                                            | Specifies the conditions that affect the operating status of this SAP. Display output includes ServiceAdminDown, PortOperDown, and so on.                                  |
| Last Status Change                               | Specifies the date and time of the most recent status change to this SAP                                                                                                   |
| Last Mgmt Change                                 | Specifies the date and time of the most recent management-initiated change to this SAP                                                                                     |
| Dot1Q Ethertype                                  | Identifies the value of the dot1q Ethertype                                                                                                                                |
| QinQ Ethertype                                   | Identifies the value of the qinq Ethertype                                                                                                                                 |
| qinq-pbit-marking                                | Indicates the qinq P-bit marking for the service: both or top                                                                                                              |
| Hold Meps Up                                     | Specifies if hold-mep-up-on-failure is enabled or disabled for a SAP Epipe                                                                                                 |
| LLF Admin State                                  | Specifies the Link Loss Forwarding administrative state                                                                                                                    |
| LLF Oper State                                   | Specifies the Link Loss Forwarding operational state                                                                                                                       |
| Admin MTU                                        | Specifies the desired largest service frame size (in octets) that can be transmitted through this SAP to the far-end router, without requiring the packet to be fragmented |

**Table 46 Service-ID All Command Field Descriptions (Continued)**

| Label              | Description                                                                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Oper MTU           | Specifies the actual largest service frame size (in octets) that can be transmitted through this SAP to the far-end router, without requiring the packet to be fragmented |
| Ingr IP Fltr-ID    | Specifies the ingress IP filter policy ID assigned to the SAP                                                                                                             |
| Egr IP Fltr-Id     | Specifies the egress IP filter policy ID assigned to the SAP                                                                                                              |
| Ingr Mac Fltr-ID   | Specifies the ingress MAC filter policy ID assigned to the SAP                                                                                                            |
| Egr Mac Fltr-Id    | Specifies the egress MAC filter policy ID assigned to the SAP                                                                                                             |
| Ingr IPv6 Fltr-Id  | Specifies the ingress IPv6 filter policy ID assigned to the SAP                                                                                                           |
| Egr IPv6 Fltr-Id   | Specifies the egress IPv6 filter policy ID assigned to the SAP                                                                                                            |
| tod-suite          | n/a                                                                                                                                                                       |
| qinq-pbit-marking  | Indicates the qinq P-bit marking for the SAP: both or top                                                                                                                 |
| Ing Scheduler Mode | Indicates the ingress scheduler mode for the SAP                                                                                                                          |
| Egr Scheduler Mode | Indicates the egress scheduler mode for the SAP                                                                                                                           |
| Ing Agg Rate Limit | Indicates the PIR rate limit in the access ingress direction for the aggregate of the SAP queues                                                                          |
| Egr Agg Rate Limit | Indicates the PIR rate limit in the access egress direction for the aggregate of the SAP queues                                                                           |
| Ing Agg cir        | Indicates the CIR rate limit in the access ingress direction for the aggregate of the SAP queues                                                                          |
| Egr Agg cir        | Indicates the CIR rate limit in the access egress direction for the aggregate of the SAP queues                                                                           |
| Ing Shaper Group   | Indicates the ingress shaper group for the SAP                                                                                                                            |
| Egr Shaper Group   | Indicates the egress shaper group for the SAP                                                                                                                             |
| Acct. Pol          | Specifies the accounting policy applied to the SAP                                                                                                                        |
| Collect Stats      | Specifies whether accounting statistics are collected on the SAP                                                                                                          |

**Table 46 Service-ID All Command Field Descriptions (Continued)**

| Label                                 | Description                                                                                         |
|---------------------------------------|-----------------------------------------------------------------------------------------------------|
| FPIPE Service Access Points specifics |                                                                                                     |
| Multi Svc Site                        | Indicates the multiservice site that the SAP is a member of. Not applicable.                        |
| Sub Type                              | The supported subtype: regular                                                                      |

| Ingress TD Ovr                           | The Ovr for the traffic descriptor applied to the ingress SAP                                                                                                                                                                                                                                                                                                                                                             |
| Egress TD Ovr                            | The Ovr for the traffic descriptor applied to the egress SAP                                                                                                                                                                                                                                                                                                                                                              |
| Alarm Cell Handling                      | Indicates that OAM cells are being processed                                                                                                                                                                                                                                                                                                                                                                              |
| OAM Termination                          | Indicates whether this SAP is an OAM termination point                                                                                                                                                                                                                                                                                                                                                                    |
| AAL-5 Encap                              | The type of AAL5 encapsulation for this ATM SAP                                                                                                                                                                                                                                                                                                                                                                           |
| <b>CEM SAP Configuration Information</b> |                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Endpoint Type                            | Specifies the type of endpoint                                                                                                                                                                                                                                                                                                                                                                                            |
| Bit-rate                                 | Specifies the number of DS0s or timeslots in the channel group                                                                                                                                                                                                                                                                                                                                                            |
| Payload Size                             | Specifies the number of octets contained in the payload of a TDM PW packet when the packet is transmitted                                                                                                                                                                                                                                                                                                                 |
| Jitter Buffer (ms)                       | Specifies the size of the receive jitter buffer, expressed in milliseconds                                                                                                                                                                                                                                                                                                                                                |
| Jitter Buffer (packets)                  | Specifies the number of packets in the receive jitter buffer                                                                                                                                                                                                                                                                                                                                                              |
| Playout Threshold (packets)              | Indicates the number of packet buffers for the playout buffer packets threshold                                                                                                                                                                                                                                                                                                                                           |
| Use RTP Header                           | Specifies whether RTP headers are used in CES packets (Yes or No)                                                                                                                                                                                                                                                                                                                                                         |
| Differential                             | Indicates whether DCR is active                                                                                                                                                                                                                                                                                                                                                                                           |
| Timestamp Freq                           | Specifies the optional timestamp frequency                                                                                                                                                                                                                                                                                                                                                                                |
| CAS Framing                              | Specifies the type of CAS framing                                                                                                                                                                                                                                                                                                                                                                                         |
| Effective PDVT                           | Displays the peak-to-peak packet delay variation (PDV) used by the circuit emulation service.<br><br>Since the operating system may adjust the jitter buffer setting in order to ensure no packet loss, the configured jitter buffer value may not be the value used by the system. The effective PDVT provides an indication that the PDV has been adjusted by the operating system (see <a href="#">Jitter Buffer</a> ) |
| AsymDelayControl                         | Specifies whether asymmetric delay control is enabled                                                                                                                                                                                                                                                                                                                                                                     |

**Table 46 Service-ID All Command Field Descriptions (Continued)**

| Label                     | Description                                                                                                                           |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| RepeatPeriod              | Specifies the number of times that the asymmetric delay control analysis is repeated                                                  |
| Samples                   | Specifies the number of packets that are analyzed (k = 1024)                                                                          |
| Cfg Alarm                 | Specifies the alarms that have alarm reporting enabled                                                                                |
| Alarm Status              | Indicates the current alarm state (stray, malformed, packet loss, overrun, underrun, remote packet loss, remote fault, or remote RDI) |
| <b>CEM SAP Statistics</b> |                                                                                                                                       |
| Packets                   | (Column heading) Displays the number of packets counted for the statistic since the last counter reset                                |
| Seconds                   | (Column heading) Displays the number of seconds elapsed for the statistic since the last counter reset                                |
| Events                    | (Column heading) Displays the number of events counted for the statistic since the last counter reset                                 |
| Egress Stats              | Indicates that the following statistics are egress statistics                                                                         |
| Forwarded                 | Displays the number of forwarded packets                                                                                              |
| Dropped                   | Displays the number of dropped packets                                                                                                |
| Missing                   | Displays the number of missing packets                                                                                                |
| Reordered Forwarded       | Displays the number of packets that have been reordered and forwarded                                                                 |
| Underrun                  | Displays the accumulated number of underrun packets for the number of underrun events                                                 |
| Overrun                   | Displays the accumulated number of overrun packets for the number of overrun events                                                   |
| Misordered Dropped        | Displays the number of misordered packets that have been dropped                                                                      |
| Malformed Dropped         | Displays the number of malformed packets that have been dropped                                                                       |
| LBit Dropped              | Displays the number of L bit marked packets that have been dropped                                                                    |
| Error                     | Displays the accumulated number of seconds that have passed while any error has occurred                                              |

**Table 46 Service-ID All Command Field Descriptions (Continued)**

| Label                           | Description                                                                                                  |
|---------------------------------|--------------------------------------------------------------------------------------------------------------|
| Severely Error                  | Displays the accumulated number of seconds that have passed while severe errors have occurred                |
| Unavailable                     | Displays the accumulated number of seconds that have passed while the Cpipe or MEF 8 Epipe is unavailable    |
| Failure Count                   | Displays the accumulated number of failed events                                                             |
| Jitter Buffer Depth             | Displays the number of packets sitting in the jitter buffer at that instant for a given Cpipe or MEF 8 Epipe |
| Jitter Buffer Sampling Complete | Displays the number of asymmetric delay control analysis periods completed                                   |
| Jitter Buffer Adjust            | Displays the number of jitter buffer adjustments made for asymmetric delay control                           |
| Ingress Stats                   | Indicates that the following statistics are ingress statistics                                               |
| Forwarded                       | Displays the number of forwarded packets                                                                     |
| Dropped                         | Displays the number of dropped packets                                                                       |

| SAP Count                                      | Displays the number of SAPs specified for this service                                                                                                                                         |
| SDP Bind Count                                 | Displays the number of SDPs bound to this service                                                                                                                                              |
| <b>Service Access &amp; Destination Points</b> |                                                                                                                                                                                                |
| Identifier                                     | Lists the SAP, SDP, and SAP group identifier (if present)                                                                                                                                      |
| Type                                           | Specifies the signaling protocol used to obtain the ingress and egress labels used in frames transmitted and received on the SDP                                                               |
| AdmMTU                                         | Specifies the desired largest service frame size (in octets) that can be transmitted through this SDP to the far-end edge services router (ESR), without requiring the packet to be fragmented |
| OprMTU                                         | Specifies the actual largest service frame size (in octets) that can be transmitted through this SDP to the far-end ESR, without requiring the packet to be fragmented                         |
| Adm                                            | Indicates the operating state of the SAP or SDP                                                                                                                                                |
| Opr                                            | Indicates the operating state of the SAP or SDP                                                                                                                                                |

## egress-label

**Syntax** **egress-label** *start-label* [*end-label*]

**Context** show>service

**Description** This command displays services using the range of egress labels.

If only the mandatory *start-label* parameter is specified, only services using the specified label are displayed.

If both *start-label* and *end-label* parameters are specified, the services using this range of labels are displayed.

Use the **show router ldp bindings** command to display dynamic labels.

**Parameters** *start-label* — indicates the starting egress label value for which to display services using the label range. If only *start-label* is specified, services only using *start-label* are displayed.

**Values** 0, 2048 to 131071

*end-label* — indicates the ending egress label value for which to display services using the label range

**Values** 2049 to 131071

**Default** the *start-label* value

**Output** The following output is an example of service egress-label information, and [Table 48](#) describes the fields.

### Output Example

```
*A:ALU-12# show service egress-label 0 131071

| Number of bindings found | Indicates the total number of SDP bindings that exist within the specified egress label range              |

## id

**Syntax** `id service-id`

**Context** `show>service`

**Description** This command displays information for a particular service-id.

**Parameters** *service-id* — identifies the service in the domain

**Values** 1 to 2147483690 or *svc-name*

## ingress-label

**Syntax** `ingress-label start-label [end-label]`

**Context** `show>service`

**Description** This command displays services using the range of ingress labels.

If only the mandatory *start-label* parameter is specified, only services using the specified label are displayed.

If both *start-label* and *end-label* parameters are specified, the services using this range of labels are displayed.

Use the **show router vprn-service-id ldp bindings** command to display dynamic labels.

**Parameters** *start-label* — indicates the starting ingress label value for which to display services using the label range. If only *start-label* is specified, services only using *start-label* are displayed.

**Values** 0, 2048 to 131071

*end-label* — indicates the ending ingress label value for which to display services using the label range

**Values** 2049 to 131071

**Default** the *start-label* value

**Output** The following output is an example of service ingress-label information, and [Table 49](#) describes the fields.

### Output Example

```
*A:ALU-12# show service ingress-label 0

| Label                    | Description                                                                                                     |
|--------------------------|-----------------------------------------------------------------------------------------------------------------|
| Svc ID                   | Identifies the service                                                                                          |
| SDP Binding              | Identifies the SDP                                                                                              |
| Type                     | Specifies the SDP binding type (for example, spoke)                                                             |
| I.Lbl                    | Displays the ingress label used by the far-end device to send packets to this device in this service by the SDP |
| E.Lbl                    | Displays the egress label used by this device to send packets to the far-end device in this service by the SDP  |
| Number of Bindings Found | Indicates the number of SDP bindings within specified the label range                                           |

## endpoint

**Syntax** **endpoint** *endpoint-name*

**Context** show>service>id

**Description** This command displays the endpoint configuration status of the active spoke SDP and lists the primary and secondary spoke SDPs used by the service.

**Output** The following output is an example of service-id endpoint information, and [Table 50](#) describes the fields.

### Output Example

```
*A:7705:Dut-C>show>service>id# endpoint Endpoint_Y

=====
Service 6 endpoints
=====
Endpoint name : Endpoint_Y

**Table 50 Service-ID Endpoint Field Descriptions**

| Label                      | Description                                                                                                                              |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Service endpoints</b>   |                                                                                                                                          |
| Endpoint name              | Identifies the endpoint                                                                                                                  |
| Revert time                | Displays the revert time setting for the active spoke SDP                                                                                |
| Act Hold Delay             | Not applicable                                                                                                                           |
| Ignore Standby Signaling   | Indicates whether standby signaling is ignored<br>True: standby signaling is ignored<br>False: standby signaling is not ignored          |
| Suppress Standby Signaling | Indicates whether standby signaling is suppressed<br>True: standby signaling is suppressed<br>False: standby signaling is not suppressed |
| Tx Active                  | Identifies the actively transmitting spoke SDP                                                                                           |
| Tx Active Up Time          | Indicates the length of time that the active spoke SDP has been up                                                                       |
| Revert Time Count Down     | Not applicable                                                                                                                           |
| Tx Active Change Count     | Indicates the number of times that there has been a change of active spoke SDPs                                                          |

**Table 50 Service-ID Endpoint Field Descriptions (Continued)**

| Label                 | Description                                                                                                                                                            |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Last Tx Active Change | Indicates the date and time when a different spoke SDP became the actively transmitting spoke SDP                                                                      |
| <b>Members</b>        |                                                                                                                                                                        |
| Spoke-sdp             | Identifies the primary and secondary spoke SDPs that are associated with this endpoint and shows their precedence value (0 precedence indicates the primary spoke SDP) |

## labels

|                    |                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>labels</b>                                                                                                           |
| <b>Context</b>     | show>service>id                                                                                                         |
| <b>Description</b> | This command displays the labels being used by the service.                                                             |
| <b>Output</b>      | The following output is an example of service-id labels information, and <a href="#">Table 51</a> describes the fields. |

### Output Example

```
*A:ALU-12# show service id 1 labels
=====
Martini Service Labels
=====
Svc Id Sdp Binding Type I.Lbl E.Lbl

1 10:1 Spok 0 0

Number of Bound SDPs : 1

*A:ALU-12#
```

**Table 51 Service-ID Labels Field Descriptions**

| Label       | Description                                                                                                |
|-------------|------------------------------------------------------------------------------------------------------------|
| Svc Id      | Identifies the service                                                                                     |
| Sdp Binding | Identifies the SDP bound to the service                                                                    |
| Type        | Indicates the SDP binding type (for example, spoke)                                                        |
| I. Lbl      | Displays the VC label used by the far-end device to send packets to this device in this service by the SDP |

**Table 51 Service-ID Labels Field Descriptions (Continued)**

| Label  | Description                                                                                                |
|--------|------------------------------------------------------------------------------------------------------------|
| E. Lbl | Displays the VC label used by this device to send packets to the far-end device in this service by the SDP |

## sap

**Syntax** **sap** *sap-id* [**atm** | **base** | **detail** | **qos** | **sap-stats** | **stats**]

**Context** show>service>id

**Description** This command displays information for the SAPs associated with the service.

If no optional parameters are specified, a summary of all associated SAPs is displayed.

**Parameters** *sap-id* — identifies the SAPs for the service in the form *slot/mda/port[.channel]* for a port or *slot/mda/bridge-id.branch-id* for a SCADA bridge. See [Table 41](#) for a full list of SAP IDs.

**atm** — displays configuration information about the ATM SAP

**base** — displays basic information for the SAP or an ATM VCC SAP that is a member of a SAP aggregation group

**detail** — displays detailed information for the SAP or an ATM VCC SAP that is a member of a SAP aggregation group

**qos** — displays detailed information for the SAP

This parameter cannot be used on a SAP that is a member of a SAP aggregation group; otherwise, the following error message appears:

**MINOR: CLI QoS is not configurable for SAPs assigned to SAP Aggregation Group.**

See the **show>sap-aggregation-group** command for information about how to show statistics for aggregation group members.

**sap-stats** — displays detailed information for the SAP

This parameter cannot be used on a SAP that is a member of a SAP aggregation group; otherwise, the following error message appears:

**MINOR: CLI Statistics are not supported for SAPs assigned to SAP Aggregation Group.**

See the **show>sap-aggregation-group** command for information about how to show statistics for aggregation group members.

**stats** — displays detailed information for the SAP

This parameter cannot be used on a SAP that is a member of a SAP aggregation group; otherwise, the following error message appears:

**MINOR: CLI Statistics are not supported for SAPs assigned to SAP Aggregation Group.**

See the **show>sap-aggregation-group** command for information about how to show statistics for aggregation group members.

**Output** The [Output Example \(Apipe\)](#) is an example of service-id SAP information. [Table 52](#) describes the fields for the Apipe example. [Table 52](#) includes additional fields that appear in the outputs of the other VLL services, which are listed below and are included after the table:

- [Output Example \(Cpipe\)](#)
- [Output Example \(Epipe\)](#)
- [Output Example \(Fpipe\)](#)
- [Output Example \(Hpipe\)](#)
- [Output Example \(Ipipe\)](#)
- [Output Example \(Ipipe with Frame Relay SAP\)](#)
- [Output Example \(Ipipe with cHDLC SAP\)](#)
- [Output Example \(Apipe in a SAP aggregation group\)](#)

### Output Example (Apipe)

```

**Table 52 Service-ID SAP Field Descriptions**

| Label                        | Description                                                   |
|------------------------------|---------------------------------------------------------------|
| <b>Service Access Points</b> |                                                               |
| Service Id                   | Identifies the service                                        |
| SAP                          | Specifies the ID of the access port where this SAP is defined |

**Table 52 Service-ID SAP Field Descriptions (Continued)**

| Label              | Description                                                                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Encap              | Specifies the encapsulation type for this SAP on the access port                                                                                                           |
| Admin State        | Specifies the desired state of the SAP                                                                                                                                     |
| Oper State         | Specifies the operating state of the SAP                                                                                                                                   |
| Flags              | Specifies the conditions that affect the operating status of this SAP. Display output includes ServiceAdminDown, PortOperDown, and so on                                   |
| Last Status Change | Specifies the date and time of the most recent status change to this SAP                                                                                                   |
| Last Mgmt Change   | Specifies the date and time of the most recent management-initiated change to this SAP                                                                                     |
| Dot1Q Ethertype    | Identifies the value of the dot1q Ethertype                                                                                                                                |
| QinQ Ethertype     | Identifies the value of the qinq Ethertype                                                                                                                                 |
| qinq-pbit-marking  | Indicates the qinq P-bit marking for the service: both or top                                                                                                              |
| LLF Admin State    | Specifies the Link Loss Forwarding administrative state                                                                                                                    |
| LLF Oper State     | Specifies the Link Loss Forwarding operational state                                                                                                                       |
| Admin MTU          | Specifies the desired largest service frame size (in octets) that can be transmitted through this SAP to the far-end router, without requiring the packet to be fragmented |
| Oper MTU           | Specifies the actual largest service frame size (in octets) that can be transmitted through this SAP to the far-end router, without requiring the packet to be fragmented  |
| Ingr IP Fltr-Id    | Specifies the ingress IP filter policy ID assigned to the SAP                                                                                                              |
| Egr IP Fltr-Id     | Specifies the egress IP filter policy ID assigned to the SAP                                                                                                               |
| Ingr Mac Fltr-Id   | Specifies the ingress MAC filter policy ID assigned to the SAP                                                                                                             |
| Egr Mac Fltr-Id    | Specifies the egress MAC filter policy ID assigned to the SAP                                                                                                              |
| Ing Scheduler Mode | The scheduler mode for the SAP in the access ingress direction: 4-priority or 16-priority                                                                                  |
| Egr Scheduler Mode | The scheduler mode for the SAP in the access egress direction: 4-priority or 16-priority                                                                                   |
| Ing Agg Rate Limit | The PIR rate limit in the access ingress direction for the aggregate of the SAP queues                                                                                     |

**Table 52 Service-ID SAP Field Descriptions (Continued)**

| Label                                      | Description                                                                                                                  |
|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| Egr Agg Rate Limit                         | The PIR rate limit in the access egress direction for the aggregate of the SAP queues                                        |
| Ing Agg cir                                | The CIR rate limit in the access ingress direction for the aggregate of the SAP queues                                       |
| Egr Agg cir                                | The CIR rate limit in the access egress direction for the aggregate of the SAP queues                                        |
| Ing Shaper Group                           | The ingress shaper group for the SAP                                                                                         |
| Egr Shaper Group                           | The egress shaper group for the SAP                                                                                          |
| Acct. Pol                                  | Specifies the accounting policy applied to the SAP                                                                           |
| Collect Stats                              | Specifies whether accounting statistics are collected on the SAP                                                             |
| <b>QOS</b>                                 |                                                                                                                              |
| Ingress qos-policy                         | Displays the SAP ingress QoS policy ID                                                                                       |
| Egress qos-policy                          | Displays the SAP egress QoS policy ID                                                                                        |
| <b>SAP Statistics</b>                      |                                                                                                                              |
| Last Cleared Time                          | Displays the date and time that a clear command was issued on statistics                                                     |
| <b>Forwarding Engine Stats (Ingress)</b>   |                                                                                                                              |
| Dropped                                    | Indicates the number of packets or octets dropped by the forwarding engine                                                   |
| Off. HiPrio                                | Indicates the number of high-priority packets or octets offered to the forwarding engine                                     |
| Off. LowPrio                               | Indicates the number of low-priority packets offered to the forwarding engine                                                |
| <b>Queueing Stats (Ingress QoS Policy)</b> |                                                                                                                              |
| Dro. HiPrio                                | Indicates the number of high-priority packets or octets discarded, as determined by the SAP ingress QoS policy               |
| Dro. LowPrio                               | Indicates the number of low-priority packets discarded, as determined by the SAP ingress QoS policy                          |
| For. InProf                                | Indicates the number of in-profile packets or octets (rate below CIR) forwarded, as determined by the SAP ingress QoS policy |

**Table 52 Service-ID SAP Field Descriptions (Continued)**

| Label                                     | Description                                                                                                                      |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| For. OutProf                              | Indicates the number of out-of-profile packets or octets (rate above CIR) forwarded, as determined by the SAP ingress QoS policy |
| <b>Forwarding Engine Stats (Egress)</b>   |                                                                                                                                  |
| Dropped                                   | Indicates the number of packets or octets dropped by the forwarding engine                                                       |
| <b>Queueing Stats (Egress QoS Policy)</b> |                                                                                                                                  |
| Dro. InProf                               | Indicates the number of in-profile packets or octets discarded, as determined by the SAP egress QoS policy                       |
| Dro. OutProf                              | Indicates the number of out-of-profile packets or octets discarded, as determined by the SAP egress QoS policy                   |
| For. InProf                               | Indicates the number of in-profile packets or octets (rate below CIR) forwarded, as determined by the SAP egress QoS policy      |
| For. OutProf                              | Indicates the number of out-of-profile packets or octets (rate above CIR) forwarded, as determined by the SAP egress QoS policy  |
| <b>Sap per Queue stats</b>                |                                                                                                                                  |
| Ingress Queue $n$                         | Specifies the index of the ingress QoS queue of this SAP, where $n$ is the index number                                          |
| Off. HiPrio                               | Indicates the number of packets or octets of high-priority traffic for the SAP (offered)                                         |
| Off. LoPrio                               | Indicates the number or packets or octets of low-priority traffic for the SAP (offered)                                          |
| Dro. HiPrio                               | Indicates the number of high-priority traffic packets or octets dropped                                                          |
| Dro. LoPrio                               | Indicates the number of low-priority traffic packets or octets dropped                                                           |
| For. InProf                               | Indicates the number of in-profile packets or octets (rate below CIR) forwarded                                                  |
| For. OutProf                              | Indicates the number of out-of-profile packets or octets (rate above CIR) forwarded                                              |
| Egress Queue $n$                          | Specifies the index of the egress QoS queue of the SAP, where $n$ is the index number                                            |

**Table 52 Service-ID SAP Field Descriptions (Continued)**

| Label                                    | Description                                                                                                                 |
|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| For. InProf                              | Indicates the number of in-profile packets or octets (rate below CIR) forwarded                                             |
| For. OutProf                             | Indicates the number of out-of-profile packets or octets (rate above CIR) forwarded                                         |
| Dro. InProf                              | Indicates the number of in-profile packets or octets dropped for the SAP                                                    |
| Dro. OutProf                             | Indicates the number of out-of-profile packets or octets discarded                                                          |
| <b>Eth-Cfm Configuration Information</b> |                                                                                                                             |
| Md-index                                 | Displays the value of the MD index                                                                                          |
| Direction                                | Displays the direction of the MEP                                                                                           |
| Ma-index                                 | Displays the value of the MA index                                                                                          |
| Admin                                    | Displays the administrative state of the MEP (enabled or disabled)                                                          |
| Mepld                                    | Displays the MEP-ID                                                                                                         |
| CCM-Enable                               | Displays the status of the Continuity Check Message (CCM)                                                                   |
| LowestDefectPri                          | Displays a configured value that defects are evaluated against                                                              |
| HighestDefect                            | Displays the highest defect                                                                                                 |
| Defect Flags                             | Indicates the defect flags                                                                                                  |
| Mac Address                              | Displays the MAC address (the MAC address for a spoke SDP is the system MAC address; for a SAP, it is the port MAC address) |
| CcmLtmPriority                           | Displays the priority of the CCM Linktrace Message (LTM)                                                                    |
| CcmTx                                    | Displays the number of CCM transmissions                                                                                    |
| CcmSequenceErr                           | Displays the number of CCM sequence errors                                                                                  |
| DmrRepliesTx                             | Displays the number of delay measurement replies transmitted                                                                |
| LmrRepliesTx                             | Displays the number of loss measurement replies transmitted                                                                 |
| Dual-Loss Test                           | Displays the status of the dual-ended loss measurement test (enabled or disabled)                                           |

**Table 52 Service-ID SAP Field Descriptions (Continued)**

| Label                                    | Description                                                                                                                     |
|------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| Dual-Loss Thresh                         | Displays the frame error threshold beyond which an alarm will be raised. The threshold is expressed as a percentage.            |
| Eth-Ais                                  | Displays the status of the ETH-AIS test (enabled or disabled)                                                                   |
| Eth-Ais Rx Ais                           | Indicates whether any ETH-AIS messages have been received                                                                       |
| Eth-Ais Tx Priorit*                      | Displays the priority value of a transmitted ETH-AIS frame                                                                      |
| Eth-Ais Rx Interv*                       | Indicates the interval of a received ETH-AIS frame                                                                              |
| Eth-Ais Tx Interva*                      | Displays the interval of a transmitted ETH-AIS frame                                                                            |
| Eth-Ais Tx Counte*                       | Displays the number of ETH-AIS frames that have been sent                                                                       |
| Eth-Ais Tx Levels                        | Indicates the MD level of transmitted ETH-AIS frames                                                                            |
| Eth-Tst                                  | Indicates the status of the ETH-Test (enabled or disabled)                                                                      |
| LbRxReply                                | Displays the number of received loopback (LB) replies                                                                           |
| LbRxBadOrder                             | Displays the number of LB replies that have been received in the wrong order                                                    |
| LbRxBadMsdu                              | Displays the number of LB replies that have been received with the wrong destination MAC address (MSDU = MAC Service Data Unit) |
| LbTxReply                                | Displays the number of LBRs (loopback replies) transmitted out this MEP                                                         |
| LbNextSequence                           | Displays the sequence number of the next LB transmission                                                                        |
| LtNextSequence                           | Displays the sequence number of the next Linktrace (LT) message transmitted                                                     |
| LtRxUnexplained                          | Displays the number of the unexplained Linktrace (LT) messages                                                                  |
| <b>ATM SAP Configuration Information</b> |                                                                                                                                 |
| Ingress TD Profile                       | The profile ID of the traffic descriptor applied to the ingress SAP                                                             |
| Egress TD Profile                        | The profile ID of the traffic descriptor applied to the egress SAP                                                              |
| Ingress TD Ovr                           | The Ovr for the traffic descriptor applied to the ingress SAP                                                                   |
| Egress TD Ovr                            | The Ovr for the traffic descriptor applied to the egress SAP                                                                    |

**Table 52 Service-ID SAP Field Descriptions (Continued)**

| Label                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Alarm Cell Handling                      | Indicates that OAM cells are being processed                                                                                                                                                                                                                                                                                                                                                                              |
| OAM Termination                          | Indicates whether this SAP is an OAM termination point                                                                                                                                                                                                                                                                                                                                                                    |
| AAL-5 Encap                              | The type of AAL5 encapsulation for this ATM SAP                                                                                                                                                                                                                                                                                                                                                                           |
| <b>CEM SAP Configuration Information</b> |                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Endpoint Type                            | Specifies the type of endpoint                                                                                                                                                                                                                                                                                                                                                                                            |
| Bit-rate                                 | Specifies the number of DS0s or timeslots in the channel group                                                                                                                                                                                                                                                                                                                                                            |
| Payload Size                             | Specifies the number of octets contained in the payload of a TDM PW packet when the packet is transmitted                                                                                                                                                                                                                                                                                                                 |
| Jitter Buffer (ms)                       | Specifies the size of the receive jitter buffer, expressed in milliseconds                                                                                                                                                                                                                                                                                                                                                |
| Playout Threshold (packets)              | Indicates the number of packet buffers for the playout buffer packets threshold                                                                                                                                                                                                                                                                                                                                           |
| Use RTP Header                           | Specifies whether RTP headers are used in CES packets (Yes or No)                                                                                                                                                                                                                                                                                                                                                         |
| Differential                             | Indicates whether DCR is active                                                                                                                                                                                                                                                                                                                                                                                           |
| Timestamp Freq                           | Specifies the optional timestamp frequency                                                                                                                                                                                                                                                                                                                                                                                |
| CAS Framing                              | Specifies the type of CAS framing                                                                                                                                                                                                                                                                                                                                                                                         |
| Effective PVDT                           | Displays the peak-to-peak packet delay variation (PDV) used by the circuit emulation service.<br><br>Since the operating system may adjust the jitter buffer setting in order to ensure no packet loss, the configured jitter buffer value may not be the value used by the system. The effective PVDT provides an indication that the PVD has been adjusted by the operating system (see <a href="#">Jitter Buffer</a> ) |
| AsymDelayControl                         | Specifies whether asymmetric delay control is enabled                                                                                                                                                                                                                                                                                                                                                                     |
| RepeatPeriod                             | Specifies the number of times that the asymmetric delay control analysis is repeated                                                                                                                                                                                                                                                                                                                                      |
| Samples                                  | Specifies the number of packets that are analyzed (k = 1024)                                                                                                                                                                                                                                                                                                                                                              |
| Cfg Alarm                                | Specifies the alarms that have alarm reporting enabled                                                                                                                                                                                                                                                                                                                                                                    |
| Alarm Status                             | Indicates the current alarm state (for example, stray, malformed, packet loss, overrun, underrun, remote packet loss, remote fault, or remote RDI)                                                                                                                                                                                                                                                                        |

**Table 52 Service-ID SAP Field Descriptions (Continued)**

| Label                     | Description                                                                                                  |
|---------------------------|--------------------------------------------------------------------------------------------------------------|
| <b>CEM SAP Statistics</b> |                                                                                                              |
| Packets                   | (Column heading) Displays the number of packets counted for the statistic since the last counter reset       |
| Seconds                   | (Column heading) Displays the number of seconds elapsed for the statistic since the last counter reset       |
| Events                    | (Column heading) Displays the number of events counted for the statistic since the last counter reset        |
| Egress Stats              | Indicates that the following statistics are egress statistics                                                |
| Forwarded                 | Displays the number of forwarded packets                                                                     |
| Dropped                   | Displays the number of dropped packets                                                                       |
| Missing                   | Displays the number of missing packets                                                                       |
| Reordered Forwarded       | Displays the number of packets that have been reordered and forwarded                                        |
| Underrun                  | Displays the accumulated number of underrun packets for the number of underrun events                        |
| Overrun                   | Displays the accumulated number of overrun packets for the number of overrun events                          |
| Misordered Dropped        | Displays the number of misordered packets that have been dropped                                             |
| Malformed Dropped         | Displays the number of malformed packets that have been dropped                                              |
| LBit Dropped              | Displays the number of L bit marked packets that have been dropped                                           |
| Error                     | Displays the accumulated number of seconds that have passed while any error has occurred                     |
| Severely Error            | Displays the accumulated number of seconds that have passed while severe errors have occurred                |
| Unavailable               | Displays the accumulated number of seconds that have passed while the Cpipe or MEF 8 Epipe is unavailable    |
| Failure Count             | Displays the accumulated number of failed events                                                             |
| Jitter Buffer Depth       | Displays the number of packets sitting in the jitter buffer at that instant for a given Cpipe or MEF 8 Epipe |

**Table 52 Service-ID SAP Field Descriptions (Continued)**

| Label                            | Description                                                                        |
|----------------------------------|------------------------------------------------------------------------------------|
| Jitter Buffer Sampling Complete  | Displays the number of asymmetric delay control analysis periods completed         |
| Jitter Buffer Adjust             | Displays the number of jitter buffer adjustments made for asymmetric delay control |
| Jitter Buffer Delay (in $\mu$ s) | Displays the total amount of TDM PW data buffered                                  |
| Ingress Stats                    | Indicates that the following statistics are ingress statistics                     |
| Forwarded                        | Displays the number of forwarded packets                                           |
| Dropped                          | Displays the number of dropped packets                                             |

| For. OutProf                                       | Indicates the number of out-of-profile packets or octets (rate above CIR) forwarded, as determined by the SAP egress QoS policy |
| <b>SAP Aggregation Group per Queue stats</b>       |                                                                                                                                 |
| Ingress Queue <i>n</i> (Unicast) (Priority)        | Specifies the index of the ingress QoS queue of the SAP, where <i>n</i> is the index number                                     |
| Off. HiPrio                                        | Indicates the number of packets or octets of high-priority traffic for the SAP (offered)                                        |
| Off. LoPrio                                        | Indicates the number of packets or octets of low-priority traffic for the SAP (offered)                                         |
| Dro. HiPrio                                        | Indicates the number of high-priority traffic packets or octets discarded                                                       |
| Dro. LoPrio                                        | Indicates the number of low-priority traffic packets or octets discarded                                                        |
| For. InProf                                        | Indicates the number of in-profile packets or octets (rate below CIR) forwarded                                                 |
| For. OutProf                                       | Indicates the number of out-of-profile packets or octets (rate above CIR) forwarded                                             |
| Egress Queue <i>n</i>                              | Specifies the index of the egress QoS queue of the SAP, where <i>n</i> is the index number                                      |
| For. InProf                                        | Indicates the number of in-profile packets or octets (rate below CIR) forwarded                                                 |
| For. OutProf                                       | Indicates the number of out-of-profile packets or octets (rate above CIR) forwarded                                             |

**Table 53 Service-ID SAP Aggregation Group Field Descriptions**

| Label        | Description                                                        |
|--------------|--------------------------------------------------------------------|
| Dro. InProf  | Indicates the number of in-profile packets or octets discarded     |
| Dro. OutProf | Indicates the number of out-of-profile packets or octets discarded |

## sap-using

**Syntax** **sap-using** [**sap** *sap-id*]  
**sap-using** [**sap-aggregation-group** *group-id*]  
**sap-using** **description**  
**sap-using** **eth-ring** [**ring-id** *eth-ring-id*]  
**sap-using** [**ingress** | **egress**] **atm-td-profile** *td-profile-id*  
**sap-using** [**ingress** | **egress**] **qos-policy** [*qos-policy-id* | *qos-policy-name*]  
**sap-using** [**ingress** | **egress**] **scheduler-mode** {**4-priority** | **16-priority**}  
**sap-using** [**ingress** | **egress**] **shaper-group** *shaper-group-name*

**Context** show>service

**Description** This command displays SAP information.

If no optional parameters are specified, the command displays a summary of all defined SAPs.

The optional parameters restrict output to only SAPs matching the specified properties.

**Parameters** *group-id* — identifies the SAP aggregation group for the SAP. The value applies to the whole node. For example, if the same identifier is used for SAP aggregation groups in multiple services, the **show** command, when issued with the identifier, displays all the associated services.

**Values** 1 to 32 characters

**description** — displays a SAP summary table with description information

**ingress** — specifies matching an ingress policy

**egress** — specifies matching an egress policy

**scheduler-mode** — specifies the scheduler mode for which to display matching SAPs

**Values** 4-priority or 16-priority

**shaper-group** — specifies the shaper group for which to display matching SAPs

*eth-ring-id* — specifies the Ethernet ring ID for which to display matching SAPs

**Values** 1 to 128

*qos-policy-id* — identifies the ingress or egress QoS policy ID for which to display matching SAPs

**Values** 1 to 65535

*qos-policy-name* — identifies the ingress or egress QoS policy name for which to display matching SAPs

**Values** up to 64 characters

*shaper-group-name* — identifies the ingress or egress shaper group name for which to display matching SAPs

**Values** up to 64 characters

*td-profile-id* — displays SAPs using this traffic description

*sap-id* — specifies the physical port identifier portion of the SAP definition. See [Table 41](#) for a full list of SAP IDs.

**Output** The following outputs are examples of service SAP-using information, and [Table 54](#) describes the fields.

### Output Example

```
*A:ALU-48# show service sap-using

| <b>Context</b>     | show>service>id                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | This command displays information for the SDPs associated with the service.<br><br>If no optional parameters are specified, a summary of all associated SDPs is displayed.                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <p><i>sdp-id</i> — displays only information for the specified SDP ID</p> <p><b>Values</b> 1 to 17407</p> <p><i>ip-address</i> — displays only SDPs matching the specified far-end IP address</p> <p><b>Default</b> SDPs with any far-end IP address</p> <p><b>detail</b> — displays detailed SDP information</p> <p><b>keep-alive-history</b> — displays the last 50 keepalive events for the SDP</p> |
| <b>Output</b>      | The following output is an example of service-id SDP information, and <a href="#">Table 56</a> describes the fields.                                                                                                                                                                                                                                                                                   |

### Output Example (Cpipe)

**Table 56 SDP Field Descriptions**

| Label                                    | Description                                                         |
|------------------------------------------|---------------------------------------------------------------------|
| <b>Service Destination Points (SDPs)</b> |                                                                     |
| Description                              | Displays generic information about the SDP                          |
| SDP Id                                   | Identifies the SDP                                                  |
| Type                                     | Identifies the service SDP binding type (for example, spoke)        |
| VC Type                                  | Displays the VC type for the SDP (for example, CESoPSN)             |
| VC Tag                                   | The explicit dot1q value used when encapsulating to the SDP far end |

**Table 56 SDP Field Descriptions (Continued)**

| Label              | Description                                                                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Admin Path MTU     | Specifies the desired largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented |
| Oper Path MTU      | Specifies the actual largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented  |
| Far End            | Displays the IP address of the far end of the MPLS or GRE tunnel defined by this SDP                                                                                       |
| Delivery           | Specifies the type of delivery used by the SDP (MPLS or GRE)                                                                                                               |
| Admin State        | Specifies the administrative state of this SDP                                                                                                                             |
| Oper State         | Specifies the operational state of this SDP                                                                                                                                |
| Acct. Pol          | The accounting policy ID assigned to the SAP                                                                                                                               |
| Collect Stats      | Specifies whether collect stats is enabled                                                                                                                                 |
| Ingress Label      | Displays the label used by the far-end device to send packets to this device in this service by this SDP                                                                   |
| Egress Label       | Displays the label used by this device to send packets to the far-end device in this service by this SDP                                                                   |
| Admin ControlWord  | Specifies the administrative state of the control word: Preferred (control word enabled) or Not Preferred (control word disabled)                                          |
| Oper ControlWord   | Specifies the operational state of the control word: True (control word enabled) or False (control word disabled)                                                          |
| Last Status Change | Specifies the time of the most recent operating status change to this spoke SDP                                                                                            |
| Signaling          | Specifies the signaling protocol used to obtain the ingress and egress labels used in frames transmitted and received on this SDP                                          |
| Last Mgmt Change   | Specifies the time of the most recent management-initiated change to this spoke SDP                                                                                        |
| Flags              | Displays the conditions that affect the operating status of this spoke SDP. Display output includes PathMTUtooSmall, SdpOperDown, NoIngvCLabel, NoEgrVCLabel, and so on    |
| Mac Move           | Indicates the administrative state of the MAC movement feature associated with the service                                                                                 |

**Table 56 SDP Field Descriptions (Continued)**

| Label                                    | Description                                                                                                                                                 |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Peer Pw Bits                             | Displays the setting of the pseudowire peer bits. Display output includes pwNotforwarding, psnIngressFault, psnEgressFault, lacIngressFault, lacEgressFault |
| Peer Fault Ip                            | N/A                                                                                                                                                         |
| Peer Vccv CV Bits                        | Displays the setting of the pseudowire peer VCCV control verification bits (IspPing)                                                                        |
| Peer Vccv CC Bits                        | Displays the setting of the pseudowire peer VCCV control channel bits (pwe3ControlWord and/or mplsRouterAlertLabel)                                         |
| <b>Keepalive Information</b>             |                                                                                                                                                             |
| Admin State                              | Specifies the administrative state of the keepalive protocol                                                                                                |
| Oper State                               | Specifies the operational state of the keepalive protocol                                                                                                   |
| Hello Time                               | Specifies how often the SDP Echo Request messages are transmitted on this SDP                                                                               |
| Hello Msg Len                            | Specifies the length of the SDP Echo Request messages transmitted on this SDP                                                                               |
| Max Drop Count                           | Specifies the maximum number of consecutive SDP Echo Request messages that can be unacknowledged before the keepalive protocol reports a fault              |
| Hold Down Time                           | Specifies the amount of time to wait before the keepalive operating status is eligible to enter the alive state                                             |
| <b>Statistics</b>                        |                                                                                                                                                             |
| I. Fwd. Pkts.                            | Specifies the number of forwarded ingress packets                                                                                                           |
| I. Dro. Pkts.                            | Specifies the number of dropped ingress packets                                                                                                             |
| I. Fwd. Octs.                            | Specifies the number of forwarded ingress octets                                                                                                            |
| I. Dro. Octs.                            | Specifies the number of dropped ingress octets                                                                                                              |
| E. Fwd. Pkts.                            | Specifies the number of forwarded egress packets                                                                                                            |
| E. Fwd. Octets                           | Specifies the number of forwarded egress octets                                                                                                             |
| <b>Eth-Cfm Configuration Information</b> |                                                                                                                                                             |
| Md-index                                 | Displays the value of the MD index                                                                                                                          |
| Direction                                | Displays the direction of the MEP                                                                                                                           |

**Table 56 SDP Field Descriptions (Continued)**

| Label                      | Description                                                                                                                     |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| Ma-index                   | Displays the value of the MA index                                                                                              |
| Admin                      | Displays the administrative state of the MEP (enabled or disabled)                                                              |
| Mepld                      | Displays the MEP-ID                                                                                                             |
| CCM-Enable                 | Displays the status of the Continuity Check Message (CCM)                                                                       |
| LowestDefectPri            | Displays a configured value that defects are evaluated against                                                                  |
| HighestDefect              | Displays the highest defect                                                                                                     |
| Defect Flags               | Indicates the defect flags                                                                                                      |
| Mac Address                | Displays the MAC address (the MAC address for a spoke SDP is the system MAC address; for a SAP, it is the port MAC address)     |
| CcmLtmPriority             | Displays the priority of the CCM Linktrace Message (LTM)                                                                        |
| CcmTx                      | Displays the number of CCM transmissions                                                                                        |
| CcmSequenceErr             | Displays the number of CCM sequence errors                                                                                      |
| LbRxReply                  | Displays the number of received loopback (LB) replies                                                                           |
| LbRxBadOrder               | Displays the number of LB replies that have been received in the wrong order                                                    |
| LbRxBadMsdu                | Displays the number of LB replies that have been received with the wrong destination MAC address (MSDU = MAC Service Data Unit) |
| LbTxReply                  | Displays the number of LBRs (loopback replies) transmitted out this MEP                                                         |
| LbNextSequence             | Displays the sequence number of the next LB transmission                                                                        |
| LtNextSequence             | Displays the sequence number of the next Linktrace (LT) message transmitted                                                     |
| LtRxUnexplained            | Displays the number of the unexplained Linktrace (LT) messages                                                                  |
| <b>Associated LSP LIST</b> |                                                                                                                                 |
| Lsp Name                   | Specifies the name of the static LSP                                                                                            |
| Admin State                | Specifies the administrative state of the associated LSP                                                                        |

**Table 56 SDP Field Descriptions (Continued)**

| Label                                            | Description                                                                                                                                         |
|--------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| Oper State                                       | Specifies the operational state of the associated LSP                                                                                               |
| Time Since Last Tr*                              | Specifies the time that the associated static LSP has been in service                                                                               |
| <b>APIPE Service Destination Point specifics</b> |                                                                                                                                                     |
| Admin Concat Limit                               | Specifies the administrative (configured) value for the maximum number of cells for cell concatenation, as defined via the <b>max-cells</b> command |
| Oper Concat Limit                                | Specifies the operational value for the maximum number of cells for cell concatenation                                                              |
| Peer Concat Limit                                | Specifies the far-end value for the maximum number of cells for cell concatenation                                                                  |
| Max Concat Delay                                 | Specifies the amount of time to wait while cell concatenation is occurring, as defined via the <b>max-delay</b> command                             |
| <b>CPIPE Service Destination Point specifics</b> |                                                                                                                                                     |
| Local Bit-rate                                   | Specifies the number of DS0s used by the local SDP                                                                                                  |
| Peer Bit-rate                                    | Specifies the number of DS0s used by the far-end SDP                                                                                                |
| Local Payload Size                               | Specifies the local payload size, in bytes, used by the local SDP                                                                                   |
| Peer Payload Size                                | Specifies the peer payload size, in bytes, used by the far-end SDP                                                                                  |
| Local Jitter Buffer                              | Specifies the jitter buffer size, in milliseconds, used by the local SDP                                                                            |
| Peer Jitter Buffer                               | Specifies the jitter buffer size, in milliseconds, used by the far-end SDP                                                                          |
| Local Asym Delay                                 | Specifies whether asymmetric delay control is enabled on the local SDP                                                                              |
| Peer Asym Delay                                  | Specifies whether asymmetric delay control is enabled on the far-end SDP                                                                            |
| Local Sig Pkts                                   | Specifies the type of signaling packets used by the local SDP                                                                                       |
| Peer Sig Pkts                                    | Specifies the type of signaling packets used by the far-end SDP                                                                                     |
| Local CAS Framing                                | Specifies the type of CAS framing used by the local SDP                                                                                             |
| Peer CAS Framing                                 | Specifies the type of CAS framing used by the far-end SDP                                                                                           |

**Table 56 SDP Field Descriptions (Continued)**

| Label            | Description                                               |
|------------------|-----------------------------------------------------------|
| Local RTP Header | Specifies whether the local router inserts the RTP header |
| Peer RTP Header  | Specifies whether the peer router inserts the RTP header  |
| Number of SDPs   | Specifies the number of SDPs bound to the service         |

## sdp-using

- Syntax** **sdp-using** [*sdp-id*[:*vc-id*] | **far-end** *ip-address*]
- Context** show>service
- Description** Displays the services using SDP or far-end address options.
- Parameters** *sdp-id* — displays the services using the specified SDP  
**Values** 1 to 17407  
*vc-id* — displays the virtual circuit identifier  
**Values** 1 to 4294967295  
*ip-address* — displays the services that match the specified far-end IP address  
**Values** 1 to 2147483647
- Output** The following output is an example of the show service sdp-using command, and [Table 57](#) describes the fields.

### Output Example

```
A:ALA-48# show service sdp-using
```

```

**Table 57**      **SDP-Using Field Descriptions**

| Label            | Description                                                                                                         |
|------------------|---------------------------------------------------------------------------------------------------------------------|
| <b>Sdp-using</b> |                                                                                                                     |
| Svc Id           | Identifies the service                                                                                              |
| Sdp Id           | Identifies the SDP                                                                                                  |
| Type             | Identifies the type of SDP                                                                                          |
| Far End          | Identifies the far-end IP address of SDP                                                                            |
| Opr State        | Identifies the operational state of this service                                                                    |
| I.Label          | Identifies the ingress label used by the far-end device to send packets to this device in this service by this SDP. |
| E.Label          | Identifies the egress label used by this device to send packets to the far-end device in this service by this SDP.  |

## service-using

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Context</b>     | show>service                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Description</b> | Displays the services matching the specified usage properties. If no optional parameters are specified, all services defined on the system are displayed.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <p><b>epipe</b> — displays matching Epipe services</p> <p><b>ies</b> — displays matching IES services</p> <p><b>vpls</b> — displays matching VPLS services</p> <p><b>vprn</b> — displays matching VPRN services</p> <p><b>apipe</b> — displays matching Apipe services</p> <p><b>fpipe</b> — displays matching Fpipe services</p> <p><b>ipipe</b> — displays matching Ipipe services</p> <p><b>cpipe</b> — displays matching Cpipe services</p> <p><b>hpipe</b> — displays matching Hpipe services</p> <p><i>sdp-id</i> — displays the services using the specified SDP</p> <p><b>Values</b>      1 to 17407</p> |

*customer-id* — displays the services using the specified customer ID

**Values** 1 to 2147483647

**Output** The following is an example of the output for the show service service-using command for an Fpipe. [Table 58](#) describes the fields.

### Output Example (Fpipe)

```
A:ALA-48# show service service-using fpipe
```

```

**Table 58** Service-Using Field Descriptions

| Label        | Description                                        |
|--------------|----------------------------------------------------|
| ServiceID    | Identifies the service                             |
| Type         | Identifies the service type                        |
| Adm          | Specifies the administrative state of this service |
| Opr          | Specifies the operational state of this service    |
| CustomerId   | Specifies the ID of the customer                   |
| Service Name | The service name                                   |

### 4.13.2.3 Clear Commands

#### counters

|                    |                                                                                |
|--------------------|--------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>counters</b>                                                                |
| <b>Context</b>     | clear>service>statistics>id                                                    |
| <b>Description</b> | This command clears all traffic queue counters associated with the service ID. |

#### id

|                    |                                                      |
|--------------------|------------------------------------------------------|
| <b>Syntax</b>      | <b>id</b> <i>service-id</i>                          |
| <b>Context</b>     | clear>service<br>clear>service>statistics            |
| <b>Description</b> | This command clears counters for a specific service. |
| <b>Parameters</b>  | <i>service-id</i> — uniquely identifies a service    |
| <b>Values</b>      | 1 to 2147483690 or <i>svc-name</i>                   |

#### sap

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>sap</b> <i>sap-id</i> { <b>all</b>   <b>cem</b>   <b>counters</b> }                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Context</b>     | clear>service>statistics                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Description</b> | This command clears SAP statistics for a SAP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <p><i>sap-id</i> — specifies the physical port or bridge identifier portion of the SAP definition. See <a href="#">Table 41</a> for a full list of SAP IDs.</p> <p><b>all</b> — clears all SAP queue statistics and STP statistics</p> <p><b>cem</b> — clears all queue statistics associated with a cem SAP</p> <p><b>counters</b> — clears all queue statistics associated with the SAP. Counters are not supported for members of SAP aggregation groups. QoS counters are not applicable to N &gt; 1 SAPs.</p> |

---

## sap-aggregation-group

|                    |                                                                                                                                                                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>sap-aggregation-group</b> <i>group-id</i> { <b>all</b>   <b>counters</b> }                                                                                                                                                                                                                  |
| <b>Context</b>     | clear>service>statistics                                                                                                                                                                                                                                                                       |
| <b>Description</b> | This command clears all non-ATM layer SAP statistics for a SAP, that is, the QoS queue counters.                                                                                                                                                                                               |
| <b>Parameters</b>  | <i>group-id</i> — specifies the identifier for the SAP aggregation group<br><b>Values</b> 1 to 32 characters<br><b>all</b> — clears all QoS queue counters<br><b>counters</b> — clears all QoS queue counters. The <b>counters</b> option performs the same function as the <b>all</b> option. |

## sdp

|                    |                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>sdp</b> <i>sdp-id</i> <b>keep-alive</b>                                                             |
| <b>Context</b>     | clear>service>statistics                                                                               |
| <b>Description</b> | This command clears keepalive statistics associated with the SDP ID.                                   |
| <b>Parameters</b>  | <i>sdp-id</i> — identifies the SDP for which to clear keepalive statistics<br><b>Values</b> 1 to 17407 |

## arp

|                    |                                                            |
|--------------------|------------------------------------------------------------|
| <b>Syntax</b>      | <b>arp</b>                                                 |
| <b>Context</b>     | clear>service>id                                           |
| <b>Description</b> | This command clears the ARP entries from an lpipe service. |

## spoke-sdp

|                    |                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>spoke-sdp</b> <i>sdp-id:vc-id</i> <b>ingress-vc-label</b><br><b>spoke-sdp</b> <i>sdp-id:vc-id</i> { <b>all</b>   <b>counters</b> } |
| <b>Context</b>     | clear>service>id<br>clear>service>statistics>id                                                                                       |
| <b>Description</b> | This command clears and resets the spoke SDP bindings for the service.                                                                |

## Parameters

*sdp-id* — the spoke SDP ID to be reset

**Values** 1 to 17407

*vc-id* — the virtual circuit ID on the SDP ID to be reset

**Values** 1 to 4294967295

**all** — clears all queue statistics and STP statistics associated with the SDP

**counters** — clears all queue statistics associated with the SDP

**ingress-vc-label** — clears the VC ingress value associated with the specified connection

## 5 VPLS

This chapter provides an overview of Virtual Private LAN Service (VPLS) on the 7705 SAR.

Topics in this chapter include:

- [VPLS Overview](#)
- [VPLS Features](#)
- [Routed VPLS](#)
- [VPLS and Spanning Tree Protocol](#)
- [ATM PVC Access and Termination on a VPLS Service](#)
- [VPLS Service Considerations](#)
- [Configuration Notes](#)
- [Configuring a VPLS Service with CLI](#)
- [VPLS Command Reference](#)

---

## 5.1 VPLS Overview

Topics in this section include:

- [VPLS Packet Walkthrough](#)
- [Bridged Mobile Backhaul](#)
- [Multi-Tenant Unit \(MTU\) Termination](#)

Virtual Private LAN Service (VPLS), as described in RFC 4762, *Virtual Private LAN Service (VPLS) Using Label Distribution Protocol (LDP) Signaling*, is a type of virtual private network service that allows the connection of multiple sites in a single bridged domain over a provider-managed IP/MPLS network or a Layer 2 Ethernet bridged network. The customer sites in a VPLS instance appear to be on the same LAN, regardless of their location. VPLS uses a native Ethernet SAP or a bridged PDU encapsulated SAP on the customer-facing (access) side, which simplifies the LAN/WAN boundary and allows for rapid and flexible service provisioning.

VPLS offers a balance between point-to-point pseudowire service (Epipe, Ipipe, etc.) and outsourced routed services (VPRN). Unlike VPRN service, VPLS enables each customer to maintain control of their own routing strategies. All customer routers in the VPLS service are part of the same subnet (LAN), which simplifies the IP addressing plan, especially when compared to a mesh architecture constructed from many separate point-to-point connections. The VPLS service management is simplified since the service is not aware of, nor participates in, the IP addressing and routing.

A VPLS service provides connectivity between two or more SAPs on one (local service) or more (distributed service) service routers. The connection appears to be a bridged domain to the customer sites so that protocols, including routing protocols, can traverse the VPLS service.

Other VPLS advantages include:

- VPLS is a transparent, protocol-independent bridged service
- no Layer 2 protocol conversion between LAN and WAN technologies
- no need to design, manage, configure, and maintain separate WAN access equipment, thereby eliminating the need to train personnel on WAN technologies such as ATM, IP over ATM, IP over PPP, and so on

VPLS is supported on the cards and platforms listed below. A VPLS SAP can reside on the following ports:

- any Ethernet port (null or tagged) in access mode
  - on an 8-port Ethernet Adapter card with CLI identifier **a8-eth** or **a8-ethv2** installed on a 7705 SAR-8 or 7705 SAR-18
  - on a 6-port Ethernet 10Gbps Adapter card with CLI identifier **a6-eth-10G** or **a6-eth-10G-e** installed on a 7705 SAR-8 Shelf V2 with CSMv2 or a 7705 SAR-18
  - on an 8-port Gigabit Ethernet Adapter card with CLI identifier **a8-1gb-sfp**, **a8-1gb-v2-sfp**, or **a8-1gb-v3-sfp** installed on a 7705 SAR-8 or 7705 SAR-18
  - on a 10-port 1GigE/1-port 10GigE X-Adapter card in 10-port 1GigE mode with CLI identifier for mda-mode **x10-1gb-sfp** installed on a 7705 SAR-18
  - on a 7705 SAR-M (all variants) with CLI identifier **i7-1gb**
  - on a GPON module and on DSL modules when the module is installed in the 7705 SAR-M (variants with module slots)
  - on a 4-port SAR-H Fast Ethernet module when the module is installed in the 7705 SAR-H
  - on a 6-port SAR-M Ethernet module when the module is installed in the 7705 SAR-M (variants with module slots)
  - on a 7705 SAR-A (both variants)
  - on a 7705 SAR-Ax
  - on a 7705 SAR-W
  - on a 7705 SAR-Wx (all variants)
  - on a 7705 SAR-H with CLI identifier **i8-1gb**
  - on a 7705 SAR-Hc with CLI identifier **i6-1gb**
  - on a 7705 SAR-X with CLI identifier **i7-mix-eth**
- any port using ATM encapsulation on a 4-port OC3/STM1 Clear Channel Adapter card installed on a 7705 SAR-8 or 7705 SAR-18

The transport of VPLS service is supported by LDP, GRE, and RSVP-TE tunnels, as well as static LSPs and dot1q-, qinq-, or null-encapsulated Ethernet SAPs at uplink.

### VPLS Redundancy

Redundancy for a VPLS instance is provided using the endpoint concept to define primary and secondary spoke SDPs. This type of redundancy functions in a similar manner to PW redundancy. Refer to [Pseudowire Redundancy](#) for more information.

In addition, VPLS supports Spanning Tree Protocol (STP) on a per-VPLS instance basis, as well as management VPLS (mVPLS), where several VPLS instances are associated with a single STP instance running over redundant SAPs. The result of this STP is applied to the other VPLS services associated with the mVPLS instance. The VLAN range covering SAPs to be managed by a mVPLS instance is set under a specific mVPLS SAP definition. The 7705 SAR supports RSTP on the designated VLAN for fast detection of failures. See [VPLS and Spanning Tree Protocol](#) for more information.

### **Access Control and Traffic Management**

Access Control to and within VPLS is controlled via IP and MAC filter policies for ingress SAPs and SDPs (spoke and mesh), and IP filter policies for egress Ethernet SAPs. Traffic Management (TM) support at ingress and egress for unicast traffic is almost the same as TM support for an Ethernet PW SAP. The TM implementation is extended to support:

- at SAP ingress, queue selection for unicast and for broadcast, multicast, and unknown (BMU) traffic
- at network ingress, separate unicast and BMU queues
- at access ingress, ATM traffic (unicast and BMU) mapped to a single queue

### **Split Horizon**

Within the context of VPLS services, a loop-free topology within a fully meshed VPLS core is achieved by applying a split-horizon forwarding concept whereby packets received from a mesh SDP are never forwarded to other mesh SDPs within the same service. The advantage of this approach is that no protocol is required to detect loops within the VPLS core network.

The 7705 SAR supports split horizon groups (SHGs) and residential SHGs, making it possible to control how traffic is propagated via configuring and applying forwarding directions to the received traffic. SHGs prevent multicast traffic from flowing within the same group, thereby preventing any loops.

In applications such as DSL aggregation, it is useful to extend the split-horizon concept to groups made up of SAPs and spoke SDPs. This extension is referred to as a split horizon group or residential bridging.

Traffic arriving on a SAP or a spoke SDP within a split horizon group is not copied to other SAPs and spoke SDPs in the same split horizon group; however, it is copied to SAPs and spoke SDPs in other split horizon groups, if these exist within the same VPLS.

Residential SHGs are only supported by ATM encapsulated SAPs. Residential (ATM) SAPs do not forward broadcast or unknown traffic; they only process known unicast traffic. Residential SAPs allow one queue per direction (ingress and egress) for all traffic types (unicast and BMU). In addition, OAM processing is allowed on residential (ATM) SAPs.

OAM support includes support for VPLS mac-ping, mac-trace, and cpe-ping.

Additional 7705 SAR support for VPLS service includes capabilities such as DHCP relay (on Ethernet SAPs). See [VPLS Enhancements](#).

## 5.1.1 VPLS Packet Walkthrough

This section describes an example of VPLS processing based on the network shown in [Figure 84](#).

**Figure 84 VPLS Service Architecture**

21559

### 1. PE Router A (Figure 85):

- a. Service packets arriving at PE A are associated with a VPLS service instance (VPLS service 2) based on the combination of the physical port and the IEEE 802.1Q tag (VLAN-ID) in the packet, if applicable.
- b. PE A learns the source MAC address in the packet and creates an entry in the Forwarding Database (FDB) table that associates the MAC address with the SAP on which it was received.
- c. The destination MAC address in the packet is looked up in the FDB table for the VPLS instance. There are two possibilities: either the destination MAC address has already been learned (known MAC address) or the destination MAC address is not yet learned (unknown MAC address).

**Figure 85 Access Port Ingress Packet Format and Lookup**

17230

### For a Known MAC Address (Figure 86):

- d. If the destination MAC address has already been learned by PE A, an existing entry in the FDB table identifies the far-end PE router and the service VC label (inner label) to be used before sending the packet to far-end PE C.
- e. PE A chooses a transport LSP to send the customer packets to PE C. The customer packet is sent on this LSP once the IEEE 802.1Q tag is stripped and the service VC label (inner label) and the transport label (outer label) are added to the packet.

### For an Unknown MAC Address (Figure 86):

- f. If the destination MAC address has not been learned, PE A will flood the packet to both PE B and PE C that are participating in the service by using the VC labels that each PE router previously signaled for the VPLS instance. The packet is not sent to PE D since this VPLS service does not exist on that PE router.

**Figure 86 Network Port Egress Packet Format and Flooding**

21560

## 2. Core Router Switching:

- a. All the core routers (P routers in IETF nomenclature) between PE A and routers PE B and PE C are Label Switch Routers (LSRs) that switch the packet based on the transport (outer) label of the packet until the packet arrives at the far-end PE router. All core routers are unaware of the content of the LSP payload (that is, the core routers do not know that this traffic is associated with a VPLS service).

## 3. PE Router C:

- a. PE C strips the transport label of the received packet to reveal the inner VC label. The VC label identifies the VPLS service instance to which the packet belongs.
- b. PE C learns the source MAC address in the packet and creates an entry in the FDB table that associates the MAC address to PE A and the VC label that PE A signaled for the VPLS service.

- c. The destination MAC address in the packet is looked up in the FDB table for the VPLS instance. Again, there are two possibilities: either the destination MAC address has already been learned (known MAC address) or it has not been learned on the access side of PE C (unknown MAC address).

**For a Known MAC Address (Figure 87):**

- d. If the destination MAC address has been learned by PE C, an existing entry in the FDB table identifies the local access port and the IEEE 802.1Q tag to be added before sending the packet to customer Location-C. The egress Q tag may be different from the ingress Q tag.

**For an Unknown MAC Address (Figure 87):**

- e. PE C will flood packets, as applicable.

**Figure 87 Access Port Egress Packet Format and Lookup**

21560

## 5.1.2 Bridged Mobile Backhaul

Figure 88 shows a PW-based backhaul option for mobile operators, where 7705 SAR-initiated Ethernet PWs terminate at 7750 SR nodes. In most cases, the 7705 SAR-initiated PWs terminate into a VPRN or IES service for routing purposes, or into a VPLS service for MAC forwarding purposes. PW termination into VPLS prevents unwanted exposure of IP addresses and eliminates concerns about the effect of IP addresses that change, thereby avoiding reconfiguration of the VPRN or IES access interfaces and routing entries.

**Figure 88 Typical Pseudowire-based Mobile Backhaul**

21553

In addition, capacity changes in a radio network could make mobile operators shuffle their transmission links. A simple Layer 2-based backhaul could avoid this complication because the IP addresses are not required to be configured on SAPs (that is, the interfaces facing the base stations or similar equipment), meaning that the 7705 SAR and the backhaul network would not be impacted by mobile layer IP changes. Alternatively, the 7705 SAR implements VPLS to provide any-to-any connectivity at the Layer 2 level and an IP-agnostic network build-out option.

As is the case with VPRN, VPLS also supports multiple virtual forwarding instances. For example, in Figure 89, the 7705 SAR access SAPs facing NodeB-1 and NodeB-2 are bound to VPLS-3G. Another VPLS instance can be configured on the same 7705 SAR for handling eNB 4G traffic. In such a scenario, MAC addresses learned via these two different VPLS instances are stored in separate FDBs ensuring virtualization, which is similar to multiple IP-VPN instances.

Returning to the VPLS-3G example in [Figure 89](#), upon receiving an Ethernet frame from a SAP, the 7705 SAR learns the MAC address and records it together with information from that SAP. If the destination MAC address is known, then the 7705 SAR switches the received Ethernet frame to its destination. If the destination MAC address is not known, then the 7705 SAR floods the frame to all possible destinations that are part of the same VPLS instance (that is, all the SAPs and the network site links).

On the network side, the 7705 SAR supports spoke SDPs to transport customer MAC frames. At ingress, the 7705 SAR strips off the dot1q or qinq header associated with the SAP and switches the Ethernet frame to its destination over the Ethernet PW. Loops can be avoided by using PW redundancy with standby signaling for spoke SDPs and mesh SDPs to ensure proper propagation of broadcast, multicast, and unknown (BMU) frames. Using standby signaling for spoke SDPs, the 7705 SAR ensures that only one spoke is active in the redundant PW deployment model. As a consequence, the 7705 SR disables the spoke SDP binding to VPLS for the standby PWs in order to ensure loop-free operation.

**Figure 89 Local VPLS on 7705 SAR in Mobile Backhaul**

21554

In the case where the 7705 SAR receives an Ethernet frame from a SAP bound to a VPLS and the destination MAC address is not known, it replicates the frame to all other SAPs that are part of the same VPLS and switches a copy of the frame over all the active Ethernet spoke and mesh SDPs. In [Figure 89](#), the 7705 SAR would switch the incoming frame over an Ethernet PW to 7750 SR-1 after stripping off the incoming dot1q or qinq header.

In terms of label activity, the inner label (the Ethernet PW label for VPLS) identifies the VPLS instance to which the frame belongs, and the outer label identifies the far-end LER node. Using a two-label model means that the traffic from multiple VPLS instances can be transported over a single tunnel between two LER nodes with unique PW labels on a per-VPLS-instance basis.

Upon receiving a VPLS packet, an LER uses the inner label to locate the correct FDB from which to perform MAC lookups. The associated FDB is checked against known and learned MAC addresses. If the lookup is successful, the frame is forwarded to the identified SAP with the appropriate dot1q or qinq header. If the lookup fails, the LER floods the frame to all SAPs that are members of the VPLS instance (that is, the VPLS instance designated by the inner PW label).

### 5.1.3 Multi-Tenant Unit (MTU) Termination

[Figure 89](#) can also be used to show how the 7705 SAR can serve as an MTU as described in RFC 4762, section 10.2, to help the scalability of a VPLS core mesh architecture. To function as an MTU, the 7705 SAR is spoke SDP-terminated to a VPLS node (7750 SR node in [Figure 89](#)), eliminating the necessity to have a full mesh architecture for all VPLS-enabled nodes. Thus the mesh requirement is “pushed” to the core nodes only (that is, to the 7750 SR nodes).

The 7750 SR nodes in [Figure 89](#) can be replaced by 7705 SAR nodes. [Figure 90](#) illustrates this scenario, where a 7705 SAR MTU is spoke SDP-terminated to two 7705 SAR-18 nodes (7705 SAR-18\_1 and 7705 SAR-18\_2).

Using spoke-SDP termination means that it is important that the PW-signaling master node is a 7705 SAR (in [Figure 90](#), the node that initiates the redundant PWs is the cell site 7705 SAR). Thus, only the 7705 SAR-18 that hosts the active spoke SDP will forward the Ethernet traffic to the 7705 SAR and the other 7705 SAR-18 will keep its spoke SDP in the operationally down state. If any failure of the active spoke SDP occurs (that is, if the PW activity switch takes place and the active endpoint of the PW moves from one 7705 SAR-18 to the other one), a mac-flush message is sent, which improves convergence times. In addition, the 7705 SAR-18 nodes can be configured to ignore standby signaling, which improves reconvergence times around failures for services that can tolerate dual-stream reception, such as broadcast TV.

**Figure 90 Spoke-SDP Termination to VPLS using 7705 SAR-18 Routers**

---

## 5.2 VPLS Features

Topics in this section include:

- [VPLS Enhancements](#)
- [Fabric Mode](#)
- [Subscriber VLAN](#)
- [ATM Encapsulated Residential SAP](#)
- [VPLS over MPLS](#)
- [VPLS MAC Learning and Packet Forwarding](#)
- [Pseudowire Control Word](#)
- [Agent Circuit ID Insertion](#)
- [MAC Filters](#)
- [FDB Table Management](#)
- [VPLS and Rate Limiting Via QoS Policy](#)
- [MAC Move](#)
- [Split Horizon Groups \(SAP and Spoke SDP\)](#)
- [Multicast for VPLS and Routed VPLS \(IGMP and MLD Snooping\)](#)
- [PIM Snooping for VPLS](#)
- [MPLS Entropy Label](#)
- [Ethernet OAM](#)

### 5.2.1 VPLS Enhancements

The Nokia VPLS implementation includes several enhancements to basic VPN connectivity. The following VPLS features can be configured individually for each VPLS:

- MAC and IP filter support (up to Layer 4). MAC and IP filters can be applied on a per-SAP ingress and per-SDP ingress (mesh and spoke) basis. IP filters can also be applied on a per-SAP egress basis (Ethernet SAPs only).
- FDB management features on a per-service level, including:
  - configurable FDB size limit
  - FDB size alarms
  - MAC learning disable
  - discard unknown

- separate aging timers for locally and remotely learned MAC addresses
- ingress rate limiting for broadcast, multicast, and (destination) unknown (BMU) flooding on a per-SAP basis
- implementation of STP parameters on a per-VPLS and per-SAP basis
- SHG on a per-SAP and per-spoke SDP basis
- DHCP snooping on a per-SAP basis
- IGMP and MLD snooping on a per-SAP and per-SDP basis
- optional spoke SDP redundancy to protect against node failure

Figure 91 illustrates VPLS enhancements using an example of ATM DSLAM backhaul, where the 7705 SAR might not be used solely for DSLAM backhaul purposes or not all the services might be bound to VPLS. In Figure 91, colocated IP DSLAM (ISAM) traffic can also be transported by the 7705 SAR.

**Figure 91 ATM and IP DSLAM Backhaul**

Ingress

21599

## 5.2.2 Fabric Mode

Similar to IES and VPRN services, to configure a VPLS instance, the fabric mode must be set to aggregate mode (not per-destination mode). Thus, VPLS service is only supported by aggregate-mode fabric profiles. The CLI blocks the creation of a VPLS instance when the fabric mode is set to per-destination. When a VPLS instance is configured, attempting to change the fabric mode to per-destination is blocked.

## 5.2.3 Subscriber VLAN

The subscriber VLAN feature can be enabled for ATM SAPs bound to a VPLS instance. Subscriber VLAN supports only residential ATM SAPs.

The subscriber VLAN pushes a VLAN tag onto the received bridged PDU on a per-subscriber basis, which helps to uniquely identify subscribers throughout the entire network. After ATM-layer VC termination—where each subscriber has a unique identifier (*port:vpi/vci*)—all the subscribers would be sharing the same uplink. This might present problems to CO IP nodes (such as a BRAS) that want to offer per-subscriber services and identify the subscribers based on dot1q and VLAN tags, which is compatible with the model offered in a native Ethernet model. In order to maintain the uniqueness of a subscriber, a subscriber VLAN tag can be pushed as per the configuration settings (commonly referred to as customer-tag, or c-tag).

A subscriber VLAN has the following characteristics.

- When subscriber VLAN is enabled, a VLAN tag (c-tag) is pushed at ATM ingress and removed at ATM egress. In other words, a symmetrical push/pop operation is supported and cannot be enabled/disabled on a per-direction basis. The exception to this occurs when the Ethernet frame received from the network side does not have any additional VLAN tags; in this case, the received frame is forwarded over the ATM SAP “as is”. That is, there is no pop operation or error message generated.
- The ATM port is always considered to be “NULL”, which means that when a frame is received at ATM egress from a dot1q port (Ethernet SAP to ATM SAP) or from a VLAN vc-type (network), the outer-most VLAN tag is removed (the subscriber tag, or s-tag). If subscriber VLAN is also enabled, the first two outer-most VLAN tags are removed (that is, the s-tag and the c-tag).

Since the ATM port is considered to be “NULL”, when a frame is received at ATM ingress and is going out on a dot1q Ethernet SAP (SAP-to-SAP) or VLAN vc-type (network), a new VLAN tag is pushed (s-tag). If the subscriber VLAN is also enabled, a c-tag and an s-tag are pushed. In short, Ethernet frames at ATM ingress or egress are manipulated in the same way as a null encapsulated Ethernet port.

## 5.2.4 ATM Encapsulated Residential SAP

For ATM encapsulated residential SAPs:

- the 7705 SAR always transmits the bridge PDU (BPDU) without FCS (PID = 0x00-07)
- the 7705 SAR supports reception of a BPDU both with FCS (PID = 0x00-01) and without FCS (PID = 0x00-07)

## 5.2.5 VPLS over MPLS

The VPLS architecture proposed in RFC 4664, *Framework for Layer 2 Virtual Private Networks (L2VPNs)* and RFC 4665, *Service Requirements for Layer 2 Provider-Provisioned Virtual Private Networks*, specifies the use of provider equipment (PE) that is capable of learning, bridging, and replicating on a per-VPLS basis. The PE routers that participate in the service are connected using MPLS LSP tunnels in a full mesh composed of mesh SDPs or based on an LSP hierarchy composed of mesh SDPs at the core and spoke SDPs as the access points.

Multiple VPLS instances can be offered over the same set of LSP tunnels. Signaling specified in RFC 4905, *Encapsulation Methods for Transport of Layer 2 Frames over MPLS Networks*, is used to negotiate a set of ingress and egress VC labels on a per-service basis. The VC labels are used by the PE routers for demultiplexing traffic arriving from different VPLS services over the same set of LSP tunnels.

VPLS is provided over MPLS by:

- connecting bridging-capable PE routers with a full mesh of MPLS LSP tunnels
- negotiating per-service VC labels using draft-Martini encapsulation
- replicating unknown and broadcast traffic in a service domain
- enabling MAC learning over tunnel and access ports (see [VPLS MAC Learning and Packet Forwarding](#))
- using a separate forwarding database (FDB) per VPLS service

## 5.2.6 VPLS MAC Learning and Packet Forwarding

The 7705 SAR edge devices perform the packet replication required for broadcast and multicast traffic across the bridged domain. MAC address learning is performed by the 7705 SAR to reduce the amount of unknown destination MAC address flooding.

7705 SAR routers learn the source MAC addresses of the traffic arriving on their access and network ports. Each 7705 SAR maintains an FDB for each VPLS service instance, and learned MAC addresses are populated in the FDB table of the service. All traffic is switched based on MAC addresses and forwarded between all participating 7705 SAR routers using the LSP tunnels. Unknown destination packets (for example, the destination MAC address has not been learned) are forwarded on all LSPs to the participating 7705 SAR routers for that service until the target station responds and the MAC address is learned by the 7705 SAR associated with that service.

## 5.2.7 Pseudowire Control Word

The **control-word** command enables the use of the control word individually on each mesh SDP or spoke SDP. The control word is optional and is disabled by default. When the control word is enabled, all VPLS packets are encapsulated along with the control word. The T-LDP control word signaling behavior is the same as that for the control word for VLL services. The configuration at the two endpoints of the VPLS service must match.

## 5.2.8 Agent Circuit ID Insertion

One of the main applications for VPLS is ATM DSLAM backhaul. DSL operators typically make use of PPPoE over ATM DSL lines for subscriber authentication, authorization, and accounting. When an ATM DSLAM is connected to VPLS service on a 7705 SAR such that the 7705 SAR offers an interworking function for ATM traffic to Ethernet traffic, the 7705 SAR can append the agent-circuit ID to the PPPoE frames received from the ATM DSLAM.

In accordance with RFC 4679, section 3.3.1: Agent-Circuit-ID, agent-circuit ID information can be appended to PPPoE Active Discovery Initiation (PADI) and PPPoE Active Discovery Request (PADR) frames on bridged llc-snap encapsulated SAPs bound to an ATM VPLS instance. [Figure 92](#) illustrates the signaling.

**Figure 92 PPPoE Initialization and Agent-Id Push Function**

21598

**Figure 93** illustrates the agent circuit ID information, where the following definitions apply:

- vendor-type—is always the value 1
- vendor-length—is less than or equal to 65 bits
- string—is the access-node identifier (**atm card/slot/port:vpi.vci**), which is automatically assigned by the 7705 SAR to be the system-name (hostname)

**Figure 93 Agent Circuit ID Information**

21381

Appending the agent circuit ID to a PADI or PADR frame is enabled and disabled via the **pppoe-circuit-id** command, which can be issued at the VPLS service and VPLS residential SAP levels. At the service level, the command sets the default value for all SAPs in the VPLS instance. At the SAP level, the command overrides the service level default. If there is a mix of enabled and disabled **pppoe-circuit-id** settings, reissuing the command at the service level will reset all SAPs to the new service level value.

---

As per the DSL Forum TR-101 April'06 specification, section 3.9.3, any PPPoE vendor-specific tag that may already be present in the received frame is replaced by the 7705 SAR client-id tag.

## 5.2.9 MAC Filters

MAC filters offer the ability to transport Ethernet frames that match certain criteria over the service to which the frames are bound. The 7705 SAR supports MAC filters at a VPLS ingress SAP and ingress SDP (spoke and mesh). MAC filters can be set to accept or reject the transport of filtered Ethernet frames over the VPLS. Via MAC filters, it is possible to filter traffic received from a defined source or destined for a certain host. MAC filters are the equivalent of IP ACLs, but apply to the Layer 2 MAC layer.

MAC filters support the following fields:

- source MAC address
- destination MAC address
- Ethertype

Any single item or combination of items can be used to define a MAC filter entry. For information on configuring MAC filters, see the “Filter Policies” chapter in the 7705 SAR Router Configuration Guide.

## 5.2.10 FDB Table Management

The following sections describe VPLS features related to management of the FDB, including:

- FDB size
- FDB size alarms
- local and remote aging timers
- Unknown MAC discard

---

### 5.2.10.1 FDB Size

The following MAC table management features are required for each instance of a SAP or spoke SDP within a particular VPLS instance:

- **MAC FDB size limits**—allows users to specify the maximum number of MAC FDB entries that are learned locally for a SAP or a spoke SDP. If the configured limit is reached, then no new addresses will be learned from the SAP until at least one FDB entry is aged out or cleared.
  - When the limit is reached on a SAP, packets with unknown source MAC addresses are still forwarded (this default behavior can be changed via configuration). By default, if the destination MAC address is known, it is forwarded based on the FDB, and if the destination MAC address is unknown, it is flooded. Alternatively, if discard unknown is enabled at the VPLS service level, any packets from unknown source MAC addresses are discarded at the SAP.
  - The log event “SAP MAC limit reached” is generated when the limit is reached. When the condition is cleared, the log event “SAP MAC Limit Reached Condition Cleared” is generated.
  - **disable-learning** allows users to disable the dynamic learning function on a SAP or a spoke SDP of a VPLS instance
  - **disable-aging** allows users to turn off aging for learned MAC addresses on a SAP or a spoke SDP of a VPLS instance

### 5.2.10.2 FDB Size Alarms

The size of the VPLS FDB can be configured with a low-water mark and a high-water mark, expressed as a percentage of the total FDB size limit. If the actual FDB size grows above the configured high-water mark percentage, an alarm is generated. If the FDB size falls below the configured low-water mark percentage, the alarm is cleared by the system.

### 5.2.10.3 Local and Remote Aging Timers

Similar to a Layer 2 switch, learned MACs within a VPLS instance can be aged out if no packets are sourced from the MAC address for a specified period of time (the aging time). In each VPLS instance, there are independent aging timers for locally learned MAC and remotely learned MAC entries in the FDB.

A local MAC address is a MAC address associated with a SAP because it ingressed on a SAP. A remote MAC address is a MAC address received via an SDP from another 7705 SAR router for the VPLS instance. The local-age timer for the VPLS instance specifies the aging time for locally learned MAC addresses, and the remote-age timer specifies the aging time for remotely learned MAC addresses.

In general, the remote-age timer is set to a longer period than the local-age timer to reduce the amount of flooding required for destination unknown MAC addresses. The aging mechanism is considered a low-priority process. In most situations, the aging out of MAC addresses can happen in within tens of seconds beyond the age time. To minimize overhead, local MAC addresses and remote MAC addresses, in some circumstances, can take about two times their respective age timers to be aged out.

#### **5.2.10.3.1 Disable MAC Aging**

The MAC aging timers can be disabled, which will prevent any learned MAC entries from being aged out of the FDB. When aging is disabled, it is still possible to manually delete or flush learned MAC entries. Aging can be disabled for learned MAC addresses on a SAP or a spoke SDP of a VPLS instance.

#### **5.2.10.3.2 Disable MAC Learning**

When MAC learning is disabled for a service, new source MAC addresses are not entered in the VPLS FDB, whether the MAC address is local or remote. MAC learning can be disabled for individual SAPs or spoke SDPs.

#### **5.2.10.4 Unknown MAC Discard**

Unknown MAC discard is a feature that discards all packets that ingress the service whose destination MAC address is not in the FDB. The normal behavior is to flood these packets to all endpoints in the service.

Unknown MAC discard can be used with the disable MAC learning and disable MAC aging options to create a fixed set of MAC addresses allowed to ingress and traverse the service.

---

## 5.2.11 VPLS and Rate Limiting Via QoS Policy

Traffic that is normally flooded throughout the VPLS can be rate-limited on SAP ingress through the use of service ingress QoS policies. In a service ingress QoS policy, individual queues can be defined per forwarding class to provide shaping of broadcast traffic, MAC multicast traffic and unknown destination MAC traffic.

For more information on QoS policies for broadcast, multicast, and unknown (BMU) traffic, see the “Filter Policies” chapter in the 7705 SAR Quality of Service Guide.

## 5.2.12 MAC Move

The MAC move feature is useful to protect against undetected loops in a VPLS topology when STP is not used. It also protects against the presence of duplicate MACs in a VPLS service.

A sustained high relearn rate can be a sign of a loop somewhere in the VPLS topology. Typically, STP detects loops in the topology, but for those networks that do not run STP, the MAC move feature is an alternative way to protect your network against loops.

When enabled in a VPLS, MAC-move monitors the relearn rate of each MAC address. If the rate exceeds the configured maximum allowed limit, MAC move disables the SAP where the source MAC address was last seen. The SAP can be disabled permanently (until a **shutdown/no shutdown** command is executed) or for a length of time that grows linearly with the number of times the given SAP was disabled. A SAP can be optionally configured as non-blockable, meaning that when the relearn rate has exceeded the limit, another (blockable) SAP will be disabled instead. By default, all SAPs and spoke SDPs are configured as blockable when MAC-move is enabled.

When MAC-move is enabled and the relearn rate exceeds the maximum limit, the 7705 SAR sends a “Mac move rate for MAC ... exceeded” alarm. This alarm is raised for both blockable and non-blockable SAPs and spoke SDPs. The alarm frequency for non-blockable SAPs and spoke SDPs decreases if the MAC-move condition persists.

The **mac-move** command enables the feature at the service level for SAPs and spoke SDPs. The operation of this feature is the same on the SAP and spoke SDP. For example, if a MAC address moves from SAP to SAP, SAP to spoke SDP, or between spoke SDPs, it will block one of them to prevent thrashing. The relearn rate is computed as the number of times a MAC address moves in a 5 s interval. Therefore, the fastest a loop can be detected and broken is 5 s.

MAC move allows sequential order port blocking. By configuration, some VPLS ports can be configured as “non-blockable”, which allows a simple level of control over which ports are being blocked during loop occurrence.

There are two control mechanisms that allow blocking of ports in a sequential order:

- configuration capabilities to group VPLS ports and to define the order in which they should be blocked
- criteria defining when individual groups should be blocked

For the first mechanism, the configuration CLI is extended by definition of “primary” and “secondary” ports. As the default, all VPLS ports are considered “tertiary” ports unless they are explicitly declared primary or secondary. The order of blocking will always follow a strict order, starting from tertiary, to secondary and then to primary.

The criterion for the second control mechanism is the number of periods during which the given relearn rate has been exceeded. The mechanism is based on the “cumulative” factor for every group of ports. Tertiary VPLS ports are blocked if the relearn rate exceeds the configured threshold during one period, while secondary ports are blocked only when relearn rates are exceeded during two consecutive periods, and so forth. The retry timeout period must be larger than the period before blocking the highest-priority port so it sufficiently spans across the period required to block all ports in sequence. The period before blocking the highest-priority port is the cumulative factor of the highest configured port multiplied by 5 s (the retry timeout can be configured through the CLI).

## 5.2.13 Split Horizon Groups (SAP and Spoke SDP)

Within the context of VPLS services, a loop-free topology within a fully meshed VPLS core is achieved by applying a split horizon forwarding concept whereby packets received from a mesh SDP are never forwarded to other mesh SDPs within the same service. The advantage of this approach is that no protocol is required to detect loops within the VPLS core network.

In applications such as DSL aggregation, it is useful to extend the split horizon concept to groups of SAPs and/or spoke SDPs. This extension is referred to as a split horizon SAP group or residential bridging.

Traffic arriving on a SAP or a spoke SDP within a split horizon group will not be copied to other SAPs and spoke SDPs in the same split horizon group (but will be copied to SAPs or spoke SDPs in other split horizon groups if these exist within the same VPLS).

A split horizon group must be created before SAPs and spoke SDPs can be assigned to the group.

The split horizon group is defined within the context of a single VPLS. The same group name can be reused in different VPLS instances. Up to 30 split horizon groups can be defined per VPLS instance. A split horizon group can contain a combination of spoke SDPs and SAPs.

A SAP or spoke SDP can only be added to a split horizon group during its creation. Similarly, a SAP or spoke SDP can be removed from a split horizon group only by its deletion. A split horizon group can be deleted only after all its members have been deleted.

### 5.2.13.1 Residential Split Horizon Groups

Residential split horizon groups are supported on ATM SAPs connected to VPLS on 4-port OC3/STM1 Clear Channel Adapter cards. While split horizon groups prevent multicast traffic from flowing within the same group, residential ATM SAPs do not forward broadcast or unknown traffic; they only process known unicast traffic.

Residential split horizon groups allow one queue per direction (ingress and egress) for all traffic types (unicast and BMU). OAM processing is also allowed on residential ATM SAPs.

## 5.2.14 Multicast for VPLS and Routed VPLS (IGMP and MLD Snooping)

IGMP and MLD snooping allows a 7705 SAR to listen to the IGMP traffic between hosts and routers. The 7705 SAR extracts information from the traffic to create and maintain a multicast forwarding information base (MFIB) to track which hosts want which IP multicast streams. Multicasts may be filtered to control which ports receive specific multicast traffic.

For example, service providers that use a flat IP network to deliver video over a mobile backhaul network can take advantage of Layer 2 services (VPLS) to save IPv4 addresses. A Layer 2 domain with  $n$  nodes needs  $n$  IP addresses, whereas a point-to-point connections requires  $2 \times n$  addresses. Service providers using VPLS and IGMP or MLD snooping to relay IGMP or MLD requests to uplink (network) PIM interfaces will save addresses.

This section contains information on the following topics:

- [Application Examples](#)
- [Group and Addressing Support](#)
- [IP Multicast in r-VPLS](#)
- [Multicast Router Ports](#)
- [Tagged Access Traffic](#)
- [Hardware Support](#)

For more information on multicast, refer to the “IP Multicast” section in the 7705 SAR Routing Protocols Guide.

### 5.2.14.1 Application Examples

[Figure 94](#) shows a typical deployment. Host traffic arrives at the routed VPLS (r-VPLS), where IGMP or MLD snooping extracts all IGMP or MLD packets and sends them to the CSM, and from the CSM the packets are forwarded via PIM to the head-end 7750 SR nodes. The VPLS multicast FIB (MFIB) tracks all the IGMP or MLD join requests in an internal 7705 SAR forwarding table. On the upstream nodes, PIM builds the multicast tree from the 7705 SAR to the 7750 SR. In the reverse direction, the video source sends multicast traffic, which is forwarded by the PIM nodes to the addresses in the previously built multicast tree. As traffic from various sources arrives at the 7705 SAR, the r-VPLS MFIB directs each multicast stream to the correct eNodeB.

**Figure 94 Video over Mobile Backhaul**

[Figure 95](#) shows another example of IGMP and MLD snooping, where service providers can offer evolved multimedia broadcast multicast services (eMBMS) on their metro cell network (data services).

In [Figure 95](#), the data VPLS performs IGMP or MLD snooping to build the MFIB. The extracted IGMP and MLD requests are forwarded via PIM over an Epipe or, preferably, via PIM over a Layer 3 spoke SDP to remove the external physical connection between two ports from the 7705 SAR. The traffic between IES access and NAT is unicast traffic. The Layer 3 spoke-SDP traffic is transported over a GRE tunnel via the Internet to the evolved packet core (EPC), where a secure gateway forwards the PIM join message to the multicast source servers. The GRE logical Layer 3 spoke SDP does not need to be part of the NAT function; if it is not, this logical interface must obtain its own public interface IP address.

[Figure 95](#) also shows the typical metro cell deployment, where IGMP snooping is done on the r-VPLS of the data IES service. The IGMP join messages translate to PIM SSM via the uplink network interface, as described at the beginning of this section.

MLD snooping allows support for IPv6 addresses through the use of r-VPLS for IPv6, allowing the network design for IPv4 and IPv6 domains to be the same.

**Figure 95 Metro Cell Multicast**

25375

## 5.2.14.2 Group and Addressing Support

This section contains information on the following topics:

- [IPv4 Multicast Support](#)
- [IPv6 Layer 2 Multicast Support and Group Address](#)

### 5.2.14.2.1 IPv4 Multicast Support

The 7705 SAR supports (S,G) and (\*,G) for IPv4 multicast in Layer 2 services only, including Layer 2 services within the context of VPLS and r-VPLS.

7705 SAR supports PIM-SSM only. For IPv4 multicast services, PIM SSM requires SSM translation in the r-VPLS interface context for (\*,G) joins.

### 5.2.14.2.2 IPv6 Layer 2 Multicast Support and Group Address

The 7705 SAR supports (S,G) and (\*,G) for IPv6 multicast in Layer 2 services only, including Layer 2 services within the context of VPLS and r-VPLS, and uses the MAC-format group-addressing scheme to minimize the size of the MFIB.

The multicast MAC-format group address consists of the IPv6 multicast prefix (33:33) and the four least significant bytes of the IPv6 address. In the CLI display below, for the IPv6 address FF04::1:FFFF:0011, the representation of the group address is 33:33:FF:FF:00:11.

```
Multicast FIB, Service 50
=====
Source Address Group Address Sap/Sdp Id Svc Id Fwd/Blk

* 33:33:FF:FF:00:11 sap:1/1/1:50 Local Fwd
=====
```

7705 SAR supports PIM-SSM only. For IPv6 multicast services, PIM SSM requires SSM translation in the r-VPLS interface context for (\*,G) joins.

### 5.2.14.3 IP Multicast in r-VPLS

When creating a Layer 2 multicast service in the context of an r-VPLS with PIM configuration on the r-VPLS Layer 3 interface, the 7705 SAR creates two multicast groups: one Layer 2 multicast group and one Layer 3 multicast group. Once the Layer 2 group is created, the Layer 3 group is created automatically. The 7705 SAR uses one Layer 3 multicast group per source, and one Layer 2 multicast group per source per VPLS.

**Note:** IP multicast on r-VPLS is supported only if IGMP or MLD snooping is enabled on the VPLS associated with the IES. That is, configuring IGMP or MLD on the IES that is associated with the VPLS without configuring snooping on the VPLS will not flood multicast traffic out the VPLS.

Figure 96 and Figure 97 illustrate how Layer 2 multicast interacts with Layer 3 multicast.

In Figure 96, there are three hosts and one channel. The Layer 3 multicast group forwards source traffic to each port for which there is a corresponding Layer 2 multicast instance of a Layer 2 FIB entry. All three Layer 2 FIB entries are within the same r-VPLS. To configure this scenario, create three Layer 2 FIB entries on the 7705 SAR (one for each host), and one Layer 3 group for the source. The single Layer 3 multicast group streams the multicast traffic to all three hosts.

**Figure 96 Multiple Hosts in an r-VPLS Receiving the Same Channel**

25376

In [Figure 97](#), there are three hosts and three channels. Each host connects to a different port and wants to receive a different (S,G) group (that is, a different channel). Thus, three layer 3 (S,G) groups are needed. To achieve this scenario, create three Layer 2 multicast groups (one for each host) and three Layer 3 multicast groups (one for each channel).

**Note:** For r-VPLS, the 7705 SAR supports multicast data flows only from a Layer 3 to a Layer 2 domain. For example, in [Figure 97](#), multicast data can only flow from the server source in the Layer 3 domain to the hosts in the Layer 2 domain. Currently, the 7705 SAR does not support multicast data flow from a Layer 2 to a Layer 3 domain.

**Figure 97 Multiple Hosts in an r-VPLS Receiving Different Channels**

25377

### 5.2.14.3.1 IPv6 Multicast Forwarding Behavior in r-VPLS

In general, the behavior of IPv6 multicast in r-VPLS is as follows.

- Multicast in Layer 2 is only supported by (\*,G). That is, (S,G) in Layer 3 gets translated to (\*,G) in Layer 2.
- Multicast in Layer 3 is only supported by (S,G).

The IPv6 multicast control plane behavior is as follows.

- (S,G) is forwarded from the Layer 2 snooping interface to PIM without translation to (\*,G).

- The Layer 2 multicast forwarding table is built based on (\*,G) and the MAC-format multicast-group address scheme, using the four least significant bytes of the IPv6 address (see [IPv6 Layer 2 Multicast Support and Group Address](#))
- The Layer 3 multicast forwarding table is built based on (S,G) and the full IPv6 multicast group address.

The IPv6 multicast data plane behavior is as follows.

- The Layer 2 forwarding table (see bullet 2 above) is downloaded to the data plane.
- The Layer 3 forwarding table (see bullet 3 above) is downloaded to the data plane.
- Layer 3 multicast for IPv6 supports the entire range of multicast addresses.
- The Layer 2 multicast address is limited and unique to prefix /96. That is, only the four least significant bytes of the IPv6 multicast address are used. Note the following items.
  - It is useful to keep the multicast table small at the network edge, where multicast groups can be effectively managed via 32-bit (4-byte) addressing.
  - A 32-bit multicast address can provide 4 bytes of multicast group addressing.
  - Optionally, multicast zones can be created on the access side with overlapping 32-bit addresses, but in the core—where the entire IPv6 multicast group is available—multicast zones can guide traffic correctly to the corresponding access group.

#### 5.2.14.4 Multicast Router Ports

Membership reports are only sent to multicast router (mrouter) ports. An mrouter port is a port through which membership queries are received. An mrouter port can be configured manually on a VPLS SAP or SDP using the **mrouter-port** command under **igmp-snooping** or **mld-snooping**.

#### 5.2.14.5 Tagged Access Traffic

The 7705 SAR processes tagged querier requests arriving on a null-encapsulated port and installs the querier message. This means that an IGMP or MLD router is recognized to exist on that port and reports (joins and leaves) will be forwarded out that port.

---

Similarly, for multicast data, the 7705 SAR processes tagged multicast traffic arriving on a null-encapsulated port according to the MFIB.

### 5.2.14.6 Hardware Support

Multicast VPLS and r-VPLS are supported on the following 7705 SAR hardware:

- 8-port Ethernet Adapter card, version 2
- 8-port Gigabit Ethernet Adapter card
- 10-port 1GigE/1-port 10GigE X-Adapter card
- 6-port Ethernet 10Gbps Adapter card
- Packet Microwave Adapter card
- standalone platforms, including the 7705 SAR-M, 7705 SAR-A, 7705 SAR-Ax, 7705 SAR-H, 7705 SAR-Hc, 7705 SAR-W, 7705 SAR-Wx, and 7705 SAR-X
- 7705 SAR-M modules, including the GPON module, 8-port xDSL module, and 6-port DSL Combination module
- 4-port SAR-H Fast Ethernet module
- hardware that supports PPP/MLPPP for uplink spoke SDPs

## 5.2.15 PIM Snooping for VPLS

PIM snooping is used in Layer 2 networks to stitch together the PIM session of two disjointed Layer 3 networks. In most provider networks, strategic industry (SI) applications, or mobile backhaul applications, the access routers are connected to the core Layer 3 network via a Layer 2 network. For multicast scenarios, PIM can be used to build the multicast data trees (MDTs) on the Layer 3 routers. However, PIM is a Layer 3 protocol and Layer 2 networks do not understand PIM messages. This creates an inefficient multicast domain in the Layer 2 network, as all packets will be broadcast. PIM snooping in a Layer 2 network can be used to stitch the PIM session from the access routers to the core Layer 3 network. [Figure 98](#) illustrates this scenario.

Because PIM snooping stitches the PIM session between two routers, it might be desirable to start the PIM session from the same router (a 7705 SAR) that initiates the VPLS PIM snooping service. In this case, an external loop cable can be used to connect the network Layer 3 interface, which has PIM configured, to the SAP of the VPLS that is performing the PIM snooping, as shown in [Figure 99](#), thereby simulating routed VPLS.

PIM snooping supports both (\*,G) as well as (S,G) to address scenarios where the sources only support PIM ASM.

The 7705 SAR supports PIM snooping for IPv4 and IPv6.

**Figure 98 PIM Snooping Example**

25920

**Figure 99 Simulating r-VPLS**

25921

### 5.2.15.1 Snooping versus Proxy Mode

Snooping mode does not stop or intercept a PIM message. Snooping listens to network traffic between hosts and routers, and maintains a table that maps multicast streams between sources and hosts.

Proxy mode intercepts PIM messages and generates a single message when necessary. Proxy allows a switch to send PIM messages on behalf of routers. For example, when multiple routers are connected to the same PIM-enabled switch and all the routers want to join to the same source, the proxy can intercept the messages and generate a single message in order to minimize the flood of PIM messages in the Layer 2 domain.

Configure snooping or proxy mode by using the **config>service>vpls>pim-snooping>mode** command. By default, proxy mode is enabled in VPLS.

### 5.2.16 MPLS Entropy Label

The router supports the MPLS entropy label as per RFC 6790. The entropy label provides greater granularity for load balancing on an LSR where load balancing is typically based on the MPLS label stack.

For more information, refer to the “MPLS Entropy Labels” section in the 7705 SAR MPLS Guide and to the “LAG and ECMP Hashing” section in the 7705 SAR Interface Configuration Guide.

### 5.2.17 Ethernet OAM

The 7705 SAR supports Ethernet OAM functions for ETH-CFM (according to the 802.1ag and Y.1731 standards) and for Y.1731 Performance Monitoring on VPLS Ethernet SAPs and SDPs. VPLS OAM MAC diagnostics are also supported.

For information on Ethernet OAM, see [ETH-CFM \(802.1ag and Y.1731\)](#) and refer to the “Ethernet OAM Capabilities” and “VPLS MAC Diagnostics” sections in the 7705 SAR OAM and Diagnostics Guide.

---

## 5.3 Routed VPLS

Topics in this section include:

- [IES or VPRN IP Interface Binding](#)
- [IP Interface MTU and Fragmentation](#)
- [ARP/ND and VPLS FIB Interactions](#)
- [The allow-ip-int-binding VPLS Flag](#)
- [DSCP Marking](#)
- [VPLS Ingress IP Filter Override](#)
- [Routed VPLS Supported Routing-Related Protocols](#)

Hosts within the same subnet communicate directly with each other without the need for a router, but any communication with a host that is external to the subnet requires routing. With routed VPLS, you can use bridging for local destinations when possible and routing for non-local destinations that cannot be reached directly.

Routed VPLS appears similar to a LAN Ethernet switch and a router. The VPLS instance on the 7705 SAR node grants Ethernet switch functionality among connected nodes. When the destination IP is not local, the 7705 SAR routes the traffic by means of the VPRN or the IES instance.

Routed VPLS is enabled for IPv4 and IPv6 forwarding.

### 5.3.1 IES or VPRN IP Interface Binding

A standard IP interface within an existing IES or VPRN service context can be bound to a VPLS service. A VPLS service only supports binding for a single IP interface.

Although an IP interface can only be bound to a single VPLS service, the routing context containing the IP interface (IES or VPRN) can have other IP interfaces bound to other VPLS service contexts.

Topics in this section include:

- [Assigning a Service Name to a VPLS Service](#)
- [Binding a Service Name to an IP Interface](#)
- [Removing a Bound VPLS Service or Service Name](#)
- [IP Interface and VPLS Operational State Coordination](#)

### 5.3.1.1 Assigning a Service Name to a VPLS Service

If a service name is applied to a VPLS service context, the name and service ID association is registered with the system. A service name cannot be assigned to more than one service ID.

If the **config>service>vpls>allow-ip-int-binding** command is enabled on the VPLS service, when the service name is applied to the VPLS service, the system will scan the existing IES and VPRN services for an IP interface that is bound to the specified service name. If found, the IP interface will be attached to the VPLS service associated with the service name. Only one interface can be bound to the specified service name.

If the **allow-ip-int-binding** command is not enabled on the VPLS service, the system will not attempt to resolve the VPLS service name to an IP interface. As soon as the **allow-ip-int-binding** flag is enabled on the VPLS, the corresponding IP interface will be attached and become operationally up. There is no need to toggle the **shutdown/no shutdown** command.

### 5.3.1.2 Binding a Service Name to an IP Interface

An IP interface within an IES or VPRN service context can be bound to a service name at any time. Only one interface can be bound to a service name.

If an IP interface is bound to a service name and the IP interface is administratively up, the system will scan for a VPLS service context using the service name and take the following actions:

- if the service name is not currently in use by a service, the IP interface will be placed in an operationally down: Non-existent service name or inappropriate service type state
- if the service name is currently in use by a VPLS service without the **allow-ip-int-binding** flag set, the IP interface will be placed in the operationally down: VPLS service allow-ip-int-binding flag not set state
- if the service name is currently in use by a valid VPLS service and the **allow-ip-int-binding** flag is set, the IP interface will be attached to the VPLS service

---

### 5.3.1.3 Removing a Bound VPLS Service or Service Name

A VPLS service that is currently attached to an IP interface cannot be deleted from the system unless the IP interface is unbound from the VPLS service name.

If an IP interface has been bound to a VPLS service by the VPLS service name, the VPLS service name cannot be removed or changed unless the IP interface is first unbound from the VPLS service name.

If an IP interface is attached to a VPLS service, the allow-ip-int-binding flag cannot be reset. The IP interface must first be unbound from the VPLS service name to reset the flag.

### 5.3.1.4 IP Interface and VPLS Operational State Coordination

If the IP interface is successfully attached to a VPLS service, the operational state of the IP interface is dependent upon the operational state of the VPLS service.

The VPLS service remains down until at least one virtual port (SAP, spoke SDP or mesh SDP) is operational.

## 5.3.2 IP Interface MTU and Fragmentation

The VPLS service is affected by two MTU values: port MTUs and the VPLS service MTU. The MTU on each physical port defines the largest Layer 2 packet (including all DLC headers) that may be transmitted out of a port. The VPLS itself has a service-level MTU that defines the largest packet supported by the service. This MTU does not include the local encapsulation overhead for each port (dot1q, qinq, or SDP service delineation fields and headers) but does include the remainder of the packet. As virtual ports are created in the system, any given virtual port cannot become operational unless the configured port MTU minus the virtual port service delineation overhead is greater than or equal to the configured VPLS service MTU. This ensures that an operational virtual port can support the largest packet traversing the VPLS service. The service delineation overhead on each Layer 2 packet is removed before forwarding into a VPLS service. VPLS services do not support fragmentation and must discard any Layer 2 packet larger than the service MTU after the service delineation overhead is removed.

If an IP interface is associated with a VPLS service, the IP MTU is based on either the administrative value configured for the IP interface or an operational value derived from the VPLS service MTU. The operational IP MTU cannot be greater than the VPLS service MTU minus 14, 18, or 22 bytes (for null, dotq1, or qinq port encapsulations, respectively) to account for the Layer 2 headers and tags.

If the configured (administrative) IP MTU is configured for a value greater than the normalized IP MTU, based on the VPLS service MTU, then the operational IP MTU is reset to equal the normalized IP MTU value (VPLS service MTU – 14 bytes).

If the configured (administrative) IP MTU is configured for a value less than or equal to the normalized IP MTU, based on the VPLS service-MTU, then the operational IP MTU is set to equal the configured (administrative) IP MTU value.

The VPLS service MTU and the IP interface MTU parameters can be changed at any time.

### 5.3.3 ARP/ND and VPLS FIB Interactions

**Note:** References to ARP in this section also apply to Neighbor Discovery (ND) protocol. ARP applies to IPv4. ND protocol applies to IPv6.

Two address-oriented table entries are used when routing into a VPLS service. On the routing side, an ARP entry is used to determine the destination MAC address used by an IP next hop. If the destination IP address in the routed packet is a host on the local subnet represented by the VPLS instance, the destination IP address is used as the next-hop IP address in the ARP cache lookup. If the destination IP address is in a remote subnet that is reached by another router attached to the VPLS service, the routing lookup returns the local IP address on the VPLS service of the remote router. If the next hop is not currently in the ARP cache, the system generates an ARP request to determine the destination MAC address associated with the next-hop IP address. IP routing to all destination hosts associated with the next-hop IP address stops until the ARP cache is populated with an entry for the next hop. The ARP cache can be populated with a static ARP entry for the next-hop IP address. Dynamically populated ARP entries will age out according to the ARP aging timer; static ARP entries never age out.

The second address table entry that affects VPLS routed packets is the MAC destination lookup in the VPLS service context. The MAC address associated with the ARP table entry for the IP next hop may or may not currently be populated in the VPLS Layer 2 FIB table. If the destination MAC address is unknown (not populated in the VPLS FIB), the system floods all packets destined for that MAC address (routed or bridged) to all virtual ports within the VPLS service context. Once the MAC address is known (populated in the VPLS FIB), all packets destined for the MAC address (routed or bridged) are targeted to the specific virtual port where the MAC address has been learned. As with ARP entries, static MAC address entries can be created in the VPLS FIB. Dynamically learned MAC addresses are allowed to age out or be flushed from the VPLS FIB while static MAC address entries always remain associated with a specific virtual port. Dynamic MAC addresses can also be relearned on another VPLS virtual port other than the current virtual port in the FIB. In this case, the system automatically moves the MAC FIB entry to the new VPLS virtual port.

5.3.3.1 Routed VPLS Specific ARP/ND Cache Behavior

**Note:** References to ARP in this section also apply to Neighbor Discovery (ND) protocol. ARP applies to IPv4. ND protocol applies to IPv6.

In typical routing behavior, the system uses the IP routing table to select the egress interface, and at the egress forwarding engine, an ARP entry is used to forward the packet to the appropriate Ethernet MAC address. With routed VPLS, the egress IP interface can be represented by multiple egress forwarding engines (wherever the VPLS service virtual ports exist). To optimize routing performance, the ingress forwarding engine performs an ingress ARP lookup in order to resolve which VPLS MAC address the IP frame must be routed towards. [Table 59](#) describes how the ARP cache and MAC FIB entry states interact at ingress and [Table 60](#) describes the corresponding egress behavior.

Table 59 Ingress Behavior for VPLS Next-Hop Routing

| Layer 3 Next-Hop ARP Cache Entry | Next-Hop MAC FIB Entry | Ingress Behavior                                                        |
|----------------------------------|------------------------|-------------------------------------------------------------------------|
| ARP Cache Miss (No Entry)        | Known or Unknown       | Flood to all egress forwarding engines associated with the VPLS context |

**Table 59 Ingress Behavior for VPLS Next-Hop Routing (Continued)**

| Layer 3 Next-Hop ARP Cache Entry | Next-Hop MAC FIB Entry | Ingress Behavior                                                                                             |
|----------------------------------|------------------------|--------------------------------------------------------------------------------------------------------------|
| ARP Cache Hit                    | Known                  | Forward to specific egress forwarding engine associated with VPLS virtual port                               |
|                                  | Unknown                | Flood to all egress forwarding engines associated with the VPLS for forwarding out to all VPLS virtual ports |

**Table 60 Egress Behavior for VPLS Next-Hop Routing**

| Layer 3 Next-Hop ARP Cache Entry | Next-Hop MAC FIB Entry | Egress Behavior                                                                                                                                                                               |
|----------------------------------|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ARP Cache Miss (No Entry)        | Known                  | No ARP entry. The MAC address is unknown and the ARP request is flooded out to all virtual ports of the VPLS instance.                                                                        |
|                                  | Unknown                | ARP processing request transmitted out to all virtual ports associated with the VPLS service. Only the first egress forwarding engine ARP processing request triggers the egress ARP request. |
| ARP Cache Hit                    | Known                  | Forward out to specific egress VPLS virtual port where MAC address has been learned                                                                                                           |
|                                  | Unknown                | Flood to all egress VPLS virtual ports on forwarding engine                                                                                                                                   |

### 5.3.4 The allow-ip-int-binding VPLS Flag

The allow-ip-int-binding flag on a VPLS service context informs the system that the VPLS service is enabled for routing support. The system uses the setting of the flag as a key to determine what type of ports and forwarding planes the VPLS service can span.

The system also uses the flag state to define which VPLS features are configurable on the VPLS service to prevent enabling a feature that is not supported if routing support is enabled.

Once the allow-ip-int-binding flag is set (routing support enabled) on a VPLS service, SAPs within the service can be created on standard Ethernet ports. ATM SAPs are not supported.

### 5.3.4.1 VPLS Feature Restrictions (due to allow-ip-int-binding)

If the allow-ip-int-binding flag is set on a VPLS service, the following features are disabled:

- residential SHG
- DHCP
- mVPLS
- mac-subnet-length
- GRE SDP (cannot be bound to the VPLS)

**Note:** The DHCP relay functionality under **config>service>ies>if>dhcp** or **config>service>ies>if>ipv6>dhcp6-relay** can be used to dynamically assign IP addresses to the clients connected to routed VPLS SAPs.

### 5.3.5 DSCP Marking

**Note:** The 7705 SAR does not support ingress DSCP marking.

Egress DSCP re-marking is supported on routed VPLS service for bridged packets only. It is not supported for packets routed out from a VPLS SAP.

The egress re-marking defined in the SAP egress QoS policy is not performed for packets that are routed out an egress VPLS SAP.

### 5.3.6 VPLS Ingress IP Filter Override

If an IP interface is attached to a VPLS service context, the VPLS SAP or SDP configured IP or MAC filter for ingress routed packets can be optionally overridden in order to provide special ingress filtering for routed packets. This allows different filtering for routed packets and non-routed packets. The filter override is defined on the IP interface bound to the VPLS service name. A separate override filter can be specified for IPv4 and IPv6 packet types.

---

If filter override is configured, the IP or MAC filter configured on the SAP or SDP applies to non-routed packets. If filter override is not configured, the IP or MAC filter configured on the SAP or SDP applies to both routed and non-routed packets.

### 5.3.7 Routed VPLS Supported Routing-Related Protocols

The following protocols are supported on IP interfaces bound to a VPLS service:

- BGP (IPv4 and IPv6)
- OSPF (IPv4 only)
- static routing (IPv4 and IPv6)
- BFD (IPv4 and IPv6)
- VRRP (IPv4 and IPv6)
- ARP
- ND protocol
- DHCP (IPv4 and IPv6)

---

## 5.4 VPLS and Spanning Tree Protocol

Topics in this section include:

- [VPLS Redundancy](#)
- [VPLS Access Redundancy](#)
- [MAC Flush Message Processing](#)

The Nokia VPLS service provides a bridged or switched Ethernet Layer 2 network. Equipment connected to SAPs or spoke SDPs forward Ethernet packets into the VPLS service. The 7705 SAR participating in the service learns where the customer MAC addresses reside on ingress SAPs or ingress SDPs.

Unknown destinations, broadcasts, and multicasts are flooded to all other SAPs or spoke SDPs in the service. If SAPs or spoke SDPs are connected together, either through misconfiguration or for redundancy purposes, loops can form and flooded packets can keep flowing through the network. The Nokia implementation of STP is designed to remove these loops from the VPLS topology. This is done by putting one or more SAPs or spoke SDPs in the discarding state.

STP parameters allow a balance between resiliency and speed of convergence extremes. Modifying particular parameters can affect the behavior. For information on command usage, descriptions, and CLI syntax, see [Configuring a VPLS Service with CLI](#).

Each VPLS instance on the 7705 SAR operates in Rapid Spanning Tree Protocol (RSTP) mode and is compliant with IEEE 802.1D-2004 - default mode.

### 5.4.1 VPLS Redundancy

The VPLS standard (RFC 4762, *Virtual Private LAN Services Using LDP Signalling*) includes provisions for hierarchical VPLS using point-to-point spoke SDPs. Two applications have been identified for spoke SDPs:

- connecting MTUs to PEs in a metro area network
- interconnecting the VPLS nodes of two metro networks

In both applications, the spoke SDPs improve the scalability of VPLS. Since node redundancy is implicit in non-hierarchical VPLS services (using a full mesh of SDPs between PEs), node redundancy for spoke SDPs needs to be provided separately.

Nokia routers have implemented special features for improving the resilience of hierarchical VPLS instances, in both MTU and inter-metro applications.

### 5.4.1.1 Spoke SDP Redundancy for Metro Interconnection

When two or more meshed VPLS instances, such as in [Figure 100](#), are interconnected by redundant spoke SDPs, a loop in the topology results. In order to remove a topology loop, STP can be run over the SDPs (links) that form the loop, which then blocks one of the SDPs.

**Figure 100 H-VPLS with Spoke Redundancy**

21877

To avoid the inefficiency of running STP separately in every VPLS in the topology, the node can associate a number of VPLS services with a single STP instance running over redundant SDPs. Node redundancy is achieved by running STP in one VPLS, and then applying the conclusions of this STP to the other VPLS services. The VPLS instance running STP is referred to as the management VPLS, or mVPLS.

If the active node fails, STP on the mVPLS on the standby node changes the link state from disabled to active. The standby node broadcasts a MAC flush LDP control message in each of the protected VPLS instances so that the address of the newly active node can be relearned by all PEs in the VPLS.

---

It is possible to configure two mVPLS services, where both mVPLS services have different active spokes (this is achieved by changing the path cost in STP). Load balancing across the spokes is achieved by associating different user VPLS services with the two mVPLS services.

### 5.4.1.2 Spoke SDP-Based Redundant Access

This feature provides the ability to have a node deployed as MTU switches to be multi-homed for VPLS to multiple routers deployed as PEs without requiring the use of mVPLS.

In the configuration example displayed in [Figure 100](#), the MTUs have spoke SDPs to two PE devices. One is designated as the primary and one as the secondary spoke SDP. This is based on a precedence value associated with each spoke.

The secondary spoke is in a blocking state (both on receive and transmit) as long as the primary spoke is available. If the primary spoke becomes unavailable (due to link failure, PEs failure, and so on), the MTU immediately switches traffic to the backup spoke and starts receiving traffic from the standby spoke. Optional revertive operation (with configurable switch-back delay) is supported. Forced manual switchover is also supported.

To speed up the convergence time during a switchover, MAC flush is configured. The MTUs generate a MAC flush message over the newly unblocked spoke when a spoke change occurs. As a result, the PEs receiving the MAC flush will flush all MACs associated with the impacted VPLS instance and forward the MAC flush to the other PEs in the VPLS network if **propagate-mac-flush** is enabled.

## 5.4.2 VPLS Access Redundancy

Another application of hierarchical VPLS uses MTUs that are not MPLS-enabled and must have Ethernet links to the closest PE node. To protect against failure of the PE node, an MTU can be dual-homed and have two SAPs on two PE nodes.

On the 7705 SAR, the mechanism used to resolve a loop in an access circuit uses STP-based access, with or without mVPLS.

### 5.4.2.1 STP-Based Redundant Access to VPLS

In the configuration shown in [Figure 101](#), STP is activated on the MTU and two PEs in order to resolve a potential loop. STP needs to run only in a single VPLS instance, and the results of the STP calculations are applied to every VPLS on the link. In this configuration, the scope of the STP domain is limited to the MTU and PEs but any topology change must be propagated across the whole VPLS domain, including mesh SDPs. This is done with MAC flush messages defined by RFC 4762.

**Figure 101 Dual Homed MTUs in Two-Tier Hierarchical VPLS**

When STP is used as a loop resolution mechanism, every Topology Change Notification (TCN) received in an STP instance is translated into a MAC flush message request to clear all FDB entries except the ones learned from the originating PE. MAC flush messages are sent to all PE peers connected through mesh and spoke SDPs in the context of the VPLS services managed by the given STP instance.

### 5.4.3 MAC Flush Message Processing

The previous sections describe the operating principle of redundancy mechanisms available in the context of a VPLS service. All of them rely on MAC flush messages as a tool to propagate topology change in the context of the given VPLS. This section summarizes basic rules for generation and processing of these messages.

The 7705 SAR supports two types of MAC flush message, flush-all-but-mine and flush-mine. The main difference between these messages is the type of action they signal.

Flush-all-but-mine requests the clearing of all FDB entries learned from all other LDP peers except the originating PE. This type is also defined by RFC 4762 as an LDP MAC address withdrawal with an empty MAC address list.

Flush-mine requests the clearing of all FDB entries learned from the originating PE. This means that this message has the opposite effect of the flush-all-but-mine message. This type is not included in the RFC 4762 definition and is implemented using vendor-specific TLV.

Upon reception of MAC flush messages (regardless of the type), the 7705 SAR PE takes the following actions:

- clears the FDB entries of all indicated VPLS services conforming to the definition
- propagates the message (preserving the type) to all LDP peers, if the propagate-mac-flush flag is enabled at the corresponding VPLS level

The flush-all-but-mine message is generated under the following conditions.

- The flush-all-but-mine message is received from an LDP peer and the propagate-mac-flush flag is enabled. The message is sent to all LDP peers in the context of the VPLS service in which it was received.
- A flush-all-but-mine message is generated when a switchover occurs between spoke SDPs of the same endpoint. The message is sent to the LDP peer connected through the newly active spoke SDP.
- A flush-all-but-mine message is generated when a TCN message is received in an STP context and the propagate-mac-flush flag is enabled. The message is sent to all LDP peers connected by spoke and mesh SDPs in the context of the VPLS service controlled by the STP instance, as determined by the mVPLS definition.

If all LDP peers are in the STP domain, it means that the mVPLS and the VPLS both have the same topology and the 7705 SAR will not send any flush-all-but-mine messages. If there are VPLS LDP peers outside the STP domain, the router sends flush-all-but-mine messages to all its VPLS peers. When a TCN occurs in the Layer 2 domain, the MAC flush message is propagated over spoke SDPs.

The 7705 SAR will only send a withdrawal request if the mVPLS contains a mesh SDP.

The flush-mine message is generated under the following conditions:

- The flush-mine message is received from an LDP peer and the propagate-mac-flush flag is enabled. The message is sent to all LDP peers in the context of the VPLS service in which it was received.

- The flush-mine message is generated when on a SAP or SDP transition from an operationally up to an operationally down state and the send-flush-on-failure flag is enabled in the context of the given VPLS service. The message is sent to all LDP peers connected in the context of the given VPLS service. The send-flush-on-failure flag is blocked in mVPLS and is only allowed to be configured in a VPLS service managed by mVPLS. This is to prevent both messages being sent at the same time.
- The flush-mine message is generated when an MC-LAG SAP or MC-APS SAP transitions from an operationally up state to an operationally down state. The message is sent to all LDP peers connected in the context of the given VPLS service.

### 5.4.3.1 Dual Homing to a VPLS Service

[Figure 102](#) illustrates a dual-homed connection to a VPLS service (PE-A, PE-B, PE-C, PE-D) and the operation in case of link failure (between PE-C and L2-B). Upon detection of a link failure, PE-C sends MAC Address Withdraw messages, which indicate to all LDP peers that they should flush all MAC addresses learned from PE-C. This triggers packets to be broadcast addressing the affected hosts and a relearning process in case an alternative route exists.

The MAC Address Withdraw message is different from the message described in *draft-ietf-l2vpn-vpls-ldp-xx.txt*, *Virtual Private LAN Services over MPLS*. The difference is in the interpretation and action performed at the receiving PE. According to the draft definition, upon receipt of a MAC withdraw message, all MAC addresses, except the ones learned from the source PE, are flushed. In the 7705 SAR implementation, upon receipt of the MAC Address Withdraw message, all MAC addresses learned from the source are flushed. In this implementation, this message is an LDP address message with vendor-specific TLV, and is called the flush-all-from-ME message.

The message as defined in the draft definition is currently used in any mVPLS that is using RSTP to recover from failures in Layer 2 topologies. The advantage of the alternative messaging behavior over RSTP-based methods is that only MAC-affected addresses are flushed, and not the full forwarding database. This method does not provide a mechanism to secure alternative loop-free topology. However, the convergence time depends on how quickly the given CE device opens the alternative link (L2-B switch in [Figure 102](#)) as well as how quickly the PE routers flush their FDBs. Additionally, since this method relies on reacting to the physical failure of the link, it is effective only if the PE and CE are directly connected with no hub or bridge.

**Figure 102 Dual-Homed CE Connection to VPLS**

25445

## 5.5 ATM PVC Access and Termination on a VPLS Service

The application shown in [Figure 103](#) provides access to a VPLS service for ATM users connected either directly or through an ATM access network to a 7705 SAR PE node. The 7705 SAR supports an ATM VC-delimited SAP terminating on a VPLS service.

**Figure 103 Example of ATM PVC Access and Termination on a VPLS**

21558

RFC 2427-encapsulated or RFC 2684-encapsulated untagged Ethernet/802.3 frames (with or without Frame Check Sequence (FCS)) or BPDUs from a customer's bridge device are received on a given SAP over an ATM interface on the 7705 SAR. The ATM-related encapsulation is stripped, and the frames (without FCS) are forwarded towards destination SAPs either locally or using SDPs associated with the VPLS service (as dictated by destination MAC address VPLS processing). In the egress direction, the received untagged frames are encapsulated into RFC 2427 or RFC 2684 (no Q-tags are added, no FCS in the forwarded frame) and sent over the ATM VC towards the customer CPE.

When AAL5 RFC 2427/2684 encapsulated tagged frames are received from the customer's bridge on an ATM SAP, the tags are transparent and the frames are processed as described above, with the exception that the frames forwarded towards the destinations will have the received tags preserved. Similarly, in the egress direction, the received tagged Ethernet frames are encapsulated as is (Q-tags are again transparent and preserved) into RFC 2427/2684 and sent over the ATM PVC towards the customer CPE.

---

Since the tagging is transparent, the 7705 SAR performs unqualified MAC learning (for example, MAC addresses are learned without reference to the VLANs they are associated with). Hence, MAC addresses used must be unique across all the VLANs used by the customer for a given VPLS service instance. If a customer wants a per-VLAN separation, then the VLAN traffic that needs to be separated must travel on different VCs (different SAPs) associated with different VPLS service instances.

All VPLS functionality available on the 7705 SAR is applicable to ATM-delimited VPLS SAPs. For example, bridged PDUs received over an ATM SAP can be tunneled through or dropped, all Forwarding Database (FDB) functionality applies, packet-level QoS and MAC filtering applies. Also, split horizon groups are applicable to ATM SAPs terminating on VPLS. In other words, frame forwarding between ATM SAPs, also referred to as VCI-to-VCI forwarding, is disabled within the same group.

The Ethernet pseudowire is established using Targeted LDP (T-LDP) signaling and uses the **ether**, **vlan**, or **vpls** VC type on the SDP. The SDP can be an MPLS or a GRE type.

---

## 5.6 VPLS Service Considerations

This section describes general 7705 SAR service features and any special capabilities or considerations as they relate to VPLS services:

- [SAP Encapsulations](#)
- [VLAN Processing](#)
- [QinQ \(VPLS\)](#)

### 5.6.1 SAP Encapsulations

VPLS services are designed to carry Ethernet frame payloads; therefore, VPLS can provide connectivity between any SAPs and SDPs that pass Ethernet frames. The following SAP encapsulations are supported on the 7705 SAR VPLS service:

- Ethernet null
- Ethernet dot1q
- Ethernet qinq
- ATM VC with RFC 2684 Ilc-snap bridged encapsulation (see [ATM PVC Access and Termination on a VPLS Service](#))

### 5.6.2 VLAN Processing

The SAP encapsulation definition on Ethernet ingress ports defines which VLAN tags are used to determine the service that the packet belongs to:

- **null** encapsulation defined at ingress—any VLAN tags are ignored and the packet goes to a default service for the SAP
- **dot1q** encapsulation defined at ingress—only the first label is considered
- **qinq** encapsulation defined at ingress—only the topmost two labels are considered

**Note:** The SAP can be defined with a wildcard (\*) for the inner label (for example, “SAP 100:100.\*”). In this example, all packets with an outer label of 100 will be treated as belonging to the SAP. If, on the same physical link, there is also a SAP defined by the QinQ encapsulation of SAP 100:100.1, then traffic with 100:1 will go to that SAP while all other traffic with 100 as the first label will go to the SAP with the SAP 100:100.\* definition.

For dot1q and qinq encapsulations, traffic encapsulated with tags for which there is no definition are discarded.

### 5.6.2.1 Tagging Rules for VPLS

VLAN tagging rules for VPLS SAPs are the same as those for Epipe SAPs except that VPLS includes the **force-c-vlan-forwarding** command.

The **force-c-vlan-forwarding** command provides users with the ability to preserve a customer VLAN tag and append a configured egress SAP VLAN ID on top of the customer tag. See the [force-c-vlan-forwarding](#) command for details.

For information on tagging rules, see [Tagging Rules for Epipe](#).

### 5.6.3 QinQ (VPLS)

VPLS supports QinQ functionality. For details, see [QinQ Support](#).

## 5.7 Configuration Notes

The following guidelines and caveats apply to the implementation of VPLS:

- fabric mode must be set to aggregate mode (not per-destination mode)
- associating a service with a filter policy other than the default policy is optional

### 5.7.1 Reference Sources

For information on supported IETF drafts and standards, as well as standard and proprietary MIBs, refer to [Standards and Protocol Support](#).

---

## 5.8 Configuring a VPLS Service with CLI

This section provides information to configure VPLS services using the command line interface.

Topics in this section include:

- [Basic Configuration](#)
- [Common Configuration Tasks](#)
- [Configuring VPLS Components](#)
- [Configuring a VPLS SAP](#)
- [Configuring SDP Bindings](#)
- [Configuring Routed VPLS](#)
- [Configuring IP Multicast in VPLS](#)
- [Configuring IP Multicast in r-VPLS](#)
- [Configuring Multicast Parameters for VPLS and r-VPLS](#)
- [Configuring a Static Multicast Group](#)
- [Configuring PIM Snooping for VPLS](#)
- [Service Management Tasks](#)

## 5.9 Basic Configuration

The following fields require specific input (there are no defaults) to configure a basic VPLS service:

- customer ID (refer to [Configuring Customer Accounts](#))
- for a local service, configure two SAPs, specifying local access ports and encapsulation values
- for a distributed service, configure a SAP and an SDP for each far-end node

The following example displays a configuration of a local VPLS service on ALU-1.

```
*A:ALU-1>config>service>vpls# info

...
vpls 9001 customer 6 create
 description "Local VPLS"
 sap 1/2/2:0 create
 description "SAP for local service"
 exit
 sap 1/1/5:0 create
 description "SAP for local service"
 exit
 no shutdown

*A:ALU-1>config>service>vpls#
```

The following example displays a configuration of a distributed VPLS service between ALU-1, ALU-2, and ALU-3. The *vc-id* for all mesh SDPs must match the *service-id*.

```
*A:ALU-1>config>service# info

...
vpls 9000 customer 6 create
 shutdown
 description "This is a distributed VPLS."
 sap 1/1/5:16 create
 description "VPLS SAP"
 exit
 spoke-sdp 2:22 create
 exit
 mesh-sdp 7:9000 create
 exit
exit
...

*A:ALU-1>config>service#
```

```
*A:ALU-2>config>service# info

...
 vpls 9000 customer 6 create
 description "This is a distributed VPLS."
 sap 1/1/5:16 create
 description "VPLS SAP"
 exit
 spoke-sdp 2:22 create
 exit
 mesh-sdp 8:9000 create
 exit
 no shutdown
 exit
...

*A:ALU-2>config>service#

*A:ALU-3>config>service# info

...
 vpls 9000 customer 6 create
 description "This is a distributed VPLS."
 sap 1/1/3:33 create
 description "VPLS SAP"
 exit
 spoke-sdp 2:22 create
 exit
 mesh-sdp 8:9000 create
 exit
 no shutdown
 exit
...

*A:ALU-3>config>service#
```

---

## 5.10 Common Configuration Tasks

This section provides a brief overview of the tasks that must be performed to configure both local and distributed VPLS services and provides the CLI commands.

For VPLS services:

1. Associate a VPLS service with a customer ID. For management VPLS, include the **m-vpls** keyword when creating the VPLS.
2. Define SAPs:
  - i. Select nodes and ports
  - ii. (optional) Select QoS policies other than the default (configured in the **config>qos** context)
  - iii. (optional) Select filter policies (configured in the **config>filter** context)
  - iv. (optional) Select accounting policy (configured in the **config>log** context)
3. Associate SDPs (for distributed services).
4. (optional) Modify STP default parameters (see [VPLS and Spanning Tree Protocol](#)).
5. Enable the service.

---

## 5.11 Configuring VPLS Components

Topics in this section include:

- [Creating a VPLS Service](#)
- [Creating a Split Horizon Group](#)
- [Enabling MAC Move](#)
- [Configuring STP Bridge Parameters in a VPLS](#)

### 5.11.1 Creating a VPLS Service

Use the following CLI syntax to create a VPLS service:

**CLI Syntax:**

```
config>service#
vpls service-id [customer customer-id] [m-vpls] [create]
 description description-string
 no shutdown
```

The following example displays a VPLS configuration:

```
*A:ALU-1>config>service>vpls# info

...
 vpls 9000 customer 6 create
 description "This is a distributed VPLS."
 shutdown
 exit
 exit
...

*A:ALU-1>config>service>vpls#
```

## 5.11.2 Creating a Split Horizon Group

Use the following CLI syntax to create a split horizon group for a VPLS instance. Including the **residential-group** parameter creates a residential split horizon group.

**CLI Syntax:**

```
config>service>vpls#
 split-horizon-group group-name [residential-group]
 [create]
```

The following example displays a VPLS configuration:

```
*A:ALU-1>config>service>vpls# info

...
 vpls 9000 customer 6 create
 description "VPLS with split horizon"
 split-horizon-group "SHG-group1" residential-group create
 description "Residential Split horizon group"
 exit
 no shutdown
 exit
...

```

## 5.11.3 Enabling MAC Move

The MAC move feature is useful to protect against undetected loops in the VPLS topology as well as the presence of duplicate MACs in a VPLS service. For example, if two clients in the VPLS have the same MAC address, the VPLS will experience a high relearn rate for the MAC and will shut down the SAP or spoke SDP when the threshold is exceeded. Use the following CLI syntax to configure MAC move parameters:

**CLI Syntax:**

```
config>service
vpls service-id [customer customer-id] [m-vpls] [create]
 mac-move
 primary-ports
 spoke-sdp spoke-id
 cumulative-factor cumulative-factor
 exit
 secondary-ports
 spoke-sdp spoke-id
 sap sap-id
 exit
 move-frequency frequency
 retry-timeout timeout
 no shutdown
```

The following example displays a MAC move configuration:

```
*A:ALU-2009>config>service>vpls>mac-move# show service id 500 mac-move
=====
Service Mac Move Information
=====
Service Id : 500 Mac Move : Enabled
Primary Factor : 4 Secondary Factor : 2
Mac Move Rate : 2 Mac Move Timeout : 10
Mac Move Retries : 3

SAP Mac Move Information: 1/1/3:501

Admin State : Up Oper State : Down
Flags : RelearnLimitExceeded
Time to come up : 1 seconds Retries Left : 1

```

---

## 5.11.4 Configuring STP Bridge Parameters in a VPLS

Modifying some of the STP parameters allows the operator to balance STP between resiliency and speed of convergence extremes.

The following STP parameters can be modified at the VPLS level:

- [Bridge STP Admin State](#)
- [Mode](#)
- [Bridge Priority](#)
- [Hello Time](#)
- [Hold Count](#)

STP always uses the locally configured values for the first three parameters (Admin State, Mode and Priority).

For the parameters Hello Time and Hold Count, the locally configured values are only used when this bridge has been elected root bridge in the STP domain; otherwise, the values received from the root bridge are used. The exception to this rule is that Hello Time is always taken from the locally configured parameter.

### 5.11.4.1 Bridge STP Admin State

The administrative state of STP at the VPLS level is controlled by the **shutdown** command.

For SAPs, if STP on the VPLS is administratively disabled, any BPDUs are forwarded transparently through the 7705 SAR. If STP on the VPLS is administratively enabled, but the administrative state of a SAP is down, BPDUs received on such a SAP are discarded.

The 7705 SAR does not support BPDU extraction over spoke SDPs. If STP on the VPLS instance is disabled, BPDUs are forwarded transparently over the spoke SDP. If STP is enabled, the spoke SDP discards all BPDUs received.

**CLI Syntax:**     `config>service>vpls service-id# stp  
no shutdown`

### 5.11.4.2 Mode

The 7705 SAR operates in the Rapid Spanning Tree Protocol (RSTP) mode and is compliant with IEEE 802.1D-2004 - default mode.

**CLI Syntax:**    `config>service>vpls service-id# stp  
mode {rstp}`

**Default:** rstp

### 5.11.4.3 Bridge Priority

The **bridge-priority** command is used to populate the priority portion of the bridge ID field within outbound BPDUs (the most significant 4 bits of the bridge ID). It is also used as part of the decision process when determining the best BPDU between messages received and sent.

All values will be truncated to multiples of 4096, conforming with IEEE 802.1t and 802.1D-2004.

**CLI Syntax:**    `config>service>vpls service-id# stp  
priority bridge-priority`

**Range:** 1 to 65535

**Default:** 32768

**Restore Default:** no priority

### 5.11.4.4 Hello Time

The **hello-time** command configures the STP hello time for the VPLS STP instance.

The seconds parameter defines the default timer value that controls the sending interval between BPDU configuration messages by this bridge, on ports where this bridge assumes the designated role.

On the 7705 SAR, the hello time for the spanning tree is determined by the locally configured parameter.

---

**CLI Syntax:** `config>service>vpls service-id# stp  
hello-time hello-time`

**Range:** 1 to 10 seconds

**Default:** 2 seconds

**Restore Default:** no hello-time

### 5.11.4.5 Hold Count

The **hold-count** command configures the peak number of BPDUs that can be transmitted in a period of one second.

**CLI Syntax:** `config>service>vpls service-id# stp  
hold-count count-value`

**Range:** 1 to 10

**Default:** 6

**Restore Default:** no hold-count

## 5.12 Configuring a VPLS SAP

A default QoS policy is applied to each ingress and egress SAP. Additional QoS policies can be configured in the **config>qos** context. There are no default filter policies. Filter policies are configured in the **config>filter** context and must be explicitly applied to a SAP.

For information on configuring ETH-CFM parameters on VPLS (Ethernet) SAPs, see [ETH-CFM \(802.1ag and Y.1731\) Tasks](#).

Topics in this section include:

- [Local VPLS SAPs](#)
- [Distributed VPLS SAPs](#)
- [Configuring SAP-Specific STP Parameters](#)
- [STP SAP Operational States](#)
- [Configuring VPLS SAPs with Split Horizon](#)

### 5.12.1 Local VPLS SAPs

To configure a local VPLS service, enter the **sap sap-id** command twice with different port IDs in the same service configuration.

All supported service types and corresponding uplink SAPs are specified in the following examples.

The following example displays a local VPLS configuration:

```
*A:ALU-1>config>service# info

...
 vpls 9000 customer 6 create
 description "Local VPLS"
 sap 1/2/2:0 create
 description "SAP for local service"
 exit
 sap 1/1/5:0 create
 description "SAP for local service"
 exit
 no shutdown
 exit

*A:ALU-1>config>service#
```

## 5.12.2 Distributed VPLS SAPs

To configure a distributed VPLS service, you must configure service entities on originating and far-end nodes. You must use the same service ID on all ends (for example, create a VPLS service ID 9000 on ALU-1, ALU-2, and ALU-3). A distributed VPLS consists of a SAP on each participating node and an SDP bound to each participating node.

For SDP configuration information, see [Configuring SDPs](#). For SDP binding information, see [Configuring SDP Bindings](#).

The following example displays a configuration of VPLS SAPs configured for ALU-1, ALU-2, and ALU-3:

```
*A:ALU-1>config>service# info

...
 vpls 9000 customer 6 create
 description "Distributed VPLS services."
 shutdown
 exit
 sap 1/2/5:0 create
 description "VPLS SAP"
 exit
...

*A:ALU-1>config>service#

*A:ALU-2>config>service# info

...
 vpls 9000 customer 6 create
 description "Distributed VPLS services."
 shutdown
 exit
 sap 1/1/2:22 create
 description "VPLS SAP"
 exit
...

*A:ALU-2>config>service#

*A:ALU-3>config>service# info

...
 vpls 9000 customer 6 create
 description "Distributed VPLS services."
 shutdown
 exit
 sap 1/1/3:33 create
 description "VPLS SAP"
 exit
...

```

---

## 5.12.3 Configuring SAP-Specific STP Parameters

When a VPLS has STP enabled, each SAP within the VPLS has STP enabled by default. The operation of STP on each SAP is governed by:

- [SAP STP Administrative State](#)
- [SAP Virtual Port Number](#)
- [SAP Priority](#)
- [SAP Path Cost](#)
- [SAP Edge Port](#)
- [SAP Auto Edge](#)
- [SAP Link Type](#)

### 5.12.3.1 SAP STP Administrative State

The administrative state of STP within a SAP controls how BPDUs are transmitted and handled when received. The allowable states are:

- **SAP Admin Up**

The default administrative state is up for STP on a SAP. BPDUs are handled in the normal STP manner on a SAP that is administratively up.

- **SAP Admin Down**

An administratively down state allows a service provider to prevent a SAP from becoming operationally blocked. BPDUs will not originate out the SAP towards the customer.

If STP is enabled on the VPLS level, but disabled on the SAP, received BPDUs are discarded. Discarding the incoming BPDUs allows STP to continue to operate normally within the VPLS service while ignoring the down SAP. The specified SAP will always be in an operationally forwarding state.

**Note:** The administratively down state allows a loop to form within the VPLS.

**CLI Syntax:** `config>service>vpls>sap>stp#  
[no] shutdown`

**Range:** shutdown or no shutdown

**Default:** no shutdown (SAP admin up)

---

### 5.12.3.2 SAP Virtual Port Number

The virtual port number uniquely identifies a SAP within configuration BPDUs. The internal representation of a SAP is unique to a system and has a reference space much bigger than the 12 bits definable in a configuration BPDU. STP takes the internal representation value of a SAP and identifies it with its own virtual port number, which is unique to every other SAP defined on the VPLS. The virtual port number is assigned at the time that the SAP is added to the VPLS.

Since the order in which SAPs are added to the VPLS is not preserved between reboots of the system, the virtual port number may change between restarts of the STP instance. To achieve consistency after a reboot, the virtual port number can be specified explicitly.

**CLI Syntax:**    `config>service>vpls>sap# stp`  
                  `port-num number`

**Range:** 1 to 2047  
**Default:** (automatically generated)  
**Restore Default:** no port-num

### 5.12.3.3 SAP Priority

SAP priority allows a configurable “tiebreaking” parameter to be associated with a SAP. When configuration BPDUs are being received, the configured SAP priority will be used in some circumstances to determine whether a SAP will be designated or blocked.

In traditional STP implementations (802.1D-1998), this field is called the port priority and has a value of 0 to 255. This field is coupled with the port number (0 to 255 also) to create a 16-bit value.

In the latest STP standard (802.1D-2004), only the upper 4 bits of the port priority field are used to encode the SAP priority. The remaining 4 bits are used to extend the port ID field into a 12-bit virtual port number field. The virtual port number uniquely references a SAP within the STP instance. See [SAP Virtual Port Number](#) for details on the virtual port number.

STP computes the actual SAP priority by taking the configured priority value and masking out the lower four bits. The result is the value that is stored in the SAP priority parameter. For example, if a value of 0 was entered, masking out the lower 4 bits would result in a parameter value of 0. If a value of 255 was entered, the result would be 240.

The default value for SAP priority is 128. This parameter can be modified within a range of 0 to 255, 0 being the highest priority. Masking causes the values actually stored and displayed to be 0 to 240, in increments of 16.

**CLI Syntax:**    `config>service>vpls>sap>stp#  
                  priority stp-priority`

**Range:** 0 to 255 (240 largest value, in increments of 16)

**Default:** 128

**Restore Default:** no priority

#### 5.12.3.4 SAP Path Cost

The SAP path cost is used by STP to calculate the path cost to the root bridge. The path cost in BPDUs received on the root port is incremented with the configured path cost for that SAP. When BPDUs are sent out other egress SAPs, the newly calculated root path cost is used.

STP suggests that the path cost is defined as a function of the link bandwidth. Since SAPs are controlled by complex queuing dynamics, in the 7705 SAR the STP path cost is a purely static configuration.

The default value for SAP path cost is 10. This parameter can be modified within a range of 1 to 200000000, 1 being the lowest cost.

**CLI Syntax:**    `config>service>vpls>sap>stp#  
                  path-cost sap-path-cost`

**Range:** 1 to 200000000

**Default:** 10

**Restore Default:** no path-cost

#### 5.12.3.5 SAP Edge Port

The SAP **edge-port** command is used to reduce the time it takes a SAP to reach the forwarding state when the SAP is on the edge of the network, and thus has no further STP bridge to handshake with.

The **edge-port** command is used to initialize the internal OPER\_EDGE variable. At any time, when OPER\_EDGE is false on a SAP, the normal mechanisms are used to transition to the forwarding state. When OPER\_EDGE is true, STP assumes that the remote end agrees to transition to the forwarding state without actually receiving a BPDU with an agreement flag set.

The OPER\_EDGE variable will dynamically be set to false if the SAP receives BPDUs (the configured **edge-port** value does not change). The OPER\_EDGE variable will dynamically be set to true if **auto-edge** is enabled and STP concludes there is no bridge behind the SAP.

When STP on the SAP is administratively disabled and re-enabled, the OPER\_EDGE is reinitialized to the value configured for **edge-port**.

Valid values for SAP **edge-port** are enabled and disabled with disabled being the default.

**CLI Syntax:**    `config>service>vpls>sap>stp#`  
                  `[no] edge-port`

**Default:** no edge-port

### 5.12.3.6 SAP Auto Edge

The SAP **auto-edge** command is used to instruct STP to dynamically decide whether the SAP is connected to another bridge.

If **auto-edge** is enabled, and STP concludes there is no bridge behind the SAP, the OPER\_EDGE variable will dynamically be set to true. If **auto-edge** is enabled and a BPDU is received, the OPER\_EDGE variable will dynamically be set to false (see [SAP Edge Port](#)).

Valid values for SAP **auto-edge** are enabled and disabled, with enabled being the default.

**CLI Syntax:**    `config>service>vpls>sap>stp#`  
                  `[no] auto-edge`

**Default:** auto-edge

### 5.12.3.7 SAP Link Type

The SAP **link-type** parameter instructs STP on the maximum number of bridges behind this SAP.

If there is only a single bridge, transitioning to the forwarding state will be based on handshaking (fast transitions). If more than two bridges are connected by a shared media, their SAPs should all be configured as shared, and timer-based transitions are used.

Valid values for SAP **link-type** are **shared** and **pt-pt**, with **pt-pt** being the default.

**CLI Syntax:**     `config>service>vpls>sap>stp#`  
                  `link-type {pt-pt|shared}`

**Default:** link-type pt-pt  
                  **Restore Default:** no link-type

## 5.12.4 STP SAP Operational States

The operational state of STP within a SAP controls how BPDUs are transmitted and handled when received. Defined states are:

- [Operationally Disabled](#)
- [Operationally Discarding](#)
- [Operationally Learning](#)
- [Operationally Forwarding](#)

### 5.12.4.1 Operationally Disabled

Operationally disabled is the normal operational state for STP on a SAP in a VPLS that has any of the following conditions:

- VPLS state administratively down
- SAP state administratively down
- SAP state operationally down

If the SAP enters the operationally up state with the STP administratively up and the SAP STP state is up, the SAP will transition to the STP SAP discarding state.

When, during normal operation, the router detects a downstream loop behind a SAP, BPDUs can be received at a very high rate. To recover from this situation, STP will transition the SAP to the disabled state for the forward-delay duration of 15 s.

### 5.12.4.2 Operationally Discarding

A SAP in the discarding state only receives and sends BPDUs, building the local proper STP state for each SAP while not forwarding actual user traffic.

**Note:** In previous versions of the STP standard, the discarding state was called a blocked state.

### 5.12.4.3 Operationally Learning

The learning state allows for the population of the MAC forwarding table before entering the forwarding state. In this state, no user traffic is forwarded.

### 5.12.4.4 Operationally Forwarding

Configuration BPDUs are sent out a SAP in the forwarding state. Layer 2 frames received on the SAP are source-learned and destination-forwarded according to the FIB. Layer 2 frames received on other forwarding interfaces and destined for the SAP are also forwarded.

## 5.12.5 Configuring VPLS SAPs with Split Horizon

To configure a VPLS service with a split horizon group, add the **split-horizon-group** parameter when creating the SAP. Traffic arriving on a SAP within a split horizon group will not be copied to other SAPs in the same split horizon group.

The following example displays a VPLS configuration with split horizon enabled:

```
*A:ALU-1>config>service# info

...
vpls 800 customer 6001 create
 description "VPLS with split horizon for DSL"
 sap 1/1/3:1/100 split-horizon-group "DSL-group1" create
 description "SAP for residential bridging"
 exit
 sap 1/1/3:1/200 split-horizon-group "DSL-group1" create
 description "SAP for residential bridging"
 exit
 split-horizon-group "DSL-group1" residential-group create
 description "Split horizon group for DSL"
 exit
 no shutdown
exit
...

*A:ALU-1>config>service#
```

---

## 5.13 Configuring SDP Bindings

This section contains the following topics:

- [Configuring Mesh SDP Bindings](#)
- [Configuring Spoke SDPs](#)
- [Configuring VPLS Spoke SDPs with Split Horizon](#)
- [Configuring Selective MAC Flush](#)

VPLS provides scaling and operational advantages. A hierarchical configuration eliminates the need for a full mesh of VCs between participating devices. Hierarchy is achieved by enhancing the base VPLS core mesh of VCs with access VCs (spoke) to form two tiers. Spoke SDPs are generally created between Layer 2 switches and placed at the Multi-Tenant Unit (MTU). The PE routers are placed at the service provider's Point of Presence (POP). Signaling and replication overhead on all devices is considerably reduced.

A spoke SDP is treated like the equivalent of a traditional bridge port, where flooded traffic received on the spoke SDP is replicated on all other “ports” (other spoke and mesh SDPs or SAPs) and not transmitted on the port it was received on (unless a split horizon group was defined on the spoke SDP; see [Configuring VPLS Spoke SDPs with Split Horizon](#)).

A spoke SDP connects a VPLS service between two sites and, in its simplest form, could be a single tunnel LSP. A set of ingress and egress VC labels are exchanged for each VPLS service instance to be transported over this LSP. The PE routers at each end treat this as a virtual spoke connection for the VPLS service in the same way as the PE-MTU connections. This architecture minimizes the signaling overhead and avoids a full mesh of VCs and LSPs between the two metro networks.

A mesh SDP bound to a service is logically treated like a single bridge “port” for flooded traffic, where flooded traffic received on any mesh SDP on the service is replicated to other “ports” (spoke SDPs and SAPs) and not transmitted on any mesh SDPs.

A VC-ID can be specified with the SDP-ID. The VC-ID is used instead of a label to identify a virtual circuit. The VC-ID is significant between peer 7705 SAR routers on the same hierarchical level. The value of a VC-ID is conceptually independent from the value of the label or any other datalink-specific information of the VC.

[Figure 104](#) displays an example of a distributed VPLS service configuration of spoke and mesh SDPs (unidirectional tunnels) between 7750 SR routers and 7705 SAR MTUs.

**Figure 104 SDPs—Unidirectional Tunnels**

21561

### 5.13.1 Configuring Mesh SDP Bindings

Use the following CLI syntax to create a mesh SDP binding with a distributed VPLS service. SDPs must be configured before binding. Refer to [Configuring SDPs](#) for information on creating SDPs. For information on configuring ETH-CFM parameters on VPLS (Ethernet) mesh SDPs, see [ETH-CFM \(802.1ag and Y.1731\) Tasks](#).

Use the following CLI syntax to configure mesh SDP bindings:

**CLI Syntax:**

```
config>service# vpls service-id
 mesh-sdp sdp-id[:vc-id] [vc-type {ether | vlan}]
 egress
 vc-label egress-vc-label
 ingress
 filter {ip ip-filter-id | mac mac-filter-id}
 vc-label ingress-vc-label
 no shutdown
 static-mac ieee-address
 vlan-vc-tag 0..4094
```

## 5.13.2 Configuring Spoke SDPs

Topics in this section include:

- [Configuring Spoke SDP Bindings](#)
- [Configuring Spoke SDP-Specific STP Parameters](#)

### 5.13.2.1 Configuring Spoke SDP Bindings

Use the following CLI syntax to create a spoke SDP binding with a distributed VPLS service. SDPs must be configured before binding. Refer to [Configuring SDPs](#) for information on creating SDPs. For information on configuring ETH-CFM parameters on VPLS (Ethernet) spoke SDPs, see [ETH-CFM \(802.1ag and Y.1731\) Tasks](#).

Use the following CLI syntax to configure spoke SDP bindings:

**CLI Syntax:**

```
config>service# vpls service-id
 spoke-sdp sdp-id:vc-id [vc-type {ether | vlan}]
 [split-horizon-group group-name]
 egress
 vc-label egress-vc-label
 ingress
 filter {ip ip-filter-id | mac mac-filter-id}
 vc-label ingress-vc-label
 limit-mac-move [non-blockable]
 no shutdown
 static-mac ieee-address
 vlan-vc-tag [0..4094]
```

The following displays SDP binding configurations for ALU-1, ALU-2, and ALU-3 for VPLS service ID 9000 for customer 6:

```
*A:ALU-1>config>service# info

vpls 9000 customer 6 create
 description "This is a distributed VPLS."
 sap 1/2/5:0 create
 exit
 spoke-sdp 2:22 create
 exit
 mesh-sdp 5:9000 create
 exit
 mesh-sdp 7:9000 create
 exit
 no shutdown
exit
```

```

*A:ALU-1>config>service#

*A:ALU-2>config>service# info

...
 vpls 9000 customer 6 create
 description "This is a distributed VPLS."
 sap 1/1/2:22 create
 exit
 spoke-sdp 2:22 create
 exit
 mesh-sdp 5:9000 create
 exit
 mesh-sdp 7:9000 create
 exit
 no shutdown
 exit

*A:ALU-3>config>service# info

...
 vpls 9000 customer 6 create
 description "This is a distributed VPLS."
 sap 1/1/3:33 create
 exit
 spoke-sdp 2:22 create
 exit
 mesh-sdp 5:9000 create
 exit
 mesh-sdp 7:9000 create
 exit
 no shutdown
 exit

*A:ALU-3>config>service#

```

### 5.13.2.2 Configuring Spoke SDP-Specific STP Parameters

When a VPLS has STP enabled, each spoke SDP within the VPLS has STP enabled by default. The operation of STP on each spoke SDP is governed by:

- [Spoke SDP STP Administrative State](#)
- [Spoke SDP Virtual Port Number](#)
- [Spoke SDP Priority](#)
- [Spoke SDP Path Cost](#)
- [Spoke SDP Edge Port](#)
- [Spoke SDP Auto Edge](#)

- [Spoke SDP Link Type](#)

#### 5.13.2.2.1 Spoke SDP STP Administrative State

The administrative state of STP within a spoke SDP controls how BPDUs are transmitted and handled when received. The allowable states are:

- **spoke SDP admin up**

The default administrative state is up for STP on a spoke SDP. BPDUs are handled in the normal STP manner on a spoke SDP that is administratively up.

- **spoke SDP admin down**

An administratively down state allows a service provider to prevent a spoke SDP from becoming operationally blocked. BPDUs will not originate out the spoke SDP towards the customer.

If STP is enabled on the VPLS level, but disabled on the spoke SDP, received BPDUs are discarded. Discarding the incoming BPDUs allows STP to continue to operate normally within the VPLS service while ignoring the down spoke SDP. The specified spoke SDP will always be in an operationally forwarding state.

**Note:** The administratively down state allows a loop to form within the VPLS.

**CLI Syntax:** `config>service>vpls>spoke-sdp>stp#  
[no] shutdown`

#### 5.13.2.2.2 Spoke SDP Virtual Port Number

The virtual port number uniquely identifies a spoke SDP within configuration BPDUs. The internal representation of a spoke SDP is unique to a system and has a reference space much larger than the 12 bits definable in a configuration BPDU. STP takes the internal representation value of a spoke SDP and identifies it with its own virtual port number, which is unique to any other spoke SDP defined on the VPLS. The virtual port number is assigned at the time that the spoke SDP is added to the VPLS.

Since the order in which spoke SDPs are added to the VPLS is not preserved between reboots of the system, the virtual port number may change between restarts of the STP instance. To achieve consistency after a reboot, the virtual port number can be specified explicitly.

---

**CLI Syntax:**    `config>service>vpls>spoke-sdp# stp  
port-num virtual-port-number`

### 5.13.2.2.3 Spoke SDP Priority

Spoke SDP priority allows a configurable “tiebreaking” parameter to be associated with a spoke SDP. When configuration BPDUs are being received, the configured spoke SDP priority will be used in some circumstances to determine whether a spoke SDP will be designated or blocked.

In traditional STP implementations (802.1D-1998), this field is called the port priority and has a value of 0 to 255. This field is coupled with the port number (also 0 to 255) to create a 16-bit value.

In the latest STP standard (802.1D-2004), only the upper 4 bits of the port priority field are used to encode the spoke SDP priority. The remaining 4 bits are used to extend the port ID field into a 12-bit virtual port number field. The virtual port number uniquely references a spoke SDP within the STP instance. See [Spoke SDP Virtual Port Number](#) for details on the virtual port number.

STP computes the actual spoke SDP priority by taking the configured priority value and masking out the lower 4 bits. The result is the value that is stored in the spoke SDP priority parameter. For example, if a value of 0 was entered, masking out the lower 4 bits would result in a parameter value of 0. If a value of 255 was entered, the result would be 240.

The default value for spoke SDP priority is 128. This parameter can be configured within a range of 0 to 255, with 0 being the highest priority. Masking causes the values actually stored and displayed to be 0 to 240, in increments of 16.

**CLI Syntax:**    `config>service>vpls>spoke-sdp>stp#  
priority stp-priority`

### 5.13.2.2.4 Spoke SDP Path Cost

The spoke SDP path cost is used by STP to calculate the path cost to the root bridge. The path cost in BPDUs received on the root port is incremented with the configured path cost for that spoke SDP. When BPDUs are sent out other egress spoke SDPs, the newly calculated root path cost is used.

STP suggests that the path cost is defined as a function of the link bandwidth. Since spoke SDPs are controlled by complex queuing dynamics, in the 7705 SAR the STP path cost is a purely static configuration.

The default value for spoke SDP path cost is 10. This parameter can be configured within a range of 1 to 200000000, with 1 being the lowest cost.

**CLI Syntax:**     `config>service>vpls>spoke-sdp>stp#  
                  path-cost stp-path-cost`

#### 5.13.2.2.5 Spoke SDP Edge Port

The spoke SDP **edge-port** command is used to reduce the time it takes a spoke SDP to reach the forwarding state when the spoke SDP is on the edge of the network and thus has no further STP bridge to handshake with.

The **edge-port** command is used to initialize the internal OPER\_EDGE variable. At any time, when OPER\_EDGE is false on a spoke SDP, the normal mechanisms are used to transition to the forwarding state. When OPER\_EDGE is true, STP assumes that the remote end agrees to transition to the forwarding state without actually receiving a BPDU with an agreement flag set.

The OPER\_EDGE variable will dynamically be set to false if the spoke SDP receives BPDUs (the configured **edge-port** value does not change). The OPER\_EDGE variable will dynamically be set to true if **auto-edge** is enabled and STP concludes there is no bridge behind the spoke SDP.

When STP on the spoke SDP is administratively disabled and re-enabled, the OPER\_EDGE is reinitialized to the value configured for **edge-port**.

Valid values for spoke SDP **edge-port** are enabled and disabled, with disabled being the default.

**CLI Syntax:**     `config>service>vpls>spoke-sdp>stp#  
                  [no] edge-port`

#### 5.13.2.2.6 Spoke SDP Auto Edge

The spoke SDP **auto-edge** command is used to instruct STP to dynamically decide whether the spoke SDP is connected to another bridge.

If **auto-edge** is enabled, and STP concludes there is no bridge behind the spoke SDP, the OPER\_EDGE variable will dynamically be set to true. If **auto-edge** is enabled and a BPDU is received, the OPER\_EDGE variable will dynamically be set to false (see [Spoke SDP Edge Port](#)).

Valid values for spoke SDP **auto-edge** are enabled and disabled, with enabled being the default.

---

**CLI Syntax:**    `config>service>vpls>spoke-sdp>stp#`  
                   `[no] auto-edge`

### 5.13.2.2.7 Spoke SDP Link Type

The spoke SDP **link-type** parameter instructs STP on the maximum number of bridges behind this spoke SDP.

If there is only a single bridge, transitioning to the forwarding state will be based on handshaking (fast transitions). If more than two bridges are connected by a shared media, their spoke SDPs should all be configured as shared, and timer-based transitions are used.

Valid values for spoke SDP **link-type** are **shared** and **pt-pt**, with **pt-pt** being the default.

**CLI Syntax:**    `config>service>vpls>spoke-sdp>stp#`  
                   `link-type {pt-pt|shared}`

## 5.13.3 Configuring VPLS Spoke SDPs with Split Horizon

To configure spoke SDPs with a split horizon group, add the **split-horizon-group** parameter when creating the spoke SDP. Traffic arriving on a SAP or spoke SDP within a split horizon group will not be copied to other SAPs or spoke SDPs in the same split horizon group.

The following example displays a VPLS configuration with split horizon enabled:

```
*A:ALU-1>config>service# info

...
 vpls 800 customer 6001 create
 description "VPLS with split horizon for DSL"
 spoke-sdp 51:15 split-horizon-group "DSL-group1" create
 exit
 split-horizon-group "DSL-group1"
 description "Split horizon group for DSL"
 exit
 no shutdown
 exit
...

*A:ALU-1>config>service#
```

## 5.13.4 Configuring Selective MAC Flush

Use the following CLI syntax to enable selective MAC flush in a VPLS instance:

**CLI Syntax:**    `config>service# vpls service-id  
                  send-flush-on-failure`

Use the following CLI syntax to disable selective MAC flush in a VPLS instance:

**CLI Syntax:**    `config>service# vpls service-id  
                  no send-flush-on-failure`

## 5.14 Configuring Routed VPLS

To establish routed VPLS (r-VPLS), a VPLS service must be bound to a standard IP interface within an IES or VPRN service. This is done by giving the VPLS a *service-name* and setting the VPLS **allow-ip-int-binding** flag. The binding is completed when the IES or VPRN interface is associated with the VPLS *service-name*. See [Routed VPLS](#) for details.

A VPLS service only supports binding for a single IP interface.

Additionally, an ingress IPv4 or IPv6 filter can be assigned to the VPLS SAP and the IES or VPRN interface. Use the **v4-** and **v6-routed-override-filter** commands to give the IP interface filter precedence over the VPLS SAP filter. See [IES Command Reference](#) and [VPRN Services Command Reference](#) for command descriptions.

Use the following CLI syntax to set up routed VPLS in a VPLS instance:

**CLI Syntax:**

```
config>service# vpls service-id
 allow-ip-int-binding
 service-name service-name
```

Use the following CLI syntax to bind an IES or VPRN interface to the routed VPLS instance and to configure an override filter:

**CLI Syntax:**

```
config>service>ies# interface ip-interface-name [create]
 vpls service-name
 ingress
 v4-routed-override-filter ipv4-filter-id
 v6-routed-override-filter ipv6-filter-id
```

**CLI Syntax:**

```
config>service>vprn# interface ip-interface-name
[create]
 vpls service-name
 ingress
 v4-routed-override-filter ipv4-filter-id
 v6-routed-override-filter ipv6-filter-id
```

---

## 5.15 Configuring IP Multicast in VPLS

Use the **config>service>vpls>igmp-snooping** (or **mld-snooping**) command to enable IP multicast in VPLS. The **igmp-snooping** and **mld-snooping** commands stop the default flooding of multicast traffic and allow the creation of a multicast forwarding database (MFIB) on a per-port basis.

The following displays a VPLS configuration with IGMP snooping. Configuring MLD snooping is similar except that the **mld-snooping** command and IPv6 addresses are used instead of the **igmp-snooping** command and IPv4 addresses:

```
*A:ALU-1>config>service>vpls# info

description "Default tls description for service id 1"
service-mtu 1400
stp
 shutdown
exit
igmp-snooping
 no shutdown
exit
service-name "snooper"
sap 1/1/5:12 create
 description "Default sap description for service id 1"
exit
sap 1/1/5:34 create
 description "Default sap description for service id 1"
exit
mesh-sdp 21:1 create
 no shutdown
exit
spoke-sdp 23:1 create
 no shutdown
exit
no shutdown

*A:ALU-1>config>service>vpls#
```

## 5.16 Configuring IP Multicast in r-VPLS

Configuring IP multicast in a routed VPLS requires several steps.

Creating a Layer 2 multicast service in the context of an r-VPLS with PIM translation configured on the r-VPLS Layer 3 interface creates two multicast groups: one Layer 2 multicast group and one Layer 3 multicast group. Creating the Layer 2 multicast group automatically creates the Layer 3 group. It is not necessary to create both groups. The 7705 SAR uses one Layer 3 multicast group per source, and one Layer 2 multicast group per source per VPLS. See [IP Multicast in r-VPLS](#) for details.

Perform the following steps to create Layer 2 and Layer 3 multicast groups on a SAP or SDP.

1. Create an r-VPLS by using the **vpls>allow-ip-int-binding** command and the **ies>interface>vpls service-name** command.
2. Configure IGMP or MLD on IES to form the link between Layer 3 and Layer 2.
3. Configure PIM on a network interface to allow the propagation of multicast join messages into the network.
4. (Optional) Configure the Layer 2 multicast service parameters, as described in [Configuring Multicast Parameters for VPLS and r-VPLS](#).

The following displays illustrate step 1 to step 3 for an r-VPLS configuration with IGMP snooping. Configuring MLD snooping is similar except that the **mld-snooping** command and IPv6 addresses are used instead of the **igmp-snooping** command and IPv4 addresses.

To create the r-VPLS:

```
*A:ALU-1>config>service>vpls# info

description "Default tls description for service id 1"
service-mtu 1400
allow-ip-int-binding
stp
 shutdown
exit
igmp-snooping
 no shutdown
exit
service-name "snooper"
sap 1/1/5:12 create
 description "Default sap description for service id 1"
exit
sap 1/1/5:34 create
 description "Default sap description for service id 1"
exit
mesh-sdp 21:1 create
 no shutdown
```

```

 exit
 spoke-sdp 23:1 create
 no shutdown
 exit
 no shutdown

*A:ALU-1>config>service>vpls#

*A:ALU-1>config>service>ies# info

 description "Default Ies description for service id 2"
 interface "rvpls_ies" create
 address 192.168.0.0/16
 ipv6
 address 2001:db8:a::123
 exit
 vpls "snooper"
 exit
 exit
 service-name "XYZ Ies 2"
 no shutdown

*A:ALU-1>config>service>ies#

```

### To link Layer 3 and Layer 2:

```

*A:ALU-1>config>router>igmp# info

 interface "rvpls_ies"
 no shutdown
 exit
 no shutdown

*A:ALU-1>config>router>igmp#

```

### To configure PIM on a network interface:

```

*A:ALU-1>config>router>pim# info

 no ipv6-multicast-disable
 interface "PimtoDut4"
 exit
 rp
 exit
 no shutdown

*A:ALU-1>config>router>pim#

```

## 5.17 Configuring Multicast Parameters for VPLS and r-VPLS

The 7705 SAR supports multicast for VPLS and r-VPLS through IGMP and MLD snooping at the VPLS service level, as well as at the VPLS SAP and SDP (mesh and spoke) levels. Note the following considerations for IGMP and MLD snooping on a SAP or SDP.

- A filter policy can be imported on a SAP or SDP. Import policies are defined in the **config>router>policy-options** context. Refer to the “Filter Policies” section in the 7705 SAR Router Configuration Guide for details.
- A SAP or SDP can be configured as a multicast router port (**mrouter-port**), meaning that a multicast router is attached to this port. However, the **mrouter-port** and the **send-queries** commands are mutually exclusive commands.
- A static multicast group can be configured on a SAP or SDP (see [Configuring a Static Multicast Group](#)).
- The **send-queries** command must be enabled for the following commands to be operational: **query-interval**, **query-response-interval**, **robust-count**, and **version**.

Use the following CLI syntax to configure IGMP snooping parameters for VPLS and r-VPLS. Configuring MLD snooping parameters is similar except that the **mld-snooping** command and IPv6 addresses are used instead of the **igmp-snooping** command and IPv4 addresses.

**CLI Syntax:**

```
config>service>vpls# igmp-snooping
 query-interval seconds
 query-src-ip ip-address
 report-src-ip ip-address
 robust-count robust-count
```

The following displays IGMP snooping configuration for a VPLS service:

```
*A:ALU-1>config>service>vpls>igmp-snooping# info detail

no shutdown
query-interval 125
robust-count 2
report-src-ip 10.0.0.0
no query-src-ip

*A:ALU-1>config>service>vpls>igmp-snooping#
```

Use the following CLI syntax to configure IGMP snooping on a SAP. Configuring IGMP snooping on an SDP is similar. Configuring MLD snooping on a SAP or SDP is also similar, except that the **mld-snooping** command and IPv6 addresses are used instead of the **igmp-snooping** command and IPv4 addresses, and the **max-num-grp-sources** and **max-num-sources** commands do not apply.

**CLI Syntax:**

```

config>service>vpls# sap sap-id
config>service>vpls>sap# igmp-snooping
config>service>vpls>sap>igmp-snooping#
 [no] disable-router-alert-check
 [no] fast-leave
 [no] import policy-name
 [no] last-member-query-interval interval
 [no] max-num-groups max-num-groups
 [no] max-num-grp-sources max-num-grp-sources
 [no] max-num-sources max-num-sources
 [no] mrouter-port
 [no] query-interval seconds
 [no] query-response-interval seconds
 [no] robust-count robust-count
 [no] send-queries
 [no] static
 [no] group grp-ip-address
 [no] source ip-address
 [no] starg
 [no] version version

```

The following displays IGMP snooping configuration for a VPLS service:

```

*A:ALU-1>config>service>vpls>sap>igmp-snooping# info detail

no fast-leave
no import
no max-num-groups
no max-num-sources
no max-num-grp-sources
last-member-query-interval 10
mrouter-port
query-interval 125
query-response-interval 10
robust-count 2
version 3
no send-queries
no disable-router-alert-check

*A:ALU-1>config>service>vpls>sap>igmp-snooping#

```

## 5.18 Configuring a Static Multicast Group

A static multicast group is not created until the **source** or **starg**—(\*,G)—is specified. More than one group can be created per SAP or SDP, and more than one source can be added to a group. A static source cannot be added to a group if a starg already exists in the group.

Use the following CLI syntax to configure a static group for IGMP snooping on a VPLS SAP. Configuring a static group for IGMP snooping on an SDP is similar. Configuring a static group for MLD snooping on a SAP or SDP is also similar, except that the **mld-snooping** command and IPv6 addresses are used instead of the **igmp-snooping** command and IPv4 addresses.

**CLI Syntax:**

```
config>service>vpls>sap# igmp-snooping
config>service>vpls>sap>igmp-snooping#
 [no] static
 [no] group grp-ip-address
 [no] source ip-address
 [no] starg
```

The following displays a static group configuration for IGMP snooping on a VPLS SAP (multiple groups and multiple sources):

```
*A:ALU-1>config>service>vpls>sap>igmp-snooping# info

 send-queries
 static
 group 192.0.2.0
 starg
 exit
 group 192.0.2.1
 source 192.0.2.10
 source 192.0.2.11
 exit
 exit

*A:ALU-1>config>service>vpls>sap>igmp-snooping#
```

## 5.19 Configuring PIM Snooping for VPLS

Use the **pim-snooping** command to connect a source in a Layer 2 access network to the host in a Layer 3 core network.

Use the following CLI syntax to configure PIM snooping for VPLS and to configure the maximum number of multicast groups for PIM snooping for VPLS SAPs and spoke SDPs.

**CLI Syntax:**

```
config>service>vpls#
pim-snooping
 [no] group-policy grp-policy-name [grp-policy-name...up to 5 max]
 [no] hold-time seconds
 [no] ipv4-multicast-disable
 [no] ipv6-multicast-disable
 mode [snoop | proxy]
```

**CLI Syntax:**

```
config>service>vpls>sap#
pim-snooping
 [no] max-num-groups max-num-groups
```

**CLI Syntax:**

```
config>service>vpls>spoke-sdp#
pim-snooping
 [no] max-num-groups max-num-groups
```

The following displays a VPLS configuration with PIM snooping.

```
*A:ALU>config>service>vpls>pim-snooping# info detail

mode proxy
hold-time 90
no group-policy
no ipv4-multicast-disable
ipv6-multicast-disable

*A:ALU>config>service>vpls>pim-snooping#

*A:ALU>config>service>vpls>sap>pim-snooping# info detail

no max-num-groups

*A:ALU>config>service>vpls>sap>pim-snooping#
```

---

## 5.20 Service Management Tasks

This section discusses the following service management tasks:

- [Modifying VPLS Service Parameters](#)
- [Modifying Management VPLS Parameters](#)
- [Deleting a Management VPLS](#)
- [Disabling a Management VPLS](#)
- [Deleting a VPLS Service](#)
- [Disabling a VPLS Service](#)
- [Re-enabling a VPLS Service](#)

### 5.20.1 Modifying VPLS Service Parameters

You can change existing service parameters. The changes are applied immediately.

To display a list of services, use the **show service service-using vpls** command. Enter the parameters such as description, SAP, SDP, and/or service-MTU command syntax, and then enter the new information.

The following displays a modified VPLS configuration:

```
*A:ALU-1>config>service>vpls# info

description "This is a different description."
disable-learning
disable-aging
discard-unknown
local-age 500
remote-age 1000
stp
 shutdown
exit
sap 1/1/5:22 create
 description "VPLS SAP"
exit
spoke-sdp 2:22 create
exit
no shutdown

*A:ALU-1>config>service>vpls#
```

---

## 5.20.2 Modifying Management VPLS Parameters

To modify the range of VLANs on an access port that are to be managed by an existing management VPLS, first the new range should be entered and then the old range removed. If the old range is removed before a new range is defined, all customer VPLS services in the old range will become unprotected and may be disabled.

**CLI Syntax:**

```
config>service# vpls service-id
sap sap-id
managed-vlan-list
[no] range vlan-range
```

## 5.20.3 Deleting a Management VPLS

As with normal VPLS service, a management VPLS cannot be deleted until SAPs are unbound (deleted), interfaces are shut down, and the service is shut down on the service level.

Use the following CLI syntax to delete a management VPLS service:

**CLI Syntax:**

```
config>service
[no] vpls service-id
shutdown
[no] sap sap-id
shutdown
```

## 5.20.4 Disabling a Management VPLS

You can shut down a management VPLS without deleting the service parameters.

When a management VPLS is disabled, all associated user VPLS services are also disabled (to prevent loops). If this is not desired, first unmanage the user's VPLS service by removing them from the managed-vlan-list.

**CLI Syntax:**

```
config>service
vpls service-id
shutdown
```

**Example:**

```
config>service# vpls 1
config>service>vpls# shutdown
config>service>vpls# exit
```

---

## 5.20.5 Deleting a VPLS Service

A VPLS service cannot be deleted until SAPs and SDPs are unbound (deleted), interfaces are shut down, and the service is shut down on the service level.

Use the following CLI syntax to delete a VPLS service:

**CLI Syntax:**

```
config>service
 [no] vpls service-id
 shutdown
 [no] mesh-sdp sdp-id
 shutdown
 sap sap-id [split-horizon-group group-name]
 no sap sap-id
 shutdown
```

## 5.20.6 Disabling a VPLS Service

Use the following CLI syntax to shut down a VPLS service without deleting the service parameters:

**CLI Syntax:**

```
config>service> vpls service-id
 [no] shutdown
```

**Example:**

```
config>service# vpls 1
config>service>vpls# shutdown
config>service>vpls# exit
```

## 5.20.7 Re-enabling a VPLS Service

To re-enable a VPLS service that was shut down:

**CLI Syntax:**

```
config>service> vpls service-id
 [no] shutdown
```

**Example:**

```
config>service# vpls 1
config>service>vpls# no shutdown
config>service>vpls# exit
```

## 5.21 VPLS Command Reference

### 5.21.1 Command Hierarchies

- [VPLS Service Configuration Commands](#)
  - [Global Commands](#)

| <b>Context</b>       | <pre> config&gt;service&gt;vpls config&gt;service&gt;vpls&gt;mac-move config&gt;service&gt;vpls&gt;split-horizon-group config&gt;service&gt;vpls&gt;sap config&gt;service&gt;vpls&gt;sap&gt;dhcp config&gt;service&gt;vpls&gt;mesh-sdp config&gt;service&gt;vpls&gt;spoke-sdp config&gt;service&gt;vpls&gt;spoke-sdp&gt;stp config&gt;service&gt;vpls&gt;stp config&gt;service&gt;vpls&gt;sap&gt;stp config&gt;service&gt;vpls&gt;igmp-snooping config&gt;service&gt;vpls&gt;sap&gt;igmp-snooping config&gt;service&gt;vpls&gt;spoke-sdp&gt;igmp-snooping config&gt;service&gt;vpls&gt;mesh-sdp&gt;igmp-snooping </pre>                                                                                                                                                                  |
| <b>Description</b>   | <p>This command administratively disables an entity. When disabled, an entity does not change, reset, or remove any configuration settings or statistics.</p> <p>The operational state of the entity is disabled as well as the operational state of any entities contained within. Many objects must be shut down before they can be deleted.</p> <p>Services are created in the administratively down (<b>shutdown</b>) state. When a <b>no shutdown</b> command is entered, the service becomes administratively up and then tries to enter the operationally up state. Default administrative states for services and service entities are described below in Special Cases.</p> <p>The <b>no</b> form of this command places the entity into an administratively enabled state.</p> |
| <b>Special Cases</b> | <p><b>Service Admin State</b> — bindings to an SDP within the service will be put into the out-of-service state when the service is shut down. While the service is shut down, all customer packets are dropped and counted as discards for billing and debugging purposes.</p> <p><b>Service Operational State</b> — a service is regarded as operational providing that two SAPs or one SDP are operational</p> <p><b>SDP (global)</b> — when an SDP is shut down at the global service level, all bindings to that SDP are put into the out-of-service state and the SDP itself is put into the administratively and operationally down states. Packets that would normally be transmitted using this SDP binding will be discarded and counted as dropped packets.</p>               |

- SDP (service level)** — shutting down an SDP within a service only affects traffic on that service from entering or being received from the SDP. The SDP itself may still be operationally up for other services.
- SDP Keepalives** — enables SDP connectivity monitoring keepalive messages for the SDP ID. The default state is disabled (shutdown), in which case the operational state of the SDP-ID is not affected by the keepalive message state.
- VPLS SAPs and SDPs** — SAPs are created in a VPLS and SDPs are bound to a VPLS in the administratively up default state. The created SAP will attempt to enter the operationally up state. An SDP will attempt to go into the in-service state once bound to the VPLS.

description

| <b>Syntax</b>      | <b>vpls</b> <i>service-id</i> [ <b>customer</b> <i>customer-id</i> ] [ <b>m-vpls</b> ] [ <b>create</b> ]<br><b>no vpls</b> <i>service-id</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Context</b>     | config>service                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Description</b> | <p>This command creates or edits a Virtual Private LAN Services (VPLS) instance. If the <i>service-id</i> does not exist, a context for the service is created. If the <i>service-id</i> exists, the context for editing the service is entered.</p> <p>A VPLS service connects multiple customer sites together acting like a zero-hop, Layer 2 switched domain. A VPLS is always a logical full mesh.</p> <p>When a service is created, the <b>create</b> keyword and the <b>customer</b> keyword and <i>customer-id</i> must be specified in order to associate the service with a customer. The <i>customer-id</i> must already exist (created using the <b>customer</b> command in the service context). Once a service has been created with a customer association, it is not possible to edit the customer association. To edit the customer association, the service must be deleted and recreated with a new customer association.</p> <p>To create a management VPLS, include the <b>m-vpls</b> keyword when creating the VPLS. Associate a range of VLANs with the mVPLS by using the <b>managed-vlan-list</b> command.</p> <p>Once a service is created, the use of the <b>customer</b> <i>customer-id</i> is optional for navigating into the service configuration context. Attempting to edit a service with the incorrect <i>customer-id</i> specified will result in an error.</p> <p>More than one VPLS service may be created for a single customer ID.</p> <p>By default, no VPLS instances exist until they are explicitly created.</p> <p>The <b>no</b> form of this command deletes the VPLS service instance with the specified <i>service-id</i>. The service cannot be deleted until all SAPs and SDPs defined within the service ID have been shut down and deleted, and the service has been shut down.</p> |
| <b>Parameters</b>  | <p><i>service-id</i> — the unique service identification number or name that identifies the service in the service domain. This ID must be unique to this service and may not be used for any other service of any type. The <i>service-id</i> must be the same number or name used for every 7705 SAR on which this service is defined.</p> <p><b>Values</b> 1 to 2147483647 or <i>service-name</i></p> <p><b>customer</b> <i>customer-id</i> — specifies the customer ID number to be associated with the service. This parameter is required on service creation and is optional for service editing or deleting. The <i>customer-id</i> is not used with routed VPLS.</p> <p><b>Values</b> 1 to 2147483647</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**m-vpls** — this keyword specifies that the VPLS is a management VPLS

**create** — this keyword is mandatory when creating a VPLS service

| <b>Description</b> | This command enables blocking (brings the entity to an operationally down state) after all configured SDPs or endpoints are in operationally down state. This event is signaled to a corresponding T-LDP peer by withdrawing the service label (status-bit-signaling non-capable peer) or by setting the “PW not forwarding” status bit in the T-LDP message (status-bit-signaling capable peer). |

| <b>Description</b> | <p>This command disables MAC address aging across a VPLS service or on a VPLS service SAP or spoke SDP.</p> <p>As is the case for a Layer 2 switch, learned MACs can be aged out if no packets are sourced from the MAC address for a period of time (the aging time). In each VPLS service instance, there are independent aging timers for local learned MAC and remote learned MAC entries in the VPLS forwarding database (FDB). The <b>disable-aging</b> command turns off aging for local and remote learned MAC addresses.</p> <p>When <b>no disable-aging</b> is specified for a VPLS, it is possible to disable aging for specific SAPs and/ or spoke SDPs by entering the <b>disable-aging</b> command at the appropriate level.</p> <p>When the <b>disable-aging</b> command is entered at the VPLS level, the <b>disable-aging</b> state of individual SAPs or SDPs will be ignored.</p> <p>The <b>no</b> form of this command enables aging on the VPLS service.</p> |
| <b>Default</b>     | no disable-aging                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Description</b> | <p>This command disables learning of new MAC addresses in the VPLS forwarding database (FDB) for the service instance, SAP instance, or spoke SDP instance.</p> <p>When <b>disable-learning</b> is enabled, new source MAC addresses will not be entered in the VPLS service forwarding database. This is true for both local and remote MAC addresses.</p> <p>When <b>disable-learning</b> is disabled, new source MAC addresses will be learned and entered into the VPLS forwarding database.</p> <p>This parameter is mainly used in conjunction with the <b>discard-unknown</b> command.</p> <p>The <b>no</b> form of this command enables learning of MAC addresses.</p> |
| <b>Default</b>     | no disable-learning (Normal MAC learning is enabled)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## discard-unknown

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Description</b> | <p>When this command is enabled, the node will ignore the standby bit received from T-LDP peers for the given spoke SDP and performs internal tasks without taking the standby bit into account—traffic can egress out to the spoke SDP.</p> <p>This command is present at the endpoint level as well as at the spoke SDP level. If the spoke SDP is part of the explicit endpoint, it is not possible to change this setting at the spoke SDP level. The existing spoke SDP will become part of the explicit endpoint only if the setting is not conflicting. The newly created spoke SDP that is a part of the given explicit endpoint will inherit this setting from the endpoint configuration.</p> |
| <b>Default</b>     | enabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Description</b> | <p>This command configures the time to wait before reverting to the primary spoke SDP.</p> <p>For a regular endpoint, the <i>revert-time</i> setting affects only the pseudowire defined as “primary” (precedence 0). If the primary pseudowire fails and is then restored, the revert timer is started. After the revert timer expires, the primary pseudowire takes the active role in the endpoint. This behavior does not apply if both pseudowires are defined as “secondary”. For example, if the active secondary pseudowire fails and is restored, it will stay in standby until a configuration change or a force command occurs.</p> |
| <b>Parameters</b>  | <p><i>revert-time</i> — specifies the time to wait, in seconds, before reverting to the primary spoke SDP defined on this service endpoint, after having failed to move over to a backup spoke SDP</p> <p><b>Values</b> 0 to 600</p> <p><b>infinite</b> — specifying this keyword makes the endpoint non-revertive</p>                                                                                                                                                                                                                                                                                                                         |

## static-mac

|                    |                                                                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>static-mac</b> <i>ieee-address</i> [ <b>create</b> ]<br><b>no static-mac</b>                                                             |
| <b>Context</b>     | config>service>vpls>endpoint                                                                                                                |
| <b>Description</b> | This command assigns a static MAC address to the endpoint. In the FDB, the static MAC address is then associated with the active spoke SDP. |
| <b>Default</b>     | n/a                                                                                                                                         |
| <b>Parameters</b>  | <i>ieee-address</i> — specifies the static MAC address assigned to the endpoint                                                             |
| <b>Values</b>      | 6-byte MAC address (xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx) - cannot be all zeros                                                           |
|                    | <b>create</b> — this keyword is mandatory when creating a static MAC address                                                                |

## suppress-standby-signaling

|                    |                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] <b>suppress-standby-signaling</b>                                                                                                                                                                                                                                                                                                                     |
| <b>Context</b>     | config>service>vpls>endpoint                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | When this command is enabled, the pseudowire standby bit (value 0x00000020) will not be sent to the T-LDP peer when the given spoke SDP is selected as a standby. This allows faster switchover because the traffic will be sent over this SDP and discarded at the blocking side of the connection. This is particularly applicable to multicast traffic. |
| <b>Default</b>     | enabled                                                                                                                                                                                                                                                                                                                                                    |

## pim-snooping

|                    |                                                                                                                                                                                                                                                                                                           |

| <b>Description</b> | <p>This command identifies one or more route policies for multicast groups applied to this VPLS entity. The sources of the multicast traffic must be members of the VPLS.</p> <p>Routing policies are configured in the <b>config&gt;router&gt;policy-options</b> context. The router policy must be defined before it can be imported. The <i>grp-policy-name</i> variable is the same as the <i>name</i> variable in the <b>policy-options&gt;policy-statement</b> <i>name</i> command.</p> <p>For details on route policies, refer to the “Route Policies” section in the 7705 SAR Router Configuration Guide.</p> <p>The <b>no</b> form of the command removes the policy association from the VPLS configuration.</p> |

| <b>Description</b> | <p>This command configures the length of time during which the PIM snooping switch snoops all the PIM states in the VPLS. During the <b>hold-time</b>, multicast traffic is flooded in the VPLS. At the end of the <b>hold-time</b>, multicast traffic is forwarded using the snooped states. The snooped state consists of the forwarding state for the (S,G) and (*,G) groups, the incoming interface, and the outgoing interfaces.</p> <p>When PIM snooping is enabled in VPLS, there is a period of time when the PIM snooping switch may not have built the complete snooping state. The switch cannot build states until the routers connected to the VPLS refresh their PIM messages.</p> <p>This parameter is applicable only when PIM snooping is enabled.</p> |               |          |                |    |

| <b>Description</b> | <p>When enabled, this command appends Agent-Circuit-Id information to PADI and PADR packets received from an ATM SAP (the subscriber) that is bound to a VPLS instance. The Agent-Circuit-Id information is compliant with RFC 4679 section-3.3.1; Agent-Circuit-Id. The ATM SAP must be configured for bridged llc-snap encapsulation.</p> <p>The <b>pppoe-circuit-id</b> command can be enabled or disabled for a VPLS instance or an individual ATM SAP. When applied to a VPLS instance, <b>pppoe-circuit-id</b> appends the Agent-Circuit-Id to all ATM SAPs bound to that VPLS instance. Furthermore, <b>pppoe-circuit-id</b> can be applied to individual SAPs bound to that VPLS instance in order to override the VPLS setting. If there is a mix of enabled and disabled SAPs bound to the VPLS instance, applying the command to the VPLS will override the mix, enabling (or disabling) <b>pppoe-circuit-id</b> on all the SAPs.</p> <p>In addition, any newly created SAPs bound to the VPLS will default to match the VPLS setting.</p> <p>As per the DSL Forum TR-101 April'06 specification, section 3.9.2, any PPPoE vendor-specific tag that may already be present in the received frame is replaced by the 7705 SAR client-id tag.</p> <p>The <b>no</b> version of this command disables appending the Agent-Circuit-Id information.</p> |
| <b>Default</b>     | disabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Description</b> | This command specifies the lower threshold value for FDB entries. The <i>low-water-mark</i> is configured as a percentage of the FDB. When the number of FDB entries drops below the <i>low-water-mark</i> , the system raises a log event. |
| <b>Parameters</b>  | <i>low-water-mark</i> — specifies the lower threshold for FDB entries, which when dropped below, causes the system to raise a log event                                                                                                     |
| <b>Values</b>      | 1 to 100                                                                                                                                                                                                                                    |
| <b>Default</b>     | 90%                                                                                                                                                                                                                                         |

## fdb-table-size

|                    |                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>fdb-table-size</b> <i>table-size</i><br><b>no fdb-table-size</b> [ <i>table-size</i> ]                                                                                                                                                                                                                                                                 |
| <b>Context</b>     | config>service>vpls                                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b> | <p>This command specifies the maximum number of MAC entries in the FDB for the VPLS instance on this node.</p> <p>The <b>fdb-table-size</b> specifies the maximum number of FDB entries for both learned and static MAC addresses for the VPLS instance.</p> <p>The <b>no</b> form of this command returns the maximum FDB table size to the default.</p> |
| <b>Default</b>     | 250                                                                                                                                                                                                                                                                                                                                                       |

| <b>Description</b> | <p>This command enables or disables Layer 4 load balancing for the VPLS instance. When enabled, Layer 4 source and destination port fields of incoming TCP/UDP packets are included in the hashing calculation to randomly determine the distribution of packets.</p> <p>Adding the Layer 4 source and destination port fields to the hashing algorithm generates a higher degree of randomness and a more even distribution of packets across the available LAG ports.</p> <p>You can add additional fields to generate more randomness and more equal distribution of packets with the <a href="#">teid-load-balancing</a> command.</p> <p>Hashing based on the <b>l4-load-balancing</b> and <b>teid-load-balancing</b> commands and hashing based on the <b>per-service-hashing</b> command are mutually exclusive.</p> <p>The <b>no</b> form of the command disables Layer 4 load balancing.</p> |
| <b>Default</b>     | no l4-load-balancing                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## per-service-hashing

|                    |                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] per-service-hashing</b>                                                                                                                                                                                                                                                                                                                   |
| <b>Context</b>     | config>service>vpls>load-balancing                                                                                                                                                                                                                                                                                                                |
| <b>Description</b> | <p>This command enables or disables hashing based on the service ID. The result of the hashing calculation is used to determine the distribution of packets.</p> <p>Hashing based on the <b>per-service-hashing</b> command and hashing based on the <b>l4-load-balancing</b> and <b>teid-load-balancing</b> commands are mutually exclusive.</p> |

**Note:** Starting with Release 8.0.R4, unless **per-service-hashing** is enabled, a 4-byte hash value will be appended to internal overhead for VPLS multicast traffic at ingress. The egress internal hash value is discarded at egress before scheduling. Therefore, shaping rates at access and network ingress and for fabric policies may need to be adjusted accordingly. In addition, the 4-byte internal hash value may be included in any affected statistics counters.

The **no** form of the command disables per-service hashing.

**Default** no per-service-hashing

spi-load-balancing

**Syntax** [no] spi-load-balancing

**Context** config>service>vpls>load-balancing

**Description** This command enables use of the SPI in hashing for ESP/AH encrypted IPv4 or IPv6 traffic at the interface level.

The **no** form of this command disables SPI hashing.

**Default** no spi-load-balancing

teid-load-balancing

**Syntax** [no] teid-load-balancing

**Context** config>service>vpls>load-balancing

**Description** This command enables or disables TEID load balancing for the VPLS instance. The TEID attribute is included in the header of GTP (general packet radio system tunneling protocol) packets. When TEID load balancing is enabled, the TEID field of incoming TCP/UDP packets is included in the hashing calculation to randomly determine the distribution of packets.

You can add additional fields to generate more randomness and more equal distribution of packets with the [l4-load-balancing](#) command.

Hashing based on the **teid-load-balancing** and **l4-load-balancing** commands and hashing based on the **per-service-hashing** command are mutually exclusive.

The **no** form of the command disables TEID load balancing.

**Default** no teid-load-balancing

| <b>Description</b> | <p>This command specifies the aging time for locally learned MAC addresses in the FDB for the VPLS instance. In a VPLS service, MAC addresses are associated with a SAP or SDP. MACs associated with a SAP are classified as local MACs, and MACs associated with an SDP are remote MACs.</p> <p>As is the case for a Layer 2 switch, learned MACs can be aged out if no packets are sourced from the MAC address for a period of time (the aging time). In each VPLS service instance, there are independent aging timers for locally learned MAC and remotely learned MAC entries in the FDB. The <b>local-age</b> timer specifies the aging time for locally learned MAC addresses.</p> <p>The <b>no</b> form of this command returns the local aging timer to the default value.</p> |

| <b>Description</b> | <p>This command enables the context to configure MAC move attributes. A sustained, high relearn rate can be a sign of a loop somewhere in the VPLS topology. Typically, the spanning tree protocol (STP) detects loops in the topology, but for those networks that do not run STP, the <b>mac-move</b> feature is an alternative way to protect the network against loops.</p> <p>When enabled in a VPLS, <b>mac-move</b> monitors the relearn rate of each MAC. If the rate exceeds the configured maximum allowed limit, it disables the SAP where the source MAC was last seen. The SAP can be disabled permanently (until a <b>shutdown/no shutdown</b> command is executed) or for a length of time that increases linearly with the number of times the given SAP was disabled. A SAP can be configured as non-blockable with the <a href="#">limit-mac-move</a> command. This means that when the relearn rate has exceeded the limit, another (blockable) SAP will be disabled instead. By default, all SAPs and spoke SDPs are configured as blockable when MAC-move is enabled.</p> <p>When MAC-move is enabled and the relearn rate exceeds the maximum limit, the 7705 SAR sends a “Mac move rate for MAC ... exceeded” alarm. This alarm is raised for both blockable and non-blockable SAPs and spoke SDPs. The alarm frequency for non-blockable SAPs and spoke SDPs decreases if the MAC-move condition persists.</p> |

The **mac-move** command enables the feature at the service level for SAPs and spoke SDPs, as only those objects can be blocked by this feature. Mesh SDPs are never blocked, but their relearn rates (SAP-to-mesh/spoke-to-mesh or vice versa) are still measured.

The operation of this feature is the same on the SAP and spoke SDP. For example, if a MAC address moves from SAP to SAP, from SAP to spoke SDP, or between spoke SDPs, one will be blocked to prevent thrashing. If the MAC address moves between a SAP and mesh SDP or spoke SDP and mesh SDP combinations, the respective SAP or spoke SDP will be blocked.

The **mac-move** command will disable a VPLS port when the number of relearns detected has reached the number of relearns needed to reach the move frequency in the 5-s interval. For example, when the move frequency is configured to 1 (1 relearn per second), **mac-move** will disable one of the VPLS ports when 5 relearns were detected during the 5-s interval because the average move frequency of 1 relearn per second has been reached. This can also occur in the first second if the relearn rate is 5 relearns per second or higher.

The **no** form of this command disables MAC move.

| <b>Description</b> | This command specifies the number of bits to be considered when performing MAC learning (MAC source) and MAC switching (MAC destination). Specifically, this value identifies how many bits are used, starting from the beginning of the MAC address. For example, if the mask value of 28 is used, MAC learning will only do a lookup for the first 28 bits of the source MAC address when comparing it with existing FDB entries. Then, it will install the first 28 bits in the FDB while zeroing out the last 20 bits of the MAC address. When performing switching in the reverse direction, only the first 28 bits of the destination MAC address will be used to perform an FDB lookup to determine the next hop.<br><br>The <b>no</b> form of this command switches back to full MAC lookup. |
| <b>Parameters</b>  | <i>subnet-length</i> — specifies the number of bits to be considered when performing MAC learning or MAC switching                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | This command indicates the maximum rate at which MACs can be relearned in the VPLS service before the SAP where the moving MAC was last seen is automatically disabled in order to protect the system against undetected loops or duplicate MACs.<br><br>The <b>no</b> form of the command reverts to the default value |
| <b>Default</b>     | 2 (when <b>mac-move</b> is enabled); for example, 10 relearns in a 5-s period.                                                                                                                                                                                                                                          |
| <b>Parameters</b>  | <i>frequency</i> — specifies the rate, in 5-s intervals, for the maximum number of relearns<br><b>Values</b> 1 to 10                                                                                                                                                                                                    |

## number-retries

|                    |                                                                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>number-retries</b> <i>number-retries</i><br><b>no number-retries</b>                                                                                                   |
| <b>Context</b>     | config>service>vpls>mac-move                                                                                                                                              |
| <b>Description</b> | This command configures the number of times that retries are performed for re-enabling the SAP or SDP bindings.                                                           |
| <b>Parameters</b>  | <i>number-retries</i> — specifies the number of retries for re-enabling the SAP/SDP. A zero (0) value indicates an unlimited number of retries.<br><b>Values</b> 0 to 255 |

## primary-ports

|                    |                                                                                                                                                                                                                                                                                                                                      |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>primary-ports</b>                                                                                                                                                                                                                                                                                                                 |
| <b>Context</b>     | config>service>vpls>mac-move                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | This command enables the context to define primary VPLS ports. VPLS ports that were declared as secondary prior to the execution of this command will be moved from secondary port level to primary port level. Changing a port to the tertiary level (default) can only be done by first removing it from the secondary port level. |

## cumulative-factor

|                |                                                                                            |
|----------------|--------------------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>cumulative-factor</b> <i>cumulative-factor</i><br><b>no cumulative-factor</b>           |
| <b>Context</b> | config>service>vpls>mac-move>primary-ports<br>config>service>vpls>mac-move>secondary-ports |

---

|                    |                                                                                                                                                                                                                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | This command configures a factor for the primary or secondary ports that defines how many MAC relearn periods should be used to measure the MAC relearn rate. The rate must be exceeded during consecutive periods before the corresponding ports (SAP and/or spoke SDP) are blocked by the <b>mac-move</b> feature. |
| <b>Parameters</b>  | <i>cumulative-factor</i> — specifies a MAC relearn period to be used for the MAC relearn rate                                                                                                                                                                                                                        |
| <b>Values</b>      | 3 to 10                                                                                                                                                                                                                                                                                                              |

## sap

|                    |                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] sap</b> <i>sap-id</i>                                                                                                                  |
| <b>Context</b>     | config>service>vpls>mac-move>primary-ports<br>config>service>vpls>mac-move>secondary-ports                                                     |
| <b>Description</b> | This command configures the specified SAP to be a primary or secondary VPLS port.                                                              |
| <b>Parameters</b>  | <i>sap-id</i> — specifies the physical port identifier portion of the SAP definition. See <a href="#">Table 41</a> for a full list of SAP IDs. |

## spoke-sdp

|                    |                                                                                                                                                                                                |                  |                     |                |            |               |                 |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|---------------------|----------------|------------|---------------|-----------------|

| <b>Context</b>     | config>service>vpls>mac-move                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | <p>This command indicates the time, in seconds, to wait before a SAP that has been disabled after exceeding the maximum relearn rate is re-enabled.</p> <p>It is recommended that the <i>timeout</i> value be equal to or larger than <math>5\text{ s} \times \text{cumulative factor}</math> of the highest-priority port so that the sequential order of port blocking will not be disturbed by reinitializing lower-priority ports.</p> <p>A zero value indicates that the SAP will not automatically be re-enabled after being disabled. If, after the SAP is re-enabled it is disabled again, the effective retry timeout is doubled in order to avoid thrashing.</p> <p>The <b>no</b> form of the command reverts to the default value.</p> |
| <b>Default</b>     | 10 (when <b>mac-move</b> is enabled)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Description</b> | <p>This command specifies the aging time for remotely learned MAC addresses in the FDB for the VPLS instance. In a VPLS service, MAC addresses are associated with a SAP or an SDP. MACs associated with a SAP are classified as local MACs, and MACs associated with an SDP are remote MACs.</p> <p>As is the case for a Layer 2 switch, learned MACs can be aged out if no packets are sourced from the MAC address for a period of time (the aging time). In each VPLS service instance, there are independent aging timers for locally learned MAC and remotely learned MAC entries in the FDB. The <b>remote-age</b> timer specifies the aging time for remotely learned MAC addresses. To reduce the amount of signaling required between switches, configure this timer to be larger than the <b>local-age</b> timer.</p> <p>The <b>no</b> form of this command returns the remote aging timer to the default value.</p> |
| <b>Default</b>     | 900                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Description</b> | This command enables sending out “flush-all-from-ME” messages to all LDP peers included in the affected VPLS, in the event of physical port failures or “oper-down” events of individual SAPs. This feature provides an LDP-based mechanism for recovering a physical link failure in a dual-homed connection to a VPLS service. This method provides an alternative to Rapid Spanning Tree Protocol (RSTP) solutions where dual homing redundancy and recovery, in the case of link failure, is resolved by RSTP running between a PE router and CE devices. If the endpoint is configured within the VPLS and <b>send-flush-on-failure</b> is enabled, “flush-all-from-ME” messages will be sent out only when all spoke SDPs associated with the endpoint go down. |
| <b>Default</b>     | no send-flush-on-failure                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Description</b> | <p>This command configures the service payload Maximum Transmission Unit (MTU), in bytes, for the service. This MTU value overrides the service-type default MTU. The <b>service-mtu</b> defines the payload capabilities of the service. It is used by the system to validate the SAP and SDP bindings' operational state within the service.</p> <p>The service MTU and a SAP's service delineation encapsulation overhead (that is, 4 bytes for a dot1q tag or 8 bytes for a qinq tag) are used to derive the required MTU of the physical port or channel on which the SAP was created. If the required payload is larger than the port or channel MTU, the SAP will be placed in an inoperative state. If the required MTU is equal to or less than the port or channel MTU, the SAP will be able to transition to the operative state.</p> <p>When binding an SDP to a service, the service MTU is compared to the path MTU associated with the SDP. The path MTU can be administratively defined in the context of the SDP. The default or administrative path MTU can be dynamically reduced due to the MTU capabilities discovered by the tunneling mechanism of the SDP or the egress interface MTU capabilities based on the next hop in the tunnel path. If the service MTU is larger than the path MTU, the SDP binding for the service will be placed in an inoperative state. If the service MTU is equal to or less than the path MTU, then the SDP binding will be placed in an operational state.</p> |

If a service MTU, port or channel MTU, or path MTU is dynamically or administratively modified, then all associated SAP and SDP binding operational states are automatically re-evaluated.

The **no** form of this command returns the default **service-mtu** for the indicated service type to the default value.

**Default** VPLS: 1514

Table 61 shows MTU values for specific VC types.

**Table 61 Service Service-MTU Field Descriptions**

| VC-Type Example                       | Service MTU | Advertised MTU |
|---------------------------------------|-------------|----------------|
| Ethernet                              | 1514        | 1500           |
| Ethernet (with preserved dot1q)       | 1518        | 1504           |
| Ethernet (with preserved qinq)        | 1522        | 1508           |
| VPLS                                  | 1514        | 1500           |
| VPLS (with preserved dot1q)           | 1518        | 1504           |
| VPLS (with preserved qinq)            | 1522        | 1508           |
| VLAN (dot1p transparent to MTU value) | 1514        | 1500           |

**Parameters** *octets* — the size of the MTU, in octets, expressed as a decimal integer

**Values** 1 to 9670

service-name

**Syntax** **service-name** *service-name*  
**no service-name**

**Context** config>service>vpls

**Description** This command configures a service name that can be used in other configuration commands and show commands that reference the service.

**Parameters** *service-name* — up to 64 characters

## split-horizon-group

| <b>Context</b>     | config>service>vpls                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b> | <p>This command creates a new split horizon group (SHG) for the VPLS instance. Traffic arriving on a SAP or spoke SDP within this split horizon group will not be copied to other SAPs or spoke SDPs in the same split horizon group. If the <b>residential-group</b> keyword is included, the split horizon group is a residential SHG.</p> <p>A split horizon group must be created before SAPs and spoke SDPs can be assigned to the group. The split horizon group is defined within the context of a single VPLS. The same <i>group-name</i> can be reused in different VPLS instances.</p> <p>An ATM SAP must be in a residential SHGs. If an Ethernet SAP is in a SHG, then that SHG cannot be a residential SHG.</p> <p>Up to 30 split horizon groups can be defined per VPLS instance.</p> <p>The <b>no</b> form of the command removes the group name from the configuration.</p>                                                                                                                                                                     |
| <b>Parameters</b>  | <p><i>group-name</i> — specifies the name of the split horizon group to which the SAP or SDP belongs</p> <p><b>residential-group</b> — defines a split horizon group as a residential split horizon group (RSHG). Doing so ensures that:</p> <ul style="list-style-type: none"> <li>• SAPs that are members of this RSHG have: <ul style="list-style-type: none"> <li>– MAC pinning enabled per default (can be disabled)</li> <li>– broadcast and multicast packets are discarded at the SAP egress point, thus blocking unknown flooded traffic</li> <li>– downstream multicast packets are allowed when IGMP snooping is enabled</li> </ul> </li> <li>• Spoke SDPs that are members of this RSHG have: <ul style="list-style-type: none"> <li>– broadcast and multicast packets are NOT discarded at the spoke SDP egress point, thus allowing the unknown flooded traffic</li> <li>– MAC pinning enabled per default (can be disabled)</li> </ul> </li> </ul> <p><b>Default</b> By default, a split horizon group is not created as a residential group</p> |

### 5.21.2.1.3 VPLS SAP Commands

| <b>Description</b>   | <p>This command creates a Service Access Point (SAP) within a service. A SAP is a combination of port and encapsulation parameters that identify the service access point on the interface and within the 7705 SAR. Each SAP must be unique. All SAPs must be explicitly created. If no SAPs are created within a service or on an IP interface, a SAP will not exist on that object.</p> <p>Enter an existing SAP without the <b>create</b> keyword to edit SAP parameters. The SAP is owned by the service in which it was created.</p> <p>A SAP can only be associated with a single service. A SAP can only be defined on a port that has been configured as an access port using the <b>config interface port-type port-id mode access</b> command. Channelized TDM ports are always access ports.</p> <p>If a port is shut down, all SAPs on that port become operationally down. When a service is shut down, SAPs for the service are not displayed as operationally down although all traffic traversing the service will be discarded. The operational state of a SAP is relative to the operational state of the port on which the SAP is defined.</p> <p>The split-horizon group can be associated with an Ethernet ring in order to prevent loops in cases where an Ethernet virtual ring is misconfigured on the main ring. Each A and B path in the major ring is configured in the group and associated with the sub-ring control instance in the VPLS service.</p> <p>The <b>no</b> form of this command deletes the SAP with the specified port. When a SAP is deleted, all configuration parameters for the SAP will also be deleted. For Internet Enhanced Service (IES), the IP interface must be shut down before the SAP on that interface may be removed.</p> |
| <b>Default</b>       | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Special Cases</b> | <b>VPLS SAP</b> — a VPLS SAP can be defined on SONET/SDH channels, on Ethernet ports, or on a GPON module port and on DSL module ports when the module is installed in the 7705 SAR-M (variants with module slots). Split horizon groups (SHGs) and residential SHGs can only be created in the scope of a VPLS service.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b>    | <p><i>sap-id</i> — specifies the physical port identifier portion of the SAP definition. See <a href="#">Table 41</a> for a full list of SAP IDs.</p> <p><i>group-name</i> — specifies the name of the split horizon group to which the SAP belongs</p> <p><i>ring-index</i> — specifies the ring index of the Ethernet ring</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**create** — keyword used to create a SAP instance. The **create** keyword requirement can be enabled or disabled in the **environment>create** context

## cflowd

| <b>Context</b>     | config>service>vpls>sap                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | <p>This command enables Cflowd to collect traffic flow samples through a SAP for analysis. When Cflowd is enabled on a VPLS service SAP, the Ethernet traffic can be sampled and processed by the system's Cflowd engine and exported to Cflowd version 10 collectors with the <b>I2-ip</b> template enabled.</p> <p>When Cflowd is enabled at the SAP level, all packets forwarded by the interface are subject to analysis according to the Cflowd configuration.</p> <p>For Layer 2 services, only ingress sampling is supported.</p> |

| <b>Description</b> | <p>This command disables relearning of MAC addresses on other SAPs or SDPs within the VPLS. The MAC address will remain attached to a given SAP or SDP for the duration of its age timer.</p> <p>The age of the MAC address entry in the FDB is set by the age timer. If <b>mac-aging</b> is disabled on a given VPLS service, any MAC address learned on a SAP or SDP with <b>mac-pinning</b> enabled will remain in the FDB on this SAP or SDP forever. Every event that would otherwise result in relearning will be logged (MAC address; original SAP; new SAP).</p> <p>MAC addresses learned during DHCP address assignment (DHCP snooping enabled) are not impacted by this command. MAC pinning for such addresses is implicit.</p> |
| <b>Default</b>     | disabled, except enabled at the creation of the SAP or spoke SDP that is part of a residential split horizon group (RSHG)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## max-nbr-mac-addr

|                    |                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>max-nbr-mac-addr</b> <i>table-size</i><br><b>no max-nbr-mac-addr</b>                                                                  |
| <b>Context</b>     | <pre>config&gt;service&gt;vpls&gt;sap config&gt;service&gt;vpls&gt;spoke-sdp config&gt;service&gt;vpls&gt;endpoint</pre>                 |
| <b>Description</b> | This command specifies the maximum number of FDB entries for both learned and static MAC addresses for this SAP, spoke SDP, or endpoint. |

When the configured limit has been reached, and **discard-unknown-source** has been enabled for this SAP or spoke SDP (see [discard-unknown-source](#)), packets with unknown source MAC addresses will be discarded.

The **no** form of the command restores the global MAC learning limitations for the SAP or spoke SDP.

| <b>Context</b>     | config>service>vpls>sap                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b> | <p>This command creates a local static MAC entry in the VPLS FDB associated with the SAP.</p> <p>In a VPLS service, MAC addresses are associated with a SAP or an SDP. MACs associated with a SAP are classified as local MACs, and MACs associated with an SDP are remote MACs.</p> <p>Local static MAC entries create a permanent MAC address-to-SAP association in the FDB for the VPLS instance so that the MAC address will not be learned on the edge device.</p> <p>Static MAC definitions on one edge device are not propagated to other edge devices participating in the VPLS instance; that is, each edge device has an independent FDB for the VPLS.</p> <p>Only one static MAC entry (local or remote) can be defined per MAC address per VPLS instance.</p> <p>By default, no static MAC address entries are defined for the SAP.</p> <p>The <b>no</b> form of this command deletes the static MAC entry with the specified MAC address associated with the SAP from the VPLS FDB.</p> |
| <b>Parameters</b>  | <p><i>ieee-address</i> — specifies the 48-bit MAC address for the static ARP in the form <i>aa:bb:cc:dd:ee:ff</i> or <i>aa-bb-cc-dd-ee-ff</i> where <i>aa</i>, <i>bb</i>, <i>cc</i>, <i>dd</i>, <i>ee</i> and <i>ff</i> are hexadecimal numbers (cannot be all zeros). Allowed values are any non-broadcast, non-multicast MAC, and non-IEEE reserved MAC addresses.</p> <p><b>create</b> — this keyword is mandatory when specifying a static MAC address</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

#### 5.21.2.1.4 VPLS SAP ATM Commands

##### atm

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Syntax</b>      | <b>atm</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Context</b>     | config>service>vpls>sap                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b> | <p>This command enables access to the context to configure ATM-related attributes. This command can only be used when a given context (for example, a channel or SAP) supports ATM functionality such as:</p> <ul style="list-style-type: none"> <li>• configuring an ATM port or ATM port-related functionality on adapter cards supporting ATM functionality</li> <li>• configuring ATM-related configuration for ATM-based SAPs that exist on adapter cards supporting ATM functionality</li> </ul> <p>If ATM functionality is not supported for a given context, the command returns an error.</p> |

##### egress

|                    |                                                                                  |
|--------------------|----------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>egress</b>                                                                    |
| <b>Context</b>     | config>service>vpls>sap>atm                                                      |
| <b>Description</b> | This command enables the context to configure egress ATM attributes for the SAP. |

##### traffic-desc

|                    |                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>traffic-desc</b> <i>traffic-desc-profile-id</i><br><b>no traffic-desc</b>                                                                                                                                                                                                                                                                          |
| <b>Context</b>     | config>service>vpls>sap>atm>egress                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | <p>This command assigns an ATM traffic descriptor profile to a given context (for example, a SAP).</p> <p>When configured under the egress context, the specified traffic descriptor profile defines the traffic contract in the backwards direction.</p> <p>The <b>no</b> form of the command reverts to the default traffic descriptor profile.</p> |
| <b>Default</b>     | The default traffic descriptor (trafficDescProfileId. = 1) is associated with newly created PVCC-delimited SAPs                                                                                                                                                                                                                                       |

---

**Parameters** *traffic-desc-profile-id* — specifies a defined traffic descriptor profile (refer to “ATM QoS Traffic Descriptor Profiles” in the 7705 SAR Quality of Service Guide for information on the **atm-td-profile traffic-desc-profile-id** command)

**Values** 1 to 1000

## encapsulation

**Syntax** **encapsulation** *atm-encap-type*

**Context** config>service>vpls>sap>atm

**Description** This command specifies the data encapsulation for an ATM PVCC-delimited SAP. The definition references RFC 2684, *Multiprotocol Encapsulation over ATM AAL5*, and the ATM Forum LAN Emulation specification.

Ingress traffic that does not match the configured encapsulation will be dropped.

**Default** The encapsulation is driven by the service for which the SAP is configured.

For VPLS SAPs, the default and only option is **aal5snap-bridged**.

**Parameters** *atm-encap-type* — specifies the encapsulation type

**Values** **aal5snap-bridged**: bridged encapsulation for LLC encapsulated circuit (LLC/ SNAP precedes protocol datagram) as defined in RFC 2684

## oam

**Syntax** **oam**

**Context** config>service>vpls>sap>atm

**Description** This command enables the context to configure OAM functionality for a PVCC delimiting a SAP. The ATM-capable adapter cards support the following F5 end-to-end OAM functionality (AIS, RDI, loopback):

- ITU-T Recommendation I.610 - B-ISDN Operation and Maintenance Principles and Functions version 11/95
- GR-1248-CORE - Generic Requirements for Operations of ATM Network Elements (NEs), Issue 3 June 1996
- GR-1113-CORE - Bellcore, Asynchronous Transfer Mode (ATM) and ATM Adaptation Layer (AAL) Protocols Generic Requirements, Issue 1, July 1994

## alarm-cells

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Description</b> | <p>This command configures AIS/RDI fault management on a PVCC. Fault management allows PVCC termination to monitor and report the status of its connection by propagating fault information through the network and by driving a PVCC operational status.</p> <p>When <b>alarm-cells</b> functionality is enabled, a PVCC operational status is affected when a PVCC goes into an AIS or RDI state because of AIS/RDI processing. This assumes that nothing else affects the PVCC operational status; for example, the PVCC goes down, or enters a fault state and comes back up, or exits that fault state. RDI cells are generated when a PVCC is operationally down. No OAM-specific SNMP trap is raised whenever an endpoint enters or exits an AIS or RDI state; however, if an OAM state change results in a change to the operational status of the PVCC, then a trap is expected from an entity that the PVCC is associated with (for example, a SAP).</p> <p>The <b>no</b> form of the command disables <b>alarm-cells</b> functionality for a PVCC. When <b>alarm-cells</b> functionality is disabled, the PVCC operational status is no longer affected by the PVCC OAM state changes due to AIS/RDI processing. When <b>alarm-cells</b> is disabled, a PVCC will change operational status to up from down due to <b>alarm-cell</b> processing. RDI cells are not generated as result of PVCC going into an AIS or RDI state; however, the PVCC OAM status will record OAM faults as described above.</p> |
| <b>Default</b>     | enabled for PVCCs delimiting VPLS SAPs                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Context</b>     | config>service>vpls>sap>atm                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b> | <p>This command enables the push operation of a configured VLAN at ingress and a pop operation at egress on a per-ATM SAP basis. After AAL5 termination at ATM access ingress as per the configured encapsulation type, the configured VLAN tag is pushed to the received subscriber frame. The type of Ethernet frame is set to 0x8100 in order to designate the existence of the VLAN header, and the original Ethertype is shifted by 4 bytes (dot1q) or 8 bytes (qinq), enlarging the resulting subscriber frame by 4 or 8 bytes.</p> <p>Using the <b>subscriber-vlan</b> command necessitates the use of the tagged (dot1q or qinq) uplink. In the uplink ingress direction (from the network to the 7705 SAR), the 7705 SAR is programmed to pop the VLAN tags. The first pop operation is mandatory, but if the frame is a single-tagged frame and there are no other VLAN tags, then the resulting untagged frame is forwarded to the subscriber interface without any errors.</p> |
| <b>Default</b>     | no subscriber-vlan                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

---

**Parameters**    *vlan-id* — specifies the VLAN ID for the subscriber VLAN

**Values**        \*, 0 to 4094 (\* represents VLAN 4095 internally)

### 5.21.2.1.5 VPLS IGMP and MLD Snooping Commands

#### igmp-snooping

|                    |                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>igmp-snooping</b>                                                                                            |
| <b>Context</b>     | config>service>vpls<br>config>service>vpls>sap<br>config>service>vpls>mesh-sdp<br>config>service>vpls>spoke-sdp |
| <b>Description</b> | This command enables the Internet Group Management Protocol (IGMP) snooping context.                            |

#### mld-snooping

|                    |                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>mld-snooping</b>                                                                                             |
| <b>Context</b>     | config>service>vpls<br>config>service>vpls>sap<br>config>service>vpls>mesh-sdp<br>config>service>vpls>spoke-sdp |
| <b>Description</b> | This command enables the Multicast Listener Discovery (MLD) snooping context.                                   |

#### disable-router-alert-check

|                    |                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] disable-router-alert-check</b>                                                                                                                                                                                                                                                                                                                                              |
| <b>Context</b>     | config>service>vpls>sap>igmp-snooping<br>config>service>vpls>sap>mld-snooping<br>config>service>vpls>mesh-sdp>igmp-snooping<br>config>service>vpls>mesh-sdp>mld-snooping<br>config>service>vpls>spoke-sdp>igmp-snooping<br>config>service>vpls>spoke-sdp>mld-snooping                                                                                                               |
| <b>Description</b> | <p>This command enables or disables router alert checking for IGMP or MLD messages received on this interface. The router alert field in the IP header is used to inform the router to extract the packet. By default, router alert checks are enabled for IGMP and MLD packets (that is, no disable).</p> <p>The <b>no</b> form of the command enables the router alert check.</p> |
| <b>Default</b>     | no disable-router-alert-check                                                                                                                                                                                                                                                                                                                                                       |

## fast-leave

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Description</b> | <p>This command enables fast leave. When IGMP or MLD fast-leave processing is enabled, the 7705 SAR immediately removes a SAP or SDP from the multicast group when it detects an IGMP or MLD leave message on that SAP or SDP. Fast-leave processing allows the 7705 SAR to remove from the forwarding table a SAP or SDP that has sent a leave message without first sending group-specific queries to the SAP or SDP. This speeds up the process of changing channels (called zapping).</p> <p>Fast leave should only be enabled when there is a single receiver present on the SAP or SDP. When fast leave is enabled, the configured <b>last-member-query-interval</b> value is ignored.</p> |
| <b>Default</b>     | no fast-leave                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## import

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Context</b>     | config>service>vpls>sap>igmp-snooping<br>config>service>vpls>sap>mld-snooping<br>config>service>vpls>mesh-sdp>igmp-snooping<br>config>service>vpls>mesh-sdp>mld-snooping<br>config>service>vpls>spoke-sdp>igmp-snooping<br>config>service>vpls>spoke-sdp>mld-snooping                                                                                                                                                                                                                                                           |
| <b>Description</b> | This command configures the maximum response time used in group-specific queries that are sent by the router acting as the querier in response to leave messages, and is also the amount of time between two consecutive group-specific queries. This value may be tuned to modify the leave latency of the network. A reduced value results in reduced time to detect the loss of the last member of a group. The configured <b>last-member-query-interval</b> is ignored when <b>fast-leave</b> is enabled on the SAP or SDP. |
| <b>Default</b>     | 10                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b>  | <i>interval</i> — the frequency, in tenths of seconds, at which query messages are sent<br><b>Values</b> 1 to 50                                                                                                                                                                                                                                                                                                                                                                                                                |

## max-num-groups

|                    |                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Description</b> | <p>This command specifies whether a multicast router is attached behind this SAP or SDP.</p> <p>Configuring a SAP as an <b>mrouter-port</b> has two effects. First, all multicast traffic received on another SAP or SDP is copied to this SAP or SDP. Second, IGMP or MLD reports generated by the system as a result of a host joining or leaving a multicast group are sent to this SAP or SDP.</p> <p>If two multicast routers exist in the network, one of them becomes the active querier and the other one (the non-querier) stops sending IGMP queries. The non-querier router continues to receive reports in order to keep its multicast trees up to date. To support this, enable <b>mrouter-port</b> on all SAPs or SDPs connected to a multicast router.</p> <p>The version used for the reports (IGMPv1, v2, or v3, or MLDv1 or v2) can only be determined after an initial query has been received. Until the version is determined, no reports are sent on the SAP or spoke SDP, even if <b>mrouter-port</b> is enabled.</p> <p>If the <b>send-queries</b> command is enabled on this SAP or spoke SDP, the <b>mrouter-port</b> command cannot be enabled. The <b>mrouter-port</b> and <b>send-queries</b> commands are mutually exclusive.</p> |
| <b>Default</b>     | no mrouter-port                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Context</b>     | config>service>vpls>igmp-snooping<br>config>service>vpls>mld-snooping                                                                                                                                                                                                                                                             |
| <b>Description</b> | This command specifies the source IP address used when generating IGMP or MLD reports. According to the IGMPv3 standard, a zero source address is allowed when sending IGMP reports. However, for interoperability with some multicast routers, the source IP address of IGMP group reports can be configured using this command. |
| <b>Default</b>     | 0.0.0.0                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <i>ip-address</i> — the source IPv4 source address in transmitted IGMP reports<br><b>Values</b> a.b.c.d<br><i>ipv6-address</i> — the source IPv6 source address in transmitted MLD reports<br><b>Values</b> x:x:x:x:x:x:x (eight 16-bit pieces)<br>x:x:x:x:x:d.d.d.d<br>x: [0 to FFFF]H<br>d: [0 to 255]D                         |

## robust-count

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Syntax</b>      | <b>robust-count</b> <i>robust-count</i><br><b>no robust-count</b>                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Context</b>     | config>service>vpls>igmp-snooping<br>config>service>vpls>mld-snooping<br>config>service>vpls>sap>igmp-snooping<br>config>service>vpls>sap>mld-snooping<br>config>service>vpls>mesh-sdp>igmp-snooping<br>config>service>vpls>mesh-sdp>mld-snooping<br>config>service>vpls>spoke-sdp>igmp-snooping<br>config>service>vpls>spoke-sdp>mld-snooping                                                                                                                                                                |
| <b>Description</b> | This command allows tuning for the expected packet loss on a SAP or an SDP, and is comparable to a retry count. For a SAP or SDP, this command is functional when the <b>send-queries</b> command is enabled. If the <b>send-queries</b> command is not enabled, <b>robust-count</b> is ignored. If the SAP or SDP is expected to experience packet loss, the <i>robust-count</i> parameter may be increased. IGMP or MLD snooping on this SAP or SDP is robust up to the <i>robust-count</i> minus 1 packet. |
| <b>Default</b>     | 2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <b>robust-count</b> — specifies the robust count for the service, SAP, or SDP                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                    | <b>Values</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                    | For VPLS: 1 to 255                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                    | For SAP or SDP: 2 to 7                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## send-queries

|                    |                                                                                                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] send-queries</b>                                                                                                                                                                                                                                              |
| <b>Context</b>     | config>service>vpls>sap>igmp-snooping<br>config>service>vpls>sap>mld-snooping<br>config>service>vpls>mesh-sdp>igmp-snooping<br>config>service>vpls>mesh-sdp>mld-snooping<br>config>service>vpls>spoke-sdp>igmp-snooping<br>config>service>vpls>spoke-sdp>mld-snooping |
| <b>Description</b> | This command specifies whether to send IGMP or MLD general query messages on the SAP or SDP.                                                                                                                                                                          |

When **send-queries** is configured, all query reports generated locally are of the type belonging to the configured **version**. If a report from a version higher than the configured version is received, the report is dropped and a “wrong version” counter is incremented. If **send-queries** is not configured, the **version** command has no effect and the version used is the version of the querier. This implies that, for example, when there is a version 2 querier, a specific version 3 group or group-source query is never sent when a host wants to leave a group.

**Default** no send-queries

## static

**Syntax** **static**

**Context** config>service>vpls>sap>igmp-snooping  
 config>service>vpls>sap>mld-snooping  
 config>service>vpls>mesh-sdp>igmp-snooping  
 config>service>vpls>mesh-sdp>mld-snooping  
 config>service>vpls>spoke-sdp>igmp-snooping  
 config>service>vpls>spoke-sdp>mld-snooping

**Description** This command enables access to the context to configure static group addresses. Static group addresses can be configured on a SAP or SDP. When present as either a (\*,G) or a (S,G) entry, multicast packets matching the configuration are forwarded even if no join message was registered for the specific group.

**Default** n/a

## group

**Syntax** [no] group *grp-ip-address*  
 [no] group *grp-ipv6-address*

**Context** config>service>vpls>sap>igmp-snooping>static  
 config>service>vpls>sap>mld-snooping>static  
 config>service>vpls>mesh-sdp>igmp-snooping>static  
 config>service>vpls>mesh-sdp>mld-snooping>static  
 config>service>vpls>spoke-sdp>igmp-snooping>static  
 config>service>vpls>spoke-sdp>mld-snooping>static

**Description** This command adds a static multicast group either as a (\*,G) or as one or more (S,G) records. When a static IGMP or MLD group is added, multicast data for that (\*,G) or (S,G) is forwarded to the specific SAP or SDP without receiving any membership report from a host.

The group is not created until the **source** or **starg** is specified.

**Default** n/a

**Parameters**    *grp-ip-address* — specifies an IGMP multicast group address that receives data on an interface. The IP address must be unique for each static group.

**Values**        a.b.c.d

*grp-ipv6-address* — specifies an MLD multicast group address that receives data on an interface. The IPv6 address must be unique for each static group.

**Values**        x:x:x:x:x:x:x (eight 16-bit pieces)  
x:x:x:x:x:d.d.d.d  
x: [0 to FFFF]H  
d: [0 to 255]D

source

**Syntax**        [no] **source** *src-ip-address*  
[no] **source** *src-ipv6-address*

**Context**        config>service>vpls>sap>igmp-snooping>static>group  
config>service>vpls>sap>mld-snooping>static>group  
config>service>vpls>mesh-sdp>igmp-snooping>static>group  
config>service>vpls>mesh-sdp>mld-snooping>static>group  
config>service>vpls>spoke-sdp>igmp-snooping>static>group  
config>service>vpls>spoke-sdp>mld-snooping>static>group

**Description**    This command adds a static (S,G) entry, to allow multicast traffic for a multicast group from a specified source. For a multicast group, more than one source address can be specified. Static (S,G) entries cannot be added if a **starg** has been created previously.

The **no** form of the command removes the source from the configuration.

**Default**        n/a

**Parameters**    *src-ip-address* — specifies the IPv4 unicast address

**Values**        a.b.c.d

*src-ipv6-address* — specifies the IPv6 unicast address

**Values**        x:x:x:x:x:x:x (eight 16-bit pieces)  
x:x:x:x:x:d.d.d.d  
x: [0 to FFFF]H  
d: [0 to 255]D

## starg

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Description</b> | <p>This command specifies the version of IGMP or MLD that is running on this SAP or SDP. This command can be used to configure a router capable of running IGMP version 1, 2, or 3, or MLD version 1 or 2. For IGMP or MLD to function correctly, all routers on a LAN must be configured to run the same version of IGMP or MLD on that LAN.</p> <p>When the <b>send-queries</b> command is configured, all query reports generated locally are of the type belonging to the configured <b>version</b>. If a report from a version higher than the configured version is received, the report gets dropped and a “wrong version” counter is incremented.</p> <p>If the <b>send-queries</b> command is not configured, the <b>version</b> command has no effect. The version used on that SAP or SDP is the version of the querier. This implies that, for example, when there is an IGMP version 2 querier, a specific version 3 group or group-source query is never sent when a host wants to leave a group.</p> <p>The <b>no</b> form of the command returns the version to the default value.</p> |

**Default**    3 (IGMP)  
              2 (MLD)

**Parameters**    *version* — specifies the IGMP or MLD version

**Values**        IGMP: 1, 2, or 3  
                  MLD: 1 or 2

| <b>Description</b> | This command enables the context to configure the Spanning Tree Protocol (STP) parameters. The 7705 SAR runs the RSTP version of STP. The Nokia implementation of STP is simply the Spanning Tree Protocol (STP) with a few modifications to better suit the operational characteristics of VPLS services. The most evident change is to the root bridge election. Since the core network operating between Nokia service routers should not be blocked, the root path is calculated from the core perspective. |

#### hello-time

| <b>Description</b> | <p>This command configures the Spanning Tree Protocol (STP) hello time for the Virtual Private LAN Service (VPLS) STP instance.</p> <p>The <b>hello-time</b> command defines the default timer value that controls the sending interval between BPDU configuration messages by this bridge, on ports where this bridge assumes the designated role.</p> <p>Since VPLS on the 7705 SAR runs in RSTP mode, the hello time is always taken from the locally configured parameter, unless RSTP fails and the SAP falls back to legacy STP operation, in which case the hello time for the spanning tree is determined by the root bridge.</p> <p>The <b>no</b> form of this command returns the hello time to the default value.</p> |
| <b>Default</b>     | 2 s                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Context</b>     | config>service>vpls>stp                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Description</b> | <p>The <b>priority</b> command is used to populate the priority portion of the bridge ID field within outbound BPDUs (the most significant 4 bits of the bridge ID). It is also used as part of the decision process when determining the best BPDU between messages received and sent. All values will be truncated to multiples of 4096, conforming with IEEE 802.1t and 802.1D-2004.</p> <p>The <b>no</b> form of this command returns the bridge priority to the default value.</p> |

---

|                   |                                                                                                                                                                                                                                                                                                                 |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | By default, the bridge priority is configured to 4096, which is the highest priority                                                                                                                                                                                                                            |
| <b>Parameters</b> | <i>bridge-priority</i> — the bridge priority for the STP instance                                                                                                                                                                                                                                               |
| <b>Values</b>     | <p>Allowed values are integers in the range of 4096 to 65535 (4096 is the highest priority).</p> <p>The actual <i>bridge-priority</i> value stored and used is the allowed value (above) with its lowest 12 bits masked off, which means the actual range of values is 4096 to 61440 in increments of 4096.</p> |

| <b>Description</b> | <p>This command configures the SAP or spoke SDP as an edge or non-edge port. If <b>auto-edge</b> is enabled for the SAP or spoke SDP, this value of the edge/non-edge setting will be used only as the initial value.</p> <p>The function of the <b>edge-port</b> command is to tell STP that it is on the edge of the network (for example, there are no other bridges connected to that port), and, as a consequence, it can immediately transition to a forwarding state if the port becomes available.</p> <p>STP, however, can detect that the actual situation is different from what <b>edge-port</b> may indicate.</p> <p>Initially, the value of the SAP or spoke SDP parameter is set to <b>edge-port</b>. This value will change if:</p> <ul style="list-style-type: none"><li>• a BPDU is received on that port, meaning that there is another bridge connected to this port. In this case, <b>edge-port</b> becomes disabled.</li><li>• <b>auto-edge</b> is configured and no BPDU is received within a certain period of time, in which case, RSTP concludes that it is on an edge. In this case, <b>edge-port</b> becomes enabled.</li></ul> <p>The <b>no</b> form of this command returns the edge port setting to the default value.</p> |
| <b>Default</b>     | no edge-port                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Description</b> | <p>This command instructs STP on the maximum number of bridges behind the SAP or spoke SDP. If there is only a single bridge, transitioning to the forwarding state will be based on handshaking (fast transitions). If two or more bridges are connected via a shared media, their SAPs or spoke SDPs should be configured as shared, and timer-based transitions are used.</p> <p>The <b>no</b> form of this command returns the link type to the default value.</p> |
| <b>Default</b>     | pt-pt                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Description</b> | <p>This command configures the STP path cost for the SAP or spoke SDP.</p> <p>The path cost is used by STP to calculate the path cost to the root bridge. The path cost in BPDUs received on the root port is incremented with the configured path cost for that SAP or spoke SDP. When BPDUs are sent out other egress SAP or spoke SDP, the newly calculated root path cost is used.</p> <p>STP suggests that the path cost is defined as a function of the link bandwidth. Since SAPs and spoke SDPs are controlled by complex queuing dynamics, in the 7705 SAR the STP path cost is a purely static configuration.</p> <p>The <b>no</b> form of this command returns the path cost to the default value.</p> |
| <b>Default</b>     | 10                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Description</b> | This command configures the virtual port number that uniquely identifies a SAP or spoke SDP within configuration BPDUs. The internal representation of a SAP or spoke SDP is unique to a system and has a reference space much larger than the 12 bits definable in a configuration BPDU. STP takes the internal representation value of a SAP or spoke SDP and identifies it with its own virtual port number, which is unique to any other SAP or spoke SDP defined on the VPLS. The virtual port number is assigned at the time that the SAP or spoke SDP is added to the VPLS. Since the order in which SAPs or spoke SDPs are added to the VPLS is not preserved between reboots of the system, the virtual port number may change between restarts of the STP instance. |
| <b>Parameters</b>  | <i>virtual-port-number</i> — the virtual port number for the SAP or spoke SDP                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Description</b> | <p>This command configures the STP priority for the SAP or spoke SDP.</p> <p>When configuration BPDUs are received, the STP priority is used in some circumstances as a tiebreaking mechanism to determine whether the SAP or spoke SDP will be designated or blocked. In traditional STP implementations (802.1D-1998), this field is called the port priority and has a value of 0 to 255. This field is coupled with the port number (0 to 255) to create a 16-bit value. In the latest STP standard (802.1D-2004), only the upper 4 bits of the port priority field are used to encode the SAP or spoke SDP priority. The remaining 4 bits are used to extend the port ID field into a 12-bit virtual port number field. The virtual port number uniquely references a SAP or spoke SDP within the STP instance.</p> <p>STP computes the actual priority by taking the input value and masking out the lower 4 bits. The result is the value that is stored in the SAP or spoke SDP priority parameter. For instance, if a value of 0 is entered, masking out the lower 4 bits results in a parameter value of 0. If a value of 255 is entered, the result is 240.</p> <p>The <b>no</b> form of this command returns the STP priority to the default value.</p> |
| <b>Default</b>     | 128                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Description</b> | <p>This command sets the aggregate rate limits (PIR and CIR) for the SAP. The <i>agg-rate</i> sets the PIR value. The <i>cir-rate</i> sets the CIR value. When aggregate rate limits are configured on a second-generation (Gen-2) Ethernet adapter card, the scheduler mode must be set to 16-priority. On a third-generation (Gen-3) Ethernet adapter card, the scheduler mode is always 4-priority. For information on adapter card generations, refer to the “Evolution of Ethernet Adapter Cards, Modules, and Platforms” section in the 7705 SAR Interface Configuration Guide.</p> <p>Configuring the <i>cir-rate</i> is optional. If a <i>cir-rate</i> is not entered, then the <i>cir-rate</i> is set to its default value (0 kb/s). If a <i>cir-rate</i> has been set and the <i>agg-rate</i> is changed without re-entering the <i>cir-rate</i>, the <i>cir-rate</i> automatically resets to 0 kb/s. For example, to change the <i>agg-rate</i> from 2000 to 1500 while maintaining a <i>cir-rate</i> of 500, use the command <b>agg-rate-limit 1500 cir 500</b>.</p> |

If the specified SAP is a LAG SAP, then *agg-rate* and *cir-rate* can be configured regardless of the scheduler mode setting on Gen-2 or Gen-3 hardware—it is not configurable if one of the ports configured in the LAG SAP is on Gen-1 hardware. If the active port is on a Gen-3 card or platform, then *agg-rate* and *cir-rate* are applicable. If the active port is on a Gen-2 card or platform, then *agg-rate* and *cir-rate* apply when the scheduler mode is set to 16-priority. If the active port is on a Gen-1 card, then *agg-rate* and *cir-rate* are not applicable. For details on the behavior of a mix-and-match LAG SAP, refer to the “LAG Support on Third-Generation Ethernet Adapter Cards, Ports, and Platforms” and “Network LAG Traffic Management” sections in the 7705 SAR Interface Configuration Guide.

**Note:** Starting with Release 7.0.R6, schedulers on Gen-3 adapter cards and platforms have been updated to better align with the scheduling behavior supported on the other 7705 SAR adapter cards and platforms. The updated scheduler mode is called “4-priority” scheduler-mode throughout the CLI. Prior to Release 7.0.R6, the CLI designation was “4-priority-hqos”. In the updated mode of operation, arbitration among different flows at the second-tier aggregate (per-SAP or per-VLAN) and third-tier aggregate (per-customer (MSS)) levels are carried out in a round-robin manner, scheduling *cir-rate* first from the shapers, followed by the *pir-rate*.

**Caution:** Any Gen-3 adapter card or platform running Release 7.0.R6 or later software uses 4-priority scheduling instead of 4-priority-hqos scheduling, which was supported previously. The migration of scheduler mode is automatic with an upgrade and there is no operator action required. As part of the migration, all CIR values at second-tier (per-SAP and per-VLAN) and third-tier (per-customer (MSS)) aggregate shaper levels are set to zero. Operators must exercise caution when performing an upgrade to Release 7.0.R6 or later from a previous Release 7.0 version, and must adjust the affected CIR values in accordance with the needs of their applications as soon as possible.

The **no** form of the command sets the *agg-rate* to the maximum and the *cir-rate* to 0 kb/s.

| <b>Description</b> | <p>This command associates a filter policy with a SAP or SDP (mesh or spoke). Filters can be applied to VPLS and routed VPLS SAPs and SDPs.</p> <p>Filter policies control the forwarding and dropping of packets based on IP or MAC matching criteria. There are two types of filter policies: IP and MAC. Only one type may be applied at a time. The filter ID must be defined before the <b>filter</b> command is executed. If the filter policy does not exist, the operation will fail and an error message will be returned.</p> <p>Only one filter ID can be assigned to an interface unless the interface is dual-stack (supports both IPv4 and IPv6). A dual-stack interface can have one IPv4 and one IPv6 filter ID assigned to it.</p> <p>In general, filters applied to SAPs or SDPs apply to all packets on the SAP or SDP. One exception is that non-IP packets are not applied to IP match criteria, so the default action in the filter policy applies to these packets.</p> <p>If an IP interface is attached to a VPLS service context (routed VPLS), the VPLS SAP or SDP configured IP or MAC filter for ingress routed packets can be optionally overridden in order to provide special ingress filtering for routed packets. This allows different filtering for routed packets and non-routed packets. The filter override is defined on the IP interface bound to the VPLS service name. A separate override filter can be specified for IPv4 and IPv6 packet types, using the <b>v4-routed-override-filter</b> or <b>v6-routed-override-filter</b> command in the IES or VPRN service contexts.</p> <p>If filter override is configured, the IP or MAC filter configured on the SAP or SDP applies to non-routed packets. If filter override is not configured, the IP or MAC filter configured on the SAP or SDP applies to both routed and non-routed packets.</p> <p>The <b>no</b> form of this command removes any configured filter ID association with the SAP or SDP. The filter ID itself is not removed from the system unless the <b>scope</b> of the created filter is set to <b>exclusive</b>. To avoid deletion of the filter ID and only break the association with the service object, use the <b>scope</b> command within the filter definition to set the <b>scope</b> to <b>template</b>. The default <b>scope</b> of a filter is <b>exclusive</b>.</p> |
| <b>Parameters</b>  | <i>ip-filter-id</i> — specifies the IP filter policy. The filter ID or filter name must already exist within the created IP filters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

*ipv6-filter-id* — specifies the IPv6 filter policy. The filter ID or filter name must already exist within the created IPv6 filters.

**Values** 1 to 65535 or *filter-name* (up to 64 characters)

*mac-filter-id* — specifies the MAC filter policy. The filter ID or filter name must already exist within the created MAC filters.

**Values** 1 to 65535 or *filter-name* (up to 64 characters)

| <b>Description</b> | <p>This command specifies which dot1q tag position (top or bottom) in a qinq-encapsulated packet should be used when QoS evaluates dot1p classification.</p> <p>The <b>no</b> form of the command restores the default dot1p evaluation behavior for the SAP, which means that the inner (bottom) tag (second tag) dot1p bits are used for classification.</p> <p>By default, the dot1p bits from the inner tag service-delineating dot1q tag are used.</p> <p><a href="#">Table 62</a> shows which set of dot1p bits are used for QoS purposes when <b>match-qinq-dot1p</b> is configured. To use the table, find the row that represents the settings for <b>Port/SAP Type</b> and <b>Match-QinQ-Dot1q Setting</b>. Use the <b>Existing Packet Tags</b> column to identify which dot1q tags are available in the packet. Then use the <b>P-bits Used for Match</b> column to identify which dot1q tag contains the dot1p bits that are used for QoS dot1p classification.</p> |
| <b>Default</b>     | no match-qinq-dot1p                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Parameters** **top** — the **top** parameter and **bottom** parameter are mutually exclusive. When the **top** parameter is specified, the outer tag's dot1p bits (topmost P-bits) are used (if existing) to match any **dot1p** *dot1p-value* entries.

**bottom** — the **bottom** parameter and **top** parameter are mutually exclusive. When the **bottom** parameter is specified, the bottommost P-bits (second tag's P-bits) are used (if existing) to match any **dot1p** *dot1p-value* entries.

**Table 62 Match-QinQ-Dot1p Matching Behavior**

| Port/ SAP Type | Match-QinQ-Dot1p Setting <sup>1</sup> | Existing Packet Tags          | P-bits Used for Match |
|----------------|---------------------------------------|-------------------------------|-----------------------|
| Null           | n/a                                   | None                          | None                  |

| QinQ/ 0.*      | Default or Bottom                     | TopQ                          | TopQ P-bits           |

**Table 62 Match-QinQ-Dot1p Matching Behavior (Continued)**

| Port/ SAP Type | Match-QinQ-Dot1p Setting <sup>1</sup> | Existing Packet Tags | P-bits Used for Match |
|----------------|---------------------------------------|----------------------|-----------------------|
| QinQ/ 0.*      | Top                                   | TopQ BottomQ         | TopQ P-bits           |
| QinQ/ 0.*      | Default or Bottom                     | TopQ BottomQ         | BottomQ P-bits        |
| QinQ/ *.*      | Top                                   | None                 | None                  |
| QinQ/ *.*      | Default or Bottom                     | None                 | None                  |
| QinQ/ *.*      | Top                                   | TopQ                 | TopQ P-bits           |
| QinQ/ *.*      | Default or Bottom                     | TopQ                 | TopQ P-bits           |
| QinQ/ *.*      | Top                                   | TopQ BottomQ         | TopQ P-bits           |
| QinQ/ *.*      | Default or Bottom                     | TopQ BottomQ         | BottomQ P-bits        |

**Notes:**

1. "Default" in this column refers to the **no** form of **match-qinq-dot1p** command.
2. For null encapsulation, the 7705 SAR does not process dot1p bits.

**qinq-mark-top-only**

**Syntax** [no] **qinq-mark-top-only**

**Context** config>service>vpls>sap>egress

**Description** When enabled, the **qinq-mark-top-only** command specifies which P-bits to mark during packet egress. When disabled, both sets of P-bits are marked. When enabled, only the P-bits in the top Q-tag are marked. The **no** form of the command is the default state (disabled).

[Table 63](#) shows the dot1p remarking behavior for different egress port type/SAP type combinations and **qinq-mark-top-only** state, where "False" represents the default (disabled) state.

If a new tag is pushed, the dot1p bits of the new tag will be zero (unless the new tag is re-marked by the egress policy. The dot1p bits are configured using the **dot1p** parameter under the **config>qos** context.

**Table 63** Dot1P Re-marking Behavior for the QinQ-mark-top-only Command

| Egress Port Type/SAP Type | QinQ-mark-top-only State | Egress P-Bits Marked or Re-marked |
|---------------------------|--------------------------|-----------------------------------|
| Null <sup>1</sup>         | n/a                      | None                              |
| Dot1q/ X <sup>1</sup>     | n/a                      | Outer tag                         |
| Dot1q/ * <sup>2</sup>     | n/a                      | None                              |
| Dot1q/ 0 <sup>2</sup>     | n/a                      | Outer tag                         |
| QinQ/ X.Y <sup>1</sup>    | False                    | Two outer tags <sup>3</sup>       |
|                           | True                     | Outer tag <sup>3</sup>            |
| QinQ/ X.* <sup>1</sup>    | True or False            | Outer tag                         |
| QinQ/ X.0 <sup>1</sup>    | True or False            | Outer tag                         |
| QinQ/ 0.* <sup>1</sup>    | True or False            | None                              |
| QinQ/ *.* <sup>2</sup>    | True or False            | None                              |

**Notes:**

1. This port type/SAP type is supported by the following services: Epipe, Ipipe, VPLS, IES, and VPRN.
2. This port type/SAP type is supported by the following services: Epipe and VPLS.
3. Normally, when a new tag is pushed, the dot1p bits of the new tag will be zero, unless the P-bits are remarked by the egress policy. However, an exception to this occurs when the egress SAP type is X.Y and only one new outer tag must be pushed. In this case, the new outer tag will have its dot1p bits set to the inner tag's dot1p bits.

**Default** no qinq-mark-top-only (disabled)

**qos**

**Syntax** **qos** *policy-id*  
**no qos**

**Context** config>service>vpls>sap>egress  
config>service>vpls>sap>ingress

**Description** This command associates a QoS policy with an ingress or egress SAP.

QoS ingress and egress policies are important for the enforcement of SLA agreements. The policy ID must be defined prior to associating the policy with a SAP. If the *policy-id* does not exist, an error will be returned.

The **qos** command is used to associate both ingress and egress QoS policies. The **qos** command only allows ingress policies to be associated with ingress SAP, and egress policies with egress SAP. Attempts to associate a QoS policy of the wrong type returns an error.

Only one ingress and one egress QoS policy can be associated with a SAP at one time.

By default, if no specific QoS policy is associated with the SAP for ingress or egress, then the default QoS policy is used.

The **no** form of this command removes the QoS policy association from the SAP, and the QoS policy for the SAP reverts to the default.

**Parameters** *policy-id* — specifies the ingress or egress policy ID to associate with a SAP on ingress or egress. The policy ID or name must already exist.

**Values** 1 to 65535, or *policy-name* (up to 64 characters)

## scheduler-mode

**Syntax** **scheduler-mode {4-priority | 16-priority}**

**Context** config>service>vpls>sap>egress  
config>service>vpls>sap>ingress

**Description** This command sets the scheduler mode for the SAP and is part of the hierarchical QoS (H-QoS) feature on the 7705 SAR.

If the mode is 4-priority, then the SAP is considered an unshaped 4-priority SAP and the [agg-rate-limit](#) cannot be changed from its default values.

If the mode is 16-priority and the **agg-rate limit** parameters are configured to be non-default values, then the SAP is considered a shaped SAP. If the **agg-rate limit** parameters are left in their default settings, the SAP is considered an unshaped, 16-priority SAP.

This command is blocked on third-generation (Gen-3) Ethernet adapter cards and platforms, such as the 6-port Ethernet 10Gbps Adapter card and the 7705 SAR-X, which only support 4-priority scheduling mode.

If the specified SAP is a LAG SAP, **scheduler-mode** can be configured but is not applied to Gen-3 adapter cards and platforms. If one of the ports in the LAG is on a Gen-1 adapter card, then **scheduler-mode** cannot be configured.

**Default** 4-priority

**Parameters** **4-priority** — sets the scheduler mode for the SAP to be 4-priority mode  
**16-priority** — sets the scheduler mode for the SAP to be 16-priority mode

## shaper-group

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Context</b>     | config>service>vpls>sap>egress<br>config>service>vpls>sap>ingress                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | <p>This command applies a shaper group to a SAP. The shaper group must already be created and must be within the shaper policy assigned to the Ethernet MDA (for ingress) or port (for egress). A shaper group is a dual-rate aggregate shaper used to shape aggregate access ingress or egress SAPs at a shaper group rate. Multiple aggregate shaper groups ensure fair sharing of available bandwidth among different aggregate shapers.</p> <p>The default shaper group cannot be deleted.</p> <p>The <b>no</b> form of this command removes the configured <b>shaper-group</b>.</p> |
| <b>Default</b>     | shaper-group "default"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <p><i>shaper-group-name</i> — the name of the shaper group. | <b>Context</b>     | config>service>vpls>sap                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b> | <p>This command preserves the VLAN tag at the ingress SAP. The default (disabled) behavior is to strip off the VLAN tag at the ingress SAP and push a new VLAN tag at the egress SAP.</p> <p>The <b>force-c-vlan-forwarding</b> command is only available on VPLS dot1q and qinq SAPs.</p> <p>When the ingress and egress port <b>encap-type</b> are both dot1q, <b>force-c-vlan-forwarding</b> has the following behavior:</p> <ul style="list-style-type: none"><li>• if <b>force-c-vlan-forwarding</b> is enabled only at the ingress SAP<br/>The VLAN tag is preserved at the ingress SAP and a new VLAN tag is pushed at the egress SAP. The net effect at the egress SAP is that the packet contains two VLAN tags, where the inner tag is the preserved ingress tag.</li><li>• if <b>force-c-vlan-forwarding</b> is enabled only at the egress SAP<br/>A VLAN tag is not pushed at the egress SAP. The effect at the egress SAP is that the VLAN tag received at the ingress SAP is stripped off.</li><li>• if <b>force-c-vlan-forwarding</b> is enabled at both the ingress and egress SAPs</li></ul> |

---

The VLAN tag is preserved at the ingress SAP and there is no tag pushed at the egress SAP. The net effect is that the packet transmitted at the egress SAP contains the same VLAN tag that was received at the ingress SAP. Dot1p re-marking may occur at the egress SAP.

When the ingress and egress port **encap-type** are both qinq, **force-c-vlan-forwarding** has the following behavior:

- if **force-c-vlan-forwarding** is enabled only at the ingress SAP  
The inner VLAN tag is preserved at the ingress SAP and two new VLAN tags are pushed at the egress SAP. The net effect at the egress SAP is that the packet contains three VLAN tags, where the innermost tag is the preserved ingress tag.
- if **force-c-vlan-forwarding** is enabled only at the egress SAP  
Only the outer VLAN tag of the egress SAP is pushed at the egress SAP. The effect at the egress SAP is that the VLAN tag received at the ingress SAP is swapped with a new tag.
- if **force-c-vlan-forwarding** is enabled at both the ingress and egress SAPs  
The VLAN tag is preserved at the ingress SAP and the outer VLAN tag of the egress SAP is pushed. The net effect is that the packet transmitted at the egress SAP contains the same inner VLAN tag that was received at the ingress SAP. Dot1p re-marking may occur at the egress SAP.

The **no** version of this command sets the default behavior.

**Default** disabled

| <b>Description</b> | <p>This command enables accounting and statistical data collection for a SAP, a network port, or an IP interface. When applying accounting policies, the data (by default) is collected in the appropriate records and written to the designated billing file.</p> <p>When the <b>no collect-stats</b> command is issued, the statistics are still accumulated by the CSM. However, the CPU will not obtain the results and write them to the billing file. If a subsequent <b>collect-stats</b> command is issued, then the counters written to the billing file include all the traffic while the <b>no collect-stats</b> command was in effect.</p> |
| <b>Default</b>     | collect-stats                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Context</b>     | config>service>vpls>sap>dhcp>option                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | <p>This command configures the Relay Agent Information Option (Option 82) processing.</p> <p>The <b>no</b> form of this command returns the system to the default value.</p>                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Default</b>     | keep                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b>  | <p><i>dhcp-action</i> — specifies the DHCP option action (<b>replace</b>, <b>drop</b>, or <b>keep</b>), as follows:</p> <p><b>replace</b> — in the upstream direction (from the client), the Option 82 field from the router is inserted in the packet (overwriting any existing Option 82 field). In the downstream direction (towards the client), the Option 82 field is stripped (in accordance with RFC 3046).</p> <p><b>drop</b> — the DHCP packet is dropped if an Option 82 field is present, and the “Client Packets Dropped” counter is incremented</p> |

**keep** — the existing information is kept in the packet and the router does not add any additional information. In the downstream direction, the Option 82 field is not stripped and is sent on towards the client.

The behavior is slightly different in the case of Vendor Specific Options (VSOs). When the **keep** parameter is specified, the router will insert its own VSO into the Option 82 field (as per RFC 4243). This will only be done when the incoming message already has an Option 82 field. However, if adding the VSO causes the Option 82 field to exceed the maximum allowable length (255 octets), the packet is dropped.

If no Option 82 field is present, the router will not create the Option 82 field. In this in that case, no VSO will be added to the message.

## circuit-id

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Description</b> | <p>This command causes the router to send an ASCII-encoded “tuple” in the <b>circuit-id</b> suboption of the DHCP packet. This ASCII-tuple consists of the access-node-identifier, service-id, and SAP-ID, separated by “ ”. If no keyword is configured, then the <b>circuit-id</b> suboption will not be part of the information option (Option 82).</p> <p>If disabled, the <b>circuit-id</b> suboption of the DHCP packet will be left empty.</p>                                                      |
| <b>Default</b>     | no circuit-id                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b>  | <p><b>ascii-tuple</b> — specifies that the included ASCII-encoded concatenated “tuple” consists of the access-node-identifier, service-id, and interface-name</p> <p><b>vlan-ascii-tuple</b> — specifies that the format will include VLAN-id and dot1p bits in addition to the <b>ascii-tuple</b> information. The format is supported on dot1q and qinq encapsulated ports only. Thus, when the Option 82 bits are stripped, dot1p bits will be copied to the Ethernet header of an outgoing packet.</p> |

## remote-id

|                    |                                                                                                                                                                                                                                                                                          |

| <b>Description</b>   | <p>This command binds a VPLS service to an existing Service Distribution Point (SDP). Mesh SDPs bound to a service are logically treated like a single bridge “port” for flooded traffic, where flooded traffic received on any mesh SDP on the service is replicated to other “ports” (spoke SDPs and SAPs) and not transmitted on any mesh SDPs.</p> <p>This command creates a binding between a service and an SDP. The SDP has an operational state that determines the operational state of the SDP within the service. For example, if the SDP is administratively or operationally down, the SDP for the service will be down.</p> <p>The SDP must already be defined in the <b>config&gt;service&gt;sdp</b> context in order to associate the SDP with a valid service. If the <b>sdp sdp-id</b> is not already configured, an error message is generated. If the <i>sdp-id</i> does exist, a binding between that <i>sdp-id</i> and the service is created.</p> <p>SDPs must be explicitly associated and bound to a service. If an SDP is not bound to a service, no far-end 7705 SAR devices can participate in the service.</p> <p>The <b>no</b> form of this command removes the SDP binding from the service. The SDP configuration is not affected; only the binding of the SDP to a service. Once removed, no packets are forwarded to the far-end router.</p> |
| <b>Default</b>       | No <i>sdp-id</i> is bound to a service                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Special Cases</b> | <b>VPLS</b> — several SDPs can be bound to a VPLS. Each SDP must be destined for a different router. If two <i>sdp-id</i> bindings terminate on the same 7705 SAR, an error occurs and the second SDP binding is rejected.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>    | <p><i>sdp-id</i> — the SDP identifier</p> <p><b>Values</b> 1 to 17407</p> <p><i>vc-id</i> — the virtual circuit identifier. This value is used to validate the VC ID portion of each mesh SDP binding defined in the service. The default value of this object is equal to the service ID.</p> <p><b>Values</b> 1 to 4294967295</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**vc-type** — this option overrides the default VC type signaled for the spoke or mesh binding to the far end of the SDP. The VC type is a 15-bit quantity containing a value that represents the type of VC. The actual signaling of the VC type depends on the signaling parameter defined for the SDP. If signaling is disabled, the **vc-type** option can still be used to define the dot1q value expected by the far-end provider equipment. A change of the VC type causes the binding to signal the new VC type to the far end when signaling is enabled. VC types are derived according to IETF *draft-martini-l2circuit-trans-mpls*, as follows:

- the VC type value for Ethernet is 0x0005
- the VC type value for an Ethernet VLAN is 0x0004

**Values** ether, vlan

**ether** — defines the VC type as Ethernet. The **ether** and **vlan** keywords are mutually exclusive. When the VC type is not defined, the default is Ethernet for spoke SDP bindings. Defining Ethernet is the same as executing **no vc-type** and restores the default VC type for the spoke SDP binding (hex 5).

**vlan** — defines the VC type as VLAN. The **ether** and **vlan** keywords are mutually exclusive. When the VC type is not defined, the default is Ethernet for spoke SDP bindings.

## spoke-sdp

| <b>Description</b> | <p>This command binds a service to an existing SDP. A spoke SDP is treated like the equivalent of a traditional bridge “port”, where flooded traffic received on the spoke SDP is replicated on all other “ports” (other spoke and mesh SDPs or SAPs) and not transmitted on the port it was received.</p> <p>The SDP has an operational state that determines the operational state of the SDP within the service. For example, if the SDP is administratively or operationally down, the SDP for the service will be down.</p> <p>The SDP must already be defined in the <b>config&gt;service&gt;sdp</b> context in order to associate an SDP with a VPLS service. If the <b>sdp</b> <i>sdp-id</i> is not already configured, an error message is generated. If the <i>sdp-id</i> does exist, a binding between that <i>sdp-id</i> and the service is created. SDPs must be explicitly associated and bound to a service. If an SDP is not bound to a service, no far-end devices can participate in the service.</p> |

The **no** form of this command removes the SDP binding from the service. The SDP configuration is not affected; only the binding of the SDP to a service. Once removed, no packets are forwarded to the far-end router.

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Default</b>       | No <i>sdp-id</i> is bound to a service                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Special Cases</b> | <p><b>VPLS</b> — several SDPs can be bound to a VPLS service. Each SDP must use unique <i>vc-ids</i>. An error message is generated if two SDP bindings with identical <i>vc-ids</i> terminate on the same router.</p> <p>Split horizon groups can only be created in the scope of a VPLS service.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>    | <p><i>sdp-id</i> — the SDP identifier</p> <p><b>Values</b> 1 to 17407</p> <p><i>vc-id</i> — the virtual circuit identifier</p> <p><b>Values</b> 1 to 4294967295</p> <p><b>vc-type</b> — this option overrides the default VC type signaled for the spoke or mesh binding to the far end of the SDP. The VC type is a 15-bit quantity containing a value that represents the type of VC. The actual signaling of the VC type depends on the signaling parameter defined for the SDP. If signaling is disabled, the <b>vc-type</b> option can still be used to define the dot1q value expected by the far-end provider equipment. A change of the VC type causes the binding to signal the new VC type to the far end when signaling is enabled. VC types are derived according to IETF <i>draft-martini-l2circuit-trans-mpls</i>, as follows:</p> <ul style="list-style-type: none"> <li>• the VC type value for Ethernet is 0x0005</li> <li>• the VC type value for an Ethernet VLAN is 0x0004</li> </ul> <p><b>Values</b> ether, vlan</p> <p><b>ether</b> — defines the VC type as Ethernet. The <b>ether</b> and <b>vlan</b> keywords are mutually exclusive. When the VC type is not defined, the default is Ethernet for spoke SDP bindings. Defining Ethernet is the same as executing <b>no vc-type</b> and restores the default VC type for the spoke SDP binding (hex 5).</p> <p><b>vlan</b> — defines the VC type as VLAN. The <b>ether</b> and <b>vlan</b> keywords are mutually exclusive. When the VC type is not defined, the default is Ethernet for spoke SDP bindings. The VLAN VC-type requires at least one dot1q tag within each encapsulated Ethernet packet transmitted to the far end.</p> <p><i>group-name</i> — specifies the name of the split horizon group to which the SDP belongs</p> <p><i>endpoint-name</i> — specifies the service endpoint to which this SDP binding is attached.<br/>The service ID of the SDP binding must match the service ID of the service endpoint.</p> <p><b>no-endpoint</b> — removes the association of a spoke SDP with an explicit endpoint name</p> |

| <b>Context</b>     | config>service>vpls>mesh-sdp<br>config>service>vpls>spoke-sdp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | <p>This command enables the use of the control word on pseudowire packets in VPLS and enables the use of the control word individually on each mesh SDP or spoke SDP. By default, the control word is disabled.</p> <p>When the control word is enabled, all VPLS packets are encapsulated with the control word when sent over the pseudowire. The T-LDP control plane behavior is the same as in the implementation of control word for VLL services. The configuration for the two directions of the Ethernet pseudowire should match.</p> <p>The <b>no</b> form of the command resets the mesh SDP or spoke SDP to the default behavior of not using the control word.</p> |
| <b>Default</b>     | no control-word                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## egress

|                    |                                                               |
|--------------------|---------------------------------------------------------------|
| <b>Syntax</b>      | <b>egress</b>                                                 |
| <b>Context</b>     | config>service>vpls>mesh-sdp<br>config>service>vpls>spoke-sdp |
| <b>Description</b> | This command configures the egress SDP context.               |

## ingress

|                    |                                                               |
|--------------------|---------------------------------------------------------------|
| <b>Syntax</b>      | <b>ingress</b>                                                |
| <b>Context</b>     | config>service>vpls>mesh-sdp<br>config>service>vpls>spoke-sdp |
| <b>Description</b> | This command configures the ingress SDP context.              |

## vc-label

|                    |                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>vc-label</b> <i>egress-vc-label</i><br><b>no vc-label</b> [ <i>egress-vc-label</i> ]                                   |
| <b>Context</b>     | config>service>vpls>mesh-sdp>egress<br>config>service>vpls>spoke-sdp>egress                                               |
| <b>Description</b> | This command configures the egress VC label.                                                                              |
| <b>Parameters</b>  | <i>egress-vc-label</i> — specifies an egress VC value that indicates a specific connection<br><b>Values</b> 16 to 1048575 |

## vc-label

|                    |                                                                                                                             |

| <b>Context</b>     | config>service>vpls>mesh-sdp<br>config>service>vpls>spoke-sdp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b> | <p>This command enables or disables the use of entropy labels for mesh or spoke SDPs.</p> <p>If <b>entropy-label</b> is enabled, the entropy label and entropy label indicator (ELI) are inserted in packets for which at least one LSP in the stack for the far end of the tunnel used by the service has advertised entropy label capability.</p> <p>If the tunnel is an RSVP-TE type, <b>entropy-label</b> can also be controlled by disabling <b>entropy-label-capability</b> under the <b>config&gt;router&gt;rsvp</b> context at the far-end LER.</p> <p>When the <b>entropy-label</b> and <b>entropy-label-capability</b> commands are both enabled, the entropy label value inserted at the iLER is always based on the service ID.</p> |
| <b>Default</b>     | no entropy-label                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## precedence

|                    |                                                                                                                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>precedence</b> [ <i>precedence-value</i>   <b>primary</b> ]<br><b>no precedence</b>                                                                                                                                              |

| <b>Context</b>     | config>service>vpls>spoke-sdp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b> | <p>This command enables pseudowire status signaling for spoke SDPs. The <b>no</b> form of this command disables pseudowire status signaling. When pseudowire status signaling is disabled, a 7705 SAR does not include the PW status TLV in the initial label mapping message of the pseudowire that is used for a spoke SDP. This forces both 7705 SAR PEs to use the pseudowire label withdrawal method for signaling pseudowire status. If the remote endpoint has <b>standby-signaling-master</b> enabled and it determines that a particular PW should be standby, based on the precedence of the PWs, it will withdraw the PW label. If the label is withdrawn for all PWs on a VPLS, the VPLS will go operationally down.</p> <p>If pseudowire status signaling is enabled, the 7705 SAR includes the pseudowire status TLV in the initial label mapping message for the pseudowire.</p> |
| <b>Default</b>     | pw-status-signaling                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## static-mac

|                    |                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] static-mac</b> <i>ieee-address</i>                                              |
| <b>Context</b>     | config>service>vpls>mesh-sdp<br>config>service>vpls>spoke-sdp                           |
| <b>Description</b> | This command creates a remote static MAC entry in the VPLS FDB associated with the SDP. |

In a VPLS service, MAC addresses are associated with a SAP or an SDP. MACs associated with a SAP are classified as local MACs, and MACs associated with an SDP are remote MACs.

Remote static MAC entries create a permanent MAC address to SDP association in the FDB for the VPLS instance so that the MAC address will not be learned on the edge device.

Static MAC definitions on one edge device are not propagated to other edge devices participating in the VPLS instance; that is, each edge device has an independent FDB for the VPLS.

Only one static MAC entry (local or remote) can be defined per MAC address per VPLS instance.

The **no** form of this command deletes the static MAC entry with the specified MAC address associated with the SDP from the VPLS FDB.

**Default** n/a

**Parameters** *ieee-address* — specifies the 48-bit MAC address for the static ARP in the form *aa:bb:cc:dd:ee:ff* or *aa-bb-cc-dd-ee-ff* where *aa*, *bb*, *cc*, *dd*, *ee* and *ff* are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC, and non-IEEE reserved MAC addresses.

## vlan-vc-tag

**Syntax** **vlan-vc-tag** *0..4094*  
**no vlan-vc-tag** [*0..4094*]

**Context** config>service>vpls>mesh-sdp  
config>service>vpls>spoke-sdp

**Description** This command specifies an explicit dot1q value that is used when encapsulating to the SDP far end. When signaling is enabled between the near and far end, the configured dot1q tag can be overridden by a received TLV specifying the dot1q value expected by the far end. This signaled value must be stored as the remote signaled dot1q value for the binding. The provisioned local dot1q tag must be stored as the administrative dot1q value for the binding.

When the dot1q tag is not defined, the default value of 0 is stored as the administrative dot1q value. Setting the value to 0 is equivalent to not specifying the value.

The **no** form of this command disables the command.

**Default** no vlan-vc-tag

**Parameters** *0..4094* — specifies a valid VLAN identifier to bind an 802.1Q VLAN tag ID

## 5.21.2.2 Routed VPLS Configuration Commands

### allow-ip-int-binding

|                    |                                                                                                                                                                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>allow-ip-int-binding</b><br><b>no allow-ip-int-binding</b>                                                                                                                                                                                                                          |
| <b>Context</b>     | config>service>vpls                                                                                                                                                                                                                                                                    |
| <b>Description</b> | This command sets a flag on the VPLS service that allows an IES or VPRN IP interface to be attached to the VPLS service in order to make the VPLS service routable. If the <b>allow-ip-int-binding</b> command is not enabled, the VPLS service cannot be attached to an IP interface. |

When attempting to set the allow-ip-int-binding VPLS flag, the system first checks to see if the correct configuration constraints exist for the VPLS service and the network ports. The following features are disabled when the allow-ip-int-binding flag is set under VPLS:

- residential SHG
- DHCP
- mVPLS
- mac-subnet-length
- GRE SDP (cannot be bound to the VPLS)

**Note:** The DHCP relay functionality under **config>service>ies>if>dhcp** or **config>service>ies>if>ipv6>dhcp6-relay** can be used to dynamically assign IP addresses to the clients connected to routed VPLS SAPs.

If a service name is applied to a VPLS service and that service name is also bound to an IP interface but the allow-ip-int-binding flag has not been set on the VPLS service context, the system attempt to resolve the service name between the VPLS service and the IP interface fails. As soon as the **allow-ip-int-binding** flag is enabled on the VPLS, the corresponding IP interface will be attached and become operationally up. There is no need to toggle the **shutdown/no shutdown** command.

The **no** form of the command resets the allow-ip-int-binding flag on the VPLS service. If the VPLS service currently has an IP interface from an IES or VPRN service attached, the **no allow-ip-int-binding** command fails. Once the allow-ip-int-binding flag is reset on the VPLS service, the configuration restrictions associated with setting the flag are removed.

## service-name

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>service-name</b> <i>service-name</i><br><b>no service-name</b>                                                                                                                                                                                                                                                                                                                                                     |
| <b>Context</b>     | config>service>vpls                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b> | <p>This command configures a service name, up to 64 characters in length, which adds a name identifier to a given service to use as display in show commands throughout the system.</p> <p>All services are required to assign a service ID to initially create a service. However, either the service ID or the service name can be used to identify and reference a given service once it is initially created.</p> |
| <b>Parameters</b>  | <i>service-name</i> — specifies a unique service name to identify the service. Service names may not begin with an integer (0-9).                                                                                                                                                                                                                                                                                     |

### 5.21.2.3 VPLS Show Commands

**Note:** The following command outputs are examples only; actual displays may differ depending on supported functionality and user configuration.

#### egress-label

**Syntax** `egress-label start-label [end-label]`

**Context** `show>service`

**Description** This command displays service information using the range of egress labels. If only the mandatory *start-label* parameter is specified, only services using the specified label are displayed. If both *start-label* and *end-label* parameters are specified, the services using the range of labels are displayed.

Use the **show router ldp bindings** command to display dynamic labels.

**Parameters** *start-label* — the starting egress label value for which to display services using the label range. If only *start-label* is specified, services only using *start-label* are displayed.

**Values** 0, 2048 to 131071

*end-label* — the ending egress label value for which to display services using the label range

**Values** 2049 to 131071

**Default** the *start-label* value

**Output** The following output is an example of service egress-label information, and [Table 64](#) describes the fields.

#### Output Example

```
*A:ALU-48>show>service# egress-label 0 100000

**Table 64 Service Egress Labels Field Descriptions**

| Label                    | Description                                                                                       |
|--------------------------|---------------------------------------------------------------------------------------------------|
| Svc Id                   | The ID that identifies a service                                                                  |
| Sdp Binding              | The binding that identifies an SDP                                                                |
| Type                     | Indicates whether the SDP binding is a spoke or a mesh                                            |
| I. Lbl                   | The VC label used by the far-end device to send packets to this device in this service by the SDP |
| E. Lbl                   | The VC label used by this device to send packets to the far-end device in this service by the SDP |
