| <b>Parameters</b> | <p><i>sap-id</i> — Specifies the physical port identifier portion of the SAP definition. See Common CLI Command Descriptions on page 1933 for command syntax.</p> <p><i>port-id</i> — Specifies the physical port ID in the <i>slot/mda/port</i> format.</p> <p>If the card in the slot has Media Dependent Adapters (MDAs) installed, the <i>port-id</i> must be in the <i>slot_number/MDA_number/port_number</i> format. For example 1/1/1 specifies port 1 on MDA 1 in slot 1.</p> <p>The <i>port-id</i> must reference a valid port type. When the <i>port-id</i> parameter represents SONET/SDH and TDM channels, the port ID must include the channel ID. A period “.” separates the physical port from the <i>channel-id</i>. The port must be configured as an access port.</p> <p>If the SONET/SDH port is configured as clear-channel then only the port is specified.</p> <p><b>create</b> — Keyword used to create a SAP instance. The <b>create</b> keyword requirement can be enabled/disabled in the <b>environment&gt;create</b> context.</p> |

| <b>Description</b> | <p>This command creates a new customer site or edits an existing customer site with the <i>customer-site-name</i> parameter. A customer site is an anchor point to create an ingress and egress virtual scheduler hierarchy. When a site is created, it must be assigned to a chassis slot or port with the exception of the 7750 SR-1 in which the slot is set to 1. When scheduler policies are defined for ingress and egress, the scheduler names contained in each policy are created according to the parameters defined in the policy. Multi-service customer sites exist for the sole purpose of creating a virtual scheduler hierarchy and making it available to queues on multiple Service Access Points (SAPs).</p> <p>The scheduler policy association with the customer site normally prevents the scheduler policy from being deleted until after the scheduler policy is removed from the customer site. The multi-service-site object will generate a log message indicating that the association was deleted due to scheduler policy removal.</p> <p>When the multi-service customer site is created, an ingress and egress scheduler policy association does not exist. This does not prevent the site from being assigned to a chassis slot or prevent service SAP assignment. After the site has been created, the ingress and egress scheduler policy associations can be assigned or removed at any time.</p> |
| <b>Default</b>     | None — Each customer site must be explicitly created.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <p><i>customer-site-name</i>: — Each customer site must have a unique name within the context of the customer. If <i>customer-site-name</i> already exists for the customer ID, the CLI context changes to that site name for the purpose of editing the site scheduler policies or assignment. Any modifications made to an existing site will affect all SAPs associated with the site. Changing a scheduler policy association may cause new schedulers to be created and existing queues on the SAPs to no longer be orphaned. Existing schedulers on the site may cease to exist, causing queues relying on that scheduler to be orphaned.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

If the *customer-site-name* does not exist, it is assumed that an attempt is being made to create a site of that name in the customer ID context. The success of the command execution depends on the following:

- The maximum number of customer sites defined for the chassis has not been met.
- The *customer-site-name* is valid.
- The **create** keyword is included in the command line syntax (if the system requires it).

When the maximum number of customer sites has been exceeded a configuration error occurs; the command will not execute and the CLI context will not change.

If the *customer-site-name* is invalid, a syntax error occurs; the command will not execute and the CLI context will not change.

**Values** Valid names consist of any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

## static-host

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Description</b> | This command configures a static host on this SAP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <p><b>ip</b> <i>ip-address</i> — Specifies the IPv4 unicast address.</p> <p><b>mac</b> <i>ieee-address</i> — Specify this optional parameter when defining a static host. Every static host definition must have at least one address defined, IP or MAC.</p> <p><b>force</b> — Specifies the forced removal of the static host addresses.</p> <p><b>sla-profile</b> <i>sla-profile-name</i> — This optional parameter is used to specify an existing SLA profile name to be associated with the static subscriber host. The SLA profile is configured in the <b>config&gt;subscr-mgmt&gt;sla-profile</b> context.</p> |

## ancp-string

|                    |                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ancp-string</b> <i>ancp-string</i><br><b>no ancp-string</b>                                       |
| <b>Context</b>     | config>service>ies>if>sap>static-host<br>config>service>ies>subscriber-inf>group-inf>sap>static-host |
| <b>Description</b> | This command specifies the ANCP string associated to this SAP host.                                  |

**Parameters**     *ancp-string* — Specifies the ANCP string up to 63 characters in length.

## app-profile

**Syntax**     **app-profile** *app-profile-name*  
**no app-profile**

**Context**     config>service>ies>if>sap>static-host  
 config>service>ies>subscriber-inf>group-inf>sap>static-host

**Description**     This command specifies an application profile name.

**Parameters**     *app-profile-name* — Specifies the application profile name up to 32 characters in length.

## inter-dest-id

**Syntax**     **inter-dest-id** *intermediate-destination-id*  
**no inter-dest-id**

**Context**     config>service>ies>if>sap>static-host  
 config>service>ies>subscriber-inf>group-inf>sap>static-host

**Description**     Specifies to which intermediate destination (for example, a DSLAM) this host belongs.

**Parameters**     *intermediate-destination-id* — Specifies the intermediate destination identifier, up to 32 characters in length.

## managed-routes

**Syntax**     **managed-routes**

**Context**     config>service>ies>sub-if>grp-if>sap>static-host>managed-routes

**Description**     This command configures managed routes.

## route

**Syntax**     **route** *{ip-prefix/length|ip-prefix netmask}* [**create**]  
**no route** *{ip-prefix/length|ip-prefix netmask}*

**Context**     config>service>ies>sub-if>grp-if>sap>static-host>managed-routes

**Description**     This command assigns managed-route to a given subscriber-host. As a consequence, a static-route pointing subscriber-host ip address as a next hop will be installed in FIB. Up to 16 managed routes per subscriber-host can be configured.

The **no** form of the command removes the respective route. Per default, there are no managed-routes configured.

## sla-profile

|                    |                                                                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>sla-profile</b> <i>sla-profile-name</i><br><b>no sla-profile</b>                                                                                                                             |
| <b>Context</b>     | config>service>ies>if>sap>static-host<br>config>service>ies>subscriber-inf>group-inf>sap>static-host                                                                                            |
| <b>Description</b> | This command specifies an existing SLA profile name to be associated with the static subscriber host. The SLA profile is configured in the <b>config&gt;subscr-mgmt&gt;sla-profile</b> context. |
| <b>Parameters</b>  | <i>sla-profile-name</i> — Specifies the SLA profile name.                                                                                                                                       |

## sub-profile

|                    |                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>sub-profile</b> <i>sub-profile-name</i><br><b>no sub-profile</b>                                          |
| <b>Context</b>     | config>service>ies>if>sap>static-host<br>config>service>ies>subscriber-inf>group-inf>sap>static-host         |
| <b>Description</b> | This command specifies an existing subscriber profile name to be associated with the static subscriber host. |
| <b>Parameters</b>  | <i>sub-profile-name</i> — Specifies the sub-profile name.                                                    |

## subscriber

|                    |                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>subscriber</b> <i>sub-ident</i><br><b>no subscriber</b>                                                             |
| <b>Context</b>     | config>service>ies>if>sap>static-host<br>config>service>ies>subscriber-inf>group-inf>sap>static-host                   |
| <b>Description</b> | This command specifies an existing subscriber identification profile to be associated with the static subscriber host. |
| <b>Parameters</b>  | <i>sub-ident</i> — Specifies the subscriber identification/                                                            |

## subscriber-sap-id

|                    |                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] subscriber-sap-id</b>                                                                        |
| <b>Context</b>     | config>service>ies>if>sap>static-host<br>config>service>ies>subscriber-inf>group-inf>sap>static-host |
| <b>Description</b> | This command enables using the SAP ID as subscriber id.                                              |
| <b>Parameters</b>  | <b>subscriber-sap-id</b> — Specifies to use the sap-id as the subscriber-id.                         |

## tod-suite

|                    |                                                                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>tod-suite</b> <i>tod-suite-name</i><br><b>no tod-suite</b>                                                                                                                                |
| <b>Context</b>     | config>service>ies>if>sap<br>config>service>ies>sub-if>grp-if>sap                                                                                                                            |
| <b>Description</b> | This command applies a time-based policy (filter or QoS policy) to the service SAP. The suite name must already exist in the <b>config&gt;cron</b> context.                                  |
| <b>Default</b>     | no tod-suite                                                                                                                                                                                 |
| <b>Parameters</b>  | <i>tod-suite-name</i> — Specifies collection of policies (ACLs, QoS) including time-ranges that define the full or partial behavior of a SAP. The suite can be applied to more than one SAP. |

## host-connectivity-verify

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Description</b> | This command enables subscriber host connectivity verification for all hosts on this interface. This tool will periodically scan all known hosts (from dhcp-state) and perform a UC ARP request. The subscriber host connectivity verification will maintain state (connected vs. not-connected) for all hosts.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Default</b>     | no host-connectivity-verify                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <p><b>source {interface}</b> — Specifies the source to be used for generation of subscriber host connectivity verification packets. The <b>interface</b> keyword forces the use of the interface mac and ip addresses. Note that there are up to 16 possible subnets on a given interface, therefore subscriber host connectivity verification tool will use always an address of the subnet to which the given host is pertaining. In case of group-interfaces. one of the parent subscriber-interface subnets (depending on host's address) will be used.</p> <p><b>interval <i>interval</i></b> — The interval, in minutes, which specifies the time interval which all known sources should be verified. The actual rate is then dependent on number of known hosts and interval.</p> <p><b>Values</b> 1 — 6000<br/>Note that a zero value can be used by the SNMP agent to disable host-connectivity-verify.</p> <p><b>action {remove   alarm}</b> — Defines the action taken on a subscriber host connectivity verification failure for a given host. The <b>remove</b> keyword raises an alarm and removes DHCP state and releases all allocated resources (queues, table entries and etc.). DHCP release will be signaled to corresponding DHCP server. Static host will never be removed. The <b>alarm</b> keyword raises an alarm indicating that the host is disconnected.</p> |

| <b>Description</b> | <p>This command specifies a default SLA profile for this SAP. The SLA profile must be defined prior to associating the profile with a SAP in the <b>config&gt;subscriber-mgmt&gt;sla-profile</b> context.</p> <p>An SLA profile is a named group of QoS parameters used to define per service QoS for all subscriber hosts common to the same subscriber within a provider service offering. A single SLA profile may define the QoS parameters for multiple subscriber hosts. SLA profiles are maintained in two locations, the subscriber identification policy and the subscriber profile templates. After a subscriber host is associated with an SLA profile name, either the subscriber identification policy used to identify the subscriber or the subscriber profile associated with the subscriber host must contain an SLA profile with that name. If both the subscriber identification policy and the subscriber profile contain the SLA profile name, the SLA profile in the subscriber profile is used.</p> <p>The <b>no</b> form of the command removes the default SLA profile from the SAP configuration.</p> |

|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>def-sub-profile</b> <i>default-subscriber-profile-name</i>                                                                                                                                                        |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>sap>sub-sla-mgmt                                                                                                                                                                    |
| <b>Description</b> | This command specifies a default subscriber profile for this SAP. The subscriber profile must be defined prior to associating the profile with a SAP in the <b>config&gt;subscriber-mgmt&gt;sub-profile</b> context. |

A subscriber profile defines the aggregate QoS for all hosts within a subscriber context. This is done through the definition of the egress and ingress scheduler policies that govern the aggregate SLA for subscriber using the subscriber profile. Subscriber profiles also allow for specific SLA profile definitions when the default definitions from the subscriber identification policy must be overridden.

The **no** form of the command removes the default SLA profile from the SAP configuration.

**Parameters** *default-sub-profile* — Specifies a default subscriber profile for this SAP. The subscriber profile must be defined prior to associating the profile with a SAP in the **config>subscriber-mgmt>sub-profile** context.

## sub-ident-policy

**Syntax** **sub-ident-policy** *sub-ident-policy-name*

**Context** config>service>ies>sub-if>grp-if>sap>sub-sla-mgmt

**Description** This command associates a subscriber identification policy to this SAP. The subscriber identification policy must be defined prior to associating the profile with a SAP in the **config>subscriber-mgmt>sub-ident-policy** context.

Subscribers are managed by the system through the use of subscriber identification strings. A subscriber identification string uniquely identifies a subscriber. For static hosts, the subscriber identification string is explicitly defined with each static subscriber host.

For dynamic hosts, the subscriber identification string must be derived from the DHCP ACK message sent to the subscriber host. The default value for the string is the content of Option 82 CIRCUIT-ID and REMOTE-ID fields interpreted as an octet string. As an option, the DHCP ACK message may be processed by a subscriber identification policy which has the capability to parse the message into an alternative ASCII or octet string value.

When multiple hosts on the same port are associated with the same subscriber identification string they are considered to be host members of the same subscriber.

The **no** form of the command removes the default subscriber identification policy from the SAP configuration.

**Default** no sub-ident-policy

**Parameters** *sub-ident-policy-name* — Specifies a subscriber identification policy for this SAP. The subscriber profile must be defined prior to associating the profile with a SAP in the **config>subscriber-mgmt>sub-ident-policy** context.

## multi-sub-sap

**Syntax** **multi-sub-sap** [*subscriber-limit*]  
**no multi-sub-sap**

**Context** config>service>ies>sub-if>grp-if>sap>sub-sla-mgmt

**Description** This command configures the maximum number of subscribers for this SAP.

The **no** form of this command returns the default value.

|                   |                                                                                     |
|-------------------|-------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>subscriber-limit</i> — Specifies the maximum number of subscribers for this SAP. |
| <b>Values</b>     | 2 — 8000                                                                            |

## single-sub-parameters

|                    |                                                                                          |
|--------------------|------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>single-sub-parameters</b>                                                             |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>sap>sub-sla-mgmt                                        |
| <b>Description</b> | This command enables the context to configure single subscriber parameters for this SAP. |

## non-sub-traffic

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Description</b> | This command configures non-subscriber traffic profiles.<br>The <b>no</b> form of the command removes the profiles and disables the feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <p><b>sub-profile</b> <i>sub-profile-name</i> — Specifies an existing subscriber profile name to be associated with the static subscriber host. The subscriber profile is configured in the <b>config&gt;subscr-mgmt&gt;sub-profile</b> context.</p> <p><b>sla-profile</b> <i>sla-profile-name</i> — Specifies an existing SLA profile name to be associated with the static subscriber host. The SLA profile is configured in the <b>config&gt;subscr-mgmt&gt;sla-profile</b> context.</p> <p><b>subscriber</b> <i>sub-ident-string</i> — Specifies an existing subscriber identification profile to be associated with the static subscriber host. The subscriber identification profile is configured in the <b>config&gt;subscr-mgmt&gt;sub-ident-policy</b> context. The subscriber information is used by the VPRN SAP arp-reply-agent to determine the proper handling of received ARP requests from subscribers.</p> <ul style="list-style-type: none"> <li>For VPRN SAPs with <b>arp-reply-agent</b> enabled with the optional <i>sub-ident</i> parameter, the static subscriber host's <i>sub-ident-string</i> is used to determine whether an ARP request received on the SAP is sourced from a host belonging to the same subscriber as the destination host. When both the destination and source hosts from the ARP request are known on the SAP and the subscriber identifications do not match, the ARP request may be forwarded to the rest of the VPRN destinations.</li> </ul> <p>If the static subscriber host's <i>sub-ident</i> string is not defined, the host is not considered to belong to the same subscriber as another host on the SAP.</p> <p>If source or destination host is unknown, the hosts are not considered to belong to the same subscriber. ARP messages from unknown hosts are subject to anti-spoof filtering rules applied at the SAP.</p> |

If *sub-ident* is not enabled on the SAP arp-reply-agent, subscriber identification matching is not performed on ARP requests received on the SAP.

ARP requests are never forwarded back to the same SAP or within the receiving SAP's split horizon group.

## profiled-traffic-only

| <b>Context</b>     | config>service>ies>if>sap<br>config>service>ies>sub-if>grp-if>sap                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | This command creates the accounting policy context that can be applied to a SAP.<br>An accounting policy must be defined before it can be associated with a SAP.<br>If the <i>policy-id</i> does not exist, an error message is generated.<br>A maximum of one accounting policy can be associated with a SAP at one time. Accounting policies are configured in the <b>config&gt;log</b> context.<br>The <b>no</b> form of this command removes the accounting policy association from the SAP, and the accounting policy reverts to the default. |
| <b>Default</b>     | Default accounting policy.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <i>acct-policy-id</i> — Enter the accounting <i>policy-id</i> as configured in the <b>config&gt;log&gt;accounting-policy</b> context.<br><b>Values</b> 1 to 99                                                                                                                                                                                                                                                                                                                                                                                     |

## collect-stats

|                    |                                                                                                                                                                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] collect-stats</b>                                                                                                                                                                                                                                      |
| <b>Context</b>     | config>service>ies>if>sap<br>config>service>ies>sub-if>grp-if>sap                                                                                                                                                                                              |
| <b>Description</b> | This command enables accounting and statistical data collection for either the SAP, network port, or IP interface. When applying accounting policies the data, by default, is collected in the appropriate records and written to the designated billing file. |

When the **no collect-stats** command is issued the statistics are still accumulated by the IOM cards. However, the CPU will not obtain the results and write them to the billing file. If a subsequent **collect-stats** command is issued then the counters written to the billing file include all the traffic while the **no collect-stats** command was in effect.

**Default**    collect-stats

## ETH-CFM Service Commands

### eth-cfm

|                    |                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>eth-cfm</b>                                                                                    |
| <b>Context</b>     | config>service>ies>if>sap<br>config>service>ies>if>spoke-sdp<br>config>service>ies>sub-if>grp-if> |
| <b>Description</b> | This command enables the context to configure ETH-CFM parameters.                                 |

### mep

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>mep</b> <i>mep-id</i> <b>domain</b> <i>md-index</i> <b>association</b> <i>ma-index</i> [ <b>direction</b> { <b>up</b>   <b>down</b> }]<br><b>no mep</b> <i>mep-id</i> <b>domain</b> <i>md-index</i> <b>association</b> <i>ma-index</i>                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Context</b>     | config>service>ies>if>sap>eth-cfm<br>config>service>ies>if>spoke-sdp>eth-cfm<br>config>service>ies>sub-if>grp-if>sap>eth-cfm                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b> | This command configures a SAP or spoke SDP ETH-CFM maintenance endpoint (MEP).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <p><i>mep-id</i> — Specifies the maintenance association end point identifier.</p> <p><b>Values</b> 1 — 8191</p> <p><i>md-index</i> — Specifies the maintenance domain (MD) index value.</p> <p><b>Values</b> 1 — 4294967295</p> <p><i>ma-index</i> — Specifies the MA index value.</p> <p><b>Values</b> 1 — 4294967295</p> <p><b>direction up down</b> — Indicates the direction in which the maintenance association (MEP or MIP) faces on the bridge port.</p> <p>down — Sends continuity check messages away from the MAC relay entity.</p> <p>up — Sends continuity check messages towards the MAC relay entity.</p> |

### ccm-enable

|                    |                                                                                      |
|--------------------|--------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] ccm-enable</b>                                                               |
| <b>Context</b>     | config>service>ies>if>sap>eth-cfm>mep<br>config>service>ies>if>spoke-sdp>eth-cfm>mep |
| <b>Description</b> | This command enables the generation of CCM messages.                                 |

The **no** form of the command disables the generation of CCM messages.

## ccm-ltm-priority

|                    |                                                                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ccm-ltm-priority</b> <i>priority</i><br><b>no ccm-ltm-priority</b>                                                                                                       |
| <b>Context</b>     | config>service>ies>if>sap>eth-cfm>mep<br>config>service>ies>if>spoke-sdp>eth-cfm>mep                                                                                        |
| <b>Description</b> | This command specifies the priority value for CCMs and LTMs transmitted by the MEP.<br>The <b>no</b> form of the command removes the priority value from the configuration. |
| <b>Default</b>     | The highest priority on the bridge-port.                                                                                                                                    |
| <b>Parameters</b>  | <i>priority</i> — Specifies the priority of CCM and LTM messages.                                                                                                           |
| <b>Values</b>      | 0 — 7                                                                                                                                                                       |

## fault-propagation-enable

|                    |                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>fault-propagation-enable</b> { <i>use-if-tlv</i>   <i>suspend-ccm</i> }<br><b>no fault-propagation-enable</b>                         |
| <b>Context</b>     | config>service>ies>if>sap>eth-cfm>mep<br>config>service>ies>if>spoke-sdp>eth-cfm>mep<br>config>service>ies>sub-if>grp-if>sap>eth-cfm>mep |
| <b>Description</b> | This command configures the fault propagation for the MEP.                                                                               |
| <b>Parameters</b>  | <b>use-if-tlv</b> — Specifies to use the interface TLV.<br><b>suspend-ccm</b> — Specifies to suspend the continuity check messages.      |

## low-priority-defect

|                    |                                                                                                                                                                                                                                                                                                                  |        |                                                                    |               |                                                              |            |                                                |

| <b>Description</b>   | <p>This command associates an IP filter policy filter policy with an ingress or egress spoke SDP. Filter policies control the forwarding and dropping of packets based on matching criteria. MAC filters are only allowed on Epipe and Virtual Private LAN Service (VPLS) SAPs.</p> <p>The <b>filter</b> command is used to associate a filter policy with a specified <i>ip-filter-id</i> with an ingress or egress spoke SDP. The <i>ip-filter-id</i> must already be defined in the <b>configure&gt;filter</b> context before the <b>filter</b> command is executed. If the filter policy does not exist, the operation will fail and an error message returned.</p> <p>In general, filters applied to SAPs or spoke SDPs (ingress or egress) apply to all packets on the SAP or spoke SDPs . One exception is non-IP packets are not applied to IP match criteria, so the default action in the filter policy applies to these packets.</p> <p>The <b>no</b> form of this command removes any configured filter ID association with the SAP or IP interface. The filter ID itself is not removed from the system unless the scope of the created filter is set to local. To avoid deletion of the filter ID and only break the association with the service object, use <b>scope</b> command within the filter definition to change the scope to <b>local</b> or <b>global</b>. The default scope of a filter is <b>local</b>.</p> |
| <b>Special Cases</b> | <b>IES</b> — Only IP filters are supported on IES IP interfaces, and the filters only apply to routed traffic.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>    | <p><b>ip</b> — Keyword indicating the filter policy is an IP filter.</p> <p><i>ip-filter-id</i> — The filter name acts as the ID for the IP filter policy. Allowed values are an integer in the range of 1 and 65535 that corresponds to a previously created IP filter policy. The filter ID must already exist within the created IP filters.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## egress

| <b>Context</b>     | config>service>ies>if>sap>egress>hsm da-queue-over<br>config>service>ies>if>sap>ingress>hsm da-queue-over                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b> | <p>This command adds or subtracts the specified number of bytes to the accounting function for each packet handled by the HSM DA queue. Normally, the accounting and leaky bucket functions are based on the Ethernet DLC header, payload and the 4-byte CRC (everything except the preamble and inter-frame gap). For example, this command can be used to add the frame encapsulation overhead (20 bytes) to the queues accounting functions.</p> <p>The accounting functions affected include:</p> <ul style="list-style-type: none"> <li>• Offered High Priority / In-Profile Octet Counter</li> <li>• Offered Low Priority / Out-of-Profile Octet Counter</li> <li>• Discarded High Priority / In-Profile Octet Counter</li> <li>• Discarded Low Priority / Out-of-Profile Octet Counter</li> <li>• Forwarded In-Profile Octet Counter</li> <li>• Forwarded Out-of-Profile Octet Counter</li> <li>• Peak Information Rate (PIR) Leaky Bucket Updates</li> <li>• Committed Information Rate (CIR) Leaky Bucket Updates</li> <li>• Queue Group Aggregate Rate Limit Leaky Bucket Updates</li> </ul> |

The secondary shaper leaky bucket, scheduler priority level leaky bucket and the port maximum rate updates are not affected by the configured packet-byte-offset. Each of these accounting functions are frame based and always include the preamble, DLC header, payload and the CRC regardless of the configured byte offset.

The packet-byte-offset command accepts either add or subtract as valid keywords which define whether bytes are being added or removed from each packet traversing the queue. Up to 20 bytes may be added to the packet and up to 43 bytes may be removed from the packet. An example use case for subtracting bytes from each packet is an IP based accounting function. Given a Dot1Q encapsulation, the command packet-byte-offset subtract 14 would remove the DLC header and the Dot1Q header

from the size of each packet for accounting functions only. The 14 bytes are not actually removed from the packet, only the accounting size of the packet is affected.

As mentioned above, the variable accounting size offered by the packet-byte-offset command is targeted at the queue and queue group level. When the queue group represents the last-mile bandwidth constraints for a subscriber, the offset allows the HSMDA queue group to provide an accurate accounting to prevent overrun and underrun conditions for the subscriber. The accounting size of the packet is ignored by the secondary shapers, the scheduling priority level shapers and the scheduler maximum rate. The actual on-the-wire frame size is used for these functions to allow an accurate representation of the behavior of the subscriber's packets on an Ethernet aggregation network.

The packet-byte-offset value can be overridden for the HSMDA queue at the SAP or subscriber profile level.

The **no** form of the command removes any accounting size changes to packets handled by the queue. The command does not effect overrides that may exist on SAPs or subscriber profiles associated with the queue.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Description</b> | <p>This command, within the QoS policy hsmda-queue context, is a container for the configuration parameters controlling the behavior of an HSMDA queue. Unlike the standard QoS policy queue command, this command is not used to actually create or dynamically assign the queue to the object which the policy is applied. The queue identified by queue-id always exists on the SAP or subscriber context whether the command is executed or not. In the case of HSMDA SAPs and subscribers, all eight queues exist at the moment the system allocates an HSMDA queue group to the object (both ingress and egress).</p> <p>Best-Effort, Expedited and Auto-Expedite Queue Behavior Based on Queue-ID</p> |

With standard service queues, the scheduling behavior relative to other queues is based on two items, the queues Best-Effort or Expedited nature and the dynamic rate of the queue relative to the defined CIR. HSMDA queues are handled differently. The create time auto-expedite and explicit expedite and best-effort qualifiers have been eliminated and instead the scheduling behavior is based solely on the queues identifier. Queues with a queue-id equal to 1 are placed in scheduling class 1. Queues with queue-id 2 are placed in scheduling class 2. And so on up to scheduling class 8. Each scheduling class is either mapped directly to a strict scheduling priority level based on the class ID, or the class may be placed into a weighted scheduling class group providing byte fair weighted round robin scheduling between the members of the group. Two weighted groups are supported and each may contain up to three consecutive scheduling classes. The weighed group assumes its highest member classis inherent strict scheduling level for scheduling purposes. Strict priority level 8 has the highest priority while strict level 1 has the lowest. When grouping of scheduling classes is defined, some of the strict levels will not be in use.

Single Type of HSMDA Queues

Another difference between HSMDA queues and standard service queues is the lack of Multipoint queues. At ingress, an HSMDA SAP or subscriber does not require Multipoint queues since all forwarding types (broadcast, multicast, unicast and unknown) forward to a single destination ñ the ingress forwarding plane on the IOM. Instead of a possible eight queues per forwarding type (for a total of up to 32) within the SAP ingress QoS policy, the hsmda-queues node supports a maximum of eight queues.

Every HSMDA Queue Supports Profile Mode Implicitly

Unlike standard service queues, the HSMDA queues do not need to be placed into the special mode profile at create time in order to support ingress color aware policing. Each queue may handle in-profile, out-of-profile and profile undefined packets simultaneously. As with standard queues, the explicit profile of a packet is dependant on ingress sub-forwarding class to which the packet is mapped.

The **no** form of the command restores the defined queue-id to its default parameters. All HSMDA queues having the queue-id and associated with the QoS policy are re-initialized to default parameters.

| <b>Description</b> | <p>This command assigns an HSMDB slope policy to the SAP. The policy may be assigned to an ingress or egress HSMDB queue. The policy contains the Maximum Buffer Size (MBS) that will be applied to the queue and the high and low priority RED slope definitions. The function of the MBS and RED slopes is to provide congestion control for an HSMDB queue. The MBS parameter defines the maximum depth a queue may reach when accepting packets. The low and high priority RED slopes provides for random early detection of congestion and slope based discards based on queue depth.</p> <p>An HSMDB slope policy can be applied to queues defined in the SAP ingress and SAP egress QoS policy HSMDB queues context. Once an HSMDB slope policy is applied to a SAP QoS policy queue, it cannot be deleted. Any edits to the policy are updated to all HSMDB queues indirectly associated with the policy.</p> <p>Default HSMDB Slope Policy</p> <p>An HSMDB slope policy named “default” always exists on the system and does not need to be created. The default policy is automatically applied to all HSMDB queues unless another HSMDB slope policy is specified for the queue. The default policy cannot be modified or deleted. Attempting to execute the <b>no hsmdb-slope-policy default</b> command results in an error.</p> <p>The <b>no</b> form of the command removes the specified HSMDB slope policy from the configuration. If the HSMDB slope policy is currently associated with an HSMDB queue, the command will fail.</p> |
| <b>Parameters</b>  | <i>hsmdb-slope-policy-name</i> — Specifies a HSMDB slope policy up to 32 characters in length. The HSMDB slope policy must be exist prior to applying the policy name to an HSMDB queue.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## secondary-shaper

|                    |                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>secondary-shaper</b> <i>secondary-shaper-name</i><br><b>no secondary-shaper</b>                      |

| <b>Description</b> | <p>This command specifies which Dot1Q tag position Dot1P bits in a QinQ encapsulated packet should be used to evaluate Dot1P QoS classification.</p> <p>The <b>match-qinq-dot1p</b> command allows the top or bottom PBits to be used when evaluating the applied sap-ingress QoS policy's Dot1P entries. The <b>top</b> and <b>bottom</b> keywords specify which position should be evaluated for QinQ encapsulated packets.</p> <p>The <b>no</b> form of the command restores the default dot1p evaluation behavior for the SAP.</p> <p>By default, the bottom most service delineating Dot1Q tags Dot1P bits are used. <a href="#">Table 17</a> defines the default behavior for Dot1P evaluation when the <b>match-qinq-dot1p</b> command is not executed.</p> |

**Default** no match-qinq-dot1p — No filtering based on p-bits.  
top or bottom must be specified to override the default QinQ dot1p behavior.

**Parameters** **top** — The top parameter is mutually exclusive to the bottom parameter. When the top parameter is specified, the top most PBits are used (if existing) to match any dot1p dot1p-value entries. [Table 18](#) defines the dot1p evaluation behavior when the top parameter is specified.

**Table 18: Top Position QinQ and TopQ SAP Dot1P Evaluation**

| Port / SAP Type | Existing Packet Tags          | PBits Used for Match |
|-----------------|-------------------------------|----------------------|
| Null            | None                          | None                 |
| Null            | Dot1P (VLAN-ID 0)             | Dot1P PBits          |
| Null            | Dot1Q                         | Dot1Q PBits          |
| Null            | TopQ BottomQ                  | TopQ PBits           |
| Null            | TopQ (No BottomQ)             | TopQ PBits           |
| Dot1Q           | None (Default SAP)            | None                 |
| Dot1Q           | Dot1P (Default SAP VLAN-ID 0) | Dot1P PBits          |

**Table 20: Default Dot1P Explicit Marking Actions**

| Egress SAP Type | Ingress Packet Preserved Dot1P State                  | Marked (or Remarked) PBits                                   |
|-----------------|-------------------------------------------------------|--------------------------------------------------------------|
| Null            | No preserved Dot1P bits                               | None                                                         |
| Null            | Preserved Dot1P bits                                  | Preserved tag PBits remarked using dot1p-value               |
| Dot1Q           | No preserved Dot1P bits                               | New PBits marked using dot1p-value                           |
| Dot1Q           | Preserved Dot1P bits                                  | Preserved tag PBits remarked using dot1p-value               |
| TopQ            | No preserved Dot1P bits                               | TopQ PBits marked using dot1p-value                          |
| TopQ            | Preserved Dot1P bits (used as TopQ and BottomQ PBits) | TopQ PBits marked using dot1p-value, BottomQ PBits preserved |
| QinQ            | No preserved Dot1P bits                               | TopQ PBits and BottomQ PBits marked using dot1p-value        |
| QinQ            | Preserved Dot1P bits (used as TopQ and BottomQ PBits) | TopQ PBits and BottomQ PBits marked using dot1p-value        |

**Table 21: QinQ Mark Top Only Explicit Marking Actions**

| Egress SAP Type | Ingress Packet Preserved Dot1P State | Marked (or Remarked) PBits                     |
|-----------------|--------------------------------------|------------------------------------------------|
| Null            | No preserved Dot1P bits              | None                                           |
| Null            | Preserved Dot1P bits                 | Preserved tag PBits remarked using dot1p-value |
| Dot1Q           | No preserved Dot1P bits              | New PBits marked using dot1p-value             |
| Dot1Q           | Preserved Dot1P bits                 | Preserved tag PBits remarked using dot1p-value |
| TopQ            | No preserved Dot1P bits              | TopQ PBits marked using dot1p-value            |

Table 21: QinQ Mark Top Only Explicit Marking Actions

| Egress SAP Type | Ingress Packet Preserved Dot1P State                  | Marked (or Remarked) PBits                                                      |
|-----------------|-------------------------------------------------------|---------------------------------------------------------------------------------|
| TopQ            | Preserved Dot1P bits (used as TopQ and BottomQ PBits) | TopQ PBits marked using dot1p-value, BottomQ PBits preserved                    |
| QinQ            | No preserved Dot1P bits                               | TopQ PBits marked using dot1p-value, BottomQ PBits marked with zero             |
| QinQ            | Preserved Dot1P bits (used as TopQ and BottomQ PBits) | TopQ PBits marked using dot1p-value, BottomQ PBits marked using preserved value |

The QinQ and TopQ SAP PBit marking follows the default behavior defined in the above tables when **qinq-mark-top-only** is not specified.

The dot1p dot1p-value command must be configured without the qinq-mark-top-only parameter to remove the TopQ PBits only marking restriction.

## agg-rate-limit

| <b>Description</b> | <p>This command defines a maximum total rate for all egress queues on a service SAP or multi-service site. The <b>agg-rate-limit</b> command is mutually exclusive with the egress scheduler policy. When an egress scheduler policy is defined, the <b>agg-rate-limit</b> command will fail. If the <b>agg-rate-limit</b> command is specified, an attempt to bind a <b>scheduler-policy</b> to the SAP or multi-service site will fail.</p> <p>A multi-service site must have a port scope defined that ensures all queues associated with the site are on the same port or channel. If the scope is not set to a port, the agg-rate-limit command will fail. Once an agg-rate-limit has been assigned to a multi-service site, the scope cannot be changed to card level.</p> <p>A port scheduler policy must be applied on the egress port or channel the SAP or multi-service site are bound to in order for the defined agg-rate-limit to take effect. The egress port scheduler enforces the aggregate queue rate as it distributes its bandwidth at the various port priority levels. The port scheduler stops offering bandwidth to member queues once it has detected that the aggregate rate limit has been reached.</p> <p>If a port scheduler is not defined on the egress port, the queues are allowed to operate based on their own bandwidth parameters.</p> <p>The <b>no</b> form of the command removes the aggregate rate limit from the SAP or multi-service site.</p> |
| <b>Parameters</b>  | <p><i>agg-rate</i> — Defines the rate, in kilobits-per-second, that the maximum aggregate rate that the queues on the SAP or MSS can operate.</p> <p><b>Values</b> 1 — 40000000, max</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**queue-frame-based-accounting** — This keyword enables frame based accounting on all queues associated with the SAP or Multi-Service Site. If frame based accounting is required when an aggregate limit is not necessary, the **max** keyword should precede the **queue-frame-based-accounting** keyword. If frame based accounting must be disabled, execute **agg-rate-limit** without the **queue-frame-based-accounting** keyword present.

**Default** Frame based accounting is disabled by default

| <b>Description</b> | <p>Associates a Quality of Service (QoS) policy with an ingress or egress Service Access Point (SAP) or IP interface.</p> <p>QoS ingress and egress policies are important for the enforcement of SLA agreements. The policy ID must be defined prior to associating the policy with a SAP or IP interface. If the <i>policy-id</i> does not exist, an error will be returned.</p> <p>The <b>qos</b> command is used to associate both ingress and egress QoS policies. The <b>qos</b> command only allows ingress policies to be associated on SAP or IP interface ingress and egress policies on SAP or IP interface egress. Attempts to associate a QoS policy of the wrong type returns an error.</p> <p>Only one ingress and one egress QoS policy can be associated with a SAP or IP interface at one time. Attempts to associate a second QoS policy of a given type will return an error.</p> <p>When an ingress QoS policy is defined on IES ingress IP interface that is bound to a VPLS, the policy becomes associated with every SAP on the VPLS and augments the QoS policy that is defined on each SAP. Packets that are bridged will be processed using the policy defined on the VPLS SAP; packets that are routed will be processed using the policy defined in the IES IP interface-binding context.</p> <p>When an egress QoS policy is associated with an IES IP interface that has been bound to a VPLS, the</p> |

policy becomes associated with every SAP on the VPLS and augments the egress QoS policy that is defined on each SAP. Packets that are bridged will be processed using the policy defined on the VPLS SAP; packets that are routed will be processed using the policy defined in the IES IP interface-binding context.

By default, no specific QoS policy is associated with the SAP or IP interface for ingress or egress, so the default QoS policy is used.

The **no** form of this command removes the QoS policy association from the SAP or IP interface, and the QoS policy reverts to the default.

*policy-id* — The policy ID to associate with SAP or IP interface on ingress/egress. The policy ID must already exist.

**Values** 1 — 65535

**shared-queuing** — This keyword can only be specified on SAP ingress. Specify the ingress shared queue policy used by this SAP. When the value of this object is null it means that the SAP will use individual ingress QoS queues, instead of the shared ones.

**multipoint-shared** — This keyword specifies that this *queue-id* is for multipoint forwarded traffic only. This *queue-id* can only be explicitly mapped to the forwarding class multicast, broadcast, or unknown unicast ingress traffic. If you attempt to map forwarding class unicast traffic to a multipoint queue, an error is generated and no changes are made to the current unicast traffic queue mapping.

A queue must be created as multipoint. The **multipoint** designator cannot be defined after the queue is created. If an attempt is made to modify the command to include the **multipoint** keyword, an error is generated and the command will not execute.

The **multipoint** keyword can be entered in the command line on a pre-existing multipoint queue to edit *queue-id* parameters.

## queue-override

| <b>Description</b> | This command enables the context to configure override values for the specified SAP egress QoS queue. These values override the corresponding ones specified in the associated SAP egress or ingress QoS policy. |

## queue

|                    |                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] queue <i>queue-id</i></b>                                                                   |
| <b>Context</b>     | config>service>ies>if>sap>egress>queue-override<br>config>service>ies>if>sap>ingress>queue-override |
| <b>Description</b> | This command specifies the ID of the queue whose parameters are to be overridden.                   |

**Parameters** *queue-id* — The queue ID whose parameters are to be overridden.

**Values** 1 — 32

## adaptation-rule

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Description</b> | <p>This command can be used to override specific attributes of the specified queue's adaptation rule parameters. The adaptation rule controls the method used by the system to derive the operational CIR and PIR settings when the queue is provisioned in hardware. For the CIR and PIR parameters individually, the system attempts to find the best operational rate depending on the defined constraint.</p> <p>The <b>no</b> form of the command removes any explicitly defined constraints used to derive the operational CIR and PIR created by the application of the policy. When a specific <b>adaptation-rule</b> is removed, the default constraints for <b>rate</b> and <b>cir</b> apply.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Default</b>     | no adaptation-rule                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <p><b>pir</b> — The <b>pir</b> parameter defines the constraints enforced when adapting the PIR rate defined within the <b>queue queue-id rate</b> command. The <b>pir</b> parameter requires a qualifier that defines the constraint used when deriving the operational PIR for the queue. When the <b>rate</b> command is not specified, the default applies.</p> <p><b>max</b> — The <b>max</b> (maximum) option is mutually exclusive with the <b>min</b> and <b>closest</b> options. When <b>max</b> is defined, the operational PIR for the queue will be equal to or less than the administrative rate specified using the <b>rate</b> command.</p> <p><b>min</b> — The <b>min</b> (minimum) option is mutually exclusive with the <b>max</b> and <b>closest</b> options. When <b>min</b> is defined, the operational PIR for the queue will be equal to or greater than the administrative rate specified using the <b>rate</b> command.</p> <p><b>closest</b> — The <b>closest</b> parameter is mutually exclusive with the <b>min</b> and <b>max</b> parameter. When <b>closest</b> is defined, the operational PIR for the queue will be the rate closest to the rate specified using the <b>rate</b> command.</p> <p><b>cir</b> — The <b>cir</b> parameter defines the constraints enforced when adapting the CIR rate defined within the <b>queue queue-id rate</b> command. The <b>cir</b> parameter requires a qualifier that defines the constraint used when deriving the operational CIR for the queue. When the <b>cir</b> parameter is not specified, the default constraint applies.</p> |

## avg-frame-overhead

|                |                                                                                                           |
|----------------|-----------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>avg-frame-overhead</b> <i>percent</i><br><b>no avg-frame-overhead</b>                                  |
| <b>Context</b> | config>service>ies>if>sap>egress>queue-override<br>config>service>ies>if>sap>ingress>queue-override>queue |

**Description** This command configures the average frame overhead to define the average percentage that the offered load to a queue will expand during the frame encapsulation process before sending traffic on-the-wire. While the avg-frame-overhead value may be defined on any queue, it is only used by the system for queues that egress a Sonet or SDH port or channel. Queues operating on egress Ethernet ports automatically calculate the frame encapsulation overhead based on a 20 byte per packet rule (8 bytes for preamble and 12 bytes for inter-frame gap).

When calculating the frame encapsulation overhead for port scheduling purposes, the system determines the following values:

- **Offered-load** — The offered-load of a queue is calculated by starting with the queue depth in octets, adding the received octets at the queue and subtracting queue discard octets. The result is the number of octets the queue has available to transmit. This is the packet based offered-load.
- **Frame encapsulation overhead** — Using the avg-frame-overhead parameter, the frame encapsulation overhead is simply the queue's current offered-load (how much has been received by the queue) multiplied by the avg-frame-overhead. If a queue had an offered load of 10000 octets and the avg-frame-overhead equals 10%, the frame encapsulation overhead would be  $10000 \times 0.1$  or 1000 octets.

For egress Ethernet queues, the frame encapsulation overhead is calculated by multiplying the number of offered-packets for the queue by 20 bytes. If a queue was offered 50 packets then the frame encapsulation overhead would be  $50 \times 20$  or 1000 octets.

- **Frame based offered-load** — The frame based offered-load is calculated by adding the offered-load to the frame encapsulation overhead. If the offered-load is 10000 octets and the encapsulation overhead was 1000 octets, the frame based offered-load would equal 11000 octets.
  - **Packet to frame factor** — The packet to frame factor is calculated by dividing the frame encapsulation overhead by the queue's offered-load (packet based). If the frame encapsulation overhead is 1000 octets and the offered-load is 10000 octets then the packet to frame factor would be  $1000 / 10000$  or 0.1. When in use, the avg-frame-overhead will be the same as the packet to frame factor making this calculation unnecessary.
  - **Frame based CIR** — The frame based CIR is calculated by multiplying the packet to frame factor with the queue's configured CIR and then adding that result to that CIR. If the queue CIR is set at 500 octets and the packet to frame factor equals 0.1, the frame based CIR would be  $500 \times 1.1$  or 550 octets.
  - **Frame based within-cir offered-load** — The frame based within-cir offered-load is the portion of the frame based offered-load considered to be within the frame-based CIR. The frame based within-cir offered-load is the lesser of the frame based offered-load and the frame based CIR. If the frame based offered-load equaled 11000 octets and the frame based CIR equaled 550 octets, the frame based within-cir offered-load would be limited to 550 octets. If the frame based offered-load equaled 450 octets and the frame based CIR equaled 550 octets, the frame based within-cir offered-load would equal 450 octets (or the entire frame based offered-load).
- As a special case, when a queue or associated intermediate scheduler is configured with a CIR-weight equal to 0, the system automatically sets the queue's frame based within-cir offered-load to 0, preventing it from receiving bandwidth during the port scheduler's within-cir pass.
- **Frame based PIR** — The frame based PIR is calculated by multiplying the packet to frame factor with the queue's configured PIR and then adding the result to that PIR. If the queue PIR is set to 7500 octets and the packet to frame factor equals 0.1, the frame based PIR would be  $7500 \times 1.1$  or 8250 octets.

- **Frame based within-pir offered-load** — The frame based within-pir offered-load is the portion of the frame based offered-load considered to be within the frame based PIR. The frame based within-pir offered-load is the lesser of the frame based offered-load and the frame based PIR. If the frame based offered-load equaled 11000 octets and the frame based PIR equaled 8250 octets, the frame based within-pir offered-load would be limited to 8250 octets. If the frame based offered-load equaled 7000 octets and the frame based PIR equaled 8250 octets, the frame based within-pir offered load would equal 7000 octets.

**Port scheduler operation using frame transformed rates** — The port scheduler uses the frame based rates to determine the maximum rates that each queue may receive during the within-cir and above-cir bandwidth allocation passes. During the within-cir pass, a queue may receive up to its frame based within-cir offered-load. The maximum it may receive during the above-cir pass is the difference between the frame based within-pir offered load and the amount of actual bandwidth allocated during the within-cir pass.

**SAP and subscriber SLA-profile average frame overhead override** — The average frame overhead parameter on a sap-egress may be overridden at an individual egress queue basis. On each SAP and within the sla-profile policy used by subscribers an avg-frame-overhead command may be defined under the queue-override context for each queue. When overridden, the queue instance will use its local value for the average frame overhead instead of the sap-egress defined overhead.

The **no** form of this command restores the average frame overhead parameter for the queue to the default value of 0 percent. When set to 0, the system uses the packet based queue statistics for calculating port scheduler priority bandwidth allocation. If the no avg-frame-overhead command is executed in a queue-override queue id context, the avg-frame-overhead setting for the queue within the sap-egress QoS policy takes effect.

**Default** 0

**Parameters** *percent* — This parameter sets the average amount of packet-to-frame encapsulation overhead expected for the queue. This value is not used by the system for egress Ethernet queues.

**Values** 0 — 100

cbs

**Syntax** **cbs** *size-in-kbytes*  
**no cbs**

**Context** config>service>ies>if>sap>egress>queue-override>queue  
config>service>ies>if>sap>ingress>queue-override>queue

**Description** This command can be used to override specific attributes of the specified queue’s CBS parameters. It is permissible, and possibly desirable, to oversubscribe the total CBS reserved buffers for a given access port egress buffer pool. Oversubscription may be desirable due to the potential large number of service queues and the economy of statistical multiplexing the individual queue’s CBS setting into the defined reserved total.

When oversubscribing the reserved total, it is possible for a queue depth to be lower than its CBS setting and still not receive a buffer from the buffer pool for an ingress frame. As more queues are using their CBS buffers and the total in use exceeds the defined reserved total, essentially the buffers are being removed from the shared portion of the pool without the shared in use average and total counts being decremented. This can affect the operation of the high and low priority RED slopes on

the pool, causing them to miscalculate when to start randomly drop packets.

If the CBS value is larger than the MBS value, an error will occur, preventing the CBS change.

The **no** form of this command returns the CBS size to the default value.

|                   |                                                                                                                                                                                                                                                                                                                                 |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | no cbs                                                                                                                                                                                                                                                                                                                          |
| <b>Parameters</b> | <i>size-in-kbytes</i> — The size parameter is an integer expression of the number of kilobytes reserved for the queue. If a value of 10KBytes is desired, enter the value 10. A value of 0 specifies that no reserved buffers are required by the queue (a minimal reserved size can still be applied for scheduling purposes). |
| <b>Values</b>     | 0 — 131072, default                                                                                                                                                                                                                                                                                                             |

## high-prio-only

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Syntax</b>      | <b>high-prio-only</b> <i>percent</i><br><b>no high-prio-only</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Context</b>     | config>service>ies>if>sap>egress>queue-override>queue<br>config>service>ies>if>sap>ingress>queue-override>queue                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Description</b> | <p>This command can be used to override specific attributes of the specified queue's high-prio-only parameters. The <b>high-prio-only</b> command configures the percentage of buffer space for the queue, used exclusively by high priority packets.</p> <p>The priority of a packet can only be set in the SAP ingress QoS policy and is only applicable on the ingress queues for a SAP. The <b>high-prio-only</b> parameter is used to override the default value derived from the <b>network-queue</b> command.</p> <p>The defined <b>high-prio-only</b> value cannot be greater than the MBS size of the queue. Attempting to change the MBS to a value smaller than the high priority reserve will generate an error and fail execution. Attempting to set the <b>high-prio-only</b> value larger than the current MBS size will also result in an error and fail execution.</p> <p>The <b>no</b> form of this command restores the default high priority reserved size.</p> |
| <b>Parameters</b>  | <i>percent</i> — The <i>percent</i> parameter is the percentage reserved for high priority traffic on the queue. If a value of 10KBytes is desired, enter the value 10. A value of 0 specifies that none of the MBS of the queue will be reserved for high priority traffic. This does not affect RED slope operation for packets attempting to be queued.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Values</b>      | 0 — 100, default                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Syntax</b>      | <b>mbs</b> { <i>size-in-kbytes</i>   <b>default</b> }<br><b>no mbs</b>                                          |
| <b>Context</b>     | config>service>ies>if>sap>egress>queue-override>queue<br>config>service>ies>if>sap>ingress>queue-override>queue |
| <b>Description</b> | This command can be used to override specific attributes of the specified queue's MBS parameters.               |

The MBS is a mechanism to override the default maximum size for the queue.

The sum of the MBS for all queues on an egress access port can oversubscribe the total amount of buffering available. When congestion occurs and buffers become scarce, access to buffers is controlled by the RED slope a packet is associated with. A queue that has not exceeded its MBS size is not guaranteed that a buffer will be available when needed or that the packet's RED slope will not force the discard of the packet. Setting proper CBS parameters and controlling CBS oversubscription is one major safeguard to queue starvation (when a queue does not receive its fair share of buffers). Another is properly setting the RED slope parameters for the needs of services on this port or channel.

If the CBS value is larger than the MBS value, an error will occur, preventing the MBS change.

The **no** form of this command returns the MBS size assigned to the queue.

|                   |                                                                                                                                                                                                                                                |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | default                                                                                                                                                                                                                                        |
| <b>Parameters</b> | <i>size-in-kbytes</i> — The size parameter is an integer expression of the maximum number of kilobytes of buffering allowed for the queue. For a value of 100 kbps, enter the value 100. A value of 0 causes the queue to discard all packets. |
| <b>Values</b>     | 0 — 131072 or default                                                                                                                                                                                                                          |

| <b>Description</b> | <p>This command can be used to override specific attributes of the specified queue's Peak Information Rate (PIR) and the Committed Information Rate (CIR) parameters.</p> <p>The PIR defines the maximum rate that the queue can transmit packets out an egress interface (for SAP egress queues). Defining a PIR does not necessarily guarantee that the queue can transmit at the intended rate. The actual rate sustained by the queue can be limited by oversubscription factors or available egress bandwidth.</p> <p>The CIR defines the rate at which the system prioritizes the queue over other queues competing for the same bandwidth. In-profile packets are preferentially queued by the system at egress and at subsequent next hop nodes where the packet can traverse. To be properly handled as in- or out-of-profile throughout the network, the packets must be marked accordingly for profiling at each hop.</p> <p>The CIR can be used by the queue's parent commands <i>cir-level</i> and <i>cir-weight</i> parameters to define the amount of bandwidth considered to be committed for the child queue during bandwidth allocation by the parent scheduler.</p> <p>The <b>rate</b> command can be executed at any time, altering the PIR and CIR rates for all queues created through the association of the SAP egress QoS policy with the <i>queue-id</i>.</p> <p>The <b>no</b> form of the command returns all queues created with the <i>queue-id</i> by association with the QoS policy to the default PIR and CIR parameters (<b>max</b>, 0).</p> |
| <b>Default</b>     | <b>rate max cir 0</b> — The <b>max</b> default specifies the amount of bandwidth in kilobits per second (thousand bits per second). The <b>max</b> value is mutually exclusive to the <b>pir-rate</b> value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Parameters</b> | <p><i>pir-rate</i> — Defines the administrative PIR rate, in kilobits, for the queue. When the <b>rate</b> command is executed, a valid PIR setting must be explicitly defined. When the <b>rate</b> command has not been executed, the default PIR of <b>max</b> is assumed.</p> <p>Fractional values are not allowed and must be given as a positive integer.</p> <p>The actual PIR rate is dependent on the queue's <b>adaptation-rule</b> parameters and the actual hardware where the queue is provisioned.</p> <p><b>Values</b>      1 — 100000000</p> <p><b>Default</b>      max</p> <p><b>cir</b> <i>cir-rate</i> — The <b>cir</b> parameter overrides the default administrative CIR used by the queue. When the <b>rate</b> command is executed, a CIR setting is optional. When the <b>rate</b> command has not been executed or the <b>cir</b> parameter is not explicitly specified, the default CIR (0) is assumed.</p> <p>Fractional values are not allowed and must be given as a positive integer. The <b>sum</b> keyword specifies that the CIR be used as the summed CIR values of the children schedulers or queues.</p> <p><b>Values</b>      0 — 100000000, <b>max</b>, <b>sum</b></p> <p><b>Default</b>      0</p> |

| <b>Description</b> | <p>This command can be used to override specific attributes of the specified scheduler name.</p> <p>A scheduler defines a bandwidth controls that limit each child (other schedulers and queues) associated with the scheduler. Scheduler objects are created within the hierarchical tiers of the policy. It is assumed that each scheduler created will have queues or other schedulers defined as child associations. The scheduler can be a child (take bandwidth from a scheduler in a higher tier, except for schedulers created in tier 1). A total of 32 schedulers can be created within a single scheduler policy with no restriction on the distribution between the tiers.</p> <p>Each scheduler must have a unique name within the context of the scheduler policy; however the same name can be reused in multiple scheduler policies. If <i>scheduler-name</i> already exists within the policy tier level (regardless of the inclusion of the keyword create), the context changes to that scheduler name for the purpose of editing the scheduler parameters. Modifications made to an</p> |

existing scheduler are executed on all instantiated schedulers created through association with the policy of the edited scheduler. This can cause queues or schedulers to become orphaned (invalid parent association) and adversely affect the ability of the system to enforce service level agreements (SLAs).

If the *scheduler-name* exists within the policy on a different tier (regardless of the inclusion of the keyword *create*), an error occurs and the current CLI context will not change.

If the *scheduler-name* does not exist in this or another tier within the scheduler policy, it is assumed that an attempt is being made to create a scheduler of that name. The success of the command execution is dependent on the following:

- 1. The maximum number of schedulers has not been configured.
- 2. The provided *scheduler-name* is valid.
- 3. The **create** keyword is entered with the command if the system is configured to require it (enabled in the **environment create** command).

When the maximum number of schedulers has been exceeded on the policy, a configuration error occurs and the command will not execute, nor will the CLI context change.

If the provided scheduler-name is invalid according to the criteria below, a name syntax error will occur, the command will not execute, and the CLI context will not change.

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Parameters | <i>scheduler-name</i> — The name of the scheduler.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Values     | Valid names consist of any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.                                                                                                                                                                                                                                                                                 |
| Default    | None. Each scheduler must be explicitly created.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|            | <i>create</i> — This optional keyword explicitly specifies that it is acceptable to create a scheduler with the given <i>scheduler-name</i> . If the <b>create</b> keyword is omitted, <b>scheduler-name</b> is not created when the system environment variable <i>create</i> is set to true. This safeguard is meant to avoid accidental creation of system objects (such as schedulers) while attempting to edit an object with a mistyped name or ID. The keyword has no effect when the object already exists. |

rate

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Description | This command can be used to override specific attributes of the specified scheduler rate. The <b>rate</b> command defines the maximum bandwidth that the scheduler can offer its child queues or schedulers. The maximum rate is limited to the amount of bandwidth the scheduler can receive from its parent scheduler. If the scheduler has no parent, the maximum rate is assumed to be the amount available to the scheduler. When a parent is associated with the scheduler, the CIR parameter provides the amount of bandwidth to be considered during the parent scheduler’s ‘within CIR’ distribution phase.<br><br>The actual operating rate of the scheduler is limited by bandwidth constraints other than its maximum rate. The scheduler’s parent scheduler may not have the available bandwidth to meet the scheduler’s |

needs or the bandwidth available to the parent scheduler could be allocated to other child schedulers or child queues on the parent based on higher priority. The children of the scheduler may not need the maximum rate available to the scheduler due to insufficient offered load or limits to their own maximum rates.

When a scheduler is defined without specifying a rate, the default rate is **max**. If the scheduler is a root scheduler (no parent defined), the default maximum rate must be changed to an explicit value. Without this explicit value, the scheduler will assume that an infinite amount of bandwidth is available and allow all child queues and schedulers to operate at their maximum rates.

The **no** form of this command returns all queues created with this *queue-id* by association with the QoS policy to the default PIR and CIR parameters.

#### Parameters

*pir-rate* — The **pir** parameter accepts a step multiplier value that specifies the multiplier used to determine the PIR rate at which the queue will operate. A value of 0 to 100000000 or the keyword **max** is accepted. Any other value will result in an error without modifying the current PIR rate.

To calculate the actual PIR rate, the rate described by the queue's **rate** is multiplied by the *pir-rate*.

The SAP ingress context for PIR is independent of the defined forwarding class (fc) for the queue. The default **pir** and definable range is identical for each class. The PIR in effect for a queue defines the maximum rate at which the queue will be allowed to forward packets in a given second, thus shaping the queue's output.

The PIR parameter for SAP ingress queues do not have a negate (**no**) function. To return the queue's PIR rate to the default value, that value must be specified as the PIR value.

**Values** 1 — 100000000, **max**

**Default** max

**cir** *cir-rate* — This parameter accepts a step-multiplier value that specifies the multiplier used to determine the CIR rate at which the queue will operate. A value of 0 — 100000000 or the keyword **max** or **sum** is accepted. Any other value will result in an error without modifying the current CIR rate.

To calculate the actual CIR rate, the rate described by the **rate pir pir-rate** is multiplied by the *cir-rate*. If the **cir** is set to max, then the CIR rate is set to infinity.

The SAP ingress context for CIR is dependent on the defined forwarding class (fc) for the queue. The default CIR and definable range is different for each class. The CIR in effect for a queue defines both its profile (in or out) marking level as well as the relative importance compared to other queues for scheduling purposes during congestion periods. The **sum** keyword specifies that the CIR be used as the summed CIR values of the children schedulers or queues.

**Values** 0 — 100000000, **max**, **sum**

**Default** sum

## scheduler-policy

**Syntax** **scheduler-policy** *scheduler-policy-name*  
no scheduler-policy

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Description</b> | <p>This command applies an existing scheduler policy to an ingress or egress scheduler used by SAP queues associated with this multi-service customer site. The schedulers defined in the scheduler policy can only be created once the customer site has been appropriately assigned to a chassis port, channel or slot. Scheduler policies are defined in the <b>config&gt;qos&gt;scheduler-policy scheduler-policy-name</b> context.</p> <p>The <b>no</b> form of this command removes the configured ingress or egress scheduler policy from the multi-service customer site. When the policy is removed, the schedulers created due to the policy are removed also making them unavailable for the ingress SAP queues associated with the customer site. Queues that lose their parent scheduler association are deemed to be orphaned and are no longer subject to a virtual scheduler. The SAPs that have ingress queues reliant on the removed schedulers enter into an operational state depicting the orphaned status of one or more queues. When the <b>no scheduler-policy</b> command is executed, the customer site ingress or egress node will not contain an applied scheduler policy.</p> <p><i>scheduler-policy-name:</i> — The <i>scheduler-policy-name</i> parameter applies an existing scheduler policy that was created in the <b>config&gt;qos&gt;scheduler-policy scheduler-policy-name</b> context to create the hierarchy of ingress or egress virtual schedulers. The scheduler names defined within the policy are created and made available to any ingress or egress queues created on associated SAPs.</p> <p><b>Values</b> Any existing valid scheduler policy name.</p> |

| <b>Description</b> | <p>This command configures AIS/RDI fault management on a PVCC. Fault management allows PVCC termination to monitor and report the status of their connection by propagating fault information through the network and by driving PVCC's operational status.</p> <p>When alarm-cells functionality is enabled, a PVCC's operational status is affected when a PVCC goes into an AIS or RDI state because of an AIS/RDI processing (assuming nothing else affects PVCC's operational status, for example, if the PVCC goes DOWN, or enters a fault state and comes back UP, or exits that fault state). RDI cells are generated when PVCC is operationally DOWN. No OAM-specific SNMP trap is raised whenever an endpoint enters/exits an AIS or RDI state, however, if as result of an OAM state change, the PVCC changes operational status, then a trap is expected from an entity the PVCC is associated with (for example a SAP).</p> <p>The <b>no</b> command disables alarm-cells functionality for a PVCC. When alarm-cells functionality is disabled, a PVCC's operational status is no longer affected by a PVCC's OAM state changes due to AIS/RDI processing (note that when alarm-cells is disabled, a PVCC will change operational status to UP due to alarm-cell processing) and RDI cells are not generated as result of the PVCC going into AIS or RDI state. The PVCC's OAM status, however, will record OAM faults as described above.</p> |
| <b>Default</b>     | Enabled for PVCCs delimiting IES SAPs                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Context</b>     | config>service>ies>if >sap>atm>oam                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b> | <p>This command enables periodic OAM loopbacks on this SAP. This command is only configurable on IES and VPRN SAPs. When enabled, an ATM OAM loopback cell is transmitted every period as configured in the config&gt;system&gt;atm&gt;oam&gt;loopback-period <i>period</i> context.</p> <p>If a response is not received and consecutive retry-down retries also result in failure, the endpoint will transition to an alarm indication signal/loss of clock state. Then, an ATM OAM loopback cell will be transmitted every period as configured in the loopback-period <i>period</i>. If a response is received for the periodic loopback and consecutive retry-up retries also each receive a response, the endpoint will transition back to the up state.</p> <p>The <b>no</b> form of the command sets the value back to the default.</p> |
| <b>Default</b>     | no periodic-loopback                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Description</b> | <p>This command creates or edits a Virtual Router ID (VRID) on the service IP interface. A VRID is internally represented in conjunction with the IP interface name. This allows the VRID to be used on multiple IP interfaces while representing different virtual router instances.</p> <p>Two VRRP nodes can be defined on an IP interface. One, both, or none may be defined as owner. The nodal context of <b>vrrp</b> <i>virtual-router-id</i> is used to define the configuration parameters for the VRID.</p> <p>The <b>no</b> form of this command removes the specified VRID from the IP interface. This terminates VRRP participation for the virtual router and deletes all references to the vrid. The VRID does not need to be shutdown in order to remove the virtual router instance.</p> |
| <b>Default</b>     | No default                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <p><i>virtual-router-id</i> — The virtual-router-id parameter specifies a new virtual router ID or one that can be modified on the IP interface.</p> <p><b>Values</b>      1 — 255</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Context</b>     | config>service>ies>if>vrrp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b> | <p>The <b>authentication-key</b> command, within the <b>vrrp</b> <i>virtual-router-id</i> context, is used to assign a simple text password authentication key to generate master VRRP advertisement messages and validating received VRRP advertisement messages.</p> <p>The authentication-key command is one of the few commands not affected by the presence of the owner keyword. If simple text password authentication is not required, the authentication-key command is not required. If the command is re-executed with a different password key defined, the new key will be used immediately. If a no authentication-key command is executed, the password authentication key is restored to the default value. The authentication-key command may be executed at any time, altering the simple text password used when authentication-type password authentication method is used by the virtual router instance. The authentication-type password command does not need to be executed prior to defining the authentication-key command.</p> <p>To change the current in-use password key on multiple virtual router instances:</p> <ul style="list-style-type: none"> <li>• Identify the current master</li> <li>• Shutdown the virtual router instance on all backups</li> </ul> |

- Execute the authentication-key command on the master to change the password key
- Execute the authentication-key command and no shutdown command on each backup key

The **no** form of this command restores the default null string to the value of key.

**Default** No default. The authentication data field contains the value 0 in all 16 octets.

**Parameters** *authentication-key* — The *key* parameter identifies the simple text password used when VRRP Authentication Type 1 is enabled on the virtual router instance. Type 1 uses a string eight octets long that is inserted into all transmitted VRRP advertisement messages and compared against all received VRRP advertisement messages. The authentication data fields are used to transmit the key.

The *key* parameter is expressed as a string consisting up to eight alpha-numeric characters. Spaces must be contained in quotation marks ( " " ). The quotation marks are not considered part of the string.

The string is case sensitive and is left-justified in the VRRP advertisement message authentication data fields. The first field contains the first four characters with the first octet (starting with IETF RFC bit position 0) containing the first character. The second field holds the fifth through eighth characters. Any unspecified portion of the authentication data field is padded with the value 0 in the corresponding octet.

**Values** Any 7-bit printable ASCII character.

|             |                    |          |
|-------------|--------------------|----------|
| Exceptions: | Double quote ( " ) | ASCII 34 |
|             | Carriage Return    | ASCII 13 |
|             | Line Feed          | ASCII 10 |
|             | Tab                | ASCII 9  |
|             | Backspace          | ASCII 8  |

*hash-key* — The hash key. The key can be any combination of ASCII characters up to 22 characters in length (encrypted). If spaces are used in the string, enclose the entire string in quotation marks ( " " ).

This is useful when a user must configure the parameter, but, for security purposes, the actual unencrypted key value is not provided.

**hash** — Specifies the key is entered in an encrypted form. If the **hash** parameter is not used, the key is assumed to be in a non-encrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** parameter specified.

**hash2** — Specifies the key is entered in a more complex encrypted form. If the **hash2** parameter is not used, the less encrypted **hash** form is assumed.

## authentication-type

**Syntax** **authentication-type** {*password* | *message-digest*}  
**no authentication-type**

**Context** config>service>ies>if>vrrp

**Description** The **authentication-type** command, within the **vrrp** *virtual-router-id* context, is used to assign the authentication method to generate master VRRP advertisement messages and validate received VRRP advertisement messages.

**NOTE:** The authentication management for VRRP closely follows the authentication management format used for IS-IS.

The **authentication-type** command is one of the commands not affected by the presence of the owner keyword. If authentication is not required, the authentication-type command must not be executed. If the command is re-executed with a different authentication type defined, the new type will be used. If the no authentication-type command is executed, authentication is removed and no authentication is performed. The authentication-type command may be executed at any time, altering the authentication method used by the virtual router instance.

The **no** form of this command removes authentication from the virtual router instance. All VRRP Advertisement messages sent will have the Authentication Type field set to 0 and the Authentication Data fields will contain 0 in all octets. VRRP Advertisement messages received with Authentication Type fields containing a value other than 0 will be discarded.

*password* — The password keyword identifies VRRP Authentication Type 1. Type 1 requires the definition of a string of eight octets long using the authentication-key command. All transmitted VRRP Advertisement messages must have the Authentication Type field set to 1 and the Authentication Data fields must contain the authentication-key password.

All received VRRP advertisement messages must contain a value of 1 in the Authentication Type field and the Authentication Data fields must match the defined authentication-key. All other received messages will be silently discarded.

*message-digest* — The message-digest keyword identifies VRRP Authentication Type 2. Type 2 defines a lower IP layer MD5 authentication mechanism using HMAC and IP authentication header standards. An MD5 key must be defined using the message-digest-key command. All transmitted VRRP advertisement messages must have the Authentication Type field set to 2 and the Authentication Data fields must contain 0 in all octets. The message-digest key is used in the hashing process when populating the IP Authentication Header fields. A sequential incrementing counter (set to zero when the message-digest-key is set) is incremented and then used in the IP Authentication Header to prevent replay attacks on authorized participating virtual router instances.

All received VRRP advertisement messages must contain a value of 2 in the Authentication Type field and the Authentication Data fields are ignored. The message must have been authorized by the lower layer IP Authentication Header process with the sequential counter field and the source IP address presented to the virtual router instance. To track the validity of the received counter, the virtual router instance maintains a master counter table containing up to 32 source IP addresses and the last received counter value. Populate the table as follows:

1. Check to see if source IP address exists in table.

**Output** If non-existent, create an entry if available.

- If no entry is available, delete the oldest and create an entry. The new entry should have a counter value of zero.
- 2. Compare the message counter value to the entry value (0 if new entry or equal to the previous message counter from the source IP address).
  - If the message counter is not greater than the entry counter value, silently discard the packet.
  - If the message counter is greater than the entry counter value, accept the message for further checking and replace the entry counter value with the message counter value and time stamp the entry.

## backup

|                    |                                                                        |
|--------------------|------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] backup</b> <i>ip-address</i>                                   |
| <b>Context</b>     | config>service>ies>if>vrrp                                             |
| <b>Description</b> | This command configures virtual router IP addresses for the interface. |

## bfd-enable

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Description</b> | <p>This commands assigns a bi-directional forwarding (BFD) session providing heart-beat mechanism for the given VRRP/SRRP instance. There can be only one BFD session assigned to any given VRRP/SRRP instance, but there can be multiple SRRP/VRRP sessions using the same BFD session.</p> <p>BFD control the state of the associated interface. By enabling BFD on a given protocol interface, the state of the protocol interface is tied to the state of the BFD session between the local node and the remote node. The parameters used for the BFD are set via the BFD command under the IP interface. The specified interface may not be configured with BFD; however, when it is, the virtual router will then initiate the BFD session.</p> <p>The <b>no</b> form of this command removes BFD from the configuration.</p> |
| <b>Default</b>     | none                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <p><i>service-id</i> — Specifies the service ID of the interface running BFD.</p> <p><b>Values</b>      <i>service-id</i>: 1 — 2147483648</p> <p><b>Values</b>      No service ID indicates a network interface.</p> <p><b>interface</b> <i>interface-name</i> — Specifies the name of the interface running BFD.</p> <p><b>dst-ip</b> <i>ip-address</i> — Specifies the destination address to be used for the BFD session.</p>                                                                                                                                                                                                                                                                                                                                                                                                    |

## init-delay

|                    |                                                                                                                            |

| <b>Description</b> | This command configures a VRRP initialization delay timer.                                                                 |
| <b>Default</b>     | no init-delay                                                                                                              |
| <b>Parameters</b>  | <p><i>seconds</i> — Specifies the initialization delay timer for VRRP, in seconds.</p> <p><b>Values</b>      1 — 65535</p> |

## mac

|                    |                                                                                                                                                                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>mac</b> <i>mac-address</i><br><b>no mac</b>                                                                                                                                                                                                                                     |
| <b>Context</b>     | config>service>ies>if>vrrp                                                                                                                                                                                                                                                         |
| <b>Description</b> | This command assigns a specific MAC address to an IES IP interface.<br>The <b>no</b> form of the command returns the MAC address of the IP interface to the default value.                                                                                                         |
| <b>Default</b>     | The physical MAC address associated with the Ethernet interface that the SAP is configured on (the default MAC address assigned to the interface, assigned by the system).                                                                                                         |
| <b>Parameters</b>  | <i>mac-address</i> — Specifies the 48-bit MAC address for the static ARP in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee, and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses. |

## master-int-inherit

|                    |                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] master-int-inherit</b>                                                                     |

| <b>Description</b> | This command sets the advertisement timer and indirectly sets the master down timer on the virtual router instance. The message-interval setting must be the same for all virtual routers participating as a virtual router. Any VRRP advertisement message received with an Advertisement Interval field different than the virtual router instance configured message-interval value will be silently discarded.<br><br>The message-interval command is available in both non-owner and owner <b>vrrp</b> <i>virtual-router-id</i> nodal contexts. If the message-interval command is not executed, the default message interval of 1 second will be used.<br><br>The <b>no</b> form of this command restores the default message interval value of 1 second to the virtual router instance. |
| <b>Parameters</b>  | <i>seconds</i> — The number of seconds that will transpire before the advertisement timer expires.<br><br><b>Values</b> 1 — 255<br><br><b>Default</b> 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

**milliseconds** *milliseconds* — Specifies the time interval, in milliseconds, between sending advertisement messages. This parameter is not supported on non-redundant chassis.

**Values** 100 — 900

## ping-reply

| <b>Description</b> | <p>This command enables the non-owner master to reply to ICMP Echo Requests directed at the virtual router instances IP addresses. The ping request can be received on any routed interface.</p> <p>Ping must not have been disabled at the management security level (either on the parental IP interface or based on the Ping source host address). When ping-reply is not enabled, ICMP Echo Requests to non-owner master virtual IP addresses are silently discarded.</p> <p>Non-owner backup virtual routers never respond to ICMP Echo Requests regardless of the setting of ping-reply configuration.</p> <p>The ping-reply command is only available in non-owner <b>vrrp</b> <i>virtual-router-id</i> nodal context. If the ping-reply command is not executed, ICMP Echo Requests to the virtual router instance IP addresses will be silently discarded.</p> <p>The <b>no</b> form of this command restores the default operation of discarding all ICMP Echo Request messages destined to the non-owner virtual router instance IP addresses.</p> |
| <b>Default</b>     | no ping-reply                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Description</b> | <p>This command creates VRRP control policies. The VRRP policy ID must be created by the policy command prior to association with the virtual router instance.</p> <p>The policy command provides the ability to associate a VRRP priority control policy to a virtual router instance. The policy may be associated with more than one virtual router instance. The priority events within the policy either override or diminish the base-priority dynamically affecting the in-use priority. As priority events clear in the policy, the in-use priority may eventually be restored to the base-priority value.</p> <p>The policy command is only available in the non-owner <b>vrrp</b> <i>virtual-router-id</i> nodal context. The priority of owner virtual router instances is permanently set to 255 and cannot be changed by VRRP priority control policies. For non-owner virtual router instances, if the policy command is not executed, the base-priority will be used as the in-use priority.</p> <p>The <b>no</b> form of this command removes any existing VRRP priority control policy association from the virtual router instance. All such associations must be removed prior to the policy being deleted</p> |

from the system.

|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | None                                                                                                                                                                                                                                            |
| <b>Parameters</b> | <i>vrp-policy-id</i> — The vrrp-policy-id parameter associated the corresponding VRRP priority control policy-id with the virtual router instance. The vrrp-policy-id must already exist in the system for the policy command to be successful. |
| <b>Values</b>     | 1 to 9999                                                                                                                                                                                                                                       |

| <b>Context</b>     | config>service>ies>if>vrrp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Description</b> | <p>The preempt command provides the ability of overriding an existing non-owner master to the virtual router instance. Enabling preempt mode is almost required for proper operation of the base-priority and vrrp-policy-id definitions on the virtual router instance. If the virtual router cannot preempt an existing non-owner master, the affect of the dynamic changing of the in-use priority is greatly diminished.</p> <p>The preempt command is only available in the non-owner vrrp virtual-router-id nodal context. The owner may not be preempted due to the fact that the priority of non-owners can never be higher than the owner. The owner will always preempt all other virtual routers when it is available.</p> <p>Non-owner virtual router instances will only preempt when preempt is set and the current master has an in-use message priority value less than the virtual router instances in-use priority.</p> <p>A master non-owner virtual router will only allow itself to be preempted when the incoming VRRP Advertisement message Priority field value is one of the following:</p> <ul style="list-style-type: none"> <li>• Greater than the virtual router in-use priority value</li> <li>• Equal to the in-use priority value and the source IP address (primary IP address) is greater than the virtual router instance primary IP address</li> </ul> <p>The <b>no</b> form of this command prevents a non-owner virtual router instance from preempting another, less desirable virtual router. Use the preempt command to restore the default mode.</p> |
| <b>Default</b>     | preempt                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## priority

|                    |                                                                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>priority</b> <i>base-priority</i><br><b>no priority</b>                                                                                                                                                                                               |
| <b>Context</b>     | config>service>ies>if>vrrp                                                                                                                                                                                                                               |
| <b>Description</b> | The priority command provides the ability to configure a specific priority value to the virtual router instance. In conjunction with an optional policy command, the base-priority is used to derive the in-use priority of the virtual router instance. |

The priority command is only available in the non-owner vrrp virtual-router-id nodal context. The priority of owner virtual router instances is permanently set to 255 and cannot be changed. For non-owner virtual router instances, if the priority command is not executed, the base-priority will be set to 100.

The **no** form of this command restores the default value of 100 to base-priority.

**Parameters**     *base-priority* — The base-priority parameter configures the base priority used by the virtual router instance. If a VRRP Priority Control policy is not also defined, the base-priority will be the in-use priority for the virtual router instance.

**Values**            1 — 254

**Default**            100

standby-forwarding

**Syntax**            **[no] standby-forwarding**

**Context**            config>service>ies>if>vrrp

**Description**        This command allows the forwarding of packets by a standby router.

                         The **no** form of the command specifies that a standby router should not forward traffic sent to virtual router's MAC address. However, the standby router should forward traffic sent to the standby router's real MAC address.

**Default**            no standby-forwarding

ssh-reply

**Syntax**            **[no] ssh-reply**

**Context**            config>service>ies>if>vrrp

**Description**        This command enables the non-owner master to reply to SSH Requests directed at the virtual router instances IP addresses. The SSH request can be received on any routed interface. SSH must not have been disabled at the management security level (either on the parental IP interface or based on the SSH source host address). Proper login and CLI command authentication is still enforced.

                         When ssh-reply is not enabled, SSH packets to non-owner master virtual IP addresses are silently discarded.

                         Non-owner backup virtual routers never respond to SSH regardless of the ssh-reply configuration.

                         The ssh-reply command is only available in non-owner vrrp virtual-router-id nodal context. If the ssh-reply command is not executed, SSH packets to the virtual router instance IP addresses will be silently discarded.

                         The **no** form of this command restores the default operation of discarding all SSH packets destined to the non-owner virtual router instance IP addresses.

**Default**            no ssh-reply

## telnet-reply

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Context</b>     | config>service>ies>if>vrrp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b> | <p>The telnet-reply command enables the non-owner master to reply to TCP port 23 Telnet Requests directed at the virtual router instances IP addresses. The Telnet request can be received on any routed interface. Telnet must not have been disabled at the management security level (either on the parental IP interface or based on the Telnet source host address). Proper login and CLI command authentication is still enforced.</p> <p>When telnet-reply is not enabled, TCP port 23 Telnet packets to non-owner master virtual IP addresses are silently discarded.</p> <p>Non-owner backup virtual routers never respond to Telnet Requests regardless of the telnet-reply configuration.</p> <p>The telnet-reply command is only available in non-owner VRRP nodal context. If the telnet-reply command is not executed, Telnet packets to the virtual router instance IP addresses will be silently discarded.</p> <p>The <b>no</b> form of this command restores the default operation of discarding all Telnet packets destined to the non-owner virtual router instance IP addresses.</p> |
| <b>Default</b>     | no telnet-reply                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## traceroute-reply

|                    |                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] traceroute-reply</b>                                                                                                                                                                                                                                                                                                                                                                           |

## IPSec Gateway Commands

### ipsec-gw

|                    |                                           |
|--------------------|-------------------------------------------|
| <b>Syntax</b>      | <b>[no] ipsec-gw</b>                      |
| <b>Context</b>     | config>service>ies>if>sap                 |
| <b>Description</b> | This command configures an IPSec gateway. |

### default-secure-service

|                    |                                                                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>default-secure-service</b> <i>service-id</i> <b>ipsec-interface</b> <i>ip-int-name</i><br><b>no default-secure-service</b>                                                                |
| <b>Context</b>     | config>service>ies>if>sap>ipsec-gateway                                                                                                                                                      |
| <b>Description</b> | This command specifies a service ID or service name of the default security service used by this SAP IPSec gateway.                                                                          |
| <b>Parameters</b>  | <i>service-id</i> — Specifies a default secure service.<br><br><b>Values</b> <i>service-id</i> : 1 — 2147483648<br><i>svc-name</i> : An existing service name up to 64 characters in length. |

### default-tunnel-template

|                    |                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>default-tunnel-template</b> <i>ipsec template identifier</i><br><b>no default-tunnel-template</b> |
| <b>Context</b>     | config>service>ies>if>sap>ipsec-gateway                                                              |
| <b>Description</b> | This command configures a default tunnel policy template for the gateway.                            |

### local-gateway-address

|                    |                                                                                   |
|--------------------|-----------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>local-gateway-address</b> <i>ip-address</i><br><b>no local-gateway-address</b> |
| <b>Context</b>     | config>service>ies>if>sap>ipsec-gateway                                           |
| <b>Description</b> | This command configures an ipsec-gateway local address.                           |

## pre-shared-key

|                    |                                                                                    |
|--------------------|------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>pre-shared-key</b> <i>key</i><br><b>no pre-shared-key</b>                       |
| <b>Context</b>     | config>service>ies>if>sap>ipsec-gateway                                            |
| <b>Description</b> | This command specifies the shared secret between the two peers forming the tunnel. |
| <b>Parameters</b>  | <i>key</i> — Specifies a pre-shared-key for dynamic-keying.                        |

## VPRN Service Overview

RFC2547bis is an extension to the original RFC 2547, which details a method of distributing routing information and forwarding data to provide a Layer 3 Virtual Private Network (VPN) service to end customers.

Each Virtual Private Routed Network (VPRN) consists of a set of customer sites connected to one or more PE routers. Each associated PE router maintains a separate IP forwarding table for each VPRN. Additionally, the PE routers exchange the routing information configured or learned from all customer sites via MP-BGP peering. Each route exchanged via the MP-BGP protocol includes a Route Distinguisher (RD), which identifies the VPRN association.

The service provider uses BGP to exchange the routes of a particular VPN among the PE routers that are attached to that VPN. This is done in a way which ensures that routes from different VPNs remain distinct and separate, even if two VPNs have an overlapping address space. The PE routers distribute routes from other CE routers in that VPN to the CE routers in a particular VPN. Since the CE routers do not peer with each other there is no overlay visible to the VPN's routing algorithm.

When BGP distributes a VPN route, it also distributes an MPLS label for that route. On a SR-Series, a single label is assigned to all routes in a VPN.

Before a customer data packet travels across the service provider's backbone, it is encapsulated with the MPLS label that corresponds, in the customer's VPN, to the route which best matches the packet's destination address. The MPLS packet is further encapsulated with either another MPLS label or GRE tunnel header, so that it gets tunneled across the backbone to the proper PE router. Each route exchanged by the MP-BGP protocol includes a route distinguisher (RD), which identifies the VPRN association. Thus the backbone core routers do not need to know the VPN routes. [Figure 125](#) displays a VPRN network diagram example.

OSSG024

**Figure 125: Virtual Private Routed Network**

## Routing Prerequisites

RFC2547bis requires the following features:

- Multi-protocol extensions
- LDP support
- Extended BGP community support
- BGP capability negotiation
- Parameters defined in RFC 2918, *BGP Route Refresh* and RFC 2796, *Route Reflector*
- 4-byte autonomous system (AS) number

Tunneling protocol requirements are as follows:

- RFC2547, *BGP/MPLS VPNs*, recommends implementing Label Distribution Protocol (LDP) to set up a full mesh of LSPs based on the IGP
- MPLS RSVP-TE tunnels can be used instead of LDP
- Generic Router Encapsulation (GRE) tunnels can also be alternatively used

## BGP Support

BGP is used with BGP extensions mentioned in [Routing Prerequisites on page 1051](#) to distribute VPRN routing information across the service provider's network.

BGP was initially designed to distribute IPv4 routing information. Therefore, multi-protocol extensions and the use of a VPN-IPv4 address were created to extend BGP's ability to carry overlapping routing information. A VPN-IPv4 address is a 12-byte value consisting of the 8-byte route distinguisher (RD) and the 4-byte IPv4 IP address prefix. The RD must be unique within the scope of the VPRN. This allows the IP address prefixes within different VRFs to overlap.

---

## eiBGP Load Balancing

eiBGP load balancing allows a route to have multiple nexthops of different types, using both IPv4 nexthops and MPLS LSPs simultaneously.

[Figure 126](#) displays a basic topology that could use eiBGP load balancing. In this topology CE1 is dual homed and thus reachable by two separate PE routers. CE 2 (a site in the same VPRN) is also attached to PE1. With eiBGP load balancing, PE1 will utilize its own local IPv4 nexthop as well as the route advertised by MP-BGP, by PE2.

Figure 126: Basic eiBGP Topology

Another use case displayed in [Figure 127](#) shows an extra net VPRN (VRF). The traffic ingressing the PE that should be load balanced is part of a second VPRN and the route over which the load balancing is to occur is part of a separate VPRN instance and are leaked into the second VPRN by route policies.

Here, both routes can have a source protocol of VPN-IPv4 but one will still have an IPv4 nexthop and the other can have a VPN-IPv4 nexthop pointing out a network interface. Traffic will still be load balanced (if eiBGP is enabled) as if only a single VRF was involved.

**Figure 127: Extranet Load Balancing**

Traffic will be load balanced across both the IPv4 and VPN-IPv4 nexthops. This helps to use all available bandwidth to reach a dual-homed VPRN.

# Route Distinguishers

The route distinguisher (RD) is an 8-byte value consisting of 2 major fields, the Type field and value field. The type field determines how the value field should be interpreted. The 7750 SR OS implementation supports the three (3) type values as defined in the internet draft.

Figure 128: Route Distinguisher

The three Type values are:

- Type 0: Value Field — Administrator subfield (2 bytes)  
Assigned number subfield (4 bytes)  
  
The administrator field must contain an AS number (using private AS numbers is discouraged). The Assigned field contains a number assigned by the service provider.
- Type 1: Value Field — Administrator subfield (4 bytes)  
Assigned number subfield (2 bytes)  
  
The administrator field must contain an IP address (using private IP address space is discouraged). The Assigned field contains a number assigned by the service provider.
- Type 2: Value Field — Administrator subfield (4 bytes)  
Assigned number subfield (2 bytes)  
  
The administrator field must contain a 4-byte AS number (using private AS numbers is discouraged). The Assigned field contains a number assigned by the service provider.

---

## Route Reflector

Per RFC2547bis the use of Route Reflectors is supported in the service provider core. The support uses multiple sets of route reflectors for different types of BGP data, including IPv4 and VPN-IPv4 as well as multicast and IPv6.

## CE to PE Route Exchange

Routing information between the Customer Edge (CE) and Provider Edge (PE) can be exchanged by the following methods:

- Static Routes
- E-BGP
- RIP
- OSPF
- OSPF3

Each protocol provides controls to limit the number of routes learned from each CE router.

---

## Route Redistribution

Routing information learned from the CE-to-PE routing protocols and configured static routes should be injected in the associated local VPN routing/forwarding (VRF). In the case of dynamic routing protocols, there may be protocol specific route policies that modify or reject certain routes before they are injected into the local VRF.

Route redistribution from the local VRF to CE-to-PE routing protocols is to be controlled via the route policies in each routing protocol instance, in the same manner that is used by the base router instance.

The advertisement or redistribution of routing information from the local VRF to or from the MP-BGP instance is specified per VRF and is controlled by VRF route target associations or by VRF route policies.

Routes belonging to a VPRN, must use the protocol owner, VPN-IPv4 to denote that it is an VPRN route. This can be used within the route policy match criteria.

## CPE Connectivity Check

Static routes are used within many IES and VPRN services. Unlike dynamic routing protocols, there is no way to change the state of routes based on availability information for the associated CPE. CPE connectivity check adds flexibility so that unavailable destinations will be removed from the service provider's routing tables dynamically and minimize wasted bandwidth.

Fig\_18

**Figure 129: Directly Connected IP Target**

Fig\_19

**Figure 130: Multiple Hops to IP Target**

The availability of the far-end static route is monitored through periodic polling. The polling period is configured. If the poll fails a specified number of sequential polls, the static route is marked as inactive.

Either ICMP ping or unicast ARP mechanism can be used to test the connectivity. ICMP ping is preferred.

If the connectivity check fails and the static route is de-activated, the SR-Series router will continue to send polls and re-activate any routes that are restored.

## VPRN Features

This section describes various VPRN features and any special capabilities or considerations as they relate to VPRN services.

    - [Multicast Protocols Supported in the Provider Network on page 1086](#)
- 

## IP Interfaces

VPRN customer IP interfaces can be configured with most of the same options found on the core IP interfaces. The advanced configuration options supported are:

- VRRP (for VPRN services with more than one IP interface)
- Cflowd
- Secondary IP addresses
- ICMP Options

Configuration options found on core IP interfaces not supported on VPRN IP interfaces are:

- NTP broadcast receipt

## Subscriber Interfaces

Subscriber interfaces are composed of a combination of two key technologies, subscriber interfaces and group interfaces. While the subscriber interface defines the subscriber subnets, the group interfaces are responsible for aggregating the SAPs.

- Subscriber interface — An interface that allows the sharing of a subnet among one or many group interfaces in the routed CO model.
- Group interface — Aggregates multiple SAPs on the same port.
- Redundant interfaces — A special spoke-terminated Layer 3 interface. It is used in a Layer 3 routed CO dual-homing configuration to shunt downstream (network to subscriber) to the active node for a given subscriber.

## Subscriber Routed Redundancy Protocol (SRRP)

Subscriber Routed Redundancy Protocol (SRRP) is closely tied to the multi-chassis synchronization protocol used to synchronize information between redundant nodes. An MCS peer must be configured and operational when subscriber hosts have a redundant connection to two nodes. Subscriber hosts are identified by the ingress SAP, the hosts IP and MAC addresses. Once a host is identified on one node, the MCS peering is used to inform the other node that the host exists and conveys the dynamic DHCP lease state information of the host. MCS creates a common association between the virtual ports (SAPs) shared by a subscriber. This association is configured at the MCS peering level by defining a tag for a port and range of SAPs. The same tag is defined on the other nodes peering context for another port (does not need to be the same port-ID) with the same SAP range. In this manner, a subscriber host and Dot1Q tag sent across the peering with the appropriate tag will be mapped to the redundant SAP on the other node.

Once SRRP is active on the group IP interface, the SRRP instance will attempt to communicate through in-band (over the group IP interfaces SAPs) and out-of-band (over the group IP interfaces redundant IP interface) messages to a remote router. If the remote router is also running SRRP with the same SRRP instance ID, one router will enter a master state while the other router will enter a backup state. Since both routers are sharing a common SRRP gateway MAC address that is used for the SRRP gateway IP addresses and for proxy ARP functions, either node may act as the default gateway for the attached subscriber hosts.

For proper operation, each subscriber subnet associated with the SRRP instance must have a gw-address defined. The SRRP instance cannot be activated (no shutdown) unless each subscriber subnet associated with the group IP interface has an SRRP gateway IP address. Once the SRRP instance is activated, new subscriber subnets cannot be added without a corresponding SRRP gateway IP address. [Table 22](#) describes how the SRRP instance state is used to manage access to subscriber hosts associated with the group IP interface.

SRRP instances are created in the disabled state (shutdown). To activate SRRP the no shutdown command in the SRRP context must be executed.

Before activating an SRRP instance on a group IP interface, the following actions are required:

- Add SRRP gateway IP addresses to all subscriber subnets associated with the group IP interface, including subnets on subscriber IP interfaces associated as retail routing contexts (at least one subnet must be on the subscriber IP interface containing the group IP interface and its SRRP instance).
- Create a redundant IP interface and associate it with the SRRP instances group IP interface for shunting traffic to the remote router when master.
- Specify the group IP interface SAP used for SRRP advertisement and Information messaging.

Before activating an SRRP instance on a group IP interface, the following actions should be considered:

- Associate the SRRP instance to a Multi-Chassis Synchronization (MCS) peering terminating on the neighboring router (the MCS peering should exist as the peering is required for redundant subscriber host management)
- Define a description string for the SRRP instance
- Specify the SRRP gateway MAC address used by the SRRP instance (must be the same on both the local and remote SRRP instance participating in the same SRRP context)
- Change the base priority for the SRRP instance
- Specify one or more VRRP policies to dynamically manage the SRRP instance base priority
- Specify a new keep alive interval for the SRRP instance

[Table 22](#) lists the SRRP's state effect on subscriber hosts associated with group IP interfaces.

**Table 22: SRRP State Effect on Subscriber Hosts Associated with Group IP Interface**

| SRRP State                                                                                  | ARP                                                                                                                                                                                                                                                                                                                                                          | Local Proxy ARP Enabled                                                                                                                                                                                            | Remote Proxy ARP Enabled                                                                                                                                                                           | Subscriber Host Routing                                                                                                                                                                                                                                                                                                                                   |

## SRRP Messaging

SRRP uses the same messaging format as VRRP with slight modifications. The source IP address is derived from the system IP address assigned to the local router. The destination IP address and IP protocol are the same as VRRP (224.0.0.18 and 112, respectively).

The message type field is set to 1 (advertisement) and the protocol version is set to 8 to differentiate SRRP message processing from VRRP message processing.

The vr-id field has been expanded to support an SRRP instance ID of 32 bits.

Due to the large number of subnets backed up by SRRP, only one message every minute carries the gateway IP addresses associated with the SRRP instance. These gateway addresses are stored by the local SRRP instance and are compared with the gateway addresses associated with the local subscriber IP interface.

Unlike VRRP, only two nodes may participate in an SRRP instance due to the explicit association between the SRRP instance group IP interface, the associated redundant IP interface and the multi-chassis synchronization (MCS) peering. Since only two nodes are participating, the VRRP skew timer is not utilized when waiting to enter the master state. Also, SRRP always preempts when the local priority is better than the current master and the backup SRRP instance always inherits the master's advertisement interval from the SRRP advertisement messaging.

SRRP advertisement messages carry a *becoming-master* indicator flag. The *becoming-master* flag is set by a node that is attempting to usurp the master state from an existing SRRP master router. When receiving an SRRP advertisement message with a better priority and with the *becoming-master* flag set, the local master initiates its *becoming-backup* state, stops routing with the SRRP gateway MAC and sends an SRRP advertisement message with a priority set to zero. The new master continues to send SRRP advertisement messages with the *becoming-master* flag set until it either receives a return priority zero SRRP advertisement message from the previous master or its *becoming-master* state timer expires. The new backup node continues to send zero priority SRRP advertisement messages every time it receives an SRRP advertisement message with the *becoming-master* flag set. After the new master either receives the old master's priority zero SRRP advertisement message or the *become-master* state timer expires, it enters the *master* state. The *become-master* state timer is set to 10 seconds upon entering the *become-master* state.

The SRRP advertisement message is always evaluated to see if it has higher priority than the SRRP advertisement that would be sent by the local node. If the advertised priority is equal to the current local priority, the source IP address of the received SRRP advertisement is used as a tie breaker. The node with the lowest IP address is considered to have the highest priority.

The SRRP instance maintains the source IP address of the current master. If an advertisement is received with the current masters source IP address and the local priority is higher priority than the masters advertised priority, the local node immediately enters the *becoming-master* state unless the advertised priority is zero. If the advertised priority is zero, the local node bypasses the *becoming-master* state and immediately enters the *master* state. Priority zero is a special case and is sent when an SRRP instance is relinquishing the master state.

## SRRP and Multi-Chassis Synchronization

In order to take full advantage of SRRP resiliency and diagnostic capabilities, the SRRP instance should be tied to a MCS peering that terminates on the redundant node. The SRRP instance is tied to the peering using the **srrp srrp-id** command within the appropriate MCS peering configuration. Once the peering is associated with the SRRP instance, MCS will synchronize the local information about the SRRP instance with the neighbor router. MCS automatically derives the MCS key for the SRRP instance based on the SRRP instance ID. For example, an SRRP instance ID of 1 would appear in the MCS peering database with a MCS-key srrp-0000000001.

The SRRP instance information stored and sent to the neighbor router consists of:

- The SRRP instance MCS key
- Containing service type and ID
- Containing subscriber IP interface name
- Subscriber subnet information
- Containing group IP interface information
- The SRRP group IP interface redundant IP interface name, IP address and mask
- The SRRP advertisement message SAP
- The local system IP address (SRRP advertisement message source IP address)
- The Group IP interface MAC address
- The SRRP gateway MAC address
- The SRRP instance administration state (up / down)
- The SRRP instance operational state (disabled / becoming-backup / backup / becoming-master / master)
- The current SRRP priority
- Remote redundant IP interface availability (available / unavailable)
- Local receive SRRP advertisement SAP availability (available / unavailable)

## SRRP Instance

The SRRP instance uses the received information to verify provisioning and obtain operational status of the SRRP instance on the neighboring router.

- [SRRP Instance MCS Key on page 1068](#)
  - [Containing Service Type and ID on page 1068](#)
  - [Containing Subscriber IP Interface Name on page 1068](#)
  - [Subscriber Subnet Information on page 1069](#)
- 

### SRRP Instance MCS Key

The SRRP instance MCS key ties the received MCS information to the local SRRP instance with the same MCS key. If the received key does not match an existing SRRP instance, the MCS information associated with the key is ignored. Once an SRRP instance is created and mapped to an MCS peering, the SRRP instance evaluates received information with the same MCS key to verify it corresponds to the same peering. If the received MCS key is on a different peering than the local MCS key an SRRP peering mismatch event is generated detailing the SRRP instance ID, the IP address of the peering the MCS key is received on and the IP address to which the local MCS key is mapped. If the peering association mismatch is corrected, an SRRP peering mismatch clear event is generated.

---

### Containing Service Type and ID

The Containing Service Type is the service type (IES or VPRN) that contains the local SRRP instance. The Containing Service ID is the service ID of that service. This information is supplied for troubleshooting purposes only and is not required to be the same on both nodes.

---

### Containing Subscriber IP Interface Name

The containing subscriber IP interface name is the subscriber IP interface name that contains the SRRP instance and its group IP interface. This information is supplied for troubleshooting purposes only and is not required to be the same on both nodes.

## Subscriber Subnet Information

The subscriber subnet information includes all subscriber subnets backed up by the SRRP instance. The information for each subnet includes the Owned IP address, the mask and the gateway IP address. If the received subscriber subnet information does not match the local subscriber subnet information, an SRRP Subscriber Subnet Mismatch event is generated describing the SRRP instance ID and the local and remote node IP addresses. Once the subscriber subnet information matches, an SRRP Subscriber Subnet Mismatch Clear event is generated.

---

## Containing Group IP Interface Information

The containing group IP interface information is the information about the group IP interface that contains the SRRP instance. The information includes the name of the group IP interface, the list of all SAPs created on the group IP interface, the administrative and operational state of each SAP and the MCS key and the peering destination IP address associated with each SAP. To obtain the MCS information, the SRRP instance queries MCS to determine the peering association of the SRRP instance and then queries MCS for each SAP on the group IP interface. If the local SRRP instance is associated with a different MCS peering than any of the SAPs or if one or more SAPs are not tied to an MCS peering, an SRRP group interface SAP peering mismatch event is generated detailing the SRRP instance ID, and the group IP interface name.

When receiving the remote containing group IP interface information, the local node compares the received SAP information with the local group IP interface SAP information. If a local SAP is not included in the SAP information or a remote SAP is not included in the local group IP interface, an SRRP Remote SAP mismatch event is generated detailing the SRRP instance ID and the local and remote group IP interface names. If a received SAP's MCS key does not match a local SAP's MCS Key, an SRRP SAP MCS key mismatch event is generated detailing the SRRP instance ID, the local and remote group IP interface names, the SAP-ID and the local and remote MCS keys.

---

## Remote Redundant IP Interface Mismatch

If the group IP remote redundant IP interface address space does not exist, is not within the local routing context for the SRRP instances group IP interface or is not on a redundant IP interface, the local node sends redundant IP interface unavailable to prevent the remote neighbor from using its redundant IP interface. An SRRP redundant IP interface mismatch event is generated for the SRRP instance detailing the SRRP instance, the local and remote system IP addresses, the local and remote group IP interface names and the local and remote redundant IP interface names and IP addresses and masks. The local redundant IP interface may still be used if the remote node is not sending redundant IP interface unavailable.

### **Remote Sending Redundant IP Interface Unavailable**

If the remote node is sending redundant IP interface unavailable, the local node will treat the local redundant IP interface associated with the SRRP instances group IP interface as down. A Local Redundant IP Interface Unavailable event is generated detailing the SRRP instance ID, the local and remote system IP addresses, the local group IP interface name, the local redundant IP interface name and the redundant IP interface IP address and mask.

---

### **Remote SRRP Advertisement SAP Non-existent**

If the remote node's SRRP advertisement SAP does not exist on the local SRRP instances group IP interface, the local node sends local receive SRRP advertisement SAP unavailable to the remote node. An SRRP receive advertisement SAP non-existent event is generated detailing the SRRP instance ID, the local and remote system IP addresses, the local group IP interface name and the received remote SRRP advertisement SAP. Since SRRP advertisement messages cannot be received, the local node will immediately become master if it has the lower system IP address.

---

### **Remote Sending Local Receive SRRP Advertisement SAP Unavailable**

If the local node is receiving local receive SRRP advertisements stating that the SAP is unavailable from the remote node, an SRRP Remote Receive advertisement SAP Unavailable event will be generated. This details the SRRP instance ID, the local and remote system IP addresses, the remote group IP interface name and the local SRRP advertisement SAP. Since the remote node cannot receive SRRP advertisement messages, the local node will immediately become master if it has the lower system IP address.

---

### **Local and Remote Dual Master Detected**

If the local SRRP state is master and the remote SRRP state is master, an SRRP dual master event is generated detailing the SRRP instance ID and the local, remote system IP addresses and the local and remote group IP interface names and port numbers.

## Subscriber Subnet Owned IP Address Connectivity

In order for the network to reliably reach the owned IP addresses on a subscriber subnet, the owning node must advertise the IP addresses as /32 host routes into the core. This is important since the subscriber subnet is advertised into the core by multiple routers and the network will follow the shortest path to the closest available router which may not own the IP address if the /32 is not advertised within the IGP.

---

## Subscriber Subnet SRRP Gateway IP Address Connectivity

The SRRP gateway IP addresses on the subscriber subnets cannot be advertised as /32 host routes since they may be active (master) on multiple group IP interfaces on multiple SRRP routers. Without a /32 host route path, the network will forward any packet destined to an SRRP gateway IP address to the closest router advertising the subscriber subnet. While a case may be made that only a node that is currently forwarding for the gateway IP address in a master state should respond to ping or other diagnostic messages, the distribution of the subnet and the case of multiple masters make any resulting response or non-response inconclusive at best. To provide some ability to ping the SRRP gateway address from the network side reliably, any node receiving the ICMP ping request will respond if the gateway IP address is defined on its subscriber subnet.

---

## Receive SRRP Advertisement SAP and Anti-Spoof

The group IP interface SAPs are designed to support subscriber hosts and perform an ingress anti-spoof function that ensures that any IP packet received on the group IP interface is coming in the correct SAP with the correct MAC address. If the IP and MAC are not registered as valid subscriber hosts on the SAP, the packet is silently discarded. Since the SRRP advertisement source IP addresses are not subscriber hosts, an anti-spoof entry will not exist and SRRP advertisement messages would normally be silently discarded. To avoid this issue, when a group IP interface SAP is configured to send and receive SRRP advertisement messages, anti-spoof processing on the SAP is disabled. This precludes subscriber host management on the SRRP messaging SAP.

## SAPs

---

### Encapsulations

The following SAP encapsulations are supported on the 7750 SR VPRN service:

- Ethernet null
  - Ethernet dot1q
  - SONET/SDH IPCP
  - SONET/SDH ATM
  - ATM - LLC SNAP or VC-MUX
  - Cisco HDLC
  - Frame Relay
- 

### ATM SAP Encapsulations for VPRN Services

The SR-Series series supports ATM PVC service encapsulation for VPRN SAPs. Both UNI and NNI cell formats are supported. The format is configurable on a SONET/SDH path basis. A path maps to an ATM VC. All VCs on a path must use the same cell format.

The following ATM encapsulation and transport modes are supported:

- RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*:
  - AAL5 LLC/SNAP IPv4 routed
  - AAL5 VC mux IPv4 routed
  - AAL5 LLC/SNAP IPv4 bridged
  - AAL5 VC mux IPv4 bridged

## QoS Policies

When applied to 7750 SR VPRN services, service ingress QoS policies only create the unicast queues defined in the policy. The multipoint queues are not created on the service.

With VPRN services, service egress QoS policies function as with other services where the class-based queues are created as defined in the policy.

Note that both Layer 2 or Layer 3 criteria can be used in the QoS policies for traffic classification in an VPRN.

ATM traffic descriptor profiles define the traffic contract in the forward direction (ingress) and the traffic contract in the backward direction (egress).

---

## Filter Policies

Only IP filter policies can be applied to VPRN services.

## DSCP Marking

Specific DSCP, forwarding class, and Dot1P parameters can be specified to be used by every protocol packet generated by the node. This enables prioritization or de-prioritization of every protocol (as required). The markings effect a change in behavior on ingress when queuing. For example, if OSPF is not enabled, then traffic can be de-prioritized to best effort (be) DSCP. This change de-prioritizes OSPF traffic to the CPU complex.

DSCP marking for internally generated control and management traffic by marking the DSCP value should be used for the given application. This can be configured per routing instance. For example, OSPF packets can carry a different DSCP marking for the base instance and then for a VPRN service. ISIS and ARP traffic is not an IP-generated traffic type and is not configurable.

When an application is configured to use a specified DSCP value then the MPLS EXP, Dot1P bits will be marked in accordance with the network or access egress policy as it applies to the logical interface the packet will be egressing.

The DSCP value can be set per application. This setting will be forwarded to the egress IOM. The egress IOM does not alter the coded DSCP value and marks the LSP-EXP and IEEE 802.1p (Dot1P) bits according to the appropriate network or access QoS policy.

**Table 23: DSCP/FC Marking**

| Protocol              | IPv4 | IPv6 | DSCP Marking | Dot1P Marking | Default FC |
|-----------------------|------|------|--------------|---------------|------------|
| IS-IS                 |      |      |              | Yes           | NC         |
| ARP                   |      |      |              | Yes           | NC         |
| LDP (T-LDP)           | Yes  |      |              |               | NC         |
| MPLS (LSP ping, etc.) | Yes  |      | Yes          | Yes           | NC         |

| af41      | 34                    | 0x22                      | 0b100010             | h2      |
| af42      | 36                    | 0x24                      | 0b100100             | h2      |
| af43      | 38                    | 0x26                      | 0b100110             | h2      |
| default*  | 0                     |                           |                      |         |

\*The default forwarding class mapping is used for all DSCP names/values for which there is no explicit forwarding class mapping.

## CE to PE Routing Protocols

The 7750 SR VPRN supports the following PE to CE routing protocols:

- BGP
  - Static
  - RIP
  - OSPF
- 

## PE to PE Tunneling Mechanisms

The 7750 SR supports multiple mechanisms to provide transport tunnels for the forwarding of traffic between PE routers within the 2547bis network.

The 7750 SR VPRN implementation supports the use of:

- RSVP-TE protocol to create tunnel LSP's between PE routers
- LDP protocol to create tunnel LSP's between PE routers
- GRE tunnels between PE routers.

These transport tunnel mechanisms provide the flexibility of using dynamically created LSPs where the service tunnels are automatically bound (the “autobind” feature) and the ability to provide certain VPN services with their own transport tunnels by explicitly binding SDPs if desired. When the autobind is used, all services traverse the same LSPs and do not allow alternate tunneling mechanisms (like GRE) or the ability to craft sets of LSP's with bandwidth reservations for specific customers as is available with explicit SDPs for the service.

---

## Per VRF Route Limiting

The 7750 SR allows setting the maximum number of routes that can be accepted in the VRF for a VPRN service. There are options to specify a percentage threshold at which to generate an event that the VRF table is near full and an option to disable additional route learning when full or only generate an event.

## Spoke SDPs

Distributed services use service distribution points (SDPs) to direct traffic to another SR-Series router via service tunnels. SDPs are created on each participating SR-Series and then bound to a specific service. SDP can be created as either GRE or MPLS. Refer to [Service Distribution Points \(SDPs\) on page 46](#) for information about configuring SDPs.

This feature provides the ability to cross-connect traffic entering on a spoke SDP, used for Layer 2 services (VLLs or VPLS), on to an IES or VPRN service. From a logical point of view, the spoke SDP entering on a network port is cross-connected to the Layer 3 service as if it entered by a service SAP. The main exception to this is traffic entering the Layer 3 service by a spoke SDP is handled with network QoS policies not access QoS policies.

[Figure 131](#) depicts traffic terminating on a specific IES or VPRN service that is identified by the *sdp-id* and VC label present in the service packet.

**Figure 131: SDP-ID and VC Label Service Identifiers**

## T-LDP Status Signaling for Spoke-SDPs Terminating on IES/VPRN

T-LDP status signaling and PW active/standby signaling capabilities are supported on ipipe and epipe spoke SDPs.

Spoke SDP termination on an IES or VPRN provides the ability to cross-connect traffic entering on a spoke SDP, used for Layer 2 services (VLLs or VPLS), on to an IES or VPRN service. From a logical point of view the spoke SDP entering on a network port is cross-connected to the Layer 3 service as if it had entered using a service SAP. The main exception to this is traffic entering the Layer 3 service using a spoke SDP is handled with network QoS policies instead of access QoS policies.

When a SAP Down or SDP binding down status message is received by the 7750 PE in which the ipipe or Ethernet spoke-sdp is terminated on an IES or VPRN interface, the interface is brought down and all associated routes are withdrawn in a similar way when the spoke-sdp goes down locally. The same actions are taken when the standby T-LDP status message is received by the 7750 IES/VPRN PE.

This feature can be used to provide redundant connectivity to a VPRN or IES from a PE providing a VLL service, as shown in [Figure 132](#).

**Figure 132: Active/Standby VRF Using Resilient L2 Circuits**

## Spoke SDP Redundancy into IES/VPRN

This feature can be used to provide redundant connectivity to a VPRN or IES from a PE providing a VLL service, as shown in [Figure 132](#), using either epipe or ipipe spoke-SDPs.

In [Figure 132](#), PE1 terminates two spoke-SDPs that are bound to one SAP connected to CE1. PE1 chooses to forward traffic on one of the spoke SDPs (the active spoke-SDP), while blocking traffic on the other spoke-SDP (the standby spoke-SDP) in the transmit direction. PE2 and PE3 take any spoke-SDPs for which PW forwarding standby has been signaled by PE1 to an operationally down state.

Note that 7x50, 7710 routers are expected to fulfill both functions (VLL and VPRN/IES PE), while the 7705 must be able to fulfill the VLL PE function. [Figure 133](#) illustrates the model for spoke-SDP redundancy into a VPRN or IES.

**Figure 133: Spoke-SDP Redundancy Model**

## IP-VPNs

---

### Using OSPF in IP-VPNs

Using OSPF as a CE to PE routing protocol allows OSPF that is currently running as the IGP routing protocol to migrate to an IP-VPN backbone without changing the IGP routing protocol, introducing BGP as the CE-PE or relying on static routes for the distribution of routes into the service providers IP-VPN. The following features are supported:

- Transportation of OSPF learned routes as OSPF externals. This feature uses OSPF as the protocol between the PE and CE routers, however instead of transporting the OSPF LSA information across the IP-VPN, the OSPF routes are “imported” into MP-BGP as AS externals. As a result, other OSPF attached VPRN sites on remote PEs receive these via type 5 LSA.

## Multicast in IP-VPN Applications

Applications for this feature include enterprise customer implementing a VPRN solution for their WAN networking needs, customer applications including stock-ticker information, financial institutions for stock and other types of trading data and video delivery systems.

Implementation of the draft-rosen-vpn-mcast, *Multicast in MPLS/BGP IP VPNs*, entails the support and separation of the providers core multicast domain from the various customer multicast domains and the various customer multicast domains from each other.

**Figure 134: Multicast in IP-VPN Applications**

Figure 134 depicts an example of multicast in an IP-VPN application. The provider's domain encompasses the core routers (1 through 4) and the edge routers (5 through 10). The various IP-VPN customers each have their own multicast domain, VPN-1 (CE routers 12, 13 and 16) and VPN-2 (CE Routers 11, 14, 15, 17 and 18). Multicast in this VPRN example, the VPN-1 data generated by the customer behind router 16 will be multicast only by PE 9 to PE routers 6 and 7 for delivery to CE routers 12 and 13 respectively. Data generated for VPN-2 generated by the customer behind router 15 will be forwarded by PE 8 to PE routers 5, 7 and 10 for delivery to CE routers 18, 11, 14 and 17 respectively.

The demarcation of these domains is in the PE's (routers 5 through 10). The PE router participates in both the customer multicast domain and the provider's multicast domain. The customer's CEs are limited to a multicast adjacency with the multicast instance on the PE specifically created to support that specific customer's IP-VPN. This way, customers are isolated from the provider's core multicast domain and other customer multicast domains while the provider's core routers only participate in the provider's multicast domain and are isolated from all customers' multicast domains.

The PE for a given customer's multicast domain becomes adjacent to the CE routers attached to that PE and to all other PE's that participate in the IP-VPN (or customer) multicast domain. This is achieved by the PE who encapsulates the customer multicast control data and multicast streams inside the provider's multicast packets. These encapsulated packets are forwarded only to the PE nodes that are attached to the same customer's edge routers as the originating stream and are part of the same customer VPRN. This prunes the distribution of the multicast control and data traffic to the PEs that participate in the customer's multicast domain. The Rosen draft refers to this as the default multicast domain for this multicast domain; the multicast domain is associated with a unique multicast group address within the provider's network.

## Use of Data MDTs

Using the above method, all multicast data offered by a given CE is always delivered to all other CEs that are part of the same multicast. It is possible that a number of CEs do not require the delivery of a particular multicast stream because they have no downstream receivers for a specific multicast group. At low traffic volumes, the impact of this is limited. However, at high data rates this could be optimized by devising a mechanism to prune PEs from the distribution tree that although forming part of the customer multicast have no need to deliver a given multicast stream to the CE attached to them. To facilitate this optimization, the Rosen draft specifies the use of data MDTs. These data MDTs are signaled once the bandwidth for a given SG exceeds the configurable threshold.

Once a PE detects it is transmitting data for the SG in excess of this threshold, it sends an MDT join TLV (at 60 second intervals) over the default MDT to all PEs. All PEs that require the SG specified in the MDT join TLV will join the data MDT that will be used by the transmitting PE to send the given SG. PEs that do not require the SG will not join the data MDT, thus pruning the multicast distribution tree to just the PEs requiring the SG. After providing sufficient time for all PEs to join the data MDT, the transmitting PE switches the given multicast stream to the data MDT.

PEs that do not require the SG to be delivered, keep state to allow them to join the data MDT as required.

When the bandwidth requirement no longer exceeds the threshold, the PE stops announcing the MDT join TLV. At this point the PEs using the data MDT will leave this group and transmission resumes over the default MDT.

Sampling to check if an s,g has exceeded the threshold occurs every ten seconds. If the rate has exceeded the configured rate in that sample period then the data MDT is created. If during that period the transmission rate has not exceeded the configured threshold then the data MDT is not created. If the data MDT is active and the transmission rate in the last sample period has not exceeded the configured rate then the data MDT is torn down and the multicast stream resumes transmission over the default MDT.

## Multicast Protocols Supported in the Provider Network

When MVPN auto-discovery is disabled, PIM-SM can be used for I-PMSI, and PIM-SSM can be used for S-PMSI; When MVPN S-PMSI auto-discovery is enabled, both PIM-SM and PIM SSM can be used for I-PMSI, and PIM-SSM can be used for S-PMSI. In the customer network, both PIM-SM and PIM-SSM are supported.

An MVPN is defined by two sets of sites: sender sites set and receiver sites set, with the following properties:

- Hosts within the sender sites set could originate multicast traffic for receivers in the receiver sites set.
- Receivers not in the receiver sites set should not be able to receive this traffic.
- Hosts within the receiver sites set could receive multicast traffic originated by any host in the sender sites set.
- Hosts within the receiver sites set should not be able to receive multicast traffic originated by any host that is not in the sender sites set.

A site could be both in the sender sites set and receiver sites set, which implies that hosts within such a site could both originate and receive multicast traffic. An extreme case is when the sender sites set is the same as the receiver sites set, in which case all sites could originate and receive multicast traffic from each other.

Sites within a given MVPN may be either within the same, or in different organizations, which implies that an MVPN can be either an intranet or an extranet. A given site may be in more than one MVPN, which implies that MVPNs may overlap. Not all sites of a given MVPN have to be connected to the same service provider, which implies that an MVPN can span multiple service providers.

Another way to look at MVPN is to say that an MVPN is defined by a set of administrative policies. Such policies determine both sender sites set and receiver site set. Such policies are established by MVPN customers, but implemented by MVPN service providers using the existing BGP/MPLS VPN mechanisms, such as route targets, with extensions, as necessary.

---

## MVPN Using BGP Control Plane

Note that the next generation MVPN solution replaces the Rosen MVPN draft and is currently being defined at the IETF. Its IETF status is still a working group draft but it has strong support. It is quite stable for implementation from a technical point of view.

The Alcatel-Lucent implementation supports the following features:

- MVPN membership auto-discovery using BGP
- PE-PE Transmission of C-Multicast Routing using BGP
- IPv4 support
- Use of PIM default and data MDTs as PMSIs
- Inter-AS support with direct VRF connect (option A)
- Backward compatibility with existing Rosen implementation to provide an easy migration path

---

## MVPN Membership Auto-discovery using BGP

BGP-based auto-discovery is performed by an multicast VPN address family. Any PE that attaches to an MVPN must issue a BGP update message containing an NLRI in this address family, along with a specific set of attributes.

The PE router uses route targets to specify MVPN route import and export. The route target may be the same as the one used for the corresponding unicast VPN, or it may be different. The PE router can specify separate import route targets for sender sites and receiver sites for a given MVPN.

The route distinguisher (RD) that is used for the corresponding unicast VPN can also be used for the MVPN.

When BGP auto-discovery is enabled, PIM peering on the I-PMSI is disabled, so no PIM hellos are sent on the I-PMSI. C-trees to P-tunnels bindings are also discovered using BGP S-PMSI AD routes, instead of PIM join TLVs. Configure PIM join TLVs when **c-mcast-signaling** is set to **pim** in the **config>service>vprn>mvpn>provider-tunnel>selective>auto-discovery-disable** context.

[Table 24](#) and [Table 25](#) describe the supported configuration combinations. If the CLI combination is not allowed, the system returns an error message. If the CLI command is marked as “ignored” in the table, the configuration is not blocked, but its value is ignored by the software.

**Table 24: Supported Configuration Combinations**

| Auto-Discovery | Inclusive PIM SSM | Action      |
|----------------|-------------------|-------------|
| Yes            | Yes               | Allowed     |
| No             | Yes               | Not Allowed |
| Yes or No      | No                | Allowed     |

**Table 25: Supported Configuration Combinations**

| <b>Auto-Discovery</b> | <b>C-Mcast-Signaling</b> | <b>s-PMSI A-D</b> | <b>Action</b> |
|-----------------------|--------------------------|-------------------|---------------|
| Yes                   | BGP                      | Ignored           | Allowed       |
| Yes                   | PIM                      | Yes               | Allowed       |
| Yes                   | PIM                      | No                | Allowed       |
| No                    | BGP                      | Ignored           | Not Allowed   |
| No                    | PIM                      | Ignored           | Allowed       |

For example, if auto-discovery is disabled, the **c-mcast-signaling bgp** command will fail with an error message stating:

**C-multicast signaling in BGP requires auto-discovery to be enabled**

If **c-mcast-signaling** is set to **bgp** then **no auto-discovery** will fail with an error message stating

**C-multicast signaling in BGP requires auto-discovery to be enabled**

When **c-mcast-signaling** is set to **bgp**, S-PMSI A-D is always enabled (its configuration is ignored);

When **auto-discovery** is disabled, S-PMSI A-D is always disabled (its configuration is ignored).

When auto-discovery is enabled and **c-multicast-signaling** is set to **pim**, S-PMSI A-D configuration value is used.

## PE-PE Transmission of C-Multicast Routing using BGP

MVPN c-multicast routing information is exchanged between PEs by using c-multicast routes that are carried using MCAST-VPN NLRI.

## Provider Tunnel Support

The following provider tunnels features are supported:

- • PIM ASM inclusive provider tunnel
  - • PIM SSM inclusive provider tunnel (only supported when auto-discovery is enabled)
  - • PIM SSM selective provider tunnel
- 

## Migration from Existing Rosen Implementation

The existing Rosen implementation is compatible to provide an easy migration path.

The following migration procedure are supported:

- Upgrade all the PE nodes that need to support MVPN to the newer release.
  - The old configuration will be converted automatically to the new style.
  - Node by node, MCAST-VPN address-family for BGP is enabled. Enable auto-discovery using BGP.
  - Change PE-to-PE signaling to BGP.
- 

## VRF Route Import Extended Community

VRF route import is an IP address-specific extended community, of an extended type, and is transitive across AS boundaries (RFC 4360, *BGP Extended Communities Attribute*).

To support MVPN, in addition to the import/export route target extended communities used by the unicast routing, each VRF on a PE must have an import route target extended community that controls imports of C-multicast routes into a particular VRF.

The c-multicast import RT uniquely identifies a VRF, and is constructed as follows:

- The Global Administrator field of the c-multicast import RT must be set to an IP address of the PE. This address should be common for all the VRFs on the PE (this address may be the PE's loopback address).
- The Local Administrator field of the c-multicast import RT associated with a given VRF contains a 2 octets long number that uniquely identifies that VRF within the PE that contains the VRF.

A PE that has sites of a given MVPN connected to it communicates the value of the c-multicast import RT associated with the VRF of that MVPN on the PE to all other PEs that have sites of that MVPN. To accomplish this, a PE that originates a (unicast) route to VPN-IP addresses includes in

the BGP updates message that carries this route the VRF route import extended community that has the value of the c-multicast import RT of the VRF associated with the route, except if it is known a priori that none of these addresses will act as multicast sources and/or RP, in which case the (unicast) route need not carry the VRF Route Import extended community.

All c-multicast routes with the c-multicast import RT specific to the VRF must be accepted. In this release, vrf-import and vrf-target policies don't apply to C-multicast routes.

The decision flow path is shown below.

```
if (route-type == c-mcast-route)
 if (route_target_list includes C-multicast_Import_RT) {
 else
 drop;
 else
 Run vrf_import and/or vrf-target;
```

## **Cflowd for IP-VPNs**

The cflowd feature allows service providers to collect IP flow data within the context of a VPRN. This data can be used to monitor types and general proportion of traffic traversing a VPRN context. This data can also be shared with the VPN customer to see the types of traffic traversing the VPN and use it for traffic engineering.

This feature should not be used for billing purposes. Existing queue counters are designed for this purpose and provide very accurate per bit accounting records.

## Inter-AS VPRNs

Inter-AS IP-VPN services have been driven by the popularity of IP services and service provider expansion beyond the borders of a single Autonomous System (AS) or the requirement for IP VPN services to cross the AS boundaries of multiple providers. Three options for supporting inter-AS IP-VPNs are described in RFC 4364, *BGP/MPLS IP Virtual Private Networks (VPNs)*.

The first option, referred to as Option-A (Figure 135), is considered inherent in any implementation. This method uses a back-to-back connection between separate VPRN instances in each AS. As a result, each VPRN instance views the inter-AS connection as an external interface to a remote VPRN customer site. The back-to-back VRF connections between the ASBR nodes require individual sub-interfaces, one per VRF.

OSSG255

**Figure 135: Inter-AS Option-A: VRF-to-VRF Model**

The second option, referred to as Option-B (Figure 136), relies heavily on the AS Boundary Routers (ASBRs) as the interface between the autonomous systems. This approach enhances the scalability of the eBGP VRF-to-VRF solution by eliminating the need for per-VPRN configuration on the ASBR(s). However it requires that the ASBR(s) provide a control plane and forwarding plane connection between the autonomous systems. The ASBR(s) are connected to the PE nodes in its local autonomous system using iBGP either directly or through route reflectors. This means the ASBR(s) receive all the VPRN information and will forward these VPRN updates, VPN-IPv4, to all its EBGP peers, ASBR(s), using itself as the next-hop. It also changes the label associated with the route. This means the ASBR(s) must maintain an associate mapping of labels received and labels issued for those routes. The peer ASBR(s) will in turn forward those updates to all local iBGP peers.

OSSG256

**Figure 136: Inter-AS Option-B**

This form of inter-AS VPRNs does not require instances of the VPRN to be created on the ASBR, as in option-A, as a result there is less management overhead. This is also the most common form of Inter-AS VPRNs used between different service providers as all routes advertised between autonomous systems can be controlled by route policies on the ASBRs.

The third option, referred to as Option-C ([Figure 137](#)), allows for a higher scale of VPRNs across AS boundaries but also expands the trust model between ASNs. As a result this model is typically used within a single company that may have multiple ASNs for various reasons.

This model differs from Option-B, in that in Option-B all direct knowledge of the remote AS is contained and limited to the ASBR. As a result, in option-B the ASBR performs all necessary mapping functions and the PE routers do not need perform any additional functions then in a non-Inter-AS VPRN.

OSSG257

**Figure 137: Option C Example**

With Option-C, knowledge from the remote AS is distributed throughout the local AS. This distribution allows for higher scalability but also requires all PEs and ASBRs involved in the Inter-AS VPRNs to participate in the exchange of inter-AS routing information.

In Option-C, the ASBRs distribute reachability information for remote PE's system IP addresses only. This is done between the ASBRs by exchanging MP-eBGP labeled routes, using RFC 3107, *Carrying Label Information in BGP-4*.

Distribution of VPRN routing information is handled by either direct MP-BGP peering between PEs in the different ASNs or more likely by one or more route reflectors in ASN.

## Traffic Leaking to GRT

Traffic leaking to Global Route Table (GRT) allows service providers to offer VPRN and Internet services to their customers over a single VRF interface. This currently supports IPv4 services and requires the customer VPRN interfaces to terminate on a minimum of IOM3-XP and IMM hardware. It is also supported on the 7750 SR-C12.

Packets entering a local VRF interface can have route processing results derived from the VPRN forwarding table or the GRT. The leaking and preferred lookup results are configured on a per VPRN basis. Configuration options can be general (for example, any lookup miss in the VPRN forwarding table can be resolved in the GRT), or specific (for example, specific route(s) should only be looked up in the GRT and ignored in the VPRN). In order to provide operational simplicity and improve streamlining, the CLI configuration is all contained within the context of the VPRN service.

This feature is enabled within the VPRN service context under **config>service>vprn>grt-lookup**. This is an administrative context and provides the container under which all specific commands can be entered, except for policy definition. Policy definitions remain unchanged but are referenced from this context.

The “enable-grt” command establishes the basic functionality. When it is configured, any lookup miss in the VRF table will be resolved in the GRT, if available. By itself, this only provides part of the solution. Packet forwarding within GRT must understand how to route packets back to the proper node and to the specific VPRN from which the destination exists. Destination prefixes must be leaked from the VPRN to the GRT through the use of policy. Policies are created under the **config>router>policy-options** hierarchy. By default, the number of prefixes leaked from the VPRN to the GRT is limited to five. The **export-limit** command under the **grt-lookup** hierarchy allows the service provider to override the default, or remove the limit.

When a VPRN forwarding table consists of a default route or an aggregate route, the customer may require the service provider to poke holes in those, or provide more specific route resolution in the GRT. In this case, the service provider may configure a “static-route”, under the “enable-grt” context. The lookup result will prefer any successful lookup in the GRT that is equal to or more specific than the static route, bypassing any successful lookup in the local VPRN.

This feature and Unicast Reverse Path Forwarding (uRPF) are mutually exclusive. When a VPRN service is configured with either of these functions, the other cannot be enabled. Also, prefixes leaked from any VPRN should never conflict with prefixes leaked from any other VPRN or existing prefixes in the GRT. Prefixes should be globally unique with the service provider network and if these are propagated outside of a single providers network, they must be from the public IP space and globally unique. Network Address Translation (NAT) is not supported as part of this feature.

## IPv6 VPRN

IP VPN services are widespread, and SR routers have been deployed by large service providers as VPRN PE routers. VPRN supports IPv4 and IPv6 address families for IP VPRN services.

IPv6 VPRN is sometimes referred to as “6VPE”. A difference between 6VPE and 6PE is that 6VPE supports multiple IPv6 VRFs on the PE routers, while 6PE only supports the default global IPv6 routing table.

## RIP Metric Propagation in VPRNs

When RIP is used as the PE-CE protocol for VPRNs (IP-VPNs), the RIP metric is only used by the local node running RIP with the Customer Equipment (CE). The metric is not used to or encoded into and MP-BGP path attributes exchanged between PE routers.

The RIP metric can also be used to exchanged between PE routers so if a customer network is dual homed to separate PEs the RIP metric learned from the CE router can be used to choose the best route to the destination subnet. By using the learned RIP metric to set the BGP MED attribute, remote PEs can choose the lowest MED and in turn the PE with the lowest advertised RIP metric as the preferred egress point for the VPRN.

**Figure 138: RIP Metric Propagation in VPRNs**

## NTP Within a VPRN Service

The NTP within a VPRN service enables the service router to act as the NTP server to CPE devices on a VPRN interface. Individual VPRN interfaces may be configured to listen to and respond to client requests, or additionally may be configured to send NTP broadcast messages. Authentication keys are configurable on a per-VPRN basis.

Only a single instance of NTP remains in the node that is time sourced to as many as five NTP servers attached to the “base” or “management” network.

The NTP show command displays NTP servers and all known clients. Because NTP is UDP based only, no state is maintained. As a result, the show command output only displays when the last message from the client was received.

## Configuring a VPRN Service with CLI

This section provides information to configure Virtual Private Routed Network (VPRN) services using the command line interface.

Topics in this section include:

- [Basic Configuration on page 1100](#)
- [Common Configuration Tasks on page 1102](#)
  - [Configuring VPRN Components on page 1103](#)
    - [Creating a VPRN Service on page 1103](#)
    - [Configuring Global VPRN Parameters on page 1104](#)
    - [Configuring VPRN Protocols - PIM on page 1106](#)
    - [Configuring VPRN Protocols - BGP on page 1108](#)
    - [Configuring VPRN Protocols - RIP on page 1111](#)
    - [Configuring VPRN Protocols - OSPF on page 1113](#)
    - [Configuring a VPRN Interface on page 1114](#)
    - [Configuring a VPRN Interface SAP on page 1115](#)
- [Configuring Overload State on a Single SFM on page 1117](#)
- [Service Management Tasks on page 1118](#)
  - [Modifying VPRN Service Parameters on page 1118](#)

  - [Disabling a VPRN Service on page 1120](#)
  - [Re-enabling a VPRN Service on page 1121](#)

## Basic Configuration

The following fields require specific input (there are no defaults) to configure a basic VPRN service:

- Customer ID (refer to [Configuring Customers on page 91](#))
- Specify interface parameters
- Specify spoke SDP parameters

The following example displays a sample configuration of a VPRN service.

```
*A:ALA-1>config>service>vprn# info

vrf-import "vrfImpPolCust1"
vrf-export "vrfExpPolCust1"
ecmp 8
autonomous-system 10000
route-distinguisher 10001:1
auto-bind ldp
vrf-target target:10001:1
interface "to-cel" create
 address 11.1.0.1/24
 proxy-arp
 exit
 sap 1/1/10:1 create
 ingress
 qos 100
 exit
 egress
 qos 1010
 filter ip 10
 exit
 exit
 dhcp
 description "DHCP test"
 exit
 vrrp 1
 exit
exit
static-route 6.5.0.0/24 next-hop 10.1.1.2
bgp
 router-id 10.0.0.1
 group "to-cel"
 export "vprnBgpExpPolCust1"
 peer-as 65101
 neighbor 10.1.1.2
 exit
exit
exit
pim
 apply-to all
 rp
 static
 exit
 bsr-candidate
 shutdown
 exit
 rp-candidate
```

```
 shutdown
 exit
 exit
 exit
 rip
 export "vprnRipExpPolCust1"
 group "cel"
 neighbor "to-cel"
 exit
 exit
exit
no shutdown

*A:ALA-1>config>service>vprn#
```

## Common Configuration Tasks

This section provides a brief overview of the tasks that must be performed to configure a VPRN service and provides the CLI commands.

1. Associate a VPRN service with a customer ID.
2. Define an autonomous system (optional).
3. Define a route distinguisher (mandatory).
4. Define VRF route-target associations or VRF import/export policies.
5. Define PIM parameters (optional).
6. Create a subscriber interface (optional).
7. Create an interface.
8. Define SAP parameters on the interface.
  - Select node(s) and port(s).
  - Optional - select QoS policies other than the default (configured in `config>qos` context).
  - Optional - select filter policies (configured in `config>filter` context).
  - Optional - select accounting policy (configured in `config>log` context).
  - Optional - configure DHCP features.
9. Define BGP parameters (optional).
  - BGP must be enabled in the `config>router>bgp` context.
10. Define RIP parameters (optional).
  - RIP must be enabled in the **config>router>rip** context.
11. Define spoke SDP parameters.
12. Enable the service.

## Configuring VPRN Components

This section provides VPRN configuration examples for the following entities:

- [Creating a VPRN Service on page 1103](#)
  - [Configuring Global VPRN Parameters on page 1104](#)
  - [Configuring VPRN Protocols - PIM on page 1106](#)
  - [Configuring Router Interfaces on page 1107](#)
  - [Configuring VPRN Protocols - OSPF on page 1113](#)
  - [Configuring a VPRN Interface SAP on page 1115](#)
  - [Configuring VPRN Protocols - BGP on page 1108](#)
  - [Configuring VPRN Protocols - RIP on page 1111](#)
- 

### Creating a VPRN Service

Use the following CLI syntax to create a VPRN service. A route distinguisher must be defined in order for VPRN to be operationally active.

**CLI Syntax:** `config>service# vprn service-id [customer customer-id]  
                   route-distinguisher [ip-address:number1 | asn:number2]  
                   description description-string  
                   no shutdown`

The following example displays a VPRN service configuration.

```
*A:ALA-1>config>service# info

...
 vprn 1 customer 1 create
 route-distinguisher 10001:0
 no shutdown
 exit
...

*A:ALA-1>config>service>vprn#
```

## Configuring Global VPRN Parameters

Refer to [VPRN Services Command Reference on page 1123](#) for CLI syntax to configure VPRN parameters.

The following example displays a VPRN service with configured parameters.

```
*A:ALA-1>config>service# info

...
 vprn 1 customer 1 create
 vrf-import "vrfImpPolCust1"
 vrf-export "vrfExpPolCust1"
 autonomous-system 10000
 route-distinguisher 10001:1
 spoke-sdp 2 create
 exit
 no shutdown
 exit
...

*A:ALA-1>config>service#
```

## Configuring a Spoke-SDP

Use the following CLI syntax to configure spoke SDP parameters:

**CLI Syntax:** config>service# vprn *service-id* [customer *customer-id*]  
 spoke-sdp *sdp-id*  
 no shutdown  
 interface *ip-int-name*  
   spoke-sdp *sdp-id:vc-id* [vc-type {ether|vlan|vpls}]  
   egress  
     filter {ip *ip-filter-id*}  
     vc-label *egress-vc-label*  
   ingress  
     filter {ip *ip-filter-id*}  
     vc-label *ingress-vc-label*  
   tos-marking-state {trusted|untrusted}  
 no shutdown

The following output displays a spoke SDP configuration

```
A:ALA-48>config>service>vprn# info

...
 interface "SpokeSDP" create
 spoke-sdp 3:4 create
 ingress
 vc-label 3000
 filter ip 10
 exit
 egress
 vc-label 2000
 filter ip 10
 exit
 exit
 exit
...
 spoke-sdp 3 create
 exit
 no shutdown

A:ALA-48>config>service>vprn#
```

## Configuring VPRN Protocols - PIM

Refer to [VPRN Services Command Reference on page 1123](#) for CLI syntax to configure VPRN parameters.

The following example displays a VPRN PIM configuration:

```
config>service# info
#-----
...
 vprn 1 customer 2 create
 route-distinguisher 1:11
 interface "if1" create
 address 12.13.14.15/32
 loopback
 exit
 interface "if2" create
 address 14.14.14.1/24
 sap 1/1/2:0 create
 exit
 exit
 pim
 interface "if1"
 exit
 interface "if2"
 exit
 rp
 static
 exit
 bsr-candidate
 shutdown
 exit
 rp-candidate
 shutdown
 exit
 exit
 exit
 no shutdown
 exit
exit
#-----
config>service#
```

## Configuring Router Interfaces

Refer to the 7750 SR OS Router Configuration Guide for command descriptions and syntax information to configure router interfaces.

The following example displays a router interface configurations:

```
ALA48>config>router# info
#-----
echo "IP Configuration"
#-----
...
 interface "if1"
 address 2.2.2.1/24
 port 1/1/33
 exit
 interface "if2"
 address 10.49.1.46/24
 port 1/1/34
 exit
 interface "if3"
 address 11.11.11.1/24
 port 1/1/35
 exit
...
#-----
ALA48>config>router#
```

## Configuring VPRN Protocols - BGP

Configuring BGP between the PE routers allows the PE routers to exchange information about routes originating and terminating in the VPRN. The PE routers use the information to determine which labels are used for traffic intended for remote sites.

In order to enable a VPRN BGP instance, the BGP protocol must be enabled in the `config>router>bgp` context on each participating SR-Series router.

**NOTE:** Careful planning is essential to implement commands that can affect the behavior of VPRN BGP global, group, and neighbor levels. Because the BGP commands are hierarchical, analyze the values that can disable features on a particular level.

The autonomous system number and router ID configured in the VPRN context only applies to that particular service.

The minimal parameters that should be configured for a VPRN BGP instance are:

- Specify an autonomous system number for the router. See [Configuring Global VPRN Parameters on page 1104](#).
- Specify a router ID - Note that if a new or different router ID value is entered in the BGP context, then the new value takes precedence and overwrites the router-level router ID. See [Configuring Global VPRN Parameters on page 1104](#).
- Specify a VPRN BGP peer group.
- Specify a VPRN BGP neighbor with which to peer.
- Specify a VPRN BGP peer-AS that is associated with the above peer.

VPRN BGP is administratively enabled upon creation. Minimally, to enable VPRN BGP in a VPRN instance, you must associate an autonomous system number and router ID for the VPRN service, create a peer group, neighbor, and associate a peer AS number. There are no default VPRN BGP groups or neighbors. Each VPRN BGP group and neighbor must be explicitly configured.

All parameters configured for VPRN BGP are applied to the group and are inherited by each peer, but a group parameter can be overridden on a specific basis. VPRN BGP command hierarchy consists of three levels:

- The global level
- The group level
- The neighbor level

For example:

|                    |                                                |                  |
|--------------------|------------------------------------------------|------------------|
| <b>CLI Syntax:</b> | <code>config&gt;service&gt;vprn&gt;bgp#</code> | (global level)   |
|                    | <code>group</code>                             | (group level)    |
|                    | <code>neighbor</code>                          | (neighbor level) |

Note that the local-address must be explicitly configured if two systems have multiple BGP peer sessions between them for the session to be established.

For more information about the BGP protocol, refer to the 7750 SR OS Router Configuration Guide.

## Configuring VPRN BGP Group and Neighbor Parameters

A group is a collection of related VPRN BGP peers. The group name should be a descriptive name for the group. Follow your group, name, and ID naming conventions for consistency and to help when troubleshooting faults.

All parameters configured for a peer group are applied to the group and are inherited by each peer (neighbor), but a group parameter can be overridden on a specific neighbor-level basis.

After a group name is created and options are configured, neighbors can be added within the same autonomous system to create IBGP connections and/or neighbors in different autonomous systems to create EBGP peers. All parameters configured for the peer group level are applied to each neighbor, but a group parameter can be overridden on a specific neighbor basis.

## Configuring Route Reflection

Route reflection can be implemented in autonomous systems with a large internal BGP mesh to reduce the number of IBGP sessions required. One or more routers can be selected to act as focal points, for internal BGP sessions. Several BGP-speaking routers can peer with a route reflector. A route reflector forms peer connections to other route reflectors. A router assumes the role as a route reflector by configuring the `cluster cluster-id` command. No other command is required unless you want to disable reflection to specific peers.

If you configure the `cluster` command at the global level, then all subordinate groups and neighbors are members of the cluster. The route reflector cluster ID is expressed in dotted decimal notation. The ID should be a significant topology-specific value. No other command is required unless you want to disable reflection to specific peers.

If a route reflector client is fully meshed, the `disable-client-reflect` command can be enabled to stop the route reflector from reflecting redundant route updates to a client.

### VPRN BGP CLI Syntax

Use the CLI syntax to configure VPRN BGP parameters ([BGP Configuration Commands on page 1154](#)).

The following example displays a VPRN BGP configuration:

```
*A:ALA-1>config>service# info

...
 vprn 1 customer 1 create
 vrf-import "vrfImpPolCust1"
 vrf-export "vrfExpPolCust1"
 ecmp 8
 autonomous-system 10000
 route-distinguisher 10001:1
 auto-bind ldp
 vrf-target target:10001:1
 interface "to-cel" create
 address 11.1.0.1/24
 sap 1/1/10:1 create
 ingress
 scheduler-policy "SLA2"
 qos 100
 exit
 egress
 scheduler-policy "SLA1"
 qos 1010
 filter ip 6
 exit
 exit
 static-route 6.5.0.0/24 next-hop 10.1.1.2
 bgp
 router-id 10.0.0.1
 group "to-cel"
 export "vprnBgpExpPolCust1"
 peer-as 65101
 neighbor 10.1.1.2
 exit
 exit
 spoke-sdp 2 create
 exit
 no shutdown
exit
...

*A:ALA-1>config>service#
```

## Configuring VPRN Protocols - RIP

PE routers which attach to a particular VPN need to know, for each of that VPN's sites, which addresses in that VPN are at each site. There are several ways that a PE router can obtain this set of addresses. The Routing Information Protocol (RIP) sends routing update messages that include entry changes. The routing table is updated to reflect the new information.

RIP can be used as a PE/CE distribution technique. PE and CE routers may be RIP peers, and the CE may use RIP to tell the PE router the set of address prefixes which are reachable at the CE router's site. When RIP is configured in the CE, care must be taken to ensure that address prefixes from other sites (i.e., address prefixes learned by the CE router from the PE router) are never advertised to the PE. Specifically, if a PE router receives a VPN-IPv4 route, and as a result distributes an IPv4 route to a CE, then that route must not be distributed back from that CE's site to a PE router (either the same router or different routers).

In order to enable a VPRN RIP instance, the RIP protocol must be enabled in the **config>router>rip** context on each participating SR-Series router. VPRN RIP is administratively enabled upon creation. Configuring other RIP commands and parameters are optional.

**NOTE:** Careful planning is essential to implement commands that can affect the behavior of VPRN RIP global, group, and neighbor levels. Because the RIP commands are hierarchical, analyze the values that can disable features on a particular level.

The parameters configured on the VPRN RIP global level are inherited by the group and neighbor levels. Many of the hierarchical VPRN RIP commands can be modified on different levels. The most specific value is used. That is, a VPRN RIP group-specific command takes precedence over a global VPRN RIP command. A neighbor-specific statement takes precedence over a global VPRN RIP and group-specific command. For example, if you modify a VPRN RIP neighbor-level command default, the new value takes precedence over VPRN RIP group- and global-level settings. There are no default VPRN RIP groups or neighbors. Each VPRN RIP group and neighbor must be explicitly configured.

The minimal parameters that should be configured for a VPRN instance are:

- Specify a VPRN RIP peer group.
- Specify a VPRN RIP neighbor with which to peer.
- Specify a VPRN RIP peer-AS that is associated with the above peer.

VPRN RIP command hierarchy consists of three levels:

- The global level
- The group level
- The neighbor level

For example:

|                    |                          |                  |
|--------------------|--------------------------|------------------|
| <b>CLI Syntax:</b> | config>service>vprn>rip# | (global level)   |
|                    | group                    | (group level)    |
|                    | neighbor                 | (neighbor level) |

### VPRN RIP CLI Syntax

The following example displays a VPRN RIP configuration:

```
*A:ALA-1>config>service# info

...
 vprn 1 customer 1 create
 vrf-import "vrfImpPolCust1"
 vrf-export "vrfExpPolCust1"
 ecmp 8
 autonomous-system 10000
 route-distinguisher 10001:1
 auto-bind ldp
 vrf-target target:10001:1
 interface "to-cel" create
 address 11.1.0.1/24
 sap 1/1/10:1 create
 ingress
 scheduler-policy "SLA2"
 qos 100
 exit
 egress
 scheduler-policy "SLA1"
 qos 1010
 filter ip 6
 exit
 exit
 static-route 6.5.0.0/24 next-hop 10.1.1.2
 bgp
 router-id 10.0.0.1
 group "to-cel"
 export "vprnBgpExpPolCust1"
 peer-as 65101
 neighbor 10.1.1.2
 exit
 exit
 rip
 export "vprnRipExpPolCust1"
 group "cel"
 neighbor "to-cel"
 exit
 exit
 spoke-sdp 2 create
 exit
 no shutdown
exit
...

*A:ALA-1>config>service# info
```

For more information about the RIP protocol, refer to the *7750 SR OS Router Configuration Guide*.

## Configuring VPRN Protocols - OSPF

Each VPN routing instance is isolated from any other VPN routing instance, and from the routing used across the backbone. OSPF can be run with any VPRN, independently of the routing protocols used in other VPRNs, or in the backbone itself. For more information about the OSPF protocol, refer to the *7750 SR OS Router Configuration Guide*.

**CLI Syntax:** `config>service>vprn>ospf#`

---

### VPRN OSPF CLI Syntax

Refer to [OSPF Configuration Commands on page 1158](#) for CLI syntax to configure VPRN parameters.

The following example displays the VPRN OSPF configuration shown above:

```
*A:ALA-48>config>service# info

 vprn 2 customer 1 create
 interface "test" create
 exit
 no shutdown
 exit
 area 0.0.0.0
 virtual-link 1.2.3.4 transit-area 1.2.3.4
 hello-interval 9
 dead-interval 40
 exit
 exit

*A:ALA-48>config>service#
```

For more information about the OSPF protocol, refer to the *7750 SR OS Router Configuration Guide*.

### Configuring a VPRN Interface

Interface names associate an IP address to the interface, and then associate the IP interface with a physical port. The logical interface can associate attributes like an IP address, port, Link Aggregation Group (LAG) or the system.

There are no default interfaces.

Note that you can configure a VPRN interface as a loopback interface by issuing the `loopback` command instead of the `sap sap-id` command. The loopback flag cannot be set on an interface where a SAP is already defined and a SAP cannot be defined on a loopback interface.

When using mtrace/mstat in a Layer 3 VPN context then the configuration for the VPRN should have a loopback address configured which has the same address as the core instance's system address (BGP next-hop).

Refer to [OSPF Configuration Commands on page 1158](#) for CLI commands and syntax.

The following example displays a VPRN interface configuration:

```
*A:ALA-1>config>service>vprn# info

...
 vprn 1 customer 1 create
 vrf-import "vrfImpPolCust1"
 vrf-export "vrfExpPolCust1"
 ecmp 8
 autonomous-system 10000
 route-distinguisher 10001:1
 auto-bind ldp
 vrf-target target:10001:1
 interface "to-cel" create
 address 11.1.0.1/24
 exit
 exit
 static-route 6.5.0.0/24 next-hop 10.1.1.2
 spoke-sdp 2 create
 exit
 no shutdown
 exit
...

*A:ALA-1>config>service#
```

## Configuring a VPRN Interface SAP

A SAP is a combination of a port and encapsulation parameters which identifies the service access point on the interface and within the SR. Each SAP must be unique within a router. A SAP cannot be defined if the interface **loopback** command is enabled.

When configuring VPRN interface SAP parameters, a default QoS policy is applied to each ingress and egress SAP. Additional QoS policies and scheduler policies must be configured in the `config>qos` context. Filter policies are configured in the `config>filter` context and must be explicitly applied to a SAP. There are no default filter policies.

VPRN interface ATM SAP parameters can only be configured on ATM-type MDAs and ATM-configured ports. The **periodic-loopback** command can only be enabled when the `config>system>atm>oam` context is enabled. See the 7750 SR OS Basic System Configuration Guide.

Refer to [OSPF Configuration Commands on page 1158](#) for CLI commands and syntax.

The following example displays a VPRN interface SAP configuration:

```
*A:ALA-1>config>service# info

...
 vprn 1 customer 1 create
 vrf-import "vrfImpPolCust1"
 vrf-export "vrfExpPolCust1"
 ecmp 8
 autonomous-system 10000
 route-distinguisher 10001:1
 auto-bind ldp
 vrf-target target:10001:1
 interface "to-cel" create
 address 11.1.0.1/24
 sap 1/1/10:1 create
 ingress
 scheduler-policy "SLA2"
 qos 100
 exit
 egress
 scheduler-policy "SLA1"
 qos 1010
 filter ip 6
 exit
 exit
 exit
 static-route 6.5.0.0/24 next-hop 10.1.1.2
 spoke-sdp 2 create
 exit
 no shutdown
 exit
...

*A:ALA-1>config>service#
```

## Configuring IPsec Parameters

The following output displays VPRN service with IPsec parameters configured.

```
*A:ALA-49>config# info

...
 vprn 200 customer 1 create
 ipsec
 security-policy 1 create
 entry 1 create
 local-ip 172.17.118.0/24
 remote-ip 172.16.91.0/24
 exit
 exit
 exit
 route-distinguisher 1:1
 ipsec-interface "ipsec-private" create
 sap ipsec-1.private:1 create
 tunnel "remote-office" create
 security-policy 1
 local-gateway-address 10.10.10.118 peer 10.10.7.91 delivery-service
100
 dynamic-keying
 ike-policy 1
 pre-shared-key "test"
 transform 1
 exit
 no shutdown
 exit
 exit
 exit
 interface "corporate-network" create
 address 172.17.118.118/24
 sap 1/1/2 create
 exit
 exit
 static-route 172.16.91.0/24 ipsec-tunnel "remote-office"
 no shutdown
 exit
exit
...

*A:ALA-49>config#
```

## Configuring Overload State on a Single SFM

A 7x50 system with a single SFM installed has a system multicast throughput that is only a half of a 7x50 system with dual SFMs installed. For example, in a mixed environment in which IOM1s, IOM2s, and IOM3s are installed in the same system (chassis mode B or C), system multicast throughput doubles when redundant SFMs are used instead of a single SFM. If the required system multicast throughput is between 16G and 32G (which means both SFMs are being actively used), when there is an SFM failure, multicast traffic needs to be rerouted around the node.

Some scenarios include:

- There is only one SFM installed in the system
- One SFM (active or standby) failed in a dual SFM configuration
- The system is in the ISSU process

You can use an overload state in IGP to trigger the traffic reroute by setting the overload bit in IS-IS or setting the metric to maximum in OSPF. Since PIM uses IGP to find out the upstream router, a next-hop change in IGP will cause PIM to join the new path and prune the old path, which effectively reroutes the multicast traffic downstream. When the problem is resolved, the overload condition is cleared, which will cause the traffic to be routed back to the router.

## Service Management Tasks

This section discusses the following service management tasks:

- [Modifying VPRN Service Parameters on page 1118](#)
  - [Deleting a VPRN Service on page 1119](#)
- 

### Modifying VPRN Service Parameters

Use the CLI syntax to modify VPRN parameters ([VPRN Services Command Reference on page 1123](#)).

The following example displays the VPRN service creation output.

```
*A:ALA-1>config>service# info

...
 vprn 1 customer 1 create
 shutdown
 vrf-import "vrfImpPolCust1"
 vrf-export "vrfExpPolCust1"
 ecmp 8
 maximum-routes 2000
 autonomous-system 10000
 route-distinguisher 10001:1
 interface "to-cel" create
 address 10.1.1.1/24
 sap 1/1/10:1 create
 exit
 exit
 static-route 6.5.0.0/24 next-hop 10.1.1.2
 bgp
 router-id 10.0.0.1
 group "to-cel"
 export "vprnBgpExpPolCust1"
 peer-as 65101
 neighbor 10.1.1.2
 exit
 exit
 exit
 spoke-sdp 2 create
 exit
 exit
 ...

*A:ALA-1>config>service>vprn#
```

## Deleting a VPRN Service

An VPRN service cannot be deleted until SAPs and interfaces are shut down and deleted. If protocols and/or a spoke-SDP are defined, they must be shut down and removed from the configuration as well.

Use the following CLI syntax to delete a VPRN service:

**CLI Syntax:** config>service#  
[no] vprn *service-id* [customer *customer-id*]  
shutdown  
[no] interface *ip-int-name*  
shutdown  
[no] sap *sap-id*  
[no] bgp  
shutdown  
[no] rip  
shutdown  
[no] spoke-sdp *sdp-id*  
[no] shutdown

## Disabling a VPRN Service

A VPRN service can be shut down without deleting any service parameters.

**CLI Syntax:** config>service#  
                   vprn *service-id* [customer *customer-id*]  
                   shutdown

**Example:** config>service# vprn 1  
               config>service>vprn# shutdown  
               config>service>vprn# exit

```
*A:ALA-1>config>service# info

...
 vprn 1 customer 1 create
 shutdown
 vrf-import "vrfImpPolCust1"
 vrf-export "vrfExpPolCust1"
 ecmp 8
 autonomous-system 10000
 route-distinguisher 10001:1
 auto-bind ldp
 vrf-target target:10001:1
 interface "to-cel" create
 address 11.1.0.1/24
 sap 1/1/10:1 create
 ingress
 scheduler-policy "SLA2"
 qos 100
 exit
 egress
 scheduler-policy "SLA1"
 qos 1010
 filter ip 6
 exit
 exit
 exit
 static-route 6.5.0.0/24 next-hop 10.1.1.2
 bgp
 router-id 10.0.0.1
 group "to-cel"
 export "vprnBgpExpPolCust1"
 peer-as 65101
 neighbor 10.1.1.2
 exit
 exit
 exit
 rip
 export "vprnRipExpPolCust1"
 group "cel"
 neighbor "to-cel"
 exit
 exit
 exit
 spoke-sdp 2 create
 exit
 exit
...

*A:ALA-1>config>service#
```

## Re-enabling a VPRN Service

To re-enable a VPRN service that was shut down.

**CLI Syntax:** `config>service#  
                vprn service-id [customer customer-id]  
                no shutdown`

---

## VPNRN Service Configuration Commands

```

config
— service
— vpn service-id [customer customer-id]
— no vpn service-id
— auto-bind {ldp | gre | rsvp-te | mpls}
— no auto-bind
— autonomous-system as-number
— no autonomous-system
— description description-string
— no description
— ecmp max-ecmp-routes
— no ecmp
— grt-lookup
— [no] enable-grt
— export-grt policy-name [policy-name ...(up to 5 max)]
— static-route {ip-prefix/prefix-length | ip-prefix netmask} [preference preference] [metric metric] [enable|disable] grt
— no static-route
— export-limit num-routes
— no export-limit
— igmp-host-tracking
— expiry-time expiry-time
— no expiry-time
— [no] shutdown
— [no] ignore-nh-metric
— maximum-ipv6-route number [log-only] [threshold percent]
— no maximum-ipv6-route
— maximum-routes number [log-only] [threshold percent]
— no maximum-routes
— mc-maximum-routes number [log-only] [threshold percent]
— no mc-maximum-routes
— multicast-info-policy policy-name
— no multicast-info-policy
— mvpn
— [no] nat
— route-distinguisher [ip-address:number1 | asn:number2]
— no route-distinguisher
— router-id ip-address
— no router-id
— service-name service-name
— no service-name
— sgt-qos
— application dscp-app-name dscp {dscp-value | dscp-name}
— application dot1p-app-name dot1p dot1p-priority

## Multicast VPN Commands

```

config
 — service
 — vprn service-id [customer customer-id]
 — no vprn service-id
 — mvpn
 — [no] auto-discovery
 — c-mcast-signaling {bgp | pim}
 — no c-mcast-signaling
 — [no] intersite-shared
 — provider-tunnel
 — inclusive
 — pim {asm | ssm} grp-ip-address
 — no pim
 — hello-interval hello-interval
 — no hello-interval
 — hello-multiplier deci-units
 — no hello-multiplier
 — [no] improved-assert
 — [no] shutdown
 — [no] three-way-hello
 — [no] tracking-support
 — selective
 — [no] auto-discovery-disable
 — data-delay-interval value
 — no data-delay-interval
 — data-threshold {c-grp-ip-addr/mask|c-grp-ip-addr
 netmask} s-psmi-threshold
 — no data-threshold {c-grp-ip-addr/mask|c-grp-ip-addr
 netmask}
 — [no] join-tlv-packing-disable
 — pim-ssm {grp-ip-address/mask|grp-ip-address net-
 mask}
 — no pim-ssm
 — umh-selection highest-ip | hash-based
 — no umh-selection
 — vrf-export {unicast | policy-name [policy-name...(up to 5 max)]}
 — no vrf-export
 — vrf-import {unicast | policy-name [policy-name...(up to 5 max)]}
 — no vrf-import
 — vrf-target {unicast | ext-community | export unicast | ext-community |
 import unicast | ext-community}
 — no vrf-target
 — export {unicast | ext-community}
 — import {unicast | ext-community}

```

## NTP Commands

Note that the **ntp-server** command is not supported in the **vpn>ntp** context. Then NTP is configured in a VPRN service, the NTP server mode is assumed and is not optional.

```

config
 — service
 — vpn
 — [no] ntp
 — [no] authentication-check
 — authentication-key key-id key key [hash | hash2] type {des | message-
 digest}
 — no authentication-key key-id
 — [no] broadcast [router router-name] {interface ip-int-name} [key-id
 key-id] [version version] [ttl ttl]

```

## Redundant Interface Commands

```

config
 — service
 — vpn service-id [customer customer-id]
 — no vpn service-id
 — [no] redundant-interface ip-int-name
 — address {ip-address/mask | ip-address netmask} [remote-ip ip-address]
 — no address
 — [no] description description-string
 — [no] shutdown
 — [no] spoke-sdp sdp-id:vc-id
 — egress
 — filter [ip ip-filter-id]
 — vc-label ingress-vc-label
 — no vc-label [ingress-vc-label]
 — ingress
 — filter [ip ip-filter-id]
 — no filter
 — vc-label ingress-vc-label
 — no vc-label [ingress-vc-label]
 — [no] shutdown

```

## Router Advertisement Commands

```

config
 — router
 — [no] router-advertisement
 — [no] interface ip-int-name
 — current-hop-limit number
 — no current-hop-limit
 — [no] managed-configuration
 — max-advertisement-interval seconds
 — no max-advertisement-interval
 — min-advertisement-interval seconds
 — no min-advertisement-interval
 — mtu mtu-bytes
 — no mtu
 — [no] other-stateful-configuration
 — prefix [ipv6-prefix/prefix-length]
 — no prefix
 — [no] autonomous
 — [no] on-link
 — preferred-lifetime {seconds | infinite}
 — no preferred-lifetime
 — valid-lifetime {seconds | infinite}
 — no valid-lifetime
 — reachable-time milli-seconds
 — no reachable-time
 — retransmit-time milli-seconds
 — no retransmit-time
 — router-lifetime seconds
 — no router-lifetime
 — [no] shutdown
 — [no] use-virtual-mac

```

## Subscriber Interface Commands

```

config

**Description** This command administratively disables an entity. When disabled, an entity does not change, reset, or remove any configuration settings or statistics.

The operational state of the entity is disabled as well as the operational state of any entities contained within. Many objects must be shut down before they may be deleted.

Services are created in the administratively down (**shutdown**) state. When a **no shutdown** command is entered, the service becomes administratively up and then tries to enter the operationally up state. Default administrative states for services and service entities is described below in Special Cases.

The **no** form of this command places the entity into an administratively enabled state.

If the AS number was previously changed, the BGP AS number inherits the new value.

**Special Cases** **Service Admin State** — Bindings to an SDP within the service will be put into the out-of-service state when the service is shutdown. While the service is shutdown, all customer packets are dropped and counted as discards for billing and debugging purposes.

A service is regarded as operational providing that one IP Interface SAP and one SDP is operational.

**VPNRN BGP and RIP** — This command disables the BGP or RIP instance on the given IP interface. Routes learned from a neighbor that is shutdown are immediately removed from the BGP or RIP database and RTM. If BGP or RIP is globally shutdown, then all RIP group and neighbor interfaces are shutdown operationally. If a BGP or RIP group is shutdown, all member neighbor interfaces are shutdown operationally. If a BGP or RIP neighbor is shutdown, just that neighbor interface is operationally shutdown.

## description

| <b>Description</b> | This command creates a text description stored in the configuration file for a configuration context.<br><br>The <b>description</b> command associates a text string with a configuration context to help identify the content in the configuration file.<br><br>The <b>no</b> form of this command removes the string from the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Default</b>     | No description associated with the configuration context.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <i>string</i> — The description character string. Allowed values are any string up to 80 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Context       | config>service                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                       |                     |                |  |                   |                       |
| Description   | <p>This command creates or edits a Virtual Private Routed Network (VPRN) service instance.</p> <p>If the <i>service-id</i> does not exist, a context for the service is created. If the <i>service-id</i> exists, the context for editing the service is entered.</p> <p>VPRN services allow the creation of customer-facing IP interfaces in the same routing instance used for service network core routing connectivity. VPRN services require that the IP addressing scheme used by the subscriber must be unique between it and other addressing schemes used by the provider and potentially the entire Internet.</p> <p>IP interfaces defined within the context of an VPRN service ID must have a SAP created as the access point to the subscriber network.</p> <p>When a service is created, the <b>customer</b> keyword and <i>customer-id</i> must be specified and associates the service with a customer. The <i>customer-id</i> must already exist having been created using the customer command in the service context. When a service is created with a customer association, it is not possible to edit the customer association. The service must be deleted and re-created with a new customer association.</p> <p>When a service is created, the use of the <b>customer</b> <i>customer-id</i> is optional to navigate into the service configuration context. If attempting to edit a service with the incorrect <i>customer-id</i> results in an error.</p> <p>Multiple VPRN services are created to separate customer-owned IP interfaces. More than one VPRN service can be created for a single customer ID. More than one IP interface can be created within a single VPRN service ID. All IP interfaces created within an VPRN service ID belongs to the same customer.</p> <p>The <b>no</b> form of the command deletes the VPRN service instance with the specified <i>service-id</i>. The service cannot be deleted until all the IP interfaces and all routing protocol configurations defined within the service ID have been shutdown and deleted.</p> |                       |                     |                |  |                   |                       |
| Default       | None — No VPRN service instances exist until they are explicitly created.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                       |                     |                |  |                   |                       |
| Parameters    | <p><i>service-id</i> — The unique service identification number identifying the service in the service domain. This ID must be unique to this service and may not be used for any other service of any type. The <i>service-id</i> must be the same number used for every 7750 SR and 7710 SR on which this service is defined.</p> <table><tr><td><b>Values</b></td><td><i>service-id</i>:</td><td>1 — 2147483648</td></tr><tr><td></td><td><i>svc-name</i>:</td><td>64 characters maximum</td></tr></table> <p><b>customer</b> <i>customer-id</i> — Specifies an existing customer identification number to be associated with the service. This parameter is required on service creation and optional for service editing or deleting.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | <b>Values</b>         | <i>service-id</i> : | 1 — 2147483648 |  | <i>svc-name</i> : | 64 characters maximum |

| <b>Context</b>     | config>service>vprn                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | <p>This command enables equal-cost multipath (ECMP) and configures the number of routes for path sharing. For example, the value of 2 means that 2 equal cost routes will be used for cost sharing.</p> <p>ECMP groups form when the system routes to the same destination with equal cost values. Routing table entries can be entered manually (as static routes), or they can be formed when neighbors are</p> |

discovered and routing table information is exchanged by routing protocols. The system can balance traffic across the groups with equal costs.

ECMP can only be used for routes learned with the same preference and same protocol. See the discussion on preferences in the **static-route** command.

When more ECMP routes are available at the best preference than configured by the `max-ecmp-routes` parameter, then the lowest next-hop IP address algorithm is used to select the number of routes configured.

The **no** form of the command disables ECMP path sharing. If ECMP is disabled and multiple routes are available at the best preference and equal cost, the newly updated route is used.

|                   |                                                                                   |
|-------------------|-----------------------------------------------------------------------------------|
| <b>Default</b>    | no ecmp                                                                           |
| <b>Parameters</b> | <i>max-ecmp-routes</i> — Specifies the maximum number of routes for path sharing. |

| <b>Context</b>     | config>service>vprn>grt-lookup                                                                                                                                                                                                                                                              |
| <b>Description</b> | This command uses route policy to determine which routes are exported from the VRF to the GRT along with all the forwarding information. These entries will be marked as BGP-VPN routes in the GRT. Routes must be in the GRT in order for proper routing to occur from the GRT to the VRF. |
| <b>Default</b>     | no export-grt                                                                                                                                                                                                                                                                               |

## export-limit

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>export-limit</b> <i>num-routes</i><br><b>no export-limit</b>                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Context</b>     | config>service>vprn>grt-lookup<br>config>service>vprn>ospf<br>config>service>vprn>ospf3<br>config>service>vprn>rip                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b> | This command provides the ability to limit the total number of routes exported from the VRF to the GRT. The value zero (0) provides an override that disables the maximum limit. Setting this value to zero (0) will not limit the number of routes exported from the VRF to the GRT. Configuring a range of one (1) to 1000 will limit the number of routes to the specified value.<br><br>The <b>no</b> form of the command sets the export-limit to a default of five (5). |
| <b>Default</b>     | export-limit 5                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <i>num-routes</i> — Specifies maximum number of routes that can be exported.<br><br><b>Values</b> 0 — 1000                                                                                                                                                                                                                                                                                                                                                                    |

## static-route

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>static-route</b> { <i>ip-prefix/prefix-length</i>   <i>ip-prefix netmask</i> } [ <b>preference</b> <i>preference</i> ] [ <b>metric</b> <i>metric</i> ] [ <b>enable disable</b> ] <b>grt</b><br><b>no static-route</b>                                                                                                                                                                                                                                                                                               |
| <b>Context</b>     | config>service>vprn>grt-lookup>enable-grt                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b> | This command is a simplified version of the traditional static-route command pointing to the base routing instance. This instructs the route lookup function to look only in the GRT for a route matching destination static route and not look up the route in the local VRF. The GRT keyword is a required parameter.<br><br>The no form casues the feature into the default mode of primary lookup for all routes in the local VRF and failing a match in the local VRF, the lookup result in the GRT will be used. |

## VPRN Service Configuration Commands

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>ip-prefix/prefix-length</i> — Specifies the IPv4 prefix and prefix length.<br><b>Values</b> ip-prefix: a.b.c.d (host bits must be 0)<br>ipv4-prefix-length: [0..32]<br><i>netmask</i> — Specifies the netmask.<br><b>Values</b> a.b.c.d (network bits all 1 and host bits all 0)<br><i>preference</i> — Specifies the preference.<br><b>Values</b> 1..255<br><i>metric</i> — Specifies the metric.<br><b>Values</b> 0..65535<br><b>enable disable</b> — Keyword; specifies the state of the static-route.<br><b>grt</b> — Keyword; Global Route Table lookup. |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## gsmp

|                    |                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>gsmp</b>                                                                                |
| <b>Context</b>     | config>service>vprn                                                                        |
| <b>Description</b> | This command enables the context to configure GSMP connections maintained in this service. |
| <b>Default</b>     | not enabled                                                                                |

## group

|                    |                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] group name</b>                                                                                                       |
| <b>Context</b>     | config>service>vprn>gsmp                                                                                                     |
| <b>Description</b> | This command specifies a GSMP name. A GSMP group name is unique only within the scope of the service in which it is defined. |
| <b>Parameters</b>  | <i>name</i> — Specifies the group name up to 32 characters in length.                                                        |

## ancp

|                    |                                                              |
|--------------------|--------------------------------------------------------------|
| <b>Syntax</b>      | <b>ancp</b>                                                  |
| <b>Context</b>     | config>service>vprn>gsmp>group                               |
| <b>Description</b> | This command configures ANCP parameters for this GSMP group. |

## dynamic-topology-discover

|                    |                                                                                                                                  |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] dynamic-topology-discover</b>                                                                                            |
| <b>Context</b>     | config>service>vprn>gsmp>group>ancp                                                                                              |
| <b>Description</b> | This command enables the ANCP dynamic topology discovery capability.<br>The <b>no</b> form of this command disables the feature. |

## oam

|                    |                                                                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] oam</b>                                                                                                                                                                        |
| <b>Context</b>     | config>service>vprn>gsmp>group>ancp                                                                                                                                                    |
| <b>Description</b> | This command specifies whether or not the GSMP ANCP OAM capability should be negotiated at startup of the GSMP connection.<br>The <b>no</b> form of this command disables the feature. |

## hold-multiplier

|                    |                                                                                        |
|--------------------|----------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>hold-multiplier</b> <i>multiplier</i><br><b>no hold-multiplier</b>                  |
| <b>Context</b>     | config>service>vprn>gsmp>group                                                         |
| <b>Description</b> | This command configures the hold-multiplier for the GSMP connections in this group.    |
| <b>Parameters</b>  | <i>multiplier</i> — Specifies the GSMP hold multiplier value.<br><b>Values</b> 1 — 100 |

## keepalive

|                    |                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>keepalive</b> <i>seconds</i><br><b>no keepalive</b>                                        |
| <b>Context</b>     | config>service>vprn>gsmp>group                                                                |
| <b>Description</b> | This command configures keepalive values for the GSMP connections in this group.              |
| <b>Parameters</b>  | <i>seconds</i> — Specifies the GSMP keepalive timer value in seconds.<br><b>Values</b> 1 — 25 |

## neighbor

|                    |                                                                          |
|--------------------|--------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] neighbor</b> <i>ip-address</i>                                   |
| <b>Context</b>     | config>service>vprn>gsmp>group                                           |
| <b>Description</b> | This command adds or removes a neighbor in this group.                   |
| <b>Parameters</b>  | <i>ip-address</i> — Specifies the IP address in dotted decimal notation. |

## local-address

|                    |                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>local-address</b> <i>ip-address</i><br><b>no local-address</b>                          |
| <b>Context</b>     | config>service>vprn>gsmp>group>neighbor                                                    |
| <b>Description</b> | This command configures the source ip-address used in the connection towards the neighbor. |
| <b>Parameters</b>  | <i>ip-address</i> — Specifies the IP address in dotted decimal notation.                   |

## priority-marking

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Description</b> | This command configure the bandwidth assigned for interface's multicast CAC policy traffic. When disabled ( <b>no unconstrained-bw</b> ), there is no constraint on bandwidth allocated at the interface. When enabled and if a multicast CAC policy is assigned on the interface, then no group (channel) from that policy is allowed on the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b> | This command configures the bandwidth for the interface's multicast CAC policy traffic. When disabled ( <b>no unconstrained-bw</b> ) there will be no checking of bandwidth constraints on the interface level. When enabled and a policy is defined, enforcement is performed. The allocated bandwidth for optional channels should not exceed the <b>unconstrained-bw</b> minus the <b>mandatory-bw</b> and the mandatory channels have to stay below the specified value for the <b>mandatory-bw</b> . After this interface check, the bundle checks are performed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <p><i>bandwidth</i> — The bandwidth assigned for interface's MCAC policy traffic, in kilo-bits per second.</p> <p><b>Values</b> 1— 2147483647</p> <p><b>mandatory-bw</b> <i>mandatory-bw</i> — Specifies the bandwidth pre-reserved for all the mandatory channels on a given interface in kilo-bits per second (kbps).</p> <p>If the <i>bandwidth</i> value is 0, no mandatory channels are allowed. If the value of <i>bandwidth</i> is '-1', then all mandatory and optional channels are allowed.</p> <p>If the value of <i>mandatory-bw</i> is equal to the value of <i>bandwidth</i>, then all the unconstrained bandwidth on a given interface is allocated to mandatory channels configured through multicast CAC policy on that interface and no optional groups (channels) are allowed.</p> <p>The value of <i>mandatory-bw</i> should always be less than or equal to that of <i>bandwidth</i>, An attempt to set the value of <i>mandatory-bw</i> greater than that of <i>bandwidth</i>, will result in inconsistent value error.</p> <p><b>Values</b> 1— 2147483647</p> |

| <b>Context</b>     | config>service>vprn>igmp>interface>static                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | <p>This command adds a static multicast group either as a (*,G) or one or more (S,G) records. Use IGMP static group memberships to test multicast forwarding without a receiver host. When IGMP static groups are enabled, data is forwarded to an interface without receiving membership reports from host members.</p> <p>When static IGMP group entries on point-to-point links that connect routers to a rendezvous point (RP) are configured, the static IGMP group entries do not generate join messages toward the RP.</p> |
| <b>Default</b>     | none                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b>  | <i>grp-ip-address</i> — Specifies an IGMP multicast group address that receives data on an interface. The IP address must be unique for each static group. The address must be in dotted decimal notation                                                                                                                                                                                                                                                                                                                         |

| <b>Context</b>     | config>service>vprn>igmp>interface                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | This command specifies the IGMP version. If routers run different versions of IGMP, they will negotiate the lowest common version of IGMP that is supported by hosts on their subnet and operate in that version. For IGMP to function correctly, all routers on a LAN should be configured to run the same version of IGMP on that LAN.<br><br>For IGMPv3, note that a multicast router that is also a group member performs both parts of IGMPv3, receiving and responding to its own IGMP message transmissions as well as those of its neighbors. |
| <b>Default</b>     | 3                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <i>version</i> — Specifies the IGMP version number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Values</b>      | 1, 2, 3                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## query-interval

|                    |                                                                                                                                                                                                                                      |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>query-interval</b> <i>seconds</i><br><b>no query-interval</b>                                                                                                                                                                     |
| <b>Context</b>     | config>service>vprn>igmp                                                                                                                                                                                                             |
| <b>Description</b> | This command specifies the frequency that the querier router transmits general host-query messages. The host-query messages solicit group membership information and are sent to the all-systems multicast group address, 224.0.0.1. |
| <b>Default</b>     | 125                                                                                                                                                                                                                                  |
| <b>Parameters</b>  | <i>seconds</i> — The time frequency, in seconds, that the router transmits general host-query messages.<br><b>Values</b> 2 — 1024                                                                                                    |

## query-last-member-interval

|                    |                                                                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>query-last-member-interval</b> <i>seconds</i>                                                                                                                                                                                                        |
| <b>Context</b>     | config>service>vprn>igmp                                                                                                                                                                                                                                |
| <b>Description</b> | This command configures the frequency at which the querier sends group-specific query messages including messages sent in response to leave-group messages. The lower the interval, the faster the detection of the loss of the last member of a group. |
| <b>Default</b>     | 1                                                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <i>seconds</i> — Specifies the frequency, in seconds, at which query messages are sent.<br><b>Values</b> 1 — 1024                                                                                                                                       |

## query-response-interval

|                    |                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>query-response-interval</b> <i>seconds</i>                                                                                                      |
| <b>Context</b>     | config>service>vprn>igmp                                                                                                                           |
| <b>Description</b> | This command specifies how long the querier router waits to receive a response to a host-query message from a host.                                |
| <b>Default</b>     | 10                                                                                                                                                 |
| <b>Parameters</b>  | <i>seconds</i> — Specifies the the length of time to wait to receive a response to the host-query message from the host.<br><b>Values</b> 1 — 1023 |

## robust-count

|                    |                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>robust-count</b> <i>robust-count</i><br><b>no robust-count</b>                                                                                                                                       |
| <b>Context</b>     | config>service>vprn>igmp                                                                                                                                                                                |
| <b>Description</b> | This command configures the robust count. The robust-count variable allows tuning for the expected packet loss on a subnet. If a subnet anticipates losses, the robust-count variable can be increased. |
| <b>Default</b>     | 2                                                                                                                                                                                                       |
| <b>Parameters</b>  | <i>robust-count</i> — Specifies the robust count value.                                                                                                                                                 |
|                    | <b>Values</b> 2 — 10                                                                                                                                                                                    |

## ssm-translate

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>igmp</b>                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Context</b>     | config>service>vprn>igmp                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | This command enables the context to configure group ranges which are translated to SSM (S,G) entries. If the static entry needs to be created, it has to be translated from a IGMPv1 IGMPv2 request to a Source Specific Multicast (SSM) join. An SSM translate source can only be added if the starg command is not enabled. An error message is generated if you try to configure the <b>source</b> command with <b>starg</b> command enabled. |

## grp-range

|                    |                                                                                                                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] grp-range</b> <i>start end</i>                                                                                                                                                                                                       |
| <b>Context</b>     | config>service>vprn>igmp>ssm-translate                                                                                                                                                                                                       |
| <b>Description</b> | This command is used to configure group ranges which are translated to SSM (S,G) entries.                                                                                                                                                    |
| <b>Parameters</b>  | <i>start</i> — An IP address that specifies the start of the group range.<br><i>end</i> — An IP address that specifies the end of the group range. This value should always be greater than or equal to the value of the <i>start</i> value. |

## source

|                    |                                                                                                                                                                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] source</b> <i>ip-address</i>                                                                                                                                                                                                                                              |
| <b>Context</b>     | config>service>vprn>igmp>ssm-translate>grp-range                                                                                                                                                                                                                                  |
| <b>Description</b> | This command specifies the source IP address for the group range. Whenever a (*,G) report is received in the range specified by <b>grp-range</b> <i>start</i> and <i>end</i> parameters, it is translated to an (S,G) report with the value of this object as the source address. |

**Parameters**     *ip-address* — Specifies the IP address that will be sending data.

### igmp-host-tracking

**Syntax**     **igmp-host-tracking**

**Context**     config>service>vprn  
config>service>vprn>sap

**Description**     This command enables the context to configure IGMP host tracking parameters.

### expiry-time

**Syntax**     **expiry-time** *expiry-time*  
**no expiry-time**

**Context**     config>service>vprn>igmp-trk  
config>service>vprn>sap>igmp-trk

**Description**     This command configures the time that the system continues to track inactive hosts.  
The **no** form of the command removes the values from the configuration.

**Default**     no expiry-time

**Parameters**     *expiry-time* — Specifies the time, in seconds, that this system continues to track an inactive host.

**Values**     1 — 65535

### import

**Syntax**     **import** *policy-name*  
**no import**

**Context**     config>service>vprn>sap>igmp-trk

**Description**     This command associates an import policy to filter IGMP packets.  
The **no** form of the command removes the values from the configuration.

**Default**     no import

**Parameters**     *policy-name* — Specifies the import policy name.

## max-num-groups

|                    |                                                                                                                                                                       |

| <b>Context</b>     | config>service>vprn                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | <p>This command specifies the maximum number of routes that can be held within a VPN routing/forwarding (VRF) context.</p> <p>Note that the VPRN service ID must be in a shutdown state in order to modify maximum-routes command parameters.</p> <p>If the <b>log-only</b> parameter is not specified and the maximum-routes value is set below the existing number of routes in a VRF, then the offending RIP peer (if applicable) is brought down (but the</p> |

VPRN instance remains up). BGP peering will remain up but the exceeding BGP routes will not be added to the VRF.

The maximum route threshold can dynamically change to increase the number of supported routes even when the maximum has already been reached. Protocols will resubmit their routes which were initially rejected.

The **no** form of the command disables any limit on the number of routes within a VRF context. Issue the **no** form of the command only when the VPRN instance is shutdown.

| <b>Context</b>     | config>service>vprn                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b> | <p>This command specifies the maximum number of multicast routes that can be held within a VPN routing/forwarding (VRF) context. When this limit is reached, a log and SNMP trap are sent. If the <b>log-only</b> parameter is not specified and the maximum-routes value is set below the existing number of routes in a VRF, then no new joins will be processed.</p> <p>The <b>no</b> form of the command disables the limit of multicast routes within a VRF context. Issue the <b>no</b> form of the command only when the VPRN instance is shutdown.</p> |
| <b>Default</b>     | no mc-maximum-routes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|                   |                                                                                                                                    |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>number</i> — Specifies the maximum number of routes to be held in a VRF context.                                                |
| <b>Values</b>     | 1 — 2147483647                                                                                                                     |
| <b>log-only</b>   | — Specifies that if the maximum limit is reached, only log the event. <b>log-only</b> does not disable the learning of new routes. |
| <b>threshold</b>  | <i>threshold</i> — The percentage at which a warning log message and SNMP trap should be sent.                                     |
| <b>Values</b>     | 0 — 100                                                                                                                            |
| <b>Default</b>    | 10                                                                                                                                 |

### route-distinguisher

|                    |                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>route-distinguisher</b> [ <i>ip-address:number</i>   <i>asn:number</i> ]<br><b>no route-distinguisher</b>                                                                                                                                                                                                                                                                                |
| <b>Context</b>     | config>service>vpn                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b> | This command sets the identifier attached to routes the VPN belongs to. Each routing instance must have a unique (within the carrier's domain) route distinguisher associated with it. A route distinguisher must be defined for a VPRN to be operationally active.                                                                                                                         |
| <b>Default</b>     | no route-distinguisher                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | The route distinguisher is a 6-byte value that can be specified in one of the following formats:<br><br><i>ip-address:number</i> — Specifies the IP address in dotted decimal notation. The assigned number must not be greater than 65535.<br><br><i>asn:number</i> — The ASN is a 2-byte value less than or equal to 65535. The assigned number can be any 32-bit unsigned integer value. |

### router-id

|                    |                                                                                                                                                                                                                                                                                                |

| <b>Description</b> | <p>This command configures an optional service name, up to 64 characters in length, which adds a name identifier to a given service to then use that service name in configuration references as well as display and use service names in show commands throughout the system. This helps the service provider/administrator to identify and manage services within the 7750 SR, 7450 ESS and 7710 SR platforms.</p> <p>All services are required to assign a service ID to initially create a service. However, either the service ID or the service name can be used to identify and reference a given service once it is initially created.</p> |
| <b>Parameters</b>  | <i>service-name</i> — Specifies a unique service name to identify the service. Service names may not begin with an integer (0-9).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Description</b> | <p>This command configures DSCP/Dot1p re-marking for self-generated traffic. When an application is configured using this command, then the specified DSCP name/value is used for all packets generated by this application within the router instance it is configured.</p> <p>Using the value configured in this command:</p> <ul style="list-style-type: none"> <li>• Sets the DSCP bits in the IP packet.</li> <li>• Maps to the FC. This value will be signaled from the CPM to the egress forwarding complex.</li> <li>• Based on this signaled FC the egress forwarding complex QoS policy sets the IEEE802.1 dot1P and LSP EXP bits.</li> <li>• The Dot1P and the LSP EXP bits are set by the egress complex for all packets based on the signaled FC. This includes ARP and IS-IS packets that, due to their nature, do not carry DSCP bits.</li> <li>• The DSCP value in the egress IP header will be as configured in this command. The egress QoS policy will not overwrite this value.</li> </ul> |

Only one DSCP name/value can be configured per application, if multiple entries are configured then the subsequent entry overrides the previous configured entry.

The **no** form of this command reverts back to the default value.

| <b>Description</b> | <p>This command creates a mapping between the DiffServ Code Point (DSCP) of the self generated traffic and the forwarding class.</p> <p>Self generated traffic that matches the specified DSCP will be assigned to the corresponding forwarding class. Multiple commands can be entered to define the association of some or all sixty-four DiffServ code points to the forwarding class. For undefined code points, packets are assigned to the forwarding class specified under the default-action command.</p> <p>All DSCP names that defines a DSCP value must be explicitly defined.</p> <p>The <b>no</b> form of this command removes the DiffServ code point to forwarding class association. The default-action then applies to that code point value.</p> |
| <b>Default</b>     | none                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <p><i>dscp-name</i> — The name of the DiffServ code point to be associated with the forwarding class. DiffServ code point can only be specified by its name and only an existing DiffServ code point can be specified. The software provides names for the well known code points.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Values** be, ef, cp1, cp2, cp3, cp4, cp5, cp6, cp7, cp9, cs1, cs2, cs3, cs4, cs5, nc1, nc2, af11, af12, af13, af21, af22, af23, af31, af32, af33, af41, af42, af43, cp11, cp13, cp15, cp17, cp19, cp21, cp23, cp25, cp27, cp29, cp31, cp33, cp35, cp37, cp39, cp41, cp42, cp43, cp44, cp45, cp47, cp49, cp50, cp51, cp52, cp53, cp54, cp55, cp57, cp58, cp59, cp60, cp61, cp62, cp63

**fc** *fc-name* — Specifies the forwarding class name. All packets with DSCP value or MPLS EXP bits that is not defined will be placed in this forwarding class.

**Default** None, the fc name must be specified

**Values** be, l2, af, l1, h2, ef, h1, nc

## single-sfm-overload

|                    |                                                                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>single-sfm-overload</b> [ <b>holdoff-time</b> <i>holdoff-time</i> ]<br><b>no single-sfm-overload</b>                                                                                                                                                  |
| <b>Context</b>     | config>service>vprn                                                                                                                                                                                                                                      |
| <b>Description</b> | This command, if enabled, will cause the IGP protocols (either IS-IS or OSPF) for the service to enter an overload state when the node only has a single SFM functioning.<br>The <b>no</b> form of this command causes the overload state to be cleared. |
| <b>Default</b>     | no single-sfm-overload                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <i>holdoff-time</i> — This parameter specifies the delay between the detection of a single SFM and enacting the overload state.<br><b>Values</b> 1—600 seconds<br><b>Default</b> 0 seconds                                                               |

| <b>Description</b> | This command creates static route entries within the associated router instance. When configuring a static route, either <b>next-hop</b> , <b>indirect</b> or <b>black-hole</b> must be configured.<br><br>The <b>no</b> form of the command deletes the static route entry. If a static route needs to be removed when multiple static routes exist to the same destination, then as many parameters to uniquely identify the static route must be entered.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

If a CPE connectivity check target address is already being used as the target address in a different static route, then `cpe-check` parameters must match. If they do not, the new configuration command will be rejected.

If a static-route command is issued with no `cpe-check` target but the destination prefix/netmask and next-hop matches a static route that did have an associated `cpe-check`, the `cpe-check` test will be removed from the associated static route.

**Default** No static routes are defined.

**Parameters** *ip-prefix* — The destination address of the aggregate route in dotted decimal notation.

|               |                    |                                     |
|---------------|--------------------|-------------------------------------|
| <b>Values</b> | ipv4-prefix        | a.b.c.d (host bits must be 0)       |
|               | ipv4-prefix-length | 0 — 32                              |
|               | ipv6-prefix        | x:x:x:x:x:x:x (eight 16-bit pieces) |
|               |                    | x:x:x:x:x:d.d.d.d                   |
|               |                    | x: [0 — FFFF]H                      |
|               |                    | d: [0 — 255]D                       |
|               | ipv6-prefix-length | 0 — 128                             |

*netmask* — The subnet mask in dotted decimal notation.

**Values** 0.0.0.0 — 255.255.255.255 (network bits all 1 and host bits all 0)

*ip-int-name* — The name of the IP interface. Interface names must be unique within the group of defined IP interfaces for **config router interface** and **config service ies interface** commands. An interface name cannot be in the form of an IP address. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed with

*ip-address* — The IP address of the IP interface. The *ip-addr* portion of the **address** command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation.

|               |              |                                                                      |
|---------------|--------------|----------------------------------------------------------------------|
| <b>Values</b> | ipv4-address | a.b.c.d (host bits must be 0)                                        |
|               | ipv6-address | x:x:x:x:x:x:x[-interface]                                            |
|               |              | x:x:x:x:x:d.d.d.d[-interface]                                        |
|               |              | x: [0..FFFF]H                                                        |
|               |              | d: [0..255]D                                                         |
|               |              | interface: 32 characters maximum, mandatory for link local addresses |

**enable** — Static routes can be administratively enabled or disabled. Use the **enable** parameter to re-enable a disabled static route. In order to enable a static route, it must be uniquely identified by the IP address, mask, and any other parameter that is required to identify the exact static route.

The administrative state is maintained in the configuration file.

**Default** enable

**disable** — Static routes can be administratively enabled or disabled. Use the **disable** parameter to disable a static route while maintaining the static route in the configuration. In order to enable a static route, it must be uniquely identified by the IP address, mask, and any other parameter that is required to identify the exact static route.

The administrative state is maintained in the configuration file.

**Default** enable

**interval** *seconds* — This optional parameter specifies the interval between ICMP pings to the target IP address.

**Values** 1 —255 seconds

**Default** 1 seconds

**drop-count** *count* — This optional parameter specifies the number of consecutive ping-replies that must be missed to declare the CPE down and to de-active the associated static route.

**Values** Value range: 1 —255

**Default** 3

**log** — This optional parameter enables the ability to log transitions between active and in-active based on the CPE connectivity check. Events should be sent to the system log, syslog and SNMP traps.

**next-hop** [*ip-address* | *ip-int-name*] — Specifies the directly connected next hop IP address used to reach the destination. If the next hop is over an unnumbered interface, the *ip-int-name* of the unnumbered interface (on this node) can be configured.

The **next-hop** keyword and the **indirect** or **black-hole** keywords are mutually exclusive. If an identical command is entered (with the exception of either the **indirect** or **black-hole** parameters), then this static route will be replaced with the newly entered command, and unless specified, the respective defaults for preference and metric will be applied.

The *ip-addr* configured here can be either on the network side or the access side on this node. This address must be associated with a network directly connected to a network configured on this node.

**ipsec-tunnel** *ipsec-tunnel-name* — specifies an IPSec tunnel name up to 32 characters in length.

**indirect** *ip-address* — Specifies that the route is indirect and specifies the next hop IP address used to reach the destination.

The configured *ip-addr* is not directly connected to a network configured on this node. The destination can be reachable via multiple paths. The static route remains valid as long as the address configured as the indirect address remains a valid entry in the routing table. Indirect static routes cannot use an ip-prefix/mask to another indirect static route.

The **indirect** keyword and the **next-hop** or **black-hole** keywords are mutually exclusive. If an identical command is entered (with the exception of either the **next-hop** or **black-hole** parameters), then this static route will be replaced with the newly entered command and unless specified the respective defaults for preference and metric will be applied.

The *ip-addr* configured can be either on the network or the access side and is normally at least one hop away from this node.

**black-hole** — Specifies a black hole route meaning that if the destination address on a packet matches this static route it will be silently discarded.

The **black-hole** keyword is mutually exclusive with either the **next-hop** or **indirect** keywords. If an identical command is entered, with exception of either the **next-hop** or **indirect** parameters, then the static route is replaced with the new command, and unless specified, the respective defaults for **preference** and **metric** are applied.

**preference** *preference* — The preference of this static route (as opposed to the routes from different sources such as BGP or OSPF), expressed as a decimal integer. When modifying the **preference** value of an existing static route, unless specified, the metric will not change.

If multiple routes are learned with an identical preference using the same protocol, the lowest cost route is used. If multiple routes are learned with an identical preference using the same protocol and the costs (metrics) are equal, then the decision of which route to use is determined by the configuration of the ECMP command.

**Default** 5

**Values** 1 — 255

**metric** *metric* — The cost metric for the static route, expressed as a decimal integer. This value is used when importing this static route into other protocols such as OSPF. This value is also used to determine the static route to install in the forwarding table: When modifying the metrics of an existing static route, unless specified, the preference will not change.

If there are multiple static routes with the same preference but unequal metrics, the lower cost (metric) route is installed. If there are multiple static routes with equal preference and metrics then ECMP rules apply. If there are multiple routes with unequal preferences, then the lower preference route is installed.

**Default** 1

**Values** 0 — 65535

**tag** — Adds a 32-bit integer tag to the static route. The tag is used in route policies to control distribution of the route into other protocols.

**Values** 1..4294967295

**bfd-enable** — Associates the state of the static route to a BFD session between the local system and the configured nexthop. This keyword cannot be configured if the nexthop is **indirect** or a **blackhole** keywords are specified.

**cpe-check** *target-ip-address* — This parameter specifies the IP address of the target CPE device. ICMP pings will be sent to this target IP address. This parameter must be configured to enable the CPE connectivity feature for the associated static route. The target-ip-address cannot be in the same subnet as the static route subnet itself to avoid possible circular references. This option is mutually exclusive with BFD support on a given static route.

**Default** no cpe-check enabled

## type

| <b>Context</b>     | config>service>vpn                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | This command sets the import policies to control routes imported to the local VPN routing/forwarding (VRF) from other VRFs on the same or remote PE routers (via MP-BGP). BGP-VPN routes imported with a vrf-import policy will use the BGP preference value of 170 when imported from remote PE routers, or retain the protocol preference value of the exported route when imported from other VRFs on the same router, unless the preference is changed by the policy.<br>The <b>no</b> form of the command removes all route policy names from the import list. |
| <b>Default</b>     | None — No routes are accepted into the VRF by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b>  | <i>policy</i> — The route policy statement name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Description</b>   | <p>This command facilitates a simplified method to configure the route target to be added to advertised routes or compared against received routes from other VRFs on the same or remote PE routers (via MP-BGP).</p> <p>BGP-VPN routes imported with a vrf-target statement will use the BGP preference value of 170 when imported from remote PE routers, or retain the protocol preference value of the exported route when imported from other VRFs in the same router.</p> <p>Specified <b>vrf-import</b> or <b>vrf-export</b> policies override the <b>vrf-target</b> policy.</p> <p>The no form of the command removes the vrf-target</p>                                                                                                                                                                                            |         |                                                                |                    |         |                  |           |                   |           |                      |                |
| <b>Default</b>       | no vrf-target                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |         |                                                                |                    |         |                  |           |                   |           |                      |                |
| <b>Parameters</b>    | <p><i>ext-comm</i> — An extended BGP community in the <b>type:x:y</b> format. The value <b>x</b> can be an integer or IP address. The <b>type</b> can be the target or origin. <b>x</b> and <b>y</b> are 16-bit integers.</p> <p><b>Values</b></p> <table> <tr> <td>target:</td> <td>{<i>ip-address:comm-val</i>   <i>as-number:ext-comm-val</i>}</td> </tr> <tr> <td><i>ip-address:</i></td> <td>a.b.c.d</td> </tr> <tr> <td><i>comm-val:</i></td> <td>0 — 65535</td> </tr> <tr> <td><i>as-number:</i></td> <td>1 — 65535</td> </tr> <tr> <td><i>ext-comm-val:</i></td> <td>0 — 4294967295</td> </tr> </table> <p><b>import</b> <i>ext-community</i> — Specify communities allowed to be accepted from remote PE neighbors.</p> <p><b>export</b> <i>ext-community</i> — Specify communities allowed to be sent to remote PE neighbors.</p> | target: | { <i>ip-address:comm-val</i>   <i>as-number:ext-comm-val</i> } | <i>ip-address:</i> | a.b.c.d | <i>comm-val:</i> | 0 — 65535 | <i>as-number:</i> | 1 — 65535 | <i>ext-comm-val:</i> | 0 — 4294967295 |

## Router L2TP Commands

### l2tp

|                    |                                                                                                                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>l2tp</b><br><b>no l2tp</b>                                                                                                                                                                               |
| <b>Context</b>     | config>service>vprn                                                                                                                                                                                         |
| <b>Description</b> | This command enables the context to configure L2TP parameters. L2TP extends the PPP model by allowing Layer 2 and PPP endpoints to reside on different devices interconnected by a packet-switched network. |

### calling-number-format

|                    |                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>calling-number-format</b> <i>ascii-spec</i><br><b>no calling-number-format</b>                                                                                                                                                                                                                                                                                                     |
| <b>Context</b>     | config>service>vprn>l2tp                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b> | This command specifies the L2TP calling number AVP.                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <i>ascii-spec</i> — Specified as either char-specification or ascii-spec.<br><i>char-specification</i> — Ascii-char   char-origin<br><i>char-origin</i> — % origin<br><i>origin</i> — S   r   s<br><b>Values</b> S : system name, the value of TIMETRA-CHASSIS_MIB::tmnxChassisName<br><b>Values</b> r : Agent Remote ID<br><b>Values</b> s : SAP ID, formatted as a character string |

### exclude-avps

|                    |                                                              |
|--------------------|--------------------------------------------------------------|
| <b>Syntax</b>      | <b>exclude-avps calling-number</b><br><b>no exclude-avps</b> |
| <b>Context</b>     | config>service>vprn>l2tp                                     |
| <b>Description</b> | This command configures the L2TP AVPs to exclude.            |

## peer-address-change-policy

|                    |                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>peer-address-change-policy</b> { <b>accept</b>   <b>ignore</b>   <b>reject</b> }     |
| <b>Context</b>     | config>service>vprn>l2tp                                                                |
| <b>Description</b> | This command configures the reaction to a change of tunnel peer address in this router. |

## receive-window-size

|                    |                                                                       |
|--------------------|-----------------------------------------------------------------------|
| <b>Syntax</b>      | <b>receive-window-size</b> [4..1024]<br><b>no receive-window-size</b> |
| <b>Context</b>     | config>service>vprn>l2tp                                              |
| <b>Description</b> | This command configures the L2TP receive window size.                 |

## session-limit

|                    |                                                                                |
|--------------------|--------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>session-limit</b> <i>session-limit</i><br><b>no session-limit</b>           |
| <b>Context</b>     | config>service>vprn>l2tp                                                       |
| <b>Description</b> | This command configures the L2TP session limit of this router.                 |
| <b>Parameters</b>  | <i>session-limit</i> — Specifies the session limit.<br><b>Values</b> 1..131071 |

## group

|                    |                                                                                                                                                                                                                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>group</b> <i>tunnel-group-name</i> [ <b>create</b> ] [ <b>role</b> <i>lac</i>   <i>lns</i> ]<br><b>no group</b> <i>tunnel-group-name</i>                                                                                                                                                           |
| <b>Context</b>     | config>service>vprn>l2tp                                                                                                                                                                                                                                                                              |
| <b>Description</b> | This command configures an L2TP tunnel group.                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <i>tunnel-group-name</i> — Specifies a name string to identify a L2TP group up to 63 characters in length.<br><b>create</b> — This keyword is mandatory when creating a tunnel group name. The <b>create</b> keyword requirement can be enabled/disabled in the <b>environment&gt;create</b> context. |

## session-limit

|               |                                                                      |
|---------------|----------------------------------------------------------------------|
| <b>Syntax</b> | <b>session-limit</b> <i>session-limit</i><br><b>no session-limit</b> |
|---------------|----------------------------------------------------------------------|

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Context</b>     | config>service>vprn>l2tp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | This command configures the L2TP session limit for the router. L2TP is connection-oriented. The L2TP Network Server (LNS) and LAC maintain state for each call that is initiated or answered by an LAC. An L2TP session is created between the LAC and LNS when an end-to-end PPP connection is established between a remote system and the LNS. Datagrams related to the PPP connection are sent over the tunnel between the LAC and LNS. There is a one to one relationship between established L2TP sessions and their associated calls. |
| <b>Parameters</b>  | <i>session-limit</i> — Specifies the number of sessions allowed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Default</b>     | no session-limit                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Values</b>      | 1 — 131071                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## avp-hiding

|                    |                                                                                                                                                                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>avp-hiding</b> <i>sensitive</i>   <i>always</i><br><b>no avp-hiding</b>                                                                                                                                                                                                  |
| <b>Context</b>     | config>service>vprn>l2tp>group                                                                                                                                                                                                                                              |
| <b>Description</b> | This command configures Attribute Value Pair (AVP) hiding. This capability can be used to avoid the passing of sensitive data, such as user passwords, as cleartext in an AVP.<br><br>The <b>no</b> form of the command returns the value to <b>never</b> allow AVP hiding. |
| <b>Parameters</b>  | <i>avp-hiding</i> — Specifies the method to be used for the authentication of the tunnels in this L2TP group.                                                                                                                                                               |
| <b>Default</b>     | no avp-hiding                                                                                                                                                                                                                                                               |
| <b>Values</b>      | <i>sensitive</i> — AVP hiding is used only for sensitive information (such as username/password).<br><i>always</i> — AVP hiding is always used.                                                                                                                             |

## challenge

|                    |                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>challenge</b> <i>always</i><br><b>no challenge</b>                                                                                                     |
| <b>Context</b>     | config>service>vprn>l2tp>group                                                                                                                            |
| <b>Description</b> | This command configures the use of challenge-response authentication.<br><br>The <b>no</b> form of the command reverts to the default <b>never</b> value. |
| <b>Parameters</b>  | <i>always</i> — Specifies when challenge-response is to be used for the authentication of the tunnels in this L2TP group.                                 |
| <b>Default</b>     | no challenge                                                                                                                                              |
| <b>Values</b>      | <i>always</i>                                                                                                                                             |

## destruct-timeout

|                    |                                                                                                                                                                                                         |

| <b>Syntax</b>      | <b>destruct-timeout</b> <i>destruct-timeout</i><br><b>no destruct-timeout</b>                                                                                                                           |
| <b>Context</b>     | config>service>vpn>l2tp>group<br>config>service>vpn>l2tp>group>tunnel                                                                                                                                   |
| <b>Description</b> | This command configures the period of time that the data of a disconnected tunnel will persist before being removed.<br><br>The <b>no</b> form of the command removes the value from the configuration. |
| <b>Default</b>     | no destruct-timeout                                                                                                                                                                                     |
| <b>Parameters</b>  | <i>destruct-timeout</i> — [Specifies the automatic removal of dynamic L2TP sessions, in seconds, that are no longer active.<br><br><b>Default</b> no destruct-timeout<br><b>Values</b> 60 — 86400]      |

## hello-interval

|                    |                                                                                                                                                                                                                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>hello-interval</b> <i>hello-interval</i><br><b>no hello-interval</b>                                                                                                                                                                                                                                                                      |
| <b>Context</b>     | config>service>vpn>l2tp>group                                                                                                                                                                                                                                                                                                                |
| <b>Description</b> | This command configures the time interval between two consecutive tunnel Hello messages. The Hello message is an L2TP control message sent by either peer of a LAC-LNS control connection. This control message is used as a keepalive for the tunnel.<br><br>The <b>no</b> form of the command removes the interval from the configuration. |
| <b>Default</b>     | 60                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <i>hello-interval</i> — Specifies the time interval, in seconds, between two consecutive tunnel Hello messages.<br><br><b>Default</b> no hello-interval<br><b>Values</b> 60 — 3600                                                                                                                                                           |

## idle-timeout

|                    |                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>idle-timeout</b> <i>idle-timeout</i><br><b>no idle-timeout</b>                                                                     |
| <b>Context</b>     | config>service>vpn>l2tp>group                                                                                                         |
| <b>Description</b> | This command configures the period of time that an established tunnel with no active sessions will persist before being disconnected. |

Enter the **no** form of the command to maintain a persistent tunnel.

The **no** form of the command removes the idle timeout from the configuration.

|                   |                                                                                                |
|-------------------|------------------------------------------------------------------------------------------------|
| <b>Default</b>    | no idle-timeout                                                                                |
| <b>Parameters</b> | <i>idle-timeout</i> — Specifies the idle timeout value, in seconds until the group is removed. |
| <b>Default</b>    | no idle-timeout                                                                                |
| <b>Values</b>     | 0 — 3600                                                                                       |

## Ins-group

|                    |                                                             |
|--------------------|-------------------------------------------------------------|
| <b>Syntax</b>      | <b>Ins-group</b> <i>Ins-group-id</i><br><b>no Ins-group</b> |
| <b>Context</b>     | config>service>vpn>l2tp>group                               |
| <b>Description</b> | This command configures the ISA LNS group.                  |
| <b>Parameters</b>  | <i>Ins-group-id</i> — Specifies the LNS group ID.           |
| <b>Values</b>      | 1..4                                                        |

## local-address

|                    |                                                                               |
|--------------------|-------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>local-address</b> <i>ip-address</i><br><b>no local-address</b>             |
| <b>Context</b>     | config>service>vpn>l2tp>group>tunnel                                          |
| <b>Description</b> | This command configures the local address.                                    |
| <b>Parameters</b>  | <i>ip-address</i> — Specifies the IP address used during L2TP authentication. |

## local-name

|                    |                                                                                                                                                                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>local-name</b> <i>host-name</i><br><b>no local-name</b>                                                                                                                                                                                                                        |
| <b>Context</b>     | config>service>vpn>l2tp>group<br>config>service>vpn>l2tp>group>tunnel                                                                                                                                                                                                             |
| <b>Description</b> | This command creates the local host name used by this system for the tunnels in this L2TP group during the authentication phase of tunnel establishment. It can be used to distinguish tunnels.<br><br>The <b>no</b> form of the command removes the name from the configuration. |
| <b>Default</b>     | local-name                                                                                                                                                                                                                                                                        |

## VPNRN Service Configuration Commands

**Parameters**     *host-name* — Specifies the host name, up to 64 characters in length, that the router will use to identify itself during L2TP authentication.

**Default**        no local-name

### max-retries-estab

**Syntax**        **max-retries-estab** *max-retries*  
**no max-retries-estab**

**Context**        config>service>vpn>l2tp>group  
config>service>vpn>l2tp>group>tunnel

**Description**    This command configures the number of retries allowed for this L2TP tunnel while it is established, before its control connection goes down.

The **no** form of the command removes the value from the configuration.

**Default**        no max-retries-estab

**Parameters**    *max-retries* — Specifies the maximum number of retries for an established tunnel.

**Default**        no max-retries-estab

**Values**        2 — 7

### max-retries-not-estab

**Syntax**        **max-retries-not-estab** *max-retries*  
**no max-retries-not-estab**

**Context**        config>service>vpn>l2tp>group  
config>service>vpn>l2tp>group>tunnel

**Description**    This command configures the number of retries allowed for this L2TP tunnel while it is not established, before its control connection goes down.

The **no** form of the command removes the value from the configuration.

**Default**        no max-retries-not-estab

**Parameters**    *max-retries* — Specifies the maximum number of retries for non-established tunnels.

**Default**        no max-retries-not-estab

**Values**        2 — 7

### password

**Syntax**        **password** *password* [*hash* | *hash2*]  
**no password**

| <b>Description</b> | This command configures the password between L2TP LAC and LNS<br>The no form of the command removes the password.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Default</b>     | no password                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <p><i>password</i> — Configures the password used for challenge/response calculation and AVP hiding. The maximum length can be up to 20 characters if unhashed, 32 characters if hashed, 54 characters if the hash2 keyword is specified.</p> <p><b>hash</b> — Specifies the key is entered in an encrypted form. If the <b>hash</b> parameter is not used, the key is assumed to be in a non-encrypted, clear text form. For security, all keys are stored in encrypted</p> <p><b>hash2</b> — Specifies the key is entered in a more complex encrypted form. If the <b>hash2</b> parameter is not used, the less encrypted <b>hash</b> form is assumed.</p> <p><b>Default</b>      no password</p> |

## ppp

|                    |                                                        |
|--------------------|--------------------------------------------------------|
| <b>Syntax</b>      | <b>ppp</b>                                             |
| <b>Context</b>     | config>service>vprn>l2tp>group                         |
| <b>Description</b> | This command configures PPP for the L2TP tunnel group. |

## authentication

|                    |                                                                       |
|--------------------|-----------------------------------------------------------------------|
| <b>Syntax</b>      | <b>authentication {chap pap pref-chap}</b>                            |
| <b>Context</b>     | config>service>vprn>l2tp>group>ppp                                    |
| <b>Description</b> | This command configures the PPP authentication protocol to negotiate. |

## authentication-policy

|                    |                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>authentication-policy <i>auth-policy-name</i></b><br><b>no authentication-policy</b>                           |
| <b>Context</b>     | config>service>vprn>l2tp>group>ppp                                                                                |
| <b>Description</b> | This command configures the authentication policy.                                                                |
| <b>Parameters</b>  | <p><i>auth-policy-name</i> — Specifies the authentication policy name.</p> <p><b>Values</b>      32 chars max</p> |

## default-group-interface

|                    |                                                                                                                                                                                                                                                                                                                                  |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>default-group-interface</b> <i>ip-int-name</i> <b>service-id</b> <i>service-id</i><br><b>no default-group-interface</b>                                                                                                                                                                                                       |
| <b>Context</b>     | config>service>vprn>l2tp>group>ppp                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | This command configures the default group interface.                                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <i>ip-int-name</i> — Specifies the interface name.<br><div> <b>Values</b> 32 chars max         </div> <i>service-id</i> — Specifies the service ID.<br><div> <b>Values</b> 1..2147483648         </div> <i>svc-name</i> — Specifies the service name (instead of service ID).<br><div> <b>Values</b> 64 chars max         </div> |

## keepalive

|                    |                                                                                                                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>keepalive</b> <i>seconds</i> [ <b>hold-up-multiplier</b> <i>multiplier</i> ]<br><b>no keepalive</b>                                                                                     |
| <b>Context</b>     | config>service>vprn>l2tp>group>ppp                                                                                                                                                         |
| <b>Description</b> | This command configures the PPP keepalive interval and multiplier.                                                                                                                         |
| <b>Parameters</b>  | <i>seconds</i> — Specifies in seconds the interval.<br><div> <b>Values</b> 10..300         </div> <i>multiplier</i> — Specifies the multiplier.<br><div> <b>Values</b> 1..5         </div> |

## mtu

|                    |                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>mtu</b> <i>mtu-bytes</i><br><b>no mtu</b>                                                                      |
| <b>Context</b>     | config>service>vprn>l2tp>group>ppp                                                                                |
| <b>Description</b> | This command configures the maximum PPP MTU size.                                                                 |
| <b>Parameters</b>  | <i>mtu-bytes</i> — Specifies, in bytes, the maximum PPP MTU size.<br><div> <b>Values</b> 512..9212         </div> |

## proxy-authentication

|                    |                                                                                   |
|--------------------|-----------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] proxy-authentication</b>                                                  |
| <b>Context</b>     | config>service>vprn>l2tp>group>ppp                                                |
| <b>Description</b> | This command configures the use of the authentication AVPs received from the LAC. |

## proxy-lcp

|                    |                                                                              |
|--------------------|------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] proxy-lcp</b>                                                        |
| <b>Context</b>     | config>service>vprn>l2tp>group>ppp                                           |
| <b>Description</b> | This command configures the use of the proxy LCP AVPs received from the LAC. |

## user-db

|                    |                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>user-db</b> <i>local-user-db-name</i><br><b>no user-db</b>                           |
| <b>Context</b>     | config>service>vprn>l2tp>group>ppp                                                      |
| <b>Description</b> | This command configures the local user database to use for PPP PAP/CHAP authentication. |
| <b>Parameters</b>  | <i>local-user-db-name</i> — Specifies the local user database name.                     |
| <b>Values</b>      | 32 chars max                                                                            |

## session-assign-method

|                    |                                                                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>session-assign-method</b> <i>weighted</i><br><b>no session-assign-method</b>                                                                                                                                                                                               |
| <b>Context</b>     | config>service>vprn>l2tp>group                                                                                                                                                                                                                                                |
| <b>Description</b> | This command specifies how new sessions are assigned to one of the set of suitable tunnels that are available or could be made available.                                                                                                                                     |
| <b>Default</b>     | no session-assign-method                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <i>weighted</i> — specifies that the sessions are shared between the available tunnels. If necessary, new tunnels are set up until the maximum number is reached. The distribution aims at an equal ratio of the actual number of sessions to the maximum number of sessions. |
| <b>Default</b>     | no session-assign-method. All new sessions are placed by preference in existing tunnels.                                                                                                                                                                                      |
| <b>Values</b>      | <i>weighted</i> — Enables weighted preference to tunnels in the group.                                                                                                                                                                                                        |

## session-limit

|                    |                                                                                                                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>session-limit</b> <i>session-limit</i><br><b>no session-limit</b>                                                                                                                                                            |
| <b>Context</b>     | config>service>vpn>l2tp>group<br>config>service>vpn>l2tp>group>tunnel                                                                                                                                                           |
| <b>Description</b> | This command configures the session limit. The value controls how many L2TP session will be allowed within a given context (system, group, tunnel).<br><br>The no form of the command removes the value from the configuration. |
| <b>Default</b>     | no session-limit                                                                                                                                                                                                                |
| <b>Parameters</b>  | <i>session-limit</i> — Specifies the allowed number of sessions within the given context.<br><br><b>Values</b> 1 — 131071                                                                                                       |

## Router L2TP Tunnel Commands

### tunnel

|                    |                                                                                                                                                                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>tunnel</b> <i>tunnel-name</i> [ <b>create</b> ]<br><b>no tunnel</b> <i>tunnel-name</i>                                                                                                                                                                                 |
| <b>Context</b>     | config>service>vprn>l2tp>group                                                                                                                                                                                                                                            |
| <b>Description</b> | This command configures an L2TP tunnel. A tunnel exists between a LAC-LNS pair and consists of a Control Connection and zero or more L2TP sessions. The tunnel carries encapsulated PPP datagrams and control messages between the LAC and the L2TP Network Server (LNS). |
| <b>Parameters</b>  | <i>tunnel-name</i> — Specifies a valid string to identify a L2TP up to 32 characters in length.<br><b>create</b> — mandatory while creating a new tunnel                                                                                                                  |

### auto-establish

|                    |                                                                                    |
|--------------------|------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [ <b>no</b> ] <b>auto-establish</b>                                                |
| <b>Context</b>     | config>service>vprn>l2tp>group>tunnel                                              |
| <b>Description</b> | This command specifies if this tunnel is to be automatically set up by the system. |
| <b>Default</b>     | no auto-establish                                                                  |

### avp-hiding

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>avp-hiding</b> { <b>never</b>   <b>sensitive</b>   <b>always</b> }<br><b>no avp-hiding</b>                                                                                                                                                                                                                                                                                                                                 |
| <b>Context</b>     | config>service>vprn>l2tp>group>tunnel                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | <p>This command configures Attribute Value Pair (AVP) hiding. This capability can be used to avoid the passing of sensitive data, such as user passwords, as cleartext in an AVP.</p> <p>Note that it is recommended that sensitive information not be sent in clear text.</p> <p>The <b>no</b> form of the command removes the parameter of the configuration and indicates that the value on group level will be taken.</p> |
| <b>Default</b>     | no avp-hiding                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Parameters</b>  | <i>avp-hiding</i> — Specifies the method to be used for the authentication of the tunnel.                                                                                                                                                                                                                                                                                                                                     |
| <b>Values</b>      | <p><b>never</b> — AVP hiding is not used.</p> <p><b>sensitive</b> — AVP hiding is used only for sensitive information (such as username/password).</p> <p><b>always</b> — AVP hiding is always used.</p>                                                                                                                                                                                                                      |

## challenge

|                    |                                                                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>challenge</b> <i>challenge-mode</i><br><b>no challenge</b>                                                                                                                                                                                                                 |
| <b>Context</b>     | config>service>vprn>l2tp>group>tunnel                                                                                                                                                                                                                                         |
| <b>Description</b> | This command configures the use of challenge-response authentication.<br><br>The <b>no</b> form of the command removes the parameter from the configuration and indicates that the value on group level will be taken.                                                        |
| <b>Default</b>     | no challenge                                                                                                                                                                                                                                                                  |
| <b>Parameters</b>  | <i>challenge-mode</i> — Specifies when challenge-response is to be used for the authentication of the tunnel.<br><br><b>Values</b> always — Always allows the use of challenge-response authentication.<br>never — Never allows the use of challenge-response authentication. |

## hello-interval

|                    |                                                                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>hello-interval</b> <i>hello-interval</i><br><b>hello-interval infinite</b><br><b>no hello-interval</b>                                                                                                          |
| <b>Context</b>     | config>service>vprn>l2tp>group>tunnel                                                                                                                                                                              |
| <b>Description</b> | This command configures the number of seconds between sending Hellos for a L2TP tunnel. The no form removes the parameter from the configuration and indicates that the value on group level will be taken.        |
| <b>Parameters</b>  | <i>hello-interval</i> — Specifies the time interval, in seconds, between two consecutive tunnel Hello messages.<br><br><b>Values</b> 60 — 3600<br><br><b>infinite</b> — Specifies that no hello messages are sent. |

## idle-timeout

|                    |                                                                                                                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>idle-timeout</b> <i>idle-timeout</i><br><b>idle-timeout infinite</b><br><b>no idle-timeout</b>                                                                                                                    |
| <b>Context</b>     | config>service>vprn>l2tp>group>tunnel                                                                                                                                                                                |
| <b>Description</b> | This command configures the idle timeout to wait before being disconnect. The no form indicates that the parameter will be removed from the configuration and that the value specified on group level will be taken. |

**Parameters** *idle-timeout* — Specifies the idle timeout, in seconds.

**Values** 0 — 3600

**infinite** — Specifies that the tunnel will not be closed when idle.

## peer

**Syntax** **peer** *ip-address*  
**no peer**

**Context** config>service>vprn>l2tp>group>tunnel

**Description** This command configures the peer address.  
The **no** form of the command removes the IP address from the tunnel configuration.

**Default** no peer

**Parameters** *ip-address* — Sets the LNS IP address for the tunnel.

## preference

**Syntax** **preference** *preference*  
**no preference**

**Context** config>service>vprn>l2tp>group>tunnel

**Description** This command configures a preference number that indicates the relative preference assigned to a tunnel when using a weighted session assignment.  
The **no** form of the command removes the preference value from the tunnel configuration.

**Default** no preference

**Parameters** *preference* — Specifies the tunnel preference number with its group. The value 0 corresponds to the highest preference.

**Values** 0 — 16777215

## remote-name

**Syntax** **remote-name** *host-name*  
**no remote-name**

**Context** config>service>vprn>l2tp>group>tunnel

**Description** This command configures a string to be compared to the host name used by the tunnel peer during the authentication phase of tunnel establishment.

**Parameters** *host-name* — Specifies a remote host name for the tunnel up to 64 characters in length.

---

## Router DHCP Configuration Commands

### dhcp

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <b>Syntax</b>      | <b>dhcp</b>                                                    |
| <b>Context</b>     | config>service>vprn                                            |
| <b>Description</b> | This command enables the context to configure DHCP parameters. |

### local-dhcp-server

|                    |                                                                                                                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>local-dhcp-server</b> <i>server-name</i> [ <b>create</b> ]<br><b>no local-dhcp-server</b> <i>server-name</i>                                                                                                                     |
| <b>Context</b>     | config>service>vprn>dhcp<br>config>service>vprn>if                                                                                                                                                                                  |
| <b>Description</b> | This command instantiates a local DHCP server. A local DHCP server can serve multiple interfaces but is limited to the routing context it was which it was created.                                                                 |
| <b>Default</b>     | none                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <i>server-name</i> — Specifies the name of local DHCP server.<br><b>create</b> — Keyword used to create the server name. The <b>create</b> keyword requirement can be enabled/disabled in the <b>environment&gt;create</b> context. |

### failover

|                    |                                                                    |
|--------------------|--------------------------------------------------------------------|
| <b>Syntax</b>      | <b>failover</b>                                                    |
| <b>Context</b>     | config>service>vprn>dhcp                                           |
| <b>Description</b> | This command enables the context to configure failover parameters. |

### maximum-client-lead-time

|                    |                                                                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>maximum-client-lead-time</b> [ <b>hrs</b> <i>hours</i> ] [ <b>min</b> <i>minutes</i> ] [ <b>sec</b> <i>seconds</i> ]<br><b>no maximum-client-lead-time</b>                                             |
| <b>Context</b>     | config>service>vprn>dhcp>server>failover                                                                                                                                                                  |
| <b>Description</b> | This command specifies the maximum client lead time (MCLT). The MCLT is the maximum amount of time that one server can extend a lease for a client's binding beyond the time known by the partner server. |

|                   |                                                                                                  |
|-------------------|--------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <b>hrs</b> <i>hours</i> — Specifies the hour parameter of the MCLT.<br><b>Values</b> 1 — 23      |
|                   | <b>min</b> <i>minutes</i> — Specifies the minute parameter of the MCLT.<br><b>Values</b> 1 — 59  |
|                   | <b>sec</b> <i>seconds</i> — Specifies the seconds parameter of the MCLT.<br><b>Values</b> 1 — 59 |

## partner-down-delay

|                    |                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>partner-down-delay</b> [ <b>hrs</b> <i>hours</i> ] [ <b>min</b> <i>minutes</i> ] [ <b>sec</b> <i>seconds</i> ]<br><b>no partner-down-delay</b>                                                                                                                                                                                                                    |
| <b>Context</b>     | config>service>vprn>dhcp>server>failover                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b> | This command specifies the minimum safe-time after the beginning of a communications-interrupted state. After the expiry of this time, the server enters a partner-down state.                                                                                                                                                                                       |
| <b>Parameters</b>  | <b>hrs</b> <i>hours</i> — Specifies the hour parameter of the partner down delay feature.<br><b>Values</b> 1 — 23<br><b>min</b> <i>minutes</i> — Specifies the minute parameter of the partner down delay feature.<br><b>Values</b> 1 — 59<br><b>sec</b> <i>seconds</i> — Specifies the seconds parameter of the partner down delay feature.<br><b>Values</b> 1 — 59 |

## peer

|                    |                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>peer</b> <i>ip-address</i> <b>tag</b> <i>sync-tag-name</i><br><b>no peer</b> <i>ip-address</i>                             |
| <b>Context</b>     | config>service>vprn>dhcp>server>failover                                                                                      |
| <b>Description</b> | This command creates a synchronization tag.                                                                                   |
| <b>Parameters</b>  | <b>sync-tag</b> <i>sync-tag</i> — Specifies a synchronization tag to be used while synchronizing with the multi-chassis peer. |

## startup-wait-time

|                    |                                                                                                                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] startup-wait-time [min <i>minutes</i>] [sec <i>seconds</i>]</b>                                                                                                                                                                                          |
| <b>Context</b>     | config>service>vprn>dhcp>server>failover                                                                                                                                                                                                                         |
| <b>Description</b> | This command specifies the startup wait time. The startup wait time is the time that one server attempts to contact the partner server. During this time, the server is unresponsive to DHCP client requests.                                                    |
| <b>Parameters</b>  | <p><b>min <i>minutes</i></b> — Specifies the minute parameter of the startup wait time feature.</p> <p><b>Values</b> 1 — 59</p> <p><b>sec <i>seconds</i></b> — Specifies the seconds parameter of the startup wait time feature.</p> <p><b>Values</b> 1 — 59</p> |

## disable-force-renews

|                    |                                                                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] disable-force-renews</b>                                                                                                                       |
| <b>Context</b>     | config>service>vprn>dhcp>server                                                                                                                        |
| <b>Description</b> | <p>This command enables the sending of sending forcerenew messages.</p> <p>The no form of the command disables the sending of forcerenew messages.</p> |
| <b>Default</b>     | no disable-force-renews                                                                                                                                |

## pool

|                    |                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## netbios-name-server

|                    |                                                                                                                     |  |  |
|--------------------|---------------------------------------------------------------------------------------------------------------------|--|--|
| <b>Syntax</b>      | <b>netbios-name-server</b> <b>ip-address</b> [ <i>ip-address</i> ...(up to 4 max)]<br><b>no netbios-name-server</b> |  |  |
| <b>Context</b>     | config>service>vprn>dhcp>server>pool>options                                                                        |  |  |
| <b>Description</b> | This command configures up to four Network Basic Input/Output System (NetBIOS) name server IP addresses.            |  |  |
| <b>Default</b>     | none                                                                                                                |  |  |

**Parameters** *ip-address* — The IP address of the NetBIOS name server. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).

## netbios-node-type

**Syntax** **netbios-node-type** *netbios-node-type*  
**no netbios-node-type**

**Context** config>service>vprn>dhcp>server>pool>options

**Description** This command configures the Network Basic Input/Output System (NetBIOS) node type.

**Default** none

**Parameters** *netbios-node-type* — Specifies the netbios node type.

**Values**

- B — Broadcast node uses broadcasting to query nodes on the network for the owner of a NetBIOS name.
- P — Peer-to-peer node uses directed calls to communicate with a known NetBIOS name server for the IP address of a NetBIOS machine name.
- M — Mixed node uses broadcasted queries to find a node, and if that fails, queries a known P-node name server for the address.
- H — Hybrid node is the opposite of the M-node action so that a directed query is executed first, and if that fails, a broadcast is attempted.

## subnet

**Syntax** **subnet** {*ip-address/mask* | *ip-address netmask*} [**create**]  
**no subnet** {*ip-address/mask* | *ip-address netmask*}

**Context** config>service>vprn>dhcp>server>pool

**Description** This command creates a subnet of IP addresses to be served from the pool. The subnet cannot include any addresses that were assigned to subscribers without those addresses specifically excluded. When the subnet is created no IP addresses are made available until a range is defined.

**Default** none

**Parameters** *ip-address* — Specifies the base IP address of the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).

*mask* — The subnet mask in dotted decimal notation. Allowed values are dotted decimal addresses in the range 128.0.0.0 – 255.255.255.252. Note that a mask of 255.255.255.255 is reserved for system IP addresses.

*netmask* — Specifies a string of 0s and 1s that mask or screen out the network part of an IP address so that only the host computer part of the address remains.

**create** — Keyword used to create the entity. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

## address-range

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Context</b>     | config>service>vpn>dhcp>server                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | <p>This command enables the use of gi-address matching. If the gi-address flag is enabled, a pool can be used even if a subnets is not found. If the local-user-db-name is not used, the gi-address flag is used and addresses are handed out by GI only. If a user must be blocked from getting an address the server maps to a local user database and configures the user with no address.</p> <p>A pool can include multiple subnets. Since the GI is shared by multiple subnets in a subscriber-interface the pool may provide IP addresses from any of the subnets included when the GI is matched to any of its subnets. This allows a pool to be created that represents a sub-int.</p> |
| <b>Default</b>     | no use-gi-address                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Syntax</b>      | <b>[no] use-pool-from-client</b>                                                                                                                                                                                                                                                                                                                                                    |
| <b>Context</b>     | config>service>vpn>dhcp>server                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | <p>This command specifies if the IP address pool to be used by this server is the pool indicated by the vendor-specific sub-option 13 of the DHCP Option 82.</p> <p>When enabled, the pool indicated by the sub-option 13 is to be used.</p> <p>The <b>no</b> form of the command indicates that the pool selection is specified by the value of <b>use-gi-address</b> setting.</p> |

## user-db

|                    |                                                                          |
|--------------------|--------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>user-db</b> <i>local-user-db-name</i><br><b>no user-db</b>            |
| <b>Context</b>     | config>service>vpn>dhcp>server                                           |
| <b>Description</b> | This command configures a local user database for authentication.        |
| <b>Default</b>     | not enabled                                                              |
| <b>Parameters</b>  | <i>local-user-db-name</i> — Specifies the name of a local user database. |

---

## Multicast VPN Commands

### mvpn

|                    |                                                                                       |
|--------------------|---------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>mvpn</b>                                                                           |
| <b>Context</b>     | config>service>vpn                                                                    |
| <b>Description</b> | This command enables the context to configure MVPN-related parameters for the IP VPN. |

### auto-discovery

|                    |                                                                                                                                                                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] auto-discovery</b>                                                                                                                                                                                                                                      |
| <b>Context</b>     | config>service>vpn>mvpn                                                                                                                                                                                                                                         |
| <b>Description</b> | <p>This command enables MVPN membership auto-discovery through BGP. When auto-discovery is enabled, PIM peering on the inclusive provider tunnel is disabled.</p> <p>The <b>no</b> form of the command disables MVPN membership auto-discovery through BGP.</p> |
| <b>Default</b>     | enabled                                                                                                                                                                                                                                                         |

### c-mcast-signaling

|                    |                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>c-mcast-signaling {bgp   pim}</b><br><b>no c-mcast-signaling</b>                                                                                                                                                                                                                                                                                                             |
| <b>Context</b>     | config>service>vpn>mvpn                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | <p>This command specifies BGP or PIM, for PE-to-PE signaling of CE multicast states. When this command is set to PIM and neighbor discovery by BGP is disabled, PIM peering will be enabled on the inclusive tree.</p> <p>Changes may only be made to this command when the mvpn node is shutdown.</p> <p>The <b>no</b> form of the command reverts it back to the default.</p> |
| <b>Default</b>     | mcast-signaling bgp                                                                                                                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <p><b>bgp</b> — Specifies to use BGP for PE-to-PE signaling of CE multicast states. Auto-discovery must be enabled.</p> <p><b>pim</b> — Specifies to use PIM for PE-to-PE signaling of CE multicast states.</p>                                                                                                                                                                 |

## intersite-shared

|                    |                                                                         |
|--------------------|-------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>intersite-shared</b><br><b>no intersite-shared</b>                   |
| <b>Context</b>     | config>service>vprn>mvpn                                                |
| <b>Description</b> | This command specifies whether to use inter-site shared C-trees or not. |
| <b>Default</b>     | intersite-shared                                                        |

## provider-tunnel

|                    |                                                                           |
|--------------------|---------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>provider-tunnel</b>                                                    |
| <b>Context</b>     | config>service>vprn>mvpn                                                  |
| <b>Description</b> | This command enables context to configure tunnel parameters for the MVPN. |

## inclusive

|                    |                                                                            |
|--------------------|----------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>inclusive</b>                                                           |
| <b>Context</b>     | config>service>vprn>mvpn>pt                                                |
| <b>Description</b> | This command enables the context for specifying inclusive provider tunnels |

## pim

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>pim {asm   ssm} grp-ip-address</b><br><b>no pim</b>                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Context</b>     | config>service>vprn>mvpn>pt>inclusive                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b> | <p>This command specifies the PIM mode to use, ASM or SSM, for PIM-based inclusive provider tunnels and the multicast group address to use. Also enables the context for specifying parameters for PIM peering on the inclusive provider tunnel.</p> <p>Note that auto-discovery must be enabled in order for SSM to operate.</p> <p>The <b>no</b> form of the command removes the pim context including the statements under the context.</p> |
| <b>Default</b>     | no pim                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <p><b>asm</b> — Specifies to use PIM ASM for inclusive provider tunnels.</p> <p><b>ssm</b> — Specifies to use PIM SSM for inclusive provider tunnels.</p> <p><b>group-address</b> — Specifies the multicast group address to use.</p>                                                                                                                                                                                                          |

## hello-interval

|                    |                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>hello-interval</b> <i>hello-interval</i><br><b>no hello-interval</b>                                                                                                                       |
| <b>Context</b>     | config>service>vprn>mvpn>provider-tunnel>inclusive>pim                                                                                                                                        |
| <b>Description</b> | This command specifies the interval at which PIM hello messages are transmitted on the PIM inclusive provider tunnel.<br><br>The <b>no</b> form of this command reverts to the default value. |
| <b>Default</b>     | 30 seconds                                                                                                                                                                                    |
| <b>Parameters</b>  | <i>hello-interval</i> — Specifies the hello interval, in seconds. A 0 (zero) value disables the sending of hello messages.<br><br><b>Values</b> 0 — 255                                       |

## hello-multiplier

|                    |                                                                                                                                                                                                                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>hello-multiplier</b> <i>deci-units</i><br><b>no hello-multiplier</b>                                                                                                                                                                                                                                              |
| <b>Context</b>     | config>service>vprn>mvpn>provider-tunnel>inclusive>pim                                                                                                                                                                                                                                                               |
| <b>Description</b> | This command specifies the hello multiplier. The hello-multiplier in conjunction with the hello-interval determines the hold time for a PIM neighbor.<br><br>$\text{Hold time} = (\text{hello-interval} * \text{hello-multiplier}) / 10.$<br><br>The <b>no</b> form of the command reverts the value to the default. |
| <b>Default</b>     | 35                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <i>deci-units</i> — Specifies the value, in multiples of 0.1, for the formula used to calculate the hold time<br><br><b>Values</b> 20 — 100                                                                                                                                                                          |

| <b>Description</b> | This command specifies the data rate threshold that triggers the switch from the inclusive provider tunnel to the selective provider tunnel for C-(S,G) within the group range. Multiple statements are allowed in the configuration.<br><br>The <b>no</b> form of the command removes the values from the configuration.          |
| <b>Default</b>     | none                                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <i>group-address/mask</i> — Specifies a multicast group address and netmask length.<br><br><i>rate-threshold</i> — Specifies the rate, in kilobits per second (kbps). If the rate for a C-(S,G) within the specified group range exceeds the threshold, traffic for the C-(S,G) will be switched to the selective provider tunnel. |

| <b>Description</b> | This command enables packing of MDT join TLVs into a single PDU to improve efficiency, if multiple Join TLVs are available at the time of transmission.<br><br>The no form of the command disables packing of MDT join TLVs into a single PDU. |
| <b>Default</b>     | no join-tlv-packing-disable                                                                                                                                                                                                                    |

### pim-ssm

|                    |                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>pim-ssm</b> { <i>grp-ip-address/mask</i>   <i>grp-ip-address netmask</i> }<br><b>no pim-ssm</b> |
| <b>Context</b>     | config>service>vprn>mvpn>provider-tunnel>selective                                                 |
| <b>Description</b> | This command specifies the PIM SSM groups to use for the selective provider tunnel.                |
| <b>Parameters</b>  | <i>group-address/mask</i> — Specifies a multicast group address and netmask length.                |

### umh-selection

|                    |                                                                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>umh-selection highest-ip   hash-based</b><br><b>no umh-selection</b>                                                                              |
| <b>Context</b>     | config>service>vprn>mvpn                                                                                                                             |
| <b>Description</b> | This command specifies which UMH selection mechanism to use, highest IP address or hash based. The no form of the command resets it back to default. |
| <b>Default</b>     | umh-selection highest-ip                                                                                                                             |

### vrf-export

|                    |                                                                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>vrf-export</b> { <b>unicast</b>   <i>policy-name</i> [ <i>policy-name...</i> (up to 5 max)]}<br><b>no vrf-export</b>                               |
| <b>Context</b>     | config>service>vprn>mvpn                                                                                                                              |
| <b>Description</b> | This command specifies the export policy (up to 5) to control MVPN routes exported from the local VRF to other VRFs on the same or remote PE routers. |
| <b>Default</b>     | vrf-export unicast                                                                                                                                    |
| <b>Parameters</b>  | <b>unicast</b> — Specifies to use unicast VRF export policy for the MVPN.<br><i>policy</i> — Specifies a route policy name.                           |

### vrf-import

|                    |                                                                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>vrf-import</b> { <b>unicast</b>   <i>policy-name</i> [ <i>policy-name...</i> (up to 5 max)]}<br><b>no vrf-import</b>                               |
| <b>Context</b>     | config>service>vprn>mvpn                                                                                                                              |
| <b>Description</b> | This command specifies the import policy (up to 5) to control MVPN routes imported to the local VRF from other VRFs on the same or remote PE routers. |
| <b>Default</b>     | vrf-import unicast                                                                                                                                    |

**Parameters**     **unicast** — Specifies to use a unicast VRF import policy for the MVPN.  
*policy* — Specifies a route policy name.

## vrf-target

**Syntax**     **vrf-target** {**unicast** | *ext-community* | **export unicast** | *ext-community* | **import unicast** | *ext-community*}  
**no vrf-target**

**Context**     config>service>vprn>mvpn

**Description**     This command specifies the route target to be added to the advertised routes or compared against the received routes from other VRFs on the same or remote PE routers. vrf-import or vrf-export policies override the vrf-target policy.  
 The **no** form of the command removes the vrf-target.

**Default**     no vrf-target

**Parameters**     **unicast** — Specifies to use unicast vrf-target ext-community for the multicast VPN.  
*ext-comm* — An extended BGP community in the **type:x:y** format. The value **x** can be an integer or IP address. The **type** can be the target or origin. **x** and **y** are 16-bit integers.

**Values**     target: {*ip-address:comm-val* | *2byte-asnumber:ext-comm-val* | *4byte-asnumber:comm-val*}  
                   *ip-address:*                    a.b.c.d  
                   *comm-val:*                      0 — 65535  
                   *2byte-asnumber:*            1 — 65535  
                   *4byte-asnumber*            0 — 4294967295

**import** *ext-community* — Specify communities allowed to be accepted from remote PE neighbors.  
**export** *ext-community* — Specify communities allowed to be sent to remote PE neighbors.

## export

**Syntax**     **export** {**unicast** | *ext-community*}

**Context**     config>service>vprn>mvpn>vrf-target

**Description**     This command specifies communities to be sent to peers.

**Parameters**     **unicast** — Specifies to use unicast vrf-target ext-community for the multicast VPN.  
*ext-comm* — An extended BGP community in the **type:x:y** format. The value **x** can be an integer or IP address. The **type** can be the target or origin. **x** and **y** are 16-bit integers.

**Values**     target: {*ip-address:comm-val* | *2byte-asnumber:ext-comm-val* | *4byte-asnumber:comm-val*}  
                   *ip-address:*                    a.b.c.d  
                   *comm-val:*                      0 — 65535

|                        |                |
|------------------------|----------------|
| <i>2byte-asnumber:</i> | 1 — 65535      |
| <i>4byte-asnumber</i>  | 0 — 4294967295 |

import

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                    |         |                  |           |                        |           |                       |                |

| <b>Description</b> | This command enables the context to configure Network Time Protocol (NTP) and its operation. This protocol defines a method to accurately distribute and maintain time for network elements. Furthermore this capability allows for the synchronization of clocks between the various network elements. Use the <b>no</b> form of the command to stop the execution of NTP and remove its configuration. |
| <b>Default</b>     | none                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Description</b> | <p>This command provides the option to skip the rejection of NTP PDUs that do not match the authentication key-id, type or key requirements. The default behavior when authentication is configured is to reject all NTP protocol PDUs that have a mismatch in either the authentication key-id, type or key.</p> <p>When <b>authentication-check</b> is enabled, NTP PDUs are authenticated on receipt. However, mismatches cause a counter to be increased, one counter for type and one for key-id, one for type, value mismatches. These counters are visible in a <b>show</b> command.</p> <p>The <b>no</b> form of this command allows authentication mismatches to be accepted; the counters however are maintained.</p> |
| <b>Default</b>     | authentication-check — Rejects authentication mismatches.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Description</b> | <p>This command sets the authentication key-id, type and key used to authenticate NTP PDUs sent to or received by other network elements participating in the NTP protocol. For authentication to work, the authentication key-id, type and key value must match.</p> <p>The <b>no</b> form of the command removes the authentication key.</p> |

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Default</b>    | none                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b> | <p><i>key-id</i> — Configure the authentication key-id that will be used by the node when transmitting or receiving Network Time Protocol packets.</p> <p>Entering the authentication-key command with a key-id value that matches an existing configuration key will result in overriding the existing entry.</p> <p>Recipients of the NTP packets must have the same authentication key-id, type, and key value in order to use the data transmitted by this node. This is an optional parameter.</p> <p><b>Default</b>      None</p> <p><b>Values</b>      1 — 255</p> <p><b>key</b> — The authentication key associated with the configured key-id, the value configured in this parameter is the actual value used by other network elements to authenticate the NTP packet.</p> <p>The key can be any combination of ASCII characters up to 8 characters in length (unencrypted). If spaces are used in the string, enclose the entire string in quotation marks (“ ”).</p> <p><b>hash</b> — Specifies the key is entered in an encrypted form. If the hash or hash2 parameter is not used, the key is assumed to be in a non-encrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the hash or hash2 parameter specified.</p> <p><b>hash2</b> — Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, this means that hash2 encrypted variable can’t be copied and pasted. If the hash or hash2 parameter is not used, the key is assumed to be in a non-encrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the hash or hash2 parameter specified.</p> <p><b>type</b> — This parameter determines if DES or message-digest authentication is used.</p> <p>This is a required parameter; either DES or message-digest must be configured.</p> <p><b>Values</b>      des — Specifies that DES authentication is used for this key<br/> message-digest — Specifies that MD5 authentication in accordance with RFC 2104 is used for this key.</p> |

## broadcast

|                    |                                                                                                                                                                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>broadcast</b> { <b>interface</b> <i>ip-int-name</i> } [ <b>key-id</b> <i>key-id</i> ] [ <b>version</b> <i>version</i> ] [ <b>tll</b> <i>tll</i> ]<br><b>no broadcast</b> { <b>interface</b> <i>ip-int-name</i> }                                                               |
| <b>Context</b>     | config>service>vprn>ntp                                                                                                                                                                                                                                                           |
| <b>Description</b> | <p>This command configures the node to transmit NTP packets on a given interface. Broadcast and multicast messages can easily be spoofed, thus, authentication is strongly recommended.</p> <p>The <b>no</b> form of this command removes the address from the configuration.</p> |
| <b>Parameters</b>  | <p><i>ip-int-name</i> — Specifies the local interface on which to transmit NTP broadcast packets. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.</p> <p><b>Values</b>      32 character maximum</p>    |

**key-id** *key-id* — Identifies the configured authentication key and authentication type used by this node to receive and transmit NTP packets to and from an NTP server and peers. If an NTP packet is received by this node both authentication key and authentication type must be valid otherwise the packet will be rejected and an event/trap generated.

**Values** 1 — 255

**Default** none

**version** *version* — Specifies the NTP version number that is generated by this node. This parameter does not need to be configured when in client mode in which case all versions will be accepted.

**Values** 1 — 4

**Default** 4

**ttl** *ttl* — Specifies the IP Time To Live (TTL) value.

**Values** 1 — 255

**Default** none

---

## Redundant Interface Commands

### redundant-interface

|                    |                                                                                                                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] redundant-interface</b> <i>ip-int-name</i>                                                                                                                                                                                                  |
| <b>Context</b>     | config>service>vpn                                                                                                                                                                                                                                  |
| <b>Description</b> | This command configures a redundant interface.                                                                                                                                                                                                      |
| <b>Parameters</b>  | <i>ip-int-name</i> — Specifies the name of the IP interface. Interface names can be from 1 to 32 alphanumeric characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes. |

### address

|                    |                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>address</b> { <i>ip-address/mask</i>   <i>ip-address netmask</i> } [ <b>remote-ip</b> <i>ip-address</i> ]<br><b>no address</b>                                                                                                                                                                                                                                                                |
| <b>Context</b>     | config>service>vpn>redundant-interface                                                                                                                                                                                                                                                                                                                                                           |
| <b>Description</b> | This command assigns an IP address mask or netmask and a remote IP address to the interface.                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <i>ip-address/mask</i> — Assigns an IP address/IP subnet format to the interface.<br><i>ip-address netmask</i> — Specifies a string of 0s and 1s that mask or screen out the network part of an IP address so that only the host computer part of the address remains.<br>Assigns an IP address netmask to the interface.<br><b>remote-ip ip-address</b> — Assigns a remote IP to the interface. |

| <b>Syntax</b>        | <b>[no] spoke-sdp</b> <i>sdp-id</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Context</b>       | config>service>vprn                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b>   | <p>This command binds a service to an existing Service Distribution Point (SDP). A spoke SDP is treated like the equivalent of a traditional bridge “port” where flooded traffic received on the spoke SDP is replicated on all other “ports” (other spoke and mesh SDPs or SAPs) and not transmitted on the port it was received.</p> <p>The SDP has an operational state which determines the operational state of the SDP within the service. For example, if the SDP is administratively or operationally down, the SDP for the service will be down.</p> <p>The SDP must already be defined in the <b>config&gt;service&gt;sdp</b> context in order to associate an SDP with a VPRN service. If the <b>sdp</b> <i>sdp-id</i> is not already configured, an error message is generated. If the <i>sdp-id</i> does exist, a binding between that <i>sdp-id</i> and the service is created.</p> <p>SDPs must be explicitly associated and bound to a service. If an SDP is not bound to a service, no far-end 7750 SR devices can participate in the service.</p> <p>The <b>no</b> form of this command removes the SDP binding from the service. The SDP configuration is not affected; only the binding of the SDP to a service. Once removed, no packets are forwarded to the far-end router.</p> |
| <b>Default</b>       | No <i>sdp-id</i> is bound to a service.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Special Cases</b> | <b>VPRN</b> — Several SDPs can be bound to a VPRN service. Each SDP must be destined to a different 7750 SR router. If two <i>sdp-id</i> bindings terminate on the same 7750 SR, an error occurs and the second SDP binding is rejected.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Description</b>   | <p>This command binds a service to an existing Service Distribution Point (SDP).</p> <p>A spoke SDP is treated like the equivalent of a traditional bridge “port” where flooded traffic received on the spoke SDP is replicated on all other “ports” (other spoke and mesh SDPs or SAPs) and not transmitted on the port it was received.</p> <p>The SDP has an operational state which determines the operational state of the SDP within the service. For example, if the SDP is administratively or operationally down, the SDP for the service will be down.</p> <p>The SDP must already be defined in the <b>config&gt;service&gt;sdp</b> context in order to associate an SDP with a service. If the <b>sdp</b> <i>sdp-id</i> is not already configured, an error message is generated. If the <i>sdp-id</i> does exist, a binding between that <i>sdp-id</i> and the service is created.</p> <p>SDPs must be explicitly associated and bound to a service. If an SDP is not bound to a service, no far-end 7750 SR devices can participate in the service.</p> <p>Class-based forwarding is not supported on a spoke SDP used for termination on an IES or VPRN services. All packets are forwarded over the default LSP.</p> <p>The <b>no</b> form of this command removes the SDP binding from the service. The SDP configuration is not affected; only the binding of the SDP to a service. Once removed, no packets are forwarded to the far-end router.</p> |
| <b>Default</b>       | none                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Special Cases</b> | <p><b>VPRN</b> — Several SDPs can be bound to a VPRN service. Each SDP must be destined to a different 7750 SR router. If two <i>sdp-id</i> bindings terminate on the same 7750 SR, an error occurs and the second SDP is binding is rejected.</p> <p><i>sdp-id</i> — The SDP identifier.</p> <p><b>Values</b> 1 — 17407</p> <p><i>vc-id</i> — The virtual circuit identifier.</p> <p><b>Values</b> 1 — 4294967295</p> <p><i>vc-type</i> — The encapsulation and PW type for the spoke-sdp.</p> <p><b>Values</b> ether—Ethernet PW. This is the default.<br/>ipipe—IP PW..</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Description</b> | <p>This command enables the use of the hash label on a VLL, VPLS, or VPRN service bound to LDP or RSVP SDP as well as to a VPRN service using the autobind mode with the with the ldp, rsvp-te, or mpls options. This feature is not supported on a service bound to a GRE SDP or for a VPRN service using the autobind mode with the gre option..</p> <p>When this feature is enabled, the ingress data path is modified such that the result of the hash on the packet header is communicated to the egress data path for use as the value of the label field of the hash label. The egress data path appends the hash label at the bottom of the stack (BoS) and sets the S-bit to 1 to indicate that.</p> <p>In order to allow for applications whereby the egress LER infers the presence of the Hash Label implicitly from the value of the label, the Most Significant Bit (MSB) of the result of the hash is set before copying into the Hash Label. This means that the value of the hash label will always be in the range [524,288 - 1,048,575] and will not overlap with the signaled/static LSP and signaled/static service label ranges. This also guarantees that the hash label will not match a value in the reserved label range.</p> <p>The (unmodified) result of the hash continues to be used for the purpose of ECMP and LAG spraying of packets locally on the ingress LER. Note however that for VLL services, the result of the hash is overwritten and the ECMP and LAG spraying will be based on service-id when ingress SAP shared queuing is not enabled. However, the hash label will still reflect the result of the hash such that an LSR can use it to perform fine grained load balancing of VLL PW packets.</p> <p>Packets that are generated in CPM and forwarded labeled within the context of a service (for example, OAM packets) must also include a Hash Label at the BoS and set the S-bit accordingly.</p> <p>The TTL of the Hash Label is set to a value of 1.</p> <p>The <b>no</b> form of this command disables the use of the hash label.</p> |
| <b>Default</b>     | no hash-label                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Description</b> | <p>This command associates an IP filter policy with an ingress or egress Service Access Point (SAP) or IP interface. An IP filter policy can be associated with spoke SDPs. Filter policies control the forwarding and dropping of packets based on IP or MAC matching criteria.</p> <p>The filter command is used to associate a filter policy with a specified ip-filter-id with an ingress or egress SAP. The ip-filter-id must already be defined before the filter command is executed. If the filter policy does not exist, the operation will fail and an error message returned.</p> <p>In general, filters applied to SAPs (ingress or egress) apply to all packets on the SAP. One exception is non-IP packets are not applied to IP match criteria, so the default action in the filter policy applies to these packets.</p> <p>The no form of this command removes any configured filter ID association with the SAP or IP interface. The filter ID itself is not removed from the system unless the scope of the created filter is set to local. To avoid deletion of the filter ID and only break the association with the service object, use scope command within the filter definition to change the scope to local or global. The default scope of a filter is local.</p> |
| <b>Parameters</b>  | <b>ip</b> <i>ip-filter-id</i> — Specifies IP filter policy. The filter ID must already exist within the created IP filters.<br><br><b>Values</b> 1 — 65535                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Description</b> | <p>This command creates a logical IP routing interface for a Virtual Private Routed Network (VPRN). Once created, attributes like an IP address and service access point (SAP) can be associated with the IP interface.</p> <p>The <b>interface</b> command, under the context of services, is used to create and maintain IP routing interfaces within VPRN service IDs. The <b>interface</b> command can be executed in the context of an VPRN service ID. The IP interface created is associated with the service core network routing instance and default routing table. The typical use for IP interfaces created in this manner is for subscriber internet access.</p> <p>Interface names are case sensitive and must be unique within the group of defined IP interfaces defined for <b>config router interface</b> and <b>config service vprn interface</b>. Interface names must not be in the dotted decimal notation of an IP address. For example, the name “1.1.1.1” is not allowed, but “int-1.1.1.1” is allowed. Show commands for router interfaces use either interface names or the IP addresses. Use unique IP address values and IP address names to maintain clarity. It could be unclear to the user if the same IP address and IP address name values are used. Although not recommended, duplicate interface names can exist in different router instances.</p> <p>The available IP address space for local subnets and routes is controlled with the <b>config router service-prefix</b> command. The <b>service-prefix</b> command administers the allowed subnets that can be defined on service IP interfaces. It also controls the prefixes that may be learned or statically defined with the service IP interface as the egress interface. This allows segmenting the IP address space into <b>config router</b> and <b>config service</b> domains.</p> <p>When a new name is entered, a new logical router interface is created. When an existing interface name is entered, the user enters the router interface context for editing and configuration.</p> <p>By default, there are no default IP interface names defined within the system. All VPRN IP interfaces must be explicitly defined. Interfaces are created in an enabled state.</p> <p>The <b>no</b> form of this command removes the interface and all the associated configuration. The interface must be administratively shutdown before issuing the <b>no interface</b> command.</p> <p>For VPRN services, the IP interface must be shutdown before the SAP on that interface may be removed. VPRN services do not have the <b>shutdown</b> command in the SAP CLI context. VPRN service SAPs rely on the interface status to enable and disable them.</p> |
| <b>Parameters</b>  | <i>ip-int-name</i> — Specifies the name of the IP interface. Interface names must be unique within the group of defined IP interfaces for <b>config router interface</b> and <b>config service vprn interface</b> commands. An interface name cannot be in the form of an IP address. Interface names can be from 1 to 32 alphanumeric characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

If *ip-int-name* already exists within the service ID, the context will be changed to maintain that IP interface. If *ip-int-name* already exists within another service ID or is an IP interface defined within the **config router** commands, an error will occur and context will not be changed to that IP interface. If *ip-int-name* does not exist, the interface is created and context is changed to that interface for further command processing.

| <b>Context</b>     | config>service>vprn>interface                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b> | <p>Assigns an IP address, IP subnet, and broadcast address format to a VPRN IP router interface. Only one IP address can be associated with an IP interface.</p> <p>An IP address must be assigned to each VPRN IP interface. An IP address and a mask are used together to create a local IP prefix. The defined IP prefix must be unique within the context of the routing instance. It cannot overlap with other existing IP prefixes defined as local subnets on other IP interfaces in the same routing context within the 7750 SR.</p> <p>The local subnet that the <b>address</b> command defines must be part of the services address space within the routing context using the <b>config router service-prefix</b> command. The default is to disallow the complete address space to services. Once a portion of the address space is allocated as a service prefix, that portion can be made unavailable for IP interfaces defined within the <b>config router interface</b> CLI context for network core connectivity with the <b>exclude</b> option in the <b>config router service-prefix</b> command.</p> <p>The IP address for the interface can be entered in either CIDR (Classless Inter-Domain Routing) or traditional dotted decimal notation. The show commands display CIDR notation and is stored in configuration files.</p> <p>By default, no IP address or subnet association exists on an IP interface until it is explicitly created.</p> <p>Use the <b>no</b> form of this command to remove the IP address assignment from the IP interface. When the <b>no address</b> command is entered, the interface becomes operationally down.</p> |

| Address    | Admin state | Oper state |
|------------|-------------|------------|
| No address | up          | down       |
| No address | down        | down       |
| 1.1.1.1    | up          | up         |
| 1.1.1.1    | down        | down       |

The operational state is a read-only variable and the only controlling variables are the address and admin states. The address and admin states are independent and can be set independently. If an interface is in an administratively up state and an address is assigned, it becomes operationally up and the protocol interfaces and the MPLS LSPs associated with that IP interface will be reinitialized.

*ip-address* — The IP address of the IP interface. The *ip-address* portion of the **address** command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).

*/* — The forward slash is a parameter delimiter and separates the *ip-address* portion of the IP address from the mask that defines the scope of the local subnet. No spaces are allowed between the *ip-address*, the “/” and the *mask-length* parameter. If a forward slash is not immediately following the *ip-address*, a dotted decimal mask must follow the prefix.

*mask-length* — The subnet mask length when the IP prefix is specified in CIDR notation. When the IP prefix is specified in CIDR notation, a forward slash (/) separates the *ip-address* from the *mask-length* parameter. The mask length parameter indicates the number of bits used for the network portion of the IP address; the remainder of the IP address is used to determine the host portion of the IP address. Allowed values are integers in the range 0 – 30. Note that a mask length of 32 is reserved for system IP addresses.

*mask* — The subnet mask in dotted decimal notation. When the IP prefix is not specified in CIDR notation, a space separates the *ip-address* from a traditional dotted decimal mask. The *mask* parameter indicates the complete mask that will be used in a logical ‘AND’ function to derive the local subnet of the IP address. Allowed values are dotted decimal addresses in the range 128.0.0.0 – 255.255.255.252. Note that a mask of 255.255.255.255 is reserved for system IP addresses.

**broadcast** — The optional **broadcast** parameter overrides the default broadcast address used by the IP interface when sourcing IP broadcasts on the IP interface. If no broadcast format is specified for the IP address, the default value is **host-ones** which indicates a subnet broadcast address. Use this parameter to change the broadcast address to **all-ones** or revert back to a broadcast address of **host-ones**.

The broadcast format on an IP interface can be specified when the IP address is assigned or changed.

This parameter does not affect the type of broadcasts that can be received by the IP interface. A host sending either the local broadcast (**all-ones**) or the valid subnet broadcast address (**host-ones**) will be received by the IP interface.

**Default**      host-ones

**all-ones** — The **all-ones** keyword following the **broadcast** parameter specifies the broadcast address used by the IP interface for this IP address will be 255.255.255.255, also known as the local broadcast.

**host-ones** — The **host-ones** keyword following the **broadcast** parameter specifies that the broadcast address used by the IP interface for this IP address will be the subnet broadcast address. This is an IP address that corresponds to the local subnet described by the *ip-address* and the *mask-length* or *mask* with all the host bits set to binary one. This is the default broadcast address used by an IP interface.

The **broadcast** parameter within the **address** command does not have a negate feature, which is usually used to revert a parameter to the default value. To change the **broadcast** type to **host-ones** after being changed to **all-ones**, the **address** command must be executed with the **broadcast** parameter defined.

| <b>Description</b> | <p>This command controls the forwarding of directed broadcasts out of the IP interface.</p> <p>A directed broadcast is a packet received on a local router interface destined for the subnet broadcast address on another IP interface. The <b>allow-directed-broadcasts</b> command on an IP interface enables or disables the transmission of packets destined to the subnet broadcast address of the egress IP interface.</p> <p>When enabled, a frame destined to the local subnet on this IP interface will be sent as a subnet broadcast out this interface. Care should be exercised when allowing directed broadcasts as it is a well-known mechanism used for denial-of-service attacks.</p> <p>When disabled, directed broadcast packets discarded at this egress IP interface will be counted in the normal discard counters for the egress SAP.</p> <p>By default, directed broadcasts are not allowed and will be discarded at this egress IP interface.</p> <p>The <b>no</b> form of this command disables the forwarding of directed broadcasts out of the IP interface.</p> |
| <b>Default</b>     | <b>no allow-directed-broadcasts</b> — Directed broadcasts are dropped.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Description</b> | <p>This command specifies the BFD parameters for the associated IP interface. If no parameters are defined the default value are used.</p> <p>The multiplier specifies the number of consecutive BFD messages that must be missed from the peer before the BFD session state is changed to down and the upper level protocols (OSPF, IS-IS, BGP or PIM) is notified of the fault.</p> <p>The <b>no</b> form of the command removes BFD from the associated IGP protocol adjacency.</p> <p><b>Important notes:</b> On the 7750-SR, the <i>transmit-interval</i>, <b>receive</b> <i>receive-interval</i>, and <b>echo-receive</b> <i>echo-interval</i> values can only be modified to a value less than 100 when:</p> <ol style="list-style-type: none"> <li>1. The <b>type cpm-np option</b> is explicitly configured.</li> <li>2. The service is shut down (<b>shutdown</b>)</li> <li>3. The interval is specified 10 — 100000.</li> <li>4. The service is re-enabled (<b>no shutdown</b>)</li> </ol> <p>To remove the <b>type cpm-np</b> option, re-issue the <b>bfd</b> command without specifying the <b>type</b> parameter.</p> |               |                                                         |                |     |               |                                                         |                |     |               |        |                |   |               |                                                         |                |     |

| <b>Description</b> | This command enables <b>cflowd</b> to collect traffic flow samples through a router for analysis. <b>cflowd</b> is used for network planning and traffic engineering, capacity planning, security, application and user profiling, performance monitoring, usage-based billing, and SLA measurement. When <b>cflowd</b> is enabled at the interface level, all packets forwarded by the interface are subjected to analysis according to the <b>cflowd</b> configuration. |
| <b>Default</b>     | no cflowd                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Description</b> | <p>This command assigns an existing CPU protection policy to the associated service interface. For these interface types, the per-source rate limit is not applicable. The CPU protection policies are configured in the <b>config&gt;sys&gt;security&gt;cpu-protection&gt;policy <i>cpu-protection-policy-id</i></b> context.</p> <p>If no CPU protection policy is assigned to a service interface, then a the default policy is used to limit the overall-rate. The default policy is policy number 1 and can be viewed in the <b>show&gt;system&gt;security&gt;cpu-protection&gt;policy 1</b> command output.</p> <p>The <b>no</b> form of the command removes CPU protection policy association from the interface, resulting in no default rate limiting of control packets.</p> |
| <b>Default</b>     | <p>cpu-protection 254 (for access interfaces)</p> <p>cpu-protection 255 (for network interfaces)</p> <p>none (for video-interfaces (where applicable), shown as <b>no cpu-protection</b> in CLI)</p> <p>The configuration of <b>no cpu-protection</b> returns the interface/SAP to the default policies as shown above.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <i>policy-id</i> — Specifies an existing CPU protection policy.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Context</b>     | config>service>vprn>interface                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b> | <p>This command creates allows access to the IPCP context within the interface configuration. Within this context, IPCP extensions can be configured to define such things as the remote IP address and DNS IP address to be signaled via IPCP on the associated PPP interface.</p> <p>This command is only applicable if the associated SAP/port is a PPP/MLPPP interface.</p> |

**Default** none

## dns

**Syntax** **dns** *ip-address* [**secondary** *ip-address*]  
**dns secondary** *ip-address*  
**no dns** [*ip-address*] [**secondary** *ip-address*]

**Context** config>service>vprn>if>ipcp

**Description** This command defines the dns address(es) to be assigned to the far-end of the associated PPP/MLPPP link via IPCP extensions.

This command is only applicable if the associated SAP/port is a PPP/MLPPP interface with an IPCP encapsulation.

The **no** form of the command deletes either the specified primary DNS address, secondary DNS address or both addresses from the IPCP extension peer-ip-address configuration.

**Default** no dns

**Parameters** *ip-address* — This parameter specifies a unicast IPv4 address for the primary DNS server to be signaled to the far-end of the associate PPP/MLPPP link via IPCP extensions.

**secondary** *ip-address* — This parameter specifies a unicast IPv4 address for the secondary DNS server to be signaled to the far-end of the associate PPP/MLPPP link via IPCP extensions.

## peer-ip-address

**Syntax** **peer-ip-address** *ip-address*  
**no peer-ip-address**

**Context** config>service>vprn>if>ipcp

**Description** This command defines the remote IP address to be assigned to the far-end of the associated PPP/MLPPP link via IPCP extensions.

This command is only applicable if the associated SAP/port is a PPP/MLPPP interface with an IPCP encapsulation.

The interface must be shut down to modify the IPCP configuration.

The **no** form of the command deletes the IPCP extension peer-ip-address configuration.

**Default** no peer-ip-address (0.0.0.0)

**Parameters** *ip-address* — Specifies a unicast IPv4 address to be signaled to the far-end of the associated PPP/MLPPP link by IPCP extensions.

## ipv6

|                    |                                            |
|--------------------|--------------------------------------------|
| <b>Syntax</b>      | <b>[no] ipv6</b>                           |
| <b>Context</b>     | config>service>vprn>interface              |
| <b>Description</b> | This command configures an IPv6 interface. |

|                    | <b>eui-64</b> — When the <b>eui-64</b> keyword is specified, a complete IPv6 address from the supplied prefix and 64-bit interface identifier is formed. The 64-bit interface identifier is derived from MAC address on Ethernet interfaces. For interfaces without a MAC address, for example ATM interfaces, the Base MAC address of the chassis is used.                                                                                                                   |                                                                                                                                                                                                                                                                                                           |                                                 |                                                                                                                                                                                                                                                                                                           |
|                    | <b>preferred</b> — specifies that the IPv6 address is the preferred IPv6 address for this interface. Preferred address is an address assigned to an interface whose use by upper layer protocols is unrestricted. Preferred addresses maybe used as the source (or destination) address of packets sent from (or to) the interface. Preferred address doesn't go through the DAD process.                                                                                     |                                                                                                                                                                                                                                                                                                           |                                                 |                                                                                                                                                                                                                                                                                                           |

## dhcp6-relay

|                    |                                                                         |
|--------------------|-------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] dhcp6-relay</b>                                                 |
| <b>Context</b>     | config>service>vprn>interface>ipv6                                      |
| <b>Description</b> | This command configures DHCPv6 relay parameters for the VPRN interface. |

## dhcp6-server

|                    |                                                                          |
|--------------------|--------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] dhcp6-server</b>                                                 |
| <b>Context</b>     | config>service>vprn>interface>ipv6                                       |
| <b>Description</b> | This command configures DHCPv6 server parameters for the VPRN interface. |

## icmp6

|                    |                                                   |
|--------------------|---------------------------------------------------|
| <b>Syntax</b>      | <b>icmp6</b>                                      |
| <b>Context</b>     | config>service>vprn>interface>ipv6                |
| <b>Description</b> | This command configures ICMPv6 for the interface. |

## local-proxy-nd

|                    |                                                                       |
|--------------------|-----------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] local-proxy-nd</b>                                            |
| <b>Context</b>     | config>service>vprn>interface>ipv6                                    |
| <b>Description</b> | This command enables or disables neighbor discovery on the interface. |

## neighbor

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |               |                                                                                                                 |

## proxy-nd-policy

|                    |                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>proxy-nd-policy</b> <i>policy-name [policy-name...(up to 5 max)]</i><br><b>no proxy-nd-policy</b> |
| <b>Context</b>     | config>service>vprn>interface>ipv6                                                                   |
| <b>Description</b> | This command configures a proxy neighbor discovery policy for the interface.                         |
| <b>Parameters</b>  | <i>policy-name</i> — Specifies the existing policy name(s).                                          |

## local-proxy-arp

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] local-proxy-arp</b>                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Context</b>     | config>service>vpn>interface<br>config>service>vpn>sub-if>grp-if                                                                                                                                                                                                                                                                                                                                                 |
| <b>Description</b> | This command enables local proxy ARP. When local proxy ARP is enabled on an IP interface, the system responds to all ARP requests for IP addresses belonging to the subnet with its own MAC address, and thus will become the forwarding point for all traffic between hosts in that subnet. When local-proxy-arp is enabled, ICMP redirects on the ports associated with the service are automatically blocked. |
| <b>Default</b>     | no local-proxy-arp                                                                                                                                                                                                                                                                                                                                                                                               |

## loopback

|                    |                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] loopback</b>                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Context</b>     | config>service>vpn>interface<br>config>service>vpn>interface                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | This command specifies that the associated interface is a loopback interface that has no associated physical interface. As a result, the associated interface cannot be bound to a SAP.<br><br>When using mtrace/mstat in a Layer 3 VPN context then the configuration for the VPN should have a loopback address configured which has the same address as the core instance's system address (BGP next-hop). |
| <b>Default</b>     | None                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Description</b> | This command assigns a specific MAC address to a VPN IP interface.<br><br>The <b>no</b> form of this command returns the MAC address of the IP interface to the default value.                                                                                                                                                                     |
| <b>Default</b>     | The physical MAC address associated with the Ethernet interface that the SAP is configured on.                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <i>ieee-mac-address</i> — Specifies the 48-bit MAC address for the static ARP in the form <i>aa:bb:cc:dd:ee:ff</i> or <i>aa-bb-cc-dd-ee-ff</i> where <i>aa</i> , <i>bb</i> , <i>cc</i> , <i>dd</i> , <i>ee</i> and <i>ff</i> are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses. |

## proxy-arp-policy

|                    |                                                                                                                                                                                                                                                                                                                                      |

| <b>Context</b>     | config>service>vprn>interface<br>config>service>vprn>sub-if>grp-if                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | This command enables remote proxy ARP on the interface.<br><br>Remote proxy ARP is similar to proxy ARP. It allows the router to answer an ARP request on an interface for a subnet that is not provisioned on that interface. This allows the router to forward to the other subnet on behalf of the requester. To distinguish remote proxy ARP from local proxy ARP, local proxy ARP performs a similar function but only when the requested IP is on the receiving interface. |
| <b>Default</b>     | no remote-proxy-arp                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Description</b> | This command assigns an secondary IP address/IP subnet/broadcast address format to the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Default</b>     | none                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <p><i>ip-address</i> — The IP address of the IP interface. The <i>ip-address</i> portion of the <b>address</b> command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).</p> <p><i>mask</i> — The subnet mask in dotted decimal notation. When the IP prefix is not specified in CIDR notation, a space separates the <i>ip-address</i> from a traditional dotted decimal mask. The <i>mask</i> parameter indicates the complete mask that will be used in a logical ‘AND’ function to derive the local subnet of the IP address. Allowed values are dotted decimal addresses in the range 128.0.0.0 – 255.255.255.252. Note that a mask of 255.255.255.255 is reserved for system IP addresses.</p> <p><i>netmask</i> — Specifies a string of 0s and 1s that mask or screen out the network part of an IP address so that only the host computer part of the address remains.</p> <p><b>broadcast</b> — The optional <b>broadcast</b> parameter overrides the default broadcast address used by the IP interface when sourcing IP broadcasts on the IP interface. If no broadcast format is specified for the IP address, the default value is <b>host-ones</b> which indicates a subnet broadcast address. Use this parameter to change the broadcast address to <b>all-ones</b> or revert back to a broadcast address of <b>host-ones</b>.</p> <p>The broadcast format on an IP interface can be specified when the IP address is assigned or changed. This parameter does not affect the type of broadcasts that can be received by the IP interface. A host sending either the local broadcast (<b>all-ones</b>) or the valid subnet broadcast address (<b>host-ones</b>) will be received by the IP interface. (<i>Default: host-ones</i>)</p> <p><b>all-ones</b> — The <b>all-ones</b> keyword following the <b>broadcast</b> parameter specifies the broadcast address used by the IP interface for this IP address will be 255.255.255.255, also known as the local broadcast.</p> <p><b>host-ones</b> — The <b>host-ones</b> keyword following the <b>broadcast</b> parameter specifies that the broadcast address used by the IP interface for this IP address will be the subnet broadcast address. This is an IP address that corresponds to the local subnet described by the <i>ip-address</i> and the <i>mask-length</i> or <i>mask</i> with all the host bits set to binary one. This is the default used by an IP interface. The <b>broadcast</b> parameter within the <b>address</b> command does not have a negate feature, which is usually used to revert a parameter to the default value. To change the <b>broadcast</b> type to <b>host-ones</b> after being changed to <b>all-ones</b>, the <b>address</b> command must be executed with the <b>broadcast</b> parameter defined.</p> <p><b>igp-inhibit</b> — The optional <b>igp-inhibit</b> parameter signals that the given secondary IP interface should not be recognized as a local interface by the running IGP. For OSPF and IS-IS, this means that the specified secondary IP interfaces will not be injected and used as passive interfaces and</p> |

will not be advertised as internal IP interfaces into the IGP's link state database. For RIP, this means that these secondary IP interfaces will not source RIP updates.

| <b>Context</b>     | config>service>vprn>interface                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b> | <p>This command configures a static address resolution protocol (ARP) entry associating a subscriber IP address with a MAC address for the core router instance. This static ARP will appear in the core routing ARP table. A static ARP can only be configured if it exists on the network attached to the IP interface. If an entry for a particular IP address already exists and a new MAC address is configured for the IP address, the existing MAC address will be replaced with the new MAC address.</p> <p>The <b>no</b> form of this command removes a static ARP entry.</p> |
| <b>Default</b>     | none                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <p><i>ip-address</i> — Specifies the IP address for the static ARP in IP address dotted decimal notation.</p> <p><i>ieee-mac-address</i> — Specifies the 48-bit MAC address for the static ARP in the form <i>aa:bb:cc:dd:ee:ff</i> or <i>aa-bb-cc-dd-ee-ff</i> where <i>aa</i>, <i>bb</i>, <i>cc</i>, <i>dd</i>, <i>ee</i> and <i>ff</i> are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.</p>                                                                                                                    |

## tos-marking-state

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Description</b> | <p>This command is used to alter the default trusted state to a non-trusted state. When unset or reverted to the trusted default, the ToS field will not be remarked by egress network IP interfaces unless the egress network IP interface has the remark-trusted state set, in which case the egress network interface treats all VPRN and network IP interface as untrusted.</p> <p>When the ingress interface is set to untrusted, all egress network IP interfaces will remark IP packets received on the network interface according to the egress marking definitions on each network interface. The egress network remarking rules also apply to the ToS field of IP packets routed using IGP shortcuts (tunneled to a remote next-hop). However, the tunnel QoS markings are always derived from the egress network QoS definitions.</p> <p>Egress marking and remarking is based on the internal forwarding class and profile state of the packet once it reaches the egress interface. The forwarding class is derived from ingress classification functions. The profile of a packet is either derived from ingress classification or ingress policing.</p> <p>The default marking state for network IP interfaces is trusted. This is equivalent to declaring no tos-marking-state on the network IP interface. When undefined or set to tos-marking-state trusted, the trusted state of the interface will not be displayed when using show config or show info unless the</p> |

detail parameter is given. The **save config** command will not store the default tos-marking-state trusted state for network IP interfaces unless the detail parameter is also specified.

The **no** tos-marking-state command is used to restore the trusted state to a network IP interface. This is equivalent to executing the tos-marking-state trusted command.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | trusted                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Parameters</b> | <p><b>trusted</b> — The default prevents the ToS field to not be remarked by egress network IP interfaces unless the egress network IP interface has the remark-trusted state set.</p> <p><b>untrusted</b> — Specifies that all egress network IP interfaces will remark IP packets received on the network interface according to the egress marking definitions on each network interface.</p> |

### ipv6

|                    |                                                                   |
|--------------------|-------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] ipv6</b>                                                  |
| <b>Context</b>     | config>service>vprn>sub-if<br>config>service>vprn>sub-if>group-if |
| <b>Description</b> | This command configures IPv6 parameters.                          |

### dhcp6

|                    |                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] dhcp6</b>                                                                                                                                  |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>ipv6                                                                                                             |
| <b>Description</b> | This command allows access to the DHCP6 context within the group interface configuration. Within this context, DHCP6 parameters can be configured. |
| <b>Default</b>     | no dhcp6                                                                                                                                           |

### proxy-server

|                    |                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] proxy-server</b>                                                                                                                                  |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>ipv6>dhcp6                                                                                                              |
| <b>Description</b> | This command allows access to the DHCP6 proxy server context. Within this context, DHCP6 proxy server parameters of the group interface can be configured |
| <b>Default</b>     | no proxy-server.                                                                                                                                          |

## renew-timer

|                    |                                                                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>renew-timer</b> <i>seconds</i><br><b>no renew-timer</b>                                                                                                                                                                               |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>ipv6>dhcp6>proxy-server                                                                                                                                                                                |
| <b>Description</b> | This command configures the renew-timer (T1), the time at which the client contacts the server from which the addresses in the IA_NA or IA_PD were obtained to extend the lifetimes of the addresses or prefixes assigned to the client. |
| <b>Default</b>     | 1800                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <i>seconds</i> — Specifies the time duration relative to the current time, expressed in units of seconds. A value of zero leaves the renew-time at the discretion of the client.                                                         |
| <b>Values</b>      | 0-604,800                                                                                                                                                                                                                                |

## rebind-timer

|                    |                                                                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>rebind-timer</b> <i>seconds</i><br><b>no rebind-timer</b>                                                                                                                           |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>ipv6>dhcp6>proxy-server                                                                                                                              |
| <b>Description</b> | This command configures the rebind-timer (T2), the time at which the client contacts any available server to extend the lifetimes of the addresses or prefixes assigned to the client. |
| <b>Default</b>     | 2880                                                                                                                                                                                   |
| <b>Parameters</b>  | <i>seconds</i> — T2 is a time duration relative to the current time. A value of zero leaves the rebind-time at the discretion of the client.                                           |
| <b>Values</b>      | 0-1,209,600                                                                                                                                                                            |

## preferred-lifetime

|                    |                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>preferred-lifetime</b> [ <i>seconds</i>   <i>infinite</i> ]<br><b>no preferred-lifetime</b>                                                                                 |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>ipv6>dhcp6>proxy-server                                                                                                                      |
| <b>Description</b> | The preferred lifetime for the IPv6 prefix or address in the option, expressed in units of seconds. When the preferred lifetime expires, any derived addresses are deprecated. |
| <b>Default</b>     | 3600                                                                                                                                                                           |
| <b>Parameters</b>  | <i>seconds</i> — Specifies a decimal time interval in seconds.                                                                                                                 |
| <b>Values</b>      | 600-4294967295                                                                                                                                                                 |
|                    | <b>infinite</b> — Specifies a 0xffffffff value, Dec = 4294967295                                                                                                               |

## valid-lifetime

|                    |                                                                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>valid-lifetime</b> [ <i>seconds</i>   <b>infinite</b> ]<br><b>no valid-lifetime</b>                                                                            |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>ipv6>dhcp6>proxy-server                                                                                                         |
| <b>Description</b> | The valid lifetime for the IPv6 prefix or address in the option, expressed in units of seconds.                                                                   |
| <b>Default</b>     | 86,400                                                                                                                                                            |
| <b>Parameters</b>  | <i>seconds</i> — Specifies a decimal time interval in seconds.<br><b>Values</b> 600-424967295<br><b>infinite</b> — Specifies a 0xffffffff value, Dec = 4294967295 |

## client-applications

|                    |                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>client-applications</b> [ <b>dhcp</b> ] [ <b>pppoe</b> ]<br><b>no client-applications</b>                  |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>ipv6>dhcp6>proxy-server                                                     |
| <b>Description</b> | This command configures the client host types to which the DHCP6 proxy server is allowed to assign addresses. |
| <b>Parameters</b>  | <b>dhcp</b> — Specifies IP over Ethernet hosts.<br><b>pppoe</b> — Specifies PPP over Ethernet hosts.          |

## router-advertisements

|                    |                                                                                 |
|--------------------|---------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] router-advertisements</b>                                               |
| <b>Context</b>     | config>service>vprn>sub-if>group-if>ipv6                                        |
| <b>Description</b> | This command enables Router Advertisement transmission on this group interface. |
| <b>Default</b>     | router-advertisements                                                           |

## current-hop-limit

|                    |                                                                                    |
|--------------------|------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>current-hop-limit</b> <i>hop-count</i><br><b>no current-hop-limit</b>           |
| <b>Context</b>     | config>service>vprn>sub-if>group-if>ipv6>router-ad                                 |
| <b>Description</b> | This command specifies the hop-limit advertised to hosts in router advertisements. |
| <b>Default</b>     | 64                                                                                 |

**Parameters** *hop-count* — Specifies the current hop limit (decimal) inserted into router advertisements.  
**Values** 0-255

## managed-configuration

**Syntax** **[no] managed-configuration**  
**Context** config>service>vpn>sub-if>group-if>ipv6>router-ad  
**Description** This command sets the managed address configuration flag. This flag indicates that DHCPv6 is available for address configuration in addition to any address auto-configured using stateless address auto-configuration. See RFC 3315, Dynamic Host Configuration Protocol (DHCP) for IPv6.  
**Default** no managed-configuration

## max-advertisement-interval

**Syntax** **max-advertisement-interval** *seconds*  
**no max-advertisement-interval**  
**Context** config>service>vpn>sub-if>group-if>ipv6>router-ad  
**Description** This command configures the maximum interval between sending router advertisement messages.  
**Default** 1800  
**Parameters** *seconds* — Specifies the maximum interval in seconds between sending router advertisement messages.  
**Values** 900-1800

## min-advertisement-interval

**Syntax** **min-advertisement-interval** *seconds*  
**no min-advertisement-interval**  
**Context** config>service>vpn>sub-if>group-if>ipv6>router-ad  
**Description** This command configures the minimum interval between sending router advertisement messages.  
**Default** 900  
**Parameters** *seconds* — Specifies the minimum interval, in seconds, between sending router advertisement messages.  
**Values** 900-1350

### mtu

|                    |                                                                                    |
|--------------------|------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>mtu</b> <i>bytes</i><br><b>no mtu</b>                                           |
| <b>Context</b>     | config>service>vprn>sub-if>group-if>ipv6>router-ad                                 |
| <b>Description</b> | This command configures the MTU for the nodes to use to send packets on the link.  |
| <b>Default</b>     | no mtu                                                                             |
| <b>Parameters</b>  | <i>bytes</i> — Specifies the MTU for the nodes to use to send packets on the link. |
|                    | <b>Values</b> 1280-9212                                                            |

### other-stateful-configuration

|                    |                                                                                                                                                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] other-stateful-configuration</b>                                                                                                                                                                                                                                                                              |
| <b>Context</b>     | config>service>vprn>sub-if>group-if>ipv6>router-ad                                                                                                                                                                                                                                                                    |
| <b>Description</b> | This command sets the “Other configuration” flag. This flag indicates that DHCPv6 is available for auto-configuration of other (non-address) information such as DNS-related information or information on other servers in the network. See RFC 3736, Stateless Dynamic Host Configuration Protocol (DHCP) for IPv6. |
| <b>Default</b>     | no other-stateful-configuration                                                                                                                                                                                                                                                                                       |

### prefix-options

|                    |                                                                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] prefix-options</b>                                                                                                                                                  |
| <b>Context</b>     | config>service>vprn>sub-if>group-if>ipv6>router-ad                                                                                                                          |
| <b>Description</b> | This command configures router advertisement parameters for IPv6 prefixes returned via RADIUS Framed-IPv6-Prefix. All prefixes will inherit these configuration parameters. |
| <b>Default</b>     | no prefix-options                                                                                                                                                           |

### autonomous

|                    |                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] autonomous</b>                                                                          |
| <b>Context</b>     | config>services>vprn>sub-if>group-if>ipv6>router-ad>prefix-op                                   |
| <b>Description</b> | This command specifies whether the prefix can be used for stateless address auto-configuration. |
| <b>Default</b>     | no autonomous                                                                                   |

## preferred-lifetime

|                    |                                                                                                                                                                                                                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>preferred-lifetime</b> [ <i>seconds</i>   <i>infinite</i> ]<br><b>no preferred-lifetime</b>                                                                                                                                                                                                                                     |
| <b>Context</b>     | config>service>vprn>sub-if>group-if>ipv6>router-ad>prefix-op<br>config>service>vprn>sub-if>group-if>ipv6>dhcp6>proxy-server                                                                                                                                                                                                        |
| <b>Description</b> | This command configures the remaining length of time in seconds that this prefix will continue to be preferred, such as, time until deprecation. The address generated from a deprecated prefix should not be used as a source address in new communications, but packets received on such an interface are processed as expected. |
| <b>Default</b>     | 3600                                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <i>seconds</i> — Specifies a decimal time interval in seconds.<br><b>Values</b> 0-4,294,967,295<br><b>infinite</b> — Sepcifies a 0xffffffff value. Dec = 4,294,967,295.                                                                                                                                                            |

## valid-lifetime

|                    |                                                                                                                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>valid-lifetime</b> [ <i>seconds</i>   <i>infinite</i> ]<br><b>no valid-lifetime</b>                                                                                                                                                                                                                   |
| <b>Context</b>     | config>service>vprn>sub-if>group-if>ipv6>router-ad>prefix-op<br>config>service>vprn>sub-if>group-if>ipv6>dhcp6>proxy-server                                                                                                                                                                              |
| <b>Description</b> | This command specifies the length of time, in seconds, that the prefix is valid for the purpose of on-link determination. A value of all one bits (0xffffffff) represents infinity. The address generated from an invalidated prefix should not appear as the destination or source address of a packet. |
| <b>Default</b>     | 86400                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <i>seconds</i> — Specifies a decimal time interval in seconds.<br><b>Values</b> 0-4,294,967,295<br><b>infinite</b> — Sepcifies a 0xffffffff value. Dec = 4,294,967,295.                                                                                                                                  |

## reachable-time

|                    |                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>reachable-time</b> <i>milliseconds</i><br><b>no reachable-time</b>                                                                               |
| <b>Context</b>     | config>services>vprn>sub-if>group-if>ipv6>router-ad                                                                                                 |
| <b>Description</b> | This command configures how long this router should be considered reachable by other nodes on the link after receiving a reachability confirmation. |
| <b>Default</b>     | no reachable-time                                                                                                                                   |

## VPRN Service Configuration Commands

**Parameters**     *milliseconds* — The length of time the router should be considered reachable for default router selection.

**Values**        0-3,600,000

### retransmit-time

**Syntax**        **retransmit-time** *milliseconds*  
**no retransmit-time**

**Context**        config>services>vprn>sub-if>group-if>ipv6>router-ad

**Description**    This command configures the retransmission frequency of neighbor solicitation messages.

**Default**        no retransmit-time

**Parameters**    *milliseconds* — Specifies how often the retransmission should occur.

**Values**        0-1,800,000

### router-lifetime

**Syntax**        **router-lifetime** *seconds*  
**router-lifetime no-default-router**  
**no router-lifetime**

**Context**        config>services>vprn>sub-if>group-if>ipv6>router-ad

**Description**    This command sets the router lifetime. A value of zero indicates this router should not be used by hosts as a default router.

**Default**        4500

**Parameters**    *seconds* — Specifies how long this router is valid for default router selection.

**Values**        2700-9000

### renew-timer

**Syntax**        **renew-timer** *seconds*  
**no renew-timer**

**Context**        config>services>vprn>sub-if>group-if>ipv6>dhcpcv6

**Description**    This command configures the renew-timer (T1). The time at which the client contacts the server from the addresses in the IA\_NA or IA\_PD were obtained to extend the lifetimes of the addresses or prefixes assigned to the client.

**Default**        1800

**Parameters** *seconds* — Time duration relative to the current time expressed in units of seconds. A value of zero (0) leaves the renew-time at the discretion of the client.

**Values** 0-604,800

## rebind-timer

**Syntax** **rebind-timer** *seconds*  
**no rebind-timer**

**Context** config>services>vprn>sub-if>group-if>ipv6>dhcpcv6

**Description** This command configures the rebind-timer (T2), the time at which the client contacts any available server to extend the lifetimes of the addresses or prefixes assigned to the client.

**Default** 2880

**Parameters** *seconds* — T2 is a time duration relative to the current time expressed in units of seconds. A value of zero (0) leaves the rebind-time at the discretion of the client.

**Values** 0-1,209,600

## delegated-prefix-length

**Syntax** [**no**] **delegated-prefix-length** *prefix-length*

**Context** config>service>vprn>sub-if>ipv6

**Description** This command defines the prefix-length used for all DHCPv6 prefix delegations on this subscriber interface.

**Parameters** *prefix-length* — Specifies the prefix length in use on this subscriber interface for DHCPv6 IA\_PD.

**Values** 48..64

**Default** 64

## subscriber-prefixes

**Syntax** **subscriber-prefixes**

**Context** config>service>vprn>sub-if>ipv6

**Description** This command specifies aggregate off-link subscriber prefixes associated with this subscriber interface. Individual prefixes are specified under the prefix context list aggregate routes in which the next-hop is indirect via the subscriber interface.

## prefix

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>prefix</b> <i>ipv6-address/prefix-length</i> [ <b>pd</b> ] [ <b>wan-host</b> ]<br><b>no prefix</b> <i>ipv6-address/prefix-length</i>                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Context</b>     | config>service>vprn>sub-if>ipv6>sub-prefixes                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | This command allows a list of prefixes(using the prefix command multiple times) to be routed to hosts associated with this subscriber interface. Each prefix will be represented in the associated FIB with a reference to the subscriber interface. Prefixes are defined as being for prefix delegation (pd) or use on a WAN interface or host (wan-host).                                                                                                                                                         |
| <b>Parameters</b>  | <p><i>ipv6-address</i> — Specifies the 128-bit IPv6 address.</p> <p><b>Values</b> 128-bit hexadecimal IPv6 address in compressed form</p> <p><i>prefix-length</i> — Specifies the length of any associated aggregate prefix.</p> <p><b>Values</b> 32-63</p> <p><b>pd</b> — Specifies that this aggregate is used by IPv6 ESM hosts for DHCPv6 prefix-delegation.</p> <p><b>wan-host</b> — Specifies that this aggregate is used by IPv6 ESM hosts for local addressing or by a routing gateway's WAN interface.</p> |

| <b>Context</b>     | config>service>vprn>sub-if                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | <p>This command controls the export of subnets to the forwarding service. When this attribute is configured, subnets defined on this retail subscriber interface will no longer be exported to the associated wholesale VPRN and will remain private to the retail VPRN. This is useful in a PPPoE business service context as it allows retail services to use overlapping IP address spaces even if these services are associated with the same wholesale service.</p> <p>PPPoE sessions are actually terminated in the retail service although their traffic transits on a SAP belonging to the wholesale service. This configuration is incompatible, however, with IPoE host management (DHCP, static-host and ARP-host) as these host types require that the retail subnets are exported to the wholesale VPRN. Thus, if PPPoE sessions need to coexist with IPoE hosts, this attribute should not be configured on this retail interface.</p> <p>This command will fail if the subscriber interface is not associated with a wholesale service.</p> <p>If the retail VPRN is of the type <b>hub</b>, this attribute is mandatory. Then, it will be enabled by default and it will not be possible to deconfigure it.</p> |

## unnumbered

|                    |                                                                                                                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>unnumbered</b> [ <i>ip-int-name</i>   <i>ip-address</i> ]<br><b>no unnumbered</b>                                                                                                                                                  |
| <b>Context</b>     | config>service>vprn>interface                                                                                                                                                                                                         |
| <b>Description</b> | This command configures the interface as an unnumbered interface. Unnumbered IP interface is supported on a Sonet/SDH access port with the PPP, ATM, or Frame Relay encapsulation. It is not supported on a TDM port or channel.      |
| <b>Parameters</b>  | <i>ip-int-name</i> — Specifies the name of an IP interface. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.<br><i>ip-address</i> — Specifies an IP address. |

## urpf-check

|                    |                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] urpf-check</b>                                                                                                                                     |
| <b>Context</b>     | config>service>vprn>interface                                                                                                                              |
| <b>Description</b> | This command enables unicast RPF (uRPF) check on this interface.<br>The <b>no</b> form of the command disables unicast RPF (uRPF) Check on this interface. |
| <b>Default</b>     | disabled                                                                                                                                                   |

| <b>Syntax</b>      | <b>mode {strict   loose}</b><br><b>no mode</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Context</b>     | config>service>vprn>interface>urfp-check                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | This command specifies the mode of unicast RPF check.<br>The <b>no</b> form of the command reverts to the default (strict) mode.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Default</b>     | strict                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <b>strict</b> — When specified, uRPF checks whether incoming packet has a source address that matches a prefix in the routing table, and whether the interface expects to receive a packet with this source address prefix.<br><b>loose</b> — In <b>loose</b> mode, uRPF checks whether incoming packet has source address with a corresponding prefix in the routing table. However, the loose mode does not check whether the interface expects to receive a packet with a specific source address prefix. This object is valid only when <b>urpf-check</b> is enabled. |

## DHCP Commands

### dhcp

|                    |                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>dhcp</b>                                                                                                    |
| <b>Context</b>     | config>service>vprn>interface<br>config>service>vprn>subscriber-interface<br>config>service>vprn>sub-if>grp-if |
| <b>Description</b> | This command enables the context to configure DHCP parameters.                                                 |

### client-applications

|                    |                                                                                                                                                                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>client-applications dhcp</b><br><b>client-applications pppoe</b><br><b>client-applications dhcp pppoe</b><br><b>no client-applications</b>                                                                                              |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>dhcp                                                                                                                                                                                                     |
| <b>Description</b> | This command enables the clients that will try to contact the DHCP server(s).<br>The <b>no</b> form of the command removes the server client type from the configuration.                                                                  |
| <b>Parameters</b>  | <b>dhcp</b> — Specifies that the DHCP relay will forward requests to the DHCP server(s).<br><b>pppoe</b> — Specifies that PPPoE will attempt to request an IP address for a PPPoE client from the DHCP server(s)ly assigned to PPPoE node. |

### action

|                    |                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>action {replace   drop   keep}</b><br><b>no action</b>                                                                                                                                                                                                                                                                                       |
| <b>Context</b>     | config>service>vprn>if>dhcp>option<br>config>service>vprn>sub-if>grp-if>dhcp>option                                                                                                                                                                                                                                                             |
| <b>Description</b> | This command configures the processing required when the SR-Series router receives a DHCP request that already has a Relay Agent Information Option (Option 82) field in the packet.<br>The <b>no</b> form of this command returns the system to the default value.                                                                             |
| <b>Default</b>     | Per RFC 3046, <i>DHCP Relay Agent Information Option</i> , section 2.1.1, <i>Reforwarded DHCP requests</i> , the default is to keep the existing information intact. The exception to this is if the giaddr of the received packet is the same as the ingress address on the router. In that case the packet is dropped and an error is logged. |

- Parameters**
- replace** — In the upstream direction (from the user), the existing Option 82 field is replaced with the Option 82 field from the router. In the downstream direction (towards the user) the Option 82 field is stripped (in accordance with RFC 3046).
  - drop** — The packet is dropped, and an error is logged.
  - keep** — The existing information is kept in the packet and the router does not add any additional information. In the downstream direction the Option 82 field is not stripped and is sent on towards the client.
- The behavior is slightly different in case of Vendor Specific Options (VSOs). When the keep parameter is specified, the router will insert his own VSO into the Option 82 field. This will only be done when the incoming message has already an Option 82 field.
- If no Option 82 field is present, the router will not create the Option 82 field. In this in that case, no VSO will be added to the message.

## circuit-id

- Syntax** **circuit-id [ascii-tuple | ifindex | sap-id | vlan-ascii-tuple]**  
**no circuit-id**
- Context** config>service>vprn>if>dhcp>option  
 config>service>vprn>sub-if>grp-if>dhcp>option
- Description** When enabled, the router sends the interface index (If Index) in the **circuit-id** suboption of the DHCP packet. The If Index of a router interface can be displayed using the command `show>router>interface>detail`. This option specifies data that must be unique to the router that is relaying the circuit.
- If disabled, the **circuit-id** suboption of the DHCP packet will be left empty.
- The **no** form of this command returns the system to the default.
- Default** circuit-id
- Parameters**
- ascii-tuple** — Specifies that the ASCII-encoded concatenated tuple will be used which consists of the access-node-identifier, service-id, and interface-name, separated by “|”.
  - ifindex** — Specifies that the interface index will be used. The If Index of a router interface can be displayed using the command `show>router>interface>detail`.
  - sap-id** — Specifies that the SAP ID will be used.
  - vlan-ascii-tuple** — Specifies that the format will include VLAN-id and dot1p bits in addition to what is included in ascii-tuple already. The format is supported on dot1q and qinq ports only. Thus, when the Option 82 bits are stripped, dot1p bits will be copied to the Ethernet header of an outgoing packet.

## gi-address

|                    |                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>gi-address</b> <i>ip-address</i> [ <i>src-ip-addr</i> ]<br><b>no gi-address</b>                                                                                                                                                                                                                                                               |
| <b>Context</b>     | config>service>vprn>if>dhcp<br>config>service>vprn>sub-if>dhcp<br>config>service>vprn>sub-if>grp-if>dhcp                                                                                                                                                                                                                                         |
| <b>Description</b> | This command configures the gateway interface address for the DHCP relay. A subscriber interface can include multiple group interfaces with multiple SAPs. The GI address is needed, when the router functions as a DHCP relay, to distinguish between the different subscriber interfaces and potentially between the group interfaces defined. |
| <b>Default</b>     | no gi-address                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <i>ip-address</i> — Specifies the host IP address to be used for DHCP relay packets.<br><i>src-ip-address</i> — Specifies the source IP address to be used for DHCP relay packets.                                                                                                                                                               |

## lease-populate

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Description</b> | <p>This command enables dynamic host lease state management for VPLS SAPs and VPRN or IES IP interfaces. Lease state information is extracted from snooped or relayed DHCP ACK messages to populate lease state table entries for the SAP or IP interface.</p> <p>The optional <i>number-of-entries</i> parameter defines the number lease state table entries allowed for this SAP or IP interface. If <i>number-of-entries</i> is not specified, only a single entry is allowed. Once the maximum number of entries has been reached, subsequent lease state entries are not allowed. If lease state population is enabled and an entry cannot be retained in the table, the DHCP Relay or DHCP snoop function will prevent the far-end host from receiving the DHCP ACK message.</p> <p>The retained lease state information representing dynamic hosts may be used to populate a SAP based anti-spoof filter table to provide dynamic anti-spoof filtering. Anti-spoof filtering is only available on VPLS SAPs, IES IP interfaces terminated on a SAP or VPRN IP interfaces terminated on a SAP.</p> <p>The retained lease state information representing dynamic hosts may be used to populate the system's ARP cache based the arp-populate feature. ARP-populate functionality is only available for static and dynamic hosts associated with IES and VPRN SAP bound IP interfaces.</p> <p>The retained lease state information representing dynamic hosts may be used to populate managed entries into a VPLS forwarding database. VPLS forwarding database population is an implicit feature that automatically places the dynamic host's MAC address into the VPLS FDB. When a dynamic host's MAC address is placed in the lease state table, it will automatically be populated into the VPLS forwarding database associated with the SAP on which the host is learned. The dynamic host MAC address will override any static MAC entries using the same MAC and prevent dynamic learning of</p> |

the MAC on another interface. Existing static MAC entries with the same MAC address as the dynamic host are marked as inactive but not deleted. If all entries in the lease state table associated with the MAC address are removed, the static MAC may be populated. New static MAC definitions for the VPLS instance may be created while a dynamic host exists associated with the static MAC address.

|                   |                                                                                                                                                                                                                                                                                                                    |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | not enabled                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b> | <i>nbr-of-entries</i> — Defines the number lease state table entries allowed for this interface. If this parameter is omitted, only a single entry is allowed. Once the maximum number of entries has been reached, subsequent lease state entries are not allowed and subsequent DHCP ACK messages are discarded. |
| <b>Values</b>     | 1 — 8000                                                                                                                                                                                                                                                                                                           |

| <b>Description</b> | <p>This command enables Option 82 circuit ID on relayed DHCP packet matching. For routed CO, the group interface DHCP relay process is stateful. When packets are relayed to the server the virtual router ID, transaction ID, SAP ID, and client hardware MAC address of the relayed packet are tracked.</p> <p>When a response is received from the server the virtual router ID, transaction ID, and client hardware MAC address must be matched to determine the SAP on which to send the packet out. In some cases, the virtual router ID, transaction ID, and client hardware MAC address are not guaranteed to be unique.</p> <p>When the <b>match-circuit-id</b> command is enabled we use this as part of the key to guarantee correctness in our lookup. This is really only needed when we are dealing with an IP aware DSLAM that proxies the client hardware MAC address.</p> |
| <b>Default</b>     | no match-circuit-id                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Description</b> | This command specifies the vendor specific suboption string of the DHCP relay packet.<br><br>The <b>no</b> form of the command returns the default value.                                |
| <b>Parameters</b>  | <i>text</i> — The string can be any combination of ASCII characters up to 32 characters in length. If spaces are used in the string, enclose the entire string in quotation marks (“ ”). |

## system-id

|                    |                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] system-id</b>                                                                                                 |
| <b>Context</b>     | config>service>vprn>if>dhcp>option>vendor<br>config>service>vprn>sub-if>grp-if>dhcp>option>vendor                     |
| <b>Description</b> | This command specifies whether the system-id is encoded in the Alcatel-Lucent vendor specific suboption of Option 82. |

**Default**     None

### proxy-server

**Syntax**     **proxy-server**

**Context**     config>service>if>dhcp  
config>service>vpn>sub-if>grp-if>dhcp

**Description**     This command configures the DHCP proxy server.

### emulated-server

**Syntax**     **emulated-server** *ip-address*  
**no emulated-server**

**Context**     config>service>vpn>if>dhcp>proxy  
config>service>vpn>sub-if>grp-if>dhcp>proxy-server

**Description**     This command configures the IP address to be used as the DHCP server address in the context of this service. Typically, the configured address should be in the context of the subnet.

The **no** form of this command reverts to the default setting. The local proxy server will not become operational without a specified emulated server address.

**Parameters**     *ip-address* — Specifies the emulated server address.

**Default**     Note that for a retail interface, the default is the local interface.

### lease-time

**Syntax**     **lease-time** [*days days*] [*hrs hours*] [*min minutes*] [*sec seconds*] [*radius-override*]  
**no lease-time**

**Context**     config>service>vpn>if>dhcp>proxy  
config>service>vpn>sub-if>grp-if>dhcp>proxy-server

**Description**     This command defines the length of lease-time that will be provided to DHCP clients. By default the local-proxy-server will always make use of the lease-time information provide by either a RADIUS or DHCP server.

The no form of this command disables the use of the lease-time command. The local-proxy-server will use the lease-time offered by either a RADIUS or DHCP server.

**Default**     7 days 0 hours 0 seconds

**Parameters**     **radius-override** — Specifies that the local-proxy-server will use the configured lease-time information to provide DHCP clients.

*days* — Specifies the number of days that the given IP address is valid.

**Values** 0 — 3650

*hours* — Specifies the number of hours that the given IP address is valid.

**Values** 0 — 23

*minutes* — Specifies the number of minutes that the given IP address is valid.

**Values** 0 — 59

*seconds* — Specifies the number of seconds that the given IP address is valid.

**Values** 0 — 59

## server

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Context</b>     | config>service>vprn>if>dhcp<br>config>service>vprn>sub-if>grp-if>dhcp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | <p>This command specifies a list of servers where requests will be forwarded. The list of servers can entered as either IP addresses or fully qualified domain names. There must be at least one server specified for DHCP relay to work. If there are multiple servers then the request is forwarded to all of the servers in the list. There can be a maximum of 8 DHCP servers configured.</p> <p>The flood command is applicable only in the VPLS case. There is a scenario with VPLS where the VPLS node only wants to add Option 82 information to the DHCP request to provider per-subscriber information, but it does not do full DHCP relay. In this case, the server is set to "flood". This means the DHCP request is still a broadcast and is sent through the VPLS domain. A node running at L3 further upstream then can perform the full L3 DHCP relay function.</p> |
| <b>Default</b>     | no server                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Description</b> | <p>According to RFC 3046, <i>DHCP Relay Agent Information Option</i>, a DHCP request where the giaddr is 0.0.0.0 and which contains a Option 82 field in the packet, should be discarded, unless it arrives on a "trusted" circuit.</p> <p>If trusted mode is enabled on an IP interface, the relay agent (the SR-Series) will modify the request's giaddr to be equal to the ingress interface and forward the request.</p> <p>Note that this behavior only applies when the action in the Relay Agent Information Option is "keep". In the case where the Option 82 field is being replaced by the relay agent (action = "replace"), the original Option 82 information is lost anyway, and there is thus no reason for enabling the trusted option.</p> <p>The <b>no</b> form of this command returns the system to the default.</p> |
| <b>Default</b>     | not enabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## host-connectivity-verify

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>host-connectivity-verify</b> [ <b>interval</b> <i>interval</i> ] [ <b>action</b> { <b>remove</b>   <b>alarm</b> }]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Context</b>     | config>service>vprn>if>sap<br>config>service>vprn>sub-if>grp-if<br>config>service>vprn>sub-if>grp-if>dhcp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Description</b> | <p>This command enables enables subscriber host connectivity verification on a given SAP within a service.</p> <p>This tool will periodically scan all known hosts (from dhcp-state) and perform a UC ARP request. The subscriber host connectivity verification will maintain state (connected vs. not-connected) for all hosts.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Default</b>     | no host-connectivity-verify                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <p><b>interval</b> <i>interval</i> — The interval, expressed in minutes, which specifies the time interval which all known sources should be verified. The actual rate is then dependent on number of known hosts and interval.</p> <p><b>Values</b> 1— 6000 ) Note that a zero value can be used by the SNMP agent to disable host-connectivity-verify.)</p> <p><b>action</b> {<b>remove</b>   <b>alarm</b>} — Defines the action taken on a subscriber host connectivity verification failure for a given host. The <b>remove</b> keyword raises an alarm and removes dhcp-state and releases all allocated resources (queues, table entries, etc.). DHCP-RELEASE will be signaled to corresponding DHCP server. Static hosts will never be removed. The <b>alarm</b> keyword raises an alarm indicating that the host is disconnected.</p> |

## Router Advertisement Commands

### router-advertisement

|                    |                                                                                                                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] router-advertisement</b>                                                                                                                                                                                                                                                         |
| <b>Context</b>     | config>service>vprn                                                                                                                                                                                                                                                                      |
| <b>Description</b> | <p>This command configures router advertisement properties. By default, it is disabled for all IPv6 enabled interfaces.</p> <p>The <b>no</b> form of the command disables all IPv6 interface. However, the <b>no interface interface-name</b> command disables a specific interface.</p> |
| <b>Default</b>     | disabled                                                                                                                                                                                                                                                                                 |

### interface

|                    |                                                                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] interface ip-int-name</b>                                                                                                                                          |
| <b>Context</b>     | config>service>vprn>router-advertisement                                                                                                                                   |
| <b>Description</b> | This command configures router advertisement properties on a specific interface. The interface must already exist in the <b>config&gt;router&gt;interface</b> context.     |
| <b>Default</b>     | No interfaces are configured by default.                                                                                                                                   |
| <b>Parameters</b>  | <i>ip-int-name</i> — Specify the interface name. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes. |

### current-hop-limit

|                    |                                                                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>current-hop-limit number</b><br><b>no current-hop-limit</b>                                                                                                            |
| <b>Context</b>     | config>service>vprn>router-advert>if                                                                                                                                      |
| <b>Description</b> | This command configures the current-hop-limit in the router advertisement messages. It informs the nodes on the subnet about the hop-limit when originating IPv6 packets. |
| <b>Default</b>     | 64                                                                                                                                                                        |
| <b>Parameters</b>  | <i>number</i> — Specifies the hop limit.<br><b>Values</b> 0 — 255. A value of zero means there is an unspecified number of hops.                                          |

## managed-configuration

|                    |                                                                                                                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] managed-configuration</b>                                                                                                                                                                                                                                                                |
| <b>Context</b>     | config>service>vprn>router-advert>if                                                                                                                                                                                                                                                             |
| <b>Description</b> | This command sets the managed address configuration flag. This flag indicates that DHCPv6 is available for address configuration in addition to any address autoconfigured using stateless address autoconfiguration. See RFC 3315, <i>Dynamic Host Configuration Protocol (DHCP) for IPv6</i> . |
| <b>Default</b>     | no managed-configuration                                                                                                                                                                                                                                                                         |

## max-advertisement-interval

|                    |                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] max-advertisement-interval</b> <i>seconds</i>                                                     |
| <b>Context</b>     | config>service>vprn>router-advert>if                                                                      |
| <b>Description</b> | This command configures the maximum interval between sending router advertisement messages.               |
| <b>Default</b>     | 600                                                                                                       |
| <b>Parameters</b>  | <i>seconds</i> — Specifies the maximum interval in seconds between sending router advertisement messages. |
| <b>Values</b>      | 4 — 1800                                                                                                  |

## min-advertisement-interval

|                    |                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] min-advertisement-interval</b> <i>seconds</i>                                                                             |
| <b>Context</b>     | config>service>vprn>router-advert>if                                                                                              |
| <b>Description</b> | This command configures the minimum interval between sending ICMPv6 neighbor discovery router advertisement messages.             |
| <b>Default</b>     | 200                                                                                                                               |
| <b>Parameters</b>  | <i>seconds</i> — Specify the minimum interval in seconds between sending ICMPv6 neighbor discovery router advertisement messages. |
| <b>Values</b>      | 3 — 1350                                                                                                                          |

## mtu

|                    |                                                                                   |
|--------------------|-----------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] mtu mtu-bytes</b>                                                         |
| <b>Context</b>     | config>service>vprn>router-advert>if                                              |
| <b>Description</b> | This command configures the MTU for the nodes to use to send packets on the link. |
| <b>Default</b>     | no mtu — The MTU option is not sent in the router advertisement messages.         |
| <b>Parameters</b>  | mtu-bytes — Specify the MTU for the nodes to use to send packets on the link.     |
| <b>Values</b>      | 1280 — 9212                                                                       |

## other-stateful-configuration

|                    |                                                                                                                                                                                                                                                                                                                                  |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] other-stateful-configuration</b>                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | This command sets the "Other configuration" flag. This flag indicates that DHCPv6lite is available for autoconfiguration of other (non-address) information such as DNS-related information or information on other servers in the network. See RFC 3736, <i>Stateless Dynamic Host Configuration Protocol (DHCP) for IPv6</i> . |
| <b>Default</b>     | no other-stateful-configuration                                                                                                                                                                                                                                                                                                  |

## prefix

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                |             |                               |                    |        |             |                                     |  |                   |  |                |  |               |                    |         |

|                    |                                                                                                                                                                                                                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>valid-lifetime</b> { <i>seconds</i>   <b>infinite</b> }                                                                                                                                                                                                                                                           |
| <b>Context</b>     | config>service>vprn>router-advert>if                                                                                                                                                                                                                                                                                 |
| <b>Description</b> | <p>This command specifies the length of time in seconds that the prefix is valid for the purpose of on-link determination. A value of all one bits (0xffffffff) represents infinity.</p> <p>The address generated from an invalidated prefix should not appear as the destination or source address of a packet.</p> |
| <b>Default</b>     | 2592000                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b>  | <p><i>seconds</i> — Specifies the remaining length of time in seconds that this prefix will continue to be valid.</p> <p><b>infinite</b> — Specifies that the prefix will always be valid. A value of 4,294,967,295 represents infinity.</p>                                                                         |

## reachable-time

|                    |                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>reachable-time</b> <i>milli-seconds</i><br><b>no reachable-time</b>                                                                              |
| <b>Context</b>     | config>service>vprn>router-advert>if                                                                                                                |
| <b>Description</b> | This command configures how long this router should be considered reachable by other nodes on the link after receiving a reachability confirmation. |
| <b>Default</b>     | no reachable-time                                                                                                                                   |
| <b>Parameters</b>  | <p><i>milli-seconds</i> — Specifies the length of time the router should be considered reachable.</p> <p><b>Values</b>      0 — 3600000</p>         |

## retransmit-time

|                    |                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>retransmit-timer</b> <i>milli-seconds</i><br><b>no retransmit-timer</b>                                               |
| <b>Context</b>     | config>service>vprn>router-advert>if                                                                                     |
| <b>Description</b> | This command configures the retransmission frequency of neighbor solicitation messages.                                  |
| <b>Default</b>     | no retransmit-time                                                                                                       |
| <b>Parameters</b>  | <p><i>milli-seconds</i> — Specifies how often the retransmission should occur.</p> <p><b>Values</b>      0 — 1800000</p> |

## router-lifetime

|                    |                                                                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>router-lifetime</b> <i>seconds</i><br><b>no router-lifetime</b>                                                                                                                                                                               |
| <b>Context</b>     | config>service>vprn>router-advert>if                                                                                                                                                                                                             |
| <b>Description</b> | This command sets the router lifetime.                                                                                                                                                                                                           |
| <b>Default</b>     | 1800                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <i>seconds</i> — The length of time, in seconds, (relative to the time the packet is sent) that the prefix is valid for route determination.<br><b>Values</b> 0, 4 — 9000 seconds. 0 means that the router is not a default router on this link. |

## use-virtual-mac

|                    |                                                                                                                                                                                                                                                                                                                                      |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] use-virtual-mac</b>                                                                                                                                                                                                                                                                                                          |
| <b>Context</b>     | config>service>vprn>router-advert>if                                                                                                                                                                                                                                                                                                 |
| <b>Description</b> | This command enables sending router advertisement messages using the VRRP virtual MAC address, provided that the virtual router is currently the master.<br>If the virtual router is not the master, no router advertisement messages are sent.<br>The <b>no</b> form of the command disables sending router advertisement messages. |
| <b>Default</b>     | no use-virtual-mac                                                                                                                                                                                                                                                                                                                   |

## Subscriber Interface Commands

### subscriber-interface

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Context</b>     | config>service>vprn                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | <p>This command allows the operator to create special subscriber-based interfaces. It is used to contain multiple group interfaces. Multiple subnets associated with the subscriber interface can be applied to any of the contained group interfaces in any combination. The subscriber interface allows subnet sharing between group interfaces.</p> <p>Use the <b>no</b> form of the command to remove the subscriber interface.</p>                                                                                                                    |
| <b>Parameters</b>  | <p><i>ip-int-name</i> — Specifies the name of the IP interface. Interface names can be from 1 to 32 alphanumeric characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.</p> <p><b>fwd-service</b> <i>service-id</i> — Specifies the forwarding service ID for a subscriber interface in a retailer context.</p> <p><b>fwd-subscriber-interface</b> <i>ip-int-name</i> — Specifies the forwarding subscriber interface for a subscriber interface in a retailer context.</p> |

| <b>Context</b>     | config>service>vprn>subscriber-interface                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b> | <p>This command configures the local subscriber subnets available on a subscriber IP interface. The configured <i>ip-address</i> and <i>mask</i> define the address space associated with the subscriber subnet. Up to 16 IP subnets can be created on a single subscriber IP interface. Each subnet supports a locally owned IP host address within the subnet that is not expected to appear on other routers that may be servicing the same subscriber subnet. For redundancy purposes, the keyword <b>gw-address</b> defines a separate IP address within the subnet for Subscriber Routed Redundancy Protocol (SRRP) routing. This IP address must be the same on the local and remote routers participating in a common SRRP instance.</p> <p>In SRRP, a single SRRP instance is tied to a group IP interface. The group IP interface is contained directly within a subscriber IP interface context and thus directly associated with the subscriber subnets on the subscriber IP interface. The SRRP instance is also indirectly associated with any subscriber subnets tied to the subscriber interface through wholesale/retail VPRN configurations. With the directly-associated and the indirectly-associated subscriber interface subnets, a single SRRP instance can manage hundreds of SRRP gateway IP addresses. This automatic subnet association to the SRRP instance is different from VRRP where the redundant IP address is defined within the VRRP context.</p> |

Defining an SRRP gateway IP address on a subscriber subnet is not optional when the subnet is associated with a group IP interface with SRRP enabled. Enabling SRRP (**no shutdown**) will fail if one or more subscriber subnets do not have an SRRP gateway IP address defined. Creating a new subscriber subnet without an SRRP gateway IP address defined will fail when the subscriber subnet is associated with a group IP interface with an active SRRP instance. Once SRRP is enabled on a group interface, the SRRP instance will manage the ARP response and routing behavior for all subscriber hosts reachable through the group IP interface.

The `no` form of the command removes the address from a subscriber subnet. The address command for the specific subscriber subnet must be executed without the `gw-address` parameter. To succeed, all SRRP instances associated with the subscriber subnet must be removed or shutdown.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <p><i>ip-address/mask</i>   <i>ip-address netmask</i> — Specifies the address space associated with the subscriber subnet</p> <p><b>gw-ip-address</b> <i>ip-address</i> — Specifies a separate IP address within the subnet for SRRP routing purposes. This parameter must be followed by a valid IP interface that exists within the subscriber subnet created by the address command. The defined gateway IP address cannot currently exist as a subscriber host (static or dynamic). If the defined <i>ip-address</i> already exists as a subscriber host address, the address command will fail. The specified <i>ip-address</i> must be unique within the system.</p> <p>The <code>gw-address</code> parameter may be specified at anytime. If the subscriber subnet was created previously, executing the address command with a <code>gw-address</code> parameter will simply add the SRRP gateway IP address to the existing subnet.</p> <p>If the address command is executed without the <code>gw-address</code> parameter when the subscriber subnet is associated with an active SRRP instance, the address will fail. If the SRRP instance is inactive or removed, executing the address command without the <code>gw-address</code> parameter will remove the SRRP gateway IP address from the specified subscriber subnet.</p> <p>If the address command is executed with a new <code>gw-address</code>, all SRRP instances currently associated with the specified subscriber subnet will be updated with the new SRRP gateway IP address.</p> |

|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] group-interface</b> <i>ip-int-name</i>                                                                                                                                                                                        |
| <b>Context</b>     | config>service>vprn>subscriber-interface                                                                                                                                                                                              |
| <b>Description</b> | This command enables the context to configure a group interface. A group interface is an interface that may contain one or more SAPs. This interface is used in triple-play services where multiple SAPs are part of the same subnet. |
| <b>Default</b>     | none                                                                                                                                                                                                                                  |
| <b>Parameters</b>  | <i>ip-int-name</i> — Configures the interface group name. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.                                                   |

|                    |                                                                    |
|--------------------|--------------------------------------------------------------------|
| <b>Syntax</b>      | <b>arp-host</b>                                                    |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if                                  |
| <b>Description</b> | This command enables the context to configure ARP host parameters. |

## host-limit

|                    |                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>host-limit</b> <i>max-num-hosts</i><br><b>no host-limit</b>                               |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>arp-host                                                   |
| <b>Description</b> | This command configures the maximum number of ARP hosts.                                     |
| <b>Parameters</b>  | <i>max-num-hosts</i> — Specifies the maximum number of ARP hosts.<br><b>Values</b> 1 — 32767 |

## min-auth-interval

|                    |                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>min-auth-interval</b> <i>min-auth-interval</i><br><b>no min-auth-interval</b>                    |
| <b>Context</b>     | onfig>service>vprn>sub-if>grp-if>arp-host                                                           |
| <b>Description</b> | This command configures the minimum authentication interval.                                        |
| <b>Parameters</b>  | <i>min-auth-interval</i> — Specifies the minimum authentication interval.<br><b>Values</b> 1 — 6000 |

## sap-host-limit

|                    |                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>sap-host-limit</b> <i>max-num-hosts-sap</i><br><b>no sap-host-limit</b>                                                             |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>arp-host                                                                                             |
| <b>Description</b> | This command configures the maximum number of ARP hosts per SAP.                                                                       |
| <b>Parameters</b>  | <i>max-num-hosts-sap</i> — Specifies the maximum number of ARP hosts per SAP allowed on this IES interface.<br><b>Values</b> 1 — 32767 |

## PPPoE Commands

### pppoe

|                    |                                                                 |
|--------------------|-----------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] pppoe</b>                                               |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if                               |
| <b>Description</b> | This command enables the context to configure PPPoE parameters. |

### dhcp-client

|                    |                                                                          |
|--------------------|--------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>dhcp-client</b>                                                       |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>pppoe                                  |
| <b>Description</b> | This command enables the context to configure the PPPoE-to-DHCP options. |

### ccag-use-origin-sap

|                    |                                                                                                                                                                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] ccag-use-origin-sap</b>                                                                                                                                                                                                            |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>pppoe>dhcp-client                                                                                                                                                                                        |
| <b>Description</b> | This command enables the original VPLS SAP to be included in the circuit-id option to send to the DHCP server (in case this interface is connected to a VPLS by a CCA MDA).<br><br>The <b>no</b> form of the command disables the feature. |
| <b>Default</b>     | no ccag-use-origin-sap                                                                                                                                                                                                                     |

### pap-chap-user-db

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>pap-chap-user-db</b> <i>local-user-db-name</i><br><b>no pap-chap-user-db</b>                                                                                                                                                                                                                                                                                                                                  |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>pppoe                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b> | This command configures the local user database to use for PPP Challenge-Handshake Authentication Protocol/Password Authentication Protocol (PAP/CHAP) authentication.<br><br>If an authentication policy is also configured, <b>pppoe-access-method</b> must be set to none in this authentication policy to use the local user database (in that case RADIUS authentication will not be used for PPPoE hosts). |
| <b>Parameters</b>  | <i>local-user-db-name</i> — Specifies the local user database to use for authentication.                                                                                                                                                                                                                                                                                                                         |

## pppoe-policy

|                    |                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>pppoe-policy</b> <i>pppoe-policy-name</i><br><b>no pppoe-policy</b>                                 |
| <b>Context</b>     | config>service>vpnrn>sub-if>grp-if>pppoe                                                               |
| <b>Description</b> | This command associates a PPPoE policy on this interface.                                              |
| <b>Default</b>     | default                                                                                                |
| <b>Parameters</b>  | <i>pppoe-policy-name</i> — Specifies a a PPPoE policy up to 32 characters in length on this interface. |

## sap-session-limit

|                    |                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>sap-session-limit</b> <i>sap-session-limit</i><br><b>no sap-session-limit</b>                           |
| <b>Context</b>     | config>service>vpnrn>sub-if>grp-if>pppoe                                                                   |
| <b>Description</b> | This command specifies the number of PPPoE hosts per SAP allowed for this group-interface.                 |
| <b>Default</b>     | 1                                                                                                          |
| <b>Parameters</b>  | <i>sap-session-limit</i> — Specifies the number of PPPoE hosts per SAP allowed.<br><b>Values</b> 1 — 20000 |

## session-limit

|                    |                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>session-limit</b> <i>session-limit</i><br><b>no session-limit</b>                          |
| <b>Context</b>     | config>service>vpnrn>sub-if>grp-if>pppoe                                                      |
| <b>Description</b> | This command specifies the number of PPPoE hosts allowed for this group interface.            |
| <b>Default</b>     | 1                                                                                             |
| <b>Parameters</b>  | <i>session-limit</i> — Specifies the number of PPPoE hosts allowed<br><b>Values</b> 1 — 20000 |

---

## Interface ICMP Commands

### icmp

|                    |                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>icmp</b>                                                                                    |
| <b>Context</b>     | config>service>vprn>interface<br>config>service>vprn>sub-if>grp-if                             |
| <b>Description</b> | This command configures Internet Control Message Protocol (ICMP) parameters on a VPRN service. |

### mask-reply

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] mask-reply</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Context</b>     | config>service>vprn>if>icmp<br>config>service>vprn>sub-if>grp-if>icmp                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | <p>This command enables responses to Internet Control Message Protocol (ICMP) mask requests on the router interface.</p> <p>If a local node sends an ICMP mask request to the router interface, the <b>mask-reply</b> command configures the router interface to reply to the request.</p> <p>By default, the router instance will reply to mask requests.</p> <p>The <b>no</b> form of this command disables replies to ICMP mask requests on the router interface.</p> |
| <b>Default</b>     | <b>mask-reply</b> — Reply to ICMP mask requests.                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Description</b> | <p>This command configures the rate for Internet Control Message Protocol (ICMP) redirect messages issued on the router interface.</p> <p>When routes are not optimal on this router and another router on the same subnetwork has a better route, the router can issue an ICMP redirect to alert the sending node that a better route is available.</p> <p>The <b>redirects</b> command enables the generation of ICMP redirects on the router interface. The rate at which ICMP redirects is issued can be controlled with the optional <i>number</i> and <i>seconds</i> parameters by indicating the maximum number of redirect messages that can be issued on the interface for a given time interval.</p> |

By default, generation of ICMP redirect messages is enabled at a maximum rate of 100 per 10 second time interval.

The **no** form of this command disables the generation of icmp redirects on the router interface.

| <b>Context</b>     | config>service>vprn>if>icmp<br>config>service>vprn>sub-if>grp-if>icmp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b> | <p>This command enables and configures the rate for ICMP host and network destination unreachable messages issued on the router interface.</p> <p>The <b>unreachables</b> command enables the generation of ICMP destination unreachables on the router interface. The rate at which ICMP unreachables is issued can be controlled with the optional <i>number</i> and <i>seconds</i> parameters by indicating the maximum number of destination unreachable messages which can be issued on the interface for a given time interval.</p> <p>By default, generation of ICMP destination unreachable messages is enabled at a maximum rate of 10 per 10 second time interval.</p> <p>The <b>no</b> form of this command disables the generation of icmp destination unreachable messages on the router interface.</p> |
| <b>Default</b>     | <b>unreachables 100 10</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <p><i>number</i> — The maximum number of ICMP unreachable messages to send. This parameter must be specified with the <i>seconds</i> parameter.</p> <p><b>Values</b>      10 — 1000</p> <p><i>seconds</i> — The time frame in seconds used to limit the <i>number</i> of ICMP unreachable messages that can be issued.</p> <p><b>Values</b>      1 — 60</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Description</b>   | <p>This command creates a Service Access Point (SAP) within a service. A SAP is a combination of port and encapsulation parameters which identifies the service access point on the interface and within the 7750. Each SAP must be unique.</p> <p>All SAPs must be explicitly created. If no SAPs are created within a service or on an IP interface, a SAP will not exist on that object.</p> <p>Enter an existing SAP without the <b>create</b> keyword to edit SAP parameters. The SAP is owned by the service in which it was created.</p> <p>A SAP can only be associated with a single service. A SAP can only be defined on a port that has been configured as an access port using the <b>config interface port-type port-id mode access</b> command. Channelized TDM ports are always access ports.</p> <p>If a port is shutdown, all SAPs on that port become operationally down. When a service is shutdown, SAPs for the service are not displayed as operationally down although all traffic traversing the service will be discarded. The operational state of a SAP is relative to the operational state of the port on which the SAP is defined.</p> <p>The <b>no</b> form of this command deletes the SAP with the specified port. When a SAP is deleted, all configuration parameters for the SAP will also be deleted.</p> |
| <b>Default</b>       | No SAPs are defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Special Cases</b> | <p><b>VPRN</b> — A VPRN SAP must be defined on an Ethernet interface.</p> <p><b>sap ipsec-id.private   public:tag</b> — This parameter associates an IPsec group SAP with this interface. This is the public side for an IPsec tunnel. Tunnels referencing this IPsec group in the private side may be created if their local IP is in the subnet of the interface subnet and the routing context specified matches with the one of the interface.</p> <p>This context will provide a SAP to the tunnel. The operator may associate an ingress and egress QoS policies as well as filters and virtual scheduling contexts. Internally this creates an Ethernet SAP that will be used to send and receive encrypted traffic to and from the MDA. Multiple tunnels can be associated with this SAP. The “tag” will be a dot1q value. The operator may see it as an identifier. The range is limited to 1 — 4094.</p>                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Parameters</b>    | <p><i>sap-id</i> — Specifies the physical port identifier portion of the SAP definition. See <a href="#">Common CLI Command Descriptions on page 1933</a> for command syntax.</p> <p><i>port-id</i> — Specifies the physical port ID in the <i>slot/mda/port</i> format.</p> <p>If the card in the slot has Media Dependent Adapters (MDAs) installed, the <i>port-id</i> must be in the <i>slot_number/MDA_number/port_number</i> format. For example 6/2/3 specifies port 3 on MDA 2 in slot 6.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

The *port-id* must reference a valid port type. When the *port-id* parameter represents SONET/SDH and TDM channels the port ID must include the channel ID. A period “.” separates the physical port from the *channel-id*. The port must be configured as an access port.

If the SONET/SDH port is configured as clear-channel then only the port is specified.

**create** — Keyword used to create a SAP instance.

**split-horizon-group** *group-name* — Specifies the name of the split horizon group to which the SAP belongs.

## tod-suite

|                    |                                                                                                                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>tod-suite</b> <i>tod-suite-name</i><br><b>no tod-suite</b>                                                                                                                                                |
| <b>Context</b>     | config>service>vprn>if>sap                                                                                                                                                                                   |
| <b>Description</b> | This command applies a time-based policy (filter or QoS policy) to the SAP. The suite name must already exist in the <b>config&gt;cron</b> context.                                                          |
| <b>Default</b>     | no tod-suite                                                                                                                                                                                                 |
| <b>Parameters</b>  | <i>tod-suite-name</i> — Specifies collection of policies (ACLs, QoS) including time-ranges that define the full or partial behavior of a SAP or a subscriber. The suite can be applied to more than one SAP. |

| <b>Description</b> | This command configures the application profile name.                                                           |
| <b>Parameters</b>  | <p><i>app-profile-name</i> — Specifies the application profile name.</p> <p><b>Values</b>      32 chars max</p> |

## collect-stats

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] collect-stats</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Context</b>     | config>service>vprn>if>sap<br>config>service>vprn>if>spoke-sdp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | <p>This command enables accounting and statistical data collection for either an interface SAP or interface SAP spoke SDP, or network port. When applying accounting policies the data, by default, is collected in the appropriate records and written to the designated billing file.</p> <p>When the <b>no collect-stats</b> command is issued the statistics are still accumulated by the IOM cards. However, the CPU will not obtain the results and write them to the billing file. If a subsequent <b>collect-stats</b> command is issued then the counters written to the billing file include all the traffic while the <b>no collect-stats</b> command was in effect.</p> |
| <b>Default</b>     | collect-stats                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Interface SAP ATM Commands

### atm

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>atm</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Context</b>     | config>service>vprn>if>sap<br>config>service>vprn>sub-if>grp-if>sap                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Description</b> | <p>This command enables the context to configure ATM-related attributes. This command can only be used when a given context (for example, a channel or SAP) supporting ATM functionality such as:</p> <ul style="list-style-type: none"> <li>Configuring ATM port or ATM port-related functionality on MDAs supporting ATM functionality.</li> <li>Configuring ATM-related configuration for ATM-based SAPs that exist on MDAs supporting ATM functionality.</li> </ul> <p>If ATM functionality is not supported for a given context, the command returns an error.</p> |

### egress

|                    |                                                                             |
|--------------------|-----------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>egress</b>                                                               |
| <b>Context</b>     | config>service>vprn>if>sap>atm<br>config>service>vprn>sub-if>grp-if>sap>atm |
| <b>Description</b> | This command configures egress ATM attributes for the SAP.                  |

### encapsulation

|                    |                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>encapsulation</b> <i>atm-encap-type</i>                                                                                                                                                                                                                                                                                                                                       |
| <b>Context</b>     | config>service>vprn>if>sap>atm<br>config>service>vprn>sub-if>grp-if>sap>atm                                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | <p>This command configures RFC 2684, <i>Multiprotocol Encapsulation over ATM AAL5</i>, encapsulation for an ATM PVCC delimited SAP. This command specifies the data encapsulation for an ATM PVCC delimited SAP. The definition also references the ATM Forum LAN Emulation specification. Ingress traffic that does not match the configured encapsulation will be dropped.</p> |
| <b>Default</b>     | The encapsulation is driven by the services for which the SAP is configured. For VPRN service SAPs, the default is <b>aal5snap-routed</b> .                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <i>atm-encap-type</i> — Specify the encapsulation type.                                                                                                                                                                                                                                                                                                                          |
| <b>Values</b>      | <b>aal5snap-routed</b> — Routed encapsulation for LLC encapsulated circuit (LLC/ SNAP precedes protocol datagram) as defined in RFC 2684.                                                                                                                                                                                                                                        |

**aal5mux-ip** — Routed IP encapsulation for VC multiplexed circuit as defined in RFC 2684.

**aal5snap-bridged** — Bridged encapsulation for LLC encapsulated circuit (LLC/ SNAP precedes protocol datagram) as defined in RFC 2684.

**aal5mux-bridged-eth-nofcs** — Bridged IP encapsulation for VC multiplexed circuit as defined in RFC 2684.

## ingress

|                    |                                                                             |
|--------------------|-----------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ingress</b>                                                              |
| <b>Context</b>     | config>service>vprn>if>sap>atm<br>config>service>vprn>sub-if>grp-if>sap>atm |
| <b>Description</b> | This command configures ingress ATM attributes for the SAP.                 |

## traffic-desc

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Description</b> | This command assigns an ATM traffic descriptor profile to a given context (for example, a SAP). When configured under the ingress context, the specified traffic descriptor profile defines the traffic contract in the forward direction. When configured under the egress context, the specified traffic descriptor profile defines the traffic contract in the backward direction.<br><br>The <b>no</b> form of the command reverts the traffic descriptor to the default traffic descriptor profile. |
| <b>Default</b>     | The default traffic descriptor (trafficDescProfileId. = 1) is associated with newly created PVCC-delimited SAPs.                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <i>traffic-desc-profile-id</i> — Specify a defined traffic descriptor profile (see the QoS atm-td-profile command).                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Description</b> | <p>This command configures AIS/RDI fault management on a PVCC. Fault management allows PVCC termination to monitor and report the status of their connection by propagating fault information through the network and by driving PVCC's operational status.</p> <p>When alarm-cells functionality is enabled, a PVCC's operational status is affected when a PVCC goes into an AIS or RDI state because of an AIS/RDI processing (assuming nothing else affects PVCC's operational status, for example, if the PVCC goes DOWN, or enters a fault state and comes back UP, or exits that fault state). RDI cells are generated when PVCC is operationally DOWN. No OAM-specific SNMP trap is raised whenever an endpoint enters/exits an AIS or RDI state, however, if as result of an OAM state change, the PVCC changes operational status, then a trap is expected from an entity the PVCC is associated with (for example a SAP).</p> <p>The <b>no</b> command disables alarm-cells functionality for a PVCC. When alarm-cells functionality is disabled, a PVCC's operational status is no longer affected by a PVCC's OAM state changes due to AIS/RDI processing (note that when alarm-cells is disabled, a PVCC will change operational status to UP due to alarm-cell processing) and RDI cells are not generated as result of the PVCC going into AIS or RDI state. The PVCC's OAM status, however, will record OAM faults as described above.</p> |
| <b>Default</b>     | Enabled for PVCCs delimiting VPRN SAPs                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Description</b> | <p>This command enables periodic OAM loopbacks on this SAP. This command is only configurable on VPRN SAPs. When enabled, an ATM OAM loopback cell is transmitted every period as configured in the <code>config&gt;system&gt;atm&gt;oam&gt;loopback-period <i>period</i></code> context.</p> <p>If a response is not received and consecutive retry-down retries also result in failure, the endpoint will transition to an alarm indication signal/loss of clock state. Then, an ATM OAM loopback cell will be transmitted every period as configured in the <code>loopback-period <i>period</i></code>. If a response is received for the periodic loopback and consecutive retry-up retries also each receive a response, the endpoint will transition back to the up state.</p> <p>The <b>no</b> form of the command sets the value back to the default.</p> |
| <b>Default</b>     | no periodic-loopback                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Context</b>     | config>service>vprn>if>sap<br>config>service>vprn>sub-if>grp-if>sap                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b> | <p>This command enables anti-spoof filtering and optionally changes the anti-spoof matching type for the interface.</p> <p>The type of anti-spoof filtering defines what information in the incoming packet is used to generate the criteria to lookup an entry in the anti-spoof filter table. The type parameter (<b>ip</b>, <b>mac</b>, <b>ip-mac</b>, <b>nh-mac</b>) defines the anti-spoof filter type enforced by the SAP when anti-spoof filtering is enabled.</p> <p>The <b>no</b> form of the command disables anti-spoof filtering on the SAP.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Default</b>     | <p>Filter type default types:</p> <ul style="list-style-type: none"> <li>• Non-Ethernet encapsulation default anti-spoof filter type — When enabled on a non-Ethernet encapsulated SAP, the anti-spoof filter default type is <b>ip</b>.</li> <li>• Ethernet encapsulated default anti-spoof filter type — When enabled on an Ethernet encapsulated SAP, the anti-spoof default type is <b>ip-mac</b>.</li> <li>• Default anti-spoof filter state — Anti-spoof filtering is disabled by default on the SAP.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <p><b>ip</b> — Configures SAP anti-spoof filtering to use only the source IP address in its lookup. If a static host exists on the SAP without an IP address specified, the anti-spoof type <b>ip</b> command will fail.</p> <p><b>mac</b> — Configures SAP anti-spoof filtering to use only the source MAC address in its lookup. Setting the anti-spoof filter type to <b>mac</b> is not allowed on non-Ethernet encapsulated SAPs. If a static host exists on the SAP without a specified MAC address, the anti-spoof type <b>mac</b> command will fail. The anti-spoof type <b>mac</b> command will also fail if the SAP does not support Ethernet encapsulation.</p> <p><b>ip-mac</b> — Configures SAP anti-spoof filtering to use both the source IP address and the source MAC address in its lookup. If a static host exists on the SAP without both the IP address and MAC address specified, the anti-spoof type <b>ip-mac</b> command will fail. This is also true if the default anti-spoof filter type of the SAP is <b>ip-mac</b> and the default is not overridden. The anti-spoof type <b>ip-mac</b> command will also fail if the SAP does not support Ethernet encapsulation.</p> <p><b>nh-mac</b> — Indicates that the ingress anti-spoof is based on the source MAC address and the egress anti-spoof is based on the nh-ip-address.</p> |

## app-profile

|                    |                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>app-profile</b> <i>app-profile-name</i><br><b>no app-profile</b>                                                                                |
| <b>Context</b>     | config>service>vprn>if>sap<br>config>service>vprn>sub-if>grp-if>sap                                                                                |
| <b>Description</b> | This command configures the application profile name.                                                                                              |
| <b>Parameters</b>  | <i>app-profile-name</i> — Specifies an existing application profile name configured in the <b>config&gt;app-assure&gt;group&gt;policy</b> context. |

## arp-populate

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Description</b> | <p>This command enables populating static and dynamic hosts into the system ARP cache. When enabled, the host's IP address and MAC address are placed in the system ARP cache as a managed entry. Static hosts must be defined on the interface using the <b>host</b> command. Dynamic hosts are enabled on the system through enabling lease-populate in the IP interface DHCP context. In the event that both a static host and a dynamic host share the same IP and MAC address, the system's ARP cache retains the host information until both the static and dynamic information are removed. Both static and dynamic hosts override static ARP entries. Static ARP entries are marked as inactive when they conflict with static or dynamic hosts and will be repopulated once all static and dynamic host information for the IP address are removed. Since static ARP entries are not possible when static subscriber hosts are defined or when DHCP lease state table population is enabled, conflict between static ARP entries and the arp-populate function is not an issue.</p> <p>The <b>arp-populate</b> command will fail if an existing static subscriber host on the SAP does not have both MAC and IP addresses specified.</p> <p>Once <b>arp-populate</b> is enabled, creating a static subscriber host on the SAP without both an IP address and MAC address will fail.</p> <p><b>arp-populate</b> can only be enabled on VPRN interfaces supporting Ethernet encapsulation.</p> <p>Use the <b>no</b> form of the command to disable ARP cache population functions for static and dynamic hosts on the interface. All static and dynamic host information in the systems ARP cache will be removed. Any existing static ARP entries previously inactive due to static or dynamic hosts will be populated in the system ARP cache.</p> <p>When <b>arp-populate</b> is enabled, the system will not send out ARP Requests for hosts that are not in the ARP cache. Only statically configured and DHCP learned hosts are reachable through an IP interface with arp-populate enabled.</p> |
| <b>Default</b>     | not enabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## arp-timeout

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Context</b>     | config>service>vprn>interface<br>config>service>vprn>sub-if>grp-if                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | This command configures the minimum time in seconds an ARP entry learned on the IP interface will be stored in the ARP table. ARP entries are automatically refreshed when an ARP request or gratuitous ARP is seen from an IP host, otherwise, the ARP entry is aged from the ARP table. If <b>arp-timeout</b> is set to a value of zero seconds, ARP aging is disabled.<br><br>The <b>no</b> form of this command restores <b>arp-timeout</b> to the default value. |
| <b>Default</b>     | 14400 seconds                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <i>seconds</i> — The minimum number of seconds a learned ARP entry will be stored in the ARP table, expressed as a decimal integer. A value of zero specifies that the timer is inoperative and learned ARP entries will not be aged.<br><br><b>Values</b> 0 — 65535                                                                                                                                                                                                  |

## authentication-policy

|                    |                                                                                                                                                                                   |

| <b>Syntax</b>      | <b>authentication-policy</b> <i>name</i><br><b>no authentication-policy</b>                                                                                                       |
| <b>Context</b>     | config>service>vprn>if<br>config>service>vprn>sub-if>grp-if                                                                                                                       |
| <b>Description</b> | This command assigns an authentication policy to the interface.<br><br>The <b>no</b> form of this command removes the policy name from the group interface configuration.         |
| <b>Default</b>     | no authentication-policy                                                                                                                                                          |
| <b>Parameters</b>  | <i>name</i> — Specifies the authentication policy name. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes. |

## delayed-enable

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>delayed-enable</b> <i>seconds</i> [ <b>init-only</b> ]<br><b>no delayed-enable</b>                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Context</b>     | config>service>vprn>sub-if                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | This command delays making interface operational by the specified number of seconds.<br><br>In environments with many subscribers, it can take time to synchronize the subscriber state between peers when the subscriber-interface is enabled (perhaps, after a reboot). To ensure that the state has time to be synchronized, the <b>delayed-enable</b> timer can be specified. The optional parameter <b>init-only</b> can be added to use this timer only after a reboot. |

|                   |                                                                                                                                                                                                                                                                                  |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | no delayed-enable                                                                                                                                                                                                                                                                |
| <b>Parameters</b> | <i>seconds</i> — Specifies the number of seconds to delay before the interface is operational.                                                                                                                                                                                   |
| <b>Values</b>     | 1 — 1200                                                                                                                                                                                                                                                                         |
| <b>init-only</b>  | — Delays the initialization of the subscriber-interface to give the rest of the system time to complete necessary tasks such as allowing routing protocols to converge and/or to allow MCS to sync the subscriber information. The delay only occurs immediately after a reboot. |

| <b>Description</b> | This command enables the inclusion of the <b>calling-station-id</b> attribute in RADIUS authentication requests and RADIUS accounting messages. The value inserted is set at the SAP level. If no value is set at the SAP level, an empty string is included. |
| <b>Default</b>     | This attribute is not sent by default.                                                                                                                                                                                                                        |

| <b>Description</b> | <p>This command assigns an existing CPU protection policy to the associated group interface SAP. The CPU protection policies are configured in the <b>config&gt;sys&gt;security&gt;cpu-protection&gt;policy</b> <i>cpu-protection-policy-id</i> context.</p> <p>If no <b>cpu-protection policy</b> is assigned to a SAP, then the default policy is used to limit the overall-rate. The default policy is policy number 254 for access interfaces and 255 for network interfaces.</p> <p>The <b>no</b> form of the command removes the association of the CPU protection policy from the associated interface and reverts to the default policy values.</p> |
| <b>Default</b>     | <p>cpu-protection 254 (for access interfaces)</p> <p>cpu-protection 255 (for network interfaces)</p> <p>none (for video-interfaces (where applicable), shown as <b>no cpu-protection</b> in CLI)</p> <p>The configuration of <b>no cpu-protection</b> returns the interface/SAP to the default policies as shown above.</p>                                                                                                                                                                                                                                                                                                                                 |
| <b>Parameters</b>  | <p><i>policy-id</i> — Specifies an existing CPU protection policy.</p> <p><b>Values</b> 1 — 255</p> <p><b>mac-monitoring</b> — When specified, the per MAC rate limiting should be performed, using the per-source-rate from the associated cpu-protection policy.</p>                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Description</b> | <p>This command creates a static host for the SAP. Applications within the system that make use of static host entries include anti-spoof, and source MAC population into the VPLS forwarding database.</p> <p>Multiple static hosts can be defined on the SAP. Each host is identified by a source IP address, a source MAC address, or both a source IP and source MAC address. When anti-spoof is enabled on the SAP, the host information will be populated into the SAP's anti-spoof table, allowing ingress packets matching the entry access to the SAP. When the MAC address exists in the host definition, the MAC address is populated into the VPLS forwarding database and associates it with the SAP. The static host definition overrides any static MAC entries using the same MAC and prevents dynamic learning of the MAC on another interface.</p> <p>Defining a static host identical to an existing static host has no effect and will not generate a log or error message.</p> <p>Every static host definition must have at least one address defined, IP or MAC.</p> <p>Static hosts may exist on the SAP even with anti-spoof and <b>arp-populate</b> (VPRN) features disabled. When enabled, each feature has different requirements for static hosts.</p> <p><b>anti-spoof</b> — When enabled, this feature uses static and dynamic host information to populate entries into an anti-spoof filter table. The anti-spoof filter entries generated will be of the same type as specified in the anti-spoof type parameter. If the SAP anti-spoof filter is defined as mac, each static host definition must specify a MAC address. If the SAP anti-spoof filter is defined as ip, each static host definition must specify an IP address. If the SAP anti-spoof filter is defined as ip-mac, each static host definition must specify both an IP address and MAC address. If definition of a static host is attempted without the appropriate addresses specified for the enabled anti-spoof filter, the static host definition will fail.</p> <p><b>arp-populate</b> — When enabled, this feature uses static and dynamic host information to populate entries into the system's ARP cache. This is only available on the VPRN service SAPs. Both a MAC address and IP address are required to populate an ARP entry in the system. If definition of a static host is attempted without both a MAC and IP address specified when arp -populate is enabled, the static host definition will fail.</p> <p><b>fdb-populate</b> — This is an implicit feature that uses the static host definition as a static MAC in the VPLS forwarding database. It cannot be enabled or disabled and has no effect on the ability to create static hosts without a MAC address specified. When a MAC address is specified for a static host, it will automatically be populated into the VPLS forwarding database associated with the SAP on which the host is created. The static host MAC address will override any static MAC entries using the same MAC and prevent dynamic learning of the MAC on another interface. Existing static MAC entries with the same MAC address as a static host are marked as inactive but not deleted. If all static hosts are removed from the SAP, the static MAC may be populated. New static MAC definitions for the VPLS instance may be created while a static host exists associated with the static MAC address.</p> <p>The <b>no</b> form of the command removes a static entry from the system. The specified <b>ip address</b> and <b>mac address</b> must match the host's exact IP and MAC addresses as defined when it was created.</p> |

When a static host is removed from the SAP, the affect of its removal on the anti-spoof filter, ARP cache or the VPLS forwarding database is also evaluated.

**Default** There are no default static entries.

**Parameters** **ip ip-address** — Specify this optional parameter when defining a static host. The IP address must be specified for **anti-spoof ip** and **anti-spoof ip-mac** commands. Only one static host can be configured on the SAP with a given IP address.

The following rules apply to configure static hosts using an IP address:

- Only one static host can be defined using a specific IP address.
- Defining a static host with the same IP address as a previous static host overwrites the previous static host.
- If a static host has an IP address assigned, the MAC address for the host is optional (depending on the features enabled on the SAP).

**mac mac-address** — Specify this optional parameter when defining a static host. The MAC address must be specified for **anti-spoof mac** and **anti-spoof ip-mac**. Multiple static hosts may be configured with the same MAC address given that each definition is distinguished by a unique IP address. The following rules apply to configuring static hosts using a MAC address:

- Multiple static hosts may share the same MAC address.
- Executing the host command with the same MAC address but a different IP address as an existing static host will create a new static host.
- If a static host has a MAC address assigned, the IP address for the host is optional (depending on the features enabled on the SAP).

**Values** 8k static and dynamic hosts per 10G forwarding complex. 64k per system.

**subscriber sub-ident-string** — Specify this optional parameter to specify an existing subscriber identification profile to be associated with the static subscriber host. The subscriber identification profile is configured in the **config>subscr-mgmt>sub-ident-policy** context. The subscriber information is used by the VPRN SAP arp-reply-agent to determine the proper handling of received ARP requests from subscribers.

- For VPRN SAPs with **arp-reply-agent** enabled with the optional *sub-ident* parameter, the static subscriber host's sub-ident-string is used to determine whether an ARP request received on the SAP is sourced from a host belonging to the same subscriber as the destination host. When both the destination and source hosts from the ARP request are known on the SAP and the subscriber identifications do not match, the ARP request may be forwarded to the rest of the VPRN destinations.

If the static subscriber host's *sub-ident* string is not defined, the host is not considered to belong to the same subscriber as another host on the SAP.

If source or destination host is unknown, the hosts are not considered to belong to the same subscriber. ARP messages from unknown hosts are subject to anti-spoof filtering rules applied at the SAP.

If *sub-ident* is not enabled on the SAP arp-reply-agent, subscriber identification matching is not performed on ARP requests received on the SAP.

ARP requests are never forwarded back to the same SAP or within the receiving SAP's split horizon group.

**sub-profile** *sub-profile-name* — Specify this optional parameter to specify an existing subscriber profile name to be associated with the static subscriber host. The subscriber profile is configured in the **config>subscr-mgmt>sub-profile** context.

**sla-profile** *sla-profile-name* — Specify this optional parameter to specify an existing SLA profile name to be associated with the static subscriber host. The SLA profile is configured in the **config>subscr-mgmt>sla-profile** context.

### frame-relay

|                    |                                                                                  |

|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command enables interleaving of high priority frames and low-priority frame fragments within a FR SAP using FRF.12 end-to-end fragmentation.</p> <p>When this option is enabled, only frames of the FR SAP non expedited forwarding class queues are subject to fragmentation. The frames of the FR SAP expedited queues are interleaved, with no fragmentation header, among the fragmented frames. In effect, this provides a behavior like in MLPPP Link Fragment Interleaving (LFI).</p> <p>When this option is disabled, frames of all the FR SAP forwarding class queues are subject to fragmentation. The fragmentation header is however not included when the frame size is smaller than the user configured fragmentation size. In this mode, the SAP transmits all fragments of a frame before sending the next full or fragmented frame.</p> <p>The receive direction of the FR SAP supports both modes of operation concurrently, with and without fragment interleaving.</p> <p>The <b>no</b> form of this command restores the default mode of operation.</p> |
| <b>Default</b>     | no interleave                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Context</b>     | config>service>vprn>if>sap>egress<br>config>service>vprn>sub-if>grp-if>sap>egress<br>config>service>vprn>ipsec-if>sap>egress                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Description</b> | This command defines a maximum total rate for all egress queues on a service SAP or multi-service site. The <b>agg-rate-limit</b> command is mutually exclusive with the egress scheduler policy. When an egress scheduler policy is defined, the <b>agg-rate-limit</b> command will fail. If the <b>agg-rate-limit</b> command is specified, an attempt to bind a <b>scheduler-policy</b> to the SAP or multi-service site will fail.<br><br>A multi-service site must have a port scope defined that ensures all queues associated with the site are on the same port or channel. If the scope is not set to a port, the agg-rate-limit command will fail. |

Once an `agg-rate-limit` has been assigned to a multi-service site, the scope cannot be changed to `card` level.

A port scheduler policy must be applied on the egress port or channel the SAP or multi-service site is bound to in order for the defined `agg-rate-limit` to take effect. The egress port scheduler enforces the aggregate queue rate as it distributes its bandwidth at the various port priority levels. The port scheduler stops offering bandwidth to member queues once it has detected that the aggregate rate limit has been reached.

If a port scheduler is not defined on the egress port, the queues are allowed to operate based on their own bandwidth parameters.

The **no** form of the command removes the aggregate rate limit from the SAP or multi-service site.

**Parameters** *agg-rate* — Defines the rate, in kilobits-per-second, that the maximum aggregate rate that the queues on the SAP or multi-service site can operate.

**Values** 1 — 40000000, max

**queue-frame-based-accounting** — This keyword enables frame based accounting on all queues associated with the SAP or Multi-Service Site. If frame based accounting is required when an aggregate limit is not necessary, the `max` keyword should precede the `queue-frame-based-accounting` keyword. If frame based accounting must be disabled, execute `agg-rate-limit` without the `queue-frame-based-accounting` keyword present.

**Default** Frame based accounting is disabled by default

## filter

**Syntax** **filter ip** *ip-filter-id*  
**no filter**

**Context** `config>service>vprn>if>sap>egress`  
`config>service>vprn>if>sap>ingress`  
`config>service>vprn>sub-if>grp-if>sap>egress`  
`config>service>vprn>ipsec-if>sap>egress`  
`config>service>vprn>ipsec-if>sap>ingress`

**Description** This command associates an IP filter policy with an ingress or egress Service Access Point (SAP) or IP interface. Filter policies control the forwarding and dropping of packets based on IP matching criteria.

The **filter** command is used to associate a filter policy with a specified *ip-filter-id* with an ingress or egress SAP. The *ip-filter-id* must already be defined before the **filter** command is executed. If the filter policy does not exist, the operation will fail and an error message returned.

In general, filters applied to SAPs (ingress or egress) apply to all packets on the SAP. One exception is non-IP packets are not applied to IP match criteria, so the default action in the filter policy applies to these packets.

The **no** form of this command removes any configured filter ID association with the SAP or IP interface. The filter ID itself is not removed from the system unless the scope of the created filter is set to `local`. To avoid deletion of the filter ID and only break the association with the service object, use **scope** command within the filter definition to change the scope to **local** or **global**. The default scope of a filter is **local**.

|                   |                                                                                                                             |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <b>ip</b> <i>ip-filter-id</i> — Specifies IP filter policy. The filter ID must already exist within the created IP filters. |
| <b>Values</b>     | 1 — 65535                                                                                                                   |

### hsmda-queue-override

|                    |                                                                         |
|--------------------|-------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] hsmda-queue-override</b>                                        |
| <b>Context</b>     | config>service>vprn>if>sap>egress<br>config>service>vprn>if>sap>ingress |
| <b>Description</b> | This command enables the context to configure HSMDA queue overrides.    |

### queue

|                    |                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>queue</b> <i>queue-id</i> [ <b>create</b> ]<br><b>no queue</b> <i>queue-id</i>                                           |
| <b>Context</b>     | config>service>vprn>if>sap>egress>hsmda-queue-overider<br>config>service>vprn>if>sap>ingress>hsmda-queue-overider           |
| <b>Description</b> | This command configures overrides for a HSMDA queue. The actual valid values are those defined in the given SAP QoS policy. |
| <b>Parameters</b>  | <i>queue-id</i> — Specifies the queue ID to override.                                                                       |
| <b>Values</b>      | 1 — 8                                                                                                                       |
|                    | <b>create</b> — This keyword is mandatory while creating a new queue override.                                              |

### packet-byte-offset

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Syntax</b>      | <b>packet-byte-offset</b> { <b>add</b> <i>add-bytes</i>   <b>subtract</b> <i>sub-bytes</i> }<br><b>no packet-byte-offset</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Context</b>     | config>service>vprn>if>sap>egress>hsmda-queue-overider<br>config>service>vprn>if>sap>ingress>hsmda-queue-overider                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b> | <p>This command adds or subtracts the specified number of bytes to the accounting function for each packet handled by the HSMDA queue. Normally, the accounting and leaky bucket functions are based on the Ethernet DLC header, payload and the 4 byte CRC (everything except the preamble and inter-frame gap). As an example, the packet-byte-offset command can be used to add the frame encapsulation overhead (20 bytes) to the queues accounting functions.</p> <p>The accounting functions affected include:</p> <ul style="list-style-type: none"> <li>• Offered High Priority / In-Profile Octet Counter</li> <li>• Offered Low Priority / Out-of-Profile Octet Counter</li> <li>• Discarded High Priority / In-Profile Octet Counter</li> </ul> |

- Discarded Low Priority / Out-of-Profile Octet Counter
- Forwarded In-Profile Octet Counter
- Forwarded Out-of-Profile Octet Counter
- Peak Information Rate (PIR) Leaky Bucket Updates
- Committed Information Rate (CIR) Leaky Bucket Updates
- Queue Group Aggregate Rate Limit Leaky Bucket Updates

The secondary shaper leaky bucket, scheduler priority level leaky bucket and the port maximum rate updates are not affected by the configured packet-byte-offset. Each of these accounting functions are frame based and always include the preamble, DLC header, payload and the CRC regardless of the configured byte offset.

The packet-byte-offset command accepts either add or subtract as valid keywords which define whether bytes are being added or removed from each packet traversing the queue. Up to 31 bytes may be added to the packet and up to 32 bytes may be removed from the packet. An example use case for subtracting bytes from each packet is an IP based accounting function. Given a Dot1Q encapsulation, the command packet-byte-offset subtract 14 would remove the DLC header and the Dot1Q header from the size of each packet for accounting functions only. The 14 bytes are not actually removed from the packet, only the accounting size of the packet is affected.

As inferred above, the variable accounting size offered by the packet-byte-offset command is targeted at the queue and queue group level. The packet-byte-offset, when set, applies to all queues in the queue group. The accounting size of the packet is ignored by the secondary shapers, the scheduling priority level shapers and the scheduler maximum rate. The actual on-the-wire frame size is used for these functions to allow an accurate representation of the behavior of the subscriber's packets on an Ethernet aggregation network.

The packet-byte-offset value may be overridden at the queue-group level.

#### Parameters

**add** *add-bytes* — Indicates that the byte value should be added to the packet for queue and queue group level accounting functions. Either the **add** or **subtract** keyword must be specified. The corresponding byte value must be specified when executing the packet-byte-offset command. The **add** keyword is mutually exclusive with the **subtract** keyword.

**Values**      0 — 31

**subtract** *sub-bytes* — Indicates that the byte value should be subtracted from the packet for queue and queue group level accounting functions. The **subtract** keyword is mutually exclusive with the **add** keyword. Either the **add** or **subtract** keyword must be specified. The corresponding byte value must be specified when executing the packet-byte-offset command.

**Values**      1 — 32

## slope-policy

|                    |                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>slope-policy</b> <i>hsmda-slope-policy-name</i><br><b>no slope-policy</b>                                      |
| <b>Context</b>     | config>service>vprn>if>sap>egress>hsmda-queue-overider<br>config>service>vprn>if>sap>ingress>hsmda-queue-overider |
| <b>Description</b> | This command specifies an existing slope policy name.                                                             |

## secondary-shaper

|                    |                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------|
|                    | <b>secondary-shaper</b> <i>secondary-shaper-name</i><br><b>no secondary-shaper</b>                                      |
| <b>Context</b>     | config>service>vprn>if>sap>egress>hsmda-queue-overider                                                                  |
| <b>Description</b> | This command configures an HSMDB secondary shaper. Note that an shaper override can only be configured on an HSMDB SAP. |
| <b>Parameters</b>  | <i>secondary-shaper-name</i> — Specifies a secondary shaper name up to 32 characters in length.                         |

## match-qinq-dot1p

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Description</b> | <p>This command specifies which Dot1Q tag position Dot1P bits in a QinQ encapsulated packet should be used to evaluate Dot1P QoS classification.</p> <p>The <b>match-qinq-dot1p</b> command allows the top or bottom PBits to be used when evaluating the applied sap-ingress QoS policy's Dot1P entries. The <b>top</b> and <b>bottom</b> keywords specify which position should be evaluated for QinQ encapsulated packets.</p> <p>The <b>no</b> form of the command restores the default dot1p evaluation behavior for the SAP.</p> <p>By default, the bottom most service delineating Dot1Q tags Dot1P bits are used. The following table defines the default behavior for Dot1P evaluation when the <b>match-qinq-dot1p</b> command is not executed.</p> |

| Port / SAP Type | Existing Packet Tags | PBits Used for Match |
|-----------------|----------------------|----------------------|
| Null            | None                 | None                 |
| Null            | Dot1P (VLAN-ID 0)    | Dot1P PBits          |
| Null            | Dot1Q                | Dot1Q PBits          |

| Port / SAP Type | Existing Packet Tags          | PBits Used for Match |
|-----------------|-------------------------------|----------------------|
| Null            | TopQ BottomQ                  | TopQ PBits           |
| Null            | TopQ (No BottomQ)             | TopQ PBits           |
| Dot1Q           | None (Default SAP)            | None                 |
| Dot1Q           | Dot1P (Default SAP VLAN-ID 0) | Dot1P PBits          |
| Dot1Q           | Dot1Q                         | Dot1Q PBits          |
| QinQ / TopQ     | TopQ                          | TopQ PBits           |
| QinQ / TopQ     | TopQ BottomQ                  | TopQ PBits           |
| QinQ / QinQ     | TopQ BottomQ                  | BottomQ PBits        |

**Default** no match-qinq-dot1p - No filtering based on p-bits.  
top or bottom must be specified to override the default QinQ dot1p behavior.

**Parameters** **top** — The top parameter is mutually exclusive to the bottom parameter. When the top parameter is specified, the top most PBits are used (if existing) to match any dot1p dot1p-value entries. The following table defines the dot1p evaluation behavior when the top parameter is specified.

| Port / SAP Type | Existing Packet Tags          | PBits Used for Match |
|-----------------|-------------------------------|----------------------|
| Null            | None                          | None                 |
| Null            | Dot1P (VLAN-ID 0)             | Dot1P PBits          |
| Null            | Dot1Q                         | Dot1Q PBits          |
| Null            | TopQ BottomQ                  | TopQ PBits           |
| Null            | TopQ (No BottomQ)             | TopQ PBits           |
| Dot1Q           | None (Default SAP)            | None                 |
| Dot1Q           | Dot1P (Default SAP VLAN-ID 0) | Dot1P PBits          |
| Dot1Q           | Dot1Q                         | Dot1Q PBits          |
| QinQ / TopQ     | TopQ                          | TopQ PBits           |
| QinQ / TopQ     | TopQ BottomQ                  | TopQ PBits           |
| QinQ / TopQ     | TopQ BottomQ                  | TopQ PBits           |

**bottom** — The bottom parameter is mutually exclusive to the top parameter. When the bottom parameter is specified, the bottom most PBits are used (if existing) to match any dot1p dot1p-value entries. The following tables define the bottom position QinQ and TopQ SAP dot1p evaluation and the default dot1p explicit marking actions.

**Table 26: Bottom Position QinQ and TopQ SAP Dot1P Evaluation**

| Port / SAP Type | Existing Packet Tags | PBits Used for Match |
|-----------------|----------------------|----------------------|
| Null            | None                 | None                 |

**Table 26: Bottom Position QinQ and TopQ SAP Dot1P Evaluation (Continued)**

| Port / SAP Type | Existing Packet Tags          | PBits Used for Match |
|-----------------|-------------------------------|----------------------|
| Null            | Dot1P (VLAN-ID 0)             | Dot1P PBits          |
| Null            | Dot1Q                         | Dot1Q PBits          |
| Null            | TopQ BottomQ                  | BottomQ PBits        |
| Null            | TopQ (No BottomQ)             | TopQ PBits           |
| Dot1Q           | None (Default SAP)            | None                 |
| Dot1Q           | Dot1P (Default SAP VLAN-ID 0) | Dot1P PBits          |
| Dot1Q           | Dot1Q                         | Dot1Q PBits          |
| QinQ / TopQ     | TopQ                          | TopQ PBits           |
| QinQ / TopQ     | TopQ BottomQ                  | BottomQ PBits        |
| QinQ / QinQ     | TopQ BottomQ                  | BottomQ PBits        |

| Egress SAP Type | Ingress Packet Preserved Dot1P State                  | Marked (or Remarked) PBits                                   |
|-----------------|-------------------------------------------------------|--------------------------------------------------------------|
| Null            | No preserved Dot1P bits                               | None                                                         |
| Null            | Preserved Dot1P bits                                  | Preserved tag PBits remarked using dot1p-value               |
| Dot1Q           | No preserved Dot1P bits                               | New PBits marked using dot1p-value                           |
| Dot1Q           | Preserved Dot1P bits                                  | Preserved tag PBits remarked using dot1p-value               |
| TopQ            | No preserved Dot1P bits                               | TopQ PBits marked using dot1p-value                          |
| TopQ            | Preserved Dot1P bits (used as TopQ and BottomQ PBits) | TopQ PBits marked using dot1p-value, BottomQ PBits preserved |
| QinQ            | No preserved Dot1P bits                               | TopQ PBits and BottomQ PBits marked using dot1p-value        |
| QinQ            | Preserved Dot1P bits (used as TopQ and BottomQ PBits) | TopQ PBits and BottomQ PBits marked using dot1p-value        |

The dot1p dot1p-value command must be configured without the qinq-mark-top-only parameter to remove the TopQ PBits only marking restriction.

## qinq-mark-top-only

|                    |                                                                                                                                                                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| <b>Description</b> | <p>Associates a Quality of Service (QoS) policy with an ingress or egress Service Access Point (SAP) or IP interface. QoS ingress and egress policies are important for the enforcement of SLA agreements. The policy ID must be defined prior to associating the policy with a SAP or IP interface. If the <i>policy-id</i> does not exist, an error will be returned.</p> <p>The <b>qos</b> command is used to associate both ingress and egress QoS policies. The <b>qos</b> command only allows ingress policies to be associated on SAP or IP interface ingress and egress policies on SAP or IP interface egress. Attempts to associate a QoS policy of the wrong type returns an error. Only one ingress and one egress QoS policy can be associated with a SAP or IP interface at one time. Attempts to associate a second QoS policy of a given type will return an error.</p> <p>When an ingress QoS policy is defined on an ingress IP interface that is bound to a VPRN, the policy becomes associated with every SAP on the VPRN and augments the QoS policy that is defined on each SAP. Packets that are bridged will be processed using the policy defined on the VPRN SAP; packets that are routed will be processed using the policy defined in the IES IP interface-binding context.</p> <p>When an egress QoS policy is associated with an IP interface that has been bound to a VPRN, the policy becomes associated with every SAP on the VPRN and augments the egress QoS policy that is defined on each SAP. Packets that are bridged will be processed using the policy defined on the VPRN SAP; packets that are routed will be processed using the policy defined in the IP interface-binding context.</p> <p>By default, no specific QoS policy is associated with the SAP or IP interface for ingress or egress, so the default QoS policy is used.</p> |

The **no** form of this command removes the QoS policy association from the SAP or IP interface, and the QoS policy reverts to the default.

**Parameters** *policy-id* — The ingress/egress policy ID to associate with SAP or IP interface on ingress/egress. The policy ID must already exist.

**Values** 1 — 65535

**shared-queuing** — Specify the ingress shared queue policy used by this SAP. When the value of this object is null it means that the SAP will use individual ingress QoS queues instead of the shared ones.

**multipoint-shared** — This keyword specifies that this *queue-id* is for multipoint forwarded traffic only. This *queue-id* can only be explicitly mapped to the forwarding class multicast, broadcast, or unknown unicast ingress traffic. Attempting to map forwarding class unicast traffic to a multipoint queue generates an error; no changes are made to the current unicast traffic queue mapping.

A queue must be created as multipoint. The **multipoint** designator cannot be defined after the queue is created. If an attempt is made to modify the command to include the **multipoint** keyword, an error is generated and the command will not execute.

The **multipoint** keyword can be entered in the command line on a pre-existing multipoint queue to edit *queue-id* parameters.

**Default** Present (the queue is created as non-multipoint).

**Values** Multipoint or not present.

## scheduler-policy

**Syntax** **scheduler-policy** *scheduler-policy-name*  
no scheduler-policy

**Context** config>service>vprn>if>sap>ingress  
config>service>vprn>if>sap>egress  
config>service>vprn>sub-if>grp-if>sap>egress  
config>service>vprn>sub-if>grp-if>sap>ingress  
config>service>vprn>ipsec-if>sap>egress  
config>service>vprn>ipsec-if>sap>ingress

**Description** This command applies an existing scheduler policy to an ingress or egress scheduler used by SAP queues associated with this multi-service customer site. The schedulers defined in the scheduler policy can only be created once the customer site has been appropriately assigned to a chassis port, channel or slot. Scheduler policies are defined in the **config>qos>scheduler-policy** *scheduler-policy-name* context.

The **no** form of this command removes the configured ingress or egress scheduler policy from the multi-service customer site. When the policy is removed, the schedulers created due to the policy are removed also making them unavailable for the ingress SAP queues associated with the customer site. Queues that lose their parent scheduler association are deemed to be orphaned and are no longer subject to a virtual scheduler. The SAPs that have ingress queues reliant on the removed schedulers enter into an operational state depicting the orphaned status of one or more queues. When the **no scheduler-policy** command is executed, the customer site ingress or egress node will not contain an applied scheduler policy.

*scheduler-policy-name*: — The *scheduler-policy-name* parameter applies an existing scheduler policy that was created in the **config>qos>scheduler-policy scheduler-policy-name** context to create the hierarchy of ingress or egress virtual schedulers. The scheduler names defined within the policy are created and made available to any ingress or egress queues created on associated SAPs.

**Values** Any existing valid scheduler policy name.

## ipsec-gw

|                    |                                                                               |
|--------------------|-------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ipsec-gw</b> <i>name</i><br><b>no ipsec-gw</b>                             |
| <b>Context</b>     | config>service>vprn>interface>sap                                             |
| <b>Description</b> | This command configures the IPSec gateway.                                    |
| <b>Parameters</b>  | <i>name</i> — Specifies the IPSec gateway name up to 32 characters in length. |

## default-secure-service

|                    |                                                                                                                     |

| <b>Context</b>     | config>service>vprn>interface>sap>ipsec-gw                                                                          |
| <b>Description</b> | This command specifies a service ID or service name of the default security service used by this SAP IPSec gateway. |
| <b>Parameters</b>  | <i>service-id</i> — Specifies a default secure service.<br><b>Values</b> <i>service-id</i> : 1 — 2147483648         |

## default-tunnel-template

|                    |                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>default-tunnel-template</b> <i>ipsec template identifier</i><br><b>no default-tunnel-template</b> |
| <b>Context</b>     | config>service>vprn>interface>sap>ipsec-gw                                                           |
| <b>Description</b> | This command configures the default tunnel policy template for the gateway.                          |
| <b>Parameters</b>  | <i>ipsec template id*</i> — [1..2048]                                                                |

## ike-policy \*\*\*\*

|                    |                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ike-policy</b> <i>ike-policy-id</i><br><b>no ike-policy</b>                                       |
| <b>Context</b>     | config>service>vprn>if>sap>ipsec-gw<br>config>service>vprn>ipsec-interface>sap>tunnel>dynamic-keying |
| <b>Description</b> | This command configures the IKE policy for the gateway.                                              |
| <b>Parameters</b>  | <i>ike-policy-id</i> — Specifies the IKE policy ID.                                                  |
| <b>Values</b>      | 1 — 2048                                                                                             |

## local-gateway-address

|                    |                                                                                   |
|--------------------|-----------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>local-gateway-address</b> <i>ip-address</i><br><b>no local-gateway-address</b> |
| <b>Context</b>     | config>service>vprn>if>sap>ipsec-gw                                               |
| <b>Description</b> | This command configures the ipsec-gateway local address.                          |
| <b>Parameters</b>  | <i>ip-address</i> — Specifies the IP unicast address.                             |

## pre-shared-key

|                    |                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>pre-shared-key</b> <i>key</i><br><b>no pre-shared-key</b>                                         |
| <b>Context</b>     | config>service>vprn>if>sap>ipsec-gw<br>config>service>vprn>ipsec-interface>sap>tunnel>dynamic-keying |
| <b>Description</b> | This command specifies the shared secret between the two peers forming the tunnel.                   |
| <b>Parameters</b>  | <i>key</i> — Specifies a pre-shared-key for dynamic-keying.                                          |

## multi-service-site

|                    |                                                                                                                                                                                                                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>multi-service-site</b> <i>customer-site-name</i><br><b>no multi-service-site</b> <i>customer-site-name</i>                                                                                                                                                                                                             |
| <b>Context</b>     | config>service>vprn>if>sap<br>config>service>vprn>sub-if>grp-if>sap                                                                                                                                                                                                                                                       |
| <b>Description</b> | This command creates a new customer site or edits an existing customer site with the <i>customer-site-name</i> parameter. A customer site is an anchor point to create an ingress and egress virtual scheduler hierarchy. When a site is created, it must be assigned to a chassis slot or port with the exception of the |

7750 SR-1 in which the slot is set to 1. When scheduler policies are defined for ingress and egress, the scheduler names contained in each policy are created according to the parameters defined in the policy. Multi-service customer sites exist for the sole purpose of creating a virtual scheduler hierarchy and making it available to queues on multiple Service Access Points (SAPs).

The scheduler policy association with the customer site normally prevents the scheduler policy from being deleted until after the scheduler policy is removed from the customer site. The multi-service-site object will generate a log message indicating that the association was deleted due to scheduler policy removal.

When the multi-service customer site is created, an ingress and egress scheduler policy association does not exist. This does not prevent the site from being assigned to a chassis slot or prevent service SAP assignment. After the site has been created, the ingress and egress scheduler policy associations can be assigned or removed at any time.

**Default** None — Each customer site must be explicitly created.

**Parameters** *customer-site-name*: — Each customer site must have a unique name within the context of the customer. If *customer-site-name* already exists for the customer ID, the CLI context changes to that site name for the purpose of editing the site scheduler policies or assignment. Any modifications made to an existing site will affect all SAPs associated with the site. Changing a scheduler policy association may cause new schedulers to be created and existing queues on the SAPs to no longer be orphaned. Existing schedulers on the site may cease to exist, causing queues relying on that scheduler to be orphaned.

If the *customer-site-name* does not exist, it is assumed that an attempt is being made to create a site of that name in the customer ID context. The success of the command execution depends on the following:

- The maximum number of customer sites defined for the chassis slot has not been met.
- The *customer-site-name* is valid.
- The **create** keyword is included in the command line syntax (if the system requires it).

When the maximum number of customer sites has been exceeded a configuration error occurs; the command will not execute and the CLI context will not change.

If the *customer-site-name* is invalid, a syntax error occurs; the command will not execute and the CLI context will not change.

**Values** Valid names consist of any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

## static-host

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Description</b> | This command configures a static host on this SAP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Syntax</b>      | <p><b>ip</b> <i>ip-address</i> — Specifies the IPv4 unicast address.</p> <p><b>mac</b> <i>ieee-address</i> — Specify this optional parameter when defining a static host. Every static host definition must have at least one address defined, IP or MAC.</p> <p><b>force</b> — Specifies the forced removal of the static host addresses.</p> <p><b>sla-profile</b> <i>sla-profile-name</i></p> <p>This optional parameter is used to specify an existing SLA profile name to be associated with the static subscriber host. The SLA profile is configured in the <b>config&gt;subscr-mgmt&gt;sla-profile</b> context.</p> |

## ancc-string

|                    |                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ancc-string</b> <i>ancc-string</i><br><b>no ancc-string</b>                              |
| <b>Context</b>     | config>service>vprn>if>sap>static-host<br>config>service>vprn>sub-if>grp-if>sap>static-host |
| <b>Description</b> | This command specifies the ANCP string associated to this SAP host.                         |
| <b>Parameters</b>  | <i>ancc-string</i> — Specifies the ANCP string up to 63 characters in length.               |

## app-profile

|                    |                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>app-profile</b> <i>app-profile-name</i><br><b>no app-profile</b>                             |
| <b>Context</b>     | config>service>vprn>if>sap>static-host<br>config>service>vprn>sub-if>grp-if>sap>static-host     |
| <b>Description</b> | This command specifies an application profile name.                                             |
| <b>Parameters</b>  | <i>app-profile-name</i> — Specifies the application profile name up to 32 characters in length. |

## inter-dest-id

|                    |                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>inter-dest-id</b> <i>intermediate-destination-id</i><br><b>no inter-dest-id</b>                |
| <b>Context</b>     | config>service>vprn>if>sap>static-host<br>config>service>vprn>sub-if>grp-if>sap>static-host       |
| <b>Description</b> | This command specifies to which intermediate destination (for example a DSLAM) this host belongs. |
| <b>Parameters</b>  | <i>intermediate-destination-id</i> — Specifies the intermediate destination ID.                   |

## managed-routes

|                    |                                                                  |
|--------------------|------------------------------------------------------------------|
| <b>Syntax</b>      | <b>managed-routes</b>                                            |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>sap>static-host>managed-routes |
| <b>Description</b> | This command configures managed routes.                          |

## route

|                    |                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>route</b> { <i>ip-prefix/length</i>   <i>ip-prefix netmask</i> } [ <b>create</b> ]<br><b>no route</b> { <i>ip-prefix/length</i>   <i>ip-prefix netmask</i> }                                                                                                                                                                                                        |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>sap>static-host>managed-routes                                                                                                                                                                                                                                                                                                       |
| <b>Description</b> | This command assigns managed-route to a given subscriber-host. As a consequence, a static-route pointing subscriber-host ip address as a next hop will be installed in FIB. Up to 16 managed routes per subscriber-host can be configured.<br><br>The <b>no</b> form of the command removes the respective route. Per default, there are no managed-routes configured. |

## sla-profile

|                    |                                                                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>sla-profile</b> <i>sla-profile-name</i><br><b>no sla-profile</b>                                                                                                                             |
| <b>Context</b>     | config>service>vprn>if>sap>static-host<br>config>service>vprn>sub-if>grp-if>sap>static-host                                                                                                     |
| <b>Description</b> | This command specifies an existing SLA profile name to be associated with the static subscriber host. The SLA profile is configured in the <b>config&gt;subscr-mgmt&gt;sla-profile</b> context. |
| <b>Parameters</b>  | <i>sla-profile-name</i> — Specifies the SLA profile name.                                                                                                                                       |

## sub-profile

|                    |                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>sub-profile</b> <i>sub-profile-name</i><br><b>no sub-profile</b>                                          |
| <b>Context</b>     | config>service>vprn>if>sap>static-host<br>config>service>vprn>sub-if>grp-if>sap>static-host                  |
| <b>Description</b> | This command specifies an existing subscriber profile name to be associated with the static subscriber host. |
| <b>Parameters</b>  | <i>sub-profile-name</i> — Specifies the sub-profile name.                                                    |

## subscriber

|                    |                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>subscriber</b> <i>sub-ident</i><br><b>no subscriber</b>                                                             |
| <b>Context</b>     | config>service>vprn>if>sap>static-host<br>config>service>vprn>sub-if>grp-if>sap>static-host                            |
| <b>Description</b> | This command specifies an existing subscriber identification profile to be associated with the static subscriber host. |
| <b>Parameters</b>  | <i>sub-ident</i> — Specifies the subscriber identification/                                                            |

## subscriber-sap-id

|                    |                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] subscriber-sap-id</b>                                                               |
| <b>Context</b>     | config>service>vprn>if>sap>static-host<br>config>service>vprn>sub-if>grp-if>sap>static-host |
| <b>Description</b> | This command enables using the SAP ID as subscriber id.                                     |
| <b>Parameters</b>  | <b>subscriber-sap-id</b> — Specifies to use the sap-id as the subscriber-id.                |

## queue-override

|                    |                                                                                                                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] queue-override</b>                                                                                                                                                                                                  |
| <b>Context</b>     | config>service>vprn>if>sap>egress<br>config>service>vprn>if>sap>ingress<br>config>service>vprn>ipsec-if>sap>egress<br>config>service>vprn>ipsec-if>sap>ingress                                                              |
| <b>Description</b> | This command enables the context to configure override values for the specified SAP egress or ingress QoS queue. These values override the corresponding ones specified in the associated SAP egress or ingress QoS policy. |

## queue

|                    |                                                                                                                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] queue</b> <i>queue-id</i>                                                                                                                                                                                          |
| <b>Context</b>     | config>service>vprn>if>sap>egress>queue-override<br>config>service>vprn>if>sap>ingress>queue-override<br>config>service>vprn>ipsec-if>sap>egress>queue-override<br>config>service>vprn>ipsec-if>sap>ingress>queue-override |
| <b>Description</b> | This command specifies the ID of the queue whose parameters are to be overridden.                                                                                                                                          |
| <b>Parameters</b>  | <i>queue-id</i> — The queue ID whose parameters are to be overridden.<br><b>Values</b> 1 — 32                                                                                                                              |

## adaptation-rule

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Description</b> | <p>This command can be used to override specific attributes of the specified queue's adaptation rule parameters. The adaptation rule controls the method used by the system to derive the operational CIR and PIR settings when the queue is provisioned in hardware. For the CIR and PIR parameters individually, the system attempts to find the best operational rate depending on the defined constraint.</p> <p>The <b>no</b> form of the command removes any explicitly defined constraints used to derive the operational CIR and PIR created by the application of the policy. When a specific <b>adaptation-rule</b> is removed, the default constraints for <b>rate</b> and <b>cir</b> apply.</p>                                                                                                                                                                                                         |
| <b>Default</b>     | no adaptation-rule                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Parameters</b>  | <p><b>pir</b> — The <b>pir</b> parameter defines the constraints enforced when adapting the PIR rate defined within the <b>queue queue-id rate</b> command. The <b>pir</b> parameter requires a qualifier that defines the constraint used when deriving the operational PIR for the queue. When the <b>rate</b> command is not specified, the default applies.</p> <p><b>cir</b> — The <b>cir</b> parameter defines the constraints enforced when adapting the CIR rate defined within the <b>queue queue-id rate</b> command. The <b>cir</b> parameter requires a qualifier that defines the constraint used when deriving the operational CIR for the queue. When the <b>cir</b> parameter is not specified, the default constraint applies.</p> <p><i>adaptation-rule</i> — Specifies the criteria to use to compute the operational CIR and PIR values for this queue, while maintaining a minimum offset.</p> |

- Values**
- max** — The **max** (maximum) keyword is mutually exclusive with the **min** and **closest** options. When **max** is defined, the operational PIR for the queue will be equal to or less than the administrative rate specified using the **rate** command.
  - min** — The **min** (minimum) keyword is mutually exclusive with the **max** and **closest** options. When **min** is defined, the operational PIR for the queue will be equal to or greater than the administrative rate specified using the **rate** command.
  - closest** — The **closest** parameter is mutually exclusive with the **min** and **max** parameter. When **closest** is defined, the operational PIR for the queue will be the rate closest to the rate specified using the **rate** command.

| <b>Description</b> | <p>This command configures the average frame overhead to define the average percentage that the offered load to a queue will expand during the frame encapsulation process before sending traffic on-the-wire. While the avg-frame-overhead value may be defined on any queue, it is only used by the system for queues that egress a Sonet or SDH port or channel. Queues operating on egress Ethernet ports automatically calculate the frame encapsulation overhead based on a 20 byte per packet rule (8 bytes for preamble and 12 bytes for Inter-Frame Gap).</p> <p>When calculating the frame encapsulation overhead for port scheduling purposes, the system determines the following values:</p> <ul style="list-style-type: none"> <li>Offered-load — The offered-load of a queue is calculated by starting with the queue depth in octets, adding the received octets at the queue and subtracting queue discard octets. The result is the number of octets the queue has available to transmit. This is the packet based offered-load.</li> <li>Frame encapsulation overhead — Using the avg-frame-overhead parameter, the frame encapsulation overhead is simply the queue's current offered-load (how much has been received by the queue) multiplied by the avg-frame-overhead. If a queue had an offered load of 10000 octets and the avg-frame-overhead equals 10%, the frame encapsulation overhead would be 10000 x 0.1 or 1000 octets.</li> </ul> <p>For egress Ethernet queues, the frame encapsulation overhead is calculated by multiplying the number of offered-packets for the queue by 20 bytes. If a queue was offered 50 packets then the frame encapsulation overhead would be 50 x 20 or 1000 octets.</p> <ul style="list-style-type: none"> <li>Frame based offered-load — The frame based offered-load is calculated by adding the offered-load to the frame encapsulation overhead. If the offered-load is 10000 octets and the encapsulation overhead was 1000 octets, the frame based offered-load would equal 11000 octets.</li> <li>Packet to frame factor — The packet to frame factor is calculated by dividing the frame encapsulation overhead by the queue's offered-load (packet based). If the frame encapsulation overhead is 1000 octets and the offered-load is 10000 octets then the packet to frame factor would be 1000 / 10000 or 0.1. When in use, the avg-frame-overhead will be the same as the packet to frame factor making this calculation unnecessary.</li> </ul> |

- **Frame based CIR** — The frame based CIR is calculated by multiplying the packet to frame factor with the queue's configured CIR and then adding that result to that CIR. If the queue CIR is set at 500 octets and the packet to frame factor equals 0.1, the frame based CIR would be 500 x 1.1 or 550 octets.
- **Frame based within-cir offered-load** — The frame based within-cir offered-load is the portion of the frame based offered-load considered to be within the frame-based CIR. The frame based within-cir offered-load is the lesser of the frame based offered-load and the frame based CIR. If the frame based offered-load equaled 11000 octets and the frame based CIR equaled 550 octets, the frame based within-cir offered-load would be limited to 550 octets. If the frame based offered-load equaled 450 octets and the frame based CIR equaled 550 octets, the frame based within-cir offered-load would equal 450 octets (or the entire frame based offered-load).

As a special case, when a queue or associated intermediate scheduler is configured with a CIR-weight equal to 0, the system automatically sets the queue's frame based within-cir offered-load to 0, preventing it from receiving bandwidth during the port scheduler's within-cir pass.

- **Frame based PIR** — The frame based PIR is calculated by multiplying the packet to frame factor with the queue's configured PIR and then adding the result to that PIR. If the queue PIR is set to 7500 octets and the packet to frame factor equals 0.1, the frame based PIR would be 7500 x 1.1 or 8250 octets.
- **Frame based within-pir offered-load** — The frame based within-pir offered-load is the portion of the frame based offered-load considered to be within the frame based PIR. The frame based within-pir offered-load is the lesser of the frame based offered-load and the frame based PIR. If the frame based offered-load equaled 11000 octets and the frame based PIR equaled 8250 octets, the frame based within-pir offered-load would be limited to 8250 octets. If the frame based offered-load equaled 7000 octets and the frame based PIR equaled 8250 octets, the frame based within-pir offered load would equal 7000 octets.

**Port scheduler operation using frame transformed rates** — The port scheduler uses the frame based rates to determine the maximum rates that each queue may receive during the within-cir and above-cir bandwidth allocation passes. During the within-cir pass, a queue may receive up to its frame based within-cir offered-load. The maximum it may receive during the above-cir pass is the difference between the frame based within-pir offered load and the amount of actual bandwidth allocated during the within-cir pass.

**SAP and subscriber SLA-profile average frame overhead override** — The average frame overhead parameter on a sap-egress may be overridden at an individual egress queue basis. On each SAP and within the sla-profile policy used by subscribers an avg-frame-overhead command may be defined under the queue-override context for each queue. When overridden, the queue instance will use its local value for the average frame overhead instead of the sap-egress defined overhead.

The **no** form of this command restores the average frame overhead parameter for the queue to the default value of 0 percent. When set to 0, the system uses the packet based queue statistics for calculating port scheduler priority bandwidth allocation. If the no avg-frame-overhead command is executed in a queue-override queue id context, the avg-frame-overhead setting for the queue within the sap-egress QoS policy takes effect.

| <b>Description</b> | <p>This command can be used to override specific attributes of the specified queue's CBS parameters.</p> <p>It is permissible, and possibly desirable, to oversubscribe the total CBS reserved buffers for a given access port egress buffer pool. Oversubscription may be desirable due to the potential large number of service queues and the economy of statistical multiplexing the individual queue's CBS setting into the defined reserved total.</p> <p>When oversubscribing the reserved total, it is possible for a queue depth to be lower than its CBS setting and still not receive a buffer from the buffer pool for an ingress frame. As more queues are using their CBS buffers and the total in use exceeds the defined reserved total, essentially the buffers are being removed from the shared portion of the pool without the shared in use average and total counts being decremented. This can affect the operation of the high and low priority RED slopes on the pool, causing them to miscalculate when to start randomly drop packets.</p> <p>If the CBS value is larger than the MBS value, an error will occur, preventing the CBS change.</p> <p>The <b>no</b> form of this command returns the CBS size to the default value.</p> |
| <b>Default</b>     | no cbs                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <p><i>size-in-kbytes</i> — The size parameter is an integer expression of the number of kilobytes reserved for the queue. If a value of 10KBytes is desired, enter the value 10. A value of 0 specifies that no reserved buffers are required by the queue (a minimal reserved size can still be applied for scheduling purposes).</p> <p><b>Values</b>      0 — 131072 or default</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## high-prio-only

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Context</b>     | config>service>vprn>if>sap>egress>queue-override>queue<br>config>service>vprn>if>sap>ingress>queue-override>queue<br>config>service>vprn>ipsec-if>sap>egress>queue-override>queue<br>config>service>vprn>ipsec-if>sap>ingress>queue-override>queue                                                                                                                                                                                                                                                                       |
| <b>Description</b> | <p>This command can be used to override specific attributes of the specified queue's high-prio-only parameters. The <b>high-prio-only</b> command configures the percentage of buffer space for the queue, used exclusively by high priority packets.</p> <p>The priority of a packet can only be set in the SAP ingress QoS policy and is only applicable on the ingress queues for a SAP. The <b>high-prio-only</b> parameter is used to override the default value derived from the <b>network-queue</b> command.</p> |

The defined **high-prio-only** value cannot be greater than the MBS size of the queue. Attempting to change the MBS to a value smaller than the high priority reserve will generate an error and fail execution. Attempting to set the **high-prio-only** value larger than the current MBS size will also result in an error and fail execution.

The **no** form of this command restores the default high priority reserved size.

**Parameters**     *percent* — The *percent* parameter is the percentage reserved for high priority traffic on the queue. If a value of 10KBytes is desired, enter the value 10. A value of 0 specifies that none of the MBS of the queue will be reserved for high priority traffic. This does not affect RED slope operation for packets attempting to be queued.

**Values**         0 — 100 | default

## mbs

**Syntax**         **mbs** {*size-in-kbytes* | **default**}  
**no mbs**

**Context**         config>service>vprn>if>sap>egress>queue-override>queue  
config>service>vprn>ipsec-if>sap>egress>queue-override>queue

**Description**     This command can be used to override specific attributes of the specified queue's MBS parameters. The MBS is a mechanism to override the default maximum size for the queue.

The sum of the MBS for all queues on an egress access port can oversubscribe the total amount of buffering available. When congestion occurs and buffers become scarce, access to buffers is controlled by the RED slope a packet is associated with. A queue that has not exceeded its MBS size is not guaranteed that a buffer will be available when needed or that the packet's RED slope will not force the discard of the packet. Setting proper CBS parameters and controlling CBS oversubscription is one major safeguard to queue starvation (when a queue does not receive its fair share of buffers). Another is properly setting the RED slope parameters for the needs of services on this port or channel.

If the CBS value is larger than the MBS value, an error will occur, preventing the MBS change.

The **no** form of this command returns the MBS size assigned to the queue.

**Default**           default

**Parameters**     *size-in-kbytes* — The *size* parameter is an integer expression of the maximum number of kilobytes of buffering allowed for the queue. For a value of 100 kbps, enter the value 100. A value of 0 causes the queue to discard all packets.

**Values**           0 — 131072 or default

## mbs

Attempting to change the MBS to a value smaller than the high priority reserve will generate an error and fail execution. Attempting to set the high-prio-only value larger than the current MBS size will also result in an error and fail execution.</p> <p>The <b>no</b> form of this command returns the MBS size assigned to the queue to the value.</p> |
| <b>Default</b>     | default                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <p><i>size-in-kbytes</i> — The size parameter is an integer expression of the maximum number of kilobytes of buffering allowed for the queue. For a value of 100 kbps, enter the value 100. A value of 0 causes the queue to discard all packets.</p> <p><b>Values</b>      0 — 131072 or default</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Description</b> | This command can be used to override specific attributes of the specified queue's Peak Information Rate (PIR) and the Committed Information Rate (CIR) parameters. The PIR defines the maximum rate that the queue can transmit packets out an egress interface (for SAP egress queues). Defining a          |

PIR does not necessarily guarantee that the queue can transmit at the intended rate. The actual rate sustained by the queue can be limited by oversubscription factors or available egress bandwidth.

The CIR defines the rate at which the system prioritizes the queue over other queues competing for the same bandwidth. In-profile packets are preferentially queued by the system at egress and at subsequent next hop nodes where the packet can traverse. To be properly handled as in- or out-of-profile throughout the network, the packets must be marked accordingly for profiling at each hop.

The CIR can be used by the queue's parent commands *cir-level* and *cir-weight* parameters to define the amount of bandwidth considered to be committed for the child queue during bandwidth allocation by the parent scheduler.

The **rate** command can be executed at any time, altering the PIR and CIR rates for all queues created through the association of the SAP egress QoS policy with the *queue-id*.

The **no** form of the command returns all queues created with the *queue-id* by association with the QoS policy to the default PIR and CIR parameters (**max**, 0).

| <b>Default</b>    | <b>rate max cir 0</b> — The <b>max</b> default specifies the amount of bandwidth in kilobits per second (thousand bits per second). The <b>max</b> value is mutually exclusive to the <b>pir-rate</b> value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b> | <p><i>pir-rate</i> — Defines the administrative PIR rate, in kilobits, for the queue. When the <b>rate</b> command is executed, a valid PIR setting must be explicitly defined. When the <b>rate</b> command has not been executed, the default PIR of <b>max</b> is assumed.</p> <p>Fractional values are not allowed and must be given as a positive integer.</p> <p>The actual PIR rate is dependent on the queue's <b>adaptation-rule</b> parameters and the actual hardware where the queue is provisioned.</p> <p><b>Values</b>      1 — 100000000</p> <p><b>Default</b>      max</p> <p><i>cir-rate</i> — The <b>cir</b> parameter overrides the default administrative CIR used by the queue. When the <b>rate</b> command is executed, a CIR setting is optional. When the <b>rate</b> command has not been executed or the <b>cir</b> parameter is not explicitly specified, the default CIR (0) is assumed.</p> <p>Fractional values are not allowed and must be given as a positive integer. The <b>sum</b> keyword specifies that the CIR be used as the summed CIR values of the children schedulers or queues.</p> <p><b>Values</b>      0 — 100000000, <b>max</b>, <b>sum</b></p> <p><b>Default</b>      0</p> |

| <b>Description</b> | <p>This command can be used to override specific attributes of the specified scheduler name.</p> <p>A scheduler defines a bandwidth controls that limit each child (other schedulers and queues) associated with the scheduler. Scheduler objects are created within the hierarchical tiers of the policy. It is assumed that each scheduler created will have queues or other schedulers defined as child associations. The scheduler can be a child (take bandwidth from a scheduler in a higher tier, except for schedulers created in tier 1). A total of 32 schedulers can be created within a single scheduler policy with no restriction on the distribution between the tiers.</p> <p>Each scheduler must have a unique name within the context of the scheduler policy; however the same name can be reused in multiple scheduler policies. If <i>scheduler-name</i> already exists within the policy tier level (regardless of the inclusion of the keyword create), the context changes to that scheduler name for the purpose of editing the scheduler parameters. Modifications made to an existing scheduler are executed on all instantiated schedulers created through association with the policy of the edited scheduler. This can cause queues or schedulers to become orphaned (invalid parent association) and adversely affect the ability of the system to enforce service level agreements (SLAs).</p> <p>If the <i>scheduler-name</i> exists within the policy on a different tier (regardless of the inclusion of the keyword create), an error occurs and the current CLI context will not change.</p> <p>If the <i>scheduler-name</i> does not exist in this or another tier within the scheduler policy, it is assumed that an attempt is being made to create a scheduler of that name. The success of the command execution is dependent on the following:</p> <ol style="list-style-type: none"> <li>1. The maximum number of schedulers has not been configured.</li> <li>2. The provided <i>scheduler-name</i> is valid.</li> <li>3. The <b>create</b> keyword is entered with the command if the system is configured to require it (enabled in the <b>environment create</b> command).</li> </ol> <p>When the maximum number of schedulers has been exceeded on the policy, a configuration error occurs and the command will not execute, nor will the CLI context change.</p> <p>If the provided scheduler-name is invalid according to the criteria below, a name syntax error will occur, the command will not execute, and the CLI context will not change.</p> |
| <b>Parameters</b>  | <p><i>scheduler-name</i> — The name of the scheduler.</p> <p><b>Values</b> Valid names consist of any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.</p> <p><b>Default</b> None. Each scheduler must be explicitly created.</p> <p><i>create</i> — This optional keyword explicitly specifies that it is acceptable to create a scheduler with the given <i>scheduler-name</i>. If the <b>create</b> keyword is omitted, <b>scheduler-name</b> is not created when the system environment variable create is set to true. This safeguard is meant to avoid accidental</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

creation of system objects (such as schedulers) while attempting to edit an object with a mistyped name or ID. The keyword has no effect when the object already exists.

## rate

| <b>Description</b> | <p>This command can be used to override specific attributes of the specified scheduler rate. The <b>rate</b> command defines the maximum bandwidth that the scheduler can offer its child queues or schedulers. The maximum rate is limited to the amount of bandwidth the scheduler can receive from its parent scheduler. If the scheduler has no parent, the maximum rate is assumed to be the amount available to the scheduler. When a parent is associated with the scheduler, the CIR parameter provides the amount of bandwidth to be considered during the parent scheduler's 'within CIR' distribution phase.</p> <p>The actual operating rate of the scheduler is limited by bandwidth constraints other than its maximum rate. The scheduler's parent scheduler may not have the available bandwidth to meet the scheduler's needs or the bandwidth available to the parent scheduler could be allocated to other child schedulers or child queues on the parent based on higher priority. The children of the scheduler may not need the maximum rate available to the scheduler due to insufficient offered load or limits to their own maximum rates.</p> <p>When a scheduler is defined without specifying a rate, the default rate is <b>max</b>. If the scheduler is a root scheduler (no parent defined), the default maximum rate must be changed to an explicit value. Without this explicit value, the scheduler will assume that an infinite amount of bandwidth is available and allow all child queues and schedulers to operate at their maximum rates.</p> <p>The <b>no</b> form of this command returns all queues created with this <i>queue-id</i> by association with the QoS policy to the default PIR and CIR parameters.</p> |
| <b>Parameters</b>  | <p><i>pir-rate</i> — The <b>pir</b> parameter accepts a step multiplier value that specifies the multiplier used to determine the PIR rate at which the queue will operate. A value of 0 to 100000000 or the keyword <b>max</b> or <b>sum</b> is accepted. Any other value will result in an error without modifying the current PIR rate.</p> <p>To calculate the actual PIR rate, the rate described by the queue's <b>rate</b> is multiplied by the <i>pir-rate</i>.</p> <p>The SAP ingress context for PIR is independent of the defined forwarding class (fc) for the queue. The default <b>pir</b> and definable range is identical for each class. The PIR in effect for a queue defines the maximum rate at which the queue will be allowed to forward packets in a given second, thus shaping the queue's output.</p> <p>The PIR parameter for SAP ingress queues do not have a negate (<b>no</b>) function. To return the queue's PIR rate to the default value, that value must be specified as the PIR value.</p> <p><b>Values</b>      1 — 100000000, <b>max</b></p> <p><b>Default</b>      max</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

*cir cir-rate* — The **cir** parameter accepts a step-multiplier value that specifies the multiplier used to determine the CIR rate at which the queue will operate. A value of 0 to 250 or the keyword **max** is accepted. Any other value will result in an error without modifying the current CIR rate.

To calculate the actual CIR rate, the rate described by the **rate pir** *pir-rate* is multiplied by the *cir cir-rate*. If the **cir** is set to **max**, then the CIR rate is set to infinity.

The SAP ingress context for CIR is dependent on the defined forwarding class (fc) for the queue. The default CIR and definable range is different for each class. The CIR in effect for a queue defines both its profile (in or out) marking level as well as the relative importance compared to other queues for scheduling purposes during congestion periods.

**Values**      0 — 10000000, **max**, **sum**

**Default**     sum

## ETH-CFM Service Commands

### eth-cfm

|                    |                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>eth-cfm</b>                                                                                          |
| <b>Context</b>     | config>service>vprn>if>sap<br>config>service>vprn>if>spoke-sdp<br>config>service>vprn>sub-if>grp-if>sap |
| <b>Description</b> | This command enables the context to configure ETH-CFM parameters.                                       |

### mep

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Context</b>     | config>service>vprn>if>sap>eth-cfm<br>config>service>vprn>if>spoke-sdp>eth-cfm<br>config>service>vprn>sub-if>grp-if>sap>eth-cfm                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Description</b> | This command configures a SAP or spoke SDP eth-cfm maintenance endpoint (MEP).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <p><i>mep-id</i> — Specifies the maintenance association end point identifier.</p> <p><b>Values</b> 1 — 8191</p> <p><i>md-index</i> — Specifies the maintenance domain (MD) index value.</p> <p><b>Values</b> 1 — 4294967295</p> <p><i>ma-index</i> — Specifies the MA index value.</p> <p><b>Values</b> 1 — 4294967295</p> <p><b>direction up down</b> — Indicates the direction in which the maintenance association (MEP or MIP) faces on the bridge port.</p> <p>down — Sends continuity check messages away from the MAC relay entity.</p> <p>up — Sends continuity check messages towards the MAC relay entity.</p> |

### ccm-enable

|                    |                                                                                        |
|--------------------|----------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] ccm-enable</b>                                                                 |
| <b>Context</b>     | config>service>vprn>if>sap>eth-cfm>mep<br>config>service>vprn>if>spoke-sdp>eth-cfm>mep |
| <b>Description</b> | This command enables the generation of CCM messages.                                   |

The **no** form of the command disables the generation of CCM messages.

## ccm-ltm-priority

|                    |                                                                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ccm-ltm-priority</b> <i>priority</i><br><b>no ccm-ltm-priority</b>                                                                                                       |
| <b>Context</b>     | config>service>vprn>if>sap>eth-cfm>mep<br>config>service>vprn>if>spoke-sdp>eth-cfm>mep                                                                                      |
| <b>Description</b> | This command specifies the priority value for CCMs and LTMs transmitted by the MEP.<br>The <b>no</b> form of the command removes the priority value from the configuration. |
| <b>Default</b>     | The highest priority on the bridge-port.                                                                                                                                    |
| <b>Parameters</b>  | <i>priority</i> — Specifies the priority of CCM and LTM messages.<br><b>Values</b> 0 — 7                                                                                    |

## fault-propagation-enable

|                    |                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>fault-propagation-enable</b> { <i>use-if-tlv</i>   <i>suspend-ccm</i> }<br><b>no fault-propagation-enable</b>                    |
| <b>Context</b>     | config>service>vprn>if>sap>eth-cfm>mep<br>config>service>vprn>if>spoke-sdp>eth-cfm>mep                                              |
| <b>Description</b> | This command configures the fault propagation for the MEP.                                                                          |
| <b>Parameters</b>  | <b>use-if-tlv</b> — Specifies to use the interface TLV.<br><b>suspend-ccm</b> — Specifies to suspend the continuity check messages. |

## low-priority-defect

|                    |                                                                                                                                                                                                                                                                                                                                                                                     |        |                                                                    |               |                                                              |            |                                                |         |                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|--------------------------------------------------------------------|---------------|--------------------------------------------------------------|------------|------------------------------------------------|---------|---------------------------------|
| <b>Syntax</b>      | <b>low-priority-defect</b> { <i>allDef</i>   <i>macRemErrXcon</i>   <i>remErrXcon</i>   <i>errXcon</i>   <i>xcon</i>   <i>noXcon</i> }                                                                                                                                                                                                                                              |        |                                                                    |               |                                                              |            |                                                |         |                                 |

| <b>Description</b> | <p>This command specifies a default SLA profile for this SAP. The SLA profile must be defined prior to associating the profile with a SAP in the <b>config&gt;subscriber-mgmt&gt;sla-profile</b> context.</p> <p>An SLA profile is a named group of QoS parameters used to define per service QoS for all subscriber hosts common to the same subscriber within a provider service offering. A single SLA profile may define the QoS parameters for multiple subscriber hosts. SLA profiles are maintained in two locations, the subscriber identification policy and the subscriber profile templates. After a subscriber host is associated with an SLA profile name, either the subscriber identification policy used to identify the subscriber or the subscriber profile associated with the subscriber host must contain an SLA profile with that name. If both the subscriber identification policy and the subscriber profile contain the SLA profile name, the SLA profile in the subscriber profile is used.</p> <p>The <b>no</b> form of the command removes the default SLA profile from the SAP configuration.</p> |

|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>def-sub-profile</b> <i>default-subscriber-profile-name</i>                                                                                                                                                        |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>sap>sub-sla-mgmt                                                                                                                                                                   |
| <b>Description</b> | This command specifies a default subscriber profile for this SAP. The subscriber profile must be defined prior to associating the profile with a SAP in the <b>config&gt;subscriber-mgmt&gt;sub-profile</b> context. |

A subscriber profile defines the aggregate QoS for all hosts within a subscriber context. This is done through the definition of the egress and ingress scheduler policies that govern the aggregate SLA for subscriber using the subscriber profile. Subscriber profiles also allow for specific SLA profile definitions when the default definitions from the subscriber identification policy must be overridden.

The **no** form of the command removes the default SLA profile from the SAP configuration.

**Parameters** *default-sub-profile* — Specifies a default subscriber profile for this SAP. The subscriber profile must be defined prior to associating the profile with a SAP in the **config>subscriber-mgmt>sub-profile** context.

## multi-sub-sap

**Syntax** **multi-sub-sap** [*number-of-sub*]  
**no multi-sub-sap**

**Context** config>service>vprn>sub-if>grp-if>sap>sub-sla-mgmt

**Description** This command configures the maximum number of subscribers for this SAP.  
 The **no** form of this command returns the default value.

**Parameters** *number-of-sub* — Specifies the maximum number of subscribers for this SAP.

**Values** 2 — 8000

## single-sub-parameters

**Syntax** **single-sub-parameters**

**Context** config>service>vprn>sub-if>grp-if>sap>sub-sla-mgmt

**Description** This command enables the context to configure single subscriber parameters for this SAP.

## non-sub-traffic

**Syntax** **non-sub-traffic sub-profile** *sub-profile-name* **sla-profile** *sla-profile-name* [**subscriber** *sub-ident-string*]  
**no non-sub-traffic**

**Context** config>service>vprn>sub-if>grp-if>sap>sub-sla-mgmt>single-sub

**Description** This command configures non-subscriber traffic profiles.  
 The **no** form of the command removes the profiles and disables the feature.

**Parameters** **sub-profile** *sub-profile-name* — Specifies an existing subscriber profile name to be associated with the static subscriber host. The subscriber profile is configured in the **config>subscr-mgmt>sub-profile** context.

**sla-profile** *sla-profile-name* — Specifies an existing SLA profile name to be associated with the static subscriber host. The SLA profile is configured in the **config>subscr-mgmt>sla-profile** context.

**subscriber** *sub-ident-string* — Specifies an existing subscriber identification profile to be associated with the static subscriber host. The subscriber identification profile is configured in the **config>subscr-mgmt>sub-ident-policy** context. The subscriber information is used by the VPRN SAP arp-reply-agent to determine the proper handling of received ARP requests from subscribers.

- For VPRN SAPs with **arp-reply-agent** enabled with the optional *sub-ident* parameter, the static subscriber host's *sub-ident-string* is used to determine whether an ARP request received on the SAP is sourced from a host belonging to the same subscriber as the destination host. When both the destination and source hosts from the ARP request are known on the SAP and the subscriber identifications do not match, the ARP request may be forwarded to the rest of the VPRN destinations.

If the static subscriber host's *sub-ident* string is not defined, the host is not considered to belong to the same subscriber as another host on the SAP.

If source or destination host is unknown, the hosts are not considered to belong to the same subscriber. ARP messages from unknown hosts are subject to anti-spoof filtering rules applied at the SAP.

If *sub-ident* is not enabled on the SAP arp-reply-agent, subscriber identification matching is not performed on ARP requests received on the SAP.

ARP requests are never forwarded back to the same SAP or within the receiving SAP's split horizon group.

### profiled-traffic-only

|                    |                                                                                                                     |

| <b>Description</b> | This command associates a subscriber identification policy to this SAP. The subscriber identification policy must be defined prior to associating the profile with a SAP in the <b>config&gt;subscriber-mgmt&gt;sub-ident-policy</b> context.<br><br>Subscribers are managed by the system through the use of subscriber identification strings. A subscriber identification string uniquely identifies a subscriber. For static hosts, the subscriber identification string is explicitly defined with each static subscriber host. |

For dynamic hosts, the subscriber identification string must be derived from the DHCP ACK message sent to the subscriber host. The default value for the string is the content of Option 82 CIRCUIT-ID and REMOTE-ID fields interpreted as an octet string. As an option, the DHCP ACK message may be processed by a subscriber identification policy which has the capability to parse the message into an alternative ASCII or octet string value.

When multiple hosts on the same port are associated with the same subscriber identification string they are considered to be host members of the same subscriber.

The **no** form of the command removes the default subscriber identification policy from the SAP configuration.

**Default** no sub-ident-policy

**Parameters** *sub-ident-policy-name* — Specifies a subscriber identification policy for this SAP. The subscriber profile must be defined prior to associating the profile with a SAP in the **config>subscriber-mgmt>sub-ident-policy** context.

## srrp

**Syntax** [**no**] **srrp** *srrp-id*

**Context** config>service>vprn>sub-if>grp-if

**Description** This command creates an SRRP instance on a group IP interface. An SRRP instance manages all subscriber subnets within the group interfaces subscriber IP interface or other subscriber IP interfaces that are associated through a wholesale/retail relationship. Only one unique SRRP instance can be configured per group interface.

The **no** form of the command removes an SRRP instance from a group IP interface. Once removed, the group interface ignores ARP requests for the SRRP gateway IP addresses that may exist on subscriber subnets associated with the group IP interface. Then the group interface stops routing using the redundant IP interface associated with the group IP interface and will stop routing with the SRRP gateway MAC address. Ingress packets destined to the SRRP gateway MAC will also be silently discarded. This is the same behavior as a group IP interface that is disabled (shutdown).

**Default** no srrp

**Parameters** *srrp-id* — Specifies a 32 bit instance ID that must be unique to the system. The instance ID must also match the instance ID used by the remote router that is participating in the same SRRP context. SRRP is intended to perform a function similar to VRRP where adjacent IP hosts within local subnets use a default gateway to access IP hosts on other subnets.

**Values** 1 — 4294967295

| <b>Description</b> | <p>This command overrides the default SRRP gateway MAC address used by the SRRP instance. Unless specified, the system uses the same base MAC address for all SRRP instances with the last octet overridden by the lower 8 bits of the SRRP instance ID. The same SRRP gateway MAC address should be in-use by both the local and remote routers participating in the same SRRP context.</p> <p>One reason to change the default SRRP gateway MAC address is if two SRRP instances sharing the same broadcast domain are using the same SRRP gateway MAC. The system will use the SRRP instance ID to separate the SRRP messages (by ignoring the messages that does not match the local instance ID), but a unique SRRP gateway MAC is essential to separate the routed packets for each gateway IP address.</p> <p>The <b>no</b> form of the command removes the explicit SRRP gateway MAC address from the SRRP instance. The SRRP gateway MAC address can only be changed or removed when the SRRP instance is shutdown.</p> |
| <b>Parameters</b>  | <p><i>mac-address</i> — Specifies a MAC address that is used to override the default SRRP base MAC address</p> <p><b>Values</b> Any MAC address except all zeros, broadcast or multicast addresses. The offset is expressed in normal Ethernet MAC address notation. The defined gw-mac cannot be 00:00:00:00:00:00, ff:ff:ff:ff:ff:ff or any multicast address.</p> <p>If not specified, the system uses the default SRRP gateway MAC address with the last octet set to the 8 least significant bits of the SRRP instance ID.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Description</b> | <p>This command defines the interval between SRRP advertisement messages sent when operating in the master state. The interval is also the basis for setting the master-down timer used to determine when the master is no longer sending. The system uses three times the keep-alive interval to set the timer. Every time an SRRP advertisement is seen that is better than the local priority, the timer is reset. If the timer expires, the SRRP instance assumes that a master does not exist and initiates the attempt to become master.</p> <p>When in backup state, the SRRP instance takes the keep-alive interval of the master as represented in the masters SRRP advertisement message. Once in master state, the SRRP instance uses its own configured keep-alive interval.</p> <p>The keep-alive-interval may be changed at anytime, but will have no effect until the SRRP instance is in the master state.</p> <p>The <b>no</b> form of the command restores the default interval.</p> |

|                   |                                                                                                                                         |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>interval</i> — Specifies the interval, in milliseconds, between SRRP advertisement messages sent when operating in the master state. |
| <b>Values</b>     | 1 — 100                                                                                                                                 |
| <b>Default</b>    | 10 milliseconds                                                                                                                         |

## message-path

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Description</b> | <p>This command defines a specific SAP for SRRP in-band messaging. A message-path SAP must be defined prior to activating the SRRP instance. The defined SAP must exist on the SRRP instances group IP interface for the command to succeed and cannot currently be associated with any dynamic or static subscriber hosts. Once a group IP interface SAP has been defined as the transmission path for SRRP Advertisement messages, it cannot be administratively shutdown, will not support static or dynamic subscriber hosts and cannot be removed from the group IP interface.</p> <p>The SRRP instance message-path command may be executed at anytime on the SRRP instance. Changing the message SAP will fail if a dynamic or static subscriber host is associated with the new SAP. Once successfully changed, the SRRP instance will immediately disable anti-spoof on the SAP and start sending SRRP Advertisement messages if the SRRP instance is activated.</p> <p>Changing the current SRRP message SAP on an active pair of routers should be done in the following manner:</p> <ol style="list-style-type: none"> <li>1. Shutdown the backup SRRP instance.</li> <li>2. Change the message SAP on the shutdown node.</li> <li>3. Change the message SAP on the active master node.</li> <li>4. Re-activate the shutdown SRRP instance.</li> </ol> <p>Shutting down the backup SRRP instance prevents the SRRP instances from becoming master due to temporarily using differing message path SAPs.</p> <p>If an MCS peering is operational between the redundant nodes and the SRRP instance has been associated with the peering, the designated message path SAP will be sent from each member.</p> <p>The <b>no</b> form of the command can only be executed when the SRRP instance is shutdown. Executing no message-path allows the existing SAP to be used for subscriber management functions. A new message-path SAP must be defined prior to activating the SRRP instance.</p> |
| <b>Parameters</b>  | <i>sap-id</i> — Specifies the physical port identifier portion of the SAP definition. See <a href="#">Common CLI Command Descriptions on page 1933</a> for command syntax.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Description</b> | <p>This command associates one or more VRRP policies with the SRRP instance. A VRRP policy is a collection of connectivity and verification tests used to manipulate the in-use priorities of VRRP and SRRP instances. A VRRP policy can test the link state of ports, ping IP hosts, discover the existence of routes in the routing table or the ability to reach L2 hosts. When one or more of these tests fail, the VRRP policy has the option of decrementing or setting an explicit value for the in-use priority of an SRRP instance.</p> <p>More than one VRRP policy may be associated with an SRRP instance. When more than one VRRP policy is associated with an SRRP instance the delta decrement of the in-use priority is cumulative unless one or more test fail that have explicit priority values. When one or more explicit tests fail, the lowest priority value event takes effect for the SRRP instance. When the highest delta-in-use-limit is used to manage the lowest delta derived in-use priority for the SRRP instance.</p> <p>VRRP policy associations may be added and removed at anytime. A maximum of two VRRP policies can be associated with a single SRRP instance.</p> <p>The <b>no</b> form of the command removes the association with vrrp-policy-id from the SRRP instance.</p> |
| <b>Parameters</b>  | <p><i>vrrp-policy-id</i> — Specifies one or more VRRP policies with the SRRP instance.</p> <p><b>Values</b>      1 — 9999</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Description</b> | <p>This command overrides the default base priority for the SRRP instance. The SRRP instance priority is advertised by the SRRP instance to its neighbor router and is compared to the priority received from the neighbor router. The router with the best (highest) priority enters the master state while the other router enters the backup state. If the priority of each router is the same, the router with the lowest source IP address in the SRRP advertisement message assumes the master state.</p> <p>The base priority of an SRRP instance can be managed by VRRP policies. A VRRP policy defines a set of connectivity or verification tests which, when they fail, may lower an SRRP instances base priority (creating an in-use priority for the instance). Every time an SRRP instances in-use priority changes when in master state, it sends an SRRP advertisement message with the new priority. If the dynamic priority drops to zero or receives an SRRP Advertisement message with a better priority, the SRRP instance transitions to the <i>becoming backup</i> state.</p> <p>When the priority command is not specified, or the no priority command is executed, the system uses a default base priority of 100. The priority command may be executed at anytime.</p> <p>The <b>no</b> form of the command restores the default base priority to the SRRP instance. If a VRRP policy is associated with the SRRP instance, it will use the default base priority as the basis for any modifications to the SRRP instances in-use priority.</p> |

**Parameters**    *priority* — Specifies a base priority for the SRRP instance to override the default.

**Values**        1 — 254

**Default**        100

| <b>Description</b> | <p>This command creates or edits a Virtual Router ID (VRID) on the service IP interface. A VRID is internally represented in conjunction with the IP interface name. This allows the VRID to be used on multiple IP interfaces while representing different virtual router instances.</p> <p>Two VRRP nodes can be defined on an IP interface. One, both, or none may be defined as owner. The nodal context of vrrp virtual-router-id is used to define the configuration parameters for the VRID.</p> <p>The <b>no</b> form of this command removes the specified VRID from the IP interface. This terminates VRRP participation for the virtual router and deletes all references to the VRID. The VRID does not need to be shutdown in order to remove the virtual router instance.</p> |
| <b>Default</b>     | No default                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Parameters</b>  | <p><i>virtual-router-id</i> — The virtual-router-id parameter specifies a new virtual router ID or one that can be modified on the IP interface.</p> <p><b>Values</b>      1 — 255</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Description</b> | <p>The <b>authentication-key</b> command, within the vrrp <i>virtual-router-id</i> context, is used to assign a simple text password authentication key to generate master VRRP advertisement messages and validate received VRRP advertisement messages.</p> <p>The <b>authentication-key</b> command is one of the few commands not affected by the presence of the <b>owner</b> keyword. If simple text password authentication is not required, this command is not required. If the command is re-executed with a different password key defined, the new key will be used immediately. If a no <b>authentication-key</b> command is executed, the password authentication key is restored to the default value. The <b>authentication-key</b> command may be executed at any time, altering the simple text password used when <b>authentication-type</b> password authentication method is used by the virtual router instance. The <b>authentication-type password</b> command does not need to be executed prior to defining the <b>authentication-key</b> command.</p> <p>To change the current in-use password key on multiple virtual router instances:</p> <ul style="list-style-type: none"> <li>Identify the current master</li> </ul> |

- Shutdown the virtual router instance on all backups
- Execute the authentication-key command on the master to change the password key
- Execute the authentication-key command and no shutdown command on each backup key

The **no** form of this command restores the default null string to the value of key.

**Default** No default. The authentication data field contains the value 0 in all 16 octets.

**Parameters** *authentication-key* — The *key* parameter identifies the simple text password used when VRRP Authentication Type 1 is enabled on the virtual router instance. Type 1 uses a string eight octets long that is inserted into all transmitted VRRP advertisement messages and compared against all received VRRP advertisement messages. The authentication data fields are used to transmit the key.

The *key* parameter is expressed as a string consisting of up to eight alpha-numeric characters. Spaces must be contained in quotation marks ( " " ). The quotation marks are not considered part of the string.

The string is case sensitive and is left-justified in the VRRP advertisement message authentication data fields. The first field contains the first four characters with the first octet (starting with IETF RFC bit position 0) containing the first character. The second field holds the fifth through eighth characters. Any unspecified portion of the authentication data field is padded with the value 0 in the corresponding octet.

**Values** Any 7-bit printable ASCII character.

|             |                  |          |
|-------------|------------------|----------|
| Exceptions: | Double quote (") | ASCII 34 |
|             | Carriage Return  | ASCII 13 |
|             | Line Feed        | ASCII 10 |
|             | Tab              | ASCII 9  |
|             | Backspace        | ASCII 8  |

*hash-key* — The hash key. The key can be any combination of ASCII characters up to 22 characters in length (encrypted). If spaces are used in the string, enclose the entire string in quotation marks ( " " ).

This is useful when a user must configure the parameter, but, for security purposes, the actual unencrypted key value is not provided.

**hash** — Specifies the key is entered in an encrypted form. If the **hash** parameter is not used, the key is assumed to be in a non-encrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** parameter specified.

**hash2** — Specifies the key is entered in a more complex encrypted form. If the **hash2** parameter is not used, the less encrypted **hash** form is assumed.

| <b>Description</b> | <p>The <b>authentication-type</b> command, within the <b>vrrp</b> <i>virtual-router-id</i> context, is used to assign the authentication method to generate master VRRP advertisement messages and validate received VRRP advertisement messages.</p> <p><b>NOTE:</b> The authentication management for VRRP closely follows the authentication management format used for IS-IS.</p> <p>The <b>authentication-type</b> command is one of the commands not affected by the presence of the owner keyword. If authentication is not required, the authentication-type command must not be executed. If the command is re-executed with a different authentication type defined, the new type will be used. If the no authentication-type command is executed, authentication is removed and no authentication is performed. The authentication-type command may be executed at any time, altering the authentication method used by the virtual router instance.</p> <p>The <b>no</b> form of this command removes authentication from the virtual router instance. All VRRP Advertisement messages sent will have the Authentication Type field set to 0 and the Authentication Data fields will contain 0 in all octets. VRRP Advertisement messages received with Authentication Type fields containing a value other than 0 will be discarded.</p> <p><i>password</i> — The password keyword identifies VRRP Authentication Type 1. Type 1 requires the definition of a string of eight octets long using the authentication-key command. All transmitted VRRP Advertisement messages must have the Authentication Type field set to 1 and the Authentication Data fields must contain the authentication-key password.</p> <p>All received VRRP advertisement messages must contain a value of 1 in the Authentication Type field and the Authentication Data fields must match the defined authentication-key. All other received messages will be silently discarded.</p> <p><i>message-digest</i> — The message-digest keyword identifies VRRP Authentication Type 2. Type 2 defines a lower IP layer MD5 authentication mechanism using HMAC and IP authentication header standards. An MD5 key must be defined using the message-digest-key command. All transmitted VRRP advertisement messages must have the Authentication Type field set to 2 and the Authentication Data fields must contain 0 in all octets. The message-digest key is used in the hashing process when populating the IP Authentication Header fields. A sequential incrementing counter (set to zero when the message-digest-key is set) is incremented and then used in the IP Authentication Header to prevent replay attacks on authorized participating virtual router instances.</p> <p>All received VRRP advertisement messages must contain a value of 2 in the Authentication Type field and the Authentication Data fields are ignored. The message must have been authorized by the lower layer IP Authentication Header process with the sequential counter field and the source IP address presented to the virtual router instance. To track the validity of the received counter, the virtual router instance maintains a master counter table containing up to 32 source IP addresses and the last received counter value. Populate the table as follows:</p> <ol style="list-style-type: none"> <li>1. Check to see if source IP address exists in table. <ul style="list-style-type: none"> <li>– If non-existent, create an entry if available.</li> </ul> </li> </ol> |

- If no entry is available, delete the oldest and create an entry. The new entry should have a counter value of zero.
- 2. Compare the message counter value to the entry value (0 if new entry or equal to the previous message counter from the source IP address).
  - If the message counter is not greater than the entry counter value, silently discard the packet.
  - If the message counter is greater than the entry counter value, accept the message for further checking and replace the entry counter value with the message counter value and time stamp the entry.

## backup

| <b>Context</b>     | config>service>vpn>if>vrrp<br>config>service>vpn>sub-if>grp-if>vrrp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | <p>This commands assigns a bi-directional forwarding (BFD) session providing heart-beat mechanism for the given VRRP/SRRP instance. There can be only one BFD session assigned to any given VRRP/SRRP instance, but there can be multiple SRRP/VRRP sessions using the same BFD session.</p> <p>BFD control the state of the associated interface. By enabling BFD on a given protocol interface, the state of the protocol interface is tied to the state of the BFD session between the local node and the remote node. The parameters used for the BFD are set via the BFD command under the IP interface. The specified interface may not be configured with BFD; when it is, the virtual router will then initiate the BFD session.</p> <p>The <b>no</b> form of this command removes BFD from the configuration.</p> |
| <b>Default</b>     | none                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <p><i>service-id</i> — Specifies the service ID of the interface running BFD.</p> <p><b>Values</b></p> <ul style="list-style-type: none"> <li><i>service-id</i>: 1 — 2147483648</li> <li><i>svc-name</i>: Specifies an existing service name up to 64 characters in length.</li> <li>No service ID indicates a network interface.</li> </ul> <p><b>interface</b> <i>interface-name</i> — Specifies the name of the interface running BFD.</p> <p><b>dst-ip</b> <i>ip-address</i> — Specifies the destination address to be used for the BFD session.</p>                                                                                                                                                                                                                                                                   |

| <b>Description</b> | <p>This command sets the advertisement timer and indirectly sets the master down timer on the virtual router instance. The message-interval setting must be the same for all virtual routers participating as a virtual router. Any VRRP advertisement message received with an Advertisement Interval field different than the virtual router instance configured message-interval value will be silently discarded.</p> <p>The message-interval command is available in both non-owner and owner <b>vrrp</b> <i>virtual-router-id</i> nodal contexts. If the message-interval command is not executed, the default message interval of 1 second will be used.</p> <p>The <b>no</b> form of this command restores the default message interval value of 1 second to the virtual router instance.</p> |
| <b>Parameters</b>  | <p><i>seconds</i> — The number of seconds that will transpire before the advertisement timer expires.</p> <p><b>Values</b> 1 — 255</p> <p><b>Default</b> 1</p> <p><b>milliseconds milliseconds</b> — Specifies the milliseconds time interval between sending advertisement messages. This parameter is not supported on the 7750 SR-1 chassis.</p> <p><b>Values</b> 100 — 900</p>                                                                                                                                                                                                                                                                                                                                                                                                                    |

## ping-reply

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Description</b> | <p>This command enables the non-owner master to reply to ICMP Echo Requests directed at the virtual router instances IP addresses. The ping request can be received on any routed interface.</p> <p>Ping must not have been disabled at the management security level (either on the parental IP interface or based on the Ping source host address). When ping-reply is not enabled, ICMP Echo Requests to non-owner master virtual IP addresses are silently discarded.</p> <p>Non-owner backup virtual routers never respond to ICMP Echo Requests regardless of the setting of ping-reply configuration.</p> <p>The ping-reply command is only available in non-owner <b>vrrp</b> <i>virtual-router-id</i> nodal context. If the ping-reply command is not executed, ICMP Echo Requests to the virtual router instance IP addresses will be silently discarded.</p> <p>The <b>no</b> form of this command restores the default operation of discarding all ICMP Echo Request messages destined to the non-owner virtual router instance IP addresses.</p> |
| <b>Default</b>     | no ping-reply                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Description</b> | <p>This command provides the ability of overriding an existing non-owner master to the virtual router instance. Enabling preempt mode is recommended for proper operation of the base-priority and vrrp-policy-id definitions on the virtual router instance. If the virtual router cannot preempt an existing non-owner master, the affect of the dynamic changing of the in-use priority is greatly diminished.</p> <p>The preempt command is only available in the non-owner <b>vrrp</b> <i>virtual-router-id</i> nodal context. The owner may not be preempted due to the fact that the priority of non-owners can never be higher than the owner. The owner will always preempt all other virtual routers when it is available.</p> <p>Non-owner virtual router instances will only preempt when preempt is set and the current master has an in-use message priority value less than the virtual router instances in-use priority.</p> <p>A master non-owner virtual router will only allow itself to be preempted when the incoming VRRP Advertisement message Priority field value is one of the following:</p> <ul style="list-style-type: none"> <li>• Greater than the virtual router in-use priority value</li> <li>• Equal to the in-use priority value and the source IP address (primary IP address) is greater than the virtual router instance primary IP address</li> </ul> <p>The <b>no</b> form of this command prevents a non-owner virtual router instance from preempting another, less desirable virtual router. Use the preempt command to restore the default mode.</p> |
| <b>Default</b>     | preempt                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Description</b> | <p>The priority command provides the ability to configure a specific priority value to the virtual router instance. In conjunction with an optional policy command, the base-priority is used to derive the in-use priority of the virtual router instance.</p> <p>The priority command is only available in the non-owner <b>vrrp</b> <i>virtual-router-id</i> nodal context. The priority of owner virtual router instances is permanently set to 255 and cannot be changed. For non-owner virtual router instances, if the priority command is not executed, the base-priority will be set to 100.</p> <p>The <b>no</b> form of this command restores the default value of 100 to base-priority.</p> |               |         |                |     |
| <b>Parameters</b>  | <p><i>base-priority</i> — The base-priority parameter configures the base priority used by the virtual router instance. If a VRRP priority control policy is not also defined, the base-priority will be the in-use priority for the virtual router instance.</p> <table> <tr> <td><b>Values</b></td><td>1 — 254</td></tr> <tr> <td><b>Default</b></td><td>100</td></tr> </table>                                                                                                                                                                                                                                                                                                                       | <b>Values</b> | 1 — 254 | <b>Default</b> | 100 |

| <b>Description</b> | <p>This command enables the non-owner master to reply to SSH Requests directed at the virtual router instance's IP addresses. The SSH request can be received on any routed interface. SSH must not have been disabled at the management security level (either on the parental IP interface or based on the SSH source host address). Proper login and CLI command authentication is still enforced.</p> <p>When ssh-reply is not enabled, SSH packets to non-owner master virtual IP addresses are silently discarded. Non-owner backup virtual routers never respond to SSH regardless of the ssh-reply configuration.</p> <p>The ssh-reply command is only available in non-owner <b>vrrp</b> <i>virtual-router-id</i> nodal context. If the ssh-reply command is not executed, SSH packets to the virtual router instance IP addresses will be silently discarded.</p> <p>The <b>no</b> form of this command restores the default operation of discarding all SSH packets destined to the non-owner virtual router instance IP addresses.</p> |
| <b>Default</b>     | no ssh-reply                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Description</b> | <p>This command enables the non-owner master to reply to TCP port 23 Telnet Requests directed at the virtual router instance's IP addresses. The Telnet request can be received on any routed interface. Telnet must not have been disabled at the management security level (either on the parental IP interface or based on the Telnet source host address). Proper login and CLI command authentication is still enforced.</p> <p>When telnet-reply is not enabled, TCP port 23 Telnet packets to non-owner master virtual IP addresses are silently discarded.</p> <p>Non-owner backup virtual routers never respond to Telnet Requests regardless of the telnet-reply configuration.</p> <p>The telnet-reply command is only available in non-owner <b>VRRP</b> nodal context. If the telnet-reply command is not executed, Telnet packets to the virtual router instance IP addresses will be silently discarded.</p> <p>The <b>no</b> form of this command restores the default operation of discarding all Telnet packets destined to the non-owner virtual router instance IP addresses.</p> |
| <b>Default</b>     | no telnet-reply                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## traceroute-reply

|                    |                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] traceroute-reply</b>                                                                              |
| <b>Context</b>     | config>service>vprn>if>vrrp<br>config>service>vprn>if>ipv6>vrrp                                           |
| <b>Description</b> | This command is valid only if the VRRP virtual router instance associated with this entry is a non-owner. |

When this command is enabled, a non-owner master can reply to traceroute requests directed to the virtual router instance IP addresses.

A non-owner backup virtual router never responds to such traceroute requests regardless of the **trace-route-reply** status.

**Default**    no traceroute-reply

| <b>Description</b> | <p>This command configures a Protocol Independent Multicast (PIM) instance in the VPRN service. When an PIM instance is created, the protocol is enabled. PIM is used for multicast routing within the network. Devices in the network can receive the multicast feed requested and non-participating routers can be pruned. The 7750 SR OS supports PIM sparse mode (PIM-SM).</p> <p>The <b>no</b> form of the command deletes the PIM protocol instance removing all associated configuration parameters.</p> |
| <b>Default</b>     | none                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Description</b> | <p>This command specifies the import route policy to be used for determining which routes are accepted from peers. Route policies are configured in the <b>config&gt;router&gt;policy-options</b> context. When an import policy is not specified, BGP routes are accepted by default.</p> <p>The <b>no</b> form of the command removes the policy association from the IGMP instance.</p>                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Default</b>     | no import join-policy<br>no import register-policy                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <p><b>join-policy</b> — Use this command to filter PIM join messages which prevents unwanted multicast streams from traversing the network.</p> <p><b>register-policy</b> — This keyword filters register messages. PIM register filters prevent register messages from being processed by the RP. This filter can only be defined on an RP. When a match is found, the RP immediately sends back a register-stop message.</p> <p><i>policy-name</i> — The route policy name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes. Route policies are configured in the <b>config&gt;router&gt;policy-options</b> context.</p> |

## interface

| <b>Description</b> | <p>This command enables PIM on an interface and enables the context to configure interface-specific parameters. By default interfaces are activated in PIM based on the <b>apply-to</b> command, and do not have to be configured on an individual basis unless the default values must be changed.</p> <p>The <b>no</b> form of the command deletes the PIM interface configuration for this interface. If the <b>apply-to</b> command parameter is configured, then the <b>no interface</b> form must be saved in the configuration to avoid automatic (re)creation after the next <b>apply-to</b> is executed as part of a reboot.</p> <p>The <b>shutdown</b> command can be used to disable an interface without removing the configuration for the interface.</p> |
| <b>Default</b>     | Interfaces are activated in PIM based on the apply-to command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <i>ip-int-name</i> — Specify the interface name. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Syntax</b>      | <b>max-groups</b> <i>value</i><br><b>no max-groups</b>                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Context</b>     | config>service>vprn>pim>interface                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | This command configures the maximum number of groups for which PIM can have downstream state based on received PIM Joins on this interface. This does not include IGMP local receivers on the interface. When this configuration is changed dynamically to a value lower than the currently accepted number of groups, the groups that are already accepted are not deleted. Only new groups will not be allowed. When this object has a value of 0, there is no limit to the number of groups. |

**Parameters**     *value* — Specifies the maximum number of groups for this interface.

**Values**         1 — 16000

### multicast-senders

**Syntax**         **multicast-senders** {**auto** | **always** | **never**}  
**no multicast-senders**

**Context**         config>service>vprn>pim>interface

**Description**     This command configures the way subnet matching is done for incoming data packets on this interface. An IP multicast sender is an user entity to be authenticated in a receiving host.

**Parameters**     **auto** — Subnet matching is automatically performed for incoming data packets on this interface.  
**always** — Subnet matching is always performed for incoming data packets on this interface.  
**never** — Subnet matching is never performed for incoming data packets on this interface.

### priority

**Syntax**         **priority** *dr-priority*  
**no priority**

**Context**         config>service>vprn>pim>interface

**Description**     This command sets the priority value to become the rendezvous point (RP) that is included in bootstrap messages sent by the router. The RP is sometimes called the bootstrap router. The **priority** command indicates whether the router is eligible to be a bootstrap router. The **no** form of the command disqualifies the router to participate in the bootstrap election.

**Default**         1 (The router is the least likely to become the designated router.)

**Parameters**     *dr-priority* — Specifies the priority to become the designated router. The higher the value, the higher the priority.

**Values**         1 — 4294967295

### sticky-dr

**Syntax**         **sticky-dr** [**priority** *dr-priority*]  
**no sticky-dr**

**Context**         config>service>vprn>pim>interface

**Description**     This command enables sticky-dr operation on this interface. When enabled, the priority in PIM hellos sent on this interface when elected as the designated router (DR) will be modified to the value configured in *dr-priority*. This is done to avoid the delays in forwarding caused by DR recovery, when switching back to the old DR on a LAN when it comes back up.

By enabling **sticky-dr** on this interface, it will continue to act as the DR for the LAN even after the old DR comes back up.

The **no** form of the command disables sticky-dr operation on this interface.

|                   |                                                                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | disabled                                                                                                                                                                            |
| <b>Parameters</b> | <b>priority</b> <i>dr-priority</i> — Sets the DR priority to be sent in PIM Hello messages following the election of that interface as the DR, when sticky-dr operation is enabled. |
| <b>Values</b>     | 1 — 4294967295                                                                                                                                                                      |

## three-way-hello

|                    |                                                                                   |
|--------------------|-----------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>three-way-hello</b> [ <b>compatibility-mode</b> ]<br><b>no three-way-hello</b> |
| <b>Context</b>     | config>service>vprn>pim>interface                                                 |
| <b>Description</b> | This command configures the compatibility mode for enabling the three way hello.  |
| <b>Parameters</b>  | <b>compatibility-mode</b> — Specifies to enable the three way hello.              |

## tracking-support

| <b>Description</b> | This command enables multicast balancing of traffic over ECMP links. When enabled, each multicast stream that needs to be forwarded over an ECMP link will be re-evaluated for the total multicast bandwidth utilization. Re-evaluation occurs on the ECMP interface in question.<br><br>The <b>no</b> form of the command disables the multicast balancing. |

## mc-ecmp-balance-hold

|                    |                                                                                                                        |

| <b>Description</b> | <p>This command specifies whether the router should ignore the designated router state and attract traffic even when it is not the designater router.</p> <p>An operator can configure an interface (router or IES or VPRN interfaces) to IGMP and PIM. The interface IGMP state will be synchronized to the backup node if it is associated with the redundant peer port. The interface can be configured to use PIM which will cause multicast streams to be sent to the elected DR only. The DR will also be the router sending traffic to the DSLAM. Since it may be required to attract traffic to both routers a flag non-dr-attract-traffic can be used in the PIM context to have the router ignore the DR state and attract traffic when not DR. Note that while using this flag the router may not send the stream down to the DSLAM while not DR.</p> <p>When enabled, the designated router state is ignored. When disabled, <b>no non-dr-attract-traffic</b>, the designated router value is honored.</p> |
| <b>Default</b>     | no non-dr-attract-traffic                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Description</b> | <p>This command enables access to the context to configure the rendezvous point (RP) ) of a PIM protocol instance.</p> <p>An Alcatel-Lucent PIM router acting as an RP must respond to a PIM register message specifying an SSM multicast group address by sending to the first hop router stop register message(s). It does not build an (S, G) shortest path tree toward the first hop router. An SSM multicast group address can be either from the SSM default range of 232/8 or from a multicast group address range that was explicitly configured for SSM.</p> |
| <b>Default</b>     | rp enabled when PIM is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Description</b> | <p>This command configures a PIM anycast protocol instance for the RP being configured. Anycast enables fast convergence when a PIM RP router fails by allowing receivers and sources to rendezvous at the closest RP.</p> <p>The <b>no</b> form of the command removes the anycast instance from the configuration.</p>                                                                                                                                            |
| <b>Default</b>     | none                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <p><i>rp-ip-address</i> — Configure the loopback IP address shared by all routes that form the RP set for this anycast instance. Only a single address can be configured. If another anycast command is entered with an address then the old address will be replaced with the new address. If no ip-address is entered then the command is simply used to enter the anycast CLI level.</p> <p><b>Values</b> Any valid loopback address configured on the node.</p> |

| <b>Description</b> | <p>This command configures a peer in the anycast rp-set. The address identifies the address used by the other node as the RP candidacy address for the same multicast group address range as configured on this node.</p> <p>This is a manual procedure. Caution should be taken to produce a consistent configuration of an RP-set for a given multicast group address range. The priority should be identical on each node and be a higher value than any other configured RP candidate that is not a member of this rp-set.</p> <p>Although there is no set maximum of addresses that can be configured in an rp-set, up to 15 multicast addresses is recommended.</p> <p>The <b>no</b> form of the command removes an entry from the list.</p> |
| <b>Default</b>     | None                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Context</b>     | config>service>vprn>pim>rp>bsr-candidate<br>config>service>vprn>pim>rp>rp-candidate                                                                                                                                                                                                                                                            |
| <b>Description</b> | This command configures a static bootstrap or rendezvous point (RP) as long as the source is not directly attached to this router.<br><br>Use the <b>no</b> form of this command to remove the static RP from the configuration.                                                                                                               |
| <b>Default</b>     | No IP address is specified.                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <i>ip-address</i> — The static IP address of the RP. The <i>ip-address</i> portion of the <b>address</b> command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation.<br><br><b>Values</b> 1.0.0.0 – 223.255.255.255 |

## hash-mask-len

|                    |                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>hash-mask-len</b> <i>hash-mask-length</i><br><b>no hash-mask-len</b>                                                                                                                                                                                                                                                                                 |
| <b>Context</b>     | config>service>vprn>pim>rp>bsr-candidate                                                                                                                                                                                                                                                                                                                |
| <b>Description</b> | This command is used to configure the length of a mask that is to be combined with the group address before the hash function is called. All groups with the same hash map to the same RP. For example, if this value is 24, only the first 24 bits of the group addresses matter. This mechanism is used to map one group or multiple groups to an RP. |
| <b>Parameters</b>  | <i>hash-mask-length</i> — The hash mask length.<br><br><b>Values</b> 0 — 32                                                                                                                                                                                                                                                                             |

## priority

|                    |                                                                                                                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>priority</b> <i>bootstrap-priority</i>                                                                                                                                                                                         |
| <b>Context</b>     | config>service>vprn>pim>rp>bsr-candidate                                                                                                                                                                                          |
| <b>Description</b> | This command defines the priority used to become the rendezvous point (RP) . The higher the priority value the more likely that this router becomes the RP. If there is a tie, the router with the highest IP address is elected. |
| <b>Parameters</b>  | <i>bootstrap-priority</i> — The priority to become the bootstrap router.<br><br><b>Values</b> 0 — 255<br><br><b>Default</b> 0 (the router is not eligible to be the bootstrap router)                                             |

## rp-candidate

|                    |                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>rp-candidate</b>                                                                           |
| <b>Context</b>     | config>service>vprn>pim>rp                                                                    |
| <b>Description</b> | This command enables the context to configure the candidate rendezvous point (RP) parameters. |
| <b>Default</b>     | Enabled when PIM is enabled.                                                                  |

## group-range

|                    |                                                                                                                                                                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] group-range</b> { <i>grp-ip-address/mask</i>   <i>grp-ip-address</i> [ <i>netmask</i> ]}                                                                                                                                                                                                |
| <b>Context</b>     | config>service>vprn>pim>rp>rp-candidate<br>config>service>vprn>pim>ssm                                                                                                                                                                                                                          |
| <b>Description</b> | This command configures the group address or range of group addresses for which this router can be the rendezvous point (RP).<br><br>Use the <b>no</b> form of this command to remove the group address or range of group addresses for which this router can be the RP from the configuration. |
| <b>Default</b>     | none                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <i>group-ip-address</i> — Specify the addresses or address ranges that this router can be an RP.<br><i>mask</i> — Specify the address mask with the address to define a range of addresses.<br><i>netmask</i> — Specify the subnet mask in dotted decimal notation.                             |
| <b>Values</b>      | 0.0.0.0 — 255.255.255.255 (network bits all 1 and host bits all 0)                                                                                                                                                                                                                              |

## holdtime

|                    |                                                                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>holdtime</b> <i>holdtime</i><br><b>no holdtime</b> <i>holdtime</i>                                                                                                     |
| <b>Context</b>     | config>service>vprn>pim>rp>rp-candidate                                                                                                                                   |
| <b>Description</b> | Use this command to define the length of time neighboring router consider this router to be up.<br>Use the <b>no</b> form of this command to revert to the default value. |
| <b>Default</b>     | 150                                                                                                                                                                       |
| <b>Parameters</b>  | <i>holdtime</i> — Specify the length of time, in seconds, that neighbor should consider the sending router to be operational.                                             |
| <b>Values</b>      | 0 — 255                                                                                                                                                                   |

## priority

|                    |                                                                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>priority</b> <i>priority</i><br><b>no priority</b> <i>priority</i>                                                                                                                                                                         |
| <b>Context</b>     | config>router>pim>rp>local<br>config>service>vprn>pim>rp>rp-candidate                                                                                                                                                                         |
| <b>Description</b> | This command defines the priority used to become the rendezvous point (RP). The higher the priority value, the more likely that this router will become the RP.<br><br>Use the <b>no</b> form of this command to revert to the default value. |
| <b>Default</b>     | 1                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <i>priority</i> — Specify the priority to become the designated router. The higher the value the more likely the router will become the RP.<br><br><b>Values</b> 0 — 255                                                                      |

## static

|                    |                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>static</b>                                                                                                         |
| <b>Context</b>     | config>service>vprn>pim>rp                                                                                            |
| <b>Description</b> | This command enables access to the context to configure a static rendezvous point (RP) of a PIM-SM protocol instance. |
| <b>Default</b>     | none                                                                                                                  |

## address

|                    |                                                                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] address</b> <i>ip-address</i>                                                                                                                           |
| <b>Context</b>     | config>service>vprn>pim>rp>static                                                                                                                               |
| <b>Description</b> | This command configures the static rendezvous point (RP) address.<br><br>The <b>no</b> form of this command removes the static RP entry from the configuration. |
| <b>Default</b>     | none                                                                                                                                                            |

## group-prefix

|                |                                                                                                                         |
|----------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>[no] group-prefix</b> { <i>grp-ip-address/mask</i>   <i>grp-ip-address netmask</i> }                                 |
| <b>Context</b> | config>service>vprn>pim>rp>static                                                                                       |
| <b>Context</b> | The <b>group-prefix</b> for a static-rp defines a range of multicast-ip-addresses for which a certain RP is applicable. |

## VPRN Service Configuration Commands

The **no** form of the command removes the criterion.

|                   |                                                                                                                                                                                                                                                                                                            |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | none                                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b> | <i>grp-ip-address</i> — Specify the multicast IP address.<br><i>mask</i> — Defines the mask of the multicast-ip-address.<br><b>Values</b> 4 — 32<br><i>netmask</i> — Enter the subnet mask in dotted decimal notation.<br><b>Values</b> 0.0.0.0 — 255.255.255.255 (network bits all 1 and host bits all 0) |

## override

|                    |                                                                                                                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] override</b>                                                                                                                                                                                         |
| <b>Context</b>     | config>service>vprn>pim>rp>static                                                                                                                                                                            |
| <b>Description</b> | This command changes the precedence of static RP over dynamically learned Rendezvous Point (RP).<br><br>When enabled, the static group-to-RP mappings take precedence over the dynamically learned mappings. |
| <b>Default</b>     | no override                                                                                                                                                                                                  |

## spt-switchover-threshold

| <b>Context</b>     | config>service>vprn>pim                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b> | This command configures a shortest path tree (SPT tree) switchover threshold for a group prefix.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <i>grp-ip-address</i> — Specify the multicast group address.<br><i>mask</i> — Defines the mask of the multicast-ip-address.<br><b>Values</b> 4 — 32<br><i>netmask</i> — Enter the subnet mask in dotted decimal notation.<br><b>Values</b> 0.0.0.0 — 255.255.255.255 (network bits all 1 and host bits all 0)<br><i>spt-threshold</i> — Specifies the configured threshold in kilo-bits per second(kbps) for the group to which this (S,G) belongs. For a group G configured with a threshold, switchover to SPT for an (S,G) is attempted only if the (S,G)'s rate exceeds this configured threshold. |

## ssm-groups

|                    |                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] ssm-groups</b>                                                                                         |
| <b>Context</b>     | config>service>vpn                                                                                             |
| <b>Description</b> | This command enables access to the context to enable a source-specific multicast (SSM) configuration instance. |
| <b>Default</b>     | none                                                                                                           |

## BGP Commands

### bgp

|                    |                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] bgp</b>                                                                                                                                          |
| <b>Context</b>     | service>vprn                                                                                                                                             |
| <b>Description</b> | This command enables the BGP protocol with the VPRN service.<br>The <b>no</b> form of the command disables the BGP protocol from the given VPRN service. |
| <b>Default</b>     | no bgp                                                                                                                                                   |

### advertise-inactive

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] advertise-inactive</b>                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Context</b>     | config>service>vprn>bgp<br>config>service>vprn>bgp>group<br>config>service>vprn>bgp>group>neighbor                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b> | This command enables or disables the advertising of inactive BGP routes to other BGP peers.<br>By default, BGP only advertises BGP routes to other BGP peers if a given BGP route is chosen by the route table manager as the most preferred route within the system and is active in the forwarding plane. This command allows system administrators to advertise a BGP route even though it is not the most preferred route within the system for a given destination. |
| <b>Default</b>     | no advertise-inactive                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

### aggregator-id-zero

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Syntax</b>      | <b>[no] aggregator-id-zero</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Context</b>     | config>service>vprn>bgp<br>config>service>vprn>bgp>group<br>config>service>vprn>bgp>group>neighbor                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b> | This command is used to set the router ID in the BGP aggregator path attribute to zero when BGP aggregates routes. This prevents different routers within an AS from creating aggregate routes that contain different AS paths.<br><br>When BGP is aggregating routes, it adds the aggregator path attribute to the BGP update messages. By default, BGP adds the AS number and router ID to the aggregator path attribute.<br><br>When this command is enabled, BGP adds the router ID to the aggregator path attribute. This command is used at the group level to revert to the value defined under the global level, while this command is used at the neighbor level to revert to the value defined under the group level. |

The **no** form of the command used at the global level reverts to default where BGP adds the AS number and router ID to the aggregator path attribute.

The **no** form of the command used at the group level reverts to the value defined at the group level.

The **no** form of the command used at the neighbor level reverts to the value defined at the group level.

**Default** no aggregator-id-zero — BGP adds the AS number and router ID to the aggregator path attribute.

| <b>Context</b>     | config>service>vprn>bgp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b> | <p>This command specifies how the Multi-Exit Discriminator (MED) path attribute is used in the BGP route selection process. The MED attribute is always used in the route selection process regardless of the peer AS that advertised the route. This parameter determines what MED value is inserted in the RIB-IN. If this parameter is not configured, only the MEDs of routes that have the same peer ASs are compared.</p> <p>The <b>no</b> form of the command removes the parameter from the configuration.</p> |
| <b>Default</b>     | no always-compare-med — Only compare MEDs of routes that have the same peer AS.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <p><b>zero</b> — Specifies that for routes learned without a MED attribute that a zero (0) value is used in the MED comparison. The routes with the lowest metric are the most preferred.</p> <p><b>infinity</b> — Specifies for routes learned without a MED attribute that a value of infinity (4294967295) is used in the MED comparison. This in effect makes these routes the least desirable.</p>                                                                                                                |

| <b>Description</b> | This command configures the BGP authentication key.<br><br>Authentication is performed between neighboring routers before setting up the BGP session by verifying the password. Authentication is performed using the MD-5 message-based digest. The authentication key can be any combination of letters or numbers from 1 to 16.<br><br>The no form of the command removes the authentication password from the configuration and effectively disables authentication.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Default</b>     | Authentication is disabled and the authentication password is empty.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <p><i>authentication-key</i> — The authentication key. The key can be any combination of ASCII characters up to 255 characters in length (unencrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").</p> <p><i>hash-key</i> — The hash key. The key can be any combination of ASCII characters up to 342 characters in length (encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").</p> <p>This is useful when a user must configure the parameter, but, for security purposes, the actual unencrypted key value is not provided.</p> <p><b>hash</b> — Specifies the key is entered in an encrypted form. If the <b>hash</b> parameter is not used, the key is assumed to be in a non-encrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the <b>hash</b> parameter specified.</p> <p><b>hash2</b> — Specifies the key is entered in a more complex encrypted form. If the <b>hash2</b> parameter is not used, the less encrypted <b>hash</b> form is assumed.</p> |

## auth-keychain

|                    |                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>auth-keychain</b> <i>name</i>                                                                                                                                   |
| <b>Context</b>     | config>service>vprn>bgp<br>config>service>vprn>bgp>group<br>config>service>vprn>bgp>group>neighbor                                                                 |
| <b>Description</b> | This command configures the BGP authentication key for all peers.<br><br>The keychain allows the rollover of authentication keys during the lifetime of a session. |
| <b>Default</b>     | <b>no auth-keychain</b>                                                                                                                                            |
| <b>Parameters</b>  | <i>name</i> — Specifies the name of an existing keychain, up to 32 characters, to use for the specified TCP session or sessions.                                   |

## bfd-enable

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] bfd-enable</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Context</b>     | config>router>bgp<br>config>router>bgp>group<br>config>router>bgp>group>neighbor                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | This command enables the use of bi-directional forwarding (BFD) to control the state of the associated protocol interface. By enabling BFD on a given protocol interface, the state of the protocol interface is tied to the state of the BFD session between the local node and the remote node. The parameters used for the BFD are set via the BFD command under the IP interface.<br><br>The <b>no</b> form of this command removes BFD from the associated BGP protocol peering. |
| <b>Default</b>     | <b>no bfd-enable</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## cluster

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Syntax</b>      | <b>cluster</b> <i>cluster-id</i><br><b>no cluster</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Context</b>     | config>service>vprn>bgp<br>config>service>vprn>bgp>group<br>config>service>vprn>bgp>group>neighbor                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b> | This command configures the cluster ID for a route reflector server.<br><br>Route reflectors are used to reduce the number of IBGP sessions required within an AS. Normally, all BGP speakers within an AS must have a BGP peering with every other BGP speaker in an AS. A route reflector and its clients form a cluster. Peers that are not part of the cluster are considered to be non-clients.<br><br>When a route reflector receives a route, first it must select the best path from all the paths received. If the route was received from a non-client peer, then the route reflector sends the route to all clients in |

the cluster. If the route came from a client peer, the route reflector sends the route to all non-client peers and to all client peers except the originator.

For redundancy, a cluster can have multiple route reflectors.

Confederations can also be used to remove the full IBGP mesh requirement within an AS.

The **no** form of the command deletes the cluster ID and effectively disables the Route Reflection for the given group.

**Default** no cluster — No cluster ID is defined.

**Parameters** *cluster-id* — The route reflector cluster ID is expressed in dot decimal notation.

**Values** Any 32 bit number in dot decimal notation. (0.0.0.1 — 255.255.255.255)

## connect-retry

**Syntax** **connect-retry** *seconds*  
**no connect-retry**

**Context** config>service>vprr>bgp  
config>service>vprr>bgp>group  
config>service>vprr>bgp>group>neighbor

**Description** This command configures the BGP connect retry timer value in seconds.

When this timer expires, BGP tries to reconnect to the configured peer. This configuration parameter can be set at three levels: global level (applies to all peers), peer-group level (applies to all peers in group) or neighbor level (only applies to specified peer). The most specific value is used.

The **no** form of the command used at the global level reverts to the default value.

The **no** form of the command used at the group level reverts to the value defined at the global level.

The **no** form of the command used at the neighbor level reverts to the value defined at the group level.

**Default** 120 seconds

**Parameters** *seconds* — The BGP Connect Retry timer value in seconds, expressed as a decimal integer.

**Values** 1 — 65535

## damping

**Syntax** [**no**] **damping**

**Context** config>service>vprr>bgp  
config>service>vprr>bgp>group  
config>service>vprr>bgp>group>neighbor

**Description** This command enables BGP route damping for learned routes which are defined within the route policy. Use damping to reduce the number of update messages sent between BGP peers and reduce the load on peers without affecting the route convergence time for stable routes. Damping parameters are set via route policy definition.

The **no** form of the command used at the global level disables route damping.

The **no** form of the command used at the group level reverts to the value defined at the global level.

The **no** form of the command used at the neighbor level reverts to the value defined at the group level.

When damping is enabled and the route policy does not specify a damping profile, the default damping profile is used. This profile is always present and consists of the following parameters:

Half-life: 15 minutes

Max-suppress: 60 minutes

Suppress-threshold:3000

Reuse-threshold 750

**Default** no damping — Learned route damping is disabled.

| <b>Description</b> | <p>This command specifies the export policies to be used to control routes advertised to BGP neighbors. When multiple policy names are specified, the policies are evaluated in the order they are specified. A maximum of five (5) policy names can be configured. The first policy that matches is applied.</p> <p>Note that if a non-existent route policy is applied to a VPRN instance, the CLI generates a warning message. This message is only generated at an interactive CLI session and the route policy association is made. No warning message is generated when a non-existent route policy is applied to a VPRN instance in a configuration file or when SNMP is used.</p> <p>The <b>no</b> form of this command removes all route policy names from the export list.</p> |
| <b>Default</b>     | no export — BGP advertises routes from other BGP routes but does not advertise any routes from other protocols unless directed by an export policy.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <i>policy</i> — A route policy statement name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Description | <p>This command creates a BGP peer/neighbor instance within the context of the BGP group.</p> <p>This command can be issued repeatedly to create multiple peers and their associated configuration.</p> <p>The <b>no</b> form of the command is used to remove the specified neighbor and the entire configuration associated with the neighbor. The neighbor must be administratively <b>shutdown</b> before attempting to delete it. If the neighbor is not shutdown, the command will not result in any action except a warning message on the console indicating that neighbor is still administratively up.</p> |                                                      |                |         |  |                |                           |  |  |                                 |  |    |            |  |    |           |  |            |                                                      |

| <b>Description</b> | <p>This command specifies the address family or families to be supported over BGP peerings in the base router. This command is additive so issuing the <b>family</b> command adds the specified address family to the list.</p> <p>The <b>no</b> form of the command removes the specified address family from the associated BGP peerings. If an address family is not specified, then reset the supported address family back to the default.</p> |

| <b>Description</b> | <p>This command configures the BGP hold time, expressed in seconds.</p> <p>The BGP hold time specifies the maximum time BGP waits between successive messages (either keepalive or update) from its peer, before closing the connection. This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in group) or neighbor level (only applies to specified peer). The most specific value is used.</p> <p>Even though the router OS implementation allows setting the <b>keepalive</b> time separately, the configured <b>keepalive</b> timer is overridden by the <b>hold-time</b> value under the following circumstances:</p> <ol style="list-style-type: none"> <li>1. If the specified hold-time is less than the configured <b>keepalive</b> time, then the operational <b>keepalive</b> time is set to a third of the <b>hold-time</b>; the configured <b>keepalive</b> time is not changed.</li> <li>2. If the <b>hold-time</b> is set to zero, then the operational value of the <b>keepalive</b> time is set to zero; the configured <b>keepalive</b> time is not changed. This means that the connection with the peer is up permanently and no <b>keepalive</b> packets are sent to the peer.</li> </ol> <p>The <b>no</b> form of the command used at the global level reverts to the default value.<br/>The <b>no</b> form of the command used at the group level reverts to the value defined at the global level.<br/>The <b>no</b> form of the command used at the neighbor level reverts to the value defined at the group level.</p> |
| <b>Default</b>     | 90 seconds                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|                   |                                                                                                                                                  |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>seconds</i> — The hold-time, in seconds, expressed as a decimal integer. A value of 0 indicates the connection to the peer is up permanently. |
| <b>Values</b>     | 0, 3 — 65535                                                                                                                                     |
| <b>strict</b>     | — When this parameter is specified, the advertised BGP hold-time from the far-end BGP peer must be greater than or equal to the specified value. |

| <b>Description</b> | This command specifies the import policies to be used to control routes advertised to BGP neighbors. Route policies are configured in the <b>config&gt;router&gt;policy-options</b> context. When multiple policy names are specified, the policies are evaluated in the order they are specified. A maximum of five (5) policy names can be specified. The first policy that matches is applied.<br><br>The <b>no</b> form of this command removes all route policy names from the import list. |
| <b>Default</b>     | no import — BGP accepts all routes from configured BGP neighbors. Import policies can be used to limit or modify the routes accepted and their corresponding parameters and metrics.                                                                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <i>policy</i> — A route policy statement name.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## keepalive

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Description</b> | <p>This command configures the BGP keepalive timer. A keepalive message is sent every time this timer expires. The <i>seconds</i> parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group) or neighbor level (only applies to specified peer). The most specific value is used.</p> <p>The <b>keepalive</b> value is generally one-third of the <b>hold-time</b> interval. Even though the OS implementation allows the <b>keepalive</b> value and the <b>hold-time</b> interval to be independently set, under the following circumstances, the configured <b>keepalive</b> value is overridden by the <b>hold-time</b> value:</p> <p>If the specified <b>keepalive</b> value is greater than the configured <b>hold-time</b>, then the specified value is ignored, and the <b>keepalive</b> is set to one third of the current <b>hold-time</b> value.</p> <p>If the specified <b>hold-time</b> interval is less than the configured <b>keepalive</b> value, then the <b>keepalive</b> value is reset to one third of the specified <b>hold-time</b> interval.</p> <p>If the <b>hold-time</b> interval is set to zero, then the configured value of the <b>keepalive</b> value is ignored. This means that the connection with the peer is up permanently and no <b>keepalive</b> packets are sent to the peer.</p> <p>The <b>no</b> form of the command used at the global level reverts to the default value.<br/>The <b>no</b> form of the command used at the group level reverts to the value defined at the global level.<br/>The <b>no</b> form of the command used at the neighbor level reverts to the value defined at the group level.</p> |
| <b>Default</b>     | 30 seconds                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Context</b>     | config>service>vprn>bgp>group<br>config>service>vprn>bgp>group>neighbor                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b> | <p>Configures the local IP address used by the group or neighbor when communicating with BGP peers. Outgoing connections use the <b>local-address</b> as the source of the TCP connection when initiating connections with a peer.</p> <p>When a local address is not specified, the 7750 SR OS uses the system IP address when communicating with IBGP peers and uses the interface address for directly connected EBGP peers. This command is used at the neighbor level to revert to the value defined under the group level.</p> |

The **no** form of the command removes the configured local-address for BGP.

The **no** form of the command used at the group level reverts to the value defined at the global level.

The **no** form of the command used at the neighbor level reverts to the value defined at the group level.

**Default**     **no local-address** — The router ID is used when communicating with IBGP peers and the interface address is used for directly connected EBGP peers.

*ip-address* — The local address expressed in dotted decimal notation. Allowed values are a valid routable IP address on the router, either an interface or system IP address.

## local-as

**Syntax**     **local-as** *as-number* [**private**]  
**no local-as**

**Context**     config>service>vprn>bgp  
 config>service>vprn>bgp>group  
 config>service>vprn>bgp>group>neighbor

**Description**     This command configures a BGP virtual autonomous system (AS) number.

In addition to the AS number configured for BGP in the `config>router>autonomous-system` context, a virtual (local) AS number is configured. The virtual AS number is added to the as-path message before the router's AS number makes the virtual AS the second AS in the as-path.

This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group) or neighbor level (only applies to specified peer). Thus, by specifying this at each neighbor level, it is possible to have a separate as-number per EBGP session.

When a command is entered multiple times for the same AS, the last command entered is used in the configuration. The **private** attribute can be added or removed dynamically by reissuing the command.

Changing the local AS at the global level in an active BGP instance causes the BGP instance to restart with the new local AS number. Changing the local AS at the global level in an active BGP instance causes BGP to re-establish the peer relationships with all peers in the group with the new local AS number. Changing the local AS at the neighbor level in an active BGP instance causes BGP to re-establish the peer relationship with the new local AS number.

This is an optional command and can be used in the following circumstance:

Provider router P is moved from AS1 to AS2. The customer router that is connected to P, however, is configured to belong to AS1. To avoid reconfiguring the customer router, the **local-as** value on router P can be set to AS1. Thus, router P adds AS1 to the as-path message for routes it advertises to the customer router.

The **no** form of the command used at the global level will remove any virtual AS number configured.

The **no** form of the command used at the group level reverts to the value defined at the global level.

The **no** form of the command used at the neighbor level reverts to the value defined at the group level.

**Default**     no local-as

**Parameters**     *as-number* — The virtual autonomous system number, expressed as a decimal integer.

**Values**         1 — 65535

**private** — Specifies the local-as is hidden in paths learned from the peering.

## local-preference

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Description</b> | <p>This command enables setting the BGP local-preference attribute in incoming routes if not specified and configures the default value for the attribute. This value is used if the BGP route arrives from a BGP peer without the <b>local-preference</b> integer set.</p> <p>The specified value can be overridden by any value set via a route policy. This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group) or neighbor level (only applies to specified peer). The most specific value is used.</p> <p>The <b>no</b> form of the command at the global level specifies that incoming routes with local-preference set are not overridden and routes arriving without local-preference set are interpreted as if the route had local-preference value of 100.</p> <p>The <b>no</b> form of the command used at the group level reverts to the value defined at the global level.</p> <p>The <b>no</b> form of the command used at the neighbor level reverts to the value defined at the group level.</p> |
| <b>Default</b>     | <b>no local-preference</b> — Does not override the local-preference value set in arriving routes and analyze routes without local preference with value of 100.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <p><i>local-preference</i> — The local preference value to be used as the override value, expressed as a decimal integer.</p> <p><b>Values</b>      0 — 4294967295</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## loop-detect

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Description</b> | <p>This command configures how the BGP peer session handles loop detection in the AS path.</p> <p>This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group) or neighbor level (only applies to specified peer). The most specific value is used.</p> <p>Note that dynamic configuration changes of <b>loop-detect</b> are not recognized.</p> <p>The <b>no</b> form of the command used at the global level reverts to default, which is <b>loop-detect ignore-loop</b>.</p> |

The **no** form of the command used at the group level reverts to the value defined at the global level.  
 The **no** form of the command used at the neighbor level reverts to the value defined at the group level.

**Default** loop-detect ignore-loop

**Parameters** **drop-peer** — Sends a notification to the remote peer and drops the session.  
**discard-route** — Discards routes received with loops in the AS path.  
**ignore-loop** — Ignores routes with loops in the AS path but maintains peering.  
**off** — Disables loop detection.

## med-out

**Syntax** **med-out {number | igp-cost}**  
**no med-out**

**Context** config>service>vprn>bgp  
 config>service>vprn>bgp>group  
 config>service>vprn>bgp>group>neighbor

**Description** This command enables advertising the Multi-Exit Discriminator (MED) and assigns the value used for the path attribute for the MED advertised to BGP peers if the MED is not already set.  
 The specified value can be overridden by any value set via a route policy.  
 This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group) or neighbor level (only applies to specified peer). The most specific value is used.  
 The **no** form of the command used at the global level reverts to default where the MED is not advertised.  
 The **no** form of the command used at the group level reverts to the value defined at the global level.  
 The **no** form of the command used at the neighbor level reverts to the value defined at the group level.

**Default** no med-out

**Parameters** *number* — The MED path attribute value, expressed as a decimal integer.  
**Values** 0 — 4294967295  
**igp-cost** — The MED is set to the IGP cost of the given IP prefix.

| <b>Description</b> | <p>This command configures the minimum interval, in seconds, at which a path attribute, originated by the local router, can be advertised to a peer.</p> <p>This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group) or neighbor level (only applies to specified peer). The most specific value is used.</p> <p>The <b>no</b> form of the command used at the global level reverts to default.</p> <p>The <b>no</b> form of the command used at the group level reverts to the value defined at the global level.</p> <p>The <b>no</b> form of the command used at the neighbor level reverts to the value defined at the group level.</p> |
| <b>Default</b>     | 15 seconds                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Context</b>     | config>service>vprn>bgp<br>config>service>vprn>bgp>group<br>config>service>vprn>bgp>group>neighbor                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b> | <p>This command configures the time to live (TTL) value entered in the IP header of packets sent to an EBGP peer multiple hops away.</p> <p>This parameter is meaningful only when configuring EBGP peers. It is ignored if set for an IBGP peer.</p> <p>The <b>no</b> form of the command is used to convey to the BGP instance that the EBGP peers are directly connected.</p> <p>The <b>no</b> form of the command reverts to default values.</p> |
| <b>Default</b>     | <p><b>1</b> — EBGP peers are directly connected.</p> <p><b>64</b> — IBGP</p>                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <p><i>ttl-value</i> — The TTL value, expressed as a decimal integer.</p> <p><b>Values</b>      1 — 255</p>                                                                                                                                                                                                                                                                                                                                           |

| <b>Description</b> | <p>This command enables BGP multipath.</p> <p>When multipath is enabled BGP load shares traffic across multiple links. Multipath can be configured to load share traffic across a maximum of 16 routes. If the equal cost routes available are more than the configured value, then routes with the lowest next-hop IP address value are chosen.</p> <p>This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in group) or neighbor level (only applies to specified peer). The most specific value is used.</p> <p>Multipath is effectively disabled if the value is set to one. When multipath is disabled, and multiple equal cost routes are available, the route with the lowest next-hop IP address will be used.</p> <p>The <b>no</b> form of the command used at the global level reverts to default values.</p> |
| <b>Default</b>     | <b>no multipath</b> — Multipath disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Parameters</b>  | <p><i>integer</i> — The number of equal cost routes to use for multipath routing. If more equal cost routes exist than the configured value, routes with the lowest next-hop value are chosen. Setting this value to 1 disables multipath.</p> <p><b>Values</b>      1 — 16</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

**eibgp** — Enables EIBGP load balancing so that routes with both MP-BGP and IPv4 next-hops can be used simultaneously. Enabling this option will disable the nexthop type (MP-BGP or IPv4 and also the next-hop metric comparison).

### next-hop-self

| <b>Context</b>     | config>service>vprn>bgp>group<br>config>service>vprn>bgp>group>neighbor                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b> | <p>This command configures the group or neighbor to always set the NEXTHOP path attribute to its own physical interface when advertising to a peer.</p> <p>This is primarily used to avoid third-party route advertisements when connected to a multi-access network.</p> <p>The <b>no</b> form of the command used at the group level allows third-party route advertisements in a multi-access network.</p> <p>The <b>no</b> form of the command used at the neighbor level reverts to the value defined at the group level.</p> |
| <b>Default</b>     | <b>no next-hop-self</b> — Third-party route advertisements are allowed.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

### passive

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] passive</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Context</b>     | config>service>vprn>bgp>group<br>config>service>vprn>bgp>group>neighbor                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b> | <p>This command enables passive mode for the BGP group or neighbor.</p> <p>When in passive mode, BGP will not attempt to actively connect to the configured BGP peers but responds only when it receives a connect open request from the peer.</p> <p>The <b>no</b> form of the command used at the group level disables passive mode where BGP actively attempts to connect to its peers.</p> <p>The <b>no</b> form of the command used at the neighbor level reverts to the value defined at the group level.</p> |
| <b>Default</b>     | <b>no passive</b> — BGP will actively try to connect to all the configured peers.                                                                                                                                                                                                                                                                                                                                                                                                                                   |

### peer-as

|                    |                                                                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>peer-as as-number</b>                                                                                                                  |
| <b>Context</b>     | config>service>vprn>bgp>group<br>config>service>vprn>bgp>group>neighbor                                                                   |
| <b>Description</b> | This command configures the autonomous system number for the remote peer. The peer AS number must be configured for each configured peer. |

For EBGp peers, the peer AS number configured must be different from the autonomous system number configured for this router under the global level since the peer will be in a different autonomous system than this router

For IBGP peers, the peer AS number must be the same as the autonomous system number of this router configured under the global level.

This is a required command for each configured peer. This may be configured under the group level for all neighbors in a particular group.

|                   |                                                                                  |
|-------------------|----------------------------------------------------------------------------------|
| <b>Default</b>    | No AS numbers are defined.                                                       |
| <b>Parameters</b> | <i>as-number</i> — The autonomous system number, expressed as a decimal integer. |
| <b>Values</b>     | 1 — 65535                                                                        |

| <b>Context</b>     | config>service>vprn>bgp<br>config>service>vprn>bgp>group                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b> | <p>This command configures the route preference for routes learned from the configured peer(s).</p> <p>This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group) or neighbor level (only applies to specified peer). The most specific value is used.</p> <p>The lower the preference the higher the chance of the route being the active route. The OS assigns BGP routes highest default preference compared to routes that are direct, static or learned via MPLS or OSPF.</p> <p>The <b>no</b> form of the command used at the global level reverts to default value.</p> <p>The <b>no</b> form of the command used at the group level reverts to the value defined at the global level.</p> <p>The <b>no</b> form of the command used at the neighbor level reverts to the value defined at the group level.</p> |
| <b>Default</b>     | 170                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <i>preference</i> — The route preference, expressed as a decimal integer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Values</b>      | 1 — 255                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## prefix-limit

|                    |                                                                                 |
|--------------------|---------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>prefix-limit</b> <i>limit</i><br><b>no prefix-limit</b>                      |
| <b>Context</b>     | config>service>vprn>bgp>group<br>config>service>vprn>bgp>group>neighbor         |
| <b>Description</b> | This command configures the maximum number of routes BGP can learn from a peer. |

## VPRN Service Configuration Commands

When the number of routes reaches 90% of this limit, an SNMP trap is sent. When the limit is exceeded, the BGP peering is dropped and disabled.

The **no** form of the command removes the **prefix-limit**.

|                   |                                                                                                      |
|-------------------|------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | no prefix-limit                                                                                      |
| <b>Parameters</b> | <i>limit</i> — The number of routes that can be learned from a peer, expressed as a decimal integer. |
| <b>Values</b>     | 1 — 4294967295                                                                                       |

### rapid-update

|                    |                                                                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>rapid-update</b> {[I2-vpn] [mvpn-ipv4]}<br><b>no rapid-update</b> {[I2-vpn] [mvpn-ipv4]}                                                                                                         |
| <b>Context</b>     | config>service>vprn>bgp                                                                                                                                                                             |
| <b>Description</b> | This command enables and disables BGP rapid update for specified address-families. When no parameter is given for the no rapid-update statement, rapid update is disabled for all address-families. |
| <b>Default</b>     | no rapid-update                                                                                                                                                                                     |

### rapid-withdrawal

|                    |                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] <b>rapid-withdrawal</b>                                                                                                                                                                                                                                                                                                                                                 |
| <b>Context</b>     | config>service>vprn>bgp                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | <p>This command disables the delay (Minimum Route Advertisement) on sending BGP withdrawals. Normal route withdrawals may be delayed up to the minimum route advertisement to allow for efficient packing of BGP updates.</p> <p>The <b>no</b> form of the command removes this command from the configuration and returns withdrawal processing to the normal behavior.</p> |
| <b>Default</b>     | no rapid-withdrawal                                                                                                                                                                                                                                                                                                                                                          |

### remove-private

|                    |                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] <b>remove-private</b>                                                                                  |
| <b>Context</b>     | config>service>vprn>bgp<br>config>service>vprn>bgp>group<br>config>service>vprn>bgp>group>neighbor          |
| <b>Description</b> | This command allows private AS numbers to be removed from the AS path before advertising them to BGP peers. |

When the **remove-private** parameter is set at the global level, it applies to all peers regardless of group or neighbor configuration. When the parameter is set at the group level, it applies to all peers in the group regardless of the neighbor configuration.

The OS software recognizes the set of AS numbers that are defined by IANA as private. These are AS numbers in the range 64512 through 65535, inclusive.

The **no** form of the command used at the global level reverts to default value. The **no** form of the command used at the group level reverts to the value defined at the global level. The **no** form of the command used at the neighbor level reverts to the value defined at the group level.

**Default** **no remove-private** — Private AS numbers will be included in the AS path attribute.

## type

**Syntax** **[no] type {internal | external}**

**Context** config>service>vpn>bgp>group  
config>service>vpn>bgp>group>neighbor

**Description** This command designates the BGP peer as type internal or external.

The type of **internal** indicates the peer is an IBGP peer while the type of external indicates that the peer is an EBGP peer.

By default, the OS derives the type of neighbor based on the local AS specified. If the local AS specified is the same as the AS of the router, the peer is considered **internal**. If the local AS is different, then the peer is considered **external**.

The **no** form of the command used at the group level reverts to the default value.  
The **no** form of the command used at the neighbor level reverts to the value defined at the group level.

**Default** **no type** — Type of neighbor is derived on the local AS specified.

**Parameters** **internal** — Configures the peer as internal.  
**external** — Configures the peer as external.

## ttl-security

**Syntax** **ttl-security min-ttl-value**  
**no ttl-security**

**Context** config>service>vpn>bgp>group  
config>service>vpn>bgp>group>neighbor

**Description** Configure TTL security parameters for incoming packets.

**Parameters** *min-ttl-value* — Specify the minimum TTL value for an incoming BGP packet.

**Values** 1 — 255

**Default** 1

---

## OSPF Commands

### ospf

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] ospf</b>                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Context</b>     | config>service>vprn                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b> | <p>This command enables access to the context to enable an OSPF protocol instance.</p> <p>When an OSPF instance is created, the protocol is enabled. To start or suspend execution of the OSPF protocol without affecting the configuration, use the <b>no shutdown</b> command.</p> <p>The <b>no</b> form of the command deletes the OSPF protocol instance removing all associated configuration parameters.</p> |
| <b>Default</b>     | <b>no ospf</b> — The OSPF protocol is not enabled.                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Description</b> | <p>This command creates the context to configure an OSPF area. An area is a collection of network segments within an AS that have been administratively grouped together. The area ID can be specified in dotted decimal notation or as a 32-bit decimal integer.</p> <p>The <b>no</b> form of the command deletes the specified area from the configuration. Deleting the area also removes the OSPF configuration of all the interfaces, virtual-links, sham-links, and address-ranges etc., that are currently assigned to this area.</p> |
| <b>Default</b>     | <b>no area</b> — No OSPF areas are defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|                   |                                                                                                        |

| <b>Description</b>   | <p>This command creates ranges of addresses on an Area Border Router (ABR) for the purpose of route summarization or suppression. When a range is created, the range is configured to be advertised or not advertised into other areas. Multiple range commands may be used to summarize or hide different ranges. In the case of overlapping ranges, the most specific range command applies.</p> <p>ABRs send summary link advertisements to describe routes to other areas. To minimize the number of advertisements that are flooded, you can summarize a range of IP addresses and send reachability information about these addresses in an LSA.</p> <p>The <b>no</b> form of the command deletes the range (non) advertisement.</p>                                                                                                                                                                                                                                    |
| <b>Default</b>       | <b>no area-range</b> — No range of addresses are defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Special Cases</b> | <p><b>NSSA Context</b> — In the NSSA context, the option specifies that the range applies to external routes (via type-7 LSAs) learned within the NSSA when the routes are advertised to other areas as type-5 LSAs.</p> <p><b>Area Context</b> — If this command is not entered under the NSSA context, the range applies to summary LSAs even if the area is an NSSA.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>    | <p><i>ipv6-prefix/prefix-length</i> — The IP prefix in dotted decimal notation for the range used by the ABR to advertise that summarizes the area into another area.</p> <p><b>Values</b>      <i>ipv6-prefix</i> - x:x:x:x:x:x:x:x (eight 16-bit pieces)<br/>                  x:x:x:x:x:d.d.d.d<br/>                  - x [0..FFFF]H - d [0..255]D<br/>                  <i>prefix-length</i> - [0..128]</p> <p><i>mask</i> — The subnet mask for the range expressed as a decimal integer mask length or in dotted decimal notation.</p> <p><b>Values</b>      0 — 32 (mask length), 0.0.0.0 — 255.255.255.255 (dotted decimal)</p> <p><b>advertise</b>   <b>not-advertise</b> — Specifies whether or not to advertise the summarized range of addresses into other areas. The <b>advertise</b> keyword indicates the range will be advertised, and the keyword <b>not-advertise</b> indicates the range will not be advertised.<br/>The default is <b>advertise</b>.</p> |

## blackhole-aggregate

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Syntax</b>      | <b>[no] blackhole-aggregate</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Context</b>     | config>service>vprn>ospf>area<br>config>service>vprn>ospf3>area                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | <p>This command installs a low priority blackhole route for the entire aggregate. Existing routes that make up the aggregate will have a higher priority and only the components of the range for which no route exists are blackholed.</p> <p>It is possible that when performing area aggregation, addresses may be included in the range for which no actual route exists. This can cause routing loops. To avoid this problem configure the blackhole aggregate option.</p> <p>Use the no form of this command to remove this option.</p> |
| <b>Default</b>     | blackhole-aggregate                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## interface

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Description</b> | <p>This command creates a context to configure an OSPF interface.</p> <p>By default interfaces are not activated in any interior gateway protocol such as OSPF unless explicitly configured.</p> <p>The <b>no</b> form of the command deletes the OSPF interface configuration for this interface. The <b>shutdown</b> command in the config&gt;router&gt;ospf&gt;interface context can be used to disable an interface without removing the configuration for the interface.</p>                                                                                                                                                                                                                                                |
| <b>Default</b>     | <b>no interface</b> — No OSPF interfaces are defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <p><i>ip-int-name</i> — The IP interface name. Interface names must be unique within the group of defined IP interfaces for <b>config router interface</b> and <b>config service vprn interface</b> commands. An interface name cannot be in the form of an IP address. Interface names can be any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.</p> <p>If the IP interface name does not exist or does not have an IP address configured an error message will be returned.</p> <p>If the IP interface exists in a different area it will be moved to this area.</p> |

| <b>Description</b> | This command is similar to a virtual link with the exception that metric must be included in order to distinguish the cost between the MPLS-VP RN link and the backdoor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <p><i>ip-int-name</i> — The local interface name used for the sham-link. This is a mandatory parameter and interface names must be unique within the group of defined IP interfaces for <b>config&gt;router&gt;interface</b>, <b>config&gt;service&gt;ies&gt;interface</b> and <b>config&gt;service&gt;vprn&gt;interface</b> commands. An interface name cannot be in the form of an IP address. Interface names can be any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters, the entire string must be enclosed within double quotes. If the IP interface name does not exist or does not have an IP address configured, an error message will be returned.</p> <p><i>ip-address</i> — The IP address of the SHAM-link neighbor in IP address dotted decimal notation. This parameter is the remote peer of the sham link's IP address used to set up the SHAM link. This is a mandatory parameter and must be a valid IP address.</p> |

## advertise-subnet

| <b>Context</b>     | config>service>vprn>ospf>area>interface<br>config>service>vprn>ospf>area>virtual-link<br>config>service>vprn>ospf>area>sham-link                                                                                                                                      |
| <b>Description</b> | <p>This command configures the password used by the OSPF interface or virtual-link to send and receive OSPF protocol packets on the interface when simple password authentication is configured.</p> <p>Note that this command is not valid in the OSPF3 context.</p> |

All neighboring routers must use the same type of authentication and password for proper protocol communication. If the **authentication-type** is configured as password, then this key must be configured.

By default, no authentication key is configured.

The **no** form of the command removes the authentication key.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Default</b>    | <b>no authentication-key</b> — No authentication key is defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Parameters</b> | <p><i>authentication-key</i> — The authentication key. The key can be any combination of ASCII characters up to 8 characters in length (unencrypted). If spaces are used in the string, enclose the entire string in quotation marks (“ ”).</p> <p><i>hash-key</i> — The hash key. The key can be any combination of ASCII characters up to 22 characters in length (encrypted). If spaces are used in the string, enclose the entire string in quotation marks (“ ”).</p> <p>This is useful when a user must configure the parameter, but, for security purposes, the actual unencrypted key value is not provided.</p> <p><b>hash</b> — Specifies the key is entered in an encrypted form. If the <b>hash</b> parameter is not used, the key is assumed to be in a non-encrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the <b>hash</b> parameter specified.</p> <p><b>hash2</b> — Specifies the key is entered in a more complex encrypted form. If the <b>hash2</b> parameter is not used, the less encrypted <b>hash</b> form is assumed.</p> |

## authentication-type

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>authentication-type {password   message-digest}</b><br><b>no authentication-type</b>                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Context</b>     | config>service>vprn>ospf>area>interface<br>config>service>vprn>ospf>area>virtual-link                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | <p>This command enables authentication and specifies the type of authentication to be used on the OSPF interface, virtual-link, and sham-link.</p> <p>Note that this command is not valid in the OSPF3 context.</p> <p>Both simple <b>password</b> and <b>message-digest</b> authentication are supported.</p> <p>By default, authentication is not enabled on an interface.</p> <p>The <b>no</b> form of the command disables authentication on the interface.</p> |
| <b>Default</b>     | <b>no authentication</b> — No authentication is enabled on an interface.                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <p><b>password</b> — This keyword enables simple password (plain text) authentication. If authentication is enabled and no authentication type is specified in the command, simple <b>password</b> authentication is enabled.</p> <p><b>message-digest</b> — This keyword enables message digest MD5 authentication in accordance with RFC1321. If this option is configured, then at least one message-digest-key must be configured</p>                           |

## dead-interval

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>        | <b>dead-interval</b> <i>seconds</i><br><b>no dead-interval</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Context</b>       | config>service>vprn>ospf>area>interface<br>config>service>vprn>ospf>area>virtual-link<br>config>service>vprn>ospf3>area>interface<br>config>service>vprn>ospf3>area>virtual-link<br>config>service>vprn>ospf>area>sham-link                                                                                                                                                                                                                                                                                                               |
| <b>Description</b>   | This command configures the time, in seconds, that OSPF waits before declaring a neighbor router down. If no hello packets are received from a neighbor for the duration of the dead interval, the router is assumed to be down. The minimum interval must be two times the hello interval.<br><br>The <b>no</b> form of the command reverts to the default value.                                                                                                                                                                        |
| <b>Default</b>       | 40                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Special Cases</b> | <b>OSPF Interface</b> — If the <b>dead-interval</b> configured applies to an interface, then all nodes on the subnet must have the same dead interval.<br><br><b>Virtual Link</b> — If the <b>dead-interval</b> configured applies to a virtual link, then the interval on both termination points of the virtual link must have the same dead interval.<br><br><b>Sham-link</b> — If the <b>dead-interval</b> configured applies to a sham-link, then the interval on both endpoints of the sham-link must have the same dead interval . |
| <b>Parameters</b>    | <i>seconds</i> — The dead interval expressed as a decimal integer.<br><br><b>Values</b> 2 — 2147483647 seconds                                                                                                                                                                                                                                                                                                                                                                                                                            |

## graceful-restart

|                    |                                                                  |
|--------------------|------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] graceful-restart</b>                                     |
| <b>Context</b>     | config>service>vprn>ospf                                         |
| <b>Description</b> | This command enables or disables graceful-restart for VPRN OSPF. |

## helper-disable

|                    |                                               |

| <b>Syntax</b>        | <b>hello-interval</b> <i>seconds</i><br><b>no hello-interval</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Context</b>       | config>service>vprn>ospf>area>interface<br>config>service>vprn>ospf3>area>interface<br>config>service>vprn>ospf>area>virtual-link<br>config>service>vprn>ospf3>area>virtual-link<br>config>service>vprn>ospf>area>sham-link                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Description</b>   | <p>This command configures the interval between OSPF hellos issued on the interface, virtual link, or sham-link.</p> <p>The hello interval, in combination with the dead-interval, is used to establish and maintain the adjacency. Use this parameter to edit the frequency that hello packets are sent.</p> <p>Reducing the interval, in combination with an appropriate reduction in the associated <b>dead-interval</b>, allows for faster detection of link and/or router failures at the cost of higher processing costs.</p> <p>The <b>no</b> form of this command reverts to the default value.</p> |
| <b>Default</b>       | <b>hello-interval 10</b> — A 10-second hello interval.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Special Cases</b> | <p><b>OSPF Interface</b> — If the <b>hello-interval</b> configured applies to an interface, then all nodes on the subnet must have the same hello interval.</p> <p><b>Virtual Link</b> — If the <b>hello-interval</b> configured applies to a virtual link, then the interval on both termination points of the virtual link must have the same hello interval.</p> <p><b>Sham Link</b> — If the hello-interval configured applies to a sham-link, then the interval on both endpoints of the sham-link must have the same hello interval</p>                                                               |
| <b>Parameters</b>    | <p><i>seconds</i> — The hello interval in seconds expressed as a decimal integer.</p> <p><b>Values</b> 1 — 65535</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
