Network Functions Manager - Packet (NFM-P)
Release 24.11

Classic Management User Guide

3HE-20021-AAAC-TQZZA
Issue 1
December 2024

Legal notice

Nokia is committed to diversity and inclusion. We are continuously reviewing our customer documentation and consulting with standards bodies to ensure that terminology is inclusive and aligned with the industry. Our future customer documentation will be updated accordingly.

Contents

About this document

Purpose

The *NSP NFM-P Classic Management User Guide* provides information about using the NFM-P to manage service-aware IP/MPLS networks, including GUI operations, device and network management, and policy and service management.

Scope

The scope of this document is limited to the NFM-P, which can accomplish many configuration, monitoring, and assurance functions.

Document organization

This guide contains the following volumes:

- Getting started—contains general NFM-P information including the following:
  - a system overview
  - basic GUI operation instructions
  - workspace customization and GUI/topology map management
- Device management—contains information about device functions that are not directly related to networking, including the following:
  - device support
  - device commissioning and management, and device discovery
  - working with network objects and device object configuration on logical groups, shelf and cards objects, and port and channel objects
  - NFM-P device and equipment management functions such as inventory management, TCA, and bulk operations
- NE maintenance—contains information about the functions that facilitate the maintenance of managed NEs, including the following:
  - when to deploy NE configuration changes and how to configure them
  - backing up device configurations on demand, or using a schedule, and restoring device configurations
  - upgrade device software on demand, or using a schedule, and how perform device configuration rollback
  - monitor and troubleshoot operations in progress and how to browse NE file systems
- Network management—contains information about network functions including the following:
  - general routing and forwarding object configuration
  - protocol-specific configuration
  - traffic management using MPLS, MPLS TP, and service tunnels
  - NE redundancy
- Policy management—contains information about configuring and applying NFM-P policies that define rules that govern how network traffic is handled and prioritized
- Service management—contains information about configuring and managing customer services.

- Service assurance—contains information about the proactive detection of service degradation and SLA verification including the following:
  - service verification using the STM and specific OAM diagnostic tests
  - networking troubleshooting activities including fault detection/verificatio/isolation and performance monitoring
  - root-cause analysis audits of services and physical links
  - service throughput configuration

Safety information

For your safety, this document contains safety statements. Safety statements are given at points where risks of damage to personnel, equipment, and operation may exist. Failure to follow the directions in a safety statement may result in serious consequences.

How to comment

Please send your feedback to documentation.feedback@nokia.com.

Part I: Getting started

Overview

Purpose

This part provides information about the NFM-P user interface, workspaces, navigation tree, map, and schedules.

Contents

1 NFM-P GUI

GUI overview

1.1 GUI workspace elements

1.1.1 Overview

The GUI on an NFM-P client station allows you to use a standard keyboard and point-and-click operations to perform device, network, policy and service management functions. The GUI simplifies operations such as service configuration, OAM, security, statistics, and other functions by allowing point-and-click selection and intuitive data entry, rather than using a CLI. Multiple NFM-P GUI clients can connect to an NFM-P server.

The main GUI window displays standard workspace elements such as a menu bar, toolbar, taskbar, and status bar.

1.1.2 Navigation tree

The navigation tree lists the managed equipment, services, protocols, and other objects that are configured on the network. By expanding the tree, you can navigate to and select network objects for configuration or to view information. You can open up to five navigation tree windows at one time.

See Chapter 3, “NFM-P navigation tree” for more information about the navigation tree.

1.1.3 Topology map

The topology map provides a view of network elements and connections. You can arrange elements on the map and create equipment groups to suit your requirements. You can select map objects and use contextual menus for configuration or to view information. You can open multiple topology map windows at one time.

See Chapter 4, “Topology map management” for more information about the topology map.

1.1.4 Windows and forms

The NFM-P displays forms in response to menu options or other on-screen selections. Forms are typically used to configure parameters and to view information. Forms allow configurations, display lists and searches, and provide other options; see “NFM-P forms” (p. 82) in this chapter.

All currently open windows and forms, except external windows, are represented by icons on the NFM-P taskbar. All currently open windows and forms, including external windows, are listed in the Window menu of the NFM-P main menu.

The NFM-P GUI provides floating windows and forms that you can move, resize, hide, and bring to the foreground to optimize the workspace. For information about managing the display of windows and forms, see 1.13 “To manage the display of windows and forms” (p. 105). A window or form in the GUI can be moved out of the main workspace and managed as an external window on a second monitor; see 1.15 “To manage a window or form as an external window” (p. 107).

Messages, warnings, dialogs, and other information appear in pop-up windows in the GUI, but are not managed as floating windows.

1.1.5 Main menu bar

The main menu bar contains menus and submenus that allow you to navigate to the forms required to perform many NFM-P functions. The available menu items vary depending on licensing and the scope of command role of the current user.

1.1.6 Toolbar

The toolbar contains icons that allow you to quickly access windows and forms. The icons represent menus or menu items in the NFM-P main menu. When a button represents a menu, the button displays the name of the menu. Clicking the button opens a drop-down of the associated menu items. When an icon represents a menu item with no submenu items, clicking the icon opens the associated form or window. You can set user preferences to show or hide the toolbar; see 1.23 “To configure NFM-P user preferences” (p. 116). You can customize the toolbar as part of a custom workspace; see 2.11 “To customize toolbars” (p. 150).

1.1.7 NFM-P objects

The term “object” in the NFM-P typically refers to an entity on the network, such as an NE, card, port, routing instance, or any other physical or logical object that is displayed in the navigation tree or map. The term “object” can also refer to entities in the NFM-P, such as policies, tests, or other objects that are displayed in lists or on configuration forms.

1.1.8 Contextual menus

Contextual menus appear when you right-click certain objects or areas in the GUI; for example, in the navigation tree and topology map. Contextual menus allow you to perform actions that are specific to the object or area.

1.1.9 Tooltips

The NFM-P provides tooltips to identify many icons, buttons, fields and other GUI elements. When you mouse over these elements, information is displayed.

1.2 GUI customization

1.2.1 Custom workspaces

The NFM-P supports custom workspaces that allow you to configure and arrange workspace elements to suit your operational requirements. You can save and select custom workspaces and update saved workspaces after an NFM-P upgrade. You must have the required scope of command permissions to customize workspaces. Permissions for workspaces are set by a system administrator. See Chapter 2, “NFM-P custom workspaces” for more information about custom workspaces.

1.2.2 Span of control

The GUI displays objects and allows object configuration based on the span of control of the user and user preferences. By default, the GUI displays the objects that are included in the View Access and Edit Access spans of the current user. To reduce the number of objects displayed, you can configure user preferences to show only the objects in the Edit Access span of control of the user; see 1.23 “To configure NFM-P user preferences” (p. 116) . The user preferences setting affects the display of objects in the GUI. You can temporarily override the user preferences setting when you configure filters to search lists; see 1.39 “To filter using span of control” (p. 136) .

For more information about span of control, see the section on creating a span of control in the *NSP System Administrator Guide*.

1.2.3 User preferences

The NFM-P allows you to configure workspace elements and functions to suit your operational requirements. You can set many preferences using the User Preferences form accessed from the main menu. User preferences are specific to a particular user; the settings are associated with the user ID and are applied to the system when that user is logged in. See 1.23 “To configure NFM-P user preferences” (p. 116) for more information about user preferences.

You can set tab preferences to show or hide tabs on forms; see 1.24 “To set local tab preferences for configuration forms” (p. 118) . You can also configure custom workspaces; see Chapter 2, “NFM-P custom workspaces”.

1.2.4 Tab preferences

Some NFM-P property forms contain numerous tabs, which you can display, hide, and arrange in a preferred sequence according to your operational requirements. On some forms, tabs are hidden by default. You can temporarily display hidden tabs, and you can configure and save your tab display preferences; see 1.24 “To set local tab preferences for configuration forms” (p. 118) and 1.25 “To temporarily display hidden tabs on property forms” (p. 119) .

You can configure a workspace to use local tab preferences or custom tab preferences. Local tab preferences are configured using the tab selector and are saved for a specific user. When your current workspace uses local tab preferences, saved local tab preferences become the default that is displayed when a form opens. Custom tab preferences are saved as part of the workspace, and are not user-specific. See 2.9 “To configure tab preferences” (p. 147) .

Local tab preferences can be exported and shared; see 1.26 “To export local tab preferences” (p. 120) and 1.27 “To import local tab preferences” (p. 121) .

An administrator can configure system preferences to enable or disable tab preferences and to define the default local behavior for hidden tabs. See the section on system preferences configuration procedures in the *NSP System Administrator Guide*.

1.2.5 Localized language support

The GUI supports localized language display. Localized language display, also known as internationalization, displays GUI text in a specified language. The localized language setting applies to most GUI objects, except system components and database objects. Contact Nokia technical support for more information about localized language support.

Note: The NFM-P supports localized language settings using predefined strings, and does not translate data to different languages.

The XML API does not support language localization.

1.3 Additional GUI operations

1.3.1 Shortcut keys and accessibility

The NFM-P supports shortcut keys to enable operation by keyboard alone, without a mouse or pointer. The following keyboard shortcuts are available:

- Standard Java-based shortcuts. The NFM-P supports many conventional keyboard shortcuts for accessibility and convenience.
- Mnemonics. You can use mnemonics to open menu items and access forms. To open a menu item, simultaneously press Alt-*key*, where *key* is the underlined letter of the menu item. For example, when the main menu is displayed, pressing Alt-P opens the Policies menu. The menu item must be displayed for the mnemonic to work.
- Keyboard shortcuts for specific NFM-P functions.

The following table describes some of the keyboard shortcuts for specific functions in the NFM-P. For multiple keystrokes, a hyphen means that the keys are pressed simultaneously.

Keyboard shortcut	Description
Ctrl-A	Selects all GUI client sessions on the Select Sessions form Selects all objects on the topology map
Ctrl-C	Stops a command, when using the command window
Ctrl-F	Opens the “Find Attribute in” form when a property form is the active GUI element Opens or closes the search panel when the navigation tree is the active GUI element
Ctrl-O	Opens a directory and lists its contents, when a directory is selected in an NE file system
Ctrl-T	Opens the tab selector dropdown on a property form
Ctrl-Shift-A	Temporarily displays all hidden tabs on a property form
F3 and Shift-F3	When search results for the navigation tree produce multiple matching objects, the F3 key selects the next object. Shift-F3 returns to the previous matching object.

1.3.2 NFM-P clipboard

As well as the standard clipboard functions for copying text, the NFM-P provides a clipboard function that copies property form identifiers. A property form identifier is a unique internal address that the NFM-P assigns to a property form.

Identifiers are copied to the clipboard using the Clipboard icon or the Copy to Clipboard option in a contextual menu. You can use the clipboard to open forms, send identifiers to other users, and configure search filters.

For more information about the NFM-P clipboard, see 1.20 “To use the NFM-P clipboard” (p. 112).

1.3.3 Broadcast messages

You can send messages to other selected NFM-P users or to all active users logged into the NFM-P. This is useful for sending maintenance and similar notifications to other users.

When you receive a message, you can click Reply to respond to the sender.

Messages are uniquely identified with the Client ID number of the sender.

See the procedures on sending a text message to other NFM-P users and sending a broadcast message to GUI clients in the *NSP System Administrator Guide* for more information.

1.3.4 Task manager

The task manager allows you to monitor the progress of operational tasks. The task manager monitors the following operations:

- all write operations that are performed from the GUI; for example, when you click Apply or OK
- all write operations that are performed using the XML API
- some read operations; for example, when you click Resync or Collect All

See 1.21 “To monitor the NFM-P Task Manager” (p. 114) for more information.

An NFM-P administrator can change the task manager settings. See the procedure to change the NFM-P Task Manager settings in the *NSP System Administrator Guide*.

You can also send the tasks displayed in the Task Manager to a file using the findToFile method. See “Inventory retrieval methods” in the *NSP NFM-P XML API Developer Guide* for more information.

NFM-P forms

1.4 Forms overview

1.4.1 Types of forms

The NFM-P displays forms in response to menu options or other on-screen selections. Forms display lists or allow you to view and configure properties. Some forms display other information.

The GUI displays the following form types:

- list forms
- configuration forms
- step forms
- property forms
- problems encountered forms
- other forms such as messages, warnings, or dialog boxes. These forms are also sometimes referred to as windows.

See Figure 1-1, “List form” (p. 83) and Figure 1-4, “Service configuration form with built-in tree” (p. 88) for examples of NFM-P forms.

Forms can be sized, positioned, and managed using standard OS functions and NFM-P display features; see 1.13 “To manage the display of windows and forms” (p. 105) . A form can be displayed anywhere in the GUI. A newly opened form is displayed in the foreground. You can do the following:

- organize forms according to your preferences
- compare information on multiple open forms
- navigate quickly to another open form
- save a set of open forms and reopen them later with one operation, to provide quick access to forms that you use often; see 1.14 “To save or open a set of forms for quick access” (p. 106) .

Forms are identified by a titlebar at the top. The displayed form name is the name specified during object creation. If the object is not named, a default name is used. When a form is minimized to the taskbar, a tool tip on the taskbar icon of the form displays the title bar information. The Window menu on the main menu lists all open forms.

Forms typically contain tabs, buttons, fields, and other elements that you can click to perform actions, depending on the form type. When these elements are not available or not applicable, they are dimmed.

1.4.2 More Actions button

Buttons that perform various functions appear at the bottom of configuration forms and on the right side of list forms. When a form is resized to a smaller size, or when there are too many buttons to fit in the available space, some of the buttons are consolidated into a More Actions button. The consolidated buttons are available as menu items when you click More Actions; see Figure 1-1, “List form” (p. 83) and Figure 1-4, “Service configuration form with built-in tree” (p. 88) .

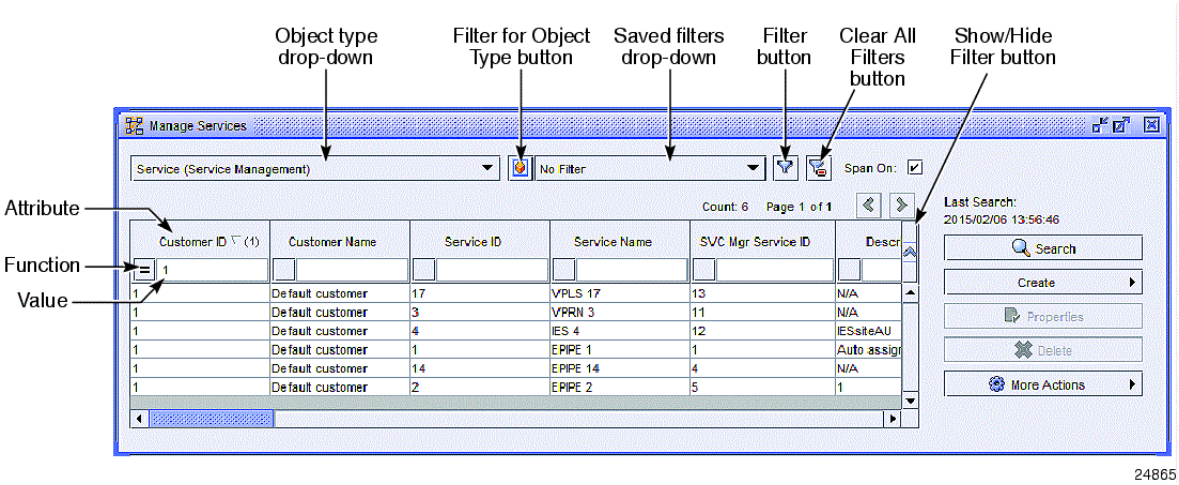
1.5 List forms

1.5.1 General information

A list form displays a list of objects in response to a menu option, tab, or other on-screen selection. Figure 1-1, “List form” (p. 82) shows the features of a list form.

Some list forms populate automatically; for others, you must click Search to see results.

Figure 1-1 List form



1.5.2 Using list forms

Some list forms contain an object type drop-down that allows you to select the type of objects in the list. When an object type drop-down menu contains more than ten items, you can apply a filter to reduce the number of drop-down items; see 1.38 “To filter object types” (p. 136) . You can customize the object drop-down and select the default object type in a custom workspace; see 2.13 “To customize list forms” (p. 153) .

Objects on a list form are displayed in table format. The column headings correspond to the attributes (parameters) for the object, for example, the Customer ID for a service. The column headings vary depending on the object type. Each object in the list is displayed in a row, showing the values for the attributes of the object. On some forms, the first column on the left displays a deployment icon for an item, when required; see 11.1.2 “Object deployment status” (p. 334) in Chapter 11, “Working with network objects” .

Objects are displayed based on the span of control of a user and user preferences. See 1.2.2 “Span of control” (p. 79) in this chapter.

List forms can contain many objects, in some cases hundreds or thousands. You can reduce the number of items in a list using search filters; see “NFM-P searches” (p. 92) in this chapter. Most list forms display the time at which the last search was performed on the form.

List forms typically display a column of buttons along the right side. On some list forms, not all buttons are displayed, but you can access them using the More Actions button. See 1.4.2 “More Actions button” (p. 82) in this section.

Many list forms contain a Customize button that allows you to quickly make changes to the list form default settings in a custom workspace. See 2.13 “To customize list forms” (p. 153) for more information.

The NFM-P provides features that allow you to manage the display of listed results and to set and save your display configuration. See 1.8.4 “Managing search results and lists” (p. 97) in this chapter, and 1.29 “To manage the display of listed information” (p. 122) . You can also save the results to a file; see 1.22 “To save listed information to a file” (p. 115) .

You can set the following user preferences for list forms:

- number of items per page
- object display based on user span of control
- default file extension for saving listed information

See 1.23 “To configure NFM-P user preferences” (p. 116) for more information about user preferences.

1.6 Configuration forms

1.6.1 General information

Configuration forms allow you to create and modify NFM-P objects and to view information about objects; see 1.17 “To use configuration forms to configure or view parameters” (p. 109) . Figure 1-4, “Service configuration form with built-in tree” (p. 88) describes the main features of a configuration form in the NFM-P.

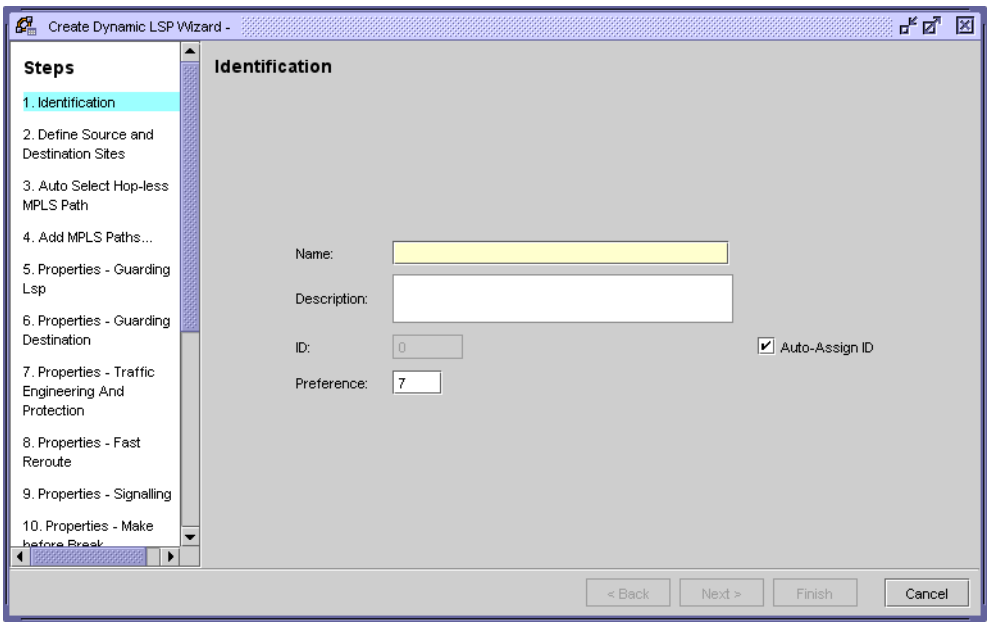
When you first create an object in the NFM-P, you use a configuration form to enter values for the parameters that define the object. For example, when you create a service, you use a service configuration form; when you create a policy, you use a policy configuration form. After object creation, the form associated with the object is typically called a property form. See 1.6.12 “Property forms” (p. 89) in this section.

You can set user preferences to suppress warnings and messages for configuration forms; see 1.23 “To configure NFM-P user preferences” (p. 116) .

1.6.2 Step forms

Some configuration activities lead the operator through a series of forms, each of which represents a step in the configuration process. Such a form is called a step form. You must click Next to proceed to the next step. The following figure shows the first step in a step form sequence. When the configuration sequence is complete, you must click Finish to commit the changes.

Figure 1-2 Step form



Some steps open a new step form. You must complete the steps in the new form before you can return to the previous form. After you click Finish on the new form, the previous form reappears.

1.6.3 Tabs

Configuration forms typically display tabs. You can use the tabs to open related forms for additional configurations or to open lists or view other information, such as deployment or fault status. Property forms allow you to show or hide tabs to suit your requirements, and to set preferences for tab display; see 1.2.4 “Tab preferences” (p. 79).

1.6.4 Collapsible panels

Configuration forms are often subdivided into specific information areas using panels. Panels are framed by border lines, with a title bar at the top that identifies the panel. Panels can be collapsed to hide areas that are not of interest, or expanded to display all information on a tab or form; see 1.17 “To use configuration forms to configure or view parameters” (p. 109).

When a configuration form closes, the current state of the panel is saved for that object type. When a user opens a configuration form, the last saved state of the panel is displayed.

1.6.5 Parameters

When you create or modify an object, you typically configure parameters, sometimes referred to as attributes. Parameter settings define the properties of an object. Some parameters are read-only, and cannot be configured. Configurable parameters typically display a white field, check box, or drop down arrow. Mandatory fields are yellow. Read-only parameter values display in a grey field.

Non-applicable parameters are dimmed. See 1.17 “To use configuration forms to configure or view parameters” (p. 109) for more information about parameters.

1.6.6 Saving configurations

When you complete a configuration, you can click OK, Apply, or other buttons to save the configured values. When you click the OK button, the information is saved and the form closes. When you click the Apply button, the information is saved and the form remains open to allow you to perform additional actions. See 1.17 “To use configuration forms to configure or view parameters” (p. 109) for more information.

1.6.7 Warning and confirmation messages

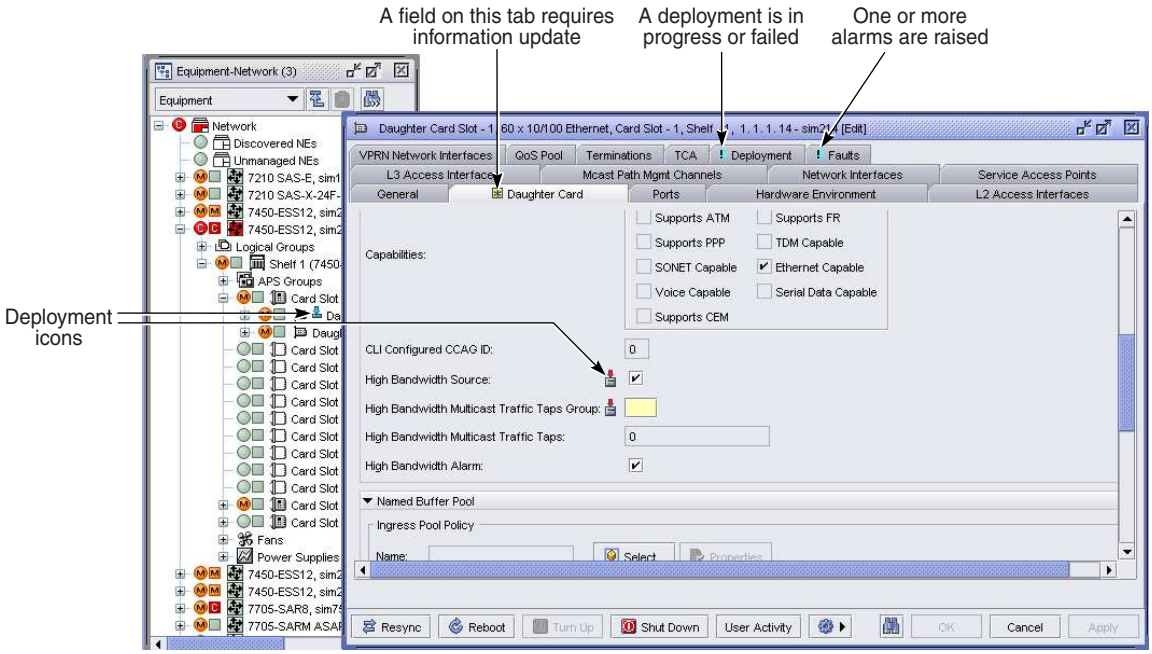
When you save configuration changes or close a form, the NFM-P typically displays a warning or confirmation message. You must acknowledge the message. Not all configurations require confirmation.

When you save changes for a child object configuration form that was launched from a parent object form, the NFM-P displays a warning that the changes are not committed until the parent object form (called the containing window) is also saved. You must acknowledge the warning. You can set user preferences to suppress containing window warnings; see 1.23 “To configure NFM-P user preferences” (p. 116). If you then attempt to close the parent form without saving it first, the NFM-P displays a warning, regardless of the user preferences setting.

1.6.8 Indicators and icons

Indicators and icons inform you of activity that is in progress or requires attention, and can appear and disappear depending on the activity that is occurring in the NFM-P, as shown in the following figure.

Figure 1-3 Indicators and icons



22870

A yellow asterisk icon on a tab or panel title bar indicates that a field contains incorrect data, or that a mandatory field requires data.

A warning indicator appears on the Deployment tab when a configuration change is not fully deployed to an NE.

When a deployment is in progress or has failed, a deployment icon appears beside parameters on an object properties form, and beside affected objects in the navigation tree, and in list forms. See 11.1.2 “Object deployment status” (p. 334) in Chapter 11, “Working with network objects” for more information.

1.6.9 Action buttons

Configuration forms typically have a row of action buttons along the bottom. The available buttons vary depending on the form. The Find icon is available on all configuration forms, and allows you to quickly locate a specific tab, panel, or parameter; see 1.37 “To locate an attribute on a configuration form” (p. 135). On some configuration forms, not all buttons are displayed, but you can access them using the More Actions button. See 1.4.2 “More Actions button” (p. 82) in this section.

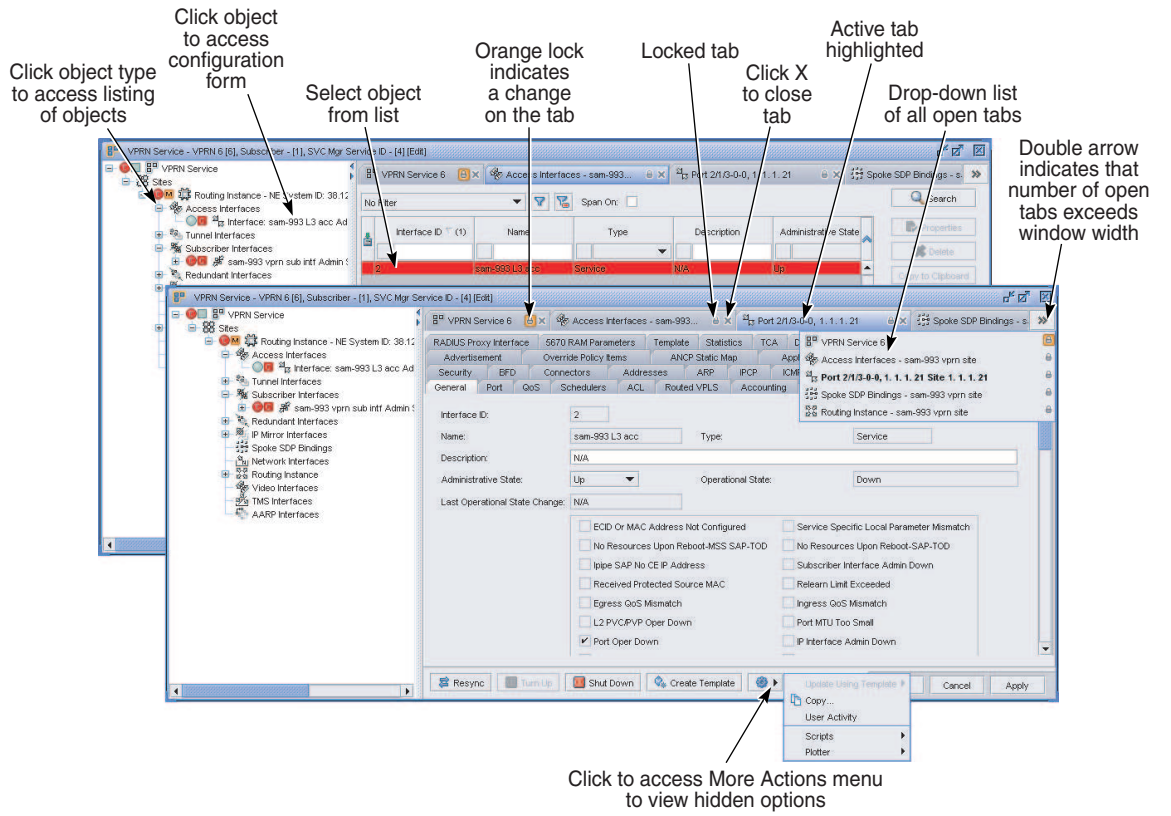
1.6.10 Configuration forms with built-in navigation trees

Services and NEs typically require configuration at several levels of the service or equipment object tree. For example, when you create a service, you configure parameters at the service, site, and interface levels. NEs require configuration at the device, shelf, card, and port levels; see Chapter 11, “Working with network objects”.

NFM-P service configuration and NE property forms display a navigation tree on the left side of the form, which provides quick access to service and NE objects. Other object types also display navigation trees in configuration or property forms. See “NFM-P navigation tree” (p. 161) for information about using navigation trees. Objects in the tree provide access to configuration forms using contextual menus.

Service navigation trees for VPLS, I-VPLS, B-VPLS, MVPLS, IES, and VPRNs display a maximum of 50 access interfaces, SAPs, MSAPs, subscriber SAPs, and spoke and mesh SDP bindings at a time. When this limit is reached, you can click on the message beside the containing object under which the SAPs or access interfaces are listed to open a tab with the full list of objects.

Figure 1-4 Service configuration form with built-in tree



21805

When you first open a configuration form with a built-in navigation tree, the form is unlocked. When you select another object in the tree, a form for the selected object replaces the unlocked form of the previous object. You can lock forms to keep them open when you select additional objects. The form for each object is displayed as a tab in the main configuration form.

You can undock tabs to detach them from the main configuration form. Undocked tabs are displayed as separate forms and are managed like other standard form in the NFM-P. You cannot undock Create forms, tabs for object type lists, or tabs with unsaved changes.

See 1.18 “To manage configuration forms with built-in navigation trees” (p. 110) for more information about managing configuration forms with built-in navigation trees.

1.6.11 Modifying configuration forms with built-in navigation trees

When you modify a docked configuration form, it becomes locked. The lock icon appears in orange until the changes are saved. An orange lock icon indicates unsaved changes on the form. You cannot undock tabs with orange lock icons. When you save the changes, the form remains locked but the icon is no longer orange.

If you attempt to close a modified configuration form that contains unsaved changes, a message prompts you to specify whether to discard the changes or return to the display. If you attempt to close a modified configuration form that has related forms with unsaved modifications, the message lists the forms that have unsaved changes.

For service configuration forms, if an object is added to the service configuration, the new object appears in the built-in navigation tree and the configuration form is displayed with the orange lock icon. The icon remains orange until the modifications are saved or discarded.

For NE property forms, if an object is added from the navigation tree, the change will be made immediately. However, if a change, such as adding or removing an object, is made to an equipment configuration form, the change will be reflected on the form immediately, but it will not be reflected on the navigation tree until the OK, Apply, or Apply Tab button is clicked.

Note: Changes implemented by pressing the OK or Apply buttons affect all tabs in the form. For some configuration forms, you can click the Apply Tab button to save changes for the current object-level tab and related objects. A message lists the affected objects.

If you save a set of forms for quick access when child forms are displayed as tabs in a parent form, all of the child tabs are saved as separate forms. When you reopen the forms, the child tabs are displayed as separate forms. See 1.14 “To save or open a set of forms for quick access” (p. 106) .

1.6.12 Property forms

Configuration forms for objects that already exist in the NFM-P (NEs for example) are typically called property forms. You can access property forms by using contextual menus, the Properties button on list forms, or by double-clicking on objects in the navigation tree that have no child objects.

A property form has a property form identifier that you can copy to the clipboard and paste for various functions; see 1.20 “To use the NFM-P clipboard” (p. 112).

Most property forms contain tabs that provide specific information. The Deployment tab allows you to monitor the deployment status of an object; see 11.1.2 “Object deployment status” (p. 334) in Chapter 11, “Working with network objects”.

1.6.13 NE sessions

You can open a CLI window using the Telnet Session or SSH Session button on NE property forms. You can access the NE file system using the File Browser button. These options are also available using the contextual menu for NE objects in the navigation tree.

1.6.14 User Activity button

The User Activity button opens a form that lists the recent NFM-P user actions performed on the object. See the section on user activity logging in the *NSP System Administrator Guide* for more information.

1.6.15 Resync button

The Resync button on a property form resynchronizes the data in the NFM-P with the current state of the corresponding object. The NFM-P requests the configuration from the object and updates the NFM-P network model accordingly. Resynchronization does not affect the contents of the historical statistics database.

1.6.16 Turn Up and Shut Down buttons

The Turn Up and Shut Down buttons on some property forms provide a convenient method for changing the administrative state of an object. When you click the Turn Up or Shut Down buttons, the change is effected immediately. When you modify the Administrative State parameter, the change is not effected until you click the OK or Apply button for the form.

1.6.17 Multi-edit property forms

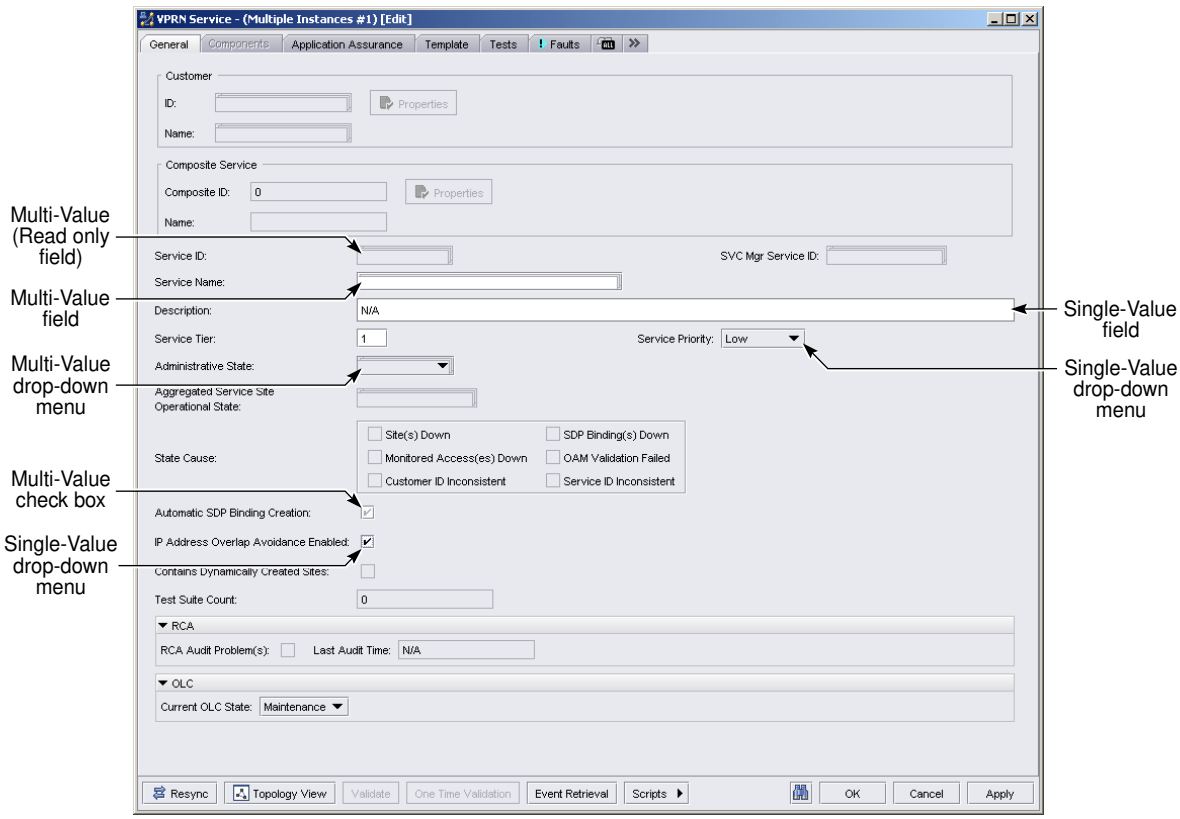
The NFM-P provides a multi-edit function that allows you to select multiple objects at one time for editing of specific properties. The objects must be of the same type (for example, services must all be VPRN, not a mixture of VPRN and other service types).

Changes for the selected objects are entered on a Multiple Instances (Edit) property form. When the objects selected for multi-edit are configured with differing parameter values, the NFM-P typically alerts you by displaying multi-value fields or drop-downs for the parameters whose values differ. Multi-value fields and drop-downs are identified by triple borders along the top and right side; see Figure 1-5, “Multi-value property form” (p. 91). Both configurable and read-only parameters may display as multi-value properties.

You can modify configurable multi-value fields. When a value is entered in a multi-value field, the value is propagated to all selected objects in the multi-edit group, and the parameter no longer displays as a multi-value property. See 1.19 “To modify multiple objects at one time (multi-edit)” (p. 111) for more information.

The NFM-P also provides a bulk operations function; see Chapter 20, “Bulk operations”.

Figure 1-5 Multi-value property form



23740

1.6.18 Problems encountered notifications

When you enter a faulty configuration or instruction in the NFM-P, a Problems Encountered form may open. The Problems Encountered form displays problems in a list. You can double-click on a problem entry, or select and click Properties to display a property form with more information about the problem. The Problems Encountered form contains a Deployment button that you can click to access the Deployment form for additional information and actions; see 25.5 “To view and manage failed deployments” (p. 769) for more information. You can copy the property form identifier for the Problems Encountered form to the NFM-P clipboard; see 1.20 “To use the NFM-P clipboard” (p. 112).

NFM-P searches

1.7 Search overview

1.7.1 Search types

The NFM-P typically manages large numbers of network objects, policies, and configurations. Searches allow you to find the objects and information required for your operations. Searches are available for list forms, navigation tree objects, configuration parameters, and online documentation.

This section provides an overview of NFM-P search features. See "Procedures for searching" (p. 127) for search procedures.

Table 1-1 NFM-P search types

Search type	Description	See
Find attribute	Locate a tab, panel, or parameter on a form using the Find icon	1.37 "To locate an attribute on a configuration form" (p. 135)
Simple search	Search lists using column headings to create filters	1.8.1 "Simple searches" (p. 95) in this section 1.30 "To perform a simple search from an object list form" (p. 127)
Advanced search	Search lists using the filter configuration form	1.8.2 "Advanced searches" (p. 95) in this section 1.31 "To perform an advanced search from an object list form" (p. 128)
Endpoint search	Search for LSPs, tunnels, and paths by specifying endpoints	1.32 "To perform a search by specifying endpoints" (p. 131)
Equipment Group filters	Search for equipment objects, and service objects, based on equipment groups	1.40 "To configure and save equipment group filters" (p. 138) and 1.41 "To use a saved equipment group filter" (p. 139)
Navigation tree	Search for network objects in the navigation tree using the Find icon or Find field	3.7 "To locate objects in the navigation tree" (p. 165)
NSP Help Center	Search the NFM-P user documentation	Help→Open Help Center in the NFM-P main menu.

1.7.2 Search filters

Some search types use configurable search filters. Filter configuration varies depending on the type of search; see Table 1-1, "NFM-P search types" (p. 92).

Search filters for lists in the NFM-P typically consist of one or more filter properties that are based on the type of objects in the list.

A filter property is a combination of an attribute, a function, and a value:

- Attribute: defines the information type, or field, to be searched. Attributes typically correspond to

the properties and parameters for objects in the list. For example, you could filter a list of services by using the Customer attribute to search for services associated with a particular customer. Attributes are specific to the object type being searched.

- Function: defines the operation that the search performs. For example, the CONTAINS function will search in the list for instances where the attribute contains a specified value, such as a number or text string. The available functions vary, depending on the selected attribute. See Table 1-2, “Search functions” (p. 93) for information about search functions.
- Value: specifies the character string or parameter setting used by the function. The available values depend on the selected attribute. For example, if the Customer ID attribute is selected, you can configure numerals in the Value field. If the Current OLC State attribute is selected, you can choose In Service or Maintenance from the drop-down menu for the Value field.

You can configure filter properties using the column headings of a list; see 1.8.1 “Simple searches” (p. 95) in this section. You can open the filter configuration form to display, create, and modify filter properties. The filter configuration form is used for advanced searches; see 1.8.2 “Advanced searches” (p. 95) in this section. Figure 1-6, “Filter configuration form” (p. 96) shows the filter configuration form.

You can save search filters for reuse or modification; see 1.33 “To save search filters” (p. 132) . Saved filters appear in the filter list drop-down menu for the list form; see Figure 1-1, “List form” (p. 83) .

When a saved search filter contains attributes or values that are not available for the object type you are searching, the NFM-P alerts you by displaying red text. See 1.8.3 “Invalid attributes or values” (p. 96) in this section for more information.

If the number of search results exceeds the allowed limit, the NFM-P displays a dialog box that indicates the number of results returned. You can modify a filter to refine the search criteria and reduce the search results.

On some list forms, you can enable a span of control filter to display only the objects that are within your Edit span of control; see 1.39 “To filter using span of control” (p. 136) .

Table 1-2 Search functions

Operator	Description
APPROXIMATELY EQUAL	Filters by object timestamp. The function allows you to specify a timestamp value using 1 min resolution rather than the 1 ms default resolution. The search returns items that match the specified timestamp value. Select a time unit in the display (yyyy/mm/dd/hh:mm) and click on the arrows in the column heading to specify a time value.
BETWEEN	Filters by object timestamp. The function allows you to specify a start time and end time. The search returns items that have a timestamp between the configured values. Click the Select icon, select a time unit in the display (yyyy/mm/dd/hh:mm), and click on the arrows in the column heading to specify a time value for Start Time and End Time. If the start and end time are the same, the OK button is dimmed.

Table 1-2 Search functions (continued)

Operator	Description
CONTAINS	Filters by comparing character strings. The search returns an item when the search term matches any part of the character string of the item. For example, the filter property “Description CONTAINS (ab)” returns all items with the string “ab” in the Description attribute, such as “ABC Industries” and “Calgary, AB”. An empty CONTAINS search returns all items. The function is not case-sensitive.
DOES NOT CONTAIN	Filters by comparing character strings. The search returns an item when the search term does not match any part of the character string of the item. For example, the filter property “Description DOES NOT CONTAIN (ab)” returns items that do not contain the string “ab” in the Description attribute. Items with Descriptions such as “ABC Industries” and “Calgary, AB” are not returned in the search results. The function is not case-sensitive.
EQUALS	The search returns an item when the search term exactly matches the attribute value of the item. The function is case-sensitive.
GREATER OR EQUAL	Filters by comparing numerical values.The search returns items that have a value greater than or equal to the search term.
GREATER THAN	Filters by comparing numerical values.The search returns items that have a value greater than the search term.
IS BLANK	The search returns items that do not have a value. For example, the filter property “Associated Template IS BLANK” returns services that have no configured value in the Associated Template field. When the IS BLANK function is selected, you cannot configure a value for the filter property.
IN THE PAST	Filters by object timestamp. The function allows you to enter a period of time. The search returns items that are within the specified period of time before the present; for example, in the past two hours. Click the Select icon in the column heading and enter a period of time.
LESS OR EQUAL	Filters by comparing numerical values.The search returns items that have a value less than or equal to the search term.
LESS THAN	Filters by comparing numerical values.The search returns items that have a value less than the search term.
MATCHES	Applies to simple searches using column headings, for a single property of a group of checkboxes. The MATCHES function filters by comparing checkbox settings. The search returns an item when the checkbox setting (selected or deselected) of the search term matches the checkbox setting of the item.
MATCHES ALL	Applies to advanced searches using the filter configuration form, for attributes that show settings for a group of checkboxes. When you choose the MATCHES ALL function, you must click Properties in the Value field and select or deselect the checkboxes associated with the attribute. The MATCHES ALL function filters by comparing checkbox settings. The search returns an item when all of the selected checkbox settings of the search term are selected for the item.

Table 1-2 Search functions (continued)

Operator	Description
MATCHES ANY	Applies to advanced searches using the filter configuration form, for attributes that show settings for a group of checkboxes. When you choose the MATCHES ANY function, you must click Properties in the Value field and select or deselect the checkboxes associated with the attribute. The MATCHES ANY function filters by comparing checkbox settings. The search returns an item when one or more of the selected checkboxes of the search term matches the corresponding checkbox of the item.
NOT EQUAL	The search returns an item when the search term does not exactly match the attribute value of the item. The function is case-sensitive.
WILDCARD	For filters based on character strings (letters, numbers, or special characters). Wildcards substitute for characters in the search term. Use a question mark (?) to substitute for a single character. Use a single asterisk (*) to substitute for multiple characters. The function is case-sensitive.

Equipment group filters

Equipment group filters allow you to search for objects that are organized by equipment group, such as managed equipment objects, and managed service objects. An equipment group is sometimes called a topology group.

An equipment group filter is created by selecting from existing equipment groups. Filters can be saved for reuse or modification. See 1.40 “To configure and save equipment group filters” (p. 138) and 1.41 “To use a saved equipment group filter” (p. 139) for more information about equipment group filters.

1.8 Searching tips

1.8.1 Simple searches

You can perform a simple search on a list form using the column headings of the list table. Each column heading displays an attribute. You can configure a filter property for an attribute by selecting a function and a value from the column heading fields.

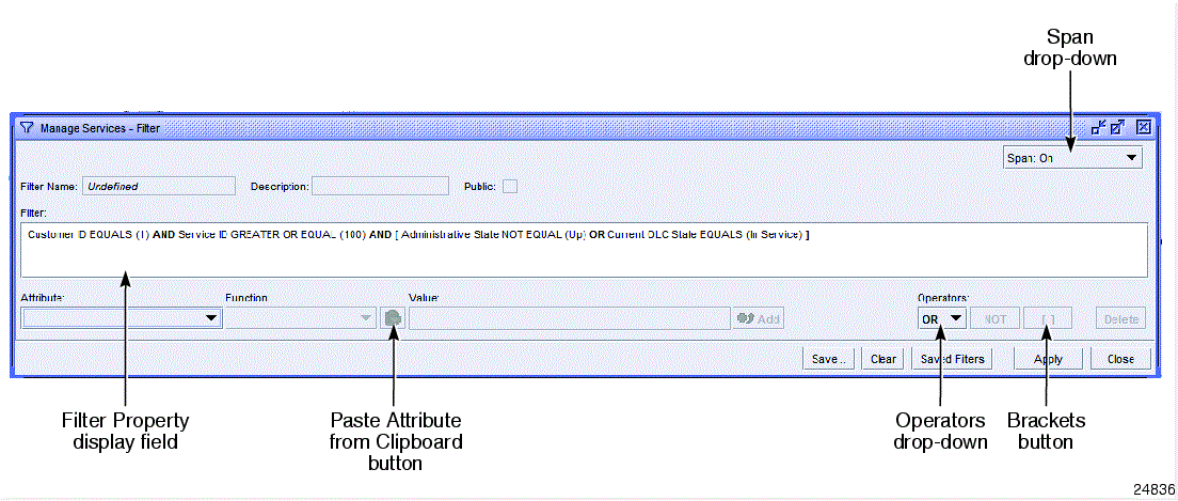
Filter properties for simple searches are displayed in the column heading, and show the attribute, the function (as a symbol, such as = or >), and the configured value. See Figure 1-1, “List form” (p. 83) . You can configure multiple filter properties at one time.

See 1.30 “To perform a simple search from an object list form” (p. 127) for more information about simple searches.

1.8.2 Advanced searches

You can perform an advanced search on a list using the filter configuration form.

Figure 1-6 Filter configuration form



With an advanced search, you can apply more than one function and value to a single attribute. For example, you could configure a filter property Customer ID GREATER THAN (1) and also, in the same filter, the property Customer ID LESS THAN (100). This is not possible with a simple search.

An advanced search filter combines filter properties using Boolean operators. You can group properties together using brackets, and apply Boolean operators to the groups. See Table 1-5, “Boolean search operators” (p. 128) for information about Boolean operators.

You can use the filter configuration form to modify simple searches. See 1.31 “To perform an advanced search from an object list form” (p. 128) for more information about advanced searches and the filter configuration form.

1.8.3 Invalid attributes or values

When a saved search filter contains attributes or values that are not available for the object type you are searching, the NFM-P alerts you by displaying red text. The filter name is displayed in red text in the saved filters drop-down of a list form. The invalid attributes or values are displayed in red text on the filter configuration form.

You can select filters with invalid attributes or values and use them to perform a search. However, the invalid attributes are not evaluated. You can also display and modify such filters using the filter configuration form. For information about using the filter configuration form, see 1.31 “To perform an advanced search from an object list form” (p. 128) .

When a filter property that contains an invalid attribute is displayed on the filter configuration form, the attribute, function, and value for that property are all shown in red text. The attribute is surrounded by asterisks (**). Both the attribute and value are displayed as a best-effort string and may not support language localization.

When you select an invalid attribute in the filter display field, it is displayed in the Attribute drop-down as a best-effort string that may not support language localization. If the attribute is not recognized, the Function drop-down and the Value field display only the configurations that are

shown in the Filter display field. They cannot be changed until a different attribute is chosen from the Attribute drop-down menu.

As long as invalid attributes or values exist, the Save button on the filter configuration form is dimmed.

When only the value in a filter property is invalid, the value is displayed in red text. The value is surrounded by asterisks (**) and may not support language localization. The Value drop-down does not display a value, but is configurable.

1.8.4 Managing search results and lists

Most list forms allow you to manage the display of search results. You can:

- specify the number of items per page and navigate through pages
- remove, resize, and rearrange columns
- sort lists based on a selected column in ascending or descending order
- save your display preferences

See 1.29 “To manage the display of listed information” (p. 122) for more information about managing the display of lists.

You can save listed information to a file; see 1.22 “To save listed information to a file” (p. 115) .

1.8.5 Parameter search

See the XML API Reference for information about parameters and configuration forms in the NFM-P.

Information about NFM-P parameters that are not found in the XML API Reference is available in Appendix A, “Parameters”.

Procedures for opening and closing the GUI

1.9 To open a single-user GUI client configured for one NFM-P system

1.9.1 Purpose

Perform this procedure to open a single-user GUI client that is configured to connect to only one NFM-P system.

By default, the NFM-P GUI client login form lists the main servers in one NFM-P system. If you manage multiple NFM-P systems at the same release, you can configure the login form to list the main servers in each system as login options; see the *NSP Installation and Upgrade Guide*.

Note: To perform the procedure, you must be logged in to the single-user client station as one of the following:

- the user who installed the client software
- a user with sufficient permissions on the client files and directories, such as a local administrator

1.9.2 Steps

1

Double-click on the NSP NFM-P Client (*server*) icon on the RHEL or Windows desktop, where *server* is a main server IP address or hostname.

If you are currently logged in to the NSP and have suppressed security messages, the NFM-P GUI opens.

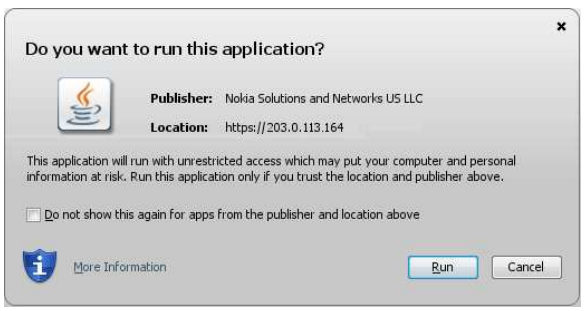
2

If the form in Figure 1-7, “Do you want to run this application?” (p. 98) is displayed, perform the following steps.

1. To suppress the form when opening subsequent GUI sessions, select the check box.
2. Click Run.

If you are currently logged in to the NSP, the NFM-P GUI opens.

Figure 1-7 Do you want to run this application?



3

If you are not currently logged in to the NSP:

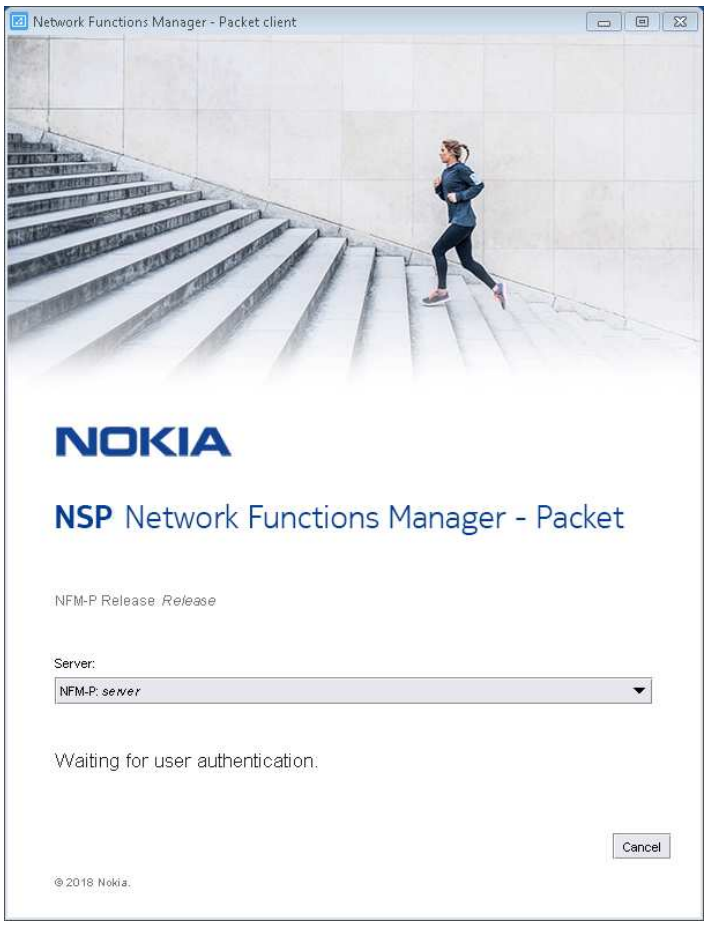
- The splash screen in Figure 1-8, “Network Functions Manager - Packet client” (p. 98) is displayed.
- The default browser opens to the NSP sign-in page.

Enter your NSP user credentials, acknowledge the security statement, if present, and click SIGN IN.

Note: If you do not enter valid credentials within the allowed authentication period, the splash screen indicates that the client has timed out; you must close the splash screen and return to Step 1.

The client splash screen indicates that the client is loading, and then closes as the NFM-P GUI opens.

Figure 1-8 Network Functions Manager - Packet client



END OF STEPS

1.10 To open a single-user GUI client configured for multiple NFM-P systems

1.10.1 Purpose

An NFM-P GUI client can be configured to connect to multiple NFM-P systems at the same release. After you configure a GUI client login form to list multiple NFM-P systems, as described in the *NSP Installation and Upgrade Guide*, perform this procedure to open a GUI client session on a specific NFM-P system.

Note: To perform this procedure, you must be logged in to the single-user client station as one of the following:

- the user who installed the client software
- a user with sufficient permissions on the client files and directories, such as a local administrator

Note: In deployments in which one NFM-P GUI client is installed on a client station and configured to point to multiple independent standalone NFM-P servers, if one of the servers is upgraded, duplicate NFM-P entries appear in the GUI for client upgrade. To work around this issue, remove the extraneous entries from the nms-client.xml file. See "To configure a GUI client login form to list multiple NFM-P systems" in the *NSP Installation and Upgrade Guide* for information about configuring this file.

1.10.2 Steps

1

Double-click on the NSP NFM-P Client (*server*) icon on the RHEL or Windows desktop, where *server* is a main server IP address or hostname.

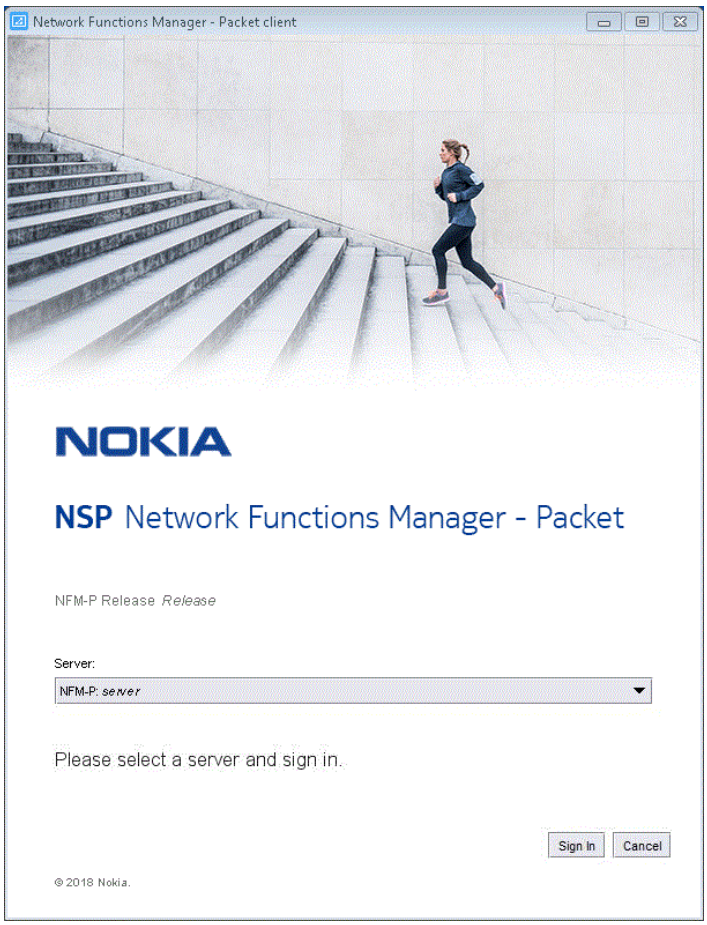
2

The form in Figure 1-9, “Network Functions Manager - Packet client” (p. 101) is displayed.

Choose a server from the drop-down list and click Sign In.

If you are currently logged in to the NSP and have suppressed security messages, the NFM-P GUI opens.

Figure 1-9 Network Functions Manager - Packet client



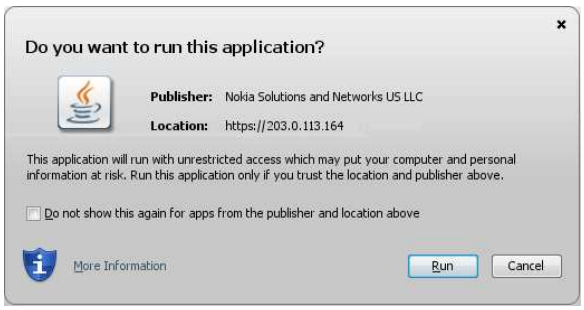
3

If the form in Figure 1-10, “Do you want to run this application?” (p. 102) is displayed, perform the following steps.

1. To suppress the form when opening subsequent GUI sessions, select the check box.
2. Click Run.

If you are currently logged in to the NSP, the NFM-P GUI opens.

Figure 1-10 Do you want to run this application?



4

If you are not currently logged in to the NSP:

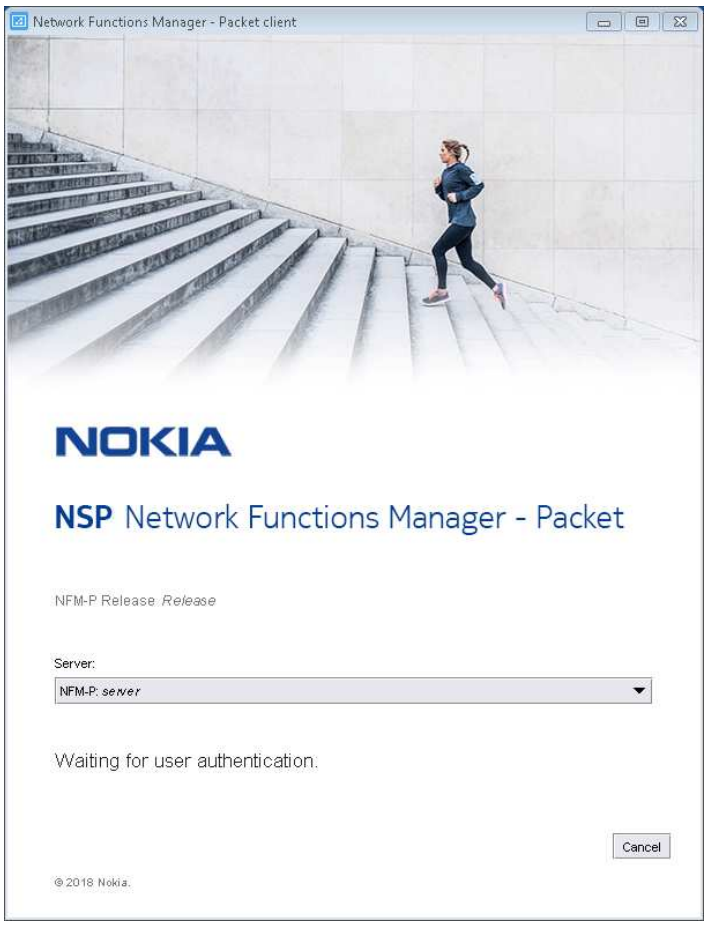
- The splash screen in Figure 1-11, “Network Functions Manager - Packet client” (p. 103) is displayed.
- The default browser opens to the NSP sign-in page.

Enter your NSP user credentials, acknowledge the security statement, if present, and click SIGN IN.

Note: If you do not enter valid credentials within the allowed authentication period, the splash screen indicates that the client has timed out; you must close the splash screen and return to Step 1.

The client splash screen indicates that the client is loading, and then closes as the NFM-P GUI opens.

Figure 1-11 Network Functions Manager - Packet client



END OF STEPS

1.11 To open the NFM-P GUI through a client delegate server

1.11.1 Steps

1

If you are not in the same physical facility as the client delegate server, log in to the facility using the appropriate access tool, for example, a Citrix gateway.

2

Log in to the client delegate server station using the appropriate method:

- RHEL client delegate server—X window session

- Windows client delegate server—Windows Remote Desktop session

3

If the client delegate server is installed on a RHEL station, redirect the display to the station that you are using. See the RHEL documentation for information about display redirection.

4

Open the GUI, as described in 1.9 “To open a single-user GUI client configured for one NFM-P system” (p. 98) or 1.10 “To open a single-user GUI client configured for multiple NFM-P systems” (p. 100).

END OF STEPS

1.12 To close the NFM-P GUI

1.12.1 Steps

1

Choose Application→Exit from the NFM-P main menu.

2

Select the Save opened configuration forms check box, if required. See 1.14 “To save or open a set of forms for quick access” (p. 106) for information.

3

Click Yes. The NFM-P GUI closes, and the client session ends.

END OF STEPS

Procedures for using the GUI

1.13 To manage the display of windows and forms

1.13.1 Purpose

You can rearrange the display of windows and forms to optimize your workspace. You can also save window layouts in custom workspaces; see 2.8 “To customize window layouts” (p. 147).

Open windows and forms display an icon on the NFM-P taskbar, and are listed in the Window menu of the NFM-P main menu. You can resize, minimize, activate, and close windows and forms using standard OS methods. The following procedure describes additional methods for managing internal windows and forms.

1.13.2 Steps

1

To open the navigation tree, perform one of the following:

a. Click the toolbar icon for the required window.

   If the toolbar is hidden, you can modify user preferences to show the toolbar; see 1.23 “To configure NFM-P user preferences” (p. 116) . If the toolbar does not contain the required icon, see information about custom workspaces in Chapter 2, “NFM-P custom workspaces” .

b. Choose Application, then the name of the required window from the NFM-P main menu.

c. Use the shortcut keys; see 1.3.1 “Shortcut keys and accessibility” (p. 80) in “GUI overview” (p. 77) .

You can open multiple navigation tree windows.

2

To make a window or form the active window, choose Window from the NFM-P main menu, then choose the name of the required window.

3

To arrange multiple open forms so that they overlap, perform one of the following:

a. Choose Window→Cascade & Reset to Preferred Sizes from the NFM-P main menu. The forms are displayed overlapping in their existing sizes, showing the titlebar for each form.

b. Choose Window→Cascade from the NFM-P main menu. The forms are displayed overlapping and equally sized, showing the titlebar for each form.

4

To arrange multiple open forms without overlapping, perform one of the following:

a. Choose Window→Tile Vertical from the NFM-P main menu. The forms are displayed side by side.

b. Choose Window→Tile Horizontal from the NFM-P main menu. The forms are displayed one above the other.

c. Choose Window→Tile Square from the NFM-P main menu. The forms are displayed in a grid.

5

To minimize all open windows and forms to the taskbar, choose Window→Minimize All from the NFM-P main menu.

6

To restore windows and forms to their preferred settings, choose Window→Reset to Preferred Sizes from the NFM-P main menu.

7

To close all open windows and forms, choose Window→Close All Internal Windows from the NFM-P main menu. External windows are not affected.

When you close all internal windows, the navigation tree is closed. To reopen it, see Step 1 .

END OF STEPS

1.14 To save or open a set of forms for quick access

1.14.1 Purpose

You can save a set of open forms and reopen them all later with one operation, to provide quick access to forms that you use often or need to return to.

CAUTION

Service Disruption

Network activity can cause changes to quick-access forms when they are not open. When reopened, the saved forms may collectively exceed the memory threshold for the NFM-P GUI.

Nokia recommends that you limit the number of quick-access forms in a set. Close any unnecessary forms before you save the set of open forms. When you save a parent form, consider whether you need to save the open child forms (tabs).

If you exceed the memory threshold, restart the NFM-P client, then save a reduced number of quick access forms.

1.14.2 Before you begin

Consider the following when you save a set of forms for quick access.

- Only configuration forms that support a property form identifier are saved in the set. See 1.3.2 “NFM-P clipboard” (p. 81) in “GUI overview” (p. 77).
- When quick-access forms are reopened, they may not appear exactly as they did when they

were saved. The size and location of configuration forms is not preserved. The current values and configurations may be different from those in effect at the time the set of forms was saved.

- If an object is deleted from NFM-P management, the configuration form for that object is removed from the saved set of forms.
- Open configuration forms that are displayed in external windows are saved with the set of quick-access forms, but they are displayed as internal windows when the forms are reopened.
- All quick-access forms display an icon on the taskbar when reopened.
- If you save a set of forms when child forms are displayed as tabs in a parent form, all of the child tabs are saved as separate forms. When you reopen the forms, the child tabs are displayed as separate forms. See 1.18 “To manage configuration forms with built-in navigation trees” (p. 110) for more information.

1.14.3 Steps

1

To save a set of open forms:

1. Open the configuration forms you need to save for quick access and close any unnecessary forms.
2. Choose Window→Save Opened Configuration Forms from the NFM-P main menu. The open forms are saved as a set of quick-access forms.

   Alternatively, when you close the NFM-P client, you can select the Save opened configuration forms check box in the confirmation dialog.

2

To reopen the set of quick-access forms, choose Window→Open Saved Configuration Forms from the NFM-P main menu. The saved set of quick-access forms opens.

Alternatively, you can click the Open Saved Configuration Forms icon on the toolbar, if available.

END OF STEPS

1.15 To manage a window or form as an external window

1.15.1 Purpose

A window or form in the NFM-P GUI can be moved from the main workspace and managed as an external window, for example, on a second monitor.

External windows are managed by the client computer OS. External windows maintain the window icon that is used in the NFM-P GUI, but the icon is placed on the OS taskbar. The NFM-P GUI taskbar does not display external windows, but they are listed in the NFM-P Window menu.

Any windows or forms that are opened from an external window appear as separate external windows.

An external window or form cannot be moved back to the NFM-P GUI. You must reopen the window in the NFM-P GUI.

1.15.2 Steps

1

To move a window or form to an external window:

1. Click on the required internal window or form to make it the active window.
2. Choose Window→Move to External Window from the NFM-P main menu.

   Alternatively, you can right-click on the title bar of the selected window and choose Move To External Window.

   External windows are listed in the NFM-P Window menu. You can activate an external window by clicking on the window or form name in the Window menu list.

2

To close all external windows, choose Window→Close All External NFM-P Windows from the NFM-P main menu.

END OF STEPS

1.16 To send a text message to other NFM-P users

1.16.1 Steps

1

Choose Application→Text Message from the NFM-P main menu. The Text Message window opens.

2

Enter the text message in the text area.

You can use the NFM-P clipboard to send a property form identifier with the message. Copy the identifier for an object and click Paste to paste it into the message area. You can paste multiple objects, up to a limit. If multiple objects do not paste, reduce the size of the clipboard contents. See 1.20 “To use the NFM-P clipboard” (p. 112) for more information about the clipboard.

The most recent information copied to the system clipboard is pasted, even if it is not a property form identifier. If you use the system clipboard to copy text or other types of information after you copy a property form identifier, the identifier is no longer available.

3

Click Send To. The Select Sessions form opens with a list of active client sessions displayed.

4

Select one or more users in the list. To select all GUI client sessions, click in the list and press Ctrl-A.

5

Click OK. The form closes and the text message is sent to the selected clients.

END OF STEPS

1.17 To use configuration forms to configure or view parameters

1.17.1 Steps

1

To open a configuration form, use one of the following methods:

a. Choose the required NFM-P main menu or submenu option.

b. Right-click on an object in the navigation tree and choose the required option.

c. Double-click on the lowest-level navigation tree object.

When you double-click on an object that has a child object, the tree expands to show the child object. When you double-click on an object that has no child objects, the object properties form opens.

d. Double-click on an object in a list.

e. Select an object in a list and click Properties.

f. Choose Application→Go To Property Form from the NFM-P main menu and paste a property form identifier from the NFM-P clipboard; see 1.20 “To use the NFM-P clipboard” (p. 112) .

2

To expand or collapse panels, click on the titlebar of the panel.

You can collapse or expand all of the panels on a tabbed form. Right-click on the tab header and choose Collapse All Panels or Expand All Panels.

When a configuration form closes, the current state of the panels is saved for that object type. When a user opens a configuration form, the last saved state of the panels is displayed.

3

Configure or view the parameters on the form.

If the configuration form is a step form, follow the form prompts.

Note: A parameter field that has a yellow background is mandatory and must be configured before you can go to the next form or apply the changes on the current form. Avoid colons in the name field because the NFM-P uses colons as separators for the object full name.

4

Save the configuration changes. Perform one of the following:

a. Click Apply to save the changes without closing the form.

b. Click OK to save the changes and close the form.

c. Click Finish to save the changes in a step form.

d. Click Cancel or Close to close the form without saving the changes.

Note: Using the Ctrl-F4 keys to close a form may cause problems if the parent form is open. Nokia recommends that you do not use Ctrl-F4 to close a form that is contained by another form or that has a parent form.

Some forms display warnings or require confirmation before changes are committed. You can configure user preferences to suppress some confirmation messages; see 1.23 “To configure NFM-P user preferences” (p. 116) .

END OF STEPS

1.18 To manage configuration forms with built-in navigation trees

1.18.1 Steps

1

Open a configuration form that displays a built-in navigation tree.

When the form opens, it is unlocked, as indicated by the open lock icon on the tab header for the form.

2

To keep the form open when additional tree objects are selected, click the lock icon. Alternatively, you can right-click on the tab header and choose Lock. The icon indicates that the form is locked.

An unlocked form closes and is replaced when another object is selected in the tree.

3

Select additional objects in the built-in navigation tree. A configuration form for each object opens as a tab on the main configuration form. Lock each tab to keep the corresponding form open when a new object is selected.

If the tabs of the open forms exceed the width of the window, double arrows are displayed. Click on the double arrows to display a drop-down menu of the open configuration forms.

For service configuration forms, you can select objects in two ways:

a. Expand the tree and select an object.

b. Open an object-type list.

An object type is an item in the tree that can be expanded to display child objects.

This method is convenient when an object type contains many child objects that require a search filter.

Note: Service navigation trees for VPLS, I-VPLS, B-VPLS, MVPLS, IES, and VPRNs display a maximum of 50 access interfaces, SAPs, MSAPs, subscriber SAPs, and spoke and mesh SDP bindings at a time. When this limit is reached, you can click on the message beside the containing object under which the SAPs or access interfaces are listed to open a tab with the full list of objects.

1. Click on an object type in the tree. A list form opens as a tab and displays the objects available for the object type.
2. Select an object in the list and click Properties. If the list form was not locked, it is automatically locked. Depending on the object type, a form for the selected object will open as a tab in the main configuration form, or a separate form will open for the object.

4

To undock a form from the main configuration form, click on the tab header and choose Undock. The tab disappears and the form is displayed as a standard NFM-P form, separate from other tabs and the main configuration form.

END OF STEPS

1.19 To modify multiple objects at one time (multi-edit)

Note: Selecting large numbers of objects for multi-edit may affect system performance.

1.19.1 Steps

1

Select multiple objects in the navigation tree or a list, then right-click and choose Properties. The object type - Multiple Instances (Edit) form opens.

2

Configure the required parameters.

When a multi-value field is changed to empty and the change is applied, and that field was previously populated with a value for one of the selected multi-edit objects, a warning message is displayed. The warning message indicates the tab and parameter affected.

3

Save your changes and close the form.

END OF STEPS

1.20 To use the NFM-P clipboard

1.20.1 When to use

You can use the NFM-P clipboard to copy property form identifiers for the following:

- property forms
- statistics forms
- objects in list forms
- objects in the navigation tree
- problems encountered notifications

A property form identifier is a unique internal address that the NFM-P assigns to a form. Property form identifiers are copied to the clipboard using the Clipboard icon or by selecting the Copy to Clipboard option from a contextual menu.

You can use the NFM-P clipboard to open forms, send identifiers to other users, configure search filters, and search for objects or create physical links on the topology map.

When you copy items from a list or from the navigation tree, you can copy multiple items at one time. For other NFM-P clipboard functions, only one item at a time is copied.

Each time a property form identifier is copied to the clipboard, the previous clipboard contents are replaced.

1.20.2 Steps

1

To copy property form identifiers to the NFM-P clipboard, perform one of the following:

a. Copy objects from a list. Select one or more items in the list and click Copy to Clipboard.

b. Copy objects from the navigation tree.
   1. Expand the tree as required.
   2. Select one or more objects from the tree. The Copy to Clipboard icon is activated.

      Objects with no properties do not activate the Copy to Clipboard icon (for example, the Fans parent object). If multiple selected objects include an object without properties, the Copy to Clipboard icon is not activated.
   3. Click the Copy to Clipboard icon.

      Alternatively, you can use the contextual menu for single objects or multiple objects that are at the same level in the tree.

c. Copy a property form identifier from a form.
   1. Open the required form.
   2. Right-click on the title bar for the form and choose Copy Property Form Identifier.

      Alternatively, you can choose Application→Copy Property Form Identifier from the NFM-P main menu.

d. Copy a property form identifier from a tab.

1. Open the required tab.
2. Right-click on the tab and choose Copy Property Form Identifier. The property form identifier link is copied to the clipboard.

   Alternatively, you can choose Application→Copy Property Form Identifier from the NFM-P main menu.

2

To open a property form from the clipboard, perform one of the following:

a. Use the Go To Property Form menu item.
   1. Choose Application→Go To Property Form from the NFM-P main menu. The Go To Property Form window opens.
   2. Click Paste. The clipboard contents appear in the Identifier field.

      The most recent information copied to the system clipboard is pasted, even if it is not a property form identifier. If you use the system clipboard to copy text or other types of information after you copy a property form identifier, the identifier is no longer available.

      If the clipboard contains multiple objects, only the first object is pasted.

      You can use this method to open a specific tab, if a tab was used to save the property form identifier.
   3. Click OK or Apply. The properties form for the object opens.

b. Use the Clipboard window.
   1. Choose Application→Clipboard from the NFM-P main menu. The Clipboard window opens.
   2. Select an object and click View Object. The properties form for the object opens.

      Use this method to open the property form for an NE. To open a specific tab, use the method described in Step 2 a .

      The clipboard window shows the most recent property form identifiers copied to the NFM-P clipboard. Property form identifiers are preserved in the clipboard window even when the system clipboard is subsequently used for other types of information. However, they are replaced when new property form identifiers are copied to the NFM-P clipboard.

3

To send the clipboard contents to other users on the NFM-P server, see 1.16 “To send a text message to other NFM-P users” (p. 108) . You can also paste the clipboard contents into another application.

4

To use the clipboard for configuring advanced search filters, see 1.31 “To perform an advanced search from an object list form” (p. 128) .

5

To create physical links, see 4.10 “To create a physical link” (p. 183) .

END OF STEPS

1.21 To monitor the NFM-P Task Manager

1.21.1 Steps

1

Choose Application→Task Manager from the NFM-P main menu. The Task Manager form opens.

The All Users check box appears for NFM-P administrators. If you are an NFM-P administrator or a user with an assigned administrator scope of command role, go to Step 2 . Otherwise, go to Step 3 .

2

Select the All Users check box to monitor operations that are performed by all users in the NFM-P server.

3

Double-click on a task. The property form for the task opens.

Note: The Task Manager automatically refreshes when the value of the autoRefreshInterval parameter is reached. The default is 20. You can also click Search to refresh the list of tasks.

4

Click on the tabs to view information about the task.

5

To view the NFM-P GUI or OSS user activity associated with a task, click User Activity. The Activity form opens and displays additional information about the task. See the section on user activity logging in the *NSP System Administrator Guide* for more information.

6

Close the forms.

END OF STEPS

1.22 To save listed information to a file

1.22.1 Purpose

You can save listed information to a file, for purposes such as:

- record keeping
- inventory management

Perform this procedure to save listed information from a list form.

1.22.2 Steps

1

Open a list form and apply a filter or click Search to produce a list.

2

Right-click on any column heading and choose Save To File. The Save As form opens.

Note: The NFM-P uses the user home directory as the default location for saved files.

3

Specify the name and location of a file for the listed information. You can save the information in the following file types:

- All Files
- HTML
- CSV

You can specify the default file type on the User Preferences form; see 1.23 “To configure NFM-P user preferences” (p. 116) .

4

Click Save. The information is saved and the Save As form closes.

END OF STEPS

Procedures for configuring user preferences

1.23 To configure NFM-P user preferences

1.23.1 Purpose

The NFM-P GUI allows you to configure workspace elements and functions to suit your operational requirements. You can set many preferences using the User Preferences form accessed from the NFM-P main menu. You can also configure custom workspaces; see Chapter 2, “NFM-P custom workspaces” . You can set tab preferences to show or hide tabs on forms; see 1.24 “To set local tab preferences for configuration forms” (p. 118) .

The User Preferences form allows you to set preferences for the following GUI functions:

- show or hide the toolbar
- set the default time zone
- suppress or allow warnings and messages
- set defaults for list forms
- configure the workspace selector

You can also use the User Preferences form to set preferences for:

- STM forms
- statistics plotters; see the *NSP NFM-P Statistics Management Guide*
- scripts
- service encapsulation dot1q values
- browser path

You can import local tab preferences from a file using the User Preferences form; see 1.27 “To import local tab preferences” (p. 121) .

User preferences are specific to a particular user; the settings are associated with the user ID and are applied to the system when that user is logged in.

1.23.2 Steps

1

Choose Application→User Preferences from the NFM-P main menu. The User Preferences form opens.

2

Click on the tabs and configure the required parameters. Table 1-3, “User preferences parameters” (p. 117) describes user preferences parameters.

The Workspaces tab allows you to configure the workspace selector; see 2.14 “To configure the workspace selector” (p. 155) .

Table 1-3 User preferences parameters

Parameter	Description	See
Access Interface Encap Value (Dot1q only)	Specifies whether the Auto-Assign ID parameter is enabled by default for dot1q encapsulation	—
Apply User Span Of Control	Specifies when enabled that the navigation tree, maps, and list forms display only the objects in the Edit Access span of control of the user	1.2.2 “Span of control” (p. 79) in this chapter 1.39 “To filter using span of control” (p. 136)
Browser Path	Specifies the file path to the system browser which must then be used for the NSP. You can configure the parameter manually or by clicking the Browse button and navigating to the file path.	—
Command Helper Key	Allows you to designate the key that activates the command helper function in the Script Editor	—
Debug STM Mode	Specifies whether the NFM-P provides additional options in the object drop-down menu for the Service Test Manager. The options allow you to configure some limits and view additional information for tests.	89.14 “To configure OAM diagnostic test limits on the STM and view additional test configuration information” (p. 2957)
Default Client Time Zone	Specifies the default time zone used by the NFM-P client. Choose a time zone from the drop-down menu. The NFM-P server provides a menu default. You can modify the current client time zone without changing the default client time zone.	1.28 “To configure the current client time zone” (p. 122)
Default Polling Interval (seconds)	Specifies the default polling interval for real-time statistics in the Statistics Plotter form. The range is 10 to 3600.	*NSP NFM-P Statistics Management Guide*
Enable Command Helper	Specifies whether the Command Helper function in the Script Editor is enabled.The Command Helper is a one-key function that completes commonly occurring script commands. You can designate the command helper key.	—
Enable Confirmation for Bulk Change Actions	Specifies whether confirmation messages are displayed before the NFM-P carries out a bulk change operation	“Bulk operations using the NFM-P” (p. 713)
GUI Builder in the Editor	Specifies whether the Velocity GUI Builder in the Script Editor is enabled	—
Maximum Data Retention Time (seconds)	Specifies the number of seconds to keep statistics data in the Statistics Plotter. The range is 3600 to 86400. The default is 43200.	*NSP NFM-P Statistics Management Guide*
Save To File Default Extension	Specifies the default file type when list information is saved to a file	1.22 “To save listed information to a file” (p. 115)
Show Toolbar	Specifies whether the NFM-P toolbar is displayed in the main GUI window	1.1.6 “Toolbar” (p. 78) in this chapter

Table 1-3 User preferences parameters (continued)

Parameter	Description	See
Specify # of Items Per Page	Specifies the maximum number of items displayed per page on a list form. The range is 1 to 9999.	1.29 “To manage the display of listed information” (p. 122)
Suppress Containing Window Warning	Specifies whether warnings are displayed when saving changes to child object forms that are launched from parent object forms	1.6.7 “Warning and confirmation messages” (p. 86) in this chapter
Suppress Template Execution Warning	Specifies whether warning messages are suppressed when you execute a template	—
Suppress Template Generation Message	Specifies whether template generation messages are suppressed	—
Suppress Service and Composite Service Map Load Warning	Specifies whether load time warnings for service and composite service maps are suppressed	—

3

Save your changes and close the form.

END OF STEPS

1.24 To set local tab preferences for configuration forms

1.24.1 When to use

Custom workspaces are configured to use either local tab preferences or custom tab preferences. Local tab preferences are configured for the current user. Custom tab preferences are set as defaults in the custom workspace. See 2.9 “To configure tab preferences” (p. 147) .

When the current workspace uses local tab preferences, you can set and save tab preferences using the tab selector. When the current workspace uses custom tab preferences, you cannot set tab preferences using the tab selector.

You can export local tab preferences by saving them to a file; see 1.26 “To export local tab preferences” (p. 120) . You can import local tab preferences from a file; see 1.27 “To import local tab preferences” (p. 121) .

1.24.2 Steps

1

Open the property form for an object.

2

Click on the tab selector button at the right of the row of tabs. The tab selector drop-down opens.

Note: The keyboard shortcut to display the tab selector drop-down is Ctrl-T. The keyboard focus must be on one of the main tabs of the form. Press the Tab key to transfer the keyboard focus to the drop-down, then use the down-arrow key.
If the Tab Preferences parameter for the current workspace is set to Custom, the buttons on the tab selector do not appear.

3

Perform any of the following:

a. To display a hidden tab, select a tab name in the Hidden Tabs list and click the Move to Displayed Tabs button.

b. To hide a displayed tab, select a tab name in the Displayed Tabs Order list and click the Move to Hidden Tabs button.

c. To reorder the sequence of tabs, select a tab name in the Displayed Tabs Order list and click the Move Up or Move Down button. You can select and move multiple tabs.

Note: Tab settings are specific to the selected object type. For example, if you open the Network Element (Edit) form for a 7705 SAR-H and hide all tabs except the General tab, then open the same form for a Wavence SM, the form displays the General tab and may also display some Wavence SM specific tabs.
At least one tab must be displayed on a form. If all tabs are moved to the Hidden Tabs list, the Save Tab Settings button is dimmed.
Mandatory tabs (such as the TCA, Faults, and Deployment tabs) do not appear in the tab selector.

4

To save the changes, click on the Save Tab Settings button. The form updates with the configured tab display.

Note: If you close the tab selector without saving, all unsaved tab preferences are lost. The Find Attribute form lists all parameters on the form including parameters located on hidden tabs. When you click on the Show on Form button, the tab is temporarily displayed.

END OF STEPS

1.25 To temporarily display hidden tabs on property forms

1.25.1 Purpose

You can temporarily display the hidden tabs on a property form. Hidden tabs that are temporarily displayed are hidden again the next time the form is opened.

1.25.2 Steps

1

Open the property form for an object.

2

Perform one of the following:

a. To temporarily display all hidden tabs on a form, click Show All Tabs at the right side of the row of tabs. The form displays all available tabs.

   If no available tabs are currently hidden, the Show All Tabs button is dimmed.

   Note: The keyboard shortcut to temporarily display all hidden tabs is Ctrl-Shift-A. The keyboard focus must be on one of the main tabs for the form.

b. To temporarily display one hidden tab, perform the following:

   1. Click the tab selector button at the right of the row of tabs. The tab selector drop-down opens.

      Note: The keyboard shortcut to display the tab selector drop-down is Ctrl-T. The keyboard focus must be on one of the main tabs for the form. Press the Tab key to transfer the keyboard focus to the drop-down, then use the down-arrow key.

   2. Double-click on a tab in the Hidden Tabs list. The form displays the chosen tab.

Hidden tabs that are displayed temporarily are shown in italics in the Displayed Tabs Order list in the tab selector drop-down.

If the Tab Preferences parameter for the current workspace is set to Local, you can click on the Save Tab Settings button to set all temporarily displayed tabs as saved tab preferences. If the Tab Preferences parameter for the current workspace is set to Custom, the buttons on the tab selector do not appear.

END OF STEPS

1.26 To export local tab preferences

1.26.1 Purpose

You can export local tab preferences and import them into an NFM-P client of a different user.

1.26.2 Steps

1

Choose Application→User Preferences from the NFM-P main menu. The User Preferences form opens.

2

Click on the Tab Preferences drop-down and choose Export. The Export Directory window opens.

3

Specify the export directory in the Save In drop-down menu, or create a directory or folder.

4

Click Save. The local tab preferences are exported and saved to the specified directory.

5

Close the User Preferences form.

END OF STEPS

1.27 To import local tab preferences

1.27.1 Steps

1

Choose Application→User Preferences from the NFM-P main menu. The User Preferences form opens.

2

Click on the Tab Preferences drop-down and choose Import. The Import Directory window opens.

3

Use the Look In drop-down menu to navigate to the required directory.

Note: The folder that contains the tab preferences must contain tab preferences of only one user. If there are multiple tab preferences of different users in the specified directory, an error message appears.

4

Click Open. A warning message is displayed.

5

Click Yes to overwrite your local tab preferences with the tab preferences from the selected directory.

All affected users that currently have a client session open, other than the client session where the import has been initiated, will receive a system-generated text message informing them that their tab preferences have been changed and they should restart their NFM-P client or risk losing the changes.

The user can click Reply to reply to the message.

6

Close the User Preferences form.

END OF STEPS

1.28 To configure the current client time zone

1.28.1 Purpose

The default time zone used by the NFM-P client is configured in user preferences; see 1.23 “To configure NFM-P user preferences” (p. 116) . Perform this procedure to choose a time zone other than the default, or to return to the default client time zone.

1.28.2 Steps

1

Click the Current Client Time Zone icon in the bottom right corner of the GUI. The Current Client Time Zone form opens.

2

Perform one of the following:

a. Select Use Default Client Time Zone.

b. Select Use Specific Client Time Zone and choose a time zone from the list.

3

Save your changes and close the form.

END OF STEPS

1.29 To manage the display of listed information

1.29.1 Purpose

Perform this procedure to configure and save display preferences for list forms. You can resize and rearrange the sequence of columns, and remove columns that are not required. You can sort lists based on a selected column (attribute), and choose to display objects in ascending or descending order.

You can save listed information to a file; see 1.22 “To save listed information to a file” (p. 115).

The following table describes the order in which different types of data are sorted from the top of the column to the bottom, based on the direction of the arrow in the column header.

Table 1-4 Sorting listed information

Entry type	Down arrow (Descending)	Up arrow (Ascending)
Numbers only	Sorted from the lowest number to the highest number	Sorted from the highest number to the lowest number
Letters	Sorted left to right, character by character, in alphabetical order	Sorted left to right, character by character, in reverse alphabetical order

Table 1-4 Sorting listed information (continued)

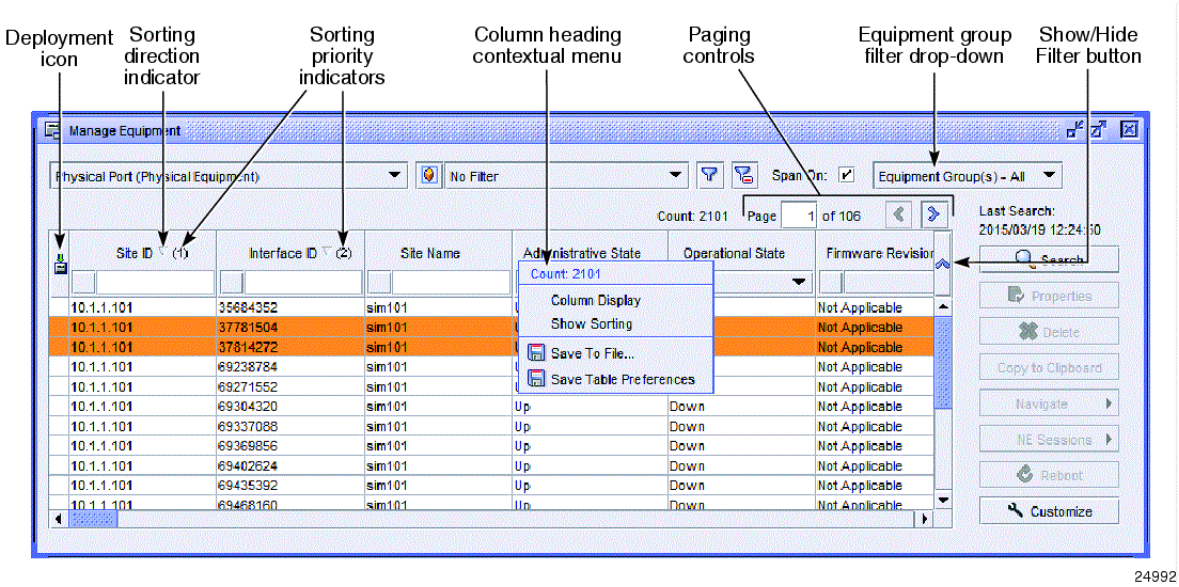
Entry type	Down arrow (Descending)	Up arrow (Ascending)
Alphanumeric	Sorted left to right, character by character, in the following order: from 0 to 9, then in alphabetical order	Sorted left to right, character by character, in the following order: in reverse alphabetical order, then from 9 to 0
Alphanumeric for IP Address fields[1]	Addresses are sorted first by type, then alphanumerically from the lowest to the highest number. For example, IPv4, IPv6 and DNS, in the following order: • 2.1.1.1 • 10.2.2.2 • 21.2.1.1 • 21.10.1.1 • 14:C8AA:0:0:0:0:0:EA • 24AA:C8:0:0:0:0:0:EA	Addresses are sorted first by type, then alphanumerically from the highest to the lowest number. For example, DNS address, IPv6, IPv4 in the following order: • 24AA:C8:0:0:0:0:0:EA • 14:C8AA:0:0:0:0:0:EA • 21.10.1.1 • 21.2.1.1 • 10.2.2.2 • 2.1.1.1
Special characters	Sorted left to right, character by character. The following characters are sorted in the following order before numbers, and uppercase and lowercase letters in a list: (space) ! # $ % & ‘ ( ) * + , . / The following characters are sorted in the following order after numbers in a list, but before uppercase and lowercase letters: : ; < = > ? @ The following characters are sorted in the following order after numbers, and uppercase and lowercase letters in a list: { | } ~	Sorted left to right, character by character. The following characters are sorted in the following order before numbers, and uppercase and lowercase letters in a list: ~ } | { The following characters are sorted in the following order before numbers in a list, but after uppercase and lowercase letters: @ ? > = < ; : The following characters are sorted in the following order after numbers, and uppercase and lowercase letters in a list: / . , + *) (‘ & % $ # ! (space)
Blanks	Blank entries are placed first at the top of the list.	Blank entries are placed last at the bottom of the list.

Notes:

1. Sorting on an IP Address field may cause performance issues when the NFM-P database is under heavy load.

The following figure describes the features of a list form.

Figure 1-12 List elements



1.29.2 Steps

1

Open a list form and choose an object type. The columns specific to the object type are displayed.

2

Configure column display preferences. Perform any of the following:

a. Remove columns.

1. Right-click on any column heading and choose Column Display. The Column Display form opens.
2. In the Displayed on Table panel, select one or more columns to remove.
3. Click on the left arrow to move the selected items to the Available for Table panel.

   Dimmed items cannot be moved.

   There must be at least one item in the Displayed on Table panel.
4. Save your changes and close the form.

b. Add columns.

1. Right-click on any column heading and choose Column Display. The Column Display form opens.
2. In the Available for Table panel, select one or more columns to add.
3. Click on the right arrow to move the selected items to the Displayed on Table panel.

4. Save your changes and close the form.

c. Rearrange the left-to-right sequence of columns.

Use this feature to place important information in the first few columns of the table, or to place related columns side by side.

1. Right-click on any column heading and choose Column Display. The Column Display form opens.
2. In the Displayed on Table panel, select the name of one or more columns to rearrange.
3. Click on the up or down arrows to move the selected items. The top-to-bottom sequence of the items reflects the left-to-right sequence of the columns in the list table.
4. Save your changes and close the form.

Alternatively, you can change the sequence of columns by clicking and dragging on a column heading.

d. Resize columns. Hover over the vertical line between two columns, then click and drag when the arrows appear.

3

Configure a filter if required and click Search to generate a list.

The total number of listed items is indicated by the Count value displayed on the form and in the contextual menu for column headings.

4

Hide the simple search fields in the column headings. Click on the Show/Hide Filter button.

5

Navigate multiple pages.

When a list uses multiple pages, the paging controls are available. Click on the paging arrows to move forward or backward one page at a time, or enter a page number to jump to a specific page. The page number and total page count are shown on the form.

You can specify a user preference for the number of items to display on a page; see 1.23 “To configure NFM-P user preferences” (p. 116) .

6

Configure sorting preferences.

Lists are sorted top-to-bottom based on selected column attributes. You can display sorted results in ascending or descending order; see Table 1-4, “Sorting listed information” (p. 122) . When no column is explicitly selected for sorting, the first column at the left of the table is used.

Perform one of the following:

a. Sort a list using a single column.

1. Click on the column heading. The list is sorted based on the values for the selected attribute.
2. Click on the column heading to reverse the sorting direction (ascending or descending).

b. Sort using multiple columns.

When a sort using a single column produces many items that all have the same value for the selected attribute, you can refine the sort by choosing additional columns. The priority order for the columns is indicated by a number in parentheses in the column heading.

1. Right-click on any column heading and choose Show Sorting. The Show Sorting form opens.
2. In the Used for Sorting panel, select any column names that are not required for sorting and click on the left arrow to move the selected items.
3. In the Available for Sorting panel, select the column names to be used for sorting and click on the right arrow. The selected items appear in the Used for Sorting panel.
4. In the Used for Sorting panel, click on the items and use the up and down arrows to arrange them in the required priority order.

   The sorting priority decreases from top to bottom; the item at the top of the panel has priority (1).
5. Click to select Sort Ascending or Sort Descending; see Table 1-4, “Sorting listed information” (p. 122) . The selected column headings display numbers in parentheses to show the sorting priority.
6. Close the form.

Alternatively, you can click on a column heading to select the priority (1) attribute, then Ctrl-click on additional column headings to further refine the sort. Priority is based on the order in which the columns are clicked. Press Ctrl-click on an already selected (numbered) column heading to reverse the sorting direction (ascending or descending).

You can navigate quickly through a long sorted list using the first character of the column that has sorting priority (1). Click in the list, then type a letter or number. The first item that begins with that letter or number in the priority (1) column is selected in the list.

7

Save your column display and sorting preferences.

1. Right-click on any column heading and choose Save Table Preferences.
2. Confirm the action. The configured display preferences are applied whenever you open a list table for the same object type.

END OF STEPS

Procedures for searching

1.30 To perform a simple search from an object list form

1.30.1 Purpose

You can perform a simple search using the column headings of a list table. Each column heading displays an attribute. You can configure a filter property for each attribute by selecting a function and a value from the column heading fields. See Figure 1-1, “List form” (p. 83). The available functions and values vary depending on the selected attribute and other settings. You can configure one function and value for each attribute.

You can show or hide the column heading search fields. You can also display a simple search filter on the filter configuration form, then save or modify it using the advanced search functions; see 1.31 “To perform an advanced search from an object list form” (p. 128) . When multiple filter properties are configured using column headings, the properties are combined using the AND Boolean operator.

Simple searches are disabled when:

- the filter configuration form is open
- a saved filter is selected in the saved filter drop-down
- a saved filter is loaded using the Saved Filters form

See “NFM-P searches” (p. 92) in this chapter for more information.

1.30.2 Steps

1

Open a list form and choose an object type, if required.

You can reduce the number of items in the object drop-down menu. See 1.38 “To filter object types” (p. 136) and 2.13 “To customize list forms” (p. 153) .

2

Choose No Filter from the saved filter drop-down menu, if required.

3

Click Show/Hide Filter to show the column heading search fields, if required.

4

Configure one or more filter properties.

1. Decide on an attribute for your filter and locate the corresponding column heading in the list.

   When a column heading has no search fields, the attribute in that column is not searchable.

2. Click on the function field in the column heading and choose a function. The symbol for the function is displayed. See Table 1-2, “Search functions” (p. 93) for a description of search functions.

3. Click on the value field and enter a value or choose one from the list. The value is displayed.

   If you enter a value without choosing a function first, a default function is used.

5

Configure the Span On parameter to override the global span of control preference, if required. See 1.39 “To filter using span of control” (p. 136) .

6

Click Search. A list of filtered results is displayed.

The Search button applies the filter even if the column heading search fields are hidden.

7

Revise the filter properties, if required.

To clear a filter property, choose (NONE) from the function menu for that attribute. The filter property is cleared from the column heading.

To clear all filter properties, click the Clear All Filters icon. All column headings return to an unconfigured state.

END OF STEPS

1.31 To perform an advanced search from an object list form

1.31.1 Purpose

You can use the filter configuration form to perform an advanced search on a list. Figure 1-6, “Filter configuration form” (p. 96) shows the filter configuration form. Advanced search filters are more detailed than simple search filters.

Multiple filter properties in an advanced search filter are combined using Boolean operators. You can apply brackets to properties or groups of properties, and apply Boolean operators to the groups. Table 1-5, “Boolean search operators” (p. 128) describes Boolean search operators.

Table 1-5 Boolean search operators

Boolean operator	Description
AND	When you combine properties using the AND operator, the search returns objects that meet both or all of the specified criteria.
OR	When you combine properties using the OR operator, the search returns objects that meet at least one of the specified criteria.
NOT	When a filter property is preceded by the NOT operator, items that meet the criteria in that filter property are excluded from the results.

You can save search filters for reuse or modification; see 1.33 “To save search filters” (p. 132) .

1.31.2 Steps

1

Open a list form and choose an object type.

You can reduce the number of items in the object menu; see 1.38 “To filter object types” (p. 136) and 2.13 “To customize list forms” (p. 153) .

2

Click the Filter icon. The filter configuration form opens.

3

Configure a filter property.

You can load a previously saved filter and modify it; see 1.34 “To use a saved search filter” (p. 133) .

1. Click on the Attribute field and choose an attribute.
2. Click on the Function field and choose a function. See Table 1-2, “Search functions” (p. 93) for a description of search functions.
3. Click on the Value field and choose a value, or enter a value manually.

   Alternatively, you can use the NFM-P clipboard to enter a value. Copy the property form identifier for a form that contains the same attribute and value that you are searching, then click on the Paste Attribute from Clipboard icon. The value field is populated with the required value. This method is useful when the value you are entering is a long text string, or when your search uses a value (such as a customer name) that you know is on a particular form. See 1.20 “To use the NFM-P clipboard” (p. 112) for more information about using the clipboard.

   The Paste Attribute from Clipboard icon is available when a search attribute is selected in 1 . A value is pasted only when the clipboard contains an attribute of the same name and type as the search attribute. If the clipboard contains multiple objects, the value for the first object is pasted.
4. Click Add. The filter property appears in the Filter display field and the Operators drop-down is available.

4

If required, change the Boolean operator. Click on the Operators drop-down and select an operator. See Table 1-5, “Boolean search operators” (p. 128) for information about Boolean operators.

The Boolean operator shown in the Operators field is inserted between the filter properties when the next filter property is added.

The Operators drop-down is available only when a filter property is displayed in the Filter display field.

5

Repeat Step 3 and Step 4 to configure additional filter properties.

6

Choose a Span setting; see 1.39 “To filter using span of control” (p. 136) and 1.2.2 “Span of control” (p. 79) in this chapter.

7

To modify filter properties, perform any of the following:

a. Add or remove brackets.
   1. Click and drag to select a filter property or properties in the Filter display field.
   2. Click Brackets. The selected properties are wrapped in brackets. When properties are already wrapped in brackets, the Brackets button unwraps the selected properties.

      You can wrap or unwrap multiple properties only when all Boolean operators within the brackets are the same.

b. Replace a filter property.
   1. Click and drag to select a filter property in the Filter display field.
   2. Configure an attribute, function, and value; see Step 3.
   3. Click Replace. The configured filter property replaces the selected filter property.

c. Exclude filter properties.
   1. Click and drag to select a filter property in the Filter display field.
   2. Click NOT. The property is wrapped in brackets and preceded by the NOT operator. Objects that match the selected property are excluded from the results.

      You can exclude multiple properties at one time.

      You can select excluded properties and click NOT to include the properties again.

d. Replace a Boolean operator.
   1. Click to select a Boolean operator in the Filter display field.
   2. Choose a Boolean operator from the Operators menu. The new selection replaces the previous operator.

      When you replace a Boolean operator, the properties associated with that operator are wrapped in brackets.

      You can replace all of the Boolean operators in a bracketed group by selecting the group and choosing a Boolean operator from the Operators menu.

e. Delete filter properties.
   1. Click and drag to select one or more filter properties in the Filter display field.
   2. Click Delete. The selected properties are deleted from the filter.

      To delete all properties from the Filter display field, click Clear.

8

Click Apply to perform the search. The filtered results are displayed.

9

To save the configured filter, see 1.33 “To save search filters” (p. 132). Otherwise, close the filter configuration form.

10

Select the required object in the list.

END OF STEPS

1.32 To perform a search by specifying endpoints

1.32.1 Purpose

Perform this procedure to find objects such as service tunnels, MPLS paths, and LSP paths by specifying endpoints. You can search based on a source site endpoint, a destination site endpoint, or both. You can also search based on multiple source or destination endpoints at the same time.

1.32.2 Steps

1

Choose Manage→MPLS→*<object submenu>* from the NFM-P main menu.

The Manage filter form for the selected object opens.

2

If required, specify the object endpoint type in the Type column, otherwise go to Step 3 .

3

Click the Filter icon. The filter configuration form opens.

4

Choose Endpoints from the Select Filter Type menu.

Note: If a saved filter is selected, or a simple search filter is configured in the column headings, the Select Filter Type displays Advanced Filter by default.

To configure an advanced search, see 1.31 “To perform an advanced search from an object list form” (p. 128) .

5

If you know the source endpoint for the tunnel or path, deselect the Any Source parameter and choose the required source site. Otherwise, go to Step 6 .

You can choose multiple source sites in one filter.

6

If you know the destination endpoint for the tunnel or path, deselect the Any Destination parameter and choose the required destination site.

You can choose multiple destination sites in one filter.

7

Click Apply to perform the search. The filtered results are displayed.

8

To save the configured filter, see 1.33 “To save search filters” (p. 131) . Otherwise, close the filter configuration form.

9

Select the required object in the list.

END OF STEPS

1.33 To save search filters

1.33.1 Purpose

You can save search filters for reuse or modification. Saved filters appear in the filter menu for the list form; see Figure 1-1, “List form” (p. 83) . Saved filters apply only to the specific object type for which they were created, and descendant objects of that object type. You can view saved filters by clicking on the Saved Filters button of the filter configuration form.

1.33.2 Steps

1

On a list form, click the Filter icon. The Filter configuration form opens.

See 1.31 “To perform an advanced search from an object list form” (p. 128) for information about advanced search filters.

See 1.32 “To perform a search by specifying endpoints” (p. 131) for information about endpoint search filters.

2

Click Save. The Save Filter form opens.

3

Configure the required parameters.

The Public parameter specifies whether a filter can be accessed by other users. When the Public parameter is disabled, the filter is private and cannot be accessed by other users.

4

Click Save. The Save Filter form closes, and the saved filter is available for future searches on the same object type.

5

Close the forms.

END OF STEPS

1.34 To use a saved search filter

1.34.1 Purpose

Perform this procedure to load and reuse saved search filters from a list form or from the filter configuration form.

Saved filters can be selected and applied directly from list forms, or from the filter configuration form. You can modify filters that are selected from the filter configuration form. Only filters that are applicable to the current object type and its descendant types are available.

Saved filters may contain attributes or values that are not valid for the current object. When filters contain invalid attributes and values, the NFM-P alerts you by displaying red text. You can select such filters and use them to perform a search. However, the invalid attributes are not evaluated. See 1.8.3 “Invalid attributes or values” (p. 96).

1.34.2 Steps

1

Open a List Form.

2

Perform one of the following:

a. Reuse a saved search filter directly from the list form. Click on the saved filters drop-down and select a filter in the list. The filter is immediately applied and the search results are displayed.

   When a saved filter is selected, simple searches using the column headings are disabled.

b. Load and reuse a saved filter using the filter configuration form.

   When you use this method, you can search for or modify a saved filter.

   1. Click the Filter icon. The filter configuration form opens.
   2. Click Saved Filters. The Saved Filters form opens.
   3. Select a filter in the list and click Load. The Saved Filters form closes and the filter properties are displayed on the filter configuration form.
   4. Modify the filter properties as required; see 1.31 “To perform an advanced search from an object list form” (p. 128) .

5. Save the modified filter, if required; see 1.33 “To save search filters” (p. 132) .

   The filter is saved for the current object type.

6. Click Apply to perform the search, then close the filter configuration form. The search results are displayed.

End of steps

1.35 To delete a saved search filter

1.35.1 Steps

1

Open a list form and click the Filter icon. The filter configuration form opens.

2

Click the Saved Filters button. The Saved Filters form opens.

3

Select a saved filter and click Delete. The filter is deleted.

4

Close the forms.

End of steps

1.36 To copy an advanced search filter

1.36.1 Purpose

You can copy saved advanced search filters for reuse or modification. You can paste a copied filter into the advanced filter configuration form; see Figure 1-1, “List form” (p. 83).

Consider the following when you copy and paste an advanced search filter:

- all of the attributes in the copied filter must have a matching property in the Object Type of the Advanced Filter window into which the filter expression is pasted
- the matching attributes must have the same displayed name, and the displayed name is case sensitive
- the matching attributes must be of the same type, for example, string, Boolean, etc.
- the corresponding properties must have a matching Function

1.36.2 Steps

1

Open a list form.

2

Click the Filter icon to open the Advanced Filter form.

3

Click Saved Filters. The Saved Filters form opens.

4

On the Saved Filters window, choose the filter you want to copy and click Copy Filter.

5

On a new filter configuration form, click Paste Filter. You can paste the filter expression only into a filter for the same object type as the filter you copied.

Note: If the filter is not compatible, the paste is not successful. An error is generated in the server.log file that indicates the attribute that failed in the paste process.

END OF STEPS

1.37 To locate an attribute on a configuration form

1.37.1 Purpose

The Find icon on configuration forms allows you to quickly locate tabs, panels, and parameters on configuration and property forms.

For service configuration and NE property forms with built-in navigation trees and tabs for multiple objects, the search is performed only on the active object.

1.37.2 Steps

1

Open a configuration form.

2

Click the Find icon or press Ctrl-F. The Find Attribute in form opens.

3

Select an attribute in the list and click Show on Form. On the configuration form, the selected name of the tab, panel, or parameter is highlighted and the associated tab is displayed.

Alternatively, you can double-click on the attribute row, or select an attribute and press Enter.

Note: If you select a parameter or panel that resides on a hidden tab, the hidden tab is temporarily displayed.

4

Close the Find Attribute in form.

END OF STEPS

1.38 To filter object types

1.38.1 Purpose

When the object type drop-down menu in a list form contains more than 10 items, you can use a filter to reduce the number of items.

You can also set defaults for list forms in custom workspaces, to reduce the number of items in the object type drop-down menu and to set the default object type; see 2.13 “To customize list forms” (p. 153) .

1.38.2 Steps

1

Open a list form and click the Filter for Object Type icon; see Figure 1-1, “List form” (p. 83) . The Select Object Type form opens.

2

Configure a simple search using column headings; see 1.30 “To perform a simple search from an object list form” (p. 127) .

Alternatively, you can configure an advanced search; see 1.31 “To perform an advanced search from an object list form” (p. 128) .

3

Click Search. A filtered list of object types is displayed.

4

Select an item from the list and click OK. The Select Object Type form closes and the selected item is displayed in the Object Type field.

END OF STEPS

1.39 To filter using span of control

1.39.1 Purpose

The NFM-P GUI displays objects and allows object configuration based on the span of control of the user and user preferences. You can configure user preferences to specify that only objects within the Edit Access span of control of the current user are displayed in list forms and on the navigation tree. See 1.23 “To configure NFM-P user preferences” (p. 116) for more information about user preferences.

For more information about span of control, see the section on creating a span of control in the *NSP System Administrator Guide*.

1.39.2 Steps

1

Open a List Form and choose an entry from the object drop-down menu.

2

Perform one of the following.

a. Configure span settings for a simple search.

1. Configure filter properties, if required; see 1.30 “To perform a simple search from an object list form” (p. 127) .
2. Configure the Span On check box to override the user preferences default span setting.
3. Click Search. A filtered list of objects is displayed.

   When Span On is enabled, only the objects that are within the Edit Access span of control of the current user are displayed.

b. Configure span settings for an advanced search.

1. Click the Filter icon to open the filter configuration form.
2. Configure filter properties, if required; see 1.31 “To perform an advanced search from an object list form” (p. 128) .
3. Configure the Span parameter. The following table describes the Span parameter options.

Option	Description
Span Off	Span of control filtering is disabled; objects in the View Access and Edit Access spans of the current user are displayed.
Span On	Span of control filtering is enabled; only objects in the Edit Access spans of the current user are displayed.
User Preference	Span of control filtering is enabled or disabled, as configured on the User Preferences form.

4. Click Apply and close the filter configuration form. The search results are displayed.

3

Select the required object in the list.

END OF STEPS

1.40 To configure and save equipment group filters

1.40.1 Purpose

Some list forms allow filtering based on equipment groups. An equipment group filter is created by selecting from existing equipment groups. You can save equipment group filters for reuse or modification.

Equipment group filters can return up to 12 000 items. If this limit is exceeded, you are prompted to modify the filter to reduce the number of items.

If you choose an equipment group filter that includes a group that has been modified since the filter was applied, an icon appears beside the equipment group filter drop-down prompting you to click the Search button to update the filter.

1.40.2 Steps

1

Open a list form and choose an entry from the object type drop-down menu. For object types based on equipment, the Equipment Group filter drop-down is displayed.

2

Choose Select Equipment Groups from the Equipment Group filter drop-down menu. The Select Equipment Groups form opens with equipment groups listed in the Available panel.

3

Perform one of the following:

a. Create an equipment group filter.
   1. In the Available panel, select the required equipment groups and click on the right arrow. The selected groups are moved to the Filtered by panel.

      To empty the Filtered by panel, click Clear. All groups in the Filtered by panel move into the Available panel.
   2. To include data from equipment in equipment subgroups, select the Include contained Equipment Groups parameter.

b. Modify an equipment group filter.
   1. Click Saved Filters. The Saved Filters form opens.
   2. Select a filter and click Load. The Saved Filters form closes and the selected filter is displayed in the Select Equipment Groups form.
   3. To remove groups from the Filtered by panel, select the groups and click the left arrow.

      To empty the Filtered by panel, click Clear. All groups in the Filtered by panel move into the Available panel.
   4. To add groups to the Filtered by panel, select the groups in the Available panel and click the right arrow.

4

Save the equipment group filter, if required.

1. Click Save. The Save Equipment Group Filter form opens.
2. Configure the required parameters.

   The Public parameter specifies whether a filter can be accessed by other users. When the parameter is disabled, the filter is private and cannot be accessed by other users.
3. Click Save. The Save Equipment Group Filter form closes, the filter is saved, and the Select Equipment Groups form displays the saved equipment group filter.

5

Click OK to apply the filter. The Select Equipment Groups form closes and the results list is displayed based on the equipment group filter and any additional filters that are applied to the list. The Last Search time is updated, and the equipment group filter name is displayed in the equipment group filter drop-down.

END OF STEPS

1.41 To use a saved equipment group filter

1.41.1 Steps

1

Open a list form and choose an entry from the object type drop-down. For object types based on equipment, the Equipment Group filter drop-down is displayed.

2

Click on the Equipment Group filter drop-down and perform one of the following:

a. Reuse a saved equipment group filter directly from the list form. Choose a saved filter from the drop-down menu. The filter is immediately applied and the search results are displayed.

b. Load and reuse a saved filter using the Select Equipment Groups form.

   When you use this method you can search for or modify a saved filter.

   1. Choose Select Equipment Groups from the Equipment Groups filter drop-down menu. The Select Equipment Groups form opens.
   2. Click Saved Filters. The Saved Filters form opens.
   3. Select a filter in the list and click Load. The filter is displayed on the Select Equipment Groups form.
   4. Click OK to apply the filter. The Select Equipment Groups form closes and the search results are displayed.

END OF STEPS

2 NFM-P custom workspaces

NFM-P custom workspaces overview

2.1 Workspace customization

2.1.1 General information

A workspace is a configuration of the main NFM-P GUI elements, such as the window layout or menu options. System-defined workspaces are provided, but you can also create and save your own customized workspaces to simplify navigation and operation according to your requirements.

There are three types of workspaces:

- System-defined—these workspaces are read-only and are provided as part of the NFM-P product. System-defined workspaces cannot be modified.
- Private—a private workspace contains your customized settings and is visible only to you and an administrator.
- Public—a public workspace is usable by all users on the same server. Only users with the required permissions can modify a public workspace.

You can customize the following workspace elements:

- Window layouts—save your window location and size preferences for the navigation tree and main NFM-P GUI window.
- Tab preferences—save tab preferences as part of a workspace.
- Menus—create custom menus with user-defined names, remove menu items that you don’t need, re-order the sequence in which menu items appear, rename menu items, and add grouping separators and custom mnemonics.
- Toolbar—add, remove, re-order and rename menu icon buttons on the toolbar. You can also add custom toolbar menus, which contain selected menu items and optional grouping separators.
- Tree labels—on the routing and equipment navigation trees, choose the information to display in the label text fields, and the order in which it appears.
- List forms—organize the content of the object type drop-down menus and select which buttons are displayed on some specific list forms.

You can create new custom workspaces based on a system-defined workspace or on another custom workspace, and you can modify existing custom workspaces. You must have the required scope of command permissions to create or modify public workspaces. Scope of command roles and user group workspace permissions are defined by a system administrator.

You can save custom workspaces by exporting them to a specified directory. You can share these saved workspaces with another user or reuse these saved workspaces by importing them into another NFM-P server.

Later releases of the NFM-P may contain newly-introduced menu items that are not in the custom workspaces of an earlier release. You can add new menu items to custom workspaces that were exported in an earlier release and then imported in a later release. For convenience, the NFM-P

separately lists the newly-introduced menu items; see 2.19 “To add new menu items to a custom workspace of an earlier NFM-P release” (p. 159) .

The workspace selector located in the upper right-hand corner of the screen contains a list of system-defined and custom workspaces, and allows you to replace the current workspace with another from this list. You can add or remove custom workspaces in the workspace selector, and change the order in which workspaces appear in the list. See 2.14 “To configure the workspace selector” (p. 155) and 2.15 “To apply a different workspace using the workspace selector” (p. 156) .

Note: Custom settings for tabs on configuration forms are saved as user preferences. They are not configured or saved as part of custom workspaces. See 1.24 “To set local tab preferences for configuration forms” (p. 118) and 1.25 “To temporarily display hidden tabs on property forms” (p. 119) .

2.2 Workflow to administer NFM-P custom workspaces

2.2.1 Purpose

A system administrator can perform the following tasks to configure users and permissions for workspaces, and to export custom workspaces.

2.2.2 Stages

1

Configure the scope of command roles for custom workspaces; see “To create a scope of command role” in the *NSP System Administrator Guide*.

2

Add or remove workspaces for a User Group and set mandatory workspaces settings; see “To add or remove workspaces for a user group” in the *NSP System Administrator Guide*.

3

Save all custom workspaces to a directory using the Export All function; see “To export all workspaces and local tab preferences” in the *NSP System Administrator Guide*.

4

Import workspaces that were previously saved as exported workspaces; see “To import workspaces and local tab preferences” in the *NSP System Administrator Guide*.

2.3 Workflow to customize NFM-P workspaces

2.3.1 Stages

1

Assess your operational requirements to determine your workspace needs.

2

Create a custom workspace; see 2.6 “To create a new custom workspace” (p. 145) .

3

Configure window layouts; see 2.8 “To customize window layouts” (p. 147) .

4

Configure tab preferences; see 2.9 “To configure tab preferences” (p. 147) .

5

Customize menus; see 2.10 “To customize menus” (p. 148) .

6

Customize toolbars; see 2.11 “To customize toolbars” (p. 150) .

7

Customize tree labels; see 2.12 “To customize tree labels” (p. 152) .

8

Customize list forms; see 2.13 “To customize list forms” (p. 153) .

9

Configure the workspace selector; see 2.14 “To configure the workspace selector” (p. 155) .

10

Modify an existing workspace, as required. See 2.7 “To modify an existing workspace” (p. 146) .

11

Update a custom workspace of an earlier NFM-P release with new menu items from a later release; see 2.19 “To add new menu items to a custom workspace of an earlier NFM-P release” (p. 159) .

12

Delete a workspace when it is no longer required; see 2.16 “To delete a custom workspace” (p. 157) .

2.4 Workflow to share workspaces

2.4.1 Purpose

You can share custom workspaces with other users of the NFM-P. The following workflow lists the sequence of steps to follow for sharing workspaces.

2.4.2 Stages

1

To share a private workspace with other users, change the scope of the workspace from Private to Public. You must have the required scope of command permissions for public workspaces. See 2.6 “To create a new custom workspace” (p. 145) .

2

To share a custom workspace by saving it to a directory:

1. Export custom workspaces to a specified directory; see 2.17 “To export custom workspaces” (p. 157) .
2. Import workspaces from a directory; see 2.18 “To import a workspace” (p. 158) .

NFM-P GUI custom workspace procedures

2.5 Overview

2.5.1 Purpose

The following procedures describe how to create and configure custom workspaces in the NFM-P.

2.6 To create a new custom workspace

2.6.1 Steps

1

Choose Application→Manage Workspaces from the NFM-P main menu. The Manage Workspaces form opens.

2

Perform one of the following:

a. Create a new workspace based on the system default workspace. Click Create. The Workspace (Create) form opens.

b. Create a new workspace based on an existing custom workspace:

1. Choose a custom workspace in the list and click Properties. The Workspace (Edit) form opens.
2. Click Copy.

3

Configure the required parameters.

Note: You must have the required scope of command permissions to create a public workspace.

4

Configure window layouts; see 2.8 “To customize window layouts” (p. 147) .

5

Configure tab preferences; see 2.9 “To configure tab preferences” (p. 147) .

6

Customize menus; see 2.10 “To customize menus” (p. 148) .

7

Customize toolbars, see 2.11 “To customize toolbars” (p. 150) .

8

Customize tree labels; see 2.12 “To customize tree labels” (p. 152) .

9

Customize list forms; see 2.13 “To customize list forms” (p. 153) .

END OF STEPS

2.7 To modify an existing workspace

Note: You cannot modify a system-defined workspace.

2.7.1 Steps

1

Perform one of the following:

a. To modify the current custom workspace, choose Application→Customize Current Workspace from the NFM-P main menu. The Workspace (Edit) form opens.

b. To modify a workspace other than the current workspace, perform the following:

1. Choose Application→Manage Workspaces from the NFM-P main menu. The Manage Workspaces form opens.
2. Choose a custom workspace in the list and click Properties. The Workspace (Edit) form opens.

2

Configure window layouts; see 2.8 “To customize window layouts” (p. 147) .

3

Configure tab preferences; see 2.9 “To configure tab preferences” (p. 147) .

4

Customize menus as required; see 2.10 “To customize menus” (p. 148) .

5

Customize toolbars as required; see 2.11 “To customize toolbars” (p. 150) .

6

Customize tree labels as required; see 2.12 “To customize tree labels” (p. 152) .

7

Customize list forms; see 2.13 “To customize list forms” (p. 153) .

END OF STEPS

2.8 To customize window layouts

2.8.1 Purpose

You can customize the sizes and locations for the navigation tree and the main NFM-P GUI window. See 1.13 “To manage the display of windows and forms” (p. 105) for information about how to arrange windows in the NFM-P GUI.

Perform this procedure to specify the window layout that appears when the custom workspace opens. You can specify the system default or the current window layout.

2.8.2 Steps

1

Open the Workspace form; see 2.6 “To create a new custom workspace” (p. 145) or 2.7 “To modify an existing workspace” (p. 146) .

2

Configure the Window Layout parameter.

You can only select the Set to Default option when Custom is displayed in the Window Layout field.

3

Save your changes and close the form.

END OF STEPS

2.9 To configure tab preferences

2.9.1 Purpose

You can configure a workspace to use either local tab preferences or custom tab preferences. Local tab preferences can be set manually using the tab selector, and are saved for a specific user. Custom tab preferences are saved as part of the workspace, with settings copied from either the currently open GUI client or another workspace. When custom tab preferences are used, the tab selector for configuration forms is disabled.

For more information about tab preferences, see 1.24 “To set local tab preferences for configuration forms” (p. 118) .

2.9.2 Steps

1

Open the Workspace form; see 2.6 “To create a new custom workspace” (p. 145) or 2.7 “To modify an existing workspace” (p. 146) .

2

Configure the Tab Preferences parameter.

If you choose Set from Workspace, the Select Workspace form opens; go to Step 3 . Otherwise, go to Step 4 .

3

Select a custom workspace and click OK. The tab preferences of the selected workspace are copied to the workspace you are configuring.

4

Save your changes and close the form.

Note: Use the Copy to Local button to copy the custom tab preferences saved in the workspace to the local tab preferences saved for the user. The Copy to Local button is not shown during initial workspace creation, and is active only when the Tab Preferences parameter for the workspace is set to Custom.

END OF STEPS

2.10 To customize menus

2.10.1 Purpose

Perform this procedure to customize menus in a new workspace or to modify menus in an existing workspace.

2.10.2 Steps

1

Open the Workspace form; see 2.6 “To create a new custom workspace” (p. 145) or 2.7 “To modify an existing workspace” (p. 146) .

Note: If the workspace was created in an earlier release of the NFM-P, see 2.19 “To add new menu items to a custom workspace of an earlier NFM-P release” (p. 159) .

2

Click on the Menus tab.

The All Menu Items panel contains a list of all available menu items in the NFM-P. The Custom Menu panel contains a list of all menu items in the custom workspace.

3

Expand items as required in the All Menu Items panel and Custom Menu panel.

4

Perform any of the following:

a. In the Custom Menu panel, remove any menu items that are not required in the workspace. Select and delete the items using the right-click menu or the keyboard.

Note: You cannot delete the User Preferences or Manage Workspaces menu items.

b. Add menu items to the Custom Menu panel. Select items in the All Menu Items panel and drag and drop or copy the selected items to the Custom Menu panel.

The usage indicator icon beside a menu in the All Menu Items panel indicates whether the menu items for that menu are all used, partially used, or not used in the Custom Menu. Usage indicator icons are described in the Legend at the bottom of the Workspace form. The usage indicators reduce the need to compare menu content between the All Menu Items panel and the Custom Menu panel.

c. Add a new custom menu in the Custom Menu panel.

1. Right-click in the location where you need to add a custom menu and choose Add Menu. A new menu appears under the selected item.

   If you right-click on empty space in the panel, the new menu appears as the last item in the list.

2. Type a name for the new menu and press Enter.

d. To locate a menu item in the All Menu Items panel, display the menu path for the item.

1. In the Custom Menu panel, select an item, right-click, and choose Show in All Menu Items Tree.

   A dialog box displays the path for the item in the All Menu Items panel.

2. Click OK to close the dialog box.

e. To locate a menu item in the Custom Menu panel, display the menu path for the item.

1. In the All Menu Items panel, select an item, right-click, and choose Show in Custom Menu Tree.

   A dialog box displays the path for the item in the Custom Menu. If the item appears more than once in the Custom Menu tree, multiple paths are displayed.

2. Click OK to close the dialog box.

f. Arrange the order of menus and menu items. Drag and drop or cut and paste selected menu items in the Custom Menu panel to other locations in the tree.

If you hold the Ctrl key while dragging, the drop action changes from move to copy.

g. Rename menus and items in the Custom Menu panel.

1. Select the item, right-click, and choose Rename.
2. Type a name and press Enter.

Renamed menu items are displayed in blue.

h. Add grouping separators in sub-menus. Right-click in the location where you need to add a separator and choose Add Separator.

i. Edit the mnemonic for an item in the Custom Menu panel.

1. Select the item, right-click, and choose Edit Mnemonic. A drop-down menu opens.
2. Choose a letter and click OK.

   The mnemonic letter is underlined in the menu item name and is used as a keyboard shortcut.

5

Save your changes and close the form.

Note: When you modify a workspace that is currently in use, the workspace selector displays Workspace Out of Sync. Select the current workspace from the workspace selector to apply the modified settings.

END OF STEPS

2.11 To customize toolbars

2.11.1 Purpose

The NFM-P toolbar contains buttons that allow quick access to menus and menu items; see 1.1.6 “Toolbar” (p. 78) in Chapter 1, “NFM-P GUI” . Perform this procedure to add or remove buttons and to change the order of buttons on the toolbar.

2.11.2 Steps

1

Open the Workspace form; see 2.6 “To create a new custom workspace” (p. 145) or 2.7 “To modify an existing workspace” (p. 146) .

2

Click on the Toolbar tab.

The Custom Menu panel contains a list of all the menu items in the custom workspace. The Appear on Toolbar panel displays a list of all items displayed as buttons or drop-down menu items on the toolbar.

3

Expand items as required in the Custom Menu panel and Appear on Toolbar panel.

4

Perform any of the following:

a. In the Appear on Toolbar panel, remove any items that are not required on the toolbar. Select and delete the items using the right-click menu or the keyboard.

b. Add menus and menu items to the Appear on Toolbar panel. Select items in the Custom Menu panel and drag and drop or copy the selected items to the Appear on Toolbar panel.

   When you add a menu, a drop-down is placed on the toolbar. The toolbar drop-down contains the sub-menus and menu items shown in the Appear on Toolbar panel.

   When you add a menu item, a unique icon button for the item is placed on the toolbar.

   Menu items without icons can only be pasted in a menu. They cannot be placed on the toolbar as separate icon buttons. For example, the menu items in the Window menu do not display icons.

   The usage indicator icon beside a menu in the Custom Menu panel indicates whether the menu items for that menu are all used, partially used, or not used in the Custom Menu. Usage indicator icons are described in the Legend at the bottom of the Workspace form.

c. Add a custom menu in the Appear on Toolbar panel.
   1. Right-click in the location where you need to add a custom menu and choose Add Menu. A new menu appears under the selected item.

      If you right-click on empty space in the panel, the new menu appears as the last item in the list.

   2. Type a name for the new menu and press Enter.

d. To locate a toolbar item in the Custom Menu panel, display the menu path for the item.
   1. In the Appear on Toolbar panel, select an item, right-click, and choose Show in Custom Menu Tree.

      A dialog box displays the path for the item in the Custom Menu. If the item appears more than once in the Custom Menu tree, multiple paths are displayed.

   2. Click OK to close the dialog box.

e. To locate a menu or item in the Appear on Toolbar panel, display the menu path for the item.
   1. In the Custom Menu panel, select an item, right-click, and choose Show in Appear on Toolbar Tree.

      A dialog box displays the path for the item in the Appear on Toolbar tree. If the item appears more than once in the Appear on Toolbar tree, multiple paths are displayed.

   2. Click OK to close the dialog box.

f. Arrange the order of toolbar buttons. In the Appear on Toolbar panel, drag and drop or cut and paste selected menu items to other locations.

g. Rename menus and items in the Appear on Toolbar panel.
   1. Select the item, right-click, and choose Rename
   2. Type a name and press Enter.

   Renamed menu items are displayed in blue.

h. Add grouping separators for toolbar drop-down menus. In the Appear on Toolbar panel, right-click in the location where you need to add a separator and choose Add Separator.

   You can add separators only within menus. Separators are not available between buttons on the toolbar.

5

Save your changes and close the form.

Note: When you modify a workspace currently in use, the workspace selector displays Workspace Out of Sync. Select the current workspace from the workspace selector to apply the modified settings.

END OF STEPS

2.12 To customize tree labels

2.12.1 Purpose

In the NFM-P GUI, navigation tree objects are displayed with icons and labels. Labels are displayed as text fields separated by commas.

You can customize labels for tree objects by selecting the text field definitions that appear and the order in which they appear. Labels for the Network, Unmanaged NEs, or Discovered NEs objects cannot be customized.

Perform this procedure to customize the labels for navigation tree objects.

2.12.2 Steps

1

Open the Workspace form; see 2.6 “To create a new custom workspace” (p. 145) or 2.7 “To modify an existing workspace” (p. 146) .

2

Click on the Trees tab.

3

Choose the view type. Object types and text fields are displayed in a table.

4

For each row in the table, perform the following as required:

1. Click on the table cell below Text Field #1 and choose a text field definition from the drop down menu.The selected text field definition appears in the table cell. On the navigation tree, the corresponding value for the text field definition will appear in the Text Field #1 position for the object.

   Some text field definitions appear as options below more than one text field heading. You can specify the display sequence of these text field definitions by choosing which text field to display them in.
2. Continue for the remaining text fields in the row.

   Note:

   Click on Restore Defaults to reset text fields to the default settings for the tree type in view.

The text field definitions for each object are displayed in navigation tree tooltips.

5

Save your changes and close the form.

Note: When you modify a workspace currently in use, the workspace selector displays Workspace Out of Sync. Select the current workspace from the workspace selector to apply the modified settings.

END OF STEPS

2.13 To customize list forms

2.13.1 Purpose

For some list forms, you can customize the object type drop-down to reduce the number of menu options displayed, to create, rename, and rearrange menu items, and to choose the default option. You can also select the action buttons that appear on the form.

2.13.2 Steps

1

Open the Workspace form; see 2.6 “To create a new custom workspace” (p. 145) or 2.7 “To modify an existing workspace” (p. 146) .

Alternatively, you can click the Customize button on a list form, if available. The Workspace (Edit) form for the current workspace opens with the List Forms tab displayed. Go to Step 4 .

2

Click on the List Forms tab and choose a list form type from the Form drop-down menu.

3

Click on the Object Types tab, if required.

The All Object Types panel contains a list of all object types available for the selected list form type. The Appear on Form panel contains the object types that appear in the object type drop-down menu.

4

Expand items as required in the All Object Types panel and Appear on Form panel.

5

Perform any of the following:

a. In the Appear on Form panel, remove any items that are not required in the object type drop-down menu. Select and delete the items using the right-click menu or the keyboard.

There must be at least one object type left in the Appear on Form panel. If all object types are removed, an error message is displayed.

b. Add a new custom folder in the Appear on Form panel.
   1. Right-click in the location where you need to add a folder and choose Add Folder. A new folder appears under the selected item.

      If you right-click on an empty space in the panel and choose Add Folder, the new folder appears as the last item in the list.
   2. Type a name for the new folder and press Enter.

      Note: If you add a new folder in the Appear on Form panel and the folder is empty, the folder is not displayed in the drop-down.

c. Rename a custom folder in the Appear on Form panel.
   1. Select the folder, right-click, and choose Rename.
   2. Type a name and press Enter.

d. Add object types to the Appear on Form panel. Select items in the All Object Types panel and drag and drop or copy the selected items to the Appear on Form panel.

   The usage indicator icon beside an object type in the All Object Types panel indicates whether the object types are all used, partially used, or not used in the Appear on Form panel. Usage indicator icons are described in the Legend at the bottom of the Workspace form. Usage indicators reduce the need to compare object types between the All Object Types panel and the Appear on Form panel.

e. To locate an object type in the All Object Types panel, display the path for the object type.
   1. In the Appear on Form panel, select an item, right-click, and choose Show in All Object Types Tree.

      A dialog box displays the path for the object type in the All Object Types Tree.
   2. Click OK to close the dialog box.

f. To locate an object type in the Appear on Form panel, display the path for the object type.
   1. In the All Object Types panel, select an object type, right-click, and choose Show in Appear on Form Tree.

      A dialog box displays the path for the object type in the Appear on Form Tree. If the object type appears more than once in the Appear on Form Tree, multiple paths are displayed.
   2. Click OK to close the dialog box.

g. Arrange the order of object types. Drag and drop or cut and paste selected menu items in the Appear on Form panel to other locations in the tree.

   The order of items in the Appear on Form panel determines their order in the drop-down menu.

h. Configure the default object type. The default object type is displayed in the drop-down when the list form opens.

   To set the default object type, select an object type in the Appear on Form panel, right-click, and choose Set Default. The selected object type is identified as the default.

To set no default for the list form, select the default object type, right-click, and choose Remove Default. When no default is set, you must select an object type each time the list form opens.

When you set a new default object type, the system overwrites any previous default.

For the Manage Services list form, the system initially assigns the Service (Service Management) object type as the default. You can change or remove this default as required.

For the Manage Equipment and Manage MPLS Objects list forms, the system does not assign a default object type until a user-configured default is set.

6

Configure the button display for the list form type selected in Step 2 . Click on the Button Panel tab and select or deselect buttons, as required. Buttons that are not selected will not appear on the list form.

The available buttons vary depending on the form type.

Mandatory buttons such as Search, Properties and Customize are dimmed and cannot be removed.

7

Save your changes and close the form.

Note: When you modify a workspace currently in use, the workspace selector displays Workspace Out of Sync. Select the current workspace from the workspace selector to apply the modified settings.

END OF STEPS

2.14 To configure the workspace selector

2.14.1 Purpose

Perform this procedure to add, remove, or change the sequence of workspaces in the workspace selector, or to set a workspace as the default workspace.

2.14.2 Steps

1

Choose Application→User Preferences from the NFM-P main menu. The User Preferences form opens.

2

Click on the Workspaces tab. A list is displayed of the workspaces that are currently available in the workspace selector.

3

Perform any of the following:

a. Add a workspace to the workspace selector.

1. Click Add. The Add Workspace form opens. A list is displayed of the workspaces not currently in the workspace selector.

   The Add button is disabled when the Allow Mandatory Workspaces Only check box is selected during user group configuration. See the procedure to add or remove workspaces for a user group in the *NSP System Administrator Guide*.

2. Choose a workspace from the list and click OK.

b. Set the default workspace that displays when the NFM-P opens. Choose a workspace in the list and click Set as Default.

c. Remove a workspace from the workspace selector. Choose a workspace in the list and click Delete.

   You cannot remove a workspace when that workspace is set as the default workspace.

   You cannot remove a workspace that is listed as a mandatory workspace in your user group.

d. Change the sequence of workspaces in the workspace selector. Choose a workspace and click Move Up or Move Down.

4

Save your changes and close the form.

Note: If the current workspace is deleted from the workspace selector, the workspace selector displays “Workspace Out of Sync”.

END OF STEPS

2.15 To apply a different workspace using the workspace selector

Note: You must add a workspace to the workspace selector before you can select it. See 2.14 “To configure the workspace selector” (p. 155) .

2.15.1 Steps

1

Click on the workspace selector drop-down in the top right corner of the GUI display.

2

Choose a workspace from the list. A confirmation dialog box appears.

a. Click Yes to close all internal and external NFM-P windows.

b. Click No to close only the navigation tree window. All other open windows are retained. The new workspace settings are not applied to the open windows.

The NFM-P GUI is displayed using the settings from the selected workspace. The workspace selector displays the workspace currently in use.

END OF STEPS

2.16 To delete a custom workspace

2.16.1 Purpose

Perform this procedure to permanently delete a custom workspace from the NFM-P. You must have the required scope of command permissions to delete a public workspace. System-defined workspaces cannot be deleted.

2.16.2 Steps

1

Choose Application→Manage Workspaces from the NFM-P main menu. The Manage Workspaces form opens.

2

Choose a workspace from the list and click Delete.

3

Save your changes and close the form.

Note: When you delete the current workspace, the workspace selector displays "Workspace Out of Sync".

END OF STEPS

2.17 To export custom workspaces

2.17.1 Purpose

Perform this procedure to export custom workspaces. You must have the required scope of command permissions to export public workspaces.

2.17.2 Steps

1

Choose Application→Manage Workspaces from the NFM-P main menu. The Manage Workspaces form opens.

2

Perform one of the following:

a. To export multiple workspaces, choose the custom workspaces in the list and click Export. The Export Directory window opens.

b. To export a single custom workspace, choose the workspace in the list and click Export. The Export Directory window opens.

   Alternatively, you can export a custom workspace by clicking on the Export button on the Workspace (Edit) form. To open the workspace (Edit) form, see 2.7 “To modify an existing workspace” (p. 146) .

Note: If you do not have permissions to export a workspace the Export button is disabled. You cannot export system-defined workspaces or private workspaces owned by other users.

3

Specify the export directory in the Save In drop-down, or create a directory or folder, and click Save. The selected workspace files are exported to the specified directory.

4

Close the Manage Workspaces form.

END OF STEPS

2.18 To import a workspace

2.18.1 Purpose

Perform this procedure to import NFM-P workspaces that were previously saved as exported workspaces. For information about how to export workspaces, see 2.17 “To export custom workspaces” (p. 157) .

2.18.2 Steps

1

Choose Application→Manage Workspaces from the NFM-P main menu. The Manage Workspaces form opens.

2

Click Import. The Import Directory window opens.

3

In the Look In drop-down, navigate to the directory that contains the workspace you need to import.

4

Configure the Overwrite User Name and Overwrite Existing Workspace(s) parameters as required, based on your permissions.

5

Click Open. A dialog box appears.

6

Click Yes. The imported workspaces are added to the Manage Workspaces form.

7

Close the Manage Workspaces form.

END OF STEPS

2.19 To add new menu items to a custom workspace of an earlier NFM-P release

2.19.1 Purpose

Later releases of the NFM-P may contain newly-introduced menu items that are not in the custom workspaces of an earlier release.

Perform this procedure to view new menu items and add them as required to an existing custom workspace of an earlier release.

2.19.2 Steps

1

Open the Workspace form; see 2.7 “To modify an existing workspace” (p. 146) .

2

Click on the All Menu Items drop-down and choose New Menu Items. A list of menu items newly-introduced in the NFM-P since the earlier release is displayed. The Finished adding New Menu Items parameter is also displayed.

Note: The New Menu Items function is available only if the workspace was created in an earlier NFM-P release.

3

Expand the items in the New Menu Items panel as required.

4

Add new menu items to the Custom Menu panel and configure as required. See 2.10 “To customize menus” (p. 148) . When you finish, if you no longer need the list of new menu items, go to Step 5 . Otherwise, go to Step 6 .

Note: When the Finished adding New Menu Items check box is left unselected, the New Menu Items panel remains as an option each time the Menus tab on the Workspace (Edit) form is opened. The usage indicator icons display the current usage of new menu items in the custom workspace.
Nokia recommends that you select the Finished adding New Menu Items check box when the New Menu Items option is no longer required.

5

Select the Finished adding New Menu Items check box.

Note: After the Finished adding New Menu Items check box is selected and you click on the Apply or OK buttons, the New Menu Items option is no longer displayed.

6

Save your changes and close the form.

END OF STEPS

3 NFM-P navigation tree

NFM-P navigation tree

3.1 Overview

3.1.1 General information

The NFM-P navigation tree provides multiple views that list the equipment groups, NEs, routing instances, protocols, and other objects in the NFM-P managed network. Objects are listed in a parent-child hierarchy. You can expand the tree to access child objects or collapse the tree for a broader view. You can access property forms, create equipment groups, and perform other functions using the navigation tree window.

For more information about network objects, see Chapter 11, “Working with network objects” .

In most system workspaces, the navigation tree window opens by default when the NFM-P client is opened. See Chapter 2, “NFM-P custom workspaces” for information about workspaces. See 1.15 “To manage a window or form as an external window” (p. 107) for information about managing the display of windows in the GUI.

You can use the navigation tree to locate specific objects in the physical and logical network views. See 3.7 “To locate objects in the navigation tree” (p. 165) for information about searching for objects in the navigation tree.

The display of objects in the navigation tree is affected by the span of control settings in user preferences; see 1.2.2 “Span of control” (p. 79) in Chapter 1, “NFM-P GUI” .

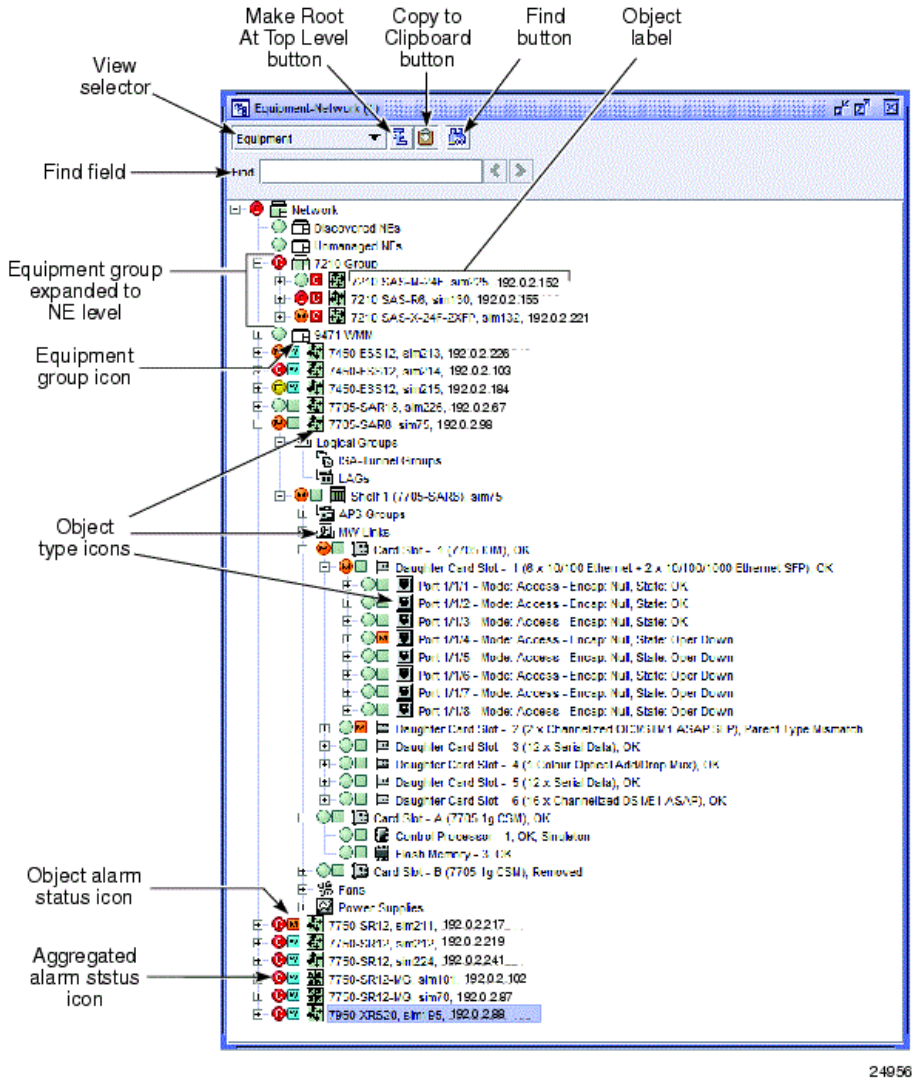
You can use the following methods to navigate the tree and manage objects.

- Double-click on an object or click on the + sign to display child objects. When you double-click on an object that has no child objects, a properties form for the object opens.
- Double-click on an object or click the - sign to hide child objects.
- Select an object and use the cursor keys to navigate the object hierarchy. The up and down arrow keys move the selection up or down in the tree. The right and left arrow keys expand or collapse objects and move up or down in the hierarchy.
- Right-click on an object to open a contextual menu, and choose an option. The menu options are specific to the object type. See 3.5 “Contextual menus” (p. 164) in this section for more information.

Note: Keyboard-based navigation tree operations may not function as expected when you open the client GUI using a third-party access tool, for example, a Citrix server.

The following figure shows the NFM-P navigation tree window, with the Equipment view selected.

Figure 3-1 NFM-P navigation tree - Equipment view



3.2 Icons and labels

3.2.1 General information

Objects in the navigation tree display on a single line with icons and labels.

Icons indicate alarm status and object type. The circle at the left indicates the aggregated alarm status. The square indicates the alarm status for the object. Object types are represented by a unique NFM-P icon for each type. Click on the Legend icon on the physical topology map toolbar for a description of alarm and equipment group icons.

Labels are displayed as text fields separated by commas, and typically provide an object description, ID number, IP address, or other information such as operational or administrative state. You can customize labels for tree objects by selecting the text field definitions that appear and the order in which they appear; see 2.12 “To customize tree labels” (p. 152) .

3.3 Equipment groups

3.3.1 General information

Equipment groups allow you to organize the network into logical groupings of NEs, for example, in a geographical area, or by equipment type. An equipment group is sometimes called a topology group. Some of the views in the view selector, for example the Equipment view, allow you to use the navigation tree to create and manage equipment groups.

An equipment group can contain up to 2000 NEs. The NFM-P client displays NEs in the navigation tree up to a limit of 500 NEs per group. An administrator can specify a system preference for the default number of NEs to display when a group is expanded on the tree (up to 500); see the procedure to configure NFM-P system preferences in the *NSP System Administrator Guide*. See 3.9 “To manage NEs in equipment groups on the navigation tree” (p. 167) for information about managing NEs in equipment groups on the navigation tree.

3.4 Navigation tree toolbar

3.4.1 General information

A toolbar in the NFM-P navigation tree window contains the view selector, the Make Root At Top Level icon, the Copy to Clipboard icon, and the Find icon. The Find field is located below the navigation tree toolbar.

3.4.2 View selector

The view selector is a drop-down menu that lists the physical and logical network views available in the main navigation tree window.

You can choose the following views:

- Equipment—displays the physical objects that the NFM-P manages
- OSPF—displays all OSPF objects in the network
- ISIS—displays all IS-IS objects in the network
- Routing—displays the device routing instances and child objects, such as the network interfaces and the configured protocols
- Ring Group—displays the ring group objects that the NFM-P manages
- Cloud Network—displays DC POD or interconnect management entities

3.4.3 Make Root At Top Level icon

The root is the highest-level object in the tree. When Equipment is selected in the view selector, you can change the root of the tree to reduce the display of objects in the tree.

The Make Root At Top Level icon restores the navigation tree to the default Network root when a lower-level object is the current root.

See 3.8 “To change the root object of a navigation tree” (p. 166) for information about changing the root object of the navigation tree.

3.4.4 Copy to Clipboard icon

You can use the Copy to Clipboard icon to copy the property form identifier for one or more objects in the tree to the NFM-P clipboard. You can use the clipboard to open forms, send identifiers to other users, and configure search filters. On the topology map, you can use the clipboard to search for objects and create physical links; see Chapter 4, “Topology map management” .

See 1.20 “To use the NFM-P clipboard” (p. 112) for more information about the NFM-P clipboard,

3.4.5 Find icon and Find field

You can use the Find icon or the Find field to locate and highlight objects in the navigation tree.

See 3.7 “To locate objects in the navigation tree” (p. 165) for more information about locating objects in the tree.

3.5 Contextual menus

3.5.1 General information

When you right-click on an object in the NFM-P navigation tree, a contextual menu opens for that object. You can use contextual menus to:

- create objects
- configure object properties
- perform maintenance functions
- change the state of objects
- open a different management interface, for example, a CLI
- change the root object in the navigation tree

The available contextual menu options vary, depending on the object type.

3.6 Basic navigation tree procedures

3.6.1 General information

The following procedures describe how to use the NFM-P navigation tree.

3.7 To locate objects in the navigation tree

3.7.1 General information

You can use the Find icon or the Find field in the navigation tree header to locate objects in the navigation tree. Objects that match the search terms are highlighted sequentially in the tree. Each search can produce up to 200 results.

A system preferences threshold may limit the number of NEs displayed in the navigation tree when an equipment group is expanded. When you use the Find icon or Find field, the search results include NEs and descendant objects that were not displayed prior to the search, even if they exceed the system preferences NE display threshold.

Note: The NFM-P client displays NEs in the navigation tree up to a maximum limit of 500 NEs per equipment group. When an equipment group contains more than 500 NEs, some objects may not appear in the search results.

When the system limit of 500 NEs is already displayed under the equipment group, and a matching NE object or descendant object is not among the displayed NEs, the matching object is not displayed or highlighted.

See 3.9 “To manage NEs in equipment groups on the navigation tree” (p. 167) for more information about managing the display of NEs in equipment groups.

3.7.2 Steps

1

To locate an object using the Find icon:

1. Click the Find icon or press Ctrl-F. The search panel appears.
2. Enter search terms in the attribute fields. The available fields vary depending on the selected view.
3. Click Find in the search panel or press Enter. The navigation tree expands to show the first matching object highlighted.
4. To find additional matching objects, click the Next button or press F3. The navigation tree expands to show the next matching object highlighted in the tree.

   The Next and Previous buttons are available when more than one object matches the search term.
5. To return to the previous matching object in the navigation tree, click the Previous button or press Shift-F3.
6. To remove all search terms from the search panel, click Clear.
7. To close the search panel, click the Find icon at the top of the navigation tree window or press Ctrl-F.

2

To locate an object using the Find field:

Note: For some of the views in the view selector the Find field is not available.

1. Enter a search term in the Find field. Search terms are based on object labels. A tooltip for the Find field shows a list of the available labels. See 2.12 “To customize tree labels” (p. 152) for information about how to customize labels.
2. Press Enter. The navigation tree expands to show the first matching object highlighted.
3. To find additional matching objects, click the Next button or press F3. The navigation tree expands to show the next matching object highlighted in the tree.

   The Next and Previous buttons are enabled when more than one object matches the search term.
4. To return to the previous matching object in the navigation tree, click on the Previous button or press Shift-F3.

END OF STEPS

3.8 To change the root object of a navigation tree

3.8.1 General information

The root is the highest-level object in the tree. When Equipment is selected in the view selector, you can change the root of the tree.

Perform this procedure to make a lower-level object the root of the current navigation tree window or a new navigation tree window, or to restore the default Network root.

3.8.2 Steps

1

Open the navigation tree window and select the Equipment view.

2

Change the root object of a tree. Perform any of the following:

a. Make a selected object the root of the current tree. Right-click on the object and choose Make Root. The navigation tree is refreshed with the selected object as the root of the tree.

b. Make a selected object the root of a new navigation tree window. Right-click on the object and choose Make Root in New Tree. A new navigation tree window opens with the selected object as the root of the tree.

   Up to five navigation tree windows can be open at one time.

   The Make Root in New Tree option is also available when you right-click on an equipment group in the topology map navigation tree, or on the map background. A new navigation tree window opens with the equipment group selected or displayed in the map as the root of the tree.

   The Make Root In New Tree option is not available for the root object of a tree.

c. Restore the default Network object as the root object. Click on the Make Root At Top Level icon on the navigation tree toolbar.

The Make Root At Top Level icon is available when a lower-level object is the root of the tree.

END OF STEPS

3.9 To manage NEs in equipment groups on the navigation tree

3.9.1 General information

On the navigation tree, you can open an NEs list form for a selected equipment group and use the form to search for NEs, to show the NEs you require on the tree, and to move NEs to other groups. The form lists all of the NEs in the selected equipment group.

An administrator can specify a threshold value in system preferences for the default number of NEs to display when a group is expanded in the tree. See the procedure to configure NFM-P system preferences in the *NSP System Administrator Guide*. When an equipment group contains more NEs than the threshold value, some of the NEs are not displayed in the tree. When the threshold value is less than 500, you can use the NEs list form to temporarily display additional NEs in the group, above the threshold amount, up to 500.

An equipment group can contain up to 2000 NEs. The NFM-P client displays NEs in the navigation tree up to a maximum limit of 500 NEs per group. When an equipment group contains more than 500 NEs, some of the NEs are not displayed in the tree. You can use the NEs list form to access all of the NEs in the group, or to move NEs to other groups.

3.9.2 Steps

1

Open the NEs list form for an equipment group in the navigation tree. Right-click on the equipment group object and choose List NEs. The NEs list form opens.

When you expand an equipment group in the tree, and the number of NEs in the group equals or exceeds the threshold value set in system preferences, a message is displayed in the navigation tree under the equipment group object. You can click on the message to open the NEs list form for the equipment group.

The message remains in the tree display, even if the number of NEs in the equipment group is reduced below the system preferences threshold.

2

Manage NEs using the NEs list form. Perform any of the following:

a. Locate NEs in the tree or display additional NEs. Select an NE in the list and click Show on Tree. The selected NE is highlighted in the tree.

   If the selected NE was not previously displayed in the tree, it is added to the display for the equipment group and highlighted.

   Alternatively, you can use the Find icon or Find field in the navigation tree header to locate NEs in the tree or to display additional NEs; see 3.7 “To locate objects in the navigation tree” (p. 165) .

The display of additional NEs is not preserved. If the navigation tree window is closed or the root object of the tree is changed, the next display of the NEs in the group reverts to the default display.

Up to 500 NEs (the maximum system limit) can be displayed under an equipment group in the navigation tree. If this limit is exceeded, a message is displayed.

b. Move NEs to other groups.
   1. Select one or more NEs in the list and click Move to Group. A drop-down menu opens.
   2. Choose an equipment group in the menu. The selected NEs are moved to the selected group.

   Alternatively, you can move NEs to different groups by clicking and dragging icons on the navigation tree or topology map.

3

Close the list form.

When the NE List form for an equipment group is opened from the navigation tree, it closes automatically when you change the view in the view selector, close the navigation tree window, or change the root object of the tree.

END OF STEPS

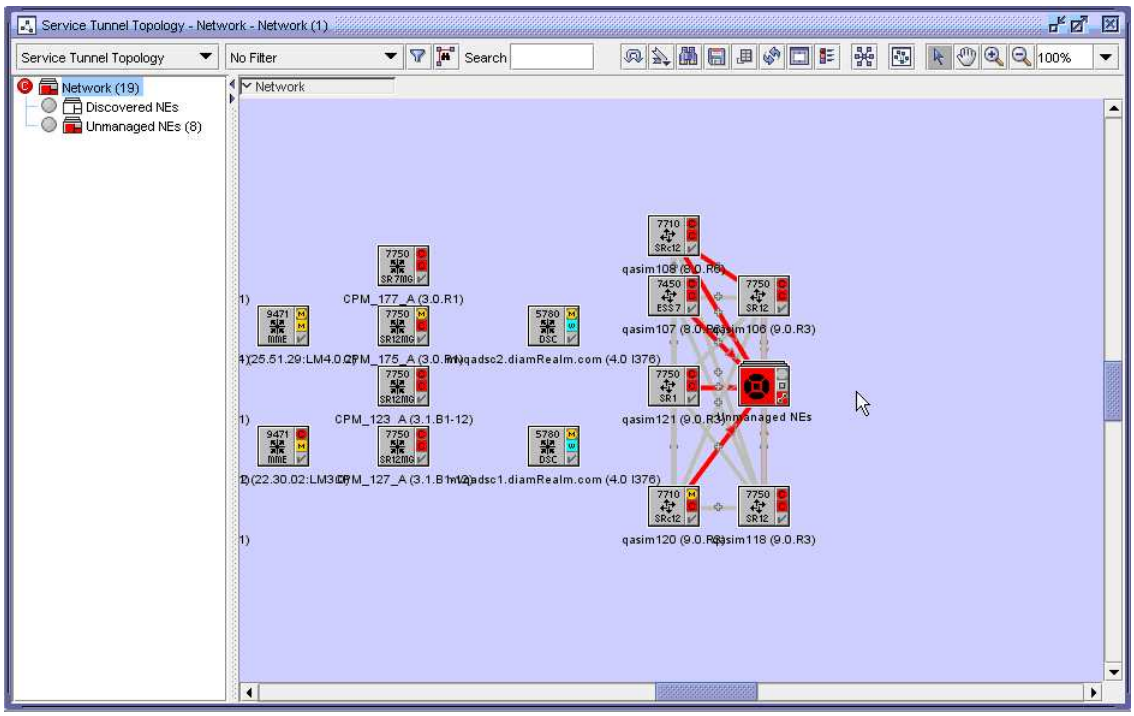
4 Topology map management

4.1 Topology map types

4.1.1 Service tunnel topology map

A service tunnel topology map is available on the NFM-P by choosing Application→Service Tunnel Topology from the NFM-P main menu. The Service Tunnel Topology map is displayed, as shown in the following figure.

Figure 4-1 Service tunnel topology map



Icons in the service path topology map represent devices. The color of the device icon represents the status of the device. Red means that the device is down. Green means that the device is up. Yellow means that the device is being synchronized. Purple means that the device is in a suspended management state. See Chapter 9, “Device discovery” for information about device discovery and management states.

Link groups between devices represent service tunnels. When a link group is red, at least one tunnel in the link group is down. For link groups between managed devices, right click the link group icon to list and edit tunnels in the link group. For link groups between managed and unmanaged devices, right-click the link group icon to open contextual menus and submenus which allow you to open additional information forms for the service tunnel, including the properties form.

4.1.2 EPS path topology maps

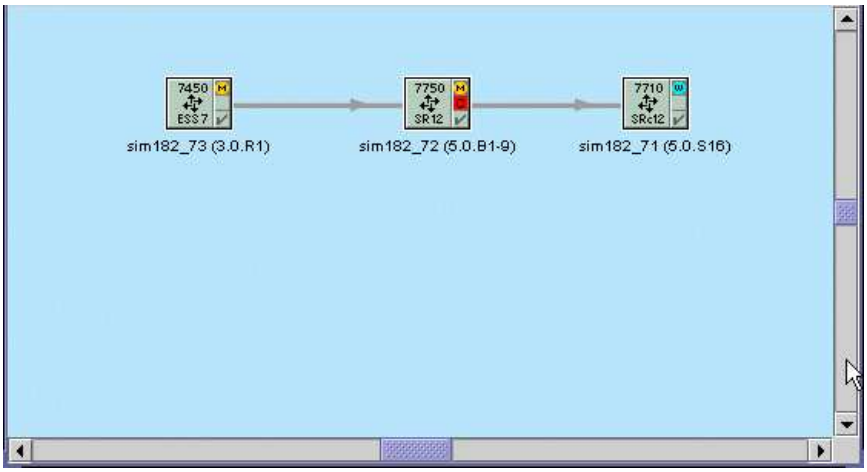
An EPS path topology map is available on the NFM-P by choosing Application→EPS Path Topology from the NFM-P main menu. The EPS path topology map displays a static representation of mobile network objects and EPS paths. Each network object icon represents an aggregate of all network objects of that type. For SGWs and PGWs, the icon represents an aggregate of all instances of that gateway type and all network objects that contain instances of that type. Each EPS path link represents an aggregate of all EPS paths of a specific type.

4.1.3 LSP path topology map

An LSP path topology map is available from the MPLS Path form and the LSP Path form. See 4.5 “To open an MPLS provisioned path map from the MPLS Path form” (p. 179) to view the map from the MPLS Path form. See 4.6 “To open a dynamic LSP path map from the LSP Path form” (p. 179) to view the map from the LSP Path form.

The LSP path topology map is used to view a specific provisioned, actual, or CSPF LSP path in the context of its source, and transient and destination hops. The following figure shows an LSP path topology map.

Figure 4-2 LSP path topology map



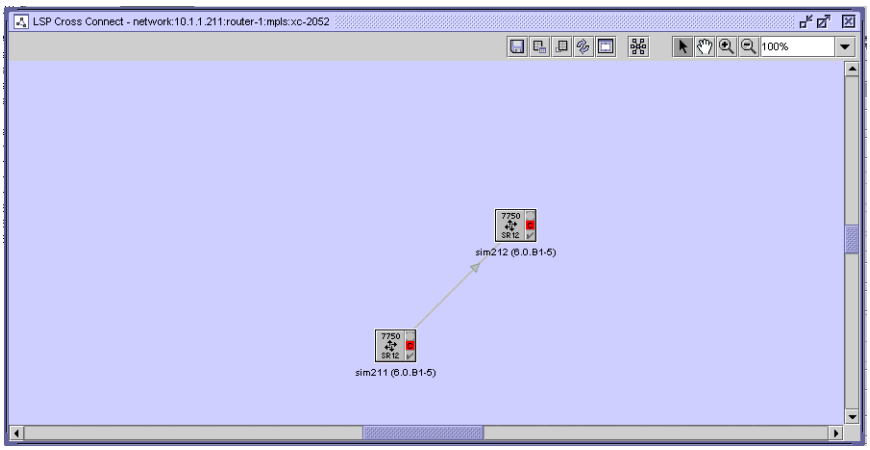
When you view the LSP path topology map, hops are linked by straight lines, where each line represents a sub-path between two hops of the LSP path. The direction of each path is indicated by an arrow. Green lines indicate provisioned paths, and gray lines indicate actual paths.

4.1.4 LSP cross-connect topology map

An LSP cross-connect topology map is available from the LSP Path form. To view the map from the LSP Path form, see 4.7 “To open a dynamic LSP cross-connect topology map” (p. 180) .

The LSP cross-connect topology map is used to view a specific LSP cross-connect in the context of its source, and transient and destination hops. The following figure shows the LSP cross-connect topology map.

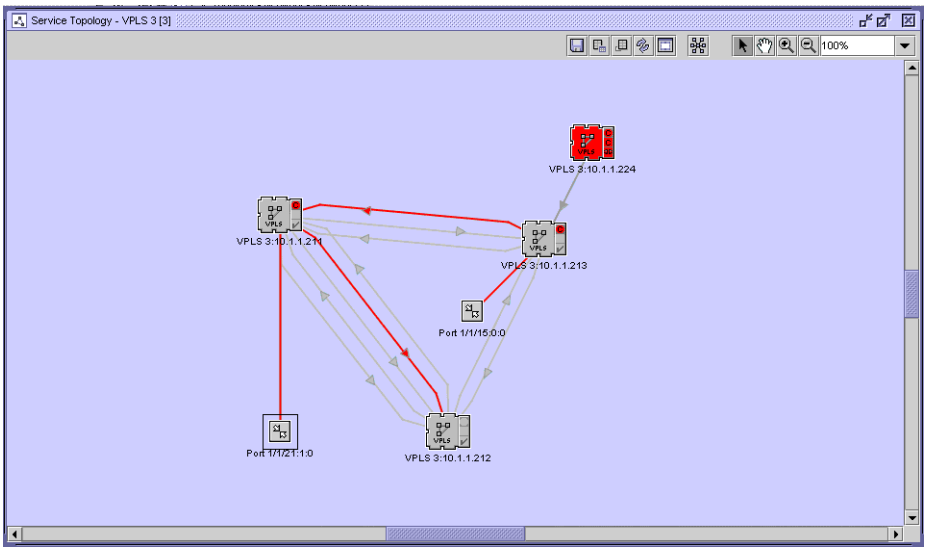
Figure 4-3 LSP cross-connect map



4.1.5 Service topology maps

You can open a topology map for a selected service from the Manage Services form by clicking Topology View. The following figure shows a service topology map. Large NE icons represent managed devices. Small NE icons represent unmanaged devices. The label of an NE icon indicates the service name and the NE IP address.

Figure 4-4 Service topology map



The symbol and color in the top-right corner of the managed device icon represents the aggregated alarm status, which is the most severe alarm on any service that includes the device. The symbol immediately below the aggregated alarm status and the color of the icon indicate the alarm status

for the currently displayed service site. A red icon indicates that the service site is down. A green icon indicates that the service site is up.

A port icon represents a managed access interface. A port label includes the port number and the inner and outer port encapsulation values. A service site can support up to 20 SAPs. When the number of SAPs on a service site exceeds 20, the SAPs on the site are grouped into a SAP group, represented by a SAP group icon. When the number of SAPs drops below 20, the SAP group icon is replaced with the icons for the individual SAPs. To view the list of SAPs in a SAP group, right-click on the SAP group icon and choose List L2 Access Interface or List L3 Access Interface, depending on the service type. The corresponding Site form for the service opens.

SAP aggregation group icons represent SAP aggregation groups configured for a VLL Apipe on the 7705 SAR. The SAP aggregation group is linked to the service site and each of the individual SAPs. To hide the associated SAPs for a SAP aggregation group, right-click on the SAP aggregation group icon and choose Hide SAPs. Choose Show SAPs to show them again.

A line between two map objects represents a link or group of links. Links between device icons represent service circuits. Links between device icons and port icons represent the binding of an access port or interface to a service. The symbol and color in the bottom right corner of the managed device icon represents the connectivity alarm status. During a resynchronization of the managed device, the icon represents the resynchronization status, and is yellow. The status is inherited from the link endpoints. A plus sign icon located in the centre of the link indicates a bidirectional group link. An arrow icon located on the link indicates a unidirectional link and identifies the direction of the path.

Right-clicking on a managed site, port, or link opens a contextual menu that allows you to perform functions that include the following:

- choose layout options
- open an object properties form
- turn up or shut down an object
- create a service object
- create a service object from a template, if a template is bound to the service
- delete an object
- open a CLI session
- manage scripts
- plot statistics
- display or highlight service topology features

You can view multiple services on a map at the same time if the services are selected from the Manage Services form during map creation.

Service segmentation

A service segmentation view is also available to aid in conceptualizing complex services. Segments are logical grouping of interconnected sites, services, and bindings. The segmentation view is available for VPLS and VLL services.

A service segment is considered to be a portion of a single service that extends to multiple sites connected within that segment. It is based on the service type through one of the possible

connection topologies (for example, mesh, PBB tunnels, a switching VLL, rings, and so on), without having to pass through any connectors such as spokes, CCAGs, or SCPs (SAP-to-SAP).

General examples of segments in Layer 2 service topologies include:

- A simple pair or single spoke/mesh SDP binding comprises one segment
- A mesh of a multi-NE VPLS service comprises one segment
- A multi-NE mesh with a spoke SDP to a single NE comprises two segments
- Each mesh of VSIs forms a segment (applicable to H-VPLS)

Just a few examples of the many possible service-specific segmentation configurations include scenarios such as the following:

- H-VPLS (Inter-Metro with redundant spoke SDPs):
  - One application of H-VPLS is the connection of two or more geographically-dispersed VPLS domains belonging to the same customer. Two spoke SDP connections are used to connect each VPLS between the two metros, either in a redundant PW spokes topology or under STP protocol. The redundant spokes comprise one segment, while each VPLS will also comprise one or more segments, depending on their specific configurations.
- VLL Switching:
  - For a VLL service at a switching router, a terminating PE device has at least one VLL SAP, while a switching PE device has a VLL instance which cross-connects two spoke bindings. All VLL instances of such a service must have the same service ID, and if the VLL has one or more switching sites, it must have at least two terminating sites. In this scenario, the primary and redundant spoke SDPs on the same network endpoint are considered to be in the same segment.
- PBB:
  - In a PBB configuration, the B-VPLS is considered a service tunnel, from the I-VPLS or I-Epipe perspective. Therefore, the sites connected via a B-VPLS (that is, having the same ISID) are considered to be in one segment.
  - I-Sites bound to the same PBB tunnel (B-VPLS) and having the same ISID exist in the same segment.
  - Epipe sites bound to same PBB tunnel (B-VPLS) exist in the same segment

Whenever you modify a service, the following actions can trigger segment creation, modification, or deletion in a segmented service view:

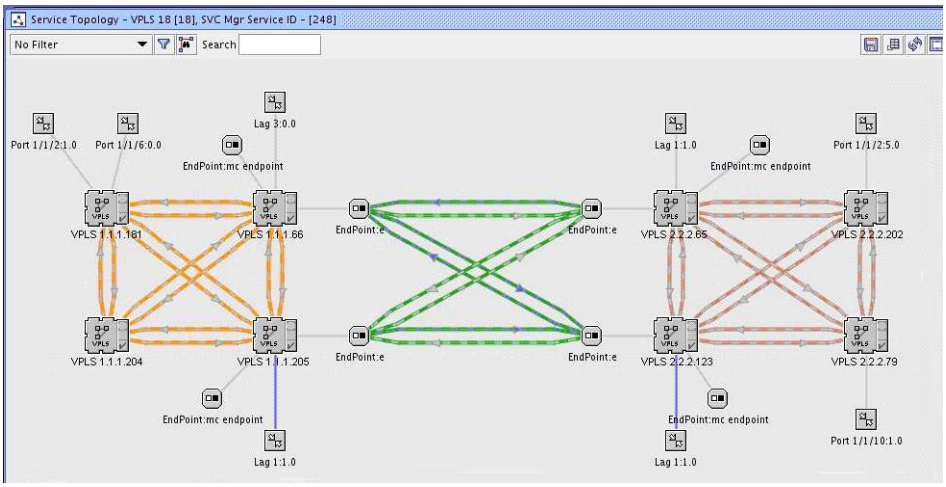
- Adding or removing service sites
- Creating or deleting spoke and/or mesh bindings (either through the NFM-P GUI or CLI)
- Creation or deletion of VLAN Uplinks by NFM-P

You can access the segmented view of a service by right-clicking on an empty portion of the background in the service's topology view. A contextual menu allows you to activate or de-activate the segmented view for the service.

In a segmented view, the outlined links of all spoke bindings, mesh bindings, or VLAN Uplinks are colored in the same distinct way for the segment they belong to. However, there are currently only 19 different colors available for use in showing service segments. If all the colors for a specific service are used, a warning message is logged to indicate this.

The following figure shows an example of how the NFM-P displays the segmented view of an H-VPLS Metro-to-Metro service.

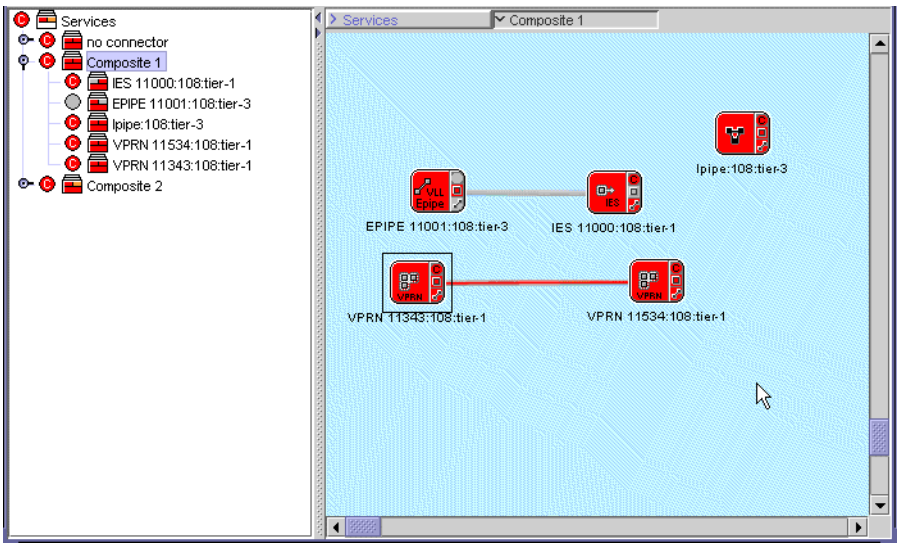
Figure 4-5 Service segmentation example



4.1.6 Composite service topology maps

You can use the NFM-P to view composite service topology and flat topology maps. The figure below shows a sample composite service topology map. When you open a flat topology view map, the navigation tree is not part of the map.

Figure 4-6 Composite service topology map



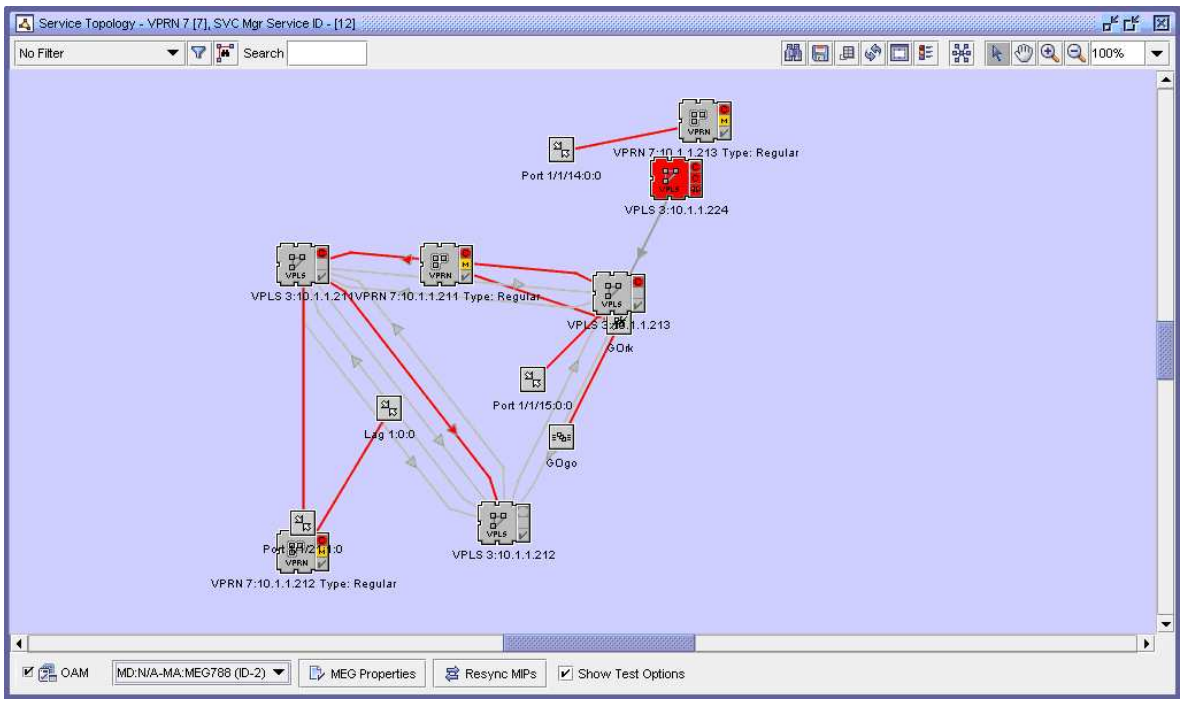
In a composite service topology map, you can use the navigation tree at the left side to display the composite service and service tier hierarchy starting from the services object. The map navigation tree displays the following:

- composite services and service tiers, including service name and tier number
- status of the composite services and their tiers

Double-click on a composite service object in the map panel to display the service objects that belong to the composite service. Double-click on the service objects to display the service sites and access interfaces. The links or groups of links between the service sites and access interfaces are also displayed.

In the composite service topology map, all service objects in the composite service are displayed simultaneously. The service sites, access interfaces, and the links or groups of links between them are also displayed. The navigation tree is thus not required in this view. The following figure shows a sample composite service flat topology map.

Figure 4-7 Composite service flat topology map



You can right-click an object icon or link group icon to turn up, shut down, or display the properties form for the item.

You can also perform Ethernet CFM diagnostics directly from the composite service flat map.

4.2 Working with topology maps

4.2.1 Modifying a service from the topology view

The topology view for a service provides a graphical representation of the various components and their interconnections. You can also use this view to add, modify, or just navigate to service components. This provides an alternative approach to performing these functions from the navigation tree view in the service configuration forms.

Working from the topology view can expedite the creation of the components, since many of the fields you would ordinarily have to set in the configuration forms will be automatically populated using this approach. The configuration forms can also be accessed directly at any time from this view by right-clicking a component. This allows quick access to conduct more detailed component configuration.

Services that can be modified from their topology views include VPLS, VPRN, VLL, IES, and composite services. See the appropriate service management chapter for procedures that describe how to modify services from the topology view.

4.2.2 Managing OAM diagnostics from the topology view

An NFM-P operator can configure and execute OAM diagnostic tests from the service topology or composite service flat topology view. A right-click contextual menu of test types and test operations allows a GUI user to perform many test-management tasks. The OAM diagnostic functions on the map are enabled and disabled using a selector in the map window.

NFM-P OAM diagnostic test management using the service topology map is supported for the following service types:

- VLAN, excluding Wavence SM VLAN
- VLL Epipe
- VPLS
- VPRN

The NFM-P OAM diagnostic test management functions are also available for composite services using the composite service flat topology map.

You can use a contextual menu option to open a test-creation form for selected map objects such as NEs, SAPs, SDPs, MEPs, and MIPs. The form is automatically populated with the information for the selected objects. After you apply the test configuration, you can use the map to execute the test and view the results. A test result summary is viewable using statically displayed or mouse-over global info tables that are shown beside the object that initiates the test. By default, the info table for a tested object displays the five most recent test results; you can enable or disable the display of individual or all results.

The general OAM contextual menu options that are available include the following:

- Create OAM Tests—lists the tests that are appropriate for the service type and selected objects; choosing a test type opens the pre-populated test-creation form
- Select OAM Tests—opens a filterable list form from which you can choose previously created tests associated with one or two objects

Note: The tests that are listed using the Select OAM Tests option do not include generated tests, or manually added first-run or last-run tests in a test suite.

See 4.8 “To use OAM diagnostic functions on service topology and composite service flat topology maps” (p. 181) for information about enabling basic OAM-related map functions.

See 90.43 “To configure and run OAM tests contextually” (p. 3052) for information about contextually configuring and executing OAM tests for entities and services on topology maps.

4.2.3 Working with Ethernet CFM objects

You can configure and manage Ethernet CFM objects such as MEGs, MEPs, and MIPs using the Ethernet CFM contextual menu option. MEPs and MIPs are represented iconically. For example, a SAP or SDP binding object can have a graphical connector to MEPs and MIPs, and a site object can be connected to a B-VPLS MEP.

Within a MEG, MEPs can be divided into logical groupings called sub-groups. A MEG which contains sub-groups is called a Global MEG. When created, a Global MEG has by default one subgroup.

A service topology map displays only one MEG at a time. The MEG is selectable using a drop-down menu in the map window when the OAM function on the map is enabled. The CFM objects associated with the currently selected MEG are displayed.

For a MEP, the following attributes are displayed:

- the MEP level, as a number inside the icon
- the MEP direction, as the up or down direction in which the icon points
- the MEP administrative state, as the icon color
- the MEG sub-group to which the MEP belongs, as the icon outline color.

Note: For composite services, MEP generation does not occur for for VLAN uplinks and overlapping service sites.

When the Show Test Options check box is enabled, the roles assigned to MEPs for Test Suite Generation are displayed beside the MEP icons. The roles are Target, Source, and Hub or Spoke. See 4.8 “To use OAM diagnostic functions on service topology and composite service flat topology maps” (p. 181) .

For a MIP, only the level is displayed.

The displayed Ethernet CFM contextual menu options for MEPs and MIPs depend on the Ethernet CFM configuration, for example, the MD level and whether MEPs and MIPs are already in the MEG.

When an operator right-clicks on the map background, the Ethernet CFM options are:

- global MEG creation, which opens a configuration form populated with the selected sites or all service sites, if none are selected.
- addition of a service to an existing global MEG
- delete selected global MEG

When the selected object is a SAP, you can create, view, change and delete MEPs. See 91.15 “To configure an Ethernet CFM MD policy and subordinate objects” (p. 3109) for information about

configuring MEPs. You can enable, disable, and view MIPs. Enabling a MIP creates a MIP only when the configuration supports this function.

When the selected object is a VLAN uplink, a solid line is displayed between the two SAPs and an OAM icon is displayed above the port icons. Right-click on the OAM icon to display the following Ethernet CFM options:

- Edit MEP
- Delete MEP
- Disable MIP
- Change MEG Sub Group

When the selected object is an SDP binding, you can enable, disable, and view the associated MEPs.

Note: When you enable a MIP on a SAP or SDP binding, the NFM-P creates a MEG site if one does not exist, and uses explicit MHF creation.

4.3 To open a map from the NFM-P main menu

4.3.1 Steps

1

Choose Application from the NFM-P main menu.

2

Choose a type of map to view from the menu options:

- Service Tunnel Topology to view service tunnels
- Flat Maps→Physical Topology
- Flat Maps→Service Tunnel Topology
- EPS Path Topology

The appropriate map opens and displays the network objects.

END OF STEPS

4.4 To open a service topology map

4.4.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select one or more services and click Topology View. A dialog box appears.

3

Click Yes to continue. The Service Topology map opens.

4

View and close the map.

END OF STEPS

4.5 To open an MPLS provisioned path map from the MPLS Path form

4.5.1 Steps

1

Choose Manage→MPLS→MPLS Paths from the NFM-P main menu. The Manage MPLS Paths form opens.

2

Select an MPLS path and click Properties. The MPLS Path configuration form for the selected path opens.

3

Click on the Provisioned Path tab. The hops of the MPLS path are listed.

4

Select a hop and click Topology View. The MPLS provisioned path map opens showing the hops between the devices.

5

View and close the map.

END OF STEPS

4.6 To open a dynamic LSP path map from the LSP Path form

4.6.1 Steps

1

Choose Manage→MPLS→Dynamic LSPs from the NFM-P main menu. The Manage Dynamic LSPs form opens.

2

Select a dynamic LSP and click Properties. The Dynamic LSP (Edit) form opens.

3

Click on the LSP-Path Bindings tab. The LSP paths are listed.

4

Select an LSP path and click Properties. The LSP-Path Binding (Edit) form opens.

5

Perform one of the following:

a. View the topology for provisioned paths:
   1. Click on the Provisioned Path tab. The LSP path hops are listed.
   2. Select a hop and click Topology View. The LSP path map opens showing the LSP path hops between the devices.

b. View the topology for actual paths:
   1. Click on the Actual Path tab. The actual path hops are listed.
   2. Select a hop and click Topology View. The LSP path map opens showing the actual path hops between the devices.

c. View the topology for CSPF paths:
   1. Click on the CSPF Path tab. The CSPF path hops are listed.
   2. Select a hop click Topology View. The LSP path map opens showing the CSPF path hops between the devices.

6

View and close the map.

END OF STEPS

4.7 To open a dynamic LSP cross-connect topology map

4.7.1 Steps

1

Choose Manage→MPLS→Dynamic LSPs from the NFM-P main menu. The Manage Dynamic LSPs form opens.

2

Choose an LSP and click Properties. The Dynamic LSP (Edit) form opens.

3

Click on the Cross Connects tab. The cross-connects of the LSP path are listed.

4

Choose a cross-connect and click Topology View. The LSP path map opens and displays the cross-connects between the devices.

5

View and close the map.

END OF STEPS

4.8 To use OAM diagnostic functions on service topology and composite service flat topology maps

4.8.1 Purpose

Perform this procedure to enable the OAM diagnostic functions on a service topology or composite service flat topology map, and use the basic OAM controls in the map window. See the other procedures in this chapter for information about using specific elements such as the toolbar icons and info tables.

4.8.2 Steps

1

Create a service topology map by selecting the service in the Manage Services form and clicking Topology View.

2

Select the OAM check box at the bottom left of the map window.

3

To manage one or more objects, select the objects and right-click on the set of objects to choose an option.

4

To select a MEG to display, choose the MEG from the drop-down menu of available MEGs at the bottom of the map window.

Note: You can also create a MEG directly from the topology map by right-clicking on an empty portion of the map to open a contextual menu. Select Ethernet CFM→Create Global MEG.

5

To view the properties of the selected MEG, click MEG Properties at the bottom of the window. The Global Maintenance Entity Group (Edit) form opens. The service displayed on the map is listed on the Service tab.

6

To resynchronize the MIPs in the selected MEG, click Resync MIPs at the bottom of the window.

7

To display the Test Generation Options for MEPs in the selected MEG, enable the Show Test Options check box at the bottom of the map window. See 4.2.3 “Working with Ethernet CFM objects” (p. 177) in 4.2 “Working with topology maps” (p. 176) .

8

Use the other procedures in this chapter to refine the map contents or display object properties, as required.

9

Use the right-click contextual menu options to configure and manage OAM objects, as required. See 4.2.2 “Managing OAM diagnostics from the topology view” (p. 176) for a functional description of the available contextual menu options for OAM diagnostics.

10

See 90.43 “To configure and run OAM tests contextually” (p. 3052) for information about contextually configuring and executing OAM tests for entities and services on topology maps.

END OF STEPS

4.9 To modify a service from the topology view

4.9.1 Steps

1

Perform one of the following to open a service topology view.

a. Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

b. Choose Manage→Service→Composite Services from the NFM-P main menu. The Manage Composite Services form opens.

2

Click Search to list the services or composite services.

3

Perform one of the following.

a. Select a service and click Topology View. The Service Topology map opens.

b. Select a composite service and click Flat Topology View. The Composite Service Flat Topology View map opens.

4

Right-click on the map background, or on one or more selected service sites or components and choose an option. A configuration form opens.

5

See the appropriate service management chapter for information about modifying a specific service type, or Chapter 90, “OAM diagnostic tests” for information about configuring OAM diagnostic tests.

END OF STEPS

4.10 To create a physical link

4.10.1 Purpose

An operator with Device Mgmt privileges can create, modify, and delete physical links.

Note: Each physical link endpoint must terminate on the same type of MDA.
You can configure only one physical link endpoint on a port.

4.10.2 Steps

1

Choose Create→Equipment→Physical Link from the NFM-P main menu. The Physical Link (Create) form opens.

2

Configure the required parameters.

3

Perform one of the following to configure the Endpoint A parameters.

a. If you set the Endpoint A Type parameter in Step 2 to Port, go to Step 4 .

b. If you set the Endpoint A Type parameter in Step 2 to Network Element, go to Step 5 .

c. If you set the Endpoint A Type parameter in Step 2 to LAG, go to Step 6 .

d. If you set the Endpoint A Type parameter in Step 2 to Bundle, go to Step 7.

4

Configure the required parameters in the Endpoint A - Port panel by performing one of the following steps.

a. Click Select to choose a port as an endpoint.

b. Choose a port from the equipment navigation tree:
   1. Select a port and click the Copy to Clipboard icon. The port information is copied to the clipboard.
   2. Click Paste from Clipboard in the Endpoint A - Port panel of the Physical Link (Create) form.

5

Configure the required parameters in the Endpoint A - Network Element panel by performing one of the following steps.

a. Click Select to choose a managed NE as an endpoint.

b. Choose an NE from the equipment navigation tree:
   1. Select an NE and click the Copy to Clipboard icon. The NE information is copied to the clipboard.
   2. Click Paste from Clipboard in the Endpoint A - Network Element panel of the Physical Link (Create) form.

6

Configure the required parameters in the Endpoint A - LAG panel by performing one of the following steps.

a. Click Select to choose a LAG as an endpoint.

b. Choose a LAG from the equipment navigation tree:
   1. Select a LAG and click the Copy to Clipboard icon. The LAG information is copied to the clipboard.
   2. Click Paste from Clipboard in the Endpoint A - LAG panel of the Physical Link (Create) form.

7

Configure the required parameters in the Endpoint A - Bundle panel by performing one of the following steps.

a. Click Select to choose a bundle as an endpoint.

b. Click Search to populate the list of bundles:
   1. Select a bundle and click the Copy to Clipboard icon. The bundle information is copied to the clipboard.
   2. Click Paste from Clipboard in the Endpoint A - Port panel of the Physical Link (Create) form.

8

Perform one of the following to configure the Endpoint B parameters.

a. If you set the Endpoint B Type parameter in Step 2 to Port, go to Step 9 .

b. If you set the Endpoint B Type parameter in Step 2 to Network Element, go to Step 10 .

c. If you set the Endpoint B Type parameter in Step 2 to Unmanaged NE, go to Step 12 .

d. If you set the Endpoint B Type parameter in Step 2 to LAG, go to Step 13 .

e. If you set the Endpoint B Type parameter in Step 2 to Bundle, go to Step 15.

9

Configure the required parameters in the Endpoint B - Port panel by performing one of the following steps.

a. Click Select to choose a port as an endpoint.

b. Choose a port from the equipment navigation tree:

1. Select a port and click the Copy to Clipboard icon. The port information is copied to the clipboard.
2. Click Paste from Clipboard in the Endpoint B - Port panel of the Physical Link (Create) form.

10

Configure the required parameters in the Endpoint B - Network Element panel by performing one of the following steps.

a. Click Select to choose a managed NE as an endpoint.

b. Choose an NE from the equipment navigation tree:

1. Select an NE and click the Copy to Clipboard icon. The NE information is copied to the clipboard.
2. Click Paste from Clipboard in the Endpoint B - Network Element panel of the Physical Link (Create) form.

11

If the Endpoint B is an unmanaged NE that the NFM-P recognizes as an unmanaged mobile NE, go to Step 16 .

12

Configure the required parameters in the Endpoint B - Unmanaged NE panel.

Note: If the NFM-P is to manage endpoint B, configure the Unmanaged - Name parameter with the management IP address of the unmanaged NE.
When the NFM-P discovers the NE, the unmanaged endpoint of the physical link is displayed as the newly managed NE on the topology map.

13

Configure the required parameters in the Endpoint B - LAG panel by performing one of the following steps.

a. Click Select to choose a LAG as an endpoint.

b. Choose a LAG from the equipment navigation tree:

1. Select a LAG and click the Copy to Clipboard icon. The LAG information is copied to the clipboard.
2. Click Paste from Clipboard in the Endpoint B - LAG panel of the Physical Link (Create) form.

14

Go to Step 17 .

15

Configure the required parameters in the Endpoint B- Bundle panel by performing one of the following steps.

a. Click Select to choose a bundle as an endpoint.

b. Click Search to populate the list of bundles:

1. Select a bundle and click the Copy to Clipboard icon. The bundle information is copied to the clipboard.
2. Click Paste from Clipboard in the Endpoint A - Port panel of the Physical Link (Create) form.

16

Click Select in the Endpoint B - Unmanaged NE (LTE) panel to choose an unmanaged mobile NE.

17

If System Bandwidth Management is in use, configure the parameters on the Bandwidth tab as needed.

For Bundle links the bandwidth unit value is Kbps by default.

18

Click OK to save your changes and close the form. The physical link is created between the two endpoints and is displayed in the physical topology map.

19

If Service Bandwidth Management is enabled, perform a system-wide CAC audit to ensure that the bandwidth on each physical link is properly calculated.

Perform the following:

- Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.
- Click CAC Audit.

END OF STEPS

4.11 To create a radio link

4.11.1 Purpose

Perform this procedure to create a radio link between NEs. You can create a link between a GNE radio interface and a managed port that has radio properties, or between two GNE radio interfaces.

You can monitor a GNE radio link endpoint when the associated GNE profile includes the appropriate GNE driver. See “GNE commissioning” (p. 246) for information about using GNE profiles. See Chapter 7, “Device management using drivers” for information about drivers.

4.11.2 Steps

1

Choose Create→Equipment→Radio Link from the NFM-P main menu. The Radio Link (Create) form opens.

2

Configure the required parameters.

3

Use the Select buttons to choose the Endpoint A and Endpoint B objects.

4

Save your changes and close the Radio Link (Create) form.

END OF STEPS

5 NFM-P-based schedules

Schedules overview

5.1 Overview

5.1.1 General information

You can create an NFM-P-based schedule for the automatic execution of tasks at a designated time as a one-time event or as an ongoing task. You can optionally specify the time at which an ongoing schedule is to stop functioning.

You can use NFM-P-based schedules for the following:

- STM test suites; see Chapter 89, “Service Test Manager”
- NE configuration backups; see Chapter 23, “NE backup and restore”
- NE checkpoint file creation and configuration rollbacks; see Chapter 24, “NE configuration rollback”
- NE software upgrades; see Chapter 26, “NE software upgrades”
- RCA service audits; see Chapter 95, “RCA audit”
- policy audits; see Chapter 49, “Policies overview”
- path optimization tasks; see Chapter 31, “MPLS”

A task such as running an STM test suite can be immediately processed, scheduled for later execution, or retained for future use. A task that is associated with a schedule is called a scheduled task. A schedule task must be created in the configuration form for the task. For example an STM test suite scheduled task must be created in the STM test suite configuration form. After scheduled tasks are created they are associated with a schedule.

5.2 Time zones and time stamps

5.2.1 General information

To simplify creating NFM-P-based schedules when the user and server are in different time zones, the NFM-P converts and displays schedule times specific to the user and server. For example, if a client user in Chicago wants to schedule a task on a server that is in New York, the NFM-P calculates the time difference and displays the local client and server times.

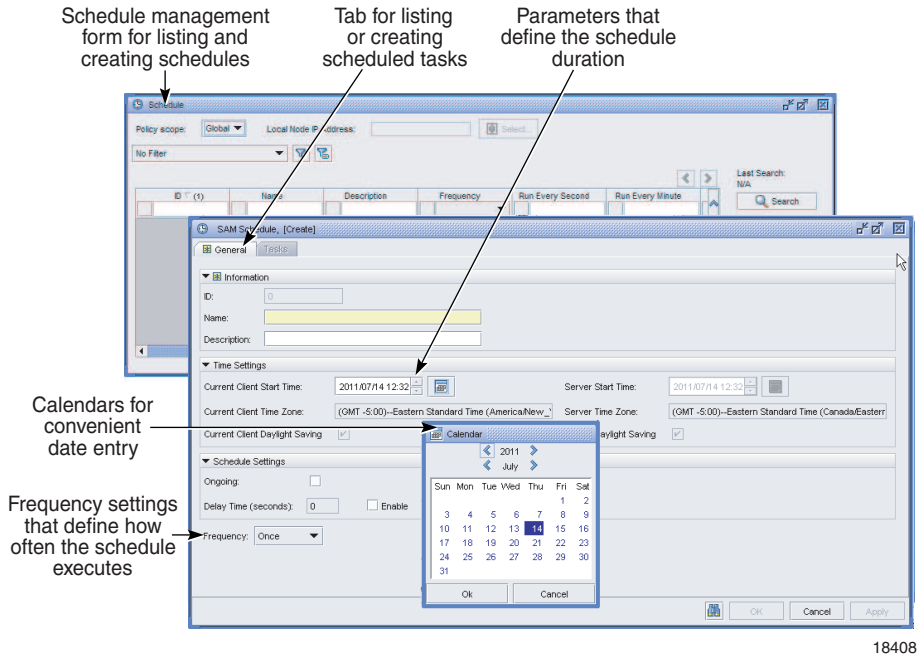
User time zones are configured in the user preferences form. If a time zone is not configured on the main server, the NFM-P uses the default time zone on the single-user client or client delegate server station, If the default time zone is not one of the NFM-P time zone options, the NFM-P displays the time zone ID and uses the UTC value without the time zone offset.

The NFM-P displays whether daylight saving time is in effect for the client and the server. Daylight saving time is specified for the user start time and is based on the client time zone. Daylight saving time does not specify the current time and end time.

For scheduled OAM tests, the timeCaptured attribute in a specific result is a time stamp inserted by NFM-P at the time that the test result is processed (accounting file transfer time plus test processing time). The date stamp is taken from the NFM-P server clock, with a resolution of milliseconds.

The scheduledTime attribute is a time stamp inserted by a managed NE, and corresponds to the accounting policy configuration on that NE. The current (or most recent) test result for each test is written to the accounting file with this time stamp. The actual timing is derived from the NE's clock. An accounting file can contain multiple test results for one such time stamp. The actual number of test results depends on the file policy rollover and accounting policy collection interval.

Figure 5-1 Schedule management and configuration forms



18408

5.3 NFM-P-based schedules

5.3.1 General information

An NFM-P-based schedule is only retained in the NFM-P db and is not deployed to the target NEs. When a configured schedule run time arrives, the NFM-P executes the associated task and compiles the task results for presentation to NFM-P clients.

A delay time for executing NFM-P-based scheduled runs can be configured to delay the execution of a run within a scheduled task in cases when a previously scheduled run is still executing. The NFM-P attempts to execute the new run at the configured delay time; if the run cannot execute at the delay time, the NFM-P skips the scheduled run. When a previous run completes and the next scheduled run is triggered, the run executes and is not delayed, whether a delay time is configured.

The NFM-P-based schedule functionality uses the NFM-P server time zone to trigger the scheduled tasks.

5.3.2 NFM-P-based schedules design considerations

Consider the following when you create an NFM-P-based schedule or add a scheduled task.

- Ensure that scheduled tasks are run sufficiently far apart to allow one task to finish before the next starts. Otherwise, the next occurrence of the task is skipped or delayed, if the delay time is configured.
- Do not create schedules that overlap, because no validation is performed to ensure that a newly configured schedule does not overlap with an existing schedule.
- A new scheduled task is shut down by default and must be turned up before it can be executed with one exception. Scheduled software upgrade tasks associated with all NE types are auto-enabled by default.
- Users with write access permissions to a specific schedule package can view or delete all the created schedules and scheduled tasks related to the package. Other users can only view schedules. See the section on NFM-P user security in the *NSP System Administrator Guide* for more information about user permissions.
- By default, the NFM-P associates a scheduled task with the user account that is used to create the scheduled task. You can assign a different user account to a scheduled task. The user account must have the assigned scope of command role that is appropriate for the task, or the NFM-P does not execute the scheduled task.
- NFM-P-based schedules are not distributed to the target NEs.
- You cannot delete a schedule that has a dependency, for example, one that is associated with a task. You must first delete the scheduled task from the schedule, then delete the schedule.
- One minute is added to the default start and end time values of an NFM-P-based schedule to allow time for schedule configuration.
- A monthly NFM-P-based schedule with the Run Every Month or Run Every Months parameter configured uses a 30-day interval.
- When you create a monthly NFM-P-based schedule using the Run Every parameter and specify a date that does not exist for the specified months, the last date of the month is used. For example, if you create a monthly scheduled task, starting January 31st, the scheduled task will run on February 28th, March 31st and April 30th when those months are specified in the schedule.

5.4 Workflow to create and manage NFM-P-based schedules

5.4.1 Stages

1

Create a task that uses the NFM-P-based scheduling function, such as an STM test suite. See “Schedules overview” (p. 189) in this chapter for information about which tasks can use NFM-P-based schedules.

2

Create or modify a schedule; see 5.6 “To configure an NFM-P-based schedule” (p. 193) .

3

Associate a task with the NFM-P-based schedule; see 5.7 “To associate a task with an NFM-P-based schedule” (p. 194) .

4

As required, view the scheduled tasks associated with an NFM-P-based schedule; see 5.8 “To view scheduled tasks associated with an NFM-P-based schedule” (p. 195) .

5

For a scheduled task that requires user account privileges other than the default privileges, assign a different user account to the scheduled task; see 5.9 “To assign a different user account to an NFM-P-based scheduled task” (p. 195) .

6

Turn up the scheduled task to put the schedule into a state that will execute according to the schedule; see 5.10 “To turn up or shut down an NFM-P-based scheduled task” (p. 196) . You can also use this procedure to prevent a scheduled task from executing.

7

If required, execute the scheduled task immediately; see 5.11 “To immediately execute an NFM-P-based scheduled task” (p. 197) .

NFM-P-based schedule procedures

5.5 Overview

5.5.1 General information

Use the following procedures to create and manage NFM-P-based schedules and to assign tasks to the schedules.

5.6 To configure an NFM-P-based schedule

5.6.1 General information

As required, review the 5.3.2 “NFM-P-based schedules design considerations” (p. 191) information in this chapter before starting this procedure.

5.6.2 Steps

1

Choose Tools→Schedules→Schedule from the NFM-P main menu. The Schedule form opens.

2

Click Create or choose an existing schedule and click Properties. The NFM-P Schedule (Create|Edit) form opens.

Note: You can modify a schedule only when you are logged in as the user account that is assigned to the schedule. To assign a different user account to the schedule, perform 5.9 “To assign a different user account to an NFM-P-based scheduled task” (p. 195) . You cannot modify a schedule that is in use by a scheduled task.

3

Configure the required NFM-P Schedule parameters.

Note: If you are creating a schedule to apply to policy audits, the Frequency parameter must be set to a value greater than 15 minutes.
When an NFM-P-based schedule is not Ongoing and is assigned to a task, the NFM-P raises an alarm when the Current Client End Time expires.

4

Save your changes and close the form.

END OF STEPS

5.7 To associate a task with an NFM-P-based schedule

5.7.1 Purpose

In this procedure, an STM test suite is used to illustrate the required steps to associate a task with an NFM-P-based schedule.

5.7.2 Steps

1

Open the properties form for a task that uses an NFM-P-based schedule. For example, perform 89.13 “To modify an STM test suite and view additional information” (p. 2955) to open the properties form associated with an STM test suite.

2

Click Schedule. The *task_name* Schedule Task (Create) form opens.

3

CAUTION

Service Disruption

Setting the Administrative State parameter to Enabled puts the scheduled task into effect according to the schedule parameters. Ensure that the test suite and the objects to which it applies are appropriately configured before you set the parameter to Enabled.

Contact your Nokia technical support representative for more information.

Configure the required parameters.

4

Select a schedule in the Schedule panel.

Note: The form lists only the schedules that are associated with the current NFM-P user.

5

Save your changes and close the form.

END OF STEPS

5.8 To view scheduled tasks associated with an NFM-P-based schedule

5.8.1 Steps

1

Choose Tools→Schedules→Schedule from the NFM-P main menu. The Schedule form opens.

2

Click Search and select an NFM-P-based schedule in the list and click Properties. The Schedule (Edit) form opens.

3

Click on the Tasks tab. A list of scheduled tasks associated with an NFM-P-based schedule is displayed.

4

Select a task and click Properties to view or change the scheduled task associated with the NFM-P-based schedule.

END OF STEPS

5.9 To assign a different user account to an NFM-P-based scheduled task

Note: By default, the NFM-P associates a scheduled task with the user account that is active when the scheduled task is created.

The NFM-P does not execute a scheduled task unless the scheduled task is associated with an NFM-P user account. If you delete the user account that is associated with a scheduled task, you must assign a different user account to the scheduled task. Only an NFM-P user with an assigned administrator scope of command role can assign a user account to a scheduled task.

5.9.1 Steps

1

Choose Tools→Schedules→Scheduled Task from the NFM-P main menu. The Scheduled Task list form opens.

2

Select a scheduled task and click Reassign User. A message indicates that the new user must have the appropriate access permissions to manage the scheduled task. See the section on NFM-P user security in the *NSP System Administrator Guide* for information about scope of command roles and access permissions.

3

Click OK. The Select User form opens.

4

Select the user account that you want to reassign to the NFM-P-based scheduled task and click OK.

5

Close the form.

END OF STEPS

5.10 To turn up or shut down an NFM-P-based scheduled task

Note: A new NFM-P-based scheduled task is shut down by default and must be turned up before it can be executed at the designated time. However, scheduled software upgrade tasks associated with all NE types are auto-enabled by default.

5.10.1 Steps

1

Choose Tools→Schedules→Scheduled Task from the NFM-P main menu. The Scheduled Task form opens.

2

Select a task entry and click Task Action.

3

Perform one of the following:

a. Turn Up—enable the scheduled task. The administrative state changes to enabled.

b. Shut Down—disable the scheduled task. The administrative state changes to disabled. The Shut Down option is enabled after the NFM-P-based scheduled task has been turned up.

4

Close the form.

END OF STEPS

5.11 To immediately execute an NFM-P-based scheduled task

5.11.1 Steps

1

Turn up the NFM-P-based scheduled task, as described in 5.10 “To turn up or shut down an NFM-P-based scheduled task” (p. 196) .

2

Choose Tools→Schedules→Scheduled Task from the NFM-P main menu. The Scheduled Task form opens.

3

Select a task entry and click Task Action.

4

Choose Execute from the menu that appears. The NFM-P executes the NFM-P-based scheduled task.

5

Close the form.

6

Perform 5.12 “To view the current status of an NFM-P-based scheduled task” (p. 196) to view the scheduled task execution status, if required.

END OF STEPS

5.12 To view the current status of an NFM-P-based scheduled task

5.12.1 Steps

1

Choose Tools→Schedules→Scheduled Task from the NFM-P main menu. The Scheduled Task form opens.

2

Select a task entry and click Task Action.

3

Choose View Result. The Execution Status indicator displays the current execution status of an NFM-P-based scheduled task for example, In Progress, Succeeded, or Failed.

4

Close the form.

END OF STEPS

5.13 To modify a scheduled task on an NFM-P schedule

Note: You can modify a scheduled task only when you are logged in as the user who is assigned to the scheduled task. To assign a different user account to the scheduled task, perform 5.9 “To assign a different user account to an NFM-P-based scheduled task” (p. 195) .

5.13.1 Steps

1

Choose Tools→Schedules→Scheduled Task from the NFM-P main menu. The Scheduled Task form opens.

2

Select a scheduled task and click Properties. The Scheduled task (Edit) form opens.

3

Modify the parameters, as required.

4

Click OK. The NFM-P Scheduled Task (Edit) form closes and the Scheduled Task form reappears.

5

Close the form.

END OF STEPS

Part II: Device management

Overview

Purpose

This part provides information about using the NFM-P for device management.

Contents

6 Device support

6.1 Device support overview

6.1.1 Device list

The NFM-P can manage devices in the following device families:

- 6.3 “1830 VWM” (p. 207)
- 6.4 “210 WBX” (p. 215)
- 6.5 “7210 SAS” (p. 216)
- 6.6 “7250 IXR” (p. 220)
- 6.7 “7450 ESS” (p. 221)
- 6.8 “7705 SAR” (p. 221)
- 6.9 “7750 SR” (p. 226)
- 6.10 “7850 VSG/VSA” (p. 227)
- 6.11 “7950 XRS” (p. 227)
- 6.13 “OmniSwitch” (p. 230)
- 6.14 “ Wavence SM and Wavence SA” (p. 231)

See the *NSP NFM-P Network Element Compatibility Guide* for specific device support information.

The NFM-P also provides limited management support for 6.12 “Generic NEs” (p. 229), which are typically devices from other vendors.

By default, for most core-network device types, the NFM-P supports the current software release and a limited number of immediately preceding major releases.

Note: If the NFM-P license includes the Extended NE Software Support option, additional device releases are supported; contact Nokia for information.

The NFM-P GUI displays a device feature or function only if the device supports the feature or function. The NFM-P user documentation describes the major variations in support, including device-specific procedures for specific implementations, but does not describe the following minor GUI variations for different devices:

- partial support for the parameter list on a form
- partial support for the buttons and tabs on a form

The NFM-P supports an NSP mediation option for the management of NEs with CLI and/or NETCONF/YANG management interfaces. MDM provides mediation between the NSP and Nokia or third-party NEs. The NSP can be used in the same way with any NE, regardless of its management operational mode. For example, you can use Service Management to create a service between NEs from different vendors that are managed using different mediation protocols.

See the *NSP Installation and Upgrade Guide* for more information.

For Release 16.0 R1 and later SROS devices, you can view the Management Operational Mode parameter on the NE object properties form:

- Classic—no model-driven management
- ModelDriven—management via model-driven interfaces only
- Mixed—management, with restrictions, by both classic and model-driven interfaces; also called dual management

The Management Operational Mode parameter is read-only in the NFM-P.

6.1.2 Device-specific release information

CAUTION

Service Disruption

When a device introduces a maintenance release, you must ensure that your NFM-P software supports the new device release before you upgrade the device to the new release.

You may need to upgrade the NFM-P to support the new device release. See the NSP NFM-P Network Element Compatibility Guide for more information.

For information about NFM-P support for specific device releases and functions, see the *NSP NFM-P Network Element Compatibility Guide*.

See the device user documentation for information about device functions, parameters, and CLI commands that are outside the scope of the NFM-P documentation. Contact Nokia technical support for specific network or facility considerations.

This chapter describes NFM-P managed devices and notable information about cards, however it does not include a comprehensive list of all supported cards on the devices. See the NE documentation for hardware specifics that are outside the scope of the NFM-P documentation.

6.1.3 Device-specific guides

The *NSP NFM-P Classic Management User Guide* describes the management of the majority of Nokia devices. However, for some devices, detailed NFM-P management is described in other guides. For the devices covered by the *NSP NFM-P Classic Management User Guide*, the sample workflow in this chapter describes the high-level steps that are required to configure and manage the device.

6.2 Sample workflow to configure and manage devices

6.2.1 Overview

The following is a generic workflow of the high-level tasks that are typically used to configure and manage supported devices using the NFM-P. This workflow is common to all NFM-P-managed devices but not all tasks apply to all device types. As appropriate, review the workflow associated with each task for detailed instructions.

Note: You can use an OSS client to configure many of the functions available on the NFM-P GUI. See “Communicating with the NFM-P” in the *NSP NFM-P XML API Developer Guide* for information.

6.2.2 Stages

Prerequisite tasks

1

Plan your NFM-P deployment for managing devices by determining the following:

- the number of NEs the NFM-P is to manage, the redundancy requirements and the hardware required for the system
- the management network latency and management network bandwidth requirements
- the naming conventions for objects that you create

See the *NSP Planning Guide* for the full list of deployment considerations.

2

Integrate the NFM-P with other EMS, as required.

3

Review the *NSP NFM-P Network Element Compatibility Guide* for release-specific information about the compatibility of managed device features in NFM-P releases. Install the physical device as per the appropriate device-specific hardware user documentation.

Review GUI basics for managing devices

4

Familiarize yourself with GUI operations for configuring and managing devices such as the following:

- navigating the GUI, performing searches, and customizing the GUI user preferences; see Chapter 1, “NFM-P GUI” .
- creating custom workspaces to simplify navigation and operation; see Chapter 2, “NFM-P custom workspaces” .
- managing devices using the equipment navigation tree; see Chapter 3, “NFM-P navigation tree” .
- managing equipment using topology maps; see Chapter 4, “Topology map management” .
- creating schedules to allow for the automatic execution of tasks at designated times; see Chapter 5, “NFM-P-based schedules” .

5

Launch the on-product user documentation to access the NFM-P customer documentation and search tools.

Perform account and security tasks

6

Set up all required NFM-P user accounts and user groups with the required scope of command roles, span of control permissions, and the ongoing monitoring and management of those accounts. See the section on NFM-P user security in the *NSP System Administrator Guide* for more information.

7

Perform the required NFM-P and UNIX security management tasks for accessing and securing the managed device. See the sections on NE user and device security and TCP enhanced authentication in the *NSP System Administrator Guide* for more information.

Prepare network devices for NFM-P management

8

Commission Nokia devices for NFM-P management and ensure all non-Nokia devices have a GNE profile. Configure how and when the NFM-P polls the devices for MIB changes; see Chapter 8, “Device commissioning and management” .

9

Create a mediation security policy and discovery rule to define the criteria required to add devices to the managed network, and optionally configure SSH2 security for CLI sessions; see Chapter 9, “Device discovery” .

10

Use a Telnet or SSH CLI from the NFM-P for device access; see Chapter 10, “Device CLI sessions” .

11

Customize the global system settings, as required. See the section on NFM-P component configuration in the *NSP System Administrator Guide*.

Configure and manage the discovered device

12

Configure and manage equipment navigation tree objects including:

- general network objects; see Chapter 11, “Working with network objects”
- device objects; see Chapter 12, “Device object configuration”
- logical group objects; see Chapter 13, “Logical group object configuration”
- ESA objects; see Chapter 14, “ESA object configuration”
- shelf, card, and daughter card objects; see Chapter 15, “Shelf and card object configuration”
- port and channel objects; see Chapter 16, “Port and channel object configuration”

13

Perform additional device management functions, as required such as the following:

- equipment inventories of managed devices; see Chapter 17, “Inventory management”
- card migrations; see Chapter 18, “Card migration”
- configure threshold-crossing alarms; see Chapter 19, “TCA”
- bulk configuration changes; see Chapter 20, “Bulk operations”

Manage the network functions

14

Configure NE routing and forwarding on NEs; see Chapter 27, “NE routing and forwarding” . As required, configure specific routing and forwarding functions and services such as:

- NE protocols; see Chapter 28, “Routing protocol configuration”
- OpenFlow; see Chapter 29, “OpenFlow”
- IS-NAT groups; see Chapter 30, “NAT”
- MPLS and LSPs; see Chapter 31, “MPLS”
- MPLS-TP; see Chapter 32, “MPLS-TP”
- service tunnels to carry service traffic; see Chapter 33, “Service tunnels”
- IPsec sessions; see Chapter 34, “IPsec”
- ISA-Video groups and members, see Chapter 35, “ISA-Video”

15

Configure network redundancy, protection, and offloading as required to ensure network availability in case of a network device or path failure using functions such as:

- VRRP; see Chapter 37, “VRRP”
- APS; see Chapter 38, “APS”
- Wi-Fi offloading; see Chapter 39, “lightRadio Wi-Fi”
- MC peer groups; see Chapter 40, “MC peer groups”
- MC IPsec; see Chapter 41, “MC IPsec”
- MC endpoint groups; see Chapter 42, “MC endpoint groups”
- MC LAG groups; see Chapter 43, “MC LAG groups”
- MC synchronization groups; see Chapter 44, “MC synchronization groups”
- MC ring groups; see Chapter 45, “MC ring groups”

Create policies to manage devices

16

Depending on your service delivery model, create, distribute, and assign the appropriate service or routing policies that define the conditions for managing network devices using the NFM-P; see Chapter 49, “Policies overview” for general information about policy management.

See Chapter 50, “QoS policies” to Chapter 68, “7705 SAR Security policies” for specific policy information and the associated workflows to configure the policy.

Create services over devices

17

Familiarize yourself with service management and QoS concepts prior to configuring services over the devices; see Chapter 70, “Service management and QoS” . Configure the following adjunct service delivery methods to support the creation of network services as required:

- shared queue groups to allow SAP or IP interface forwarding classes to be redirected; see Chapter 71, “Queue groups” .
- virtual ports to support clustering and enforce the aggregate rate of each destination BSAN; see Chapter 72, “Virtual ports” .
- create and manage customers and the services they subscribe to; see Chapter 73, “Customer configuration and service management” .
- tunnel administrative groups to enable services to use a PW template; see Chapter 88, “Tunnel administrative groups” .

18

Configure the following network services as required:

- services for residential subscribers; see Chapter 74, “Residential subscriber management” .
- VLAN services; see Chapter 75, “VLAN service management” .
- VLL services; see Chapter 76, “VLL service management” .
- VPLS; see Chapter 77, “VPLS management ” .
- IES; see Chapter 78, “IES management” .
- VPRN services; see Chapter 79, “VPRN service management” .
- SPB services; see Chapter 80, “SPB service management” .
- PW routing and dynamic MS-PW services; see Chapter 81, “PW routing and dynamic MS-PW service management” and Chapter 83, “Service PW template policies” .
- Composite services; see Chapter 85, “Composite service management” .
- Dynamic services; see Chapter 86, “Dynamic service management” .

Monitor, maintain, and troubleshoot devices

19

Configure alarm policies, and monitor incoming alarms to check the type and characteristics of the alarms, and to resolve the network problems or physical equipment failures identified by the alarms; see Chapter 36, “Alarm management” .

20

Perform the following service assurance functions as required, to ensure that services offered over network devices meet the pre-defined service quality level expected by customers:

- use the NFM-P Service Test Manager to group OAM diagnostic tests into suites of manual and automatically-generated tests; see Chapter 89, “Service Test Manager” .
- use OAM diagnostic tools to troubleshoot network problems and for SLA verification; see Chapter 90, “OAM diagnostic tests” .
- configure Ethernet CFM to detect, isolate, and report connectivity faults in Ethernet networks; see Chapter 91, “Ethernet CFM” .
- create mirror services to troubleshoot customer traffic issues or for use with Lawful Intercept; see Chapter 93, “Mirror services” and Chapter 94, “Lawful Intercept” .
- test and report network delay and loss using CFM messaging in Layer 2 networks; see Chapter 92, “Performance Monitoring tests” .
- perform on-demand verifications of the configuration of services and physical links using an RCA audit; see Chapter 95, “RCA audit” .
- create a copy of the SAP configuration of an end-user service to emulate the bandwidth, throughput, and QoS requirements of a service; see Chapter 96, “Service throughput configuration” .
- configure Application Assurance to provide deep-packet inspection and NSP subscriber traffic management; see Chapter 87, “Application assurance” .

21

Collect NFM-P and NE statistics to monitor network and service performance, compile equipment usage and billing data, and ensure SLA compliance; see the *NSP NFM-P Statistics Management Guide*.

22

Perform device maintenance functions, as required, for example:

- configuration backups and restores; see Chapter 23, “NE backup and restore”
- checkpoint file creation and configuration rollbacks; see Chapter 24, “NE configuration rollback”
- deployment management; see Chapter 25, “NE deployment”
- software upgrades; see Chapter 26, “NE software upgrades”

23

Identify and resolve performance issues in an NFM-P-managed network or on an NFM-P system as required.

6.3 1830 VWM

6.3.1 Overview

The 1830 VWM constitutes the backbone of the wireless fronthaul solution by establishing an end-to-end transport line between RRHs and the centralized BBUs.

At the cell site: The 1830 VWM TLU provides the colorization of the black and white signals and the 1830 VWM PMU provides the add-drop functionality. The 1830 VWM ITP is an integrated TLU and PMU device that provides wavelength translation and passive wavelength division multiplexing capabilities.

At the central office: The 1830 VWM TLUs and 1830 VWM PMUs are connected to an 1830 VWM OSU to form the central management hub for OSC signals transported using the out-of-band channels from the peripheries. The 1830 VWM OSU provides the management interface to the NFM-P.

6.3.2 Supported functions

The NFM-P provides the following FCAPS functions for 1830 VWM devices, as listed in Table 6-1, “NFM-P support for 1830 VWM devices” (p. 207).

Table 6-1 NFM-P support for 1830 VWM devices

Function	Support	References
NE discovery	1830 VWM device discovery Enable SNMPv3 management Configure device mediation Configure a discovery rule	6.3.3 “1830 VWM discovery” (p. 209) 9.12 “To enable SNMPv3 management and discover an 1830 VWM device” (p. 294)
	IPv6 device management	9.1.2 “Device discovery using IPv6” (p. 277)
	CLI session	10.4 “To open and close an NFM-P device CLI session” (p. 329)
Device object	Shelf craft port configuration	“Shelf craft port” (p. 210) 12.64 “To configure shelf craft port IP address on an 1830 VWM device” (p. 394)

Table 6-1 NFM-P support for 1830 VWM devices (continued)

Function	Support	References
Shelf, card, and port objects	Shelf configuration Restart shelf Lamp test	15.12 “To configure an 1830 VWM shelf” (p. 470) “Warm and cold restart” (p. 210) 15.51 “To restart an 1830 VWM shelf” (p. 512) “Lamp test” (p. 210)
	Card object configuration 1830 VWM OPS – OSM protection switching	6.3.4 “Shelf, card, and port objects” (p. 210) 6.3.12 “1830 VWM OPS – OSM protection switching and bi-directional protection switching” (p. 214)
	Port object configuration RFLM port configuration CPRI monitoring using the 1830 VWM TLU 9M MON ports CPRI rate configuration for a CDR channel CDR channels Mapping of ports and CDR channels associated with it. SFP frequency	16.21 “To configure 1830 VWM ports” (p. 596) 16.3 “Remote fiber link monitoring in 1830 VWM devices” (p. 568) 16.78 “To configure an OSC port of an 1830 VWM OSU as a RFLM port” (p. 680) “CPRI channel monitoring” (p. 211) 16.79 “To perform CPRI monitoring using 1830 VWM TLU 9M MON ports” (p. 681) 15.75 “To configure a CPRI rate and channel management for a CDR channel on an 1830 VWM TLU or ITP card slot” (p. 532) 16.76 “To view the channels associated with a 1830 VWM TLU port” (p. 679) “CDR channels” (p. 211) “SFP frequency” (p. 211)
Link management	Equipment connection topology	6.3.8 “Equipment connection topology” (p. 212)
Alarm management	Alarm severity configuration	See Procedure “To configure alarm severity and deletion behavior” in the *NSP System Administrator Guide*
	SNMP traps	6.3.5 “SNMP traps” (p. 212)
	SNMP trap destination configuration	*1830 VWM node documentation*
	SNMP trap restoration	6.3.6 “SNMP trap restoration” (p. 212)
Service test manager	PRBS test	“PRBS test” (p. 3000) 90.41 “To create and run a PRBS test” (p. 3048)

Table 6-1 NFM-P support for 1830 VWM devices (continued)

Function	Support	References
Statistics management	Statistics management	6.3.13 “Statistics management” (p. 215) See the procedure “To assign the default 1830 VWM OSU performance management policy to 1830 VWM devices” in the *NSP NFM-P Statistics Management Guide*
	Counters	*NSP NFM-P Statistics Management Guide*
	DDM data retrieval	“DDM data retrieval” (p. 215) 16.2.2 “1830 VWM − DDM data retrieval” (p. 568) 16.77 “To retrieve 1830 VWM DDM data” (p. 680)
Inventory management	Inventory management	6.3.11 “1830 VWM inventory management” (p. 213) Chapter 17, “Inventory management”
License management	View the NFM-P license information	See the section on software and license configuration procedures in the *NSP System Administrator Guide* for information about creating a license point inventory.

6.3.3 1830 VWM discovery

The 1830 VWM discovery rule requires the SNMPv3 read, write, and security access mediation policies and SNMPv2 trap access mediation policy. The NFM-P supports 1830 VWM device management using IPv4 and IPv6. See 9.12 “To enable SNMPv3 management and discover an 1830 VWM device” (p. 294) for more information about 1830 VWM SNMPv3 management, device mediation, and discovery.

6.3.4 Shelf, card, and port objects

Shelf objects

NFM-P supports the configuration of the 1830 VWM shelves. See 15.12 “To configure an 1830 VWM shelf” (p. 470) for more information about 1830 VWM shelf configuration. The 1830 VWM OSU shelf components are sorted on the equipment tree, based on the alphabetical order of the shelf name and not based on the shelf number.

Warm and cold restart

You can perform either a warm or cold restart of the 1830 VWM OSU using the NFM-P. A warm restart restarts the software without unnecessary reconfiguration of the hardware. Therefore the warm restart operation does not affect data transmission. The cold restart restarts the software and reconfigures all hardware from the internal database. See 15.51 “To restart an 1830 VWM shelf” (p. 512) for more information about performing a warm or cold restart.

Lamp test

The RMUs are automatically assigned a shelf ID based on detection by the 1830 VWM OSU. When you look at a stack of installed units in a rack, it is not obvious which shelf ID belongs to which physical unit. You can perform a lamp test by configuring the Lamp Test parameter as Active in the Shelf Specifics tab of the Shelf (Edit) form. The LEDs on the selected unit flash, enabling quick identification of a particular unit in a large array.

Shelf craft port

NFM-P supports the configuration of the craft port parameters at the NE level or shelf level.

On the equipment tree, right-click on the 1830 VWM device object and choose Properties. The Network Element (Edit) form opens. The Shelf Craft Port tab in the Network Element (Edit) form lists the craft port parameters of all the shelves except the OPS shelf. You can configure the craft port IP address, craft port gateway, and the craft port IP prefix length.

The Shelf Craft Port tab in the Shelf (Edit) form displays craft port parameters of the specific shelf in the Shelf Craft IP Details panel. You can configure the craft port IP address, craft port gateway, and the craft port IP prefix length. The Shelf Craft Port tab is not available for the OPS shelf.

See 12.64 “To configure shelf craft port IP address on an 1830 VWM device” (p. 394) for more information about configuring the craft port parameters.

Card objects

The card objects are configured automatically when the 1830 VWM shelf is configured. To view the card properties, you can right-click on the Network→1830 VWM-OSU NE→Shelf→Card Slot object and choose Properties. The Card Slot (Edit) form opens.

Port objects

The port objects are configured automatically when the 1830 VWM shelf is configured. See 16.21 “To configure 1830 VWM ports” (p. 596) for more information about port configuration.

The operational state of the ports can change due to traffic impact. For example, fiber pull and so on. Because of the missing traps, the NFM-P cannot automatically update the state change values from the network. You need to perform manual resynchronization of the ports to get the real time value.

Port label – SNMP and CLI

NFM-P displays both the Name and CLI Name parameters to identify the ports in the General tab of the Physical Port (Edit) form. The Name parameter displays the value derived from the SNMP; for example, 3/1/15 where 15 is the port number. The CLI Name parameter displays the value in the alphanumeric format derived from the CLI; for example, 3/1/C8 where C8 is the port number.

NFM-P displays the CLI Name parameter to identify the ports in the Info tab of the Alarm Info form. The Alarmed Object Name parameter value appears in the alphanumeric format derived from the CLI and identifies the port object.

SFP frequency

NFM-P supports the configuration of SFP transmission frequency on the line and client ports of the TLU 9 and TLU 9M cards. You can configure the Sfp transmission Frequency parameter on the Sfp Details panel in the Sfp Specifics tab of the Physical Port (Edit) form.

CPRI channel monitoring

NFM-P supports the following CPRI monitoring function using the 1830 VWM TLU 9M MON ports:

- in-service monitoring of interference on a specific CPRI channel

- in-service monitoring of a downlink signal on a specific CPRI channel
- allows injection and extraction of C and M traffic to commission RRH
- perform loopback tests on RRH and monitor round-trip integrity

See 16.79 “To perform CPRI monitoring using 1830 VWM TLU 9M MON ports” (p. 681) for more information about performing the CPRI monitoring function.

CDR channels

The CPRI interface supports various line rates. When you configure a CPRI rate, the 1830 VWM treats the corresponding client and line ports (C1 and L1, C2 and L2, and so on) as a CDR Channel. A CDR channel is a traffic connection between two ports on the first slot of a TLU. The TLU slot has nine CDR channels. The ports and the CDR channel mapping is preconfigured on the 1830 VWM TLU device and you cannot change the mapping.

You can configure a CPRI rate for a CDR channel using the NFM-P. See 15.75 “To configure a CPRI rate and channel management for a CDR channel on an 1830 VWM TLU or ITP card slot” (p. 532) for more information about configuring a CPRI rate for a CDR channel. The 1830 VWM TLU ports show the mapping of the ports and the CDR channels associated with it. See 16.76 “To view the channels associated with a 1830 VWM TLU port” (p. 679) for more information about viewing the channel-to-port mapping.

6.3.5 SNMP traps

The NFM-P supports traps associated with alarm management and the traps related to configuration changes on the 1830 VWM Release 8.3 and later. You can perform the configuration changes for the 1830 VWM devices using the NFM-P or CLI and the data is synchronized.

6.3.6 SNMP trap restoration

The NFM-P retrieves the last trap sequence number sent from all network elements at a configurable interval. This interval is configurable on a per resource group basis. Resource groups allow the user to configure the communications behavior of a group of network elements. By default, the core resource group includes all network elements, and verifies the trap sequence number every 4 minutes. The NFM-P compares that sequence number with the sequence number of the last trap it received from that network element. If they do not match, NFM-P will request only the missing traps from the network element. If NFM-P is missing more than 200 traps from a network element, or if the network element no longer has the missed trap, the NFM-P will request a full resynchronization on that network element rather than just request the missing traps. This behavior occurs by default and is not configurable. See the *NSP Planning Guide* for more information.

6.3.7 Synchronization of operational state

NFM-P updates the operational state dynamically to display the Operational State parameter as Down when LOS or LOF alarms are generated from the 1830 VWM device and Up when the LOS or LOF alarms are cleared from the 1830 VWM device.

6.3.8 Equipment connection topology

The equipment connection topology provides internal connections between two ports within a shelf or external connections between two ports in two different shelves.

There are two types of equipment connection topologies:

- Layer 1 connections
- Layer 2 connections

Note: The far end address is not displayed because it is applicable to the far end type, External. You cannot select the port which is already participating in any of the L1 or L2 topology links. The used ports are not listed in the selection window of the far end port.

Layer 1 connections

Layer 1 connections are the physical connections of fibers or LAN cables. NFM-P supports the configuration of layer 1 connections.

Layer 2 connections

Layer 2 connections are derived from the Ethernet RSTP attributes. NFM-P supports the discovery of layer 2 connections.

The characteristics of layer 2 connections are:

- Although the NFM-P allows the configuration and discovery of misconfigured links, the validity of the links is not guaranteed.
- If incomplete links are discovered as part of 1830 VWM device discovery, and the links are listed in the Physical Links→VwmOSU Links tab of the Network Element (Edit) form, delete the link and re-configure the link with valid interfaces. The incomplete links are discovered to identify erroneous links and rectify them.

Device-level physical topology map

NFM-P supports device-level physical topology map at the 1830 VWM device-level that displays the 1830 VWM shelves, the internal links within the shelves, and the external links between the shelves.

You can use one of the following options to open the device-level physical topology map:

- Right-click on the 1830 VWM device object on the navigation tree and choose Topology View from the contextual menu.
- Click Topology View on the Network Element (Edit) form.

6.3.9 Backup and restore considerations for 1830 VWM

- Configuration save is not supported.
- Only SFTP protocol is supported.

6.3.10 Software upgrade

NFM-P supports in-service software upgrades (ISSU) of the 1830 VWM.

See 26.5 “To configure a software upgrade policy” (p. 776) for more information about how to configure a software upgrade policy.

See 26.24 “To perform an 1830 VWM on-demand software upgrade” (p. 812) for more information about how to perform an 1830 VWM on-demand software upgrade.

Image software database

NFM-P lists the respective active and inactive 1830 VWM software images in the Shelf ISD tab of the OSU, PMU, TLU, and ITP Shelf (Edit) forms. If the ISD status is active, it is the software load currently active on the system. If the ISD status is inactive, it is the previous software load.

6.3.11 1830 VWM inventory management

You can list the 1830 VWM card inventory information using the VWM MS Card object. You can list the 1830 VWM CDR channel inventory information using the CDR Channel object. See Chapter 17, “Inventory management” for more information about inventory management.

6.3.12 1830 VWM OPS − OSM protection switching and bi-directional protection switching

The OPS OSM card of the 1830 VWM OPS shelf provides optical protection switching and the OPS OSM-DSV card provides bi-directional protection switching for both Tx and Rx. You can configure up to four OPS OSM cards or OPS OSM-DSV cards, or a mix of both on an 1830 VWM OPS shelf. The OPS OSM-DSV card is intended for use in a C-RAN hub. See 15.52 “To configure optical protection switching on an 1830 VWM OPS shelf” (p. 513) and 15.53 “To configure bi-directional protection switching on an 1830 VWM OPS shelf” (p. 513) for more information.

The OPS shelf supports the following external switch commands from the 1830 VWM OSU:

- No Command
- Clear - clears all current external switch requests
- Forced Switch to Worker
- Forced Switch to Protection
- Manual Switch to Worker
- Manual Switch to Protection

OPS protection audit entity

The Protection Audit Entity (PAE) checks the consistency of the receive selectors in the near-end and far-end optical switches.

The following events are audited:

- elapsed time since the previous check is 10 minutes
- wait-to-restore timer expiry
- if one of the associated optical switches is re-initialized
- if one of the associated optical switches generates an event when it transits from a state in which both the inputs are failed to a state in which one or no input is failed

NFM-P supports the configuration of a PAE on the 1830 VWM OSU. See 15.54 “To configure an OPS protection audit entity on an 1830 VWM OSU shelf” (p. 515) for more information about configuring a PAE.

You must activate a PAE configured on an OSU. Upon activation, the PAE attempts to read the data from the near-end and far-end selector. If the data is not accessible, the PAE generates an AUDITBLOCK alarm on the optical protection switch module. You can deactivate an active PAE, which stops the auditing functionality and clears all involved alarms. You can delete an inactive PAE, which removes all associated configurations from the OSU database. See 15.55 “To activate or deactivate a PAE” (p. 515) for more information.

1830 VWM OPS – NTP

You can view the NTP parameters and server for the 1830 VWM OPS shelf by navigating to the NTP→General and NTP→Server tabs of the Shelf (Edit) form. The NTP Enabled check box is selected, by default, and cannot be configured. The Shelf Time parameter is read-only.

6.3.13 Statistics management

Table 6-2, “Supported statistics” (p. 214) lists the supported statistics.

Table 6-2 Supported statistics

1830 VWM devices	Supported statistics
1830 VWM PMU	• DDM statistics • Ethernet statistics • Optical statistics
1830 VWM TLU 9 and TLU 9M	• DDM statistics • Optical statistics • PCS statistics
1830 VWM TLU 200	• DDM statistics • Optical statistics • PCS statistics • Ethernet statistics • FEC statistics
1830 VWM OPS	• Ethernet statistics • Optical statistics
1830 VWM SMM	• DDM statistics • Ethernet statistics
1830 VWM ITP	• DDM statistics • Optical statistics • PCS statistics

See the procedure “To assign the default 1830 VWM OSU performance management policy to 1830 VWM devices” in the *NSP NFM-P Statistics Management Guide* for more information about assigning the default PM policy.

DDM data retrieval

See 16.2.2 “1830 VWM − DDM data retrieval” (p. 568) and 16.77 “To retrieve 1830 VWM DDM data” (p. 680) for more information about DDM data retrieval.

6.4 210 WBX

6.4.1 Overview

The 210 WBX is a compact datacenter gateway designed for leaf and spine deployments in data centers and IP fabric networks, or as an overlay VPN PE. The 210 WBX performs dataplane management using a Nuage SROS VM in a Linux hypervisor environment, allowing the installation of third-party tools and applications in the Linux layer. For more information about supported features and limitations, see the *NSP NFM-P Network Element Compatibility Guide* and the NFM-P Release Notice.

The NFM-P supports the following SR management features for the 210 WBX:

- Equipment management
- NE maintenance (backup and restore, software update)
- Services management
- Statistics & Accounting management
- ICMP Ping

Note: The Product parameter for WBX 210 NEs displays as DC 210 in the NFM-P.

210 WBX software upgrade

The NFM-P supports a 210 WBX hypervisor software upgrade. In order to upgrade the 210 WBX, you must upgrade the Linux hypervisor, which supports an ONIE image. A new ONIE image is downloaded to the NE SD card and the 210 WBX is rebooted with a hypervisor upgrade, which results in an upgrade of both the 210 WBX hypervisor and the SROS VM.

See 26.5 “To configure a software upgrade policy” (p. 776) for more information about how to configure a software upgrade policy.

6.5 7210 SAS

6.5.1 7210 SAS-D support

The 7210 SAS-D is an intelligent Ethernet edge-demarcation device that extends enhanced Carrier Ethernet VPN service delivery to the CE. The license for a 7210 SAS-D is based on the chassis type.

Note: The NFM-P supports only access mode for 7210 SAS-D 6F 4T ETR ports.

6.5.2 7210 SAS-Dxp support

The 7210 SAS-Dxp is an intelligent Ethernet demarcation switch that extends enhanced Carrier Ethernet VPN service delivery to the CE and can operate in access-uplink mode. The 7210 SAS-Dxp router uplinks to the network using Layer 2 Ethernet VLAN switching (without IP/MPLS).

The 7210 SAS-Dxp 16 and 24 port variants supports PoE connections. See 16.49 “To configure PoE ports on a 7210 SAS” (p. 641) for more information.

6.5.3 7210 SAS-E support

The 7210 SAS-E is a Carrier Ethernet CE device that is typically owned and managed by a customer. Using software based on the 7750 SR OS and managed by the NFM-P, the 7210 SAS-E extends Carrier Ethernet VPN services to the CE. The 7210 SAS-E can also be deployed as an aggregation device for smaller sites.

7210 SAS-E daughter cards

The 7210 SAS-E supports an integrated 2 × 12-Gig IOM card on a single chassis. The equipment navigation tree displays a card slot with one daughter card that contains 12 × 100/1000 Ethernet SFP ports and 12 × 10/100/1000 Ethernet ports.

6.5.4 7210 SAS-K support

The 7210 SAS-K is an intelligent Gigabit Ethernet switch that provides aggregation and demarcation for services managed to the customer edge.

6.5.5 7210 SAS-M support

The 7210 SAS-M is a CE device that provides MPLS-enabled metropolitan and WAN Carrier Ethernet service delivery, Ethernet-based mobile backhaul, and residential service access. In access uplink mode, the 7210 SAS-M provides Ethernet aggregation and demarcation for services managed to the customer edge.

The chassis mode is changed using a CLI to modify the device BOF. A reboot of the device is required for the change to take effect. When you change the chassis mode of a 7210 SAS-M, you must un-manage and re-manage the NE. The NFM-P displays the chassis mode as the State parameter, in the Uplink Mode panel on the General tab of the shelf properties form for the device.

See the NE documentation for more information.

6.5.6 7210 SAS-Mxp support

The 7210 SAS-Mxp is an IP/MPLS-enabled 1GigE and 10GigE access and aggregation device that can operate in two modes:.

- Standalone mode, in which the NE is managed as an IP/MPLS-enabled service aggregation device at the customer edge
- Satellite mode, in which the NE is connected by the uplink port to an SR device, to provide port expansion

Note: The 7210 SAS-Mxp is not a variant of the 7210 SAS-M.

The 7210 SAS-Mxp ETR supports PoE connections on ports 23 and 24. See 16.49 “To configure PoE ports on a 7210 SAS” (p. 641) for more information.

6.5.7 7210 SAS-R support

The 7210 SAS-R Ethernet switch is suitable for aggregation in access Ethernet networks, and is also capable of MPLS and MPLS-TP service transport. The 7210 SAS-R has multiple IMM card slots and dual redundant CPM/SF slots.

IMM card support

First-generation IMM cards (also called KT1 or imm-sas-r) are supported on the 7210 SAS-R6. Access, network, and hybrid port modes are supported. For 1-Gig ports, the port speed is variable.

The NFM-P supports a third IMM card family, called TR3 (or imm-sas-r-c) on supporting releases of the 7210 SAS-R6 and 7210 SAS-R12. Ports on TR3 cards are supported in network mode only. The port speed is not configurable.

For the 22 CSFP card, the NFM-P displays 22 ports on the navigation tree, even when SFP transceivers are used.

Automatic provisioning of IMM cards

The NFM-P automatically provisions and configures IMM cards on the 7210 SAS-R. Auto-provision occurs for unprovisioned cards during node discovery, or when the NFM-P receives notification that a card is inserted in a managed 7210 SAS-R.

The NFM-P auto-provisions cards that match the operational IMM family type displayed on the shelf properties form for the device. See 15.16 “To configure the IMM card type on a 7210 SAS-R” (p. 474). The 7210 SAS-R6 supports KT1, KT2, and TR3 IMM cards. If no IMM family type is configured, then by default only KT1 cards are auto-provisioned. The 7210 SAS-R12 supports KT2 and TR3 IMM cards. If no IMM family type is configured, then by default only KT2 cards are auto-provisioned.

6.5.8 7210 SAS-S support

The 7210 SAS-S is a 1-Gig and 10-Gig Ethernet switch that can operate in two modes:

- Standalone mode, in which the NE is managed as an IP/MPLS-enabled service aggregation device at the customer edge
- Satellite mode, in which the NE is connected by the uplink port to an SR device, to provide port expansion

The 7210 SAS-S is similar to the 7210 SAS-Sx, but has a reduced set of hardware features.

6.5.9 7210 SAS-S/Sx virtual chassis support

The 7210 SAS includes support for virtual chassis/stacking with 7210 SAS-Sx/S 1/10GE platforms for EPIPE, VPLS, RVPLS services with IP/MPLS. To increase port density at an access aggregation site, virtual stack of nodes can be configured using the stacking ports available on the rear of the chassis. To simplify the operations and management, the stack of nodes is presented as a virtual chassis, with a single IP address to use for managing the platform.

With stacking, operators have an option to add ports at an access aggregation site as connectivity requirements increase, while maintaining the operational simplicity of managing a single node.

7210 SAS-S/Sx VC in the NFM-P equipment tree

When the 7210 SAS-S/Sx VC is displayed in the NFM-P equipment tree, the IMM functionality of the CPM-IMM cards is shown as Card Slot- *n*, based on the configuration specified while bringing up the node. The CPM functionality of the CPM-IMM cards is shown as Card Slot- A and Card Slot- B.

Ethernet IMMs can be provisioned in any of the six IMM slots on the 7210 SAS-S/Sx VC, and can be managed by either of the CPM-IMM cards, depending on configuration and the operational state of the CPM-IMMs. If a CPM-IMM is removed or goes down, control of the MDAs is taken over by the other CPM-IMM to provide redundancy.

The power supplies and fan tray parameters are displayed under navigation tree equipment view for all the stack members. For each power supply and fan tray, the corresponding card number is listed. Power supply 1 on card 1 is displayed as 1/1 under power supplies.

6.5.10 7210 SAS-Sx support

The 7210 SAS-Sx is an Ethernet switch that can operate in two modes:

- Standalone mode, in which the NE is managed as an IP/MPLS-enabled service aggregation device at the customer edge
- Satellite mode, in which the NE is connected by the uplink port to an SR device, to provide port expansion

The 7210 SAS-Sx is similar to the 7210 SAS-S, but has an enhanced set of hardware features. NFM-P support for the 7210 SAS-Sx and 7210 SAS-S is not identical.

6.5.11 7210 SAS-T support

The 7210 SAS-T is an Ethernet access device that provides MPLS-enabled metropolitan and WAN Carrier Ethernet service delivery, Ethernet-based mobile backhaul, and residential service access. In access uplink mode, the 7210 SAS-T provides Ethernet aggregation and demarcation for services managed to the customer edge.

The NFM-P supports two chassis modes for the 7210 SAS-T:

- Access uplink: the device provides network service transport using Ethernet QinQ encapsulation. Ports are configured in access or L2 uplink mode.
- Network: the device provides network service transport using IP/MPLS encapsulation. Ports are configured in access, network, or hybrid mode.

The chassis mode is changed using a CLI to modify the device BOF. A reboot of the device is required for the change to take effect. When you change the chassis mode of a 7210 SAS-T, you must un-manage and re-manage the NE. The NFM-P displays the chassis mode as the State parameter, in the Uplink Mode panel on the General tab of the shelf properties form for the device.

See the NE documentation for more information.

The 7210 SAS-T ETR supports PoE connections on ports 19, 20, 21, and 22. See 16.49 “To configure PoE ports on a 7210 SAS” (p. 641) for more information.

6.5.12 7210 SAS-X support

The 7210 SAS-X is an MPLS-enabled Ethernet aggregation device for small and medium-sized networks that provides business, mobile backhaul, and residential services. The 7210 SAS-X is similar to the 7210 SAS-M, but has 10Gb/s uplink ports, enhanced traffic management, greater scalability, and hierarchical QoS functions.

6.5.13 System resource profile

The NFM-P supports system resource allocation on 7210 SAS devices using the system resource profile. You can configure system resources to suit your network requirements by assigning more resources to functions that are used extensively, and fewer resources to functions that are used less. Unused functions can be disabled, and their resources made available for other functions. The functional areas that are configurable vary depending on the chassis type.

System resources are allocated in units called chunks. The number of chunks and the chunk size vary by device chassis.

Resources are allocated by assigning a value from the applicable range. A value of zero disables the function. The sum of resources allocated must not exceed the total available resources for the system. If you assign more than the allocated number of chunks, functions are disabled.

For SAP ACL and SAP QoS functions, configuring system resources is accomplished in two steps. First, divide overall system resources among the main functional areas: SAP ingress internal ACL, SAP egress internal ACL, and SAP ingress QoS. Second, allocate the resources specified for each functional area to the criteria within that function, such as MAC, IPv4, and 64 or 128-bit IPv4/v6. The total number of chunks assigned to the criteria must not exceed the number of chunks allocated to the function. When you specify a value of MAX, the system allocates resources as required on a first-come, first-served basis, up to the available limit.

For all 7210 SAS chassis types except the 7210 SAS-R and 7210 SAS-VC, system resource profile allocations are configured globally on the NE properties form; see 12.50 “To configure the global system resource profile on a 7210 SAS or 7250 IXR” (p. 380) .

For the 7210 SAS-R and 7210 SAS-VC, some resource allocations are configured globally on the NE properties form, and some are configured using system resource profile policies assigned to card slots on the device; see 12.51 “To configure a system resource profile policy for the 7210 SAS-R/T/Mxp, 7210 SAS-S/Sx, or 7210 SAS-S/Sx VC” (p. 382) and 15.71 “To select system resource profile policies for the 7210 SAS-R or 7210 SAS-S/Sx VC” (p. 529) .

See the 7210 SAS documentation for more information about system resource allocation.

6.6 7250 IXR

6.6.1 Overview

The 7250 IXR interconnect router is deployed for interconnect applications in core, metro, and data center networks, with optimized power efficiency, expandability, and modularity.

See the *NSP NFM-P Network Element Compatibility Guide* for supported IXR variant information.

Note: You can enable USB storage on all IXR variants except for IXR-s, where USB support is enabled by default. In the equipment tree and on Alarm Info forms, the NFM-P displays only Flash Memory. The display does not distinguish between compact flash memory and USB flash memory.

6.6.2 GNSS receiver support

The GNSS receiver supports GPS and GPS plus GLONASS. The GNSS port is listed under Management Port (expand Network→ NE→ Properties→ Inventory→ Management Port (Physical Equipment)→ gnss port. See 12.68 “To configure GNSS receiver functions on supported IXR and SR NEs” (p. 397) for more information.

6.6.3 System resource profile

The NFM-P supports system resource allocation on 7250 IXR devices using the system resource profile. System resource profile allocations are configured globally on the NE properties form; see 12.50 “To configure the global system resource profile on a 7210 SAS or 7250 IXR” (p. 380) .

6.6.4 Forwarding path resource allocation

Supporting releases of the 7250 IXR allow custom forwarding path resource allocation for resource-intensive functions such as multicast, ACL classification criteria, policers, etc. The NFM-P supports this resource allocation using the NE properties form; see 12.57 “To configure forwarding path options or resource allocation on a 7250 IXR” (p. 388).

6.7 7450 ESS

6.7.1 Overview

The Nokia 7450 Ethernet Service Switch supports service-aware Ethernet aggregation across IP/MPLS-based networks, providing VPLS, VLL and advanced IP services. The 7450 ESS supports a wide range of interfaces.

A Network Domain feature allows users to determine which network ports are eligible to transport traffic of individual SDPs. This information is used for the SAP-ingress queue allocation algorithm applied to VPLS SAPs. See Chapter 27, “NE routing and forwarding” for more information.

The NFM-P provides network management functions for the 7450 ESS.

The 7450 ESS OAM toolkit includes ITU-TY.1731 with Synthetic Loss Measurement (SLM), IEEE 802.1ag, IEEE 802.3ah, Ethernet local management interface (E-LMI), VPLS OAM and service mirroring. This toolkit is also integrated into the NFM-P.

6.7.2 Mixed-mode

Mixed-mode is the default behavior for all 7450 ESS chassis. This mode of operation allows a 7450 ESS chassis to support all 7750 SR functionality. All supported IOMs and IMMs for the 7450 ESS chassis are 7750 SR-capable, so the 7450 ESS chassis will always operate in this mode.

6.7.3 Automatic provisioning for CPM5 SFMs

The NFM-P automatically provisions and configures the integrated SFMs of CPM5s that feature built-in modules. The automated provisioning occurs during node discovery.

6.7.4 7750 SR-B chassis support

The 7750 SR-12-B and 7750 SR-7-B chassis types are supported on both 7450 ESS and 7750 SR, Release 15.0 R5 or later. The chassis employ the FP4 chipset, which supports multi-terabit-per-second routing.

All existing features, IOM/IMMs, SFMs, CPMs, PEMs, and fan trays are supported in the B chassis.

6.8 7705 SAR

6.8.1 Overview

The 7705 SAR is an IP/MPLS aggregation and mobile backhaul router for the mobile RAN. Located at cell sites, the 7705 SAR uses PW over MPLS to aggregate mobile 2G and 3G traffic that it backhauls to the core network. The 7705 SAR supports ATM, TDM, and Ethernet.

6.8.2 7705 SAR MWA support

A packet microwave card is required to support MWA. The first four ports of the card are microwave aware. An MW link must be configured to enable MWA. MW link support includes 1+0 and 1+1 HSB protection. When configuring 1+1 HSB, each of the two radios is assigned a role of main radio or spare radio. By default, the main radio assumes the active status and the spare radio assumes the standby status. For 1+0 protection, MPT-HC, MPT-HCv2, MPT-HLC, MPT-HQAM, and MPT-MC are supported. For 1+1 HSB protection, MPT-HC, MPT-HCv2, MPT-HLC, and MPT-HQAM are supported.

1+1 HSB protection is displayed in the NFM-P physical topology map. The protection state is shown on the links, and 1+1 links are grouped in a common link group. The expansion of radio links on the physical map displays eight links. See 4.1 “Topology map types” (p. 169) for more information about the NFM-P physical topology map.

Note: If the Wavence SA is discovered before the 7705 SAR (single NE with 1+0 protection), the radio link is not shown on the topology map. Only after discovering the 7705 SAR will the radio link be shown on the topology map between the 7705 SAR and the Wavence SA.

1+1 HSB protection is only supported between two 7705 SAR NEs.

The following protection types are supported:

- Radio Protection Switching (RPS)

  RPS is always supported in 1+1 radio configurations (HSB). RPS is implemented directly on a pair of MPTs.
- Transmission Protection Switching (TPS)

  TPS is always supported in 1+1 HSB radio configurations.
- Equipment Protection Switching (EPS)

  EPS protects the MPT and cables connecting the MPT to the IDU. RPS protection always assumes the MPT EPS.

See 15.38 “To configure a 7705 SAR MW link” (p. 499) for more information about configuring an MW link. See 15.39 “To configure a 7705 SAR MW link member” (p. 501) for more information about configuring an MW link member.

6.8.3 7705 SAR NEtO support

The NFM-P supports an integrated MCT from the port or NE level on the 7705 SAR-8 and 7705 SAR-18. The MCT is distributed with a NEtO client in the NFM-P. The configuration of radio parameters is through the MCT. See 12.61 “To launch an MCT on a Wavence SA NE connected to a 7705 SAR” (p. 392) for more information about starting the MCT from the NE level.

6.8.4 7705 SAR SCADA support

The NFM-P supports SCADA on the 7705 SAR-8 and 7705 SAR-18, Release 6.1 R1 or later. SCADA is an industrial data management system that monitors and controls IEDs. See 15.1.1 “Shelf objects in the NFM-P navigation tree” (p. 453) for more information about SCADA. See 15.36 “To configure SCADA on a 7705 SAR” (p. 495) for more information about configuring SCADA on the 7705 SAR.

6.8.5 7705 SAR ISC

The 7705 SAR-8 and 7705 SAR-18 support an ISC that is equipped with a large FPGA and a Winpath network processor. The FPGA supports multiple applications on the same card by using separate images while providing the ability to perform IP/MPLS functionality such as pseudowire termination.

The ISC only supports one application running per card at a time. Multiple ISCs can be supported on a 7705 SAR-8 or 7705 SAR-18. At least one networking card is required to provide access to the ISCs.

Network or access mode configuration is not applicable on the ISC; however, the card provides access capabilities.

An ISC is required to configure SCADA and VCB on the 7705 SAR-8 and 7705 SAR-18. For more information about SCADA, see 15.1.1 “Shelf objects in the NFM-P navigation tree” (p. 453) . For more information about VCB, see 15.37 “To configure voice conference bridging on a 7705 SAR” (p. 496).

Note: MDDB and PCM multidrop bridge applications are supported on the ISC.

6.8.6 7705 SAR-A

The 7705 SAR-A is equipped with integrated twelve-port Ethernet MDA daughter cards.

6.8.7 7705 SAR-Ax

The 7705 SAR-Ax transports all types of data from a mobile cell site to a higher aggregation point of presence. The 7705 SAR-Ax also targets fixed and vertical networks.

The 7705 SAR-Ax maintains the same data plane forwarding capacity and control plane scalability as the 7705 SAR-A. The IP MPLS features are also similar to the 7705 SAR-A.

The security features such as IPsec, NAT, Firewall, and NGE are similar to the 7705 SAR Wx.

6.8.8 7705 SAR-F

The 7705 SAR-F integrates eight-port Ethernet v3 and 16-port DS1/E1 v2 ASAP MDA functions in one chassis. When the NFM-P discovers a 7705 SAR-F, the integrated MDAs are automatically configured and displayed in the equipment tree.

6.8.9 7705 SAR-H

The 7705 SAR-H is a hardened router and is based on the 7705 SAR-8, 7705 SAR-18, 7705 SAR-F, and 7705 SAR-M functionality.

The NFM-P allows you to configure the MDA mode of some MDA types on the 7705 SAR-H. There are two types of MDAs:

- Compact MDAs
- Combo MDAs

The 7705 SAR-H supports the 4 × 10/100 Ethernet module card in slots 2 and 3. The module card supports four fast Ethernet ports in access or network mode. The ports can be bound to a network interface, all routing protocols, and a VPRN, IES and VLL service.

The 7705 SAR-H supports power supply tray objects, which are automatically provisioned.

6.8.10 7705 SAR-Hc

The 7705 SAR-Hc is equipped with six Ethernet ports:

- two SFP Gigabit Ethernet ports
- two RJ-45 10/100/1000 Ethernet ports
- two PoE-capable RJ-45 10/100/1000 Ethernet ports

The 7705 SAR-Hc is equipped with a single internal power supply that operates at +/–20 V dc to 75 V dc. When the 7705 SAR-Hc is used for high-voltage applications, an external high voltage power supply is available.

The 7705 SAR-Hc supports power supply tray objects, which are automatically provisioned.

6.8.11 7705 SAR-Hm

The 7705 SAR-Hm is a small-form wireless router that extends IP/MPLS services over secure 3G/LTE wireless networks. The 7705 SAR-Hm is equipped with six Ethernet ports, two RS-232 ports, two SIM card slots, a WLAN interface, GPS, a GNSS receiver, and an alarm port. The 7705 SAR-Hm system software is a variant of the SROS, and supports IP/MPLS features that are supported on 7750 SR nodes.

7705 SAR-Hm configurations

Information about SIM cards installed on the 7705 SAR-Hm is displayed on the Cellular tab of the cellular port configuration form. The 7705 SAR-Hm is discovered through ADP-Hm; see 47.1.10 “Device discovery and deployment using ADP” (p. 1427). For information on cellular domain management; see Chapter 47, “Cellular domain management”.

The following table lists where to find information about configuring the 7705 SAR-Hm:

Table 6-3 Configuring the 7705 SAR-Hm

To configure:	See:
Cards, ports and interfaces	
Cellular ports	16.27 “To configure a cellular port on a 7705 SAR-Hm” (p. 609)
Dual SIM switchover parameters	15.78 “To configure an MDA” (p. 536) 15.85 “To perform a manual SIM switchover on a 7705 SAR-Hm ” (p. 546)
PDN policies	Chapter 69, “PDN profile policies”
PDN interfaces	27.4 “To configure a cellular interface on a 7705 SAR-Hm” (p. 839)
Serial raw sockets	Chapter 21, “Serial raw sockets for IP transport services”
GNSS for IP transport	21.9 “To configure IP transport on a VPRN site” (p. 729) 21.8 “To configure IP transport on an IES site” (p. 727)
GNSS for data streaming, location details, and listing visible satellites	15.84 “To configure GNSS receiver functions on a 7705 SAR-Hm” (p. 545)
WLAN ports (Access Point)	16.28 “To configure a WLAN port on a 7705 SAR-Hm” (p. 610)
Security	
New security PIN	47.10 “To configure a new PIN value for a cellular carrier” (p. 1452)

6.8.12 7705 SAR-Hmc

The 7705 SAR-Hmc is a compact variant of the 7705 SAR-Hm. The 7705 SAR-Hmc is equipped with three Ethernet ports, two RS-232 ports, two SIM card slots, GPS, a GNSS receiver, and an alarm port. The 7705 SAR-Hmc system software is a variant of the SROS, and supports IP/MPLS features that are supported on 7750 SR nodes. Besides the 7705 SAR-Hmc having three Ethernet ports (compared to six Ethernet ports on the 7705 SAR-Hm), and no WLAN interface, the 7705 SAR-Hmc supports the same features as the 7705 SAR-Hm.

You must configure CBSD information for the 7705 SAR-Hmc to execute the CBSD state machine, register with the CBRS Spectrum Access System (SAS) and be granted access before ADP-Hm is allowed to run. Once “Authorized”, the ADP-Hm can start sending SNMP traps over the router interface. For CBSD-related configuration, see 16.27 “To configure a cellular port on a 7705 SAR-Hm” (p. 609).

In the NFM-P documentation, mentions of 7705 SAR-Hm also apply to 7705 SAR-Hmc unless otherwise stated, or unless a WLAN interface is required.

The 7705 SAR-Hmc supports both ADP and non-ADP radio card firmware upgrade.

6.8.13 7705 SAR-M

The 7705 SAR-M variants are equipped with an integrated 7-port Ethernet card. Depending on the variant, a 7705 SAR-M may have an integrated 16-port channelized DS1/E1 ASAP card or a module slot.

6.8.14 7705 SAR-W

The 7705 SAR-W is equipped with an integrated daughter card that supports five data plane Ethernet ports: three SFP ports and two RJ-45 ports. The Ethernet ports are classified as permanent connections with primary surge protection.

6.8.15 7705 SAR-Wx

The 7705 SAR-Wx transports all types of traffic over a packet-switched network from a mobile cell site to a higher point of presence or to a mobile telephone switching office.

The Ethernet data ports support the following types of connections:

- metrocell connections
- microwave device connections—NLOS or LOS microwave connections on the RJ-45 PoE+ ports
- network connections—Gigabit Ethernet fiber connections on the three SFP ports

6.8.16 7705 SAR-X

The 7705 SAR-X is a fixed variant with three integrated MDAs.

6.8.17 Dynamic system IP address updates for 7705 SAR nodes

When a 7705 SAR node is configured to acquire an address from a DHCP pool, the system IP address may change. You can configure the NFM-P to react automatically to the change, and adjust to use the new IP address for communication and for SDPs destined for the node.

See the procedure to enable dynamic system IP address updates for 7705 SAR nodes in the *NSP System Administrator Guide* for information about enabling this feature.

6.9 7750 SR

6.9.1 Overview

The 7750 SR is a multi-service edge router designed for service providers, cable MSO, and enterprise customers that deliver residential, business and mobile services through an IP/MPLS network.

See the *NSP NFM-P Network Element Compatibility Guide* for supported SR variant information.

6.9.2 Ethernet port utilization summary

Ethernet ports on NEs using SR-OS display a summary of input and output port utilization on the Ethernet tab of the port configuration form. The summary is expressed as a percentage, and summarizes utilization over the interval specified in the Utilization Stats Interval parameter.

6.9.3 Automatic provisioning for CPM5 SFMs

The NFM-P automatically provisions and configures the integrated SFMs of CPM5s that feature built-in modules. The automated provisioning occurs during node discovery.

6.9.4 7450 ESS emulation

A 7750 SR node can be configured to operate in 7450 ESS emulation mode. While in emulation mode, the 7750 SR appears in the NFM-P as a 7450 ESS node, and supports 7450 ESS features and cards. See the 7750 SR node documentation for information about how to configure 7450 ESS emulation mode, and which variants of the 7750 SR support emulation.

6.9.5 ESA support

The Extended Services Appliance (ESA) operates as a resource server that provides packet buffering and processing, and is logically part of the 7750 SR router system. The ESA connects to the 7750 SR using standard SR interface ports, so all communication passes through the IOM, making use of the network processor complex on the host IOM for queuing and filtering functions, as with other MDAs and ISAs. The ESA hosts up to four Virtual Machine (VM) instances for multiservice processing.

See the *NSP NFM-P Network Element Compatibility Guide* for information about which SR devices support ESAs.

6.9.6 GNSS receiver support

All FP5-enabled SR NEs support integrated dual band GNSS receivers. The GNSS receiver supports GPS and GPS plus GLONASS. See 12.68 “To configure GNSS receiver functions on supported IXR and SR NEs” (p. 397) for more information.

6.9.7 Discovering VSR-I using an AIM agent

The AirFrame Infrastructure Manager (AIM) is a proxy SNMP agent running on an AirFrame box in a VSR-I stack.

You need to initiate the discovery of the AIM in order to automatically discover the VSR-I . After the AIM for the VSR-I is discovered, the VSR-I is automatically added to the AIM discovery rule, so that the VSR-I is automatically discovered.

See 9.13 “To configure the AIM mediation and discovery for management of the VSR-I” (p. 298).

6.10 7850 VSG/VSA

6.10.1 Overview

The Nokia 7850 Virtual Switch Gateway (7850 VSG) is the main hardware component of the data center solution. The 7850 VSG is a top-of-rack switch that provides connectivity to servers which store virtual machines (VMs). It is based on the SROS platform and includes standard Ethernet and L3 routing functionality.

The 7850 Virtual Switch Aggregator (7850 VSA) is a variant of the 7850 VSG. The 7850 VSA functions as an IP router as an end-of-rack switch. It includes the SROS feature set, like the 7850 VSG. It can be deployed with the standalone VSC in a two-part router setup.

6.11 7950 XRS

6.11.1 Overview

The Nokia 7950 XRS is a large-scale routing system that is designed for core deployments. The NFM-P supports the management of the 7950 XRS including device discovery, equipment management, routing management, OAM, MPLS, QoS policies, and services.

6.11.2 Shelf components

You can monitor and manage the following 7950 XRS shelf components using the navigation tree:

- CCMs
- XCM or XCM2 card slots; each slot has two XMA daughter card slots
- CPM card slots
- SFM or SFM2 card slots
- fan trays
- PEQ power supply trays
- PCM trays

The number of the preceding components depends on the variant of the 7950 XRS.

The shelf components are N+1 redundant. The fan tray and power supply tray objects are automatically discovered and provisioned, and require no configuration using the NFM-P. See Chapter 12, “Device object configuration” for more information about configuring shelf objects.

CCMs

The 7950 XRS-20 shelf includes CCMs that support operator access to the routing system. You can view and monitor CCM and flash memory module properties from the CCM properties form. The CCMs are automatically detected and provisioned.

Each CCM includes three flash memory modules which can be viewed and monitored by the NFM-P. The “cf1” module is an internal flash module that is embedded in the system. The “cf2” and “cf3” modules are external compact flash slots.

XCM cards

The 7950 XRS-20 shelf includes ten XCM card slots that can be configured with XCM X20 cards. The 7950 XRS-16c shelf includes eight XCM card slots that can be configured with XCM X16 cards. Each XCM card can house up to two XMA cards for a total of twenty XMAs per 7950 XRS-20 shelf or sixteen XMAs per 7950 XRS-16c shelf. XMA card slots can also be configured with a compact XMA card, or C-XMA card. The 7950 XRS-16c can be configured only with C-XMA cards.

Note: To configure the 40-port 10 GE SFP+ XMA or 4-port 100 GE CXP XMA cards on the 7950 XRS-20, you must configure SFM X20 B cards on the shelf. You cannot configure the XMA cards if the shelf is configured with SFM X20 cards.

XCM2 cards

These cards enable redundant switching capacity up to 2.4T FD per XMA or 4.8T FD per XCM, and can accommodate any FP3-based or FP4-based XMA.

CPM cards

The 7950 XRS shelf includes two redundant CPM card slots. Each slot is automatically provisioned with CPM X20 or CPM X16 cards, depending on the variant of the 7950 XRS.

On the 7950 XRS-20, each CPM card slot has an association with a CCM. If one of the components is removed, the appropriate status is applied to the corresponding CPM or CCM. In the navigation tree, the CPM in Card Slot A is associated with CCM A. The CPM in Card Slot B is associated with CCM B.

On the 7950 XRS-16c, each CPM X16 card includes three flash memory modules, which can be viewed and monitored with the NFM-P. There is no associated CCM for the CPM X16.

SFM cards

The 7950 XRS shelf includes eight SFM card slots. SFM card slots on the 7950 XRS-20 can be configured with SFM X20 or SFM X20 B cards. SFM card slots on the 7950 XRS-16c can be configured with SFM X16 or SFM X16 B cards. You cannot configure a mix of SFM card types cards on one shelf. All configured slots must contain the same type of SFM card. Seven SFM cards must be operational to provide full capacity to the XCM cards, and one SFM card is redundant. At least one SFM card must be configured for the system to function.

SFM2 cards

After SFM2 slots are configured, the new XCM2 cards can be configured. The SFM2 and XCM2 cards enable redundant switching capacity up to 2.4T FD per XMA or 4.8T FD per XCM. SFM2 cards support FP3-based and FP4-based XCM cards. FP3-based XCMs can be intermixed with FP4-based SFM2s.

Automatic provisioning for CPM5 SFMs

The NFM-P automatically provisions and configures the integrated SFMs of CPM5s that feature built-in modules. The automated provisioning occurs during node discovery.

6.12 Generic NEs

6.12.1 Overview

The NFM-P provides limited management support of generic NEs, or GNEs, which are typically non-Nokia devices.

NFM-P GNE support is limited to the following:

- display on topology maps and in the navigation tree, interfaces excluded
- physical link creation and representation as a graphical and logical object
- trap translation into alarms
- status polling using enterprise MIB object interface alarms

- Telnet, SSH, and web sessions invocation
- provisioning using CLI scripts
- inclusion in a service instance using NFM-P scripts

6.12.2 Statistics support

The NFM-P supports the collection of a limited set of statistics counters from standard system, interface, and routing MIBs on GNEs. These statistics are processed and presented in the same manner as statistics from other devices. You can view GNE statistics on the Statistics tab of a GNE interface properties form, retrieve them using the XML API, and display them graphically using the NFM-P Statistics Plotter.

Note: If persistent SNMP indexes are not enabled on a GNE, one or more GNE interface indexes may change after a GNE reboots. This can cause a mismatch between the statistics records collected before the reboot and the current interface indexes. The NFM-P takes no action to identify or correct such a mismatch.

6.12.3 Alarm support

By default, the NFM-P supports a limited number of standard system and interface SNMP traps for GNEs. You can configure the NFM-P to raise user-defined alarms in response to specific GNE traps using alarm catalogs. See “GNE commissioning” (p. 246) for information about configuring user-defined alarms for GNEs.

6.12.4 GNE drivers

For some specific GNEs, drivers have been developed to extend management of the NE beyond the basic GNE management functions. Drivers translate proprietary MIBs to the normalized NFM-P model. See Chapter 7, “Device management using drivers” for information about drivers.

6.13 OmniSwitch

6.13.1 Overview

CAUTION

Service Disruption

OmniSwitch devices do not support automatic synchronization with the NFM-P database when you use the CLI to make configuration changes.

To ensure that you are viewing accurate OmniSwitch information in the NFM-P, you must resynchronize the NE by clicking on the appropriate Resync button.

OmniSwitch NEs do not send trap notifications for all MIB changes on the NE. To ensure that you are viewing the current configuration information in the NFM-P, you must resynchronize the NE by clicking on the appropriate Resync button.

The OmniSwitch family of devices is a group of Enterprise and Metro Ethernet LAN switches. The NFM-P supports the OmniSwitch chassis types listed in the *NSP NFM-P Network Element Compatibility Guide*.

6.13.2 OmniSwitch LAG objects

OmniSwitch NEs support static and dynamic LAGs. When you create a static LAG, you can add ports as LAG members. The ports that you select as members of a dynamic LAG are first placed into an Unassigned Dynamic LAG Members group. The OmniSwitch uses LACP to dynamically assign ports from an Unassigned Dynamic LAG Members group to the appropriate LAG. When a port is assigned to a dynamic LAG, the port is removed from the Unassigned Dynamic LAG Members group.

You can create VLANs, use 802.1Q framing, configure QoS conditions, and enable other networking functions on a LAG, which is treated the same as a physical link.

OmniSwitch LAG support includes:

- up to 32 LAGs on an OS 6250, OS 6400, OS 6450, OS 6465, OS 6850, OS 6850E, OS 6855, or on a stack of OmniSwitch devices
- up to 128 LAGs on an:
  - OS 9600, OS 9700, and OS 9800
  - OS 9700E, or OS 9800E
  - OS 10K
  - OS 6860, OS 6860E, OS 6860N, OS 6865, or OS 6900
- two, four, or eight Ethernet links in a LAG
- access or network LAGs

6.13.3 Using WebView to manage an OmniSwitch

You can configure and manage an OmniSwitch using the WebView application, a web-based EM tool that runs on an OmniSwitch. See the*NSP Planning Guide* for information about browser compatibility.

Note: You must enable cookies and Java in the web browser that you use to open WebView.

See the appropriate OmniSwitch *Switch Management Guide* for information about configuring and using WebView. See Chapter 12, “Device object configuration” for information about opening WebView using the GUI.

6.13.4 OmniSwitch port modes

The ports of OmniSwitch NEs can operate in either access mode or network mode. Access ports can be added to stacked VLANs as UNI ports, or to standard VLANs as tagged or untagged ports. Network ports can automatically bind to stacked VLANs as NNI ports when the service is created. OmniSwitch NEs using AOS Release 6.4.6 or later, or AOS Release 6.6.5 or later, can operate in hybrid mode. Hybrid ports can be added to standard VLANs as tagged or untagged ports, and also bind to all stacked VLANs on an NE as NNI ports.

Note: When a port is changed to hybrid mode, any previous UNI associations will be deleted.

6.13.5 OmniSwitch splitter ports

The NFM-P supports splitter ports and sub-ports where equipped on OmniSwitch devices (typically, QSFP+ ports). Sub-ports are identified by the CLI Name parameter on the port properties form.

6.14 Wavence SM and Wavence SA

6.14.1 Overview

The Nokia Wavence SM is a microwave digital radio that supports PDH and Ethernet to migrate from TDM to IP. The Wavence SM provides a generic, modular IP platform for multiple network applications, such as 2G, 3G, HSDPA, and WiMAX to accommodate broadband services.

The Wavence SA is the standalone, fully outdoor application of the MPT ODU, with no shelf unit. The Wavence SA provides fixed or mobile Ethernet site backhauling and supports converged MPLS metro networks.

The following documents describe NFM-P discovery, management, configuration, and administration of Wavence SM/Wavence SA devices:

- *NSP NFM-P Classic Management User Guide* — Describes general device discovery, configuration, and management
- *NSP Wavence Device Support Guide*— Describes how to commission, configure, and manage Wavence SM and Wavence SA devices, policies and services
- *NSP System Administrator Guide* — Describes device security management

7 Device management using drivers

7.1 Overview

7.1.1 Support for drivers in the NFM-P

Note: NFM-P multi-vendor drivers are no longer supported; instead, multi-vendor support is managed using model-driven adaptors. See the Network Developer Portal for more information.

Drivers are optional software modules corresponding to specific devices. They can be used to increase or extend management of NEs currently managed as GNEs. Drivers mediate between the NE and the NFM-P, allowing the NFM-P operator to manage non-standard equipment and services from the GUI or the NFM-P XML OSS interface.

See section 6.12 “Generic NEs” (p. 229) for more information about managing other vendors’ NEs without a driver.

With the addition of a driver, management capabilities are added in the following areas, depending on the driver and release:

- configuration management
- software management
- network assurance
- service assurance
- service provisioning
- device life cycle management

7.1.2 Driver development

A number of GNE drivers are developed, delivered, and installed on the same product release cycle as the NFM-P as part of the overall product offering. Many of these drivers have been designed to support specific capabilities relevant to a particular managed device, such as radio port properties configuration for Wavence MPT devices.

7.2 Driver framework capabilities

7.2.1 Capabilities summary

The NFM-P driver framework offers a robust feature set that all drivers can employ to attain management parity with NEs natively managed by the NFM-P. The extent to which each driver takes advantage of the capabilities of the NFM-P driver framework varies from driver to driver, however.

In conjunction with the NFM-P driver framework, drivers enable users to discover, provision, and manage other vendors’ equipment and services using the same XML API, script and GUI workflows

as are used for natively managed Nokia devices and services. When a driver is employed, the NEs become available in NFM-P map and service topology views, and configuration management is synchronized through the GUI or through an XML API interface.

The driver architecture supports SNMP, NETCONF, and CLI management protocols.

Note: Manual or scheduled resynchronization of a device is required if any direct CLI changes are made while the device is managed by the NFM-P.

The NFM-P discovers the NEs that will be managed by drivers using a GNE Profile. The NE and the driver are associated with a GNE Profile through the standard sysObjectId MIB attribute of the NE and the “Driver module” selection, respectively. Once this association is made, the NFM-P expects a driver to be used for all NEs of that type. You can either manage all nodes of a particular SNMP sysOID with a driver or all nodes as a GNE. In most cases, a GNE Profile for the driver is automatically created in the NFM-P.

7.2.2 Extended management features

The NFM-P driver framework supports drivers designed to extend NE management in the following areas:

- node, shelf and port discovery and display in the GUI topologies
- MPLS dynamic LSP and SDP discovery and provisioning
- VLL Epipe service discovery and provisioning
- VPRN service discovery and provisioning (PE-CE IP, OSPF, BGP, static routes, loopback on L3 access interface, L3 access interface on physical ports)
- VPLS service discovery and provisioning (RSVP-TE and LDP)
- LLDP link endpoint specification at the physical port level rather than GNE interface level
- alarm integration, correlation and aggregation
- QoS and policer control policy definition
- interface statistics and plotting

For information about RCA audits for Epipe, VPLS, and VPRN services with multi-vendor NE sites, see 95.3.3 “RCA audit for services with multi-vendor NE sites” (p. 3232).

7.3 Driver availability

7.3.1 Timing

GNE drivers and new driver versions are developed and delivered on the same product release cycle as the NFM-P.

7.3.2 Location

GNE drivers are installed with the NFM-P software. It is no longer necessary to obtain these drivers separately from the NSP software delivery site.

7.3.3 Documentation

Driver compatibility information is located in the *NSP NFM-P Network Element Compatibility Guide*. Driver capabilities and driver-specific discovery and management information are provided in the appropriate domain user guides.

Table 7-1 Location of driver information

Driver name	Reference
MPTGM MPTGS MPTSUB6 MPTBWA is installed with the name MPTSUB6	*NSP Wavence Device Support Guide*
CloudBand Application Manager	*Network and Service Assurance Guide*

Note: The 9500 MPT-BWA device is a hardware variant of the MPT-SUB6. The NFM-P uses the MPT-SUB6 driver to manage the MPT-BWA.

7.4 Driver installation and upgrade

7.4.1 Overview

Drivers that manage the devices listed in Table 7-1, “Location of driver information” (p. 235) are automatically installed during NFM-P installation and are preserved during upgrade.

7.5 View installed drivers on the NFM-P

7.5.1 Steps

Perform this procedure to determine which drivers are installed on the NFM-P.

1

Choose Administration→Generic NE Manager from the NFM-P main menu. The Generic NE Manager form opens.

2

Choose Generic NE Driver (Generic NE) from the drop-down menu and click Search. A list of installed drivers appears.

3

To view the properties of a driver, select a driver and click Properties. The Properties form opens. You can view the driver and driver version.

The Maximum NFM-P Version parameter shows the highest NFM-P release that the driver supports.

The Operational State parameter shows the current operational status of the GNE driver. The operational state can be Operational, Unsupported, or File Missing.

Note: GNEs cannot be managed using a driver which is not Operational. If a driver is in a File Missing state, the driver must be re-installed. The driver cannot be replaced until the original driver is re-installed. If a driver is in an Unsupported state, a supported driver is required to replace the unsupported driver.

END OF STEPS

7.6 View the automatically created Generic NE profile

7.6.1 Steps

1

Choose Administration→Generic NE Manager from the NFM-P main menu. The Generic NE Manager form opens.

2

Choose Generic NE Profile (Generic NE) and click Search. A list of Generic NE Profiles appears.

3

Select a Generic NE Profile and click Properties. The Generic NE Profile (Edit) form opens with the General tab displayed.

4

Click on the Interface Types, Other MIBs, and Translators tabs to view information about the Generic NE Profile.

5

Close the form.

END OF STEPS

7.7 View the automatically created alarm catalog

7.7.1 Steps

1

Choose Administration→Generic NE Manager from the NFM-P main menu. The Generic NE Manager form opens.

2

Choose Generic NE Alarm Catalogue (Trap to Alarm Mapper) and click Search. A list of alarm catalogs appears.

3

Select an alarm catalog and click Properties. The Generic Alarm Catalogue (Edit) form opens.

4

Click on the Mappings, Transform Functions, and Generic NE Profiles tabs to view information.

To modify the alarm catalog, see 8.17 “To create a GNE alarm catalog” (p. 269).

5

Close the form.

END OF STEPS

8 Device commissioning and management

Device commissioning

8.1 Overview

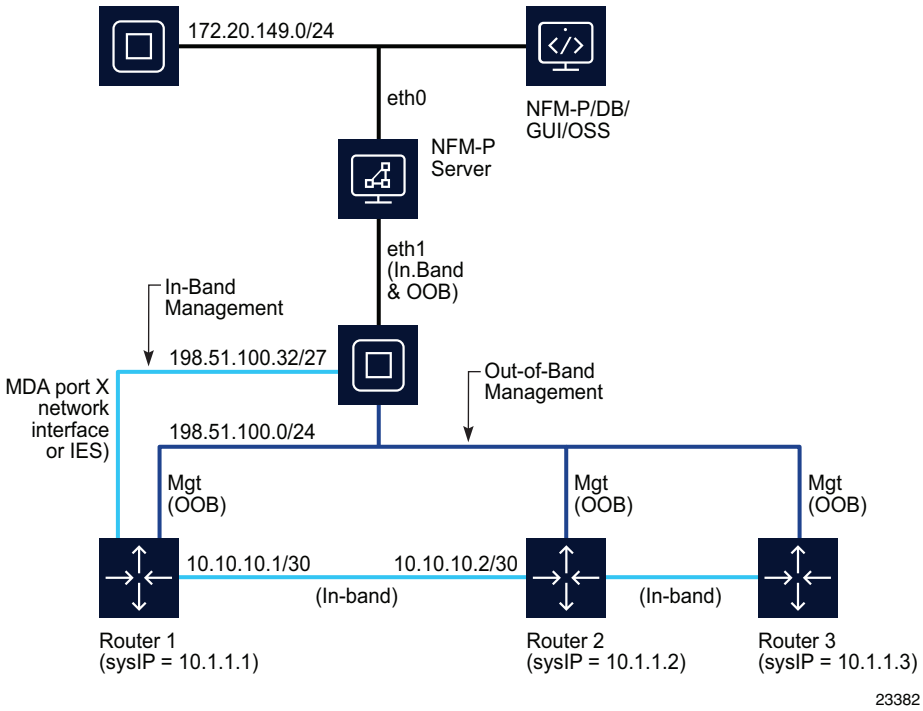
8.1.1 Preconfiguration

A device requires preconfiguration before NFM-P management of the device is possible. When the preconfiguration is complete, the NFM-P can discover the device, as described in Chapter 9, “Device discovery” . See 8.3 “Workflow to commission Nokia devices” (p. 244) for the device commissioning workflow.

8.1.2 In-band and out-of-band management

The NFM-P supports the in-band and out-of-band management of devices. The following figure shows an example of in-band and out-of-band management.

Figure 8-1 Example of in-band and out-of-band management



When you configure only in-band management, management traffic between the NFM-P and a device is transmitted through any port that is configured for network access, except the

management port. For in-band management, the NFM-P sends management traffic to the device system IP address, or to an optionally specified L3 management interface.

When you configure only out-of-band management, management traffic between the NFM-P and a device is transmitted through the management port of the device. For out-of-band management, the NFM-P sends management traffic to the management IP address of the device.

When a device is configured for both in-band and out-of-band management, one method provides management redundancy for the other. However, if the in-band and out-of-band IP addresses are the same, the NFM-P cannot determine which NE interface is active, and management redundancy is compromised. If the in-band and out-of-band IP addresses are the same on a newly discovered NE, the NFM-P raises an alarm.

Note: The OmniSwitch does not support management redundancy.

The NFM-P uses one SNMP trap target for in-band and out-of-band management. The NFM-P SNMP IP address must be routable from each IP address when in-band and out-of-band management are used. See the device documentation for information about configuring an SNMP trap target.

The type of management is determined during device discovery. When the device is discovered using its management IP address, system IP address, or L3 interface IP address, the in-band and out-of-band addresses are synced in the NFM-P. This enables configuration of management redundancy, if both in-band and out-of band are available. In each case, a valid route to the device must exist. See Chapter 9, “Device discovery” for more information about the discovery process.

In Figure 8-1, “Example of in-band and out-of-band management” (p. 239) , an out-of-band management route allows a ping from the NFM-P to the management IP address of Router 1 (192.168.10.1/32). The in-band connection sends management packets to the system IP address on Router 2 (12.12.12.2/32) on MDA port X.

Important information

CAUTION

Service Disruption

Do not use the NFM-P to modify the configuration of the in-band port. If the port is shut down, network visibility is lost.

Note: In Figure 8-1, “Example of in-band and out-of-band management” (p. 239) , the IP address of Routers 1 and 2 ends with /*number*, which is the subnet mask. Common subnet mask values are:

- /31 for two hosts
- /30 for two hosts with network and broadcasts numbers
- /24 for 254 hosts

Some device types require configuration in addition to the SNMP configuration before they can be managed by the NFM-P. See the appropriate part of this section for device-specific management information.

8.1.3 Firewalls and management bandwidth

The ports between NFM-P components, and between the NFM-P system and the managed devices, must be open through firewalls to allow proper operation of the software. See the*NSP Planning Guide* for more information about requirements for the following:

- firewalls and open ports
- communication bandwidth between NFM-P components
- communication bandwidth between the NFM-P and managed network

8.1.4 IPv6 device management

The NFM-P supports device management using IPv6. When a device management port or system interface is configured with an IPv6 address, and the associated discovery rule is configured to scan for the IPv6 address, the NFM-P discovers and manages the device using IPv6. To switch between IPv4 and IPv6 management of a device, you must unmanage the device, create a new discovery rule that specifies the other protocol, and then rediscover the device.

The NFM-P supports the configuration of IPv4 and IPv6 in-band and out-of-band management addresses on the same device.

Note: To use IPv6 for out-of-band management of a 7210 SAS-E, 7210 SAS-M, 7210 SAS-Mxp, 7210 SAS-R, 7210 SAS-S, 7210 SAS-Sx, 7210 SAS-T, 7210 SAS-X, or 7705 SAR, you must configure an IPv6 address on the management port and an IPv4 address on the system interface.

The 7210 SAS-D, 7210 SAS-K, 7210 SAS-M, 7210 SAS-Mxp, 7210 SAS-R,7210 SAS-S, 7210 SAS-Sx, 7210 SAS-T, 7210 SAS-X, and 7705 SAR support in-band management using IPv6.

8.1.5 Secure file transfers

The NFM-P supports secure and non-secure file transfers for backups, restores, software upgrades, and statistics collection. The device mediation policy determines whether FTP or SCP is used to perform file transfers to and from the managed devices. SCP requires SSH2. See Chapter 9, “Device discovery” for more information about configuring SSH2.

8.2 Device-specific commissioning information

8.2.1 7705 SAR management bandwidth

Some additional bandwidth management configuration is required on the NFM-P, if you want to transmit on in-band management on the 7705 SAR. Currently, if in-band and out-of-band management are both used, then the 7705 SAR will only transmit on the out-of-band management out-of-preference if that route exists.

You need to configure NFM-P so that each 7705 SAR with out-of-band management connectivity has the following parameter values:

- Active Management IP - In Band
- Auto Revert to Preferred - True or False
- Management IP selection - in Band Preferred

See 8.10 “To configure polling for a 7250 IXR, 7450 ESS, 7705 SAR, 7750 SR, 7950 XRS, VSR, or Wavence SM” (p. 260) for the steps on how to configure these values.

8.2.2 7210 SAS in-band and out-of-band management

The NFM-P supports the in-band and out-of-band management of 7210 SAS NEs, except for the 7210 SAS-D and 7210 SAS-K, which do not support out-of-band management. In-band management uses the system address on a network interface. Out-of-band management uses the management address on the management port. Addresses are assigned using a CLI on the console port; see 8.7 “To commission a device for NFM-P management” (p. 251).

IPv6 is supported for management port addresses on all 7210 SAS chassis types except the 7210 SAS-D, 7210 SAS-K, 7210 SAS-S, and 7210 SAS-Sx. The management port address can be IPv4 or IPv6, but not both.

IPv6 is supported for system interface addresses on the following 7210 SAS chassis types:

- 7210 SAS-D
- 7210 SAS-M
- 7210 SAS-Mxp
- 7210 SAS-R
- 7210 SAS-T
- 7210 SAS-X

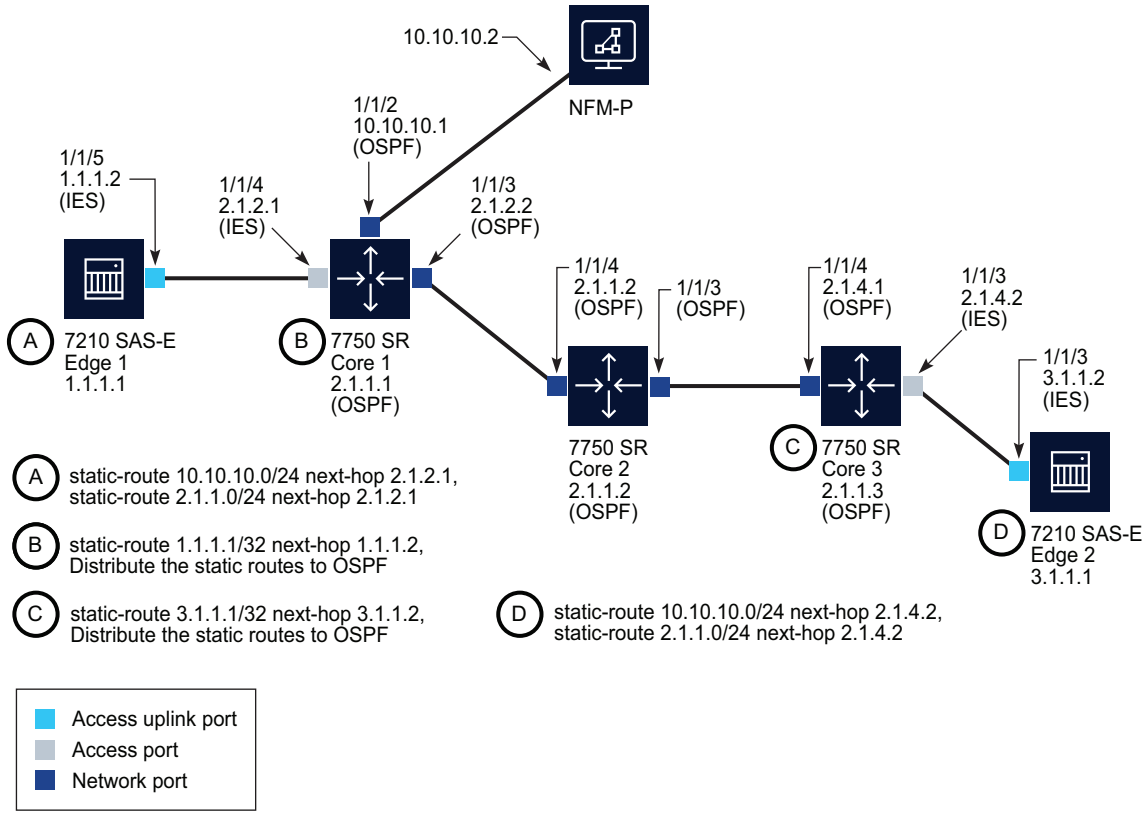
Where IPv6 is supported, you can assign a system interface address using IPv4, IPv6, or both. When both IPv4 and IPv6 addresses are assigned, the address used is determined by the Management Protocol parameter configured in 9.23 “To configure a discovery rule” (p. 310).

Note: For 7210 SAS NEs, when both the management address and the system address use only IPv6, the following network functions and protocols are not supported:

- MPLS
- LDP
- Services with SDPs
- OAM tests related to services
- IPv6 peers for BGP, RIP-NG, MC-LAG, and MC-APS

The 7210 SAS-D, 7210 SAS-E, and 7210 SAS-K support static routes, but do not support an IGP or SDPs. The example network shown in the following figure and the associated configuration steps describe the configuration required to enable 7210 SAS-E in-band management using static routes that are distributed to an IGP, which, in the example, is OSPF.

Figure 8-2 Example 7210 SAS-E in-band management network



The following configuration steps are required to set up the example network:

1. Using the CLI, configure the SNMP security parameters on the devices that you need to discover. See 8.7 “To commission a device for NFM-P management” (p. 251) for more information.
2. Perform the following steps on Core 1.
   - Configure an interface on port 1/1/2 that connects to the NFM-P server interface.
   - Configure an interface on port 1/1/3, which is connected to Core 2.
   - Create an L3 interface on port 1/1/4 by creating an IES.
   - Create a static route to Edge 1.
   - Create an ASBR OSPF (area 0.0.0.0) instance on the system and enable OSPF on the interfaces to Core 2 and the NFM-P server.
   - Create a routing policy to distribute the static route to OSPF.
3. Perform the following steps on Core 2.
   - Configure an L3 interface on port 1/1/4, which is connected to Core 1.
   - Configure an L3 interface on port 1/1/3, which is connected to Core 3.

- Enable OSPF (area 0.0.0.0) on the system and the interfaces connected to Core 1 and Core 3.

4. Perform the following steps on Core 3.
   - Create an L3 interface on port 1/1/4, which is connected to Core 2.
   - Create an L3 interface on port 1/1/3, which is connected to Edge 2.
   - Create a static route to Edge 2.
   - Create an ASBR OSPF (area 0.0.0.0) instance on the system and enable OSPF on the interface to Core 2.
   - Create a routing policy to distribute the static route to OSPF.
5. Perform the following steps on Edge 2.
   - Create an IES L3 interface on port 1/1/3, which is an uplink port.
   - Create static routes that direct traffic to the IES L3 interface.
6. Perform the following steps on Edge 1.
   - Create an IES L3 interface on port 1/1/5, which is configured as an uplink port.
   - Create static routes to direct traffic to the IES L3 interface.
7. Ensure that each 7210 SAS-E can ping the network interface IP address which is configured on the NFM-P main server.
8. Ensure that the NFM-P main server can ping the system IP address of each 7210 SAS-E.
9. Configure an in-band polling policy using the NFM-P. See 8.11 “To configure polling for a 7210 SAS” (p. 262) for more information.

8.2.3 Model driven devices

Model driven devices are read-only in the NFM-P.

8.3 Workflow to commission Nokia devices

8.3.1 Stages

1

Enable and configure SNMP on the device.

a. See 8.7 “To commission a device for NFM-P management” (p. 251) for NFM-P natively-managed devices.

b. See 8.8 “To commission an OmniSwitch for NFM-P management” (p. 254) for the OmniSwitch.

2

If required, configure the source of device SNMP traps; see 8.9 “To configure the NFM-P SNMP trap listener” (p. 258) .

3

If required, use a CLI to enable NFM-P in-band management of the device by to configure a second trap destination and trap log on the device. See “GNE commissioning” (p. 246) for information about in-band management. See the device documentation for configuration information.

4

If required, establish a route for in-band traffic. For example, to configure a static route or use OSPF. See Chapter 27, “NE routing and forwarding” for more information on static routes. See Chapter 28, “Routing protocol configuration” for more information about OSPF.

5

Configure the NFM-P to use in-band polling, out-of-band polling, or in-band and out-of-band polling for the device. An NFM-P mediation policy specifies the polling interval. See Chapter 9, “Device discovery” for information about mediation policies.

a. For 7450 ESS, 7705 SAR, 7750 SR, and 7950 XRS polling configuration information, see 8.10 “To configure polling for a 7250 IXR, 7450 ESS, 7705 SAR, 7750 SR, 7950 XRS, VSR, or Wavence SM” (p. 260)

b. For 7210 SAS polling configuration information, see 8.11 “To configure polling for a 7210 SAS” (p. 262) .

c. For 7705 SAR-Hm polling configuration information, see 8.12 “To configure polling for a 7705 SAR-Hm” (p. 264) .

d. To edit polling settings for multiple managed devices, see 8.13 “To edit polling settings for multiple devices” (p. 265) .

GNE commissioning

8.4 Overview

8.4.1 Preconfiguration

A GNE requires preconfiguration for NFM-P management. When the preconfiguration is complete, the NFM-P can discover the device, as described in Chapter 9, “Device discovery” .

The NFM-P uses configurable profiles and CLI configuration scripts to discover and manage GNEs. You can use one GNE profile for multiple GNEs of the same type.

By default, only the NFM-P admin user, or a user with an assigned admin scope of command role, can manage GNE objects. To create and configure GNE objects, a non-admin user requires a scope of command role that has Create and Update/Execute permissions on packages and classes that include the following:

- genericne—to create GNE interfaces and configure profiles
- netw—to create discovery rules
- script—to manage scripts
- security.MediationPolicy and snmp.PollerManager—to create mediation policies
- trapmapper—to create alarm catalogs that map SNMP traps to NFM-P alarms

The NFM-P can discover a device as a GNE only when the following conditions are in place.

- The GNE preconfiguration is complete.
  - The System Object ID of the GNE is required for the GNE Profile, for example 1.3.6.1.4.1. When multiple GNE profiles contain possible matches for a system object ID, the profile that contains the system object ID with the longest or most specific match is chosen.
  - SNMP and/or NETCONF is configured and enabled on the device, as appropriate.
  - Telnet or SSH is enabled on the device.
- An NFM-P GNE profile for the device exists.
- An NFM-P mediation policy is configured with SNMP and NETCONF settings that match the device configuration.
- A discovery rule for the device exists.

See 8.6 “Workflow to commission GNEs” (p. 250) for the GNE commissioning workflow. See Chapter 9, “Device discovery” for information about mediation policies and device discovery.

8.4.2 NFM-P upgrade and native GNE management

If an NFM-P system that is to be upgraded manages a device as a GNE, and the new NFM-P release supports native management of the device, you must unmanage the device and delete it from the NFM-P database before the upgrade.

After the upgrade, you can use the NFM-P to discover and manage the device natively, rather than as a GNE.

Note: GNE management cannot be used to extend the release support of a device. The same release compatibility between NEs and NFM-P applies whether the device is natively managed or managed as a GNE.

8.4.3 Invoking alternate element managers

If an EMS client application for a GNE is installed on an NFM-P GUI client station, you can use a right-click GNE menu option in the network navigation tree to open the EMS client application. The OS-level command that opens the client must be specified in the associated GNE profile, or in the individual GNE configuration, to enable the function. A command in the configuration of a specific GNE overrides a command in the associated GNE profile.

If the command path is not included, the NFM-P attempts to locate the command using the paths listed in the PATH environment variable of the client station OS.

If the command that opens an EMS client accepts an NE IP address as an argument, you can specify the address using a keyword in the command entry. The NFM-P replaces the keyword with the target GNE IP address as it runs the command.

An alternate GNE manager is configurable using the GUI or OSS. See 8.14 “To prepare a GNE for NFM-P management” (p. 266) for information about configuring an alternate EMS in a GNE profile. See 8.15 “To configure an alternate EMS for a specific GNE” (p. 268) for information about specifying an alternate EMS in the GNE configuration.

8.4.4 GNE profiles

NFM-P management of a device as a GNE requires a GNE profile, which defines how the NFM-P communicates with the device. A GNE profile includes the following elements:

- a unique GNE name
- the system object ID from the device MIB
- the GNE category
- the interface types that the GNE supports
- the interfaces that can be specified as the endpoints of NFM-P physical links
- an SNMP trap management configuration that associates trap configuration and deconfiguration scripts with the profile
- CLI profile information
- an optional alarm catalog that defines the alarms that the NFM-P raises in response to SNMP traps from the device

8.5 Configuring user-defined alarms for GNEs

8.5.1 Standard alarms

The NFM-P monitors SNMP reachability and interface status, and raises a standard alarm for each of the following events:

- coldStart—The GNE restarts.
- linkDown—An interface goes out of service.

- linkUp—An interface returns to service.

8.5.2 GNE alarm catalogs

You can map GNE SNMP traps to user-defined NFM-P alarms in an alarm catalog, and associate the catalog with a GNE profile. A GNE profile can have one alarm catalog that contains up to 150 trap-to-alarm mappings.

A mapping is one of the following types:

- static—A specific SNMP trap is associated with a specific alarm.
- dynamic—The mapping includes one or more transform functions that define alarm properties based on values in SNMP trap PDUs.

Each mapping in a catalog defines an alarm that the NFM-P raises or clears when it receives a specific SNMP trap. When the NFM-P receives a high trap volume and must discard traps that it cannot process, it does not distinguish between standard and user-defined traps. To conserve system resources, Nokia recommends that you configure a GNE to send only the required traps to the NFM-P.

Traps that map to user-defined alarms require extra processing by the NFM-P and are managed in a separate, resource-limited queue. When this queue fills, the NFM-P discards some of the traps and raises an alarm. You can monitor the queue length using the NFM-P Resource Manager. When a mapping is administratively disabled, the NFM-P raises no alarm in response to an associated trap from a GNE.

GNE trap sequencing and throttling support are configurable in a GNE profile. After the NFM-P finishes throttling traps from a GNE or encounters a trap sequence error, it resynchronizes the discovered device MIBs.

A mapping includes standard elements such as the trap OID, alarm type, probable cause, and severity, but can include the following optional elements:

- trap name
- self-clearing designation—specifies that the alarm clears when a specific clearing trap is received, and has the following requirements:
  - If the severity of the raising alarm is a static value, the clearing trap must have a static mapping in the same catalog as the raising trap, and can be linked to only one raising trap.
  - If the severity of the raising alarm is defined using a transform function, the transform function must include a raising value pair and a clearing value pair.
- FDN extension, which is an alarm-name extension that can include the following:
  - static text
  - scripting functions—expressions that specify the trap PDU values to include; these allow the same alarm type to be raised in response to different traps while uniquely identifying the trap origin in the alarm name.
- additional text—used to provide information of value related to the trap event, for example, troubleshooting actions; the additional text consists of the trap OID by default, but can include the following:
  - static text
  - scripting functions—expressions that specify the trap PDU values to include; these are used to generate a more precise description of the alarm condition

- System Address and/or Interface Index varbind positions for a GNE on which to raise an alarm

Note: The FDN extension of a GNE alarm is not appended to the Alarm Name field in the NFM-P GUI, but is included in the Additional Text field. To create a filter for GNE alarms that have FDN extensions, you must filter on the Additional Text field.

You cannot filter on the Additional Text column on the dynamic alarm list, Faults tab, and Correlated Alarms tab.

When the NFM-P drops or fails to receive an SNMP trap from a GNE, the trap is lost. The NFM-P is unable to request that a GNE resend an SNMP trap.

If reliable communication via SNMP protocol is required, use “inform event” messaging instead of trap notifications.

A change to an alarm catalog or to a mapping in a catalog takes effect immediately after you commit the change.

You can use an NFM-P GUI or OSS client to configure GNE alarm catalogs and alarm mappings. The GUI supports the following methods:

- configuration forms—for object creation, modification, viewing, and deletion
- XML API script—for object creation and modification only

  A script template for alarm catalog configuration is available at the following location:

  /opt/nsp/nfmp/server/nms/sample/xmlapi/AlarmCatalogue-Template.txt

An OSS client can also retrieve a catalog or a subset of the alarm mappings in a catalog using the standard methods.

8.5.3 Transform functions

A transform function is an optional catalog component that associates one or more values in an SNMP trap PDU with an alarm property such as the alarm name, probable cause, or severity. For example, you can create a transform function that assigns an alarm severity of Critical when the value in a specific varbind is 1, Major when the value is 2, and Minor when the value is 3.

When an alarm mapping includes one or more transform functions, the NFM-P can raise multiple alarms in response to the same SNMP trap. A trap value and the associated alarm property value are specified as a value pair in a transform function. You can also specify a default alarm property value that the NFM-P assigns to an alarm when a received value is not defined in a value pair.

A transform function defines the input value type, such as integer, and the output alarm property type, such as severity. You can modify these parameters only when the transform function does not contain a value pair and is not used by a mapping.

A transform function returns an empty string when a received value is not defined in a value pair and no default alarm property value is assigned. When the transform function defines the alarm name, probable cause, or severity, the NFM-P logs an error in response and does not raise an alarm.

8.6 Workflow to commission GNEs

8.6.1 Stages

1

Create a CLI script to enable trap forwarding to each main server in the NFM-P system. See the device documentation for information about configuring SNMP trap targets. Workflows could be used for this task.

2

Create a CLI script to disable trap forwarding to each main server in the NFM-P system. See the device documentation for information about configuring SNMP trap targets.

3

Prepare the device for NFM-P discovery and management using a GNE profile; see 8.14 “To prepare a GNE for NFM-P management” (p. 266) .

4

If required, configure or modify a GNE alarm catalog for use with a GNE profile.

- Create a GNE alarm catalog; see 8.17 “To create a GNE alarm catalog” (p. 269) .
- Create a transform function for the alarm catalog; see 8.18 “To create a transform function for a GNE alarm catalog” (p. 273) .
- Add an alarm mapping to the alarm catalog; see 8.19 “To add an alarm mapping to a GNE alarm catalog” (p. 274) .

Procedures for device commissioning

8.7 To commission a device for NFM-P management

8.7.1 Commissioning tasks not covered in this procedure

Table 8-1 Location of device commissioning information

Device	Information location
Devices for model-driven management	*NSP System Administrator Guide*

CAUTION

Service Disruption

Do not apply an SNMP log filter to the NFM-P SNMP log. The NFM-P cannot manage an NE that has an SNMP log filter applied to the log used by the NFM-P, which is typically log ID 98. In rare cases, Nokia may apply filters.

8.7.2 Steps

1

Open a console window on the device.

2

Enter the following command to configure the system address:

`configure router interface system address nnn.nnn.nnn.nnn/mask` ↵

where *nnn.nnn.nnn.nnn* is the system IP address

mask is the subnet mask

3

Enter the following command to enable Telnet:

`configure system security telnet-server` ↵

4

Enter the following command to enable FTP:

`configure system security ftp-server` ↵

5

If required, enter the following command to enable SSH2:

`configure system security ssh version 2` ↵

6

Enter the following command to enable console, FTP, and SNMP access for the appropriate user account on the device:

configure system security user *user_account* access console ftp snmp ↵

where *user_account* is the appropriate user account for Telnet, FTP, and SNMP access, for example, admin

7

If required, enter one of the following commands to enable hash encryption for passwords and authentication keys during device configuration save or list operations:

a. For 7x50 devices, Release 16.0 R3 and earlier, enter the following:

configure system security hash-control read-version *read-version* write-version *write-version* ↵

where

read-version is the version of encryption accepted during read operations, for example, 1, 2, or all to indicate that both are accepted

write-version is the version of encryption used during write operations, for example, 1 or 2

Version 1 encryption uses a simple key algorithm that generates the same character string each time it hashes a specific password or authentication key.

Version 2 encryption uses a more complex key algorithm that generates a different character string each time it hashes a specific password or authentication key.

b. For 7x50 devices, Release 16.0 R4 and later, enter one of the following:

configure system security management-interface classic-cli read-algorithm *read-algorithm* ↵

configure system security management-interface classic-cli write-algorithm *write-algorithm* ↵

configure system security management-interface md-cli hash-algorithm *hash-algorithm* ↵

configure system security management-interface netconf hash-algorithm *hash-algorithm* ↵

configure system security management-interface grpc hash-algorithm *hash-algorithm* ↵

where

read-algorithm is the version of encryption accepted during read operations. Nokia recommends using hash2.

write-algorithm/hash-algorithm is the version of encryption accepted during write operations. Nokia recommends using hash2.

8

Enter the following commands in sequence to set the time zone and time:

configure system time zone *time_zone -offset_from_UCT* ↵

admin set-time *YYYY/MM/DD hh:mm:ss* ↵

where

time_zone is the appropriate time zone, for example, EST

offset_from_UCT is the offset, in hours, from Universal Co-ordinated Time, also known as Greenwich Mean Time, for example, if you specify EST, *offset_from_UCT* is -5, as EST lags UCT by five hours

YYYY/MM/DD hh:mm:ss is the current local time

9

If required, perform one of the following to enable a time protocol.

a. Enter the following command to enable NTP:

configure system time ntp server-address *server_IP_address* ↵

where

server_IP_address is the IP address of the NTP server

b. Enter the following command to enable SNTP:

configure system time sntp server-address *server_IP_address* ↵

where

server_IP_address is the IP address of the SNTP server

10

Enter the following in sequence to enable the SNMPv2 engine and to configure an SNMP community:

configure system snmp no shutdown ↵

configure system snmp packet-size 9216 ↵

configure system security snmp community *community_name* rwa version both ↵

where *community_name* is the SNMPv2 community name

Caution: When configuring a mediation policy, you need use a community string that uses rwa in order for the trap destination is set on the NE. This ensures fault conditions and alarms are reported.

Note: The command is used for the NFM-P write mediation policy. If you are using SNMPv2, you must use this mediation policy for read as well, or create another mediation policy that is also configured for rwa.
The SNMPv2 community string name rwa attributes must be enabled for the NFM-P to properly manage a device, even if the NFM-P is only used to monitor a network.

11

Enter the following commands in sequence to ensure that the device uses persistent SNMP indexes:

bof persist on ↵

```
bof save ↲
```

12

Enter the following command to save the configuration changes:

```
admin save ↲
```

13

If the device has redundant CPMs, enter the following command to synchronize the CPMs:

```
admin redundancy synchronize boot-env ↲
```

14

Enter the following command to reboot the device:

```
admin reboot now ↲
```

The device initializes with SNMP communication enabled.

15

Enter the following to clear the log ID and trap group ID:

```
configure log ↲
log-id 98 ↲
shutdown ↲
exit ↲
no log-id 98 ↲
no snmp-trap-group 98 ↲
exit all ↲
```

16

Use an NFM-P client to discover the device and to verify that the device configuration allows management of the device. See Chapter 9, “Device discovery” for information about device discovery.

END OF STEPS

8.8 To commission an OmniSwitch for NFM-P management

8.8.1 Before you begin

See the appropriate OmniSwitch documentation for more information about the CLI command syntax and SNMP.

Note: The NFM-P cannot discover an OmniSwitch that is configured with the factory default settings.

Note: You must use a direct console port connection to access an OmniSwitch for the first

time. All other management methods such as SNMP, Telnet, FTP, and HTTP, are disabled until you enable them.

8.8.2 Steps

1

Open a console window using a direct console port connection to the OmniSwitch.

2

Create a Loopback0 interface and assign an IP address to the interface by entering the following:

ip interface Loopback0 address *xxx.xxx.xxx.xxx* ↵

where

xxx.xxx.xxx.xxx is the IP address of the interface

Note: Loopback0 is the name assigned to an IP interface to identify an address that is used for network management purposes. The Loopback0 interface is not bound to any VLAN, therefore it always remains operationally active.
The Loopback0 interface name is case-sensitive. Ensure that you enter the name exactly as shown.

3

Enable SNMP sessions on the switch by entering the following:

aaa authentication snmp local ↵

4

Enable FTP, Telnet, HTTP, or SSH sessions, if required, by entering the following:

aaa authentication ftp local ↵

aaa authentication telnet local ↵

aaa authentication http local ↵

aaa authentication ssh local ↵

5

Perform one of the following to configure the required version of SNMP on the switch and the NFM-P:

Note: The OmniSwitch default user, admin, does not have SNMP access. Before the NFM-P can discover an OmniSwitch, you must create at least one user on the switch with SNMP access.

a. For SNMP v2c:
   1. Configure an SNMP v2 user by entering the following:

      user *user_name* password *password* no auth ↵

where

user_name is a username that corresponds to an SNMP v2 user who the NFM-P can identify; Nokia recommends that you use the name sam, which is the NFM-P default name

password is a password associated with the username; the password is between 8 and 47 characters

Note:

If you need to use a different SNMPv2 default user name, create an SNMPv2 default user name on the NFM-P. See the procedure to create a default SNMPv2 OmniSwitch user in the *NSP System Administrator Guide* for information about creating an SNMPv2 default user name.

2. Configure SNMP v2 trap forwarding to the NFM-P by entering the following:

   snmp station *xxx.xxx.xxx.xxx v2 user_name* ↵

   where

   xxx.xxx.xxx.xxx is the IP address of the NFM-P main server

   user_name is the username that you created in 1

   Note:

   Trap forwarding configuration occurs automatically when the NFM-P discovers a switch and uses the default SNMP v2 user name sam or the user name configured, if any.

3. Configure an SNMP security level that allows the switch to accept all SNMP queries by entering the following:

   snmp security no security ↵

4. Configure an SNMP v2 community string by entering the following:

   snmp community map *community_string* user *user_name* ↵

   where

   community_string is the name of an SNMP v2 community string that the NFM-P can identify

   user_name is the SNMP v2 username created in 1

5. Create a mediation security policy on the NFM-P that uses a community string that matches the string created in 4 . See 9.17 “To configure device mediation” (p. 301) for information about creating a mediation security policy.

6. Create a discovery rule on the NFM-P to discover the switch and reference the policy created in 5 . See 9.23 “To configure a discovery rule” (p. 310) for information about creating a discovery rule.

b. For SNMP v3:

1. Configure an SNMP v3 user on the switch by entering the following:

   user *user_name* password *password security_level* ↵

   where

   user_name is a username that matches an SNMP v3 USM username configured on the NFM-P

password is a password associated with the username; the password is between 8 and 47 characters. The password is the plain text ASCII MD5/SHA authentication key and DES privacy key.

security_level is MD5, MD5 + DES, SHA, or SHA + DES

2. Configure SNMP v3 trap forwarding to the NFM-P by entering the following:

   `snmp station xxx.xxx.xxx.xxx v3 user_name` ↵

   where

   xxx.xxx.xxx.xxx is the IP address of the NFM-P main server

   user_name is the username created in 1

   Note:

   Trap forwarding occurs automatically when the NFM-P discovers a device with a username that matches the SNMP v3 USM username specified in the NFM-P mediation policy.

3. Configure the SNMP v3 switch security option that you need by entering the following:

   `snmp security security_option` ↵

   where *security_option* is one of the security options described in the following table

Option	Description
no security	All SNMP queries are accepted.
authentication set	Includes: • SNPM v1 and v2 Gets • Non-authenticated v3 Gets and Get-Nexts • Authenticated v3 Sets, Gets, and Get-Nexts • Encrypted v3 Sets, Gets, and Get-Nexts
authentication all	Includes: • Authenticated v3 Sets, Gets, and Get-Nexts • Encrypted v3 Sets, Gets, and Get-Nexts
privacy set	Includes: • Authenticated v3 Gets and Get-Nexts • Encrypted v3 Sets, Gets, and Get-Nexts
privacy all (default)	Includes: • Encrypted v3 Sets, Gets, and Get-Nexts
traps only	Includes: • All SNMP requests are rejected

4. Create an SNMP v3 user on the NFM-P using the NE User Configuration manager. See the section on NE user and device security in the *NSP System Administrator Guide* for information about NE user configuration.
   - Enable SNMP to give the SNMP v3 user SNMP access.
   - Choose a username that matches the name created on the switch in 1 .

- Choose the same SNMP v3 authentication protocol, privacy protocol, and password that is configured on the switch.

5. Create an SNMP v3 mediation security policy. See 9.17 “To configure device mediation” (p. 301) for information about configuring a mediation security policy.
   - Choose the SNMP v3 (USM) security model option.
   - Choose a username that matches the name created on the switch in 1 .
6. Create a discovery rule that uses the mediation security policy created in 5 . See 9.23 “To configure a discovery rule” (p. 310) for information about creating discovery rules.

6

Use an NFM-P client to discover the switch and to verify that the switch configuration allows you to manage the switch.

END OF STEPS

8.9 To configure the NFM-P SNMP trap listener

8.9.1 Purpose

As an SNMP trap destination, the NFM-P listens to certain SROS event logs. Perform this procedure to configure the NFM-P as an SNMP trap listener to the SNMP trap sources, which are certain SROS event logs associated with log ID 98. If no SNMP log ID on a managed SROS device matches the log ID in the NFM-P configuration, the NFM-P recreates the log ID and SNMP trap group on the device, which results in a single log file that receives traps from the following sources:

- main
- security—always included as an SNMP source
- change—supported by the NFM-P for the 7950 XRS and for the 7750 SR

CAUTION

Service Disruption

This procedure requires a restart of each NFM-P main server, which is service-affecting. Perform this procedure only during a scheduled maintenance window.

8.9.2 Steps

1

If the NFM-P is deployed in a standalone configuration, go to Step 3 .

2

Perform the following steps to stop the standby main server.

1. Log in to the standby main server station as the nsp user.
2. Open a console window.

3. Enter the following:

   ```
   bash$ cd /opt/nsp/nfmp/server/nms/bin ↵
   ```

4. Enter the following to stop the main server application:

   ```
   bash$ ./nmsserver.bash stop ↵
   ```

5. Enter the following to display the main server status:

   ```
   bash$ ./nmsserver.bash appserver_status ↵
   ```

   The command displays a status message.

6. The main server is stopped when the command displays the following status message:

   ```
   Application Server is stopped
   ```

   If the command displays a different message, wait 5m and repeat Step 2 5 . Do not proceed to the next step until the server is stopped.

3

Perform the following steps on the primary main server station or the standby main server station:

1. Log in to the main server station as the nsp user.
2. Open the /opt/nsp/nfmp/server/nms/config/nms-server.xml file using a plain-text editor.

   Caution: Contact your Nokia technical support representative before you attempt to modify the nms-server.xml file. Modifying the nms-server.xml file can have serious consequences that can include service disruption.

3. Locate the following section:

   ```
   <snmp
   ip="IP_address"
   port="nnn"
   trapLogId="98"
   ```

   where

   IP_address is the IP address of the NFM-P main server

   nnn is the SNMP port number

   This default configuration applies to traps from main, security, and change, if available.

4. Perform one of the following:

   To restrict the trap source to main only, add the following line:

   ```
   logIdSourceBits="80"
   ```

   To restrict the trap source to main and change, add the following line:

   ```
   logIdSourceBits="A0"
   ```

5. Save and close the nms-server.xml file.
6. Open a console window.
7. Navigate to the /opt/nsp/nfmp/server/nms/bin directory.
8. Enter the following to restart the main server:

```
bash$ ./nmsserver.bash force_restart ↵
```

The main server restarts, and the configuration change takes effect.

4

Close the console windows.

END OF STEPS

8.10 To configure polling for a 7250 IXR, 7450 ESS, 7705 SAR, 7750 SR, 7950 XRS, VSR, or Wavence SM

8.10.1 Purpose

Perform this procedure to configure polling and the schedule resynchronizing settings for a specified NE type. You can also optionally configure the system initialization commands configured in the BOF such as the primary/secondary/tertiary DNS addresses, Lawful Intercept settings, and the scaling profile that specifies the type of network scale usage that is applied to the hardware configured in the network. The parameters that display vary depending on the NE type, release, and the settings of other parameters.

8.10.2 Steps

1

Choose Equipment or Routing from the navigation tree view selector, right-click on a supported NE, and choose Properties. The Network Element (Edit) form opens.

2

Record the system IP address and the management IP address.

3

If required, configure the Location parameters.

4

Click on the Polling tab.

5

Enable or disable the Scheduled Polling parameter as required. Scheduled polling is configured using the Mediation configuration form. See 9.17 “To configure device mediation” (p. 301) for more information.

6

If required, configure the Redundant Synchronization Mode parameter.

7

Verify that the Persistent SNMP Indices parameter is set to true to ensure persistent SNMP indices are used.

8

Configure the parameters in the Bof Configuration panel as required.

Note: To configure LI parameters, or view LI configuration information, you require LI user privileges. Right-click on a discovered device in the navigation tree and choose Properties from the contextual menu, and click on the LI Configuration Status tab.

Note: If you enable encryption, you must run bof save.

9

View the read-only parameters to determine the current polling status:

- Resync Status indicates whether the last poll was successfully completed.
- Last Resync Start Time and Last Resync End Time indicate the start and finish of the last poll.
- Scheduled Resync Status indicates whether the last scheduled poll was successfully completed.
- Last Scheduled Resync Start Time and Last Scheduled Resync End Time indicate the start and finish of the last scheduled poll.

10

Click on the Management tab and configure the required parameters.

The Auto Revert to Preferred parameter is configurable when the Management IP Selection parameter is set to Out Of Band Preferred or In Band Preferred.

Note: To avoid a communications outage between the NFM-P and managed NEs, the parameter settings in the Management Preference panel must match the parameter settings in the Notifications Preferred Management panel. See the Management IP Selection parameter description for more information.
If you want to transmit on in-band management on the 7705 SAR when both in-band and out-of-band management are both used, configure the Active Management IP, Auto Revert to Preferred, and Management IP Selection parameters as described in 8.2.1 “7705 SAR management bandwidth ” (p. 241) .

11

Save your changes and close the form.

END OF STEPS

8.11 To configure polling for a 7210 SAS

8.11.1 Steps

1

Choose Equipment or Routing from the navigation tree view selector, right-click on a 7210 SAS, and choose Properties. The Network Element form opens.

2

Record the system IP address and the management IP address.

3

If required, configure the Location parameters.

4

Click on the Polling tab, then the General tab.

5

Enable or disable the Scheduled Polling parameter. Scheduled polling is configured using the Mediation configuration form. See 9.17 “To configure device mediation” (p. 301) for more information.

6

Verify that the Persistent SNMP Indices parameter is set to true to ensure that persistent SNMP indices are used.

7

Configure the parameters in the Bof Configuration panel as required.

8

View the read-only parameters to determine the current polling status:

- Resync Status indicates whether the last poll was successfully completed.
- Last Resync Start Time and Last Resync End Time indicate the start and finish of the last poll.
- Scheduled Resync Status indicates whether the last scheduled poll was successfully completed.
- Last Scheduled Resync Start Time and Last Scheduled Resync End Time indicate the start and finish of the last scheduled poll.

9

Click on the Management tab and configure the required parameters.

The Auto Revert to Preferred parameter is configurable when the Management IP Selection parameter is set to Out Of Band Preferred or In Band Preferred.

Note: The Active Management IP, Auto Revert to Preferred, and Management IP Selection parameters are not supported on the 7210 SAS-D or 7210 SAS-K. The 7210 SAS-D and 7210 SAS-K support only in-band management.

10

Click on the 7210 BOF tab to configure uplinks in the BOF for port redundancy.

Note: If the image path and configuration file path are local, you do not need to configure the IP address and routing information for uplink A and uplink B. You can optionally obtain IP parameters using DHCP when you configure a value of 0 for the uplink port IP address. The DHCP server should be configured to provide the IP address and the default gateway information that is used to reach the server where the image and configuration files are stored.

11

Select an uplink port in the Uplink A panel.

12

Configure the required parameters in the Uplink A panel.

13

Select an uplink port in the Uplink B panel.

14

Configure the required parameters in the Uplink B panel.

15

Click on the Uplink Routes tab and click Create. The Uplink Route Configuration form opens.

16

Configure the required parameters and click Apply.

17

Repeat Step 16 to add another uplink route. You can add up to ten routes for each uplink.

18

Save your changes and close the form.

END OF STEPS

8.12 To configure polling for a 7705 SAR-Hm

8.12.1 Purpose

Perform this procedure to configure the SNMP polling interval for 7705 SAR-Hm NEs. The default polling cycle is one day (1440 minutes). You can change the polling to up to once a week.

8.12.2 Steps

1

If the NFM-P is deployed in a standalone configuration, go to Step 3 .

2

Perform the following steps to stop the standby main server.

1. Log in to the standby main server station as the nsp user.
2. Open a console window.
3. Enter the following:

   ```
   bash$ cd /opt/nsp/nfmp/server/nms/bin ↲
   ```

4. Enter the following to stop the main server application:

   ```
   bash$ ./nmsserver.bash stop ↲
   ```

5. Enter the following to display the main server status:

   ```
   bash$ ./nmsserver.bash appserver_status ↲
   ```

   The command displays a status message.

6. The main server is stopped when the command displays the following status message:

   ```
   Application Server is stopped
   ```

   If the command displays a different message, wait 5m and repeat Step 2 5 . Do not proceed to the next step until the server is stopped.

3

Perform the following steps on the primary main server station or the standby main server station:

1. Log in to the main server station as the nsp user.
2. Open the /opt/nsp/nfmp/server/nms/config/nms-server.xml file using a plain-text editor.

   Caution: Contact your Nokia technical support representative before you attempt to modify the nms-server.xml file. Modifying the nms-server.xml file can have serious consequences that can include service disruption.

3. Locate the following parameter:

   ```
   <snmp reachabilityCheckInterval="
   ```

4. Modify the number of minutes as needed.
5. Save and close the nms-server.xml file.
6. Open a console window.

7. Navigate to the /opt/nsp/nfmp/server/nms/bin directory.
8. Enter the following to restart the main server:

   ```
   bash$ ./nmsserver.bash force_restart ↵
   ```

   The main server restarts, and the configuration change takes effect.

4

Close the console windows.

END OF STEPS

8.13 To edit polling settings for multiple devices

8.13.1 Purpose

You can use the list of managed devices from the Discovery Manager Resync Status tab to modify polling settings for a device or devices; for example, when you want to enable or disable polling on numerous managed devices.

8.13.2 Steps

1

Choose Administration→Discovery Manager from the NFM-P main menu. The Discovery Manager form opens.

2

Click on the Resync Status tab, select multiple devices from the list, and click Properties. The Network Element (Multiple Instances) form opens.

Note: You can only configure those parameters that are common to all devices selected from the list.

3

Click on the Polling tab and enable or disable the Scheduled Polling parameter.

4

Save your changes and close the forms.

END OF STEPS

Procedures for GNE commissioning

8.14 To prepare a GNE for NFM-P management

8.14.1 Purpose

Perform this procedure to prepare a GNE, which is typically a non-proprietary device, for NFM-P discovery and management.

8.14.2 Steps

1

Preconfigure the device using a CLI:

1. Enable FTP.
2. Enable Telnet.
3. Enable SNMP and/or NETCONF, as appropriate.
4. Configure at least one SNMPv2c or SNMPv3 community.
5. Set the SNMP PDU size to 9216.
6. Enable persistent SNMP indexes.

2

Choose Administration→Generic NE Manager from the NFM-P main menu. The Generic NE Manager form opens.

3

Click Create and choose Generic NE Profile. The Generic NE Profile (Create) form opens.

4

Configure the required parameters.

The Sys Object ID parameter must begin with the following, which identifies the SMI enterprises subtree defined in RFC 1213: .1.3.6.1.4.1

Do not enclose the Alternate Element Manager value in quotation marks; the NFM-P automatically encloses the value in quotation marks at run time.

You cannot modify the Generic NE Type parameter after the GNE profile is created; you must delete the GNE profile and create a profile using the new Generic NE Type parameter value.

Note: To specify the target GNE IP address in the Default Element Manager URL or as a Default Alternate Element Manager command argument, use the %IP% keyword.

5

If applicable, select a driver to associate with the GNE profile from the Driver Module panel.

6

Click on the CLI Profile tab and configure the required parameters.

7

If required, configure the login confirmation parameters.

The Prompt and Answer parameters are configurable when the Enable Confirm Prompt parameter is selected.

8

If required, configure the second level login security parameters.

The Enable Login Command and Enable Login Prompt parameters are configurable when the Enable Second Login parameter is selected.

9

To configure an interface for the GNE, perform the following steps:

1. Click on the Interface Types tab and click Add. The Select Generic NE Interface Type form opens.
2. Choose an interface type and click OK. The form closes.

10

To associate one or more routing MIBs with the GNE profile, perform the following steps.

Note: After you discover the device using the GNE profile, you can use the Routing view in the network navigation tree to view the discovered routing objects.
You must configure the GNE interface types before you associate a routing MIB with a GNE profile. Otherwise, you must perform a customized NE resync of all MIBs and select the Ignore Timestamps parameter.

1. Click on the Other MIBs tab and click Add. The Select Generic NE Routing MIB form opens.
2. Select one or more MIBs and click OK.

11

Click Apply and confirm your actions. The Trap Configuration tab is enabled.

12

Click on the Trap Configuration tab and perform one of the following, if required select a script in the Trap Configuration Script panel. During device discovery, the NFM-P runs this script on the GNE to enable trap forwarding to the NFM-P.

13

Select a script in the Trap De-Configuration Script panel. During device discovery, the NFM-P runs this script on the GNE to disable trap forwarding to the NFM-P.

14

Select an alarm catalog in the Alarm Catalogue panel.

15

Save your changes and close the forms.

END OF STEPS

8.15 To configure an alternate EMS for a specific GNE

8.15.1 Purpose

Perform this procedure to specify an alternate EMS client application for a specific NE.

Note: The EMS that you specify overrides an EMS specified in the associated GNE profile.

8.15.2 Steps

1

Right-click on a GNE object in the network navigation tree and choose Properties. The GNE properties form opens.

2

Configure the Alternate Element Manager parameter.

Note: Do not enclose the Alternate Element Manager value in quotation marks; the NFM-P automatically encloses the value in quotation marks at run time.
To specify the target GNE IP address as an Alternate Element Manager command argument, use the %IP% keyword.

3

Save your changes and close the form.

END OF STEPS

8.16 To modify a GNE profile

8.16.1 Purpose

Perform this procedure to change a GNE profile configuration.

8.16.2 Steps

1

Choose Administration→Generic NE Manager from the NFM-P main menu. The Generic NE Manager form opens.

2

Choose Generic NE Profile (Generic NE), select a GNE profile in the list, and click Properties. The Generic NE Profile form opens.

The following tabs contain configurable parameters:

- General—contains parameters that identify the GNE type
- CLI Profile—contains parameters that define the console window prompts and commands
- Trap Configuration—contains parameters that define the SNMP trap management configuration
- Interface Types—allows the association of multiple types of interfaces with the GNE profile

  Caution: If you modify the list of interfaces on the Interface Types tab, you must resynchronize the entire GNE, as described in Step 4 .

3

Modify the required parameters for the GNE profile, click OK, and confirm your actions. The form closes.

4

If you modified the list of interfaces on the Interface Types tab, perform the following steps:

1. Right-click on the GNE in the NFM-P topology map and choose Resync→Customized Resync. The Resync Site(s) form opens.
2. Click Next and select the Ignore Timestamps parameter.
3. Click Finish and close the Resync Site(s) form. The NFM-P resynchronizes the GNE.

END OF STEPS

8.17 To create a GNE alarm catalog

8.17.1 Purpose

Perform this procedure to create an alarm catalog for use with a GNE profile.

8.17.2 Steps

1

Choose Administration→Generic NE Manager from the NFM-P main menu. The Generic NE Manager form opens.

2

Click Create and choose Generic NE Alarm Catalogue. The Generic NE Alarm Catalogue (Create) form opens.

3

Configure the required parameters.

4

If required, perform Step 3 to Step 12 of 8.18 “To create a transform function for a GNE alarm catalog” (p. 273) to create a transform function for the catalog.

5

Click on the Mappings tab and click Create. The Generic NE Alarm Mapping (Create) form opens.

6

Configure the required parameters.

7

Perform one of the following:

a. Configure the Alarm Name parameter to specify a static alarm name.

b. Specify a dynamic alarm name:

   1. Enable the Specify Transform Function parameter.
   2. Select a transform function beside the Transform Varbind Function parameter.
   3. Configure the Varbind Position parameter.

8

Perform one of the following:

a. Select a probable cause beside the Probable Cause parameter to specify a static probable cause.

b. Specify a dynamic probable cause:

   1. Enable the Specify Transform Function parameter.
   2. Select a transform function beside the Varbind Transform Function parameter.
   3. Configure the Varbind Position parameter.

9

Perform one of the following:

a. Specify a static severity by configuring the Severity parameter.

b. Specify a dynamic severity:

Note: When you specify the use of a transform function for the alarm severity, the Mapping Type changes to Raising/Clearing. You cannot create a clearing mapping for this type of mapping; you must use a transform function to clear an alarm when the alarm severity is defined using a transform function.

1. Enable the Specify Transform Function parameter.
2. Select a transform function beside the Varbind Transform Function parameter.
3. Configure the Varbind Position parameter.

10

Configure the varbind positions for specific objects on a GNE in the Alarmed Object panel:

- System Address Varbind Position
- Interface Index Varbind Position

Note: In order to configure the System Address Varbind Position and Interface Index Varbind Position parameters, you must set the Alarm Name parameter to GNE MTIE Alarm.

11

Click OK and confirm your actions. The form closes.

12

Repeat Step 5 to Step 11 to create an additional raising alarm mapping, if required.

13

Perform one of the following:

a. If you need to create a clearing alarm, continue to Step 14 .

b. If you do not need to create a clearing alarm, go to Step 20 .

14

Select a raising alarm mapping and click Create Clearing. The Generic NE Alarm Mapping form opens.

Note: A raising alarm mapping is indicated by the word Raising in the Mapping Type list column.
You can create a clearing alarm mapping only when the corresponding raising alarm is in the same alarm catalog.
You can associate a clearing alarm mapping with only one raising alarm mapping.
You cannot create a clearing mapping for a mapping that uses a transform function to define the alarm severity; you must use a transform function to clear an alarm when the alarm severity is defined using a transform function.

15

Configure the required parameters:

Note: A static clearing alarm mapping inherits the following values from the associated raising alarm:

- Alarm Name—must match raising alarm Alarm Name
- Probable Cause—must match raising alarm Probable Cause
- FDN Extension—resulting text string must match text string generated by raising alarm mapping
- Additional Text—resulting text string must match text string generated by raising alarm mapping

  See 8.17 “To create a GNE alarm catalog” (p. 269) for information about modifying the Alarm Name or Probable Cause value.

  The explicit FDN Extension and Additional Text values can differ from the values in the raising mapping, but the generated text strings must match. For example, if the object name is in varbind 2 of the raising trap and in varbind 3 of the clearing trap, the parameter values name different varbinds but the script output is identical.

  The alarm severity in a clearing alarm mapping is set to Cleared and cannot be changed.

16

If required, specify a dynamic alarm name:

1. Enable the Specify Transform Function parameter.
2. Select a transform function beside the Varbind Transform Function parameter.
3. Configure the Varbind Position parameter.

17

If required, specify a dynamic probable cause:

1. Enable the Specify Transform Function parameter.
2. Select a transform function beside the Varbind Transform Function parameter.
3. Configure the Varbind Position parameter.

18

Click OK and confirm your actions. The form closes.

19

Repeat Step 14 to Step 18 to create additional clearing alarm mappings, if required.

20

Save your changes and close the forms.

END OF STEPS

8.18 To create a transform function for a GNE alarm catalog

8.18.1 Steps

1

Choose Administration→Generic NE Manager from the NFM-P main menu. The Generic NE Manager form opens.

2

Click Create and choose Create Generic NE Alarm Catalogue. The Generic NE Alarm Catalogue form opens.

3

Click on the Transform Functions tab and click Create. The Generic NE Alarm Transform Function form opens

4

Configure the required parameters.

5

If you enabled the Specify Default Out Value parameter, select a value beside the Default Out Value parameter.

6

Click on the Pairs tab and click Create. The Pair form opens.

7

Configure the In Value parameter.

8

Select a value beside the Out Value parameter.

9

Click OK and confirm your actions. The form closes.

10

Repeat Step 6 to Step 9 to add another value pair, if required.

11

Click OK and confirm your actions. The form closes.

12

Repeat Step 3 to Step 11 to create another transform function, if required.

13

Save your changes and close the forms.

END OF STEPS

8.19 To add an alarm mapping to a GNE alarm catalog

Note: A modification to a GNE alarm catalog takes effect immediately after you commit the change.

8.19.1 Steps

1

Choose Administration→Generic NE Manager from the NFM-P main menu. The Generic NE Manager form opens.

2

Choose Generic NE Alarm Catalogue (Trap to Alarm Mapper), select an alarm catalog, and click Properties. The Generic NE Alarm Catalogue form opens.

3

If required, configure the Description and Version parameters.

4

Perform Step 5 to Step 18 in 8.17 “To create a GNE alarm catalog” (p. 269) .

END OF STEPS

8.20 To delete a GNE alarm catalog

Note: You cannot delete an alarm catalog that is associated with a GNE profile. You must remove the alarm catalog from each associated GNE profile before you can delete the catalog.

Note: When you delete a GNE alarm catalog, you delete the alarm mappings that the catalog contains.

8.20.1 Steps

1

Choose Administration→Generic NE Manager from the NFM-P main menu. The Generic NE Manager form opens.

2

Choose Generic NE Alarm Catalogue (Trap to Alarm Mapper), select a GNE alarm catalog, and click Properties. The Generic NE Alarm Catalogue form opens.

3

Click on the Generic NE Profiles tab and perform one of the following:

a. If no profiles are listed, go to Step 4 .

b. If profiles are listed, perform the following steps to remove the profile associations:

1. Select a profile and click Properties. The Generic NE Profile form opens.
2. Click on the Trap Configuration tab and click Clear in the Alarm Catalogue panel.
3. Click OK and confirm your actions. The form closes.
4. Repeat 1 to 3 for each listed profile.

4

Close the Generic NE Alarm Catalogue form.

5

Select the alarm catalog and click Delete.

6

Confirm your actions and close the form.

END OF STEPS

9 Device discovery

Discovering devices using the NFM-P

9.1 Overview

9.1.1 Functional description

The NFM-P discovers devices using SNMP and stores the device properties in the NFM-P database. To discover one or more devices in your network, you create a discovery rule and then scan the network for devices according to the IP addresses or address ranges specified in the discovery rule.

A discovery rule contains one or more rule elements that specify which devices or subnets are to be included in, or excluded from, the discovery process. For example, you can configure one rule element to discover a subnet, and another to exclude specific IP addresses from the subnet.

The NFM-P periodically scans the network for new devices according to a discovery rule scan interval. By default, the scan interval specified in the NFM-P mediation configuration applies to all NFM-P discovery rules. However, in a discovery rule, you can specify a scan interval that overrides the scan interval in the mediation configuration. For example, to reduce the amount of network-management traffic created by the periodic scans in a busy subnet, you can increase the scan interval in the discovery rule for the subnet.

When the system IP address is used to discover a device, the management is in-band. When the management IP address is used to discover a device, the management is out-of-band. See Chapter 8, “Device commissioning and management” for information about in-band and out-of-band management.

Note: The NFM-P does not attempt to discover tests or test suites that are configured on a device using a CLI.

Note: If a discovered chassis exceeds the NFM-P license count during the execution of a discovery rule, the NFM-P marks the device as Unmanaged.

Note: After you update the NFM-P license to accommodate an additional chassis, you must manage the device manually. See 9.27 “To manage, suspend, or unmanage a device” (p. 316) for information.

Note: If you change the system name of a device, you must unmanage the device and then remanage the device in order for the NFM-P to recognize the new system name. See 9.27 “To manage, suspend, or unmanage a device” (p. 316) for information.

Note: The NFM-P blocks the discovery of mixed mode SROS devices.

9.1.2 Device discovery using IPv6

The NFM-P supports the discovery of devices that use IPv6 in-band or out-of-band management IP addresses. In order for the NFM-P to discover and manage a device that uses IPv6, the device

must have an IPv6 address on the management port, system interface, or both. The NFM-P main server must also be given an IPv6 address during installation.

The IP version that the NFM-P uses to discover a device is specified in each discovery rule. If the NFM-P discovers both IPv4 and IPv6 addresses on the system interface of a device, it discovers the device using the address that corresponds to the IP version specified in the discovery rule.

9.1.3 Dying Gasp trap target support for IXR-E

NSP automatically enables Dying Gasp trap target on IXR-E when new IXR is discovered by NSP. If NE manual changes are made on Dying Gasp trap target after discovery, the IXR-E will need to be unmanaged and remanaged for NSP to enable the Dying Gasp trap target again.

Note: The discovery of IXR-E node in more than 3 NFM-P is not possible due to node limitation on setting Dying Gasp. If a user wants to discover IXR-E node on 4th NFM-P, they will need to either remove the feature of Dying Gasp in an already discovered node (from node side) or they will need to unmanage the node which is already discovered NFM-P.

9.2 Device SNMP management

9.2.1 SNMP overview

Simple Network Management Protocol, or SNMP, is an application-layer protocol that provides a message format to facilitate communication between SNMP managers and agents. SNMP provides a standard framework for NE monitoring and management from a central location.

An SNMP manager controls and monitors the activities of network hosts that use SNMP. An SNMP manager uses a get operation to obtain a value from an SNMP agent, and uses a set operation to store a value in the agent. The manager uses definitions from a management information base, or MIB, to perform operations on the managed device, for example, retrieving data values, replying to requests, and processing SNMP notifications called traps.

SNMPv1 and SNMPv2c provide no security, authentication, or encryption. Without authentication, an unauthorized user is able to perform SNMP network management functions and eavesdrop on management information as it passes from one system to another.

SNMPv3 requires that an authentication and encryption method such as SSH is assigned to each user for validation by the NE. SNMPv3 authentication and encryption enable an NE to validate the system that issues an SNMP message and to determine whether another system has tampered with the message. When creating an SNMPv3 NE user on the NFM-P, ensure that the NEs support a valid combination of authentication and privacy protocols. See 9.11 “To enable SNMPv3 management of a device” (p. 291) for more information.

For information about device-specific SNMP support, see the SNMP chapter of the appropriate *System Management Guide* for the device. For information about SSH security, see 9.6 “Configuring SSH security on devices” (p. 283) .

9.2.2 SNMP packet size considerations for device discovery

The network infrastructure carrying traffic between the NFM-P main and auxiliary servers and the managed NEs must support packet fragmentation and reassembly when the PDU size is greater than the MTU of the network path. The 7210 SAS, 7450 ESS, 7705 SAR, 7750 SR, and 7950 XRS

require an SNMP PDU size of 9216 bytes to be configured and fragmentation support is required in the network path between the NFM-P and the NE.

Consider the following:

- When an intermediate network device receives SNMP traffic, it must be able to process fragmentation of packets. If the SNMP packet exceeds the MTU size of the intermediate device, and the device does not support fragmentation of packets, the packets may be dropped and device discovery may fail.
- Verify that data payloads of the SNMP PDU size can travel from the managed devices to the NFM-P by using a CLI to ping the IP address of the NFM-P main server, using a packet size of the configured SNMP PDU.

9.2.3 SNMP streaming

During the initial discovery of supported 7250 IXR platforms, or a 7450 ESS, 7750 SR, or 7950 XRS, the NFM-P enables SNMP streaming on the device, if it is not currently enabled. SNMP streaming facilitates the bulk transfer of MIB-based configuration data using a streaming mechanism. SNMP streaming may substantially reduce the time that operations such as NE discovery and resynchronization require in a high-latency network. See 9.14 “To enable or disable SNMP streaming on an NE” (p. 299) for information about enabling and disabling SNMP streaming on an NE.

9.3 Device management states

9.3.1 Description

A device can be in one of the following management states:

- discovered—the NFM-P manages the device
- unmanaged—an operator has unmanaged the formerly managed device; the management information is removed from the NFM-P database. See see 9.3.2 “Unmanaging and deleting devices” (p. 280) for more information
- suspended—an operator has suspended management of the device; see 9.3.3 “Suspending device management” (p. 280) for more information

NEs not associated with a discovery rule

After a discovery rule is deleted, any managed devices associated with the discovery rule are not subsequently included in certain network administration tasks such as NE version change detection.

In the event that a discovery rule is deleted, perform 9.28 “To associate a device with a discovery rule” (p. 317) to ensure that the managed devices associated with the discovery rule are included in subsequent network administration activities,

9.3.2 Unmanaging and deleting devices

CAUTION

Service Disruption

Unmanaging or deleting a device results in the loss of all historical AA statistics for the device.

Using the NFM-P to unmanage a device excludes the device from the managed network, but a reference to the device remains in the NFM-P discovery system. The unmanage function may be used for unusual conditions such as when the NFM-P requires a complete refresh of device data because of data corruption. Unmanaging a device results in a loss of management data for the selected device, which includes, but is not limited to, the following:

- object names and descriptions
- statistics
- alarms
- physical links
- policies
- script results
- scheduled activities
- device configuration backups

Deleting a device results in the complete loss of management data for the device and completely removes the device from the managed network.

9.3.3 Suspending device management

CAUTION

Service Disruption

When you suspend the management of a device, the NFM-P raises a critical alarm against the device.

When you need to exclude a device from NFM-P management but do not want to lose the NFM-P information about the device, for example, during a maintenance period that may generate an exceptional number of SNMP traps, you can use a GUI or OSS client to suspend the management of the device.

When you suspend management of a device, the NFM-P removes the associated trap targets from the device configuration, and blocks the following operations:

- SNMP deployment and trap handling; all traps from the device are dropped
- NETCONF deployments and event subscriptions
- statistics collection
- automated FTP and other file transfers
- GUI or OSS client configuration of device parameters; a configuration attempt results in a failed deployment
- scheduled or periodic operations that the NFM-P initiates, for example:
  - connectivity checks
  - resynchronizations
  - device configuration backups

- device software upgrades
- OAM test and test suite execution

Note: You cannot suspend the management of a device while a software upgrade or configuration backup is in progress on the device.

By default, the NFM-P does not raise alarms against suspended NEs. You can override the default setting using a parameter in the main-server configuration file. Contact technical support for more information.

You can use the NFM-P to perform the following on a suspended device:

- open a Telnet or SSH CLI session
- execute CLI scripts
- open an FTP session
- configure NFM-P parameters that affect the device management but are not deployed, such as the in-band or out-of-band management preferences

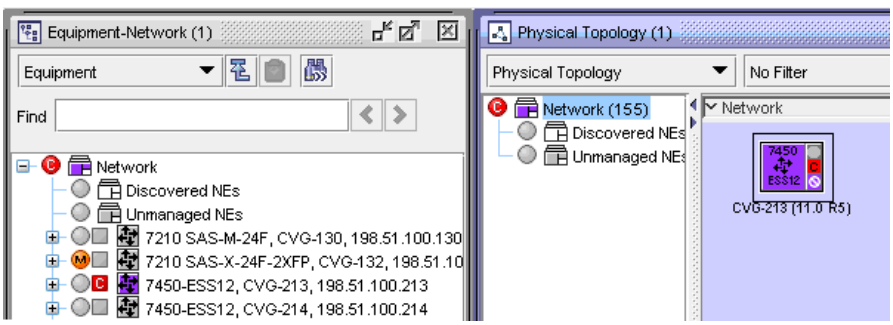
Note: By default, the NFM-P suppresses alarms for suspended NEs. If you attempt to modify an OAM test or test suite that is deployed to a suspended NE, the NFM-P raises an alarm. The alarm does not automatically clear when the NE is remanaged.

As shown in Figure 9-1, “GUI representation of suspended device” (p. 281) , when a device is suspended, the device icons in the network navigation tree and physical topology map are colored purple. When a suspended device is in a group other than the Network group, only the lower right corner of the Network group icon is colored purple.The following icons are also colored purple to indicate that at least one device is suspended:

- parent group icon in the network navigation tree Equipment and Routing views
- parent group icon in the physical topology map

Note: The group icon colors are prioritized; when a group contains one or more unreachable NEs and one or more suspended NEs, the group icon is colored red.

Figure 9-1 GUI representation of suspended device



When you return a suspended device to the managed state, the NFM-P rediscovers the device to capture events such as device reboots or software release changes, and initiates a full device resynchronization based on the response to a trap sequence ID check.

Note: The NFM-P also checks the device management parameters to adapt to a switch from one type of management to another, for example, from in-band to out-of-band.

9.4 Using multiple management interfaces

9.4.1 Overview

A default SNMP management interface on an NFM-P main or auxiliary server is defined during NFM-P system deployment. To segregate the management traffic of different groups of NEs, for example, IPv4 and IPv6 networks, you can configure additional main and auxiliary server management interfaces.

After you create the required interfaces, you must define the management network and subnets to associate with the interfaces. The NFM-P subsequently attempts to discover the NEs in each network and subnet.

Note: In a segregated network, the same NFM-P management interface must be used for the in-band and out-of-band management of an NE.

When an NE is managed in-band and out-of-band using a non-default interface, you must assign the in-band and out-of-band subnets to the interface.

9.5 Post-discovery actions on discovered NEs

9.5.1 Overview

In a discovery rule, you can create and specify a post-discovery action to perform on the successfully discovered NEs included in the rule. The NFM-P performs the post-discovery action automatically at the end of rule execution.

A post-discovery action requires an NFM-P control script that manages the auto-configuration actions performed on discovered NEs.

For example, an operator specifies a control script as a post-discovery action in a discovery rule for a subnet. The control script co-ordinates the execution of device-specific child control scripts. The child control scripts call XML API scripts that each configure a group of discovered NEs, such as aggregation ring or IP backhaul NEs. After the NFM-P executes the discovery rule, it invokes the control script to auto-configure the successfully discovered NEs in the subnet.

Note: Because a post-discovery action is intended to be autonomous, the NFM-P displays an error message and halts a post-discovery action that requires user interaction.

Workflows could be used to perform post-discovery actions..

From the Managed State tab of the Discovery Manager form, you can do the following:

- List the post-discovery action associated with each managed NE.
- View the status of the script execution as it occurs.
- View the script run result.

The Node Discovery Control form of an NE displays additional information and allows post-discovery action management. See 9.26 “To manage a post-discovery action failure on an NE” (p. 315) for more information.

9.5.2 Post-discovery action design considerations

The following conditions apply to post-discovery actions.

- The NFM-P performs no logic validation of the associated scripts.
- Deletion of the associated control script is blocked.
- After a discovery rule runs, the action is not automatically executed on new NEs that are added to the rule. To execute the action on the new NEs, you must rescan the network using the rule.
- An action is performed on an NE only when the Full Resync Status of the NE is Full Resync Done.
- If a device fails discovery, the action is not performed, and the script execution status is Not Executed. Resynchronization of the NE does not invoke the script or change the execution status.
- If the control script execution fails, an alarm is raised.
- After a post-discovery action is performed on an NE:
  - Unmanaging and remanaging the NE has no effect.
  - Deleting and rediscovering the NE causes the action to be performed on the NE.

9.6 Configuring SSH security on devices

9.6.1 About the SSH protocol

The SSH protocol provides secure file transfer and file system access between the NFM-P and managed NEs. SSH version 2, or SSH2, is enabled by default on many devices. SSH2 uses paired public and private encryption keys to perform authentication. After an SSH key pair is generated on an NE, the private key is stored locally, and the public key is used by SSH2 clients. A public key persists in the NFM-P for future SSH2 communication with the NE, and is used to verify that the client is connecting to the correct SSH2 entity. An SSH2 server on an NE identifies itself to a client by sending a message that is signed using the private key of the server. The NFM-P uses the public key of the SSH2 server to authenticate the server identity.

9.6.2 SSH2 host key management

An NE sends an SSH2 host key when the NFM-P first tries to establish an SSH2 connection. The NFM-P automatically accepts the public key fingerprint and stores it locally. The NFM-P uses the local fingerprint copy for authentication during subsequent sessions.

If an NE sends a different host key in a subsequent session, the NFM-P rejects the connection attempt and raises an alarm. If an operator determines that the host key change is valid, for example, because of an NE reboot while host key persistence on the NE is disabled, the operator can manually delete the mismatched host key from the NFM-P and accept the new key. The NFM-P subsequently accepts SSH2 connection requests from the NE.

Note: Nokia recommends that you enable host key persistence on an SSH2 NE to retain the public key fingerprint after NE reboots. If public key persistence is disabled, connection attempts after an NE reboot fail until an NFM-P operator manually deletes the stored key. See 9.34 “To manually accept a mismatched SSH host key” (p. 323) for information about deleting a mismatched host key.

By default, SSH host keys persistence is disabled on the 7210 SAS, 7450 ESS, 7705 SAR, 7750 SR, and 7950 XRS.

9.6.3 SSH2 and device CLI sessions

When SSH2 for CLI sessions is enabled in the mediation policy of an SSH2-capable device, SSH2 instead of Telnet is used for each CLI session.

SSH1 is used only in SSH CLI sessions on NEs that do not support SSH2. SSH1 is not supported for communications with GNEs.

9.6.4 SSH2 and secure file transfers

When secure file transfers are specified in the mediation policy of an SSH2-capable device, SCP is used instead of FTP for backups, restores, software upgrades, and statistics collection.

9.7 Mediation and event notification policies

9.7.1 Mediation policies

To discover and manage devices in your network, you must create a mediation security policy to setup the security and communication infrastructure between the NFM-P and each device within the specified discovery rule IP range.

You can also optionally configure other mediation policies to specify other network mediation tasks such as specifying the polling interval for MIB configuration changes, how the NFM-P processes specific events, and how the NFM-P pings devices in the network to ensure they are reachable.

Caution: When configuring a mediation policy, you need use a community string that uses rwa in order for the trap destination is set on the NE. This ensures fault conditions and alarms are reported.

The following table describes the device mediation policies you can configure using the NFM-P.

Table 9-1 NFM-P device mediation policies

Policy type	Purpose	See
Mediation security	Defines the network security model and communication protocols used to discover and manage NEs for all NFM-P user types except LI users. The policy specifies the SNMP, CLI, and file transfer settings, and the credentials for security functions. A discovery rule requires a mediation security policy for: • read access • write access • SNMP trap access	9.17 “To configure device mediation” (p. 301)
MIB entry	Defines the interval at which the NFM-P polls NEs MIBs for configuration changes.	
Management ping	Defines the management IP address of the device that the NFM-P pings periodically to verify reachability. You can specify which of the following interfaces the NFM-P pings: • Out of Band Management Interface Ping • In Band Management Interface Pin • Standby CPM Ping	
Event notification	Defines how the NFM-P processes specific SNMP events from specific NE types and releases. See 9.7.2 “Event notification polices” (p. 285) in this section for more information.	
LI mediation security	Defines the network security model used for LI mirror service creation; LI users do not use a standard mediation security policy. The policy specifies the NE LI user credentials, the authentication and privacy protocol types, and the required passwords. The NFM-P GUI displays an LI mediation security policy only for an LI user. See Chapter 94, “Lawful Intercept” for information about configuring LI.	94.14 “To configure an LI security mediation policy” (p. 3207)

9.7.2 Event notification polices

CAUTION

Service Disruption

The NFM-P uses SNMP notifications to verify network management functions. Before you configure an event notification policy, consult Nokia support to ensure that you do not disable the processing of traps that the NFM-P requires.

To reduce the NFM-P processing load associated with SNMP events, you can configure a policy that specifies which SNMP traps the NFM-P processes. An event notification policy acts as a filter that enables or disables the processing of specific SNMP traps for a specific NE type and release.

An NFM-P operator with an admin or operations scope of command role and write access permission to the policy package can create an event notification policy during mediation configuration. The NFM-P assigns a default event notification policy to an NE during initial device discovery. You can optionally specify which traps to process and which to ignore; processing is enabled for all supported traps in the default policy.

The following conditions apply to event notification policies:

- After an NE upgrade, the NFM-P processes the new traps generated by the upgraded NE. An NFM-P administrator must ensure that the event notification policies that are in effect before an NE upgrade are correctly configured, and must modify them after the upgrade for new traps, as required.
- An NFM-P software upgrades does not affect an existing policy.

SNMP statistics that include the number of ignored traps for an NE are available from the Statistics tab of an NE properties form.

9.8 NE resynchronization

9.8.1 Full and custom NE resynchronization

The Resync contextual menu option for an object specifies that SNMP MIB and CLI information bases for the object are reread to resynchronize them with the NFM-P database. The NFM-P database is updated to reflect the NE information. When you choose the Resync option at the NE level, you can choose to resynchronize all MIBs or perform a customized resynchronization. When you choose to resynchronize all MIBs, the color of the NE object in the navigation tree is yellow during the resynchronization. When you choose a customized resynchronization, you can choose the MIB entries to synchronize. See 9.33 “To partially or fully resynchronize NEs with the NFM-P database” (p. 322) for more information about performing NE resynchronizations.

If SNMP streaming is enabled on an NE, the resynchronization time may be significantly reduced in a high-latency network. See 9.2.3 “SNMP streaming” (p. 279) in “Discovering devices using the NFM-P” (p. 277) for more information.

9.8.2 Initial synchronization

An NFM-P operator must ensure that the discovery of each managed NE completes successfully, and that the NE and NFM-P database information are fully synchronized. The First Full Resync Done attribute on the Managed State tab of the Discovery Manager form indicates whether an NE has undergone one full resynchronization since the NE discovery, most recent NE software upgrade, or an NFM-P system upgrade. If an NE has not undergone one full resynchronization, and the Resync Status of the NE on the Resync Status tab is Resync Failed, the operator must manually resynchronize the NE.

9.8.3 Scheduled NE resynchronization

Some MIBs and device types are set with a scheduled resynchronization value when the device is discovered. Resynchronization is scheduled to capture any device changes that are not event notified or available in SNMP traps. Scheduled polling can be added or changed for MIBs as needed. Scheduled resynchronization is enabled in the Polling tab in the device properties and configured in the Mediation menu. See 8.10 “To configure polling for a 7250 IXR, 7450 ESS, 7705 SAR, 7750 SR, 7950 XRS, VSR, or Wavence SM” (p. 260) and 9.17 “To configure device mediation” (p. 301) for more information.

9.8.4 Resynchronization status

The Resync Status tab of the Discovery Manager form displays the following resynchronization attributes for each managed NE; the attributes are updated after an attempted resynchronization of all MIBs, but not after a customized resynchronization attempt:

- Resync Status
- Last Resync Start Time
- Last Resync End Time
- Scheduled Resync Status
- Last Scheduled Resync Start Time
- Last Scheduled Resync End Time

The Resync Status value is one of the following:

- Full Resync Done—a resynchronization has successfully completed
- Full Resync Failed—a resynchronization attempt has failed

  Full Resync Failed does not indicate that the SNMP agent on the NE is unreachable; if the agent is unreachable, an alarm is raised against the NE and the NE icon color changes to red. When the agent is again reachable, the alarm clears and the NE icon color changes to green.
- In Progress—a resynchronization is in progress
- Not Attempted—no resynchronization has been requested
- Requested—the resynchronization request is queued for processing.

The Scheduled Resync Status value is one of the following:

- In Progress—a resynchronization is in progress
- Not Attempted—no resynchronization has been requested
- Scheduled Resync Done—a resynchronization has successfully completed
- Scheduled Resync Failed—a resynchronization attempt has failed

9.9 Server resource management

9.9.1 Resource grouping

CAUTION

Service Disruption

Only a qualified Nokia support representative can assess or configure NFM-P server resource management. Contact Nokia technical support for more information.

The NFM-P supports the grouping of NEs by network function for increased SNMP mediation efficiency.

Resource allocation is automatically configured during NFM-P installation and network discovery based on the available system resources, and the numbers and types of NEs that are to be managed. The resource group to which an NE belongs is initially determined by the device type. The following are the NFM-P NE resource groups and the default device assignments:

- global—for NFM-P tasks that are not associated with NEs
- default—for NEs that do not belong to a specific resource group
- core—for 7450 ESS, 7750 SR, and 7950 XRS devices
- middle—for 7210 SAS and 7705 SAR devices
- edge—for OmniSwitch and similar devices
- GNE—for other network devices

The NFM-P logs the system load of each resource group at regular intervals. An Nokia support representative can monitor system resource usage, determine whether the current resource allocation is appropriate, and reconfigure resource management, if required.

9.10 Workflow for device discovery

9.10.1 Stages

Preconfigure device for management

1

Configure the Nokia and GNE devices for management; see Chapter 8, “Device commissioning and management” .

Configure SNMP

2

As required, enable SNMPv3 device management; see 9.11 “To enable SNMPv3 management of a device” (p. 291) .

3

As required, enable or disable SNMP streaming on a device for configuration data transfers to the NFM-P; see 9.14 “To enable or disable SNMP streaming on an NE” (p. 299) .

Configure SSH

4

As required, configure SSH for secure device CLI access.

1. Configure SSH servers on devices; see the device documentation for configuration information.
2. Ensure that SSH2 is enabled on devices; see 9.15 “To verify that SSH2 is enabled on a device” (p. 300) .
3. Enable SSH2 host key persistence on devices that support host key persistence; see 9.16 “To enable SSH host key persistence on a device” (p. 301) .

Configure device mediation

5

Specify the network mediation parameters, and optionally configure the following mediation policies for devices in specific discovery rules; see 9.17 “To configure device mediation” (p. 301) :

- MIB entry policies that define how to poll specific device MIBs for changes
- management ping policies that define periodic device connectivity checks
- event notification policies that define how the NFM-P processes SNMP traps

6

As required, assign event notification policies to devices; see 9.18 “To assign an event notification policy to an NE” (p. 305) .

Configure additional management networks

7

If required, configure one or more additional management networks.

1. Define the management network and subnets to associate with non-default management interfaces on main and auxiliary servers; see 9.19 “To configure a management network” (p. 306) .
2. Create additional main-server management interfaces; see 9.20 “To configure an additional management interface on a main server” (p. 307) .
3. Create additional auxiliary-server management interfaces; see 9.21 “To configure an additional management interface on an auxiliary server” (p. 308) .

Configure device discovery

8

If required, create a workflow for post-discovery actions using Workflows.

9

If required, create post-discovery actions; see 9.22 “To configure a post-discovery action” (p. 309) .

Note: You can also create post-discovery actions during discovery rule creation.

10

Create the required device discovery rules and use the rules to discover devices; see 9.23 “To configure a discovery rule” (p. 310) .

11

Manage discovery rules; see 9.24 “To enable, disable, or delete a discovery rule” (p. 313) .

12

As required, manage the post-discovery actions in discovery rules.

a. View the execution status of an associated script; see 9.25 “To view the post-discovery action execution status” (p. 314) .

b. Manually execute a failed script; see 9.26 “To manage a post-discovery action failure on an NE” (p. 315) .

Incidental tasks

13

As required, perform the following.

a. Change the management state of a device; see 9.27 “To manage, suspend, or unmanage a device” (p. 316) .

b. Change from SNMPv2c to SNMPv3 management of a device; see 9.29 “To change from SNMPv2 to SNMPv3 management of a device” (p. 318) .

c. Switch from non-secure to secure mediation; see 9.30 “To switch from non-secure to secure mediation” (p. 319) .

d. Specify which management IP address is saved for a device when the device is set to an unmanaged state; see 9.31 “To specify which management address the NFM-P uses to remanage a device” (p. 321) .

e. Rescan the network using a discovery rule; see 9.32 “To rescan the network for a device according to a discovery rule” (p. 322) .

f. Synchronize the NFM-P information with the device configuration; see 9.33 “To partially or fully resynchronize NEs with the NFM-P database” (p. 322) .

g. Manage SSH2 host key acceptance; see 9.34 “To manually accept a mismatched SSH host key” (p. 323) and 9.35 “To view the SSH2 host keys to identify active and mismatched keys” (p. 324) .

h. View and save collected SNMP MIB information; see 9.36 “To list and save SNMP MIB information” (p. 324) .

i. Delete a device from the NFM-P; see 9.37 “To delete a device from the managed network” (p. 325) .

Procedures for device discovery

9.11 To enable SNMPv3 management of a device

9.11.1 Before you begin

If you are configuring an NE for LI, you must create a second access group. See Chapter 94, "Lawful Intercept" for information about creating an LI user and access group.

SROS 22.2 R1 and later NEs do not support some combinations of authentication and privacy:

- hmac-md5-96 cannot be combined with cfb128-aes-192 or cfb128-aes-256
- hmac-sha1-96 cannot be combined with cfb128-aes-192 or cfb128-aes-256
- hmac-sha2-224 cannot be combined with cfb128-aes-256

9.11.2 Steps

1

Open a CLI session on the device.

2

Enter the following commands in the order shown to create a read-write-notify group for general SNMP mediation on the managed device:

```
configure system security snmp ↲
access group "SNMPv3_group" security-model usm security-level privacy
read "iso" write "iso" notify "iso" ↲
```

where

SNMPv3_group is the name to assign to the new SNMP group

3

If mediation of VPRN objects is required (for configured VPRN or internal VPRN from an Ethernet satellite), enter the following command to create a read-write-notify group for this purpose on the managed device:

```
access group "SNMPv3_group" security-model usm security-level privacy
context vprn prefix read "vprn-view" write "vprn-view" notify "iso" ↲
```

where

SNMPv3_group is the name to assign to the new SNMP group

4

Enter the following command to exit the SNMP group configuration.

```
exit ↲
```

5

Enter the following command to obtain the SNMP engine ID of the device.

show system info ↵

The SNMP engine ID is displayed as SNMP Engine ID.

6

Generate an authentication key and a privacy key.

- An authentication key is used to encrypt a user password.
- A privacy key is used to encrypt the user SNMP packets.

Note: The key authentication method determines the key length.

1. Log in to an NFM-P single-user client, client delegate server, or main server station.

   Note:

   If you log in to a RHEL main or client delegate server station, you must log in as the nsp user.

   If you log in to a single-user client station, you must log in as the user who installed the client, or as a local administrator.

2. Open a console window.
3. On a RHEL station, navigate to the *install_directory*/nms/bin directory, where *install_directory* is one of the following:
   - the NFM-P main server installation location, /opt/nsp/nfmp/server
   - the NFM-P single-user client or client delegate server installation location, typically /opt/nsp/client
4. On a Windows station, navigate to the *install_directory*\nms\bin directory, where *install_directory* is the NFM-P single-user client or client delegate server installation location, typically C:\nsp\client.
5. Enter one of the following to create an authentication key:
   - on a RHEL station:

     ./nmsclient.bash password2key *method password engine_ID* ↵
   - on a Windows station:

     nmsclient.bat password2key *method password engine_ID* ↵

   where

   method is the authentication method, either MD5, SHA, SHA224, SHA256, SHA384 or SHA512

   password is the authentication key password

   engine_ID is the SNMP engine ID obtained in Step 5

   Note: You must enclose a password that contains a special character in single quotation marks; for example:

   password2key *method* 'Mypa$$word'

   Only use the authentication key from the output.
6. Enter the following to create a privacy key.
   - on a RHEL station:

     ./nmsclient.bash password2key *method password engine_ID* ↵

- on a Windows station:

  nmsclient.bat password2key *method password engine_ID* ↵

  where

  method is the authentication method, either MD5, SHA, SHA224, SHA256, SHA384 or SHA512

  password is the privacy key password

  engine_ID is the SNMP Engine ID of the SR, in hexadecimal form with 10-64 hex digits (5-32 bytes)

  Note: You must enclose a password that contains a special character in single quotation marks; for example:

  password2key *method* 'Mypa$$word'

  The list of privacy keys for each privacy method is displayed.

7. Store the generated keys for your applicable authentication and privacy methods.

7

Using the keys generated in Step 6 , create an SNMPv3 user on the managed device.

1. Enter the following sequence of commands at the prompt:

   configure system security user *SNMPv3_user* ↵

   access snmp ↵

   snmp ↵

   authentication *auth_method authentication_key* privacy *priv_method privacy_key* ↵

   group *SNMPv3_group* ↵

   exit all ↵

   where

   SNMPv3_user is the name to assign to the new user

   SNMPv3_group is the name of the new SNMP user group created in Step 2

   auth_method can be:

   hmac-md5-96 hmac-sha1-96 hmac-sha2-224 hmac-sha2-256 hmac-sha2-384 hmac-sha2-512

   authentication_key is the authentication key value generated in Step 6

   priv_method can be:

   cbc-des cfb128-aes-128 cfb128-aes-192 cfb128-aes-256

   privacy_key is the privacy key value generated in Step 6

2. Enter the following to save the configuration changes:

   admin save ↵

   The device is now ready for management using SNMPv3.

3. Close the CLI session.

8

Create an SNMPv3 NE user in the NFM-P.

See the section on NE user and device security in the *NSP System Administrator Guide* for specific information about creating and configuring NE users.

1. Choose Administration→Security→NE User Configuration from the NFM-P main menu. The NE User Configuration form opens.
2. Click Create. The NE User (Create) form opens.
3. Configure the parameters as follows:
   - Enter the *SNMPv3_username* value from Step 7 as the User Name.
   - Enable the SNMP option of the Access parameter.
   - On the SNMPv3 tab:
     — Configure the authentication and privacy parameters. Ensure the NEs support a valid combination of authentication and privacy protocols.
     — Enter the password used to generate the authentication key in Step 6 .
     — Enter the password used to generate the privacy key in Step 6 .

   Note: In the mediation security policy that you create for the device, you must specify the following:
   - SNMPv3 (USM) as the Security Model value
   - the *SNMPv3_user* value from Step 7 as the User Name

   See 9.17 “To configure device mediation” (p. 301) for specific information about creating and configuring mediation security policies.

9

If you are performing this procedure for device discovery, see 9.10 “Workflow for device discovery” (p. 288) for the next steps.

END OF STEPS

9.12 To enable SNMPv3 management and discover an 1830 VWM device

9.12.1 Purpose

Perform this procedure to enable SNMPv3 management of an 1830 VWM device, configure the mediation policies, and discover the 1830 VWM device.

Note: You can either use the 1830 VWM default SNMPv3 user or configure a new SNMPv3 user in the 1830 VWM device.

9.12.2 Steps

SNMPv3 user configuration in the 1830 VWM device

1

Perform the following to configure a new SNMPv3 user in the 1830 VWM device, if required.

1. Open a CLI session on the device.
2. Enter the following commands in the order shown to create a read-write-notify group for general SNMP mediation on the managed device:

   # config admin snmpusers add "*SNMPv3_user*" admin auth sha "*password*" priv des "*password*"

   # config admin snmpuser edit "*SNMPv3_user*" status enabled

   where

   SNMPv3_user is the name to assign to the new SNMPv3 user

   password is the password of the new SNMPv3 user.
3. Close the CLI session.

SNMPv3 user configuration in the NFM-P

2

Note: See the section on NE user and device security in the *NSP System Administrator Guide* for specific information about creating and configuring NE users.

Perform the following to configure an SNMPv3 user in the NFM-P.

1. Choose Administration→Security→NE User Configuration from the NFM-P main menu. The NE User Configuration form opens.
2. Click Create. The NE User (Create) form opens.
3. Enter the *SNMPv3_username* value from Step 1 or the default user name as the User Name.
4. Check the SNMP option of the Access parameter.
5. Click on the SNMPv3 tab and configure the parameters as follows:
   - Choose SHA as the Authentication Protocol.
   - Choose AES 128 as the Privacy Protocol.
   - Enter the password provided in Step 1 or the default password.
6. Save your changes and close the form.

Mediation policy configuration

3

Note: The 1830 VWM discovery rule requires the SNMPv3 read, write, and security access mediation policies and SNMPv2 trap access mediation policy.

Choose Administration→Mediation from the NFM-P main menu. The Mediation (Edit) form opens.

4

Configure the parameters on the General tab and verify the SNMP trap destination parameters in the SNMP Trap panel.

5

Click on the Mediation Security tab and click Create. The Mediation Policy (Create) form opens.

6

Configure the Policy ID and Displayed Name parameters.

7

Perform the following to configure the SNMPv3 mediation policy.

1. Configure the Security Model parameter to SNMPv3 (USM).
2. Select the required SNMPv3 user in the SNMPv3 panel.

8

Perform the following to configure the SNMPv2 mediation policy.

1. Configure the Security Model parameter to SNMP v2c.
2. Configure the Community String parameter in the SNMP v1/v2c panel.

   The community string configured in the NFM-P is automatically added in the node.

9

Configure the parameters in the SNMP panel. The Table 9-2, “ SNMP timeout” (p. 296) lists the recommended values for Timeout (milliseconds) and Retry parameters.

Table 9-2 SNMP timeout

Timeout (milliseconds)	Retry
60000	1
50000	2

10

Save your changes and close the form.

Discovery of the 1830 VWM device

11

Choose Administration→Discovery Manager from the NFM-P main menu. The Discovery Manager form opens.

12

Click Create to configure a new discovery rule. The Create Discovery Rule step form opens.

13

Configure the required parameters in the Specify General Attributes step and click Next. The Add Rule Elements step form opens.

14

Click Create, configure the required IP parameters, and click OK. The rule element is added to the list.

15

Click Next. The Add Auto Discovery Rule Elements ACL step form opens.

16

Click Create, configure the required IP parameters, and click OK.

17

Click Next and the Configure Mediation Security step form opens.

18

Click Select in each of the following panels to specify the mediation security policies. Choose the SNMPv3 mediation security policy for read, write, and security access mediation policies and choose the SNMPv2 mediation policy for trap access mediation policy.

- Read Access Mediation Policy
- Write Access Mediation Policy
- Trap Access Mediation Policy
- Security Access Mediation Policy

Note: If you do not specify a policy, the default policy is applied.

19

Click Finish to close the Create Discovery Rule form.

20

Apply your changes in the Discovery Manager form. If the Administrative State of the newly created discovery rule is set to Up, the NFM-P scans the network using the discovery rule.

END OF STEPS

9.13 To configure the AIM mediation and discovery for management of the VSR-I

9.13.1 General information

The NFM-P uses SNMPv2 or SNMPv3 to manage the AIM for VSR-I. After the AIM is discovered, the VSR-I IP is automatically added to the AIM discovery rule, so that it is automatically discovered.

Note: AIM does not support auto-registration of the NFM-P IP address for trap forwarding during discovery. You must manually enter the NFM-P IP address during AIM agent configuration at start-up so that traps from the AIM agent are sent to the NFM-P.

Note: You must configure the SNMPv2 or SNMPv3 parameters the same way for AIM and the VSR-I.

9.13.2 Steps

1

Configure an SNMPv2c or SNMPv3 mediation security policy on the NFM-P.

1. Choose Administration→Mediation from the NFM-P main menu. The Mediation (Edit) form opens.
2. Click on the Mediation Security tab.
3. Click Create. The Mediation Policy (Create) form opens.
4. Configure the Displayed Name parameter.
5. Set the Security Model parameter to SNMP v2c or SNMPv3.
6. In the SNMP panel, set the Port parameter to 161.
7. To create an SNMPv2 user on the NFM-P, go to the next step. To create an SNMPv3 user on the NFM-P, go to step 9.
8. **Create an SNMPv2 user on the NFM-P:**
   a. Configure the Community String parameter to XYZ, where XYZ is the SNMP community string configured on the AIM node.
   b. Go to step 10
9. **Create an SNMPv3 user on the NFM-P:**
   a. Choose Administration→Security→NE User Configuration from the NFM-P main menu. The NE User Configuration form opens.
   b. Click Create. The NE User, Global Policy (Create) form opens.
   c. Configure the user name and other required parameters, and choose the SNMP option for the Access parameter.

d. Click on the SNMPv3 tab and provide the authentication and privacy parameters.
e. In the CLI/NETCONF panel, configure the required parameters.

10. Save your changes.

2

Create a discovery rule for the VSR-I on the NFM-P:

a. Choose Administration→Discovery Manager from the NFM-P main menu. The Discovery Manager (Edit) form opens.
b. Click Create. The Create Discovery Rule step form opens.
c. In step 1 (Specify General Attributes), configure the required parameters, then click Next.
d. In step 2 (Add Rule Elements), click Create. The Topology Discovery Rule Element (Create) form opens.
e. Enter the AIM management IP address as the rule element for the discovery rule.
f. Click OK, then click Next.
g. In step 3 of the step form (Configure Mediation Security), click Select and choose the mediation security policy that you created in step 1 for the Read Policy ID, Write Policy ID, and Trap Policy ID parameters.
h. Save your changes.

3

Use the NFM-P client to discover the VSR-I. The NFM-P discovers both AIM and VSR-I in a new topology group under the equipment tree named VSR-a..

END OF STEPS

9.14 To enable or disable SNMP streaming on an NE

9.14.1 Purpose

Perform this procedure to control whether an NE uses SNMP streaming for configuration data transfers to the NFM-P.

9.14.2 Steps

1

Right-click on an NE in the network navigation tree and choose Properties. The NE properties form opens.

2

Click on the Polling tab, then on the Management tab.

3

Configure the Enable SNMP Streaming parameter.

4

Save your changes and close the form.

5

If you are performing this procedure for device discovery, see 9.10 “Workflow for device discovery” (p. 288) for the next steps.

END OF STEPS

9.15 To verify that SSH2 is enabled on a device

9.15.1 Purpose

Perform this procedure to verify that SSH2 is enabled on a device, and to enable SSH2 on the device, if required.

9.15.2 Steps

1

Open a CLI session on the device.

2

Run the following CLI command to see whether SSH2 is enabled:

```
show system security ssh ↵
```

3

If required, enter the following command at the prompt to enable SSH2:

```
configure system security ssh version 2 ↵
```

Note: A 7705 SAR may become temporarily unreachable after you enable SSH and start the SSH server on the device.

4

Close the CLI session.

5

If you are performing this procedure for device discovery, see 9.10 “Workflow for device discovery” (p. 288) for the next steps.

END OF STEPS

9.16 To enable SSH host key persistence on a device

9.16.1 Purpose

Perform this procedure to enable the persistence of the server host key on a 7210 SAS, 7450 ESS, 7750 SR, 7705 SAR, or 7950 XRS. For other devices, see the user documentation for information about configuring SSH2 host key persistence.

9.16.2 Steps

1

Open a CLI session on the device.

2

Enter the following at the prompt to disable the SSH server:

```
configure system security ssh server-shutdown ↵
```

3

Enter the following at the prompt to enable host key persistence:

```
configure system security ssh preserve-key ↵
```

4

Enter the following at the prompt to enable the SSH server:

```
configure system security ssh no server-shutdown ↵
```

5

Enter the following at the prompt to verify that the preserve-key function is enabled on the server:

```
show system security ssh ↵
```

6

Close the CLI session.

7

If you are performing this procedure for device discovery, see 9.10 “Workflow for device discovery” (p. 288) for the next steps.

END OF STEPS

9.17 To configure device mediation

9.17.1 Purpose

Perform this procedure to create a mediation policy.

As part of creation of a mediation policy, you will configure the following communication and security policies for discovery rules:

- MIB entry policies that define how to poll specific device MIBs for changes
- management ping policies that define periodic device connectivity checks
- event notification policies that define how the NFM-P processes SNMP traps

Note: LI mediation has special configuration requirements; see 94.14 “To configure an LI security mediation policy” (p. 3207) for information.

Note: To configure SNMPv3 security, you must preconfigure the NFM-P and managed devices. See 9.11 “To enable SNMPv3 management of a device” (p. 291) for information.

Note: For Wavence SNMPv3 password information, see the Wavence documentation.

9.17.2 Steps

1

Choose Administration→Mediation from the NFM-P main menu. The Mediation (Edit) form opens.

2

Configure the parameters on the General tab.

3

Configure a mediation security policy.

Note: Some NEs require specific mediation security policies. See the NFM-P device-specific documentation for information.

1. Click on the Mediation Security tab.
2. Click Create or choose the default policy and click Properties. The Mediation Policy form (Create | Edit) opens.
3. Configure the general policy and SNMP mediation parameters.

   Note:

   The Community String value must match the community string value on the managed device.
4. If you set the Security Model parameter to SNMPv3 (USM), click Select to choose the required SNMPv3 user. SNMPv3 user creation is described in 9.11 “To enable SNMPv3 management of a device” (p. 291) .

   Note:

   If you specify the use of SNMPv3 in the policy, you must enable SSH2 in the policy.
5. Configure the remaining parameters.

   Note:

If you choose Secure as the File Transfer Type value, you must set the Communication Protocol parameter to SSH2.

To use SSH2, you must enable SSH2 and host key persistence on the SSH server of the device. See 9.6 “Configuring SSH security on devices” (p. 283) for information about configuring SSH2.

If you choose SSH2 as the Communication Protocol, you must specify the mediation policy for read and write access in the discovery rule of the device.

If you choose SSH2 as the Communication Protocol, the User Name and User Password parameters must be the SSH user name and password configured on the device.

See Chapter 8, “Device commissioning and management” for information about enabling FTP access for a device user account.

6. Save your changes and close the form.

4

To configure one or more MIB Entry policies, perform the following steps.

1. Click on the MIB Entry Policies tab and click Search. A list of MIBs appears, organized by the product name of the device that supports the MIB.
2. Choose one or more MIBs from the list and click Properties. The MIB Entry Policy (Edit) form opens.
3. Configure the required parameters in the Configuration panel.

   Caution: Changing the Number of Varbind per PDU value may affect the time required for subsequent NE resynchronizations and degrade NFM-P system performance. Do not configure the parameter without consulting Nokia technical support.
4. Save your changes and close the form.

5

To configure a management ping policy, perform the following steps. A management ping policy specifies how the NFM-P checks the connection to device management IP addresses. Each managed device may provide one or more of the following addresses:

- the system IP address, which is an in-band management interface
- the management IP address, which is an out-of-band management interface
- the IP address of the standby CPM

Note: When the device does not have one or two of the IP addresses, for example, there is no CPM IP address, ensure that you do not enable the schedule on the ping policy assigned to missing interfaces. This allows the assignment of an inactive ping policy during discovery configuration.
The destination interface of the ping is determined during discovery-rule creation. You can also perform an unscheduled ping from the Managed State tab of the Discovery Manager configuration form.
You can view management connection alarms from the NE properties form of the managed device that was pinged. For example, from the Discovery Manager form, click on the Resync Status tab. Choose a device from the list and click Properties. From the NE properties form, click on the Faults tab to view the alarms.

1. Click on the Ping tab.
2. Click Create or choose a ping policy and click Properties. The Management Ping Policy (Create | Edit) form opens.
3. Configure the required parameters.

   Note:

   You must enable scheduling for a ping policy to be active. When scheduling is not enabled, and an assigned managed device is not reachable, management connection alarms may not be raised.
4. Save your changes and close the form.

6

CAUTION

Service Disruption

The NFM-P uses SNMP notifications to verify network management functions. Before you configure an event notification policy, consult Nokia support to ensure that you do not disable the processing of traps that the NFM-P requires.

To configure event notification policies, perform one of the following. Otherwise, go to Step 8 .

a. Select a default trap policy from the list and click Properties. The Event Notification Policy (Edit) form opens.

b. Create an event notification policy:
   1. Click on the Event Notification Policies tab.
   2. Click Create or select a policy and click Properties. The Event Notification Policy (Create | Edit) form opens.
   3. Configure the parameters.
   4. Click OK. The policy is listed on the form.
   5. Apply the changes in the Mediation (Edit) form.
   6. Select the new policy in the list and click Properties. The Event Notification Policy (Edit) form opens.

7

Enable or disable collection of traps in a policy.

Note: You cannot configure the Administrative State parameter in a default event notification policy. A default policy is indicated by a check mark beside the Default Policy indicator on the General tab of the Event Notification Policy (Edit) form.

1. Click on the Notification Policies tab. A list of SNMP traps is displayed.
2. Select an SNMP trap entry in the list and click Properties. The MIB Entry Policy - trappolicy (Edit) form opens.
3. Configure the Administrative State parameter.

4. Save your changes and close the forms.

8

Click OK to save your changes and close the Mediation (Edit) form.

9

If you are performing this procedure for device discovery, see 9.10 “Workflow for device discovery” (p. 288) for the next steps.

END OF STEPS

9.18 To assign an event notification policy to an NE

CAUTION

Service Disruption

The NFM-P uses SNMP notifications to verify network management functions. Before you assign an event notification policy to a device, consult Nokia support to ensure that you do not disable the processing of traps that the NFM-P requires.

9.18.1 Steps

1

On the equipment tree, right-click on an NE icon and choose Properties. The Network Element (Edit) form opens.

2

Click on the Polling tab and click Clear in the Assigned Event Notification Policy panel. The Select button in the panel is enabled.

3

Select an event notification policy.

4

Save your changes and close the form.

5

If you are performing this procedure for device discovery, see 9.10 “Workflow for device discovery” (p. 288) for the next steps.

END OF STEPS

9.19 To configure a management network

9.19.1 Purpose

Perform this procedure to create a management network and subnets to segregate the traffic between the non-default management interfaces on the main and auxiliary servers.

9.19.2 Steps

1

Choose Administration→System Information from the NFM-P main menu. The System Information form opens.

2

Click on the Management Networks tab.

3

Click Create. The Management Network (Create) form opens.

4

Configure the required parameters.

5

Click on the Management Interfaces tab.

6

Click Add. The Select Interface for Management Network (Create) form opens.

7

Click Search. The management interfaces are listed.

Note: The default management interfaces are not listed.

8

Select an interface and click OK.

9

In a redundant NFM-P system, you must assign one interface from each main server to a managed network.

To add another interface, repeat Step 6 to Step 8 .

10

Click on the Management Subnets tab.

11

Click Create. The Management Subnet (Create) form opens.

12

Configure the required parameters.

Note: The Subnet Address value that you specify must include a mask that is between /24 and /32 for IPv4 NEs, and between /120 and /128 for IPv6 NEs.
The subnets must not overlap.

13

To create an additional subnet, click Apply to save your changes and repeat Step 12 .
Otherwise, click OK to save your changes and close the form.

14

Click Apply to save your changes. The NFM-P attempts to discover NEs in the subnets using the associated interfaces. The discovered NEs are listed on the Member Network Elements tab.

15

Save your changes and close the forms.

16

If you are performing this procedure for device discovery, see 9.10 “Workflow for device discovery” (p. 288) for the next steps.

END OF STEPS

9.20 To configure an additional management interface on a main server

Note: In a redundant NFM-P system, you must configure management interfaces for the required networks and subnets on each main server. Otherwise, visibility of the networks and subnets is lost after a server activity switch.

9.20.1 Steps

1

Choose Administration→System Information from the NFM-P main menu. The System Information form opens.

2

Click Properties in the Primary Server panel. The Main Server (Edit) form opens.

3

Click on the Management Interfaces tab.

4

Click Create. The Management Interface (Create) form opens.

5

Configure the required parameters.

6

Click OK. The interface appears in the list.

7

Save your changes and close the forms, as required.

8

If you are performing this procedure for device discovery, see 9.10 “Workflow for device discovery” (p. 288) for the next steps.

END OF STEPS

9.21 To configure an additional management interface on an auxiliary server

9.21.1 Steps

1

Choose Administration→System Information. The System Information form opens.

2

Click on the Auxiliary Servers tab.

3

Select an auxiliary server and click Properties. The Auxiliary Server (Edit) form opens.

4

Click on the Management Interfaces tab.

5

Click Create. The Management Interface (Create) form opens.

6

Configure the required parameters.

7

Click OK. The interface appears in the list.

8

Save your changes and close the forms, as required.

9

If you are performing this procedure for device discovery, see 9.10 “Workflow for device discovery” (p. 288) for the next steps.

End of steps

9.22 To configure a post-discovery action

9.22.1 Purpose

Perform this procedure to create a post-discovery action that you can associate with one or more discovery rules.

Note: You can also create a post-discovery action during discovery rule creation.

9.22.2 Steps

1

Choose Administration→Discovery Manager from the NFM-P main menu. The Discovery Manager form opens.

2

Click on the Post Discovery Actions tab.

3

Click Create or select a post-discovery action and click Properties. The Post Discovery Action (Create | Edit) form opens.

4

Configure the required parameters.

5

Click Select beside the Control Script Name parameter and choose a control script.

6

Click Select beside the Control Script Instance Name parameter and choose a control script instance.

7

Save your changes and close the form.

8

If you are performing this procedure for device discovery, see 9.10 “Workflow for device discovery” (p. 288) for the next steps.

END OF STEPS

9.23 To configure a discovery rule

9.23.1 Purpose

Perform this procedure to configure a discovery rule that contains the mediation, IP information, and policies required to add NEs or EMS to the managed network.

9.23.2 Steps

1

Choose Administration→Discovery Manager from the NFM-P main menu. The Discovery Manager form opens.

2

Click Create to create a new discovery rule. The Create Discovery Rule step form opens.

Note: When you are finished each step, click Next to advance to the next step. You can click Finish at any time.
Depending on the purpose of the discovery rule, not every step in this procedure needs to be completed.

3

Configure the required parameters in the Specify General Attributes step.

Note: When you close the Discovery Manager form, the NFM-P scans the network using the discovery rule, if the Administrative State parameter of the discovery rule is set to Up. The Group Name parameter specifies the equipment group that discovered NEs are added to. If the selected equipment group reaches the maximum element limit, any additional discovered NEs are automatically added to the Discovered NEs group.
The Discovered NEs Group Name cannot be chosen when configuring a Discovery Rule for an EM system.

4

To add rule elements in the Add Rule Elements step, click Create, configure the required IP parameters, and click OK. The rule element is added to the list.

5

To add auto discovery rule elements in the Add Auto Discovery Rule Elements ACL step, click Create, configure the required parameters, and click OK. The rule element is added to the list.

6

In the Configure Mediation Security step, click Select in each of the following panels, as required, to specify the mediation security policies for:

- Read Access Mediation Policy
- Write Access Mediation Policy
- Trap Access Mediation Policy
- Security Access Mediation Policy

Note: If you do not specify a policy, the default policy is applied.
A Wavence MSS-1c discovery rule requires the default SNMPv2 read and write access policies.

7

In the Configure Management Ping Policy step, click Select in each of the following panels, as required, to specify the ping policies for:

- Out Of Band Management Interface Ping
- In Band Management Interface Ping
- Standby CPM Ping

Note: If you do not specify a policy, the default policy is applied.
Management ping policies are created using the Mediation configuration form. These are the policies applied during discovery rule creation. You must apply a ping policy even to interfaces that do not exist. When there is no interface, you must choose a ping policy that has its Schedule Enabled parameter set to disabled.
For example, if there is no standby CPM or out-of-band management IP address, specify a ping policy that has the Schedule Enabled parameter set to disabled for the nonexistent management and standby CPM interfaces. In this example, a ping policy with the Schedule Enabled parameter enabled is required for the in-band interface that does exist.
See 9.17 “To configure device mediation” (p. 301) for information about creating ping policies.

8

In the Configure MIB Statistics Policy step, select a MIB statistics policy, if required.

9

In the Add Discovered Routers to Span(s) step, click Add to specify a span of control for the new NE contained in the discovery rule. If you do not specify a span, the default span is applied.

Note: New devices added to a span from a discovery rule are added explicitly to the span. When a discovered NE group is part of a user-defined span, new devices that are discovered using the discovery rule are automatically added to the span.

10

In the Configure Backup Policy step, select a backup policy, if required. If you do not specify a backup policy, the default policy is applied.

11

If the NFM-P manages wireless NEs in your network, perform the Add NE Self Config Policies step.

12

To configure an EMS in the Add EM Systems step:

1. Click Create. The EM System (Create) form opens.
2. Configure the required parameters in the General tab.
3. Click on the Element Managers tab.
4. Click Create. The Element Manager (Create) form opens.

   Note:

   After discovering an EM system, the system should be opened and its administrative state set to Up in order to enable the connection to the NFM-P. A maximum of four EM Systems may have their administrative state set to Up at any time within the NFM-P.

   A manual resynchronization must be performed in order for alarms from an EM system to be displayed in the NFM-P. This does not apply to the NEtO EM system for Wavence devices; alarms are aggregated automatically provided the Trap Access Mediation policy in the Discovery step form is configured.

   The NFM-P is able to manage 10 000 alarms per EM system. When this limit is reached, a critical alarm is raised and new incoming alarms are deleted. When the alarm counter for the EM System drops to 9000, the critical alarm is cleared and the NFM-P performs an alarm resynchronization on the EM system.
5. Configure the required parameters for host, communication, and identification.
6. Save your changes and return to the Create Discovery Rule form.

13

To specify a post-discovery action in the Add Post Discovery Action step, perform one of the following:

a. Click Select and use the list form that opens to associate an existing post-discovery action with the discovery rule.

b. Create a post-discovery action to associate with the discovery rule. Perform the following steps.
   1. Click Select. The Select Post Discovery Action form opens.
   2. Click Create. The Post Discovery Action (Create) form opens.
   3. Configure the required parameters:
   4. Click Select beside the Control Script Name parameter and use the list form that opens to choose a control script.
   5. Click Select beside the Control Script Instance Name parameter and use the list form that opens to choose a control script instance.
   6. Save your changes and close the form.
   7. Select the new post-discovery action and click OK. The new post-discovery action is associated with the discovery rule.

14

Click Finish to close the Create Discovery Rule form.

15

Apply your changes in the Discovery Manager form. If the Administrative State of the newly created discovery rule is set to Up, the NFM-P scans the network using the discovery rule.

16

See 9.10 “Workflow for device discovery” (p. 288) for other optional steps.

END OF STEPS

9.24 To enable, disable, or delete a discovery rule

9.24.1 Before you begin

When a discovery rule is enabled, the network is scanned according to the discovery rule when the discovery rule is saved or rescanned. The network is also scanned according to the discovery rule as specified by the Discovery Rule Scan Interval parameter in the Mediation form. If your discovery rule is disabled, the network is not scanned as specified by these conditions.

When you delete a discovery rule, only the rule is removed. The NEs discovered using the rule are not removed from the NFM-P, but the Discovery Rule ID for each of the NEs set to 0.

9.24.2 Steps

1

Choose Administration→Discovery Manager from the main menu. The Discovery Manager (Edit) form opens.

2

Select a discovery rule and click Turn Up to enable the rule, Shut Down to disable the rule, or Delete to delete the rule.

3

Close the form.

END OF STEPS

9.25 To view the post-discovery action execution status

9.25.1 Steps

1

Choose Administration→Discovery Manager from the NFM-P main menu. The Discovery Manager form opens.

2

Click on the Managed State tab.

3

View the entries in the Script Execution Status column. The possible values are:

- unspecified—post-discovery action not specified in discovery rule
- Pending—post-discovery action execution awaits discovery completion
- Not Executed—control script not executed
- In Progress—control script execution in progress
- Successful—control script execution completed without failure indication
- Failed—control script execution unsuccessful
- Cleared—Failed state manually cleared

4

For each NE that has a Failed entry, perform the following steps to view the script execution result.

1. Click Show Results. The Results form for the NE opens.
2. Click Search. A list of script results is displayed.
3. Select a result in the list and click Properties. The View Result form opens. The form displays information such as the script name, version, run time, and execution status.
4. View the information to determine the required corrective action.
5. If required, perform the following steps to export the result information to a file.
   - Choose File→Export from the View Result form main menu, or click on the Export icon. The Export form opens.

- Navigate to the location in which you want to save the file, and enter a filename in the File Name field.
- Click Export. The result text is saved in the specified file.

Note:

You can also export a script result to a file using the Export button on the Results form for the NE.

5

To delete a result, perform the following steps.

1. Select the result on the Results form and click Delete. A dialog box appears.
2. Click Yes. The result is deleted.

END OF STEPS

9.26 To manage a post-discovery action failure on an NE

9.26.1 Purpose

Perform this procedure to do the following:

- reset the script execution status for an NE
- manually run the post-discovery action script against the NE

This action may be required after the script associated with a post-discovery action fails and the cause of the failure is corrected.

Note: Clearing the status also clears the associated alarm that is raised when post-discovery script execution fails.

9.26.2 Steps

1

Choose Administration→Discovery Manager from the NFM-P main menu. The Discovery Manager form opens.

2

Click on the Managed State tab.

3

Select an NE with an Execution Status of Failed and click Properties. The Node Discovery Control (Edit) form opens.

4

Click on the Post Discovery tab.

5

Click Clear. The Script Execution Status changes from Failed to unspecified.

6

To execute the script:

1. Click Execute Script. The Execute script form opens.
2. Click Execute. The script executes, and a script object is displayed in the navigation tree of the form.
3. Select the script object in the navigation tree.
4. Expand the Status and Script Results panels on the right side of the form to reveal the script execution information.
5. Click Save Result to save the result in the NFM-P database.

7

Close the forms, as required.

END OF STEPS

9.27 To manage, suspend, or unmanage a device

9.27.1 Purpose

CAUTION

Service Disruption

Suspending the management of a device results in a loss of communication with the device.

Unmanaging a device results in a loss of management data for the device. See 9.3.2 "Unmanaging and deleting devices" (p. 280) in "Discovering devices using the NFM-P" (p. 277) for more information.

Unmanaging a device results in the loss of all historical AA statistics for the device.

When you suspend the management of a device, the NFM-P raises a critical alarm against the device.

Perform this procedure to change the management state of a device.

9.27.2 Steps

1

Choose Administration→Discovery Manager from the NFM-P main menu. The Discovery Manager (Edit) form opens.

2

Click on the Managed State tab.

3

Select a device in the list.

4

Perform one of the following:

a. Click Manage to return an unmanaged or suspended device to the managed state.

b. Click Suspend to suspend the management of the device.

c. Click Unmanage to stop the management of the device.

5

Save your changes. The Managed State of the device changes to one of the following:

- managed, if you are remanaging the device
- suspended, if you are suspending management of the device
- not managed, if you are unmanaging the device

6

If Service Bandwidth Management is enabled, perform a system-wide CAC audit to ensure that the bandwidth is properly calculated:

1. Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.
2. Click on CAC Audit.

END OF STEPS

9.28 To associate a device with a discovery rule

9.28.1 Purpose

After a discovery rule is deleted, any managed devices associated with the discovery rule are not associated with a discovery rule. Perform this procedure to associate one or more managed devices with a discovery rule to ensure that the devices are included in subsequent network administration activities.

9.28.2 Steps

1

Choose Administration→Discovery Manager from the NFM-P main menu. The Discovery Manager (Edit) form opens with the Discovery rules tab displayed.

2

Select the discovery rule to associate the NE with and click Properties, or use the Create button to create a discovery rule. The Topology Discovery Rule (Edit) form opens.

Note: Ensure that the mediation policy and other policies associated with the discovery rule are appropriate for the devices that you intend to add.

3

Click on the Rule Elements tab.

4

Select an exiting rule element and click Properties, or use the Create button to create a new rule element.

Note: The rule element must be configured to include the device IP address, for example, explicitly or using a subnet specification.

5

Click Assign Node and use the form that opens to select the devices that you want to add to the discovery rule.

6

Click OK. The devices are associated with the discovery rule.

7

Click OK to save the change, if required, and close the form.

8

Close the Discovery Manager (Edit) form.

END OF STEPS

9.29 To change from SNMPv2 to SNMPv3 management of a device

9.29.1 Purpose

Perform this procedure to change the management protocol that the NFM-P uses for a device from SNMPv2 to SNMPv3.

9.29.2 Steps

1

Perform 9.11 “To enable SNMPv3 management of a device” (p. 291) to do the following:

- Configure an SNMPv3 user and group on the device.
- Configure an SNMPv3 user in NFM-P.

2

Perform 9.17 “To configure device mediation” (p. 301) to configure an SNMPv3 mediation policy.

3

Modify the mediation policy of the managed device that you need to change from SNMPv2 to SNMPv3:

1. Choose Administration→Discovery Manager from the NFM-P main menu. The Discovery Manager (Edit) form opens with the Discovery rules tab displayed.
2. Click on the Managed State tab, choose the managed device that you need to change from SNMPv2 to SNMPv3, and click Properties. The Node Discovery Control (Edit) form opens.
3. Click Select and choose the SNMPv3 mediation policy configured in Step 2, in the read, write, trap, and Security Access Mediation Policy panels.
4. Save your changes and close the forms.

4

Perform 9.23 “To configure a discovery rule” (p. 310) to configure a new discovery rule for the SNMPv3 device.

5

Edit the SNMPv2 discovery rule for the device to exclude the device from discovery.

6

Use a CLI session on the device to remove the following items, which are no longer required:

- SNMPv2 user
- SNMPv2 group
- SNMPv2 trap targets

7

Resynchronize the device with the NFM-P; see 9.33 “To partially or fully resynchronize NEs with the NFM-P database” (p. 322).

END OF STEPS

9.30 To switch from non-secure to secure mediation

9.30.1 Steps

1

Choose Administration→Mediation from the NFM-P main menu. The Mediation (Edit) form opens.

2

Click on the Mediation Security tab. You can create a mediation policy as described in 9.17 “To configure device mediation” (p. 301) , or modify the default mediation policy to use SSH2. Perform one of the following.

a. Click Create to create a new mediation policy. The Mediation Policy (Create) form opens.

b. Choose the default policy from the list, and click Edit. The Mediation Policy (Edit) form opens.

3

Configure the required parameters using the prescribed values:

- SSH2 as the Communication Protocol
- The SSH2 server user name and password as the User Name and User Password
- Secure as the File Transfer Type

  Note:

  When the File Transfer Type is set to Secure, the Communication Protocol, User Name, and User Password parameters must be configured with the SSH2 information.
- The port that the NE uses for SSH2 communication as the SSH2 Server Port

4

Configure the remaining parameters on the form.

5

Save your changes and close the form.

6

Create a new discovery rule that uses the new SSH2 mediation policy as the read-access mediation policy and the write-access mediation policy. See 9.23 “To configure a discovery rule” (p. 310) for information about creating discovery rules.

7

Choose Administration→Discovery Manager from the NFM-P main menu. The Discovery Manager (Edit) form opens.

8

Click on the Managed State tab. A list of managed devices appears.

9

Choose the device from the list that you want to use SSH2 for CLI sessions and secure file transfers.

10

Click Properties and click on the Mediation Security tab.

11

Choose the newly created SSH2 mediation policy as the read access mediation policy.

Note: You can also change the mediation policy for a discovery rule by performing Step 11 and choosing a discovery rule from the Discovery Rules tab.

12

Save your changes and close the form.

END OF STEPS

9.31 To specify which management address the NFM-P uses to remanage a device

9.31.1 Before you begin

You can specify which management IP address is saved for a device when the device is set to an unmanaged state. You can configure the NFM-P to save the original management IP address or the most recently used management IP address for a device.

9.31.2 Steps

1

Choose Administration→Discovery Manager from the NFM-P main menu. The Discovery Manager (Edit) form opens.

2

Click on the Managed State tab.

3

Choose a device and click Properties. The Node Discovery Control (Edit) form opens.

4

Configure the Use Original Management IP parameter and click OK.

5

Save your changes and close the forms.

END OF STEPS

9.32 To rescan the network for a device according to a discovery rule

9.32.1 Steps

1

Choose Administration→Discovery Manager from the NFM-P main menu. The Discovery Manager (Edit) form opens.

2

Select one or more discovery rules and click Rescan.

The NFM-P scans the network as specified by the discovery rules and discovers devices. After a device is discovered, the NFM-P server sets the device in a managed state and adds the NE properties to the NFM-P database.

END OF STEPS

9.33 To partially or fully resynchronize NEs with the NFM-P database

9.33.1 Steps

1

On the equipment tree, select one or more NEs, as required.

Note: If more than one NE is selected, only full resynchronization is available.

2

Choose a resynchronization option.

a. Right-click on one of the selected devices you want to resynchronize with the NFM-P database and choose Resync→Resync All MIBs.

Note: Choosing Resync All MIBs will fully resynchronize all MIBs for the devices, ignoring timestamps.

b. Perform a partial resynchronization.

1. Right-click on one of the selected devices you want to resynchronize with the NFM-P database and choose Resync→Customized Resync. The Resync Site(s) form opens.
2. Select Choose MIB Entries and click Next.
3. Select one or more MIB entries from the list and click Next.
4. Configure the Ignore Timestamps parameter.
5. Click Finish and close the form.

END OF STEPS

9.34 To manually accept a mismatched SSH host key

9.34.1 Purpose

Perform this procedure to manually accept a rejected SSH host key in order to establish a connection to the SSH server on an NE.

Note: Before you accept a mismatched host key, you must verify the validity of the SSH connection.

9.34.2 Steps

1

Open the SSH2 Known Host Key Manager by performing one of the following.

a. Choose Administration→Security→SSH2 Known Host Key Manager from the NFM-P main menu. The SSH2 Known Host Key Manager filter form opens.

b. Perform the following steps.

1. Choose Administration→Discovery Manager from the NFM-P main menu. The Discovery Manager (Edit) form appears.
2. Click on the Managed State tab and click Search. A list of managed devices appears.
3. Select a device in the list and click Properties. The Node Discovery Control (Edit) form opens.
4. Click on the Mediation Security tab.
5. Click SSH2 Known Host Key. The SSH2 Known Host Key Manager filter form opens.

2

In the SSH2 Server Key Status column header, choose Mismatch SSH2 Host Key as a match criterion using the drop-down menu.

3

Click Search. A list of mismatched host keys is displayed.

4

Select the required host key entry.

5

Verify with the device management that the key fingerprint is the host key of the required device.

6

Click Delete to delete the mismatched host key. The mismatched host key is deleted and a connection to the SSH server can be established.

7

Close the forms.

END OF STEPS

9.35 To view the SSH2 host keys to identify active and mismatched keys

9.35.1 Steps

1

Open the SSH2 known host key manager by performing one of the following.

a. To view the active and mismatched SSH host keys on all managed NEs, choose Administration→Security→SSH2 Known Host Key from the NFM-P main menu. The SSH2 Known Host Key Manager form opens.

b. To view the active and mismatched SSH host keys on specific managed NEs:

1. Choose Administration→Discovery Manager from the NFM-P main menu. The Discovery Manager (Edit) form appears.
2. Click on the Managed State tab and click Search. A list of managed devices appears.
3. Select a device and click Properties. The Node Discovery Control (Edit) form opens.
4. Click on the Mediation Security tab.
5. Click SSH2 Known Host Key. The SSH2 Known Host Key Manager form opens.

2

Configure the filter criteria and click Search. A list of active and mismatched host keys appears.

3

Close the forms.

END OF STEPS

9.36 To list and save SNMP MIB information

9.36.1 Purpose

You can list and save SNMP MIB information, which may be of use for purposes such as the following:

- to maintain a record of the SNMP MIBs that the NFM-P supports
- to compare SNMP MIB support between NFM-P releases
- to identify the polling interval for a MIB entry

9.36.2 Steps

1

Choose Administration→Mediation from the NFM-P main menu. The Mediation (Edit) form opens.

2

Click on the MIB Entry Policies tab.

3

View the polling interval for a MIB entry.

1. Select a MIB entry and click Properties. The MIB Entry Policy (Edit) form opens.
2. View the polling interval setting in the Configuration panel.
3. Close the form.

4

Sort the list according to the contents of a column by clicking on the column header.

5

Save the listed information to a file.

1. Right-click on a column header and choose Save to File. The Save As form opens.
2. Use the form to specify the file that is to contain the saved information.
3. Click Save. The information is saved to the specified file.

6

Close the form.

END OF STEPS

9.37 To delete a device from the managed network

CAUTION

Service disruption

Deleting a device results in a loss of management data and completely removes the device from the managed network.

Deleting a device results in the loss of all historical AA statistics for the device.

See "Discovering devices using the NFM-P" (p. 277) for more information.

9.37.1 Steps

1

Choose Administration→Discovery Manager from the NFM-P main menu. The Discovery Manager (Edit) form opens.

2

Click on the Managed State tab and select a device.

3

If the device is managed, click Unmanage and wait for the state to change to Unmanaged. Otherwise, go to Step 4 .

4

Click Delete.

5

Save your changes and close the form. The device is deleted from the NFM-P database.

END OF STEPS

10 Device CLI sessions

Managing device CLI sessions using the NFM-P

10.1 Overview

10.1.1 Functions that require CLI

You can perform most NE management functions using the NFM-P client GUI. Functions such as the following, however, require CLI access to a managed NE:

- validating GUI configuration actions
- configuring items that the GUI cannot, such as LI user access
- troubleshooting using device debug files

The NFM-P client GUI provides CLI access to the managed NEs from the main menu and from NE contextual menus in topology maps and navigation trees.

10.1.2 Security

Scope of command roles and user permissions on the cli package control CLI command access on an NE. The user permissions are set when security is configured on the NE locally or by using NFM-P configuration forms. See the section on NE user and device security in the *NSP System Administrator Guide* for information about setting NE access privileges.

Note: When you use a CLI to change security parameters on an NE, the changes may not be synchronized with the NFM-P and subsequently not displayed in the GUI. For security reasons, the NFM-P cannot retrieve parameters such as passwords from an NE. To ensure that the security parameters are synchronized, you must use the client GUI to change the values.

Note: One CLI login failure from the NFM-P client GUI may generate more than one login failure message in the NE session logs. This is because the CLI window is opened using an internal utility rather than a command shell, and the utility may attempt the login more than once for various reasons, for example, excessive retries or the use of multiple authentication sources.

10.1.3 vi editor support

On a 7450 ESS, 7750 SR, or 7950 XRS, you can use the vi editor to modify local files. The vi editor is available in NFM-P Telnet and SSH sessions. The vi editor supports the standard vi navigation keys as well as the cursor keys (which are often called the arrow keys). See the appropriate device documentation for information about the supported vi commands and functions for a specific device.

10.2 Workflow to use an NFM-P CLI

10.2.1 Purpose

The following workflow describes the sequence of high-level tasks required to open and use a device CLI from the NFM-P client GUI. The following must be true before you can use the NFM-P to open a device CLI using the GUI.

- The NFM-P user account has console access privileges on the managed devices. See the section on NE user and device security in the *NSP System Administrator Guide* for more information about user account privileges.
- The Telnet server on the managed devices is started.
- If required, SSH2 is properly configured on the managed devices; see Chapter 9, “Device discovery” for more information.

10.2.2 Stages

1

Configure the NFM-P CLI preferences. See 10.3 “To configure the NFM-P CLI console preferences” (p. 328) for more information.

2

Open a CLI session and log in to a managed device. See 10.4 “To open and close an NFM-P device CLI session” (p. 329) for more information.

3

Configure the device, view device information, and modify files, as required.

4

Close the CLI session. See 10.3 “To configure the NFM-P CLI console preferences” (p. 328) for more information.

10.3 To configure the NFM-P CLI console preferences

10.3.1 Purpose

Perform this procedure to customize the NFM-P CLI window settings, such as the following:

- the console text style and appearance
- the size of the scrolling buffer
- whether to save the session output to a file

10.3.2 Steps

1

Open a CLI session, as described in 10.4 “To open and close an NFM-P device CLI session” (p. 328) .

2

Right-click in the CLI window and choose Configure. The Terminal Configuration form opens.

3

Configure the required parameters.

Note: When the Send Console To a File parameter is enabled and the Append to file parameter is disabled, the log file is overwritten each time a new CLI session starts.

4

Click OK. The Terminal Configuration form closes.

END OF STEPS

10.4 To open and close an NFM-P device CLI session

10.4.1 Purpose

Perform this procedure to open a Telnet or SSH session on a managed device using the NFM-P client GUI.

10.4.2 Steps

1

Perform one of the following to open a device CLI session.

a. Use the NFM-P navigation tree.
   1. Choose Equipment from the view selector.
   2. Right-click on a device icon and choose NE Sessions→Telnet Session or NE Sessions→SSH Session from the contextual menu.

      The Telnet Session or SSH Session window opens.

      Note: The managed device must be configured for Telnet access. See the appropriate device documentation for information about configuring Telnet access to the device.

      Note: SSH sessions use SSH2 by default on the 7210 SAS, 7450 ESS, 7750 SR, 7950 XRS, and GNEs. Ensure that SSH2 is properly configured on the device and that an SSH2 mediation policy is specified in the device discovery rule. See Chapter 9, “Device discovery” for more information about configuring SSH2 security.

b. Use the NFM-P main menu.

1. Choose one of the following main menu options:
   - Tools→Network Elements→NE Sessions→Telnet Session
   - Tools→Network Elements→NE Sessions→SSH Session

   The Telnet Session or SSH Session window opens.
2. Perform one of the following to specify an NE as the CLI session target.
   - Enter the management IP address of the NE beside the dimmed Connect button.
   - Select an IP address from the drop-down menu.
   - Click Select to search for the NE.

   The Connect button is enabled.
3. Click Connect.

c. Use the Manage Equipment form.
1. Choose Manage→Equipment→Equipment from the NFM-P main menu. The Manage Equipment form opens.
2. Select an NE in the list.
3. Click NE Sessions and choose Telnet Session or SSH Session. The Telnet Session or SSH Session window opens.

d. Use a service topology map.
1. Choose one of the following from the NFM-P main menu:
   - Manage→Service→Services
   - Manage→Service→Composite Services
   - Manage→Service→Mirror Services

   The appropriate management list form opens.
2. Choose a port and click Topology View. The Service Topology map opens.
3. Right-click on an NE in the map and choose NE Sessions→Telnet Session or NE Sessions→SSH Session. The Telnet Session or SSH Session window opens.

e. Use the Physical Topology map.
1. Choose Application→Physical Topology from the NFM-P main menu. The Physical Topology map opens.
2. Right-click on an NE in the map and choose NE Sessions→Telnet Session or NE Sessions→SSH Session. The Telnet Session or SSH Session window opens.

2

Enter the login credentials. You can use the CLI as specified by your user account permissions.

Note: One login failure may generate more than one login failure message in the NE session logs. This is because the CLI window is opened using an internal utility rather than a command shell, and the utility may attempt the login more than once for various reasons, for example, excessive retries or the use of multiple authentication sources.

3

Perform NE management tasks, as required.

4

Click Disconnect to end the CLI session.

Note: When you disconnect from a CLI session, the session window remains open to facilitate the opening of a subsequent CLI session.

5

Perform one of the following.

a. Open a new CLI session:
   1. Perform one of the following to specify an NE as the CLI session target.
      - Enter the management IP address of an NE beside the dimmed Connect button.
      - Select an IP address from the drop-down menu.
      - Click Select to search for an NE.

      The Connect button is enabled.
   2. Click Connect.

b. Close the Telnet Session or SSH Session window.

END OF STEPS

11 Working with network objects

Working with network objects using the NFM-P

11.1 Overview

11.1.1 NFM-P management of network objects

The NFM-P is used to create, configure, and manage a device with the various hierarchical objects required to be part of a network. Equipment such as the routers, which are at the top of the hierarchy, have properties that are configured using the CLI and discovered when the NFM-P discovery process is run. After the device is discovered, it is displayed as an object in the navigation tree. See Chapter 3, “NFM-P navigation tree” for more information about the navigation tree.

Objects in the NFM-P are considered to have parent/child relationships that are contained within a hierarchy. For example, a card in a card slot is the parent object of a daughter card. The behavior of each object is defined using parameters that are specific to the function required. Those parameters can be managed to suit the needs of the service required. Objects are created and managed using the properties forms found in the contextual menus of the equipment view.

The network is the top object in the navigation tree. The network icon in the navigation tree is the parent object of all managed devices. When you expand the network icon, all managed devices are shown as children of the network parent.

The device object is the discovered device at the top of the hierarchy in the navigation tree, directly below the network icon. The following children objects of the router are created automatically in the navigation tree after the device is discovered.

- CCAG
- ISA-Tunnel Group
- ISA-AA Group
- ISA-LNS Group
- ISA-NAT Group
- ISA-Video Group
- LAG
- IGH
- Shelf
- Power Shelf
- Card Slot
- Card Slot A for the CPM and switch fabric
- Card Slot B for the redundant CPM and switch fabric
- Fans
- PCM Trays
- Power Supplies
- CCM
- SFM Slot

The following objects must be created using property forms or create forms from the contextual menus of the equipment view or the ring group view.

- equipment groups
- individual CCAGs with VSM-CCA members
- individual ISA-Tunnel Groups with ISA IPsec MDA members
- individual ISA-AA Groups with ISA-AA MDA or ESA-AA VM members and ISA-AA partitions
- individual ISA-LNS Groups with ISA broadband applications MDA members
- individual ISA-NAT Groups with ISA broadband applications MDA members

- individual ISA-Video Groups with ISA-Video MDA or ESA Video Group members
- individual LAGs with subgroups of LAG member ports
- IGH members
- cards
- ring groups
- daughter cards

  Ports are automatically created when the daughter card is created.
- channels

Configuring an object is accomplished in two steps. First the object must exist or be created, second, the object parameters are modified. See 12.4 “To create an object” (p. 343) to create objects using the navigation tree.

11.1.2 Object deployment status

When you configure an object using the NFM-P GUI or the NFM-P OSS, the NFM-P saves the configuration and attempts to deploy the changes to the network. Although the value is changed on the configuration forms, the configuration change may not be fully deployed to the NE.

The NFM-P allows you to monitor the deployment state for objects. The Deployment tab on all object properties forms notifies you of configuration changes that are not fully deployed to the NE. The parameter that was unsuccessfully deployed is listed, along with the old value and the new value. A deployment icon or warning indicator appears in the following locations when you change the configuration of an object:

- beside all of the parameters on an object properties form for which a deployment is in progress (yellow icon) or has failed (red icon)
- beside the object in the navigation tree (blue icon, regardless of state)
- in info tables in map views (blue icon, regardless of state)
- in the Deployment column on object list forms (blue icon, regardless of state)
- on the Deployment tab (warning indicator)

See Chapter 25, “NE deployment” for information about how to configure a deployment policy, manage deployments, and troubleshoot failed deployments. See 11.5 “To monitor the deployment status of a network object” (p. 336) for information about how to monitor the deployment of an object configuration change.

11.2 Working with equipment group objects

11.2.1 Overview

The equipment group icons in the navigation tree represent logical equipment groups. Initially, an equipment group object is created by choosing Create→Equipment→Group from the NFM-P main menu. A Group (Create) form opens. Additional equipment groups can be created using the Copy button on the equipment group properties form.

The Discovered NEs and the Unmanaged NEs equipment groups are created by default. The Discovered NEs equipment group contains the discovered devices. The Unmanaged NEs

equipment group contains non NFM-P managed NEs that have been added to the network. You can create new equipment groups and move devices to them using the topology maps. The topology map supports equipment groups of up to 250 NEs.

Note: For existing topologies, an NFM-P managed NE is not moved automatically to the Unmanaged NEs equipment group if it is unmanaged by the user.

See Chapter 4, “Topology map management” for information about configuring equipment group objects and managing equipment groups using maps.

11.2.2 Performance considerations

Although there is no limit to the number of equipment groups, Nokia recommends a maximum of 10 000 equipment groups per system for optimal performance. Each equipment group can contain a maximum of 2000 objects. Network elements and immediate child groups are considered objects in an equipment group. A bracketed number is displayed beside the name of each equipment group in the navigation tree. This number indicates the current number of objects in the group.

11.3 Working with physical links

11.3.1 Overview

The NFM-P allows you to create and manage links at the Layer 1 level. The physical links represent the actual physical configuration of network connections between ports. You can view and manage physical links from the physical topology map and the Manage Equipment list form.

When a physical link becomes operationally down, an alarm is raised against the link, and correlated to alarms on the ports on either end of the link.

Although there is no limit to the number of physical links you can have in a system, Nokia recommends a maximum of 10 000 physical links for optimal system performance.

Radio links between Wavence SMs are shown as physical links by the NFM-P, with ports as the endpoint type.

See Chapter 4, “Topology map management” for information about configuring physical links and managing physical links using maps.

11.4 Workflow to manage network objects

11.4.1 Purpose

The following workflow describes the sequence of high-level tasks required to manage and configure network objects. This workflow assumes that the physical devices have been installed, commissioned, and discovered. See Chapter 8, “Device commissioning and management” for more information about device commissioning. See Chapter 9, “Device discovery” for more information about device discovery.

Note: Network objects can be accessed using the equipment navigation tree. See Chapter 3, “NFM-P navigation tree” for more information.

11.4.2 Stages

1

Create network equipment groups as required; see Chapter 4, “Topology map management” .

2

Configure device objects as required; see Chapter 12, “Device object configuration” .

3

Configure logical group objects as required; see Chapter 13, “Logical group object configuration” .

4

Configure shelf, card, and daughter card objects as required; see Chapter 15, “Shelf and card object configuration” .

5

Configure port and channel objects as required; see Chapter 16, “Port and channel object configuration” .

6

Create physical links as required; see Chapter 4, “Topology map management” .

7

Monitor the deployment status of network objects as required; see 11.5 “To monitor the deployment status of a network object” (p. 336) .

8

View the current network resources assigned to network objects such as IP or MAC addresses as required; see 11.6 “To view network resources assigned to network objects” (p. 337) .

11.5 To monitor the deployment status of a network object

11.5.1 Steps

1

Open the properties form for the network object.

You can click on the Deployment tab if a warning indicator appears when you open a properties form.

2

Configure the required parameters and click Apply. An icon appears beside the modified parameter:

- yellow icon—deployment in progress; the icon disappears when the deployment succeeds
- red icon—failed deployment

In addition, a blue deployment icon appears beside the NE object in the navigation tree, in list forms, and in configured info tables in map views.

A warning indicator appears on the Deployment tab.

3

Click on the Deployment tab.

4

In the Name column, verify the name of the parameter for which the deployment was unsuccessful. You can also verify the old value of the parameter before the change was applied, the new parameter value, and the deployer ID.

5

Navigate to the parameter on the configuration form that failed to deploy, if necessary, by selecting an entry in the Attributes list and clicking Show Attribute. The attribute is highlighted for a few seconds on the configuration form.

Note: If you choose an entry in the Attributes list that is located on a hidden tab and click Show Attribute, the hidden tab is temporarily displayed. See 1.24 “To set local tab preferences for configuration forms” (p. 118) on how to configure hidden tabs.

6

Troubleshoot the cause of the failed deployment; see 25.5 “To view and manage failed deployments” (p. 769) .

End of steps

11.6 To view network resources assigned to network objects

11.6.1 Purpose

Perform this procedure as required to view network resources assigned to network objects such as IP or MAC addresses.

11.6.2 Steps

1

Choose Tools→Network Resources→ Network Resources from the NFM-P main menu. The Network resources form opens.

2

Select the appropriate tab for the network resource you need to query.

3

CAUTION

Service Disruption

This operation may take a long time to complete for some network resources such as viewing IP addresses, route distinguishers and route targets, and MAC addresses. Nokia recommends that you use a specific search filter to narrow down the scope of search.

Customize the search fields as required to view the chosen network resource assigned to the network objects.

4

Click Search. For some search queries, for example IP addresses, a dialog box appears.

5

If required, acknowledge the dialog box and click Search. The results of your customized search are displayed.

6

Close the form.

END OF STEPS

12 Device object configuration

Working with device objects

12.1 Overview

12.1.1 Device objects

The device object is the discovered device at the top of the hierarchy in the navigation tree, directly below the network icon.

This chapter contains the procedures to configure device objects using the navigation tree. Device object properties forms, which are used to configure specific parameters for discovered devices, are accessed using objects on the NFM-P navigation tree. See Chapter 3, “NFM-P navigation tree” for more information about using the navigation tree.

The device icons in the navigation tree represent device objects. See Chapter 6, “Device support” for more information about the supported device types.

Most of the configured properties for this object are inherited from the device. The Properties contextual menu option from the navigation tree allows you to configure or modify the parameters for the object. See the specific procedures in this chapter for the respective tab of the properties form that is to used to configure the device object.

12.1.2 Ring group objects

The NFM-P allows you to create and manage ring groups in the ring group view of the navigation tree. Ring groups are used to group devices logically to represent a typical network topology.

Note: The NFM-P uses VLAN groups instead of ring groups to group OmniSwitch NEs. See Chapter 76, “VLL service management” for more information about VLAN groups.

12.2 Workflow to manage device objects

12.2.1 Purpose

The following workflow describes the sequence of high-level tasks required to manage and configure device objects. This workflow assumes that the physical devices have been installed, commissioned, and discovered. See Chapter 8, “Device commissioning and management” for more information about device commissioning. See Chapter 9, “Device discovery” for more information about device discovery.

Note: Device objects can be accessed using the equipment navigation tree. See Chapter 3, “NFM-P navigation tree” for more information about using the equipment navigation tree.

12.2.2 Stages

1

As required, configure the following general NE capabilities:

a. Create an object; see 12.4 “To create an object” (p. 343) .

b. Modify an NE configuration; see 12.5 “To modify NE properties” (p. 343) .

c. Customize the NE property labels and values in the System preferences form, for example, to specify the location and site name that differs from the actual NE site name. See the *NSP System Administrator Guide* for more information about configuring system preferences.

d. Customize the NE property values in the NE form; see 12.6 “To configure NE custom properties” (p. 343) .

e. Create an operational group; see 12.8 “To create an operational group” (p. 345) and 12.9 “To configure a 7210 SAS operational group” (p. 346) .

f. Enable and configure global Cflowd on an NE, and create Cflowd collectors; see 12.10 “To enable and configure global Cflowd sampling on an NE” (p. 347) .

g. Associate a span of control with an NE; see 12.13 “To add a span of control to an NE” (p. 350) .

h. Configure load balancing on an NE; see 12.14 “To configure load balancing” (p. 351) .

i. Configure 802.1x authentication on an NE; see 12.17 “To enable or disable 802.1X” (p. 353) .

j. Enable or disable an exclusive policy editing restriction on one or more NEs or remove any exclusive edit locks that were previously set; see 12.18 “To configure an exclusive policy editing restriction on an NE” (p. 354) .

k. Configure active card alarms on an NE; see 12.19 “To configure active card alarms on an NE” (p. 355) .

l. Configure a TWAMP server on an NE; see 12.20 “To configure a TWAMP server” (p. 355) .

m. Enable LLDP on an NE; see 12.21 “To enable LLDP on an NE” (p. 358) .

n. Configure BFD flap detection on an NE; see 12.22 “To configure the BFD flap detection interval on an NE” (p. 360) .

o. Enable a Q in Q untagged SAP on an NE; see 12.23 “To enable a Q in Q untagged SAP on an NE” (p. 360) .

p. Configure the DHCPv6 advertise message format on an NE; see 12.24 “To configure DHCPv6 Advertise messages on an NE” (p. 361) .

q. Configure Python script protection on an NE; see 12.25 “To configure Python script protection on an NE” (p. 362) .

r. Configure SFLOW on an NE; see 12.29 “To configure sFlow on an NE” (p. 364) .

s. Create a chassis-level PBB configuration; see 12.31 “To create a chassis-level PBB configuration” (p. 367) .

t. Configure serving network information; see 12.32 “To configure serving network information on an NE” (p. 367) .

u. Configure the RADIUS CoA port on an NE; see 12.36 “To configure the RADIUS CoA port on an NE” (p. 369) .

v. Configure data persistence on an NE; see 12.37 “To configure data persistence on an NE” (p. 370) .

w. Configure DNS security extensions on an NE; see 12.38 “To configure DNS security extensions” (p. 371) .

x. Configure the use of vendor-specific ICMP extensions on an NE; see 12.39 “To enable or disable ICMP extensions on a NE” (p. 372) .

2

As required, configure the following functionality on 7210 SAS NEs:

a. Configure operational groups for fault propagation on a 7210 SAS; see 12.9 “To configure a 7210 SAS operational group” (p. 346) .

b. Configure a no-service loopback port on a 7210 SAS; see 12.46 “To configure a no-service loopback port on the 7210 SAS” (p. 378) .

c. Configure two WRED slopes on a 7210 SAS; see 12.48 “To configure two WRED slopes on a 7210 SAS” (p. 379) .

d. Enable frame-based accounting on a 7210 SAS; see 12.49 “To configure frame-based accounting for QoS policies on a 7210 SAS” (p. 380) .

e. Configure the system resource profile on a 7210 SAS or 7250 IXR; see 12.50 “To configure the global system resource profile on a 7210 SAS or 7250 IXR” (p. 380) .

f. Configure a system resource profile policy for 7210 SAS-R or 7210 SAS-S/Sx VC NEs; see 12.51 “To configure a system resource profile policy for the 7210 SAS-R/T/Mxp, 7210 SAS-S/Sx, or 7210 SAS-S/Sx VC” (p. 382) .

g. Configure port-based access egress scheduling on 7210 SAS-Mxp or 7210 SAS-R NEs; see 12.53 “To configure port-based scheduling on the 7210 SAS” (p. 384) .

h. Configure buffer management for the 7210 SAS; see 12.54 “To configure buffer management for the 7210 SAS” (p. 385) .

3

As required, configure the system resource profile on a 7250 IXR; see 12.50 “To configure the global system resource profile on a 7210 SAS or 7250 IXR” (p. 380).

4

As required, configure the following functionality on 7705 SAR NEs:

a. Configure the watermark settings on a 7705 SAR; see 12.59 “To configure watermark settings on a 7705 SAR” (p. 391) .

b. Configure the QoS ingress aggregate rates on a 7705 SAR-M; see 12.60 “To configure QoS

ingress aggregate rates on the 7705 SAR-M/ME" (p. 1818) .

c. Launch an MCT from a Wavence SA NE connected to a 7705 SAR; see 12.61 "To launch an MCT on a Wavence SA NE connected to a 7705 SAR" (p. 392) .

5

As required, configure the following functionality on OmniSwitch NEs:

a. Start and stop a Webview or Secure Webview session on an OmniSwitch; see 12.62 "To start and stop a Webview or Secure Webview session on an OmniSwitch" (p. 393) .

b. Configure the dying gasp alarm on an OmniSwitch; see 12.63 "To configure the dying gasp alarm on an OmniSwitch" (p. 394) .

6

As required, configure ring group objects; see 12.73 "To create a ring group" (p. 401) and 12.74 "To remove a device from a ring group or a ring group" (p. 402) .

12.3 Workflow to configure UNP 802.1x at port level for OmniSwitch devices

12.3.1 Purpose

The following is the sequence of high-level actions required to configure UNP 802.1x at port level.

12.3.2 Stages

1

Manage Omni nodes and add it in VLAN Group; see 75.13 "To create a VLAN group" (p. 2083).

2

Configure an AOS UNP Profile; see 61.6 "To configure an OmniSwitch Ethernet UNP profile" (p. 1818).

3

Configure UNP profile at port level; see 12.70 "To configure an UNP at port-level" (p. 398).

Note: UNP profile can also be configured globally; see 12.69 "To configure global-level UNP" (p. 398)

General device configuration procedures

12.4 To create an object

12.4.1 Steps

1

On the equipment tree, right-click on an empty object and choose Properties, or, when available, Create <*objectname*>. The properties form or the create form, as applicable, opens.

2

Configure the required parameters.

Certain object parameters are available for configuration. Configuring these parameters creates the object, however, after the object is created you may need to edit it using properties forms.

3

Save your changes and close the form.

END OF STEPS

12.5 To modify NE properties

12.5.1 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Use the form to view or modify the NE parameters, as required.

3

Save your changes and close the form.

END OF STEPS

12.6 To configure NE custom properties

12.6.1 Steps

1

On the equipment or routing tree, right-click on an NE. The Network Element (Edit) form opens.

2

In the Custom Properties panel, configure the user-defined values.

Note: The NE custom properties support the extended character set including multi-byte characters.
The configured labels and values are displayed in the following locations. You can configure the labels and values, if required.

- NE list form: Choose Manage→Equipment→Equipment→Network Element (from the object drop-down menu). The appropriate columns display the values and labels.
- Tree labels: See 2.12 “To customize tree labels” (p. 152) .
  You can also configure Custom NE property values using the XML API. See the *NSP NFM-P XML API Developer Guide*.
  The NFM-P GUI supports localized language display. See Chapter 1, “NFM-P GUI” for more information.

3

Save your changes and close the form.

END OF STEPS

12.7 To enable FIPS-140-2

12.7.1 Purpose

Perform this procedure to enable FIPS-140-2 level 1 support.

The NFM-P returns an SNMP deployment error from the NE for operations that are not supported because of FIPS restrictions.

Consider the following when you enable FIPS-140-2:

- The following algorithms are not accessible for keychains:
  - MD5
  - HMAC-MD5
  - DES
- The following algorithms are not available:
  - MD5
  - DES

Note: FIPS-140-2 level 1 is only supported on the 7705 SAR, Release 8.0 R6 or later. If you enable FIPS-140-2 from the node CLI and perform an NE reboot or software upgrade from Release 8.0 R4 to Release 8.0 R5 in the NFM-P GUI, the 7705 SAR NE will not boot.

12.7.2 Steps

1

On the equipment or routing tree, right-click on an NE. The Network Element (Edit) form opens.

2

Click on the Polling tab. In the General sub-tab, enable the Enable FIPS-140-2 parameter.

3

Save your changes and close the form.

4

Reboot the NE.

END OF STEPS

12.8 To create an operational group

12.8.1 Before you begin

Multiple objects can be bundled in operational groups. If you change the status of the operational group, the status of every object in the group is changed.

12.8.2 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, and then the Service tab.

3

Click on the Operational Groups tab and then click Create. The Operational Group (Create) form opens.

4

Configure the required parameters.

5

Bind a BFD interface to the operational group.

1. In the BFD Interface Monitored panel, click Create. The Operational Group BFD Interface (Create) form opens.
2. Configure the Interface Type parameter.
3. For service interfaces, click Select in the Service panel. For network interfaces, click Select beside the Interface Name parameter.
4. Choose a service or interface from the displayed list and click OK.

5. Configure the Destination Address parameter.

6

Save your changes and close the forms.

END OF STEPS

12.9 To configure a 7210 SAS operational group

12.9.1 Purpose

You can create operational groups for VLANs on supported 7210 SAS NEs. Operational groups provide fault propagation for ports with null, dot1q, and QinQ encapsulation types.

You can assign an L2 uplink port to an operational group. Access ports on the same device can monitor the group. When the L2 uplink port goes down or loses connectivity, the access ports monitoring the group go operationally down. SAPS associated with the affected ports also switch to operationally down.

Perform this procedure to create or modify an operational group. To associate ports with the group, see 16.24 “To configure Ethernet ports” (p. 599) .

12.9.2 Steps

1

In the equipment view of the navigation tree, right-click on a 7210 SAS NE and choose Properties. The properties form for the NE opens.

2

Click on the Globals tab, then on the Oper Group tab.

3

Click Create, or choose an operational group and click Properties.

4

Configure the required parameters.

You cannot modify the Displayed Name of an operational group after creation.

Note: Oper Group Member and Open Group LAG Member are mutually exclusive, meaning, the Oper Group can be associated only to a Port or LAG, not both. Multiple port/LAG can be associated to a monitor an Oper Group.

5

For existing operational groups, click on the Monitor Oper Group Ports tab to view a list of the ports that are monitoring the group.

6

For existing operational groups, click on the Monitor Oper Group LAGs tab to view a list of the LAGs that are monitoring the group.

7

Save your changes and close the form.

END OF STEPS

12.10 To enable and configure global Cflowd sampling on an NE

12.10.1 Purpose

Cflowd collects statistical data based on traffic flows. A flow is a series of packets in a user session. Cflowd data is used to monitor network usage trends and detect security threats. You can use the NFM-P to configure Cflowd sampling for:

- global traffic that passes through an NE; you must enable Cflowd globally on an NE before you can configure Cflowd collectors. You can create multiple Cflowd collectors on an NE. Each collector is deleted if Cflowd sampling is disabled.
- traffic that passed through an ISA-AA group and/or partitions within the group as well as TCP performance data collection for AA applications and application groups; see 13.9 “To configure Cflowd collectors on an ISA-AA group or partition” (p. 422) .
- unicast and multicast traffic on a routing network interface, IES/VPRN L3 access interface, IES/VPRN tunnel interface, and VPRN network interface; see 27.17 “To create an L3 network interface on a routing instance” (p. 856) , 34.20 “To configure a tunnel interface on an IES or VPRN” (p. 1249) , 78.28 “To configure an L3 access interface on an IES site” (p. 2472) , 79.83 “To configure an L3 access interface on a VPRN site” (p. 2656) , or 79.44 “To configure a network interface on a VPRN site” (p. 2603) .
- traffic that passes through a group interface on an IES or VPRN; see 78.19 “To configure a group interface on an IES” (p. 2449) or 79.37 “To configure a group interface on a VPRN” (p. 2586).
- traffic that is redirected to Cflowd using an ACL IP or IPv6 filter policy; see 51.5 “To configure an ACL IP filter policy” (p. 1671) or 51.6 “To configure an ACL IPv6 filter policy” (p. 1677).

You can create up to five Cflowd sampling rate profiles per system. Sampling rate profiles allow you to set different sampling rates on a per interface basis. This allows you to choose the appropriate sampling rate based on the services or type of traffic that is to be received or sent through the associated interface.

12.10.2 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the CFLOWD tab.

3

Set the CFLOWD State parameter to Enabled.

4

Configure the required parameters in the CFLOWD Attributes panel.

5

Add a collector.

Note: A global NE Cflowd configuration can contain up to eight collectors.

1. Click on the Collector tab and click Create. The Cflowd Collector Configuration (Create) form opens.
2. Configure the required parameters.

   The parameters vary based on the value of the Version parameter.
3. Save your changes and close the form.

6

If you added a collector with the value of the Version parameter set to version 9 or 10, you can create filters that specify which flows are sent to a collector.

1. Select a version 9 or 10 collector and click Create. The Cflowd Collector Configuration (New Instance) (Create) form opens.
2. Click on the Export Filters and Interface List tabs and click Create. The Export Filter Interface List (Create) form opens.
3. Configure the required parameters.
4. Save your changes and close the form.

7

As required, create a Cflowd sampling rate profile.

1. Click on the Sample Profile tab. The Cflowd Sample Profile (New Instance) form opens.
2. Configure the parameters.
3. Save your changes and close the form.
4. Repeat these steps for up to five profiles.

8

Save your changes and close the form.

END OF STEPS

12.11 To enable the automatic selection of an RD on an NE

12.11.1 Before you begin

Since an RD must be unique on each PE in the network, you can allocate either a route distinguisher that you manually select or an NE-selected route distinguisher for each service. When you configure an auto-RD on an NE, a Type-1 RD is automatically allocated by the NE based on the community range that you configure.

12.11.2 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, and then the Service tab.

3

Click on the BGP Groups tab and configure the Enable Auto Route Distinguisher parameter.

4

Configure the IP Address parameter in the Auto RD panel.

5

Configure the parameters in the Community Range panel.

6

Save your changes and close the forms.

END OF STEPS

12.12 To configure a Service MAC list

12.12.1 Purpose

Use this procedure to configure a list of MAC addresses to be excluded from auto learn mac protect (ALMP). ALMP is used along with the Restrict Protected Source, Discard-Frame action to prevent specified MACs from moving across PEs. This is used to prevent loops or MAC spoofing attacks.

The list can be added to the FIB configuration of a VPLS L2 Access Interface or Spoke SDP Binding, to an SHG, or to a PW Template.

12.12.2 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, and then the Service tab.

3

Click on the Service MAC List tab and click Create. The Service MAC List (Create) form opens.

4

Click Create to add MAC addresses to the list.

5

Add additional MAC addresses as needed and click OK.

6

Save your changes and close the forms.

END OF STEPS

12.13 To add a span of control to an NE

12.13.1 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Spans tab and click Add. The Select Span(s) - Network Element form opens with a list of available spans.

3

Choose one or more spans to apply to the NE.

4

Save your changes and close the forms.

END OF STEPS

12.14 To configure load balancing

12.14.1 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab. The Load Balancing tab is displayed.

3

Configure the required load balancing parameters.

To enable system-wide enhanced multicast load balancing to send multicast traffic over a LAG, set the Multicast Enhanced Load Balancing parameter to true.

To improve the LAG spraying of VLL service packets when ECMP and LAG hashing are performed by the same NE, set the Service ID Lag Hashing parameter to true.

For 7250 IXR, Release 19.7 and later, you can specify the CRC polynomials used in ECMP and LAG hashing, by setting the Hash Polynomial values. This is a global setting that affects system-wide ECMP and LAG hashing. The same value cannot be used for both ECMP and LAG. The Hash Polynomial settings use the hash seed result obtained by shifting to optimize the load balancing distribution of packet flows under ECMP and LAG. The number of bits the hash seed result is shifted is specified by the Hash Seed Shift parameter at the card level.

4

Save your changes and close the form.

END OF STEPS

12.15 To configure proxy ARP and proxy node discovery for an NE

12.15.1 Purpose

Use this procedure to create a list of MAC addresses that can be advertised in EVPN for proxy ARP or proxy ND IP entries on VPLS services.

12.15.2 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, then the Service sub-tab, then the Proxy ARP/ND sub-tab.

3

To configure a MAC list entry:

1. Click on the MAC list tab.
2. Click Create. The Proxy ARP/ND MAC List (Create) form opens.
3. Configure the MAC List name parameter.
4. To add a MAC address to the list, click Create, configure the MAC Addr parameter, and click OK.

4

Save the changes and close the forms.

END OF STEPS

12.16 To configure a node discovery profile on an NE

12.16.1 Purpose

Use this procedure to create a profile for node discovery using OSPF Type 10 LSA TLV. When a network element profile is assigned to a VPRN OSPFv2 area site, its information will be advertised via LSA type 10 opaque.

See 79.22 “To configure ISIS, L2TP, MLD, OSPFv2, OSPFv3, PIM, RIP, or WPP on a VPRN routing instance” (p. 2555) and 28.67 “To create an OSPF area” (p. 963) for information about configuring an OSPFv2 area site on a VPRN.

Note: When a node is discovered using OSPF Type 10 LSA TLV, the network element information will not be automatically added to the routing table (RIB) or forwarding table (FIB). If the NE IP address provided in the profile needs to be visible to the network, you need to configure a loopback interface or physical interface with the same IP address and add it to the OSPFv2 area.

12.16.2 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, then the Node Discovery sub-tab.

3

Click Create. The Node Discovery Profile (Create) form opens.

4

Configure the required parameters.

5

Save the changes and close the forms.

END OF STEPS

12.17 To enable or disable 802.1X

Note: Before you can create an 802.1X policy, 802.1X must be enabled on the NE. Before you can configure 802.1X on an Ethernet access port, 802.1X must be enabled on the NE and an 802.1X policy must be created and distributed to the NE.

Note: To create and distribute 802.1X policies to the NEs that use 802.1X, see Chapter 59, “802.1x policies” .

Note: To configure 802.1X on Ethernet access ports, see 16.24 “To configure Ethernet ports” (p. 599) in Chapter 16, “Port and channel object configuration” .

12.17.1 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab.

3

Click on the PAE tab and set the Administrative State parameter to Up.

To disable 802.1X on a managed NE, set the Administrative State to Down.

4

Save your changes and close the form.

END OF STEPS

12.18 To configure an exclusive policy editing restriction on an NE

12.18.1 Before you begin

You can enable or disable an exclusive policy editing restriction on one or more NEs. When enabled, this prevents any local policy definitions that reside on the NE from being changed by a global policy update. You can also remove any exclusive edit locks that were previously set for the selected NE(s).

Note: This procedure can only be performed by admin users or users with an assigned policy management scope of command role.

Note: This functionality is not supported on all devices.

12.18.2 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

Note: You can perform this procedure on multiple NEs if needed. Select the required NEs from the navigation tree, right-click on any one of them, and then select Properties.

2

Click on the Globals tab. The Load Balancing tab is displayed.

3

Click on the Exclusive Edit tab.

4

Perform one of the following:

a. Configure the Use Exclusive Edit parameter to enable or disable an exclusive policy editing restriction for the selected NE(s).

b. Click Reset Exclusive Edit and click Yes to remove any exclusive edit locks that were previously set for the selected NE(s).

Note: The Reset Exclusive Edit option is also available in global routing policies under the Local Definitions tab.

5

Save your changes and close the form.

END OF STEPS

12.19 To configure active card alarms on an NE

12.19.1 Before you begin

You can configure supporting devices to view NE alarms through the CLI.

12.19.2 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab. The Load Balancing tab is displayed.

3

Click on the Alarm Management tab and configure the required parameters.

4

Save your changes and close the form.

END OF STEPS

12.20 To configure a TWAMP server

12.20.1 Before you begin

You can enable or disable Two-Way Active Measurement Protocol on a server and view session and connection statistics.

Note: You cannot configure a TWAMP server after an NE upgrade until the NE is fully resynchronized.

12.20.2 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab. The Load Balancing tab is displayed.

3

Click on the OAM tab and scroll to the OAM TWAMP panel.

4

Configure the Administrative Status parameter.

Note: To make changes to TWAMP server parameters, the Administrative Status parameter must be set to Disabled.
If you are configuring a 7705 SAR, Release 6.1 R5 or later, you can modify the TWAMP prefix Description parameter when the Administrative Status parameter is set to Enabled.

5

Configure the required parameters in the Server Configuration panel.

6

If you are configuring a 7705 SAR, the Reflector Configuration panel is displayed.

Expand the Reflector Configuration panel and configure the Reflector Test Session Timeout (Seconds) parameter.

7

Configure the required parameters in the Time stamping Configuration panel.

8

Click on the Prefix tab.

9

Perform one of the following:

a. Click Create to add a new prefix. The Prefix TWAMP Server (Create) form opens, with the General tab displayed.

Note: The NFM-P allows you to create an unlimited number of prefixes. However, an NE can only accept a maximum of 100 prefixes. If more than 100 prefixes are created in the NFM-P, the affected NE will issue a deployment error.

b. Select an existing prefix and click Properties. The Prefix TWAMP Server (Edit) form opens, with the General tab displayed.

10

Configure the required parameters.

11

Click on the Statistics tab.

12

Select either Srv Conns Stats (Assurance) or Prefix Srv Stats (Assurance), as required, from the Select Object Type drop-down menu.

13

Select either Past 4 Hour(s) or No Filter, as required, from the filter selector.

14

Click Statistics Policies and select Statistics Policy from the menu. The Statistics Policy form opens, with the General tab displayed.

15

Configure the required parameters.

16

Click on the Thresholds tab.

17

Perform one of the following, depending on your selection in Step 12 .

a. Configure the Prefix Srv Stats (Assurance) threshold parameters.

b. Configure the Srv Conns Stats (Assurance) threshold parameters.

18

Save your changes and close the forms.

19

To view TWAMP statistics on a server:

1. Perform Step 1 to Step 3 of this procedure.
2. Click on the Prefix tab.
3. Select either Srv Conns Stats (Assurance) or Prefix Srv Stats (Assurance), as required, from the Select Object Type drop-down menu.
4. Select either Past 4 Hour(s) or No Filter, as required, from the filter selector.
5. Click Collect or Collect All. The system compiles the statistics and displays the available records in the table.

   Note:

   The objects listed in the table control the behavior of the TWAMP connections that match the defined IP prefix.
6. Select the required record from the table and click Properties. The Statistics Record is displayed.
7. Save your changes and close the forms.

END OF STEPS

12.21 To enable LLDP on an NE

12.21.1 Before you begin

LLDP is a not a routing protocol, but instead, a neighbor-discovery protocol that allows an NE to advertise its identity and capabilities to other NEs attached to the same physical IEEE 802.1 LAN. As such, it is configured in a different manner than standard routing protocols.

LLDP also permits information that the device discovers about peer devices to be stored. LLDP is only applicable for devices using Ethernet connectivity. To enable LLDP, you must configure the protocol at both the system level and at the port level. This is done using the NFM-P equipment navigation tree.

When LLDP is enabled on a device, it sends and receives LLDP messages on all of the physical interfaces that are enabled for LLDP transmission. These messages are sent periodically to ensure that information is accurate. These messages are stored on the local device for a configurable amount of time, and after this time has expired, the information is discarded.

The NFM-P uses the information stored in the applicable LLDP tables on the node to automatically discover the physical topology in the network. You can use this information to examine the L1/L2 topology and perform appropriate diagnostics and troubleshooting. Care must be taken when configuring the Port ID SubType parameter, as the setting may affect the ability to build the Layer 2 topology map using LLDP. See the NE documentation for more information.

In LLDP, a single LLDP Protocol Data Unit is transmitted in a single Ethernet frame. The basic LLDP PDU consists of a header, followed by a variable number of information elements known as TLVs that each include fields for Type, Length, and Value. Type identifies what kind of information is being sent. Length indicates the length of the information string. Value is the actual information sent. Each LLDP PDU includes three mandatory TLVs followed by optional TLVs.

Mandatory TLVs include:

- Chassis ID: represents the identification of the device transmitting the LLDP frame
- Port ID: represents the identification of the port transmitting the LLDP frame
- TTL: represents the length of time the receive frame shall be valid

Optional TLVs include:

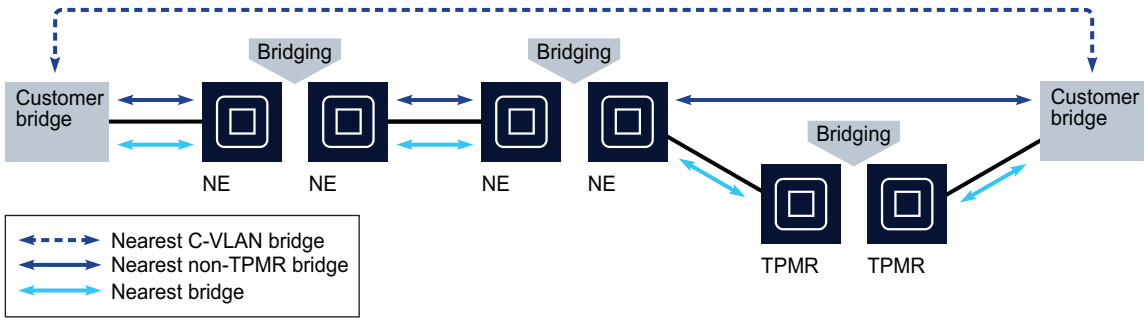
- Port Description: represents the description of the port
- System Name: this is the administratively-assigned name of the device
- System Description: this is a textual description of the device
- System Capabilities: this identifies the capabilities of the device and its function (such as router, switch, repeater, etc.)

LLDP also supports multiple transmission scopes. The destination MAC address in the LLDP PDU determines how a frame is propagated through the network, thereby determining the LLDP message scope. The following table and figure identify a set of destination MAC address and describes the different transmission scopes associated with each address.

Table 12-1 MAC Addresses and transmission scopes

Name	Value	Purpose
Nearest Bridge	01-80-C2-00-00-0E	Propagation constrained to a single physical link
Nearest non-TPMR bridge	01-80-C2-00-00-03	Propagation constrained by all bridges other than TPMR; intended for use within provider bridged networks
Nearest Customer Bridge	01-80-C2-00-00-00	Propagation constrained by customer bridges

Figure 12-1 LLDP Multiple Transmission Scopes



12.21.2 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Enable LLDP.

1. Click on the Globals tab and then on the LLDP tab.
2. Configure the required parameters.

   Care must be taken when configuring the Port ID SubType parameter, as the setting may affect the ability to build the Layer 2 topology map using LLDP. See the NE documentation for more information.

3

Save your changes and close the forms. See Table 12-2, “LLDP related tasks” (p. 360) for additional procedures related to LLDP information.

Table 12-2 LLDP related tasks

Task	See
Configure LLDP on supported ports to send the ifDesc value in place of the ifAlias value over port TLV. Additionally, IPv6 addresses can be configured on the Transmit MGMT Address tab.	16.24 “To configure Ethernet ports” (p. 599)
Configure LLDP on OmniSwitch Ethernet ports.	16.56 “To configure OmniSwitch Ethernet ports” (p. 647)
Configure LLDP on module cards on a 7705 SAR-M/ME or 7705 SAR-H	15.83 “To configure a module card on a 7705 SAR-M/ME or 7705 SAR-H” (p. 543)

END OF STEPS

12.22 To configure the BFD flap detection interval on an NE

12.22.1 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, then on the BFD tab.

3

Configure the Operational State Transition Interval (seconds) parameter.

4

Save your changes and close the form.

END OF STEPS

12.23 To enable a Q in Q untagged SAP on an NE

Note: The Enable Q in Q Untagged Sap parameter is not supported on the 7950 XRS as it is enabled by default.

12.23.1 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, then on the Ethernet tab.

3

Enable the Enable Q in Q Untagged Sap parameter.

When you enable the Enable Q in Q Untagged Sap parameter, the NFM-P allows the creation of the following two default SAP types:

- The SAP type *.null functions as a default SAP for single-tagged frames on a Q in Q port. This SAP accepts single tags in the range 0 to 4095 as well as untagged traffic.
- The SAP type *.* functions as a default SAP for double-tagged frames in a Q on Q port. This SAP accepts untagged, single-tagged, and double-tagged frames with tags in the range 0 to 4095.

4

Save your changes and close the form.

END OF STEPS

12.24 To configure DHCPv6 Advertise messages on an NE

12.24.1 Purpose

Complete this procedure to specify which DHCPv6 client applications on an NE are sent NO_ADDRS_AVAILABLE messages when the server runs out of addresses.

12.24.2 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, then on the Subscriber Management tab.

3

On the DHCPv6 panel, specify one or more DHCPv6 Advertise message format options for the Advertise Message parameter, and configure other required parameters if available.

4

Save your changes and close the form.

END OF STEPS

12.25 To configure Python script protection on an NE

12.25.1 Purpose

Complete this procedure to configure an NE with a protection key, shared with a Python script policy, and with source and destination URLs for a protected Python script. For information on Python script policies, see 58.1 “Python policies and Python script policies” (p. 1807) .

12.25.2 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, then on the Subscriber Management tab.

3

Configure the required parameters on the Python Script Protection panel.

The Protection Key parameter value must match the protection key value of the specified Python script policy. The two values are validated against each other when Python script protection is enabled.

4

Click on the Protect Script button.

5

Save your changes and close the form.

END OF STEPS

12.26 To configure home LAN extension functionality on an NE

12.26.1 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, then on the Subscriber Management tab.

3

Configure the Router Target AS Number parameter on the LAN Extension panel.

4

Save your changes and close the form.

END OF STEPS

12.27 To configure ISA service chaining on an NE

12.27.1 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, then on the Subscriber Management tab.

3

Configure the MAC Prefix parameter on the ISA Service Chaining panel.

4

Save your changes and close the form.

END OF STEPS

12.28 To configure optimized HTTP redirects on an NE

12.28.1 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, then on the Subscriber Management tab.

3

Configure the Optimized Mode parameter on the CPM HTTP Redirect panel.

4

Save your changes and close the form.

END OF STEPS

12.29 To configure sFlow on an NE

12.29.1 Purpose

Perform this procedure to configure an sFlow receiver and counters on a supporting NE. Data for sFlow is collected on ports; for information about enabling sFlow on ports, see 16.24 “To configure Ethernet ports” (p. 599).

12.29.2 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the SFLOW tab.

3

Configure SFLOW receivers.

1. Select a receiver in the Receiver tab and click Properties. The Receiver (Edit) form opens.
2. Configure the required parameters.
3. Save and close the form.

4

Note: If you are configuring egress counter queues for 7250 IXR, go to Step 5.

Configure egress counter policers and queues

1. Click on the Egress Counter Map tab, then on the Policers tab.
2. Click Create. The SFlow Egress Counter Policer form opens.
3. Configure the required parameters.
4. Save and close the form.
5. Click on the Queues tab and then click Create. The SFlow Egress Counter Queue form opens.
6. Configure the required parameters.
7. Save your changes and close the form.

5

Configure egress counter queues for 7250 IXR

1. Click on the Egress Counter Map tab.
2. In the Queues tab, click Create. The SFlow Egress Counter Queue form opens.
3. Configure the required parameters.
4. Save your changes and close the form.

6

Note: If you are configuring ingress counter policers for 7250 IXR, go to Step 7.

Configure ingress counter policers and queues

1. Click on the Ingress Counter Map tab, then on the Policers tab.
2. Click Create. The SFlow Ingress Counter Policer form opens.
3. Configure the required parameters.
4. Save and close the form.
5. Click on the Queues tab and then click Create. The SFlow Ingress Counter Queue form opens.
6. Configure the required parameters.
7. Save your changes and close the form.

7

Configure ingress counter policers for 7250 IXR

1. Click on the Ingress Counter Map tab.
2. In the Policer tab, click Create. The SFlow Ingress Counter Policer form opens.
3. Configure the required parameters.
4. Save and close the form.

8

Click on the Counter Pollers tab to view counter pollers.

9

Click on the Statistics tab and select Receiver Statistics (sFlow) in the Object Type drop-down to view sFlow statistics.

10

Save your changes and close the form.

END OF STEPS

12.30 To configure ANYsec encryption on an NE

12.30.1 Purpose

Perform this procedure to configure an sFlow receiver and counters on a supporting NE. Data for sFlow is collected on ports; for information about enabling sFlow on ports, see 48.5 “To configure a local connectivity association” (p. 1458).

12.30.2 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the ANYSec tab.

3

Configure the required general parameters.

4

Click on the Security Termination Policy tab and click Create. The Security Termination Policy (Create) form opens.

1. Configure the required parameters.
2. Save your changes and close the form.

5

Click on the Encryption Group tab and click Create. The Encryption Group (Create) form opens.

1. Select a security termination policy in the Security Termination Policy Name panel.
2. Select a MACsec connectivity association site in the Connectivity Association panel.
3. Configure the other parameters, as required.
4. Click on the Peer tab and click Create. The Peer (Create) form opens.
5. Configure the required parameters.
6. Save your changes and close the forms.

6

Save your changes and close the form.

END OF STEPS

12.31 To create a chassis-level PBB configuration

12.31.1 Purpose

Perform this procedure to provide the PBB MAC name configuration at the NE level.

12.31.2 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, then on the Service tab.

3

Configure the required parameters.

4

Click on the MAC Name tab and click Create. The PBB MAC Name (Create) form opens.

5

Configure the required parameters.

6

Save your changes and close the form.

END OF STEPS

12.32 To configure serving network information on an NE

12.32.1 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, then on the Serving Network tab.

3

Configure the required parameters.

4

Save your changes and close the form.

END OF STEPS

12.33 To configure L2TP on an NE

12.33.1 Purpose

Perform this procedure to configure a non-multi-chassis tunnel ID range on an NE.

12.33.2 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, then on the L2TP tab.

3

Configure the Non MC Tunnel ID Range Start and End parameters.

The Non MC Tunnel ID Range Start value must not be greater than the End value.

4

Save your changes and close the form.

END OF STEPS

12.34 To configure WLAN GW redundancy on an NE

12.34.1 Purpose

Perform this procedure to configure a virtual chassis identifier on an NE for the purpose of fail-over redundancy in WLAN GW configurations. You must perform this procedure on each NE in the redundancy configuration. The NEs must all use the same virtual chassis ID string or dual homing key.

12.34.2 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, then on the WLAN GW Sys Config tab.

3

Configure the Virtual Chassis ID and Max Number of GTP Session Held parameters.

4

Save your changes and close the form.

END OF STEPS

12.35 To configure call-trace debug storage on an NE

12.35.1 Purpose

Perform this procedure to configure debug log file storage information for NEs associated with trace profiles.

12.35.2 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, then on the Call-Trace tab.

3

Configure the Maximum Number of Log Files and Primary Compact Flash Card parameters.

4

Save your changes and close the form.

END OF STEPS

12.36 To configure the RADIUS CoA port on an NE

12.36.1 Purpose

Perform this procedure to configure the RADIUS change of authorization port on an NE.

Note: You cannot configure the RADIUS CoA port on the 7950 XRS.

12.36.2 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, then on the RADIUS tab.

3

Configure the RADIUS CoA Port parameter.

Note: If the routing instance is bound to a RADIUS proxy server and the RADIUS CoA port is set to 1812, all CoA messages are received by the RADIUS proxy server and dropped by port 1812.

4

Save your change and close the form.

END OF STEPS

12.37 To configure data persistence on an NE

12.37.1 Purpose

Use this procedure to configure data persistence on an NE that allows you to store dynamic object information about an application in a file on the NE.

12.37.2 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Node Persistence tab.

3

Configure the required parameters on each of the following application panels:

- ANCP
- Application Assurance
- DHCP Server
- NAT Port Forwarding

- Python Policy Cache
- Subscriber Management
- DHCP Lease Time Threshold

Note: Configuring the File Location parameter for any of the above applications enables data persistency for that application. Ensure that the specified location has sufficient disk space to handle the volume of dynamic objects that will persist on it. If the system is unable to store persistency data because the device is inaccessible or full, an alarm is raised.

4

Save your changes and close the form.

END OF STEPS

12.38 To configure DNS security extensions

12.38.1 Before you begin

The NFM-P supports configuring DNS security options on 7450 ESS, 7750 SR, and 7950 XRS nodes.

12.38.2 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the DNS tab.

3

Configure the required parameters.

4

Save your changes and close the form.

END OF STEPS

12.39 To enable or disable ICMP extensions on a NE

12.39.1 Purpose

Use this procedure to configure the use of vendor-specific ICMP extensions on the 7950 XRS, 7450 ESS, 7705 SAR, and 7750 SR NEs. Network operators can use the information provided by the ICMP extensions to diagnose routing problems. By default, ICMP extensions are disabled on devices.

12.39.2 Steps

1

On the equipment tree, right-click on a NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the ICMP tab.

3

Configure the Vendor-Specific ICMP Extensions parameter.

4

Save your changes and close the form.

END OF STEPS

12.40 To configure a PPPoE Intermediate Agent on an NE

12.40.1 Purpose

Perform this procedure to enable a supporting OmniSwitch NE as an Intermediate Agent (IA) for Point-to-Point Protocol over Ethernet (PPPoE).

12.40.2 Steps

1

On the equipment navigation tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, then on the PPPoE-IA tab.

3

Configure the required parameters.

Configure port parameters

4

On the Network Element (Edit) form navigation tree, expand the Shelf icon.

5

Expand to the port level and click on a port object. The Physical Port (Edit) form opens.

6

Click on the PPPoE-IA tab. The PPPoE-IA configuration form opens.

7

Configure the required parameters.

8

Save your changes and close the forms.

Configure LAG parameters

9

On the equipment navigation tree, expand Network→*NE*→Logical Groups→LAGs→LAG *n*.

10

Right-click on the LAG *n* object and choose Properties. The LAG (Edit) form opens.

11

Click on the PPPoE-IA tab. The PPPoE-IA configuration form opens.

12

Configure the required parameters.

13

Save your changes and close the forms.

END OF STEPS

12.41 To create an FPE

12.41.1 Before you begin

Use this procedure to configure a Forward Path Extension on an NE for traffic pre-processing. FPE is supported on the following NEs:

- SR-7/12/12e (chassis mode D)
- SR-1e/2e/3e
- SR-a4/a8
- ESS-7/12 (chassis mode D) with Mixed-Mode enabled
- XRS-20/16/40

Creation of a PXC or LAG path is required for enabling PwPort or a VXLAN. For a LAG path, two LAGs are required. LAG members should be PXC SubPorts.

When the FPE path is composed of PXC SubPorts (PXC path), the direction b sub-port is the egress sub-port. When the FPE path is composed of a pair of LAGs, the LAG configured as the FPE Xb LAG represents the egress direction, regardless of the direction of the SubPorts in the LAG.

To use the FPE for PW Port FPE on an Epipe service site, the Pw Port parameter must be enabled. To use the FPE for VXLAN tunnel termination, Vxlan termination must be enabled.

Supported breakout ports can be associated to a PXC. The PXC ports can added to either a LAG or an FPE. The LAG with the PXC can be associated to the FPE.

12.41.2 Steps

1

On the equipment tree, right-click on a NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Forward Path Extension tab.

3

Click on the SPD ID sub-tab and configure the required SPD ID parameters.

4

Configure an FPE:

1. Click on the FPE tab.
2. Click Create. The Forwarding Path Extension (Create) form appears.

   If the FPE is to be assigned to a GTP group interface, place a check mark in the Extensions Enabled parameter.
3. In the Path panel, select one or more of the PXC, FPE Xa LAG, and FPE Xb LAG objects.

4. Configure the required parameters.

   If the FPE is to be assigned to a GTP group interface or to a bonded group interface configuration, place a check mark in the Extensions Enabled parameter.

5. Save your changes and close the form.

END OF STEPS

12.42 To configure satellite file transfer

12.42.1 Purpose

Perform this procedure to specify the satellite file transfer protocol to be used for the boot process when transferring boot images and configuration files from the 7x50 host to the Ethernet satellite.

12.42.2 Steps

1

On the equipment tree, right-click on a NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Satellite Features tab and configure the Satellite File Transfer parameter.

3

Save your changes and close the form.

END OF STEPS

12.43 To create a port template

12.43.1 Before you begin

Perform this procedure to create a port template on an NE, Release 15.0 R4 or later, that supports Ethernet satellites. A port template allows the satellite port type to be configured as client or uplink. A port template can only be edited or deleted if it is not associated to an active satellite.

12.43.2 Steps

1

On the equipment tree, right-click on the NE with the Ethernet satellite shelf and choose Properties.

2

Click on the Port Templates tab and click Create. The Satellite Port Template Create form opens.

3

Configure the required parameters.

4

Save your changes and close the form.

5

Click on the Satellite Port Template and click Properties. The Satellite Port Template form opens.

6

Set the Admin State parameter to Down and configure the rest of the required parameters on the General tab.

7

Click on the Ports tab, click on a Satellite Physical Port Id, and click Properties.

8

Set the Port Role parameter.

For 100 GE client ports, 1/1/c3/1 and 1/1/c4/1 must both have the same roles.

Role of none means the port is neither a data port nor uplink satellite port.

For 10 GE uplink port template, you must set the 100 GE ports to role of none, and there is a maximum of 16 sequential 10 GE ports that can be configured as uplink ports.

9

Configure the other parameters, as required.

10

Save your changes and close the form.

11

Associate the port template to a satellite. See 15.98 “To associate a port template on an Ethernet satellite shelf” (p. 560).

END OF STEPS

12.44 To configure the Sender-ID TLV of a CFM PDU for an NE

12.44.1 Before you begin

On supporting NEs, you can specify a user-defined ID in the Sender ID TLV of CFM PDUs. To use this option, the ID-Permission parameter on the MEG Service form for the NE MEG must be set to “chassis”; see 91.15 “To configure an Ethernet CFM MD policy and subordinate objects” (p. 3109).

12.44.2 Steps

1

On the equipment tree, right-click on a device and select Properties. The Network Element (Edit) form opens with the General tab displayed.

2

Click on the Globals tab and on the OAM tab.

3

Configure the parameters in the Sender ID panel.

When the Sender ID Type parameter is set to Local, you can configure the Sender ID Name parameter with a user-defined ID to be used in the Sender ID TLV of CFM PDUs.

4

Save your changes and close the form.

End of steps

12.45 To configure the global EVPN proxy ARP and node discovery on an NE

12.45.1 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, then on the Service tab.

3

Configure the System EVPN Proxy ARP ND parameter.

4

Save your changes and close the form.

End of steps

12.46 To configure a no-service loopback port on the 7210 SAS

12.46.1 Before you begin

When you configure a port loopback with MAC swap on a 7210 SAS NE, you must configure a no-service port. You can select a physical port or a virtual port. Not all chassis types support virtual no-service ports.

If you select a physical port as a no-service port, the port cannot contain any SAPs.

For virtual no-service ports, the number of available ports and the port names vary depending on the chassis type. Virtual ports are not displayed on the navigation tree.

You cannot select the same no-service port for more than one function.

See the NE documentation for more information.

12.46.2 Steps

1

On the equipment tree, right-click on a 7210 SAS NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, then click on the Service tab.

3

Select a loopback no-service port. Perform one of the following:

a. Select a physical loopback no-service port.

b. Select a virtual loopback no-service port and configure all other required parameters.

The availability of virtual ports varies depending on the chassis type and card type.

4

Save your changes and close the forms.

END OF STEPS

12.47 To configure CFM DMM version 1 interoperability on the 7210 SAS

12.47.1 Steps

1

On the equipment tree, right-click on a 7210 SAS NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, then click on the CFM tab.

3

Configure the DMM Version 1 Compatibility parameter.

4

Save your changes and close the form.

END OF STEPS

12.48 To configure two WRED slopes on a 7210 SAS

12.48.1 Purpose

The 7210 SAS-D and 7210 SAS-M support three WRED slopes per queue:

- High priority/in-profile TCP
- Low priority/out-of-profile TCP
- Non-TCP

Perform this procedure to specify whether only the high priority and low priority slopes are used, and non-TCP slopes are ignored.

12.48.2 Steps

1

On the equipment tree, right-click on a 7210 SAS NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the QoS tab.

3

Configure the Use WRED Slopes parameter.

4

Save your changes and close the form.

END OF STEPS

12.49 To configure frame-based accounting for QoS policies on a 7210 SAS

12.49.1 Steps

1

On the equipment tree, right-click on a 7210 SAS NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Frame Based Accounting tab.

3

Configure the required parameters.

4

Save your changes and close the form.

END OF STEPS

12.50 To configure the global system resource profile on a 7210 SAS or 7250 IXR

12.50.1 Purpose

Perform this procedure to allocate the system resources on 7210 SAS or 7250 IXR NEs.

The functional areas for which you can allocate resources vary, depending on the chassis type. See 6.5.13 “System resource profile” (p. 220) and the NE documentation for more information about system resource allocation.

For the 7210 SAS-R, system resources for the G8032 Fast Flood, VPLS Up MEP Resource, and Router functions are configured on the device properties form using this procedure. Other system resources for the 7210 SAS-R are allocated using a policy; see 12.51 “To configure a system resource profile policy for the 7210 SAS-R/T/Mxp, 7210 SAS-S/Sx, or 7210 SAS-S/Sx VC” (p. 382) .

To configure port-based scheduling on the 7210 SAS-Mxp or 7210 SAS-R, see 12.53 “To configure port-based scheduling on the 7210 SAS” (p. 384) .

Note: System hardware resources are shared. Do not assign more than the available resources. Functions are disabled if you assign more than the amount of available resources.

Supporting releases of the 7250 IXR allow custom forwarding path resource allocation for resource-intensive functions such as multicast, ACL classification criteria, policers, etc.; see 12.57 “To configure forwarding path options or resource allocation on a 7250 IXR” (p. 388).

12.50.2 Steps

1

On the equipment tree, right-click on a 7210 SAS or 7250 IXR NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, then click on the System Resource Profile tab.

3

Configure the required parameters.

Configuration changes for some parameters require a reboot of the NE to take effect; see the NE documentation for more information.

If you are configuring ECMP profiles for a 7250 IXR NE, consider the following:

- There are no default ECMP profiles for 7250 IXR.
- For 7250 IXR with SR OS, ECMP profiles can be modified.
- For 7250 IXR with SR OS, MPLS profiles are supported.

If you are configuring a 7210 SAS NE, consider the following:

- To configure MAC authentication, set the Ingress MAC Authentication Resource and Egress MAC Authentication Resource parameters to 1 in the MAC Authentication panel.
- To enable port-based access-ingress policies on a 7210 SAS-R6 or R12, set the Sap Scale Mode parameter to High.
- The SAP Egress Aggregate Meter parameter is configurable when the Total ACL Resource parameter in the SAP Egress Internal ACL panel is set to a value of 1 or less.
- If you set the SAP Egress Aggregate Meter parameter and then configure egress meters on SAPs, you cannot reset the parameter to a lower value unless you remove all egress meter configurations for all SAPs on the NE.
- In the SAP Ingress Internal ACL panel, the sum of the values for the IPv4 Resource, IPv4/128-bit IPv6 Resource, and 64-bit IPv6 Resource parameters must not be greater than the value specified for the Total ACL Resource parameter.
- In the SAP Egress Internal ACL panel, the sum of the values for the MAC Resource, IPv4 Resource, 128-bit IPv6 Resource, and 64-bit IPv6 Resource parameters must not be greater than the value specified for the Total ACL Resource parameter.
- In the SAP Ingress QoS Resources panel, the sum of the values for the MAC Resource, IPv4 Resource, and IPv4/v6 Resource parameters must not be greater than the value specified for the Total QoS Resource parameter.
- Each 128-bit address consumes two entries of the available entry resources.
- The value for the Up MEP Resource parameter must not be greater than the value for the Total CFM Resource parameter.
- For the Max IP Subnets parameter, IPv4 subnets use one entry each and IPv6 subnets use two entries each.

- You cannot set the Mbs Pool Type parameter to Node when ports on the NE are decommissioned.

4

Save your changes and close the form.

END OF STEPS

12.51 To configure a system resource profile policy for the 7210 SAS-R/T/Mxp, 7210 SAS-S/Sx, or 7210 SAS-S/Sx VC

12.51.1 Purpose

System resource profiles for the 7210 SAS-R/T/Mxp, 7210 SAS-S/Sx or 7210 SAS-S/Sx VC are configured using the NFM-P policy distribution framework (except for the G8032 Fast Flood, VPLS Up MEP Resource, and Router functions; see 12.50 “To configure the global system resource profile on a 7210 SAS or 7250 IXR” (p. 380)). See Chapter 49, “Policies overview” for more information about NFM-P policies. You can configure up to 16 system resource profile policies and distribute them to 7210 SAS-R/T/Mxp, 7210 SAS-S/Sx or 7210 SAS-S/Sx VC devices. A selected policy is assigned to the card slot of the device; see 15.71 “To select system resource profile policies for the 7210 SAS-R or 7210 SAS-S/Sx VC” (p. 529) .

To configure port-based scheduling on the 7210 SAS-R using the system resource profile, see 12.53 “To configure port-based scheduling on the 7210 SAS” (p. 384) .

Note: The Total QoS Resource and MAC Authentication parameters are not supported on 7210 SAS-S/Sx VC.

See 6.5.13 “System resource profile” (p. 220) in 6.5 “7210 SAS” (p. 216) and the NE documentation for more information about system resource allocation.

12.51.2 Steps

1

Choose Policies→QoS→SROS QoS→7210 System Resource Profile Policy from the NFM-P main menu. The 7210 System Resource Profile Policies form opens.

2

Click Create or choose a policy and click Properties.

3

Configure the required parameters.

When the policy is assigned to a card slot and the SAP Aggregate Meter parameter is modified, you must reboot the card or the node for the modified value to take effect.

To enable Primary VLAN for egress MIPs on supporting 7210 SAS-R or 7210 SAS-S/Sx VC NEs, you must allocate resources to the Bi Directional MIP Egress parameter.

In the SAP Ingress Internal ACL panel, the sum of the values for the MAC Resource, IPv4 Resource, 64-bit IPv6 Resource, and 128-bit IPv4/v6 Resource parameters must not be greater than the value specified for the Total ACL Resource parameter.

In the SAP Egress Internal ACL panel, the sum of the values for the MAC Resource, MAC/IPv4 Resource, 128-bit IPv6 Resource, and 64-bit MAC/IPv6 Resource parameters must not be greater than the value specified for the Total ACL Resource parameter.

In the SAP Ingress QoS Resources panel, the sum of the values for the MAC Resource, MAC/IPv4 Resource, and 64-bit MAC/IPv4/v6 Resource parameters must not be greater than the value specified for the Total QoS Resource parameter.

The sum of the values for the Down MEP Resource and Up MEP Resource parameters must not be greater than the value for the Total CFM Resource parameter.

Each 128-bit address consumes two entries of the available entry resources.

To configure MAC authentication, set the Ingress MAC Authentication Resource and Egress MAC Authentication Resource parameters to 1 in the MAC Authentication panel.

4

Save your changes and close the form. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

12.52 To configure chassis MAC address on the 7210 SAS-S/Sx VC

12.52.1 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, and then on the Virtual Chassis tab.

3

Configure the required VC Configuration parameters.

The user must specify a range of MAC addresses to use if LAGs are used, with the following conditions:

- The number of MAC addresses range from 1 to 126.
- The first MAC address in the block of MAC addresses is used as the chassis MAC address, and the subsequent MAC addresses are used to assign MAC addresses to LAGs configured in the VC.
- The number of MAC addresses specified must match up with the number of LAGs in use.
- A LAG will be operationally down if no MAC addresses are available for allocation.

- By default, the LAG MAC addresses are allocated from the active CPM MAC address pool (the base MAC address and the number of MAC addresses available in this pool are printed on the label of the chassis).
- The user can use a fixed MAC address for a LAG that is independent of the CPM chassis in use. This simplifies provisioning by removing the need to change the MAC addresses on peer nodes in the network when MC-LAG is in use.

4

Click Ok to save your changes and close the form.

5

Reboot the NE.

Configuration changes require a reboot of the NE to take effect; see the NE documentation for more information. After reboot, the base MAC address is replaced with the configured VC MAC address.

END OF STEPS

12.53 To configure port-based scheduling on the 7210 SAS

12.53.1 Purpose

Using the global system resource profile, you can configure access ports on the 7210 SAS-Mxp or 7210 SAS-R to use either port-based or SAP-based egress scheduling. When port-based scheduling is enabled, the port supports eight egress queues, and all SAPs on the port share the same set of eight queues.

Queues for port-based scheduling are configured in the 7210 port access egress policy assigned to the port; see 50.31 “To configure a 7210 and 1830 port access egress policy” (p. 1556) . See 70.15 “Sample QoS configuration on the 7210 SAS” (p. 1954) for more information about configuring scheduling on the 7210 SAS-Mxp and 7210 SAS-R.

SAP-based egress queues are not available when port-based scheduling is enabled. See the NE documentation for more information.

You must enable port-based scheduling before configuring egress meters.

12.53.2 Steps

1

On the equipment tree, right-click on the required NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, then click on the System Resource Profile tab.

3

Configure the Port Scheduler Mode (Configured) parameter.

Changes to the Port Scheduler Mode (Configured) parameter require a reboot of the NE to take effect. The Port Scheduler Mode (Active) parameter displays the parameter setting currently in effect on the NE.

4

Save your changes and close the form.

END OF STEPS

12.54 To configure buffer management for the 7210 SAS

12.54.1 Before you begin

For the 7210 SAS-M and 7210 SAS-T, queue buffer resources are by default allocated equally to all ports on the device. You can decommission unused ports and assign their buffer resources to other ports. Decommissioned ports cannot be turned up or used for any function. Configurations deployed to a device with decommissioned ports will not take effect on the decommissioned ports.

Port decommissioning and buffer resource assignment are configured using profiles. You can configure up to 30 buffer management profiles per NE. Changes to profile configuration take effect when the NE is rebooted. The status for a profile indicates whether it is currently active or if it requires a reboot before it takes effect.

For the 7210 SAS-T, you must configure the system resource profile before you configure buffer management; see 12.50 “To configure the global system resource profile on a 7210 SAS or 7250 IXR” (p. 380) .

See the NE documentation for more information about buffer management.

12.54.2 Steps

1

On the equipment tree, right-click on a 7210 SAS NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, then on the Port Decommission tab. A list of buffer management profiles is displayed.

3

Delete one or more buffer management profiles, if required. Choose the profile and click Delete.

4

Configure a buffer management profile:

1. Click Create or choose a profile and click Properties. The Buffer Management form opens.
2. Configure the ID and Description parameters.
3. Click on the From tab, then click Add. The Select form opens.
4. Select one or more ports to decommission and click OK. The Select form closes.

   The selected ports are decommissioned the next time the NE reboots.
5. Click on the To tab, then click Add. The Select form opens.
6. Select one or more ports and click OK. The Select form closes.

   The buffer resources of the decommissioned ports are assigned to the selected ports the next time the NE reboots.
7. Save your changes and close the form.

5

Repeat Step 4 to create additional profiles. You can create up to 30 profiles.

Note: You must reboot the NE for changes to buffer management profiles to take effect. The status for a profile indicates whether it is currently active or if it requires a reboot in order to take effect.

END OF STEPS

12.55 To configure 7210 SAS-R device properties for MVPN

12.55.1 When to use

When you configure 7210 SAS-R sites in a VPRN for multicast VPN using a P2MP LSP, you must configure the device properties appropriately. Also, PIM or IGMP must be enabled on the site.

Perform the following to configure the device properties for a 7210 SAS-R site.

12.55.2 Steps

1

On the equipment tree, right-click on the required 7210 SAS-R NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab.

3

To allocate system resources to enable the P2MP function, click on the System Resource Profile tab and configure the MPLS P2MP Resource parameter.

4

Specify a no-service P2MP bud port. You can use a virtual port or a physical port. Click on the Service tab, then on the General tab, and perform one of the following:

Note: You can only configure a no-service P2MP bud port when LDP is disabled on the site routing instance. You must set the Administrative State to Down on the General tab of the LDP properties form. See 28.51 “To configure global-level LDP” (p. 941).

a. Select the Use Virtual P2MP Bud Port parameter and choose a virtual port. The number of available ports and the port names vary depending on the card type and release. Virtual ports are not displayed on the navigation tree.

b. Select a physical P2MP Bud port. The physical port cannot contain any SAPs.

5

Save your changes and close the form.

To configure MVPN on the 7210 SAS-R site, see 79.28 “To configure an MVPN VRF instance on a VPRN site” (p. 2570).

To enable PIM on the 7210 SAS-R site, see 28.99 “To create a PIM site on a VPRN routing instance” (p. 1003).

To enable IGMP on the 7210 SAS-R site, see 28.104 “To configure an IGMP site on a router” (p. 1017).

END OF STEPS

12.56 To configure IP fragmentation for 7210 SAS

12.56.1 When to use

For 7210 SAS-Mxp, native IP fragmentation for IP packets exceeding the configured MTU is not supported by default. You can configure CPM to extract oversized IPv4 packets from the datapath, fragment them using the system CPU, and insert the fragmented packets back into the datapath.

Note: Even when IP fragmentation is enabled, packets that exceed the configured MTU are dropped if the Do not Fragment (DF) bit is set in the IP header.

Perform the following to configure the IP fragmentation for a 7210 SAS-Mxp site.

12.56.2 Steps

1

On the equipment tree, right-click on the required 7210 SAS-Mxp NE and choose Properties. The Network Element (Edit) form opens.

2

Click the General tab.

3

Configure the Allow CPU Fragmentation parameter.

4

Save your changes and close the form.

END OF STEPS

12.57 To configure forwarding path options or resource allocation on a 7250 IXR

12.57.1 Purpose

Supported releases of the 7250 IXR allow custom forwarding path options such as 802.1x Host Authentication, or resource allocation for resource-intensive functions such as multicast, ACL classification criteria, policers, etc.

A reboot of the NE is required for changes made using this procedure to take effect.

Depending on the 7250 IXR release, the displayed tabs and parameters may vary.

12.57.2 Steps

1

On the equipment tree, right-click on a supporting 7250 IXR NE and choose Properties. The Network Element (Edit) form opens.

2

Click the Globals tab, then click the Forwarding Path tab.

3

Configure the parameters, as required.

4

Click the Options subtab and configure the required parameters.

Note: Forwarding path option resources are shared. When some functions are enabled, others may be disabled. The NFM-P displays an error message when mutually exclusive functions are selected.

Note: After you change the administrative state, enable the Reboot Required check box to reboot the NE and apply the changes.

5

Click the Resource Allocation subtab and configure the required parameters on the following subtabs:

- General
- Filter Ingress IPv4
- Filter Ingress IPv6
- Policer Application Group. To configure the policer scale:
  1. Choose an item in the list and click Properties. The Policer Application Group form opens.
  2. Click on the Policer Application subtab, choose an item, and click Properties. The Application Group (Edit) form opens.
  3. Configure the required parameters.

     When the Override Administrative State and Override Operational State parameters on the General subtab are enabled, you cannot modify the scale values.

After the configuration, the Reboot Required parameter is enabled.

6

Click the LPM subtab and configure the scale options.

7

Save your changes and close the form.

8

Reboot the NE for configuration changes to take effect.

END OF STEPS

12.58 To configure policer allocation

12.58.1 When to use

Perform this procedure to enable policer allocation on 7250 IXR-J2 NE variants to support a higher SAP scale. In this policer allocation model, the 8, 16, and 32 policer allocation model is disabled, and the 2, 4, and 8 policer allocation model is enabled.

12.58.2 Steps

1

On the equipment tree, right-click on a supporting 7250 IXR NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, the Forwarding Path tab, then on the Resource Allocation subtab.

3

The override administrative state must be disabled, and a reboot is required, before you can make any modifications.

1. Click on the General subtab.
2. Disable the Override Administrative State parameter, and enable the Reboot Required check box.
3. Save your changes.

4

Configure the new policer application group, which refers to the 2, 4, 8 policer model; perform 12.57 “To configure forwarding path options or resource allocation on a 7250 IXR” (p. 388), Step 5.

5

Configure the policer application bank:

1. Click on the Policer Application Bank subtab.
2. Click Search to populate the list if required, or choose a policer model, then click Properties. The Application Bank form opens.
3. Configure the required parameters.
4. Save your changes.

6

Configure the application bank group if it refers to the old policer model (8, 16, 32) instead of the new policer model (2, 4, 8). The Override Administrative State must be disabled and a reboot is required before you do this:

1. Perform Step 1 to Step 3 to access the Resource Allocation subtab, then the General subtab, to disable the Override Administrative State parameter, and enable the Reboot Required check box.
2. Save your changes.
3. Perform Step 5 to configure the parameters on the Application Bank form to refer to the new policer model.
4. Perform Step 1 to Step 3 to access the Resource Allocation subtab, then the General subtab, to enable the Override Administrative State parameter, and enable the Reboot Required check box.

7

Create a 7250 IXR SAP access ingress policy; see 50.29 “To configure a 7210, 7250, and 1830 SAP Access Ingress policy” (p. 1544).

8

Perform 12.57 “To configure forwarding path options or resource allocation on a 7250 IXR” (p. 388) to reconfigure the scale options on the LPM subtab, and to change the application bank group to the correct policer model, if required.

9

Create the SAP access ingress policy and assign it to the SAP:

1. Perform 50.28 “To configure a SAP access ingress policy” (p. 1538) to create a SAP access ingress policy.
2. Perform 77.9 “To modify a VPLS” (p. 2259) to associate the SAP access ingress policy to the SAP on the QoS tab.

10

Create a 7250 SROS network ingress policy and assign it to the network interface:

1. Perform 50.43 “To configure a 7250 SROS Network Ingress policy” (p. 1575).
2. Associate the 7250 SROS network ingress policy to the network interface on the Policies tab of the Network Interface – Routing Instance (Edit) form; see 27.17 “To create an L3 network interface on a routing instance” (p. 856) for information about creating a network interface.

11

Save and close the forms.

END OF STEPS

12.59 To configure watermark settings on a 7705 SAR

12.59.1 Steps

1

On the equipment tree, right-click on a 7705 SAR NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Security tab.

3

Configure the required parameters in the Water Mark Settings (Active Sessions) panel.

4

Save your changes and close the form.

END OF STEPS

12.60 To configure QoS ingress aggregate rates on the 7705 SAR-M/ME

12.60.1 Steps

1

On the equipment tree, right-click on the 7705 SAR-M/ME NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the QoS tab.

3

Configure the Aggregate Rate parameter in the Access Ingress panel and in the Network Ingress panel.

4

Save your changes and close the form.

END OF STEPS

12.61 To launch an MCT on a Wavence SA NE connected to a 7705 SAR

12.61.1 Before you begin

The NFM-P supports an integrated MCT from the port or NE level on the 7705 SAR-8 and the 7705 SAR-18. The MCT is distributed with a NEtO client in the NFM-P. The MCT can be launched from the port that is associated with the MW link in the navigation tree or from the MW Link Member (Edit) form. You can configure radio parameters using the MCT.

Consider the following before you launch the MCT:

- Java version 1.6 is required to launch the MCT.
- The MCT is only supported on a Windows client; however, it is not supported on Windows 7.
- Only one MCT session can be open at a time.

12.61.2 Steps

1

On the equipment tree, right-click on a discovered 7705 SAR-8 or 7705 SAR-18 NE and choose External Element Manager.

2

Choose the corresponding MW member from the list and click Launch MCT.

3

Enter your login credentials and click OK. A dialog box appears.

Note: If the client system does not have the required MCT packages, the packages are downloaded from the NFM-P and saved in a third-party folder.

4

Click Accept. The MCT initialization starts, and the MCT main view screen appears.

Note: If the MCT is not installed on the client system, the MCT installer window opens. After the MCT is installed, the MCT main view screen appears for all subsequent launches, with the MCT version adjusted to the NE version from which the MCT launched.

END OF STEPS

12.62 To start and stop a Webview or Secure Webview session on an OmniSwitch

12.62.1 Steps

1

Choose one of the following to start a Webview or Secure Webview session:

a. On the equipment tree, right-click on a discovered OmniSwitch and choose Launch Webview or Launch Secure Webview. A web browser starts and the Webview or Secure Webview login screen appears.

b. On the equipment tree, right-click on a discovered OmniSwitch and choose Equipment Window. The Equipment Window form opens. Select the Launch Webview or Launch Secure Webview button on the form. A web browser starts and the Webview or Secure Webview login screen appears.

2

Enter your user name and password. After a successful login, the Chassis Management Home Page appears.

3

To stop a Webview or Secure Webview session:

1. Click on the Log Out text at the top of the Webview or Secure Webview window. A Confirm Log Out dialog box appears.
2. Click Log Out to end the Webview or Secure Webview session.

See the appropriate OmniSwitch *Switch Management Guide* for information about configuring and using Webview or Secure Webview.

END OF STEPS

12.63 To configure the dying gasp alarm on an OmniSwitch

12.63.1 Before you begin

Perform the following procedure to configure the dying gasp alarm on supporting OmniSwitch NEs.

Note: To view the dying gasp alarm on the NFM-P, the OmniSwitch NE must be managed using SNMP v2 with the community string set to public.

12.63.2 Steps

1

On the equipment tree, right-click on a supported OmniSwitch icon and choose NE Sessions→Telnet Session. The Telnet Session window opens.

2

Perform Step 5 of 8.8 “To commission an OmniSwitch for NFM-P management” (p. 254) to configure the NE to be managed using SNMP v2 with a community string configured to public.

Note: If the Backup/Primary power supply fails, a major alarm will be raised. This alarm will be sent only to the first two SNMP stations configured on the NE. “Show snmp station” lists the management station address. NFM-P ip should be first or second.
The "Loopback 0" address should not be used for the source IP address field on the NE.

END OF STEPS

12.64 To configure shelf craft port IP address on an 1830 VWM device

12.64.1 Steps

1

Perform one of the following:

a. From the device:
   1. On the equipment tree, right-click on the 1830 VWM device object and choose Properties. The Network Element (Edit) form opens.
   2. Click on the Shelf Craft Port tab. The craft port IP address of all the shelves except the OPS shelf are listed.
   3. Choose the shelf for which you need to configure the craft port IP address and click Properties. The Shelf Craft IP (Edit) form opens.

b. From the shelf:
   1. On the equipment tree, expand Network→1830 VWM.
   2. Right-click on the shelf object (not OPS shelf) and choose Properties. The Shelf (Edit) form opens.
   3. Click on the Shelf Craft Port tab.

2

Configure the parameters in the Shelf Craft IP Details panel.

Note:

- The craft port IP address and the craft port gateway cannot be the same.
- Ensure that the craft port IP address and the craft port gateway are in the same subnet.

3

Save your changes and close the form.

END OF STEPS

12.65 To configure an Auto-ID range for policies

12.65.1 Before you begin

NEs that support next-generation CLI use the policy name as the key for internal system reference. For these NEs, a policy ID is also configurable. If a policy ID is not configured, the system auto-assigns a numerical policy ID. When the policy is distributed to an NE, the auto-assigned ID is generated from a specified range of values.

Perform this procedure to configure a numerical range on the NE for auto-assigned policy IDs.

Before you change an existing range configuration on an NE, you must delete any policies on the NE that have IDs within the existing range.

If you configure a range that comprises a policy ID that already exists on the NE, deployment fails.

12.65.2 Steps

1

On the equipment tree, right-click on a supporting NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, and then the Policies tab.

3

For each policy type, configure the start and end values for the ID range.

4

Save your changes and close the form.

END OF STEPS

12.66 To enable USB support on a 7250 IXR

12.66.1 Purpose

Perform this procedure to enable the USB storage option on all 7250 IXR variants, Release 21.2 R1 and later, except for 7250 IXR-s, where USB support is enabled by default.

12.66.2 Steps

1

On the equipment tree, right-click on a supporting NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, and then the USB Support tab.

3

Set the USB Administrative State parameter to Enabled.

4

Save your changes and close the form.

END OF STEPS

12.67 To globally enable or disable Packet Byte Offset on a 7250 IXR

12.67.1 Before you begin

QoS Packet Byte Offset (PBO) allows scheduler policies to operate based on frame sizes with modified overhead values, to automatically account for different service configurations.

Perform this procedure to globally enable or disable QoS PBO on supporting 7250 IXR NEs. The actual offset values for PBO are configured in 7250 SROS VLAN QoS policies or 7250 SROS Port QoS policies; see 50.54 “To configure a 7250 SROS VLAN QoS policy” (p. 1594) and 50.61 “To configure a 7250 SROS Port QoS policy” (p. 1603).

12.67.2 Steps

1

On the equipment tree, right-click on a supporting NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, and then the Policies tab.

3

In the QoS Packet Byte Offset panel, configure the Enable Packet Byte Offset parameter.

4

Save your changes and close the form.

END OF STEPS

12.68 To configure GNSS receiver functions on supported IXR and SR NEs

12.68.1 Before you begin

This procedure applies to 7250 IXR-e, 7250 IXR-e2, 7250 IXR-e2c, 7250 IXR-R6, 7250 IXR-R6d, 7250 IXR-R6dl, or FP5-enabled SRs.

Note: For FP5-enabled SRs, the A/gnss and B/gnss management ports are supported only on the 7750 SR-2se. For all other FP5 chassis, only the A/gnss port is supported.

12.68.2 Steps

1

On the equipment tree, right-click on the NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Inventory tab and select Management Port (Physical Equipment).

3

Select a GNSS port and click Properties. The Management Port (Edit) form opens.

4

Click on the GNSS tab to view GNSS location information and to configure the required parameters.

5

Close the form.

END OF STEPS

12.69 To configure global-level UNP

12.69.1 Steps

1

On the equipment tree, right-click on the NE and choose Properties. The Network Element (Edit) form opens.

2

Click the Globals tab, and then the UNP tab.

3

Click the Classification tab. Click Create. The UNP Classification LLDP (Edit) form opens.

4

Configure the required parameters.

5

Save your changes and close the form.

END OF STEPS

12.70 To configure an UNP at port-level

12.70.1 Steps

1

On the equipment tree, expand Network→*NE*→Shelf→Card Slot *n*→Port *n/n/n*.

2

Right-click on the Port icon and choose Properties. The Physical Port (Edit) form opens.

3

Click Policies tab, and then the General tab.

4

Configure the UNP Port Type parameter.

5

Click UNP Port tab and configure the required parameters.

6

Save your changes and close the form.

END OF STEPS

12.71 To configure DHCPv6 snooping on an NE

12.71.1 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the DHCPv6 Snooping tab.

3

Configure the DHCPv6 Snooping parameter.

4

Save your changes and close the form.

END OF STEPS

12.72 To configure the log encryption key

12.72.1 Before you begin

Use this procedure to create a log encryption key. The log encryption key prevents external attackers from obtaining critical network information from the configuration file, such as users, IP addresses, and protocols. This procedure applies to 7250 IXR-6, 7250 IXR-R6, 7250 IXR-10, 7250 IXR-R4, 7250 IXR-e, 7250 IXR-e2, 7250 IXR-e2c, 7250 IXR-ec, 7250 IXR-s, 7750 SR, 7950 XRS, and VSR NEs.

12.72.2 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, then on the Log Configuration tab.

3

Configure the Encryption Key parameter.

4

Click OK and close the form.

END OF STEPS

Ring group configuration procedures

12.73 To create a ring group

12.73.1 Before you begin

You can use the ring group creation function to:

- indicate a VLAN ring topology
- indicate a VPLS ring topology
- configure the properties of the ring group to provide VLAN Internet, BTV (MVR), and L2 VPN (TLS) services
- group devices by geographic region

Consider the following before you create a ring group.

- Ensure that the devices are commissioned, as described in Chapter 8, “Device commissioning and management” .
- Ensure that mediation policies are configured to allow CLI access to the managed devices, as described in Chapter 9, “Device discovery” .
- If you want specific access interfaces to be part of a VLAN service, ensure that the parent device of the interface is a member of the ring group.

12.73.2 Steps

1

Choose Ring Group from the navigation tree view selector. The navigation tree displays the Ring Group view.

2

Right-click on the Network object and choose Create Ring Group. The Ring Group (Create) form opens.

3

Configure the required parameters.

4

Click Apply. If you set the Ring Group Type parameter to VPLS in Step 3 , go to Step 6 .

5

Click on the TLS tab to configure the TLS parameters. The Ethertype and Jumbo Frame parameters are configurable when the Enabled parameter is selected.

6

Perform one of the following to add a device to the ring group.

a. To add a device using the current properties form:

1. Click on the Group Members tab click Create. The Select Network Elements form opens.
2. Choose one or more NEs and click OK. The selected devices are listed on the Ring Group (Create) form.
3. Click OK and then click Yes. The device objects are listed in the navigation tree under the new ring group object.

b. To add a device from the navigation tree:

1. Right-click on the device object in the Equipment view of the navigation tree and choose Add To Ring Group. The Select Group form opens to display a list of ring groups.
2. Choose the new ring group and click OK. The device object is listed under the ring group in the Ring Group view of the navigation tree.

Note: All device types can be added as members of a VLAN ring group. Only devices that support VPLS can be added to a VPLS ring group.

7

To apply a span of control to a ring group:

1. Click on the Spans tab and click Add. The Select Span(s) - Ring Groups form opens with a list of available spans.
2. Choose one or more spans of control to apply to the ring group.
3. Save your changes and close the form.

8

As required, provision VLAN services for the ring group as described in Chapter 75, “VLAN service management” .

END OF STEPS

12.74 To remove a device from a ring group or a ring group

12.74.1 Steps

1

Choose Ring Group from the navigation tree view selector. The navigation tree displays the Ring Group view.

2

Navigate to the required ring group object. The path is Network→Ring Group→Device.

3

To remove a device from the ring group, right-click on the device object under the ring group and choose Remove From Ring Group. The device is removed from the ring group.

4

Removing a ring group deletes the VLAN services that are associated with the ring group.

To remove a ring group:

1. Perform Step 3 to remove all devices from the ring group.
2. Right-click on the Ring Group object and choose Remove Ring Group.
3. Save your changes and close the form.

END OF STEPS

12.75 To configure the global sampling rate on an NE

12.75.1 Purpose

Perform this procedure to configure the global sampling rate from the chassis at the NE level.

12.75.2 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, then on the Service tab.

3

Click on the Mirror tab.

4

Configure the Global Sampling Rate parameter.

5

Save your changes and close the form.

END OF STEPS

13 Logical group object configuration

Logical group object configuration using the NFM-P

13.1 Overview

13.1.1 Logical group objects

Logical group objects are children of the device object. They appear below the device object in the navigation tree. The following logical group objects are created automatically in the navigation tree after the device is discovered.

- CCAG
- ISA-AA Group
- ISA-Tunnel Group
- ISA-LNS Group
- ISA-NAT Group
- ISA-Video Group
- LAG
- IGH

Properties forms for logical group objects are accessed using the NFM-P navigation tree.

This chapter contains the procedures to configure logical group objects using the navigation tree. See Chapter 3, “NFM-P navigation tree” for more information about using the navigation tree.

13.1.2 Working with CCAG objects

CCAGs are navigation tree objects located below device icons. CCAGs are configured manually using the CCAG object navigation tree menu and subsequent forms. For proper CCAG configuration, a VSM-CCA card must be present in the NE. In the navigation tree, a VSM-CCA card can be opened to show its ports. The ports are indicated by VSM Port x/y/z, which shows port type and the ID of the port.

You must configure the following in the CCAG configuration forms:

- General properties such as CCAG ID, Description, CCA Rate Enabled, CCA Rate, Access Adapt QoS, and Administrative State
- CCAG MDA Members which are compatible ports that can belong to a CCAG.

When you create a CCAG, the NFM-P creates virtual paths to be used as interconnections to bind services together. Two unidirectional paths are created: Alpha and Beta. For each path, three virtual ports are created: one for SAP-SAP connections, one for SAP-NET connections, and one for NET-SAP connections. The last two virtual ports are used to bind a service and a network interface together.

A maximum of eight cards can be added to a CCAG, with a maximum of eight CCAGs per NE.

13.1.3 Working with ISA-AA groups

ISA-AA groups provide AA load balancing, scaling, and redundancy on NEs that contain multiple ISA-AA MDAs or ESA VMs. ISA-AA MDAs and ESA VMs cannot be members of the same ISA-AA group.

ISA-AA redundancy protects against card failure and minimizes service disruption during maintenance or protocol signature upgrades.

The NFM-P supports AA group configuration on the 7450 ESS and 7750 SR. An NE can have up to seven ISA-AA groups.

Note: A single-slot chassis does not support AA configuration.

ISA-AA group configuration requires the following:

- group number, which can be set only during group creation
- up to seven primary group members and one optional backup member
- one or more forwarding classes to divert to the AA group

You can use multiple ISA-AA groups to scale the application of AA policies, and can divide an AA group into partitions that are customized for specific VPN services. Each partition has an AA policy, and supports the configuration of custom protocols, applications, and application groups. Within a partition, you can use application service options, or ASOs, to create multiple application QoS policies (AQPs). AA partitions support statistics collection and data reporting functions.

Note: When you create an ISA-AA group or partition, a default AA policy is automatically created for the group or partition. When you delete a group or partition, the default policy is also deleted.

See Chapter 87, “Application assurance” for more information about AA groups, partitions, and policies. See 13.5 “To configure an ISA-AA group and ISA-AA partitions” (p. 415) for information about creating ISA-AA groups and partitions. See 13.8 “To configure an AA subscriber policy override on an ISA-AA group or partition” (p. 421) and 13.9 “To configure Cflowd collectors on an ISA-AA group or partition” (p. 422) for information about configuring additional ISA-AA group and partition functions.

13.1.4 Working with ISA-Tunnel groups

ISA-tunnel groups provide redundancy for IPsec tunneling and encryption functions when multiple ISA-IPSEC MDAs or ESA VMs are installed on an NE. ISA-IPSEC redundancy protects against card failure and minimizes service interruption during maintenance or protocol signature upgrades. You can configure up to 16 ISA-Tunnel groups on one NE.

An ISA-tunnel group can operate in one of the following modes:

- primary/backup active member (ISA-IPSEC MDA only)
- multiple active members (MDAs or ESA VMs)

The primary/backup configuration provides fault tolerance in the event of an MDA failure. An ISA-tunnel group in a primary/backup configuration can contain a maximum of two MDAs.

ISA-IPSEC MDAs and ESA VMs cannot be members of the same ISA-Tunnel group.

Using multiple active members provides load balancing in addition to fault tolerance. This mode of operation is supported on a 7750 SR in chassis mode D or higher, and on a 7450 ESS in mixed mode. You can include up to 16 members in an ISA-tunnel group when the use of multiple active members is enabled.

You can configure an ISA-tunnel group on a 7750 SR or 7450 ESS in mixed mode to act only as an IKEv2 responder during a MC IPsec switchover. This is the automatic behavior for dynamic tunnels, but not for static tunnels. See Chapter 34, “IPsec” for more information about MC IPsec.

13.1.5 Working with ISA-LNS groups

The NFM-P supports the creation and configuration of ISA-LNS groups. ISA-LNS groups provide LNS PPP session termination on 7750 SR NEs. You can assign an ISA-LNS group to a tunnel group profile or a tunnel profile. When an operational L2TP tunnel is established, peers that are associated with the ISA-LNS group are automatically created. Session traffic is automatically balanced across the available active ISA broadband application MDAs in the group. You can add ISA broadband application MDAs to an ISA-LNS group, and up to four ISA-LNS groups on each NE. See 13.12 “To configure an ISA-LNS group” (p. 426) for information about how to create and configure an ISA-LNS group.

You must configure the following on the ISA-LNS groups configuration form:

- General properties, such as Group Number, Description, and Administrative State
- ISA-LNS Group members

Note: You can configure an ISA broadband application MDA only on an IOM3-XP module in a 7750 SR -7 or 7750 SR-12, Release 20.10 and earlier.

13.1.6 Working with ISA-NAT groups

An ISA-NAT group provides a redundant NAT function for routing instances using ISA Broadband Applications MDAs or ESA VMs. See Chapter 30, “NAT” for information about ISA-NAT group configuration.

13.1.7 Working with ISA-Video groups

ISA-Video groups are created to provide packet buffering and packet processing in support of the IPTV video features.

When configured in the router, video ISAs are logically grouped into video groups. An ISA-Video group allows more than one video ISA to be treated as a single logical entity for a specific application, where the system performs a load-balancing function when it assigns tasks to a member of the group.

ISA-Video groups provide a redundancy mechanism to guard against hardware failure within a group. ISA-Video groups pool the processing capacity of all the group members and increase the application throughput because of the increased packet processing capability of the group.

You must configure the following on the ISA-Video groups configuration form:

- General parameters
- ISA-Video Group members
- ESA Video Group members

An ISA-Video group supports ISA or ESA-VM video group members, and not a mix of group members under the same ISA-Video group.

You can add up to four MDAs to an ISA-Video group, and up to four ISA-Video groups on each NE. All members of an ISA-Video group are primary members.

13.1.8 Working with WLAN GW groups

A WLAN GW group is used to represent multiple hardware adapters as a single entity, allowing for warm redundancy between multiple WLAN GW MDAs or ESAs. Only one WLAN GW group can be created per NE. This group can be numbered 1 to 4, but this number must be exclusive and cannot be in use by an ISA-NAT group.

The IOM is the child of the WLAN GW group. The required IOMs should be added before the WLAN GW group is turned administratively up.

WLAN GW members are created automatically by the NE when the WLAN GW group is administratively up, and deleted automatically when the administrative state is down. The number of members is equal to the active IOM limit.

You can globally list WLAN GW groups from the Manage→ ISA Functions→ ISA-WLAN main menu, or from from Manage→ Equipment→Equipment→ISA-WLAN GW Group (WLAN Gateway).

WLAN GW tunnels

WLAN GW tunnels are created dynamically by the NE when the first UE attempts to connect. The tunnel is used to backhaul traffic from the access point or residential gateway to the WLAN GW. The NE creates tunnels on a per-access point or per-residential gateway basis. WLAN GW tunnels terminate on the WLAN-GW MDA or ESA.

WLAN GW tunnels are viewable on the configuration form for base routing instances, VPRN routing instances, group interfaces, and WLAN GW groups. The WLAN GW tunnels tab lists the WLAN GW tunnels belonging to a given routing instance. User equipment information is viewable from the properties form for individual WLAN GW tunnels. GTP session information (including bearer information) is viewable from the properties form for individual user equipment items. You can globally list WLAN GW tunnels from the Manage→ ISA Functions→ ISA-WLAN main menu.

13.1.9 Working with IGH objects

IGHs are navigation tree objects located below the device icon. IGHs are configured manually using the configuration forms available when you choose Create IGH from the IGH object navigation tree contextual menu.

You create an IGH to group together IP links and POS links so that if a configured number of links go out of service for any reason, the remaining links in the IGH go out of service too. This causes the routing protocols to re-converge to switch from the primary path to an alternate path.

The following requirements and restrictions apply to IGHs.

- IGHs are supported only on network links.
- IGHs are supported only on SONET/TDM interfaces with PPP auto encapsulation.
- A port or channel needs to be bound to a router interface after the member is added to an IGH.
- You can assign a port to only one IGH.

13.1.10 Working with LAG objects

LAGs are navigation tree objects located below a device icon which aggregate multiple network connections in parallel to increase throughput beyond what a single connection can sustain, and to provide redundancy in case one of the links fails.

The following minimum configuration is required to enable LACP.

- Enable LACP at either end of the LAG group.
- Set one end of the LAG group as LACP active.

You must configure the following in the LAG configuration forms:

- General properties, such as LAG description, configured address, encapsulation type, and administrative state
- Link aggregation group parameters, such as port threshold, port threshold action, and dynamic cost
- LACP parameters, such as LACP mode, LACP transmit interval, actor administration key, LACP transmission standby, and LACP selection criteria
- LAG members, which are the compatible ports that can belong to a LAG

Because all ports can have their own MAC address, when ports are part of a LAG, the LAG must have an MAC address.

The port configuration of the first port added to the LAG is used to compare with subsequently added ports. If a discrepancy is found with a newly added port, that port is not added to the LAG.

The maximum number of ports you can add to or remove from a LAG is 64. The number of ports depends on the NE type; see the NE documentation for more information. All ports added to a LAG must have the same parameter settings.

Only ports belonging to one LAG subgroup are considered eligible members of a LAG and can be selected as active links.

A LAG can be configured with weighted per-link hashing, which allows a more balanced distribution of subscribers and services across LAG links. For example, significant differences in subscriber or SAP bandwidth requirements could lead to unbalanced traffic on LAG egress. You can configure each service or subscriber on a LAG with one of three unique classes and a weight value to distribute services and subscribers across LAG links.

A LAG can be configured with LAG adaptive load balancing to resolve a traffic imbalance between LAG member ports on the FP-based SR family of NEs. Adaptive load balancing monitors the traffic utilization of each LAG member port and identifies whether the traffic needs to be shifted toward certain ports based on a tolerance value. If the tolerance value is exceeded, the system identifies the best way to shift traffic to resolve this imbalance. Adaptive load balancing is mutually exclusive with per-link-hashing.

On supporting devices, you can enable LACP tunneling to transparently forward LACP packets. LACP tunneling is configured on Ethernet ports; see 16.24 “To configure Ethernet ports” (p. 599).

See 6.13 “OmniSwitch” (p. 230) for OmniSwitch-specific LAG information.

See the *NSP Wavence Device Support Guide* for Wavence-specific LAG information.

LAG link mapping profiles

You can use a LAG link mapping profile to assign a specific LAG egress port to a SAP or interface, and control how egress traffic is handled if the specified port fails. You can then configure the specified port to perform admission control and QoS contract with the knowledge that all traffic for the SAP or interface will egress on that port. You can also specify a secondary port to handle traffic in the event that the primary port fails. See 13.21 “To create a LAG link mapping profile” (p. 443) for more information about creating LAG link mapping profiles.

LAG utilization TCAs

You can enable TCA on a LAG object and determine whether the LAG utilization value exceeds a TCA policy threshold. The following nodes support enabling TCA on LAG objects:

- 7450 ESS
- 7750 SR
- 7950 XRS
- Wavence SM

You can associate a TCA policy with a LAG object from the TCA policy configuration form. See 19.5 “To apply a TCA policy to objects using the object properties forms” (p. 711) for information about applying an existing TCA policy to an object from the object properties form. The NFM-P compares the utilization value at each statistics collection to the threshold value in the TCA policy and raises an alarm when the LAG utilization value crosses the specified limit. You need to enable performance statistics collection on the LAG object to configure a TCA policy. See Chapter 19, “TCA” for more information about TCA.

L1 LAGs support collection of scheduled and on-demand statistics, and plotting of real-time and historical statistics. L2 and Ethernet LAGs support collection of scheduled statistics and plotting of historical statistics.

BFD on Ethernet LAGs

On supporting NEs, you can configure an Ethernet LAG to use BFD to speed up the detection of link failures. When BFD is enabled on a LAG, micro-BFD sessions are automatically created for each link in the group.

For information about configuring BFD on a LAG, see 13.17 “To modify a LAG” (p. 435) . For information about viewing micro-BFD sessions on a LAG, see 13.22 “To view micro-BFD sessions on a LAG” (p. 445) .

13.2 Workflow to manage logical group objects

13.2.1 Purpose

The following workflow describes the sequence of high-level tasks required to manage and configure logical group objects. This workflow assumes that the physical devices have been installed, commissioned, and discovered. See Chapter 8, “Device commissioning and management” for more information about device commissioning. See Chapter 9, “Device discovery” for more information about device discovery.

Note: Logical group objects can be accessed using the equipment navigation tree. See Chapter 3, “NFM-P navigation tree” for more information about using the equipment navigation tree.

13.2.2 Stages

1

As required, configure CCAG objects. See 13.4 “To configure a CCAG” (p. 414) for more information.

2

As required, create and configure ISA-AA groups and ISA-AA partitions. See 13.5 “To configure an ISA-AA group and ISA-AA partitions” (p. 415) for more information. Additionally, perform the following, as required:

a. Configure AA subscriber statistics collection. See 13.6 “To configure AA subscriber statistics collection on an ISA-AA group or partition” (p. 418) for more information.

b. Configure AA special study objects. See 13.7 “To configure special study objects on an ISA-AA group or partition” (p. 419) for more information.

c. Configure a subscriber policy override on an ISA-AA group or ISA-AA partition. See 13.8 “To configure an AA subscriber policy override on an ISA-AA group or partition” (p. 421) for more information.

d. Configure Cflowd collectors on an ISA-AA group and/or ISA-AA partition. See 13.9 “To configure Cflowd collectors on an ISA-AA group or partition” (p. 422) for more information.

3

As required, configure ISA-Tunnel groups. See 13.10 “To configure an ISA-tunnel group” (p. 424) for more information.

4

As required, configure ISA-Tunnel member-pool groups. See 13.11 “To configure an ISA-tunnel member-pool group” (p. 425) for more information.

5

As required, configure ISA-LNS groups. See 13.12 “To configure an ISA-LNS group” (p. 426) for more information.

6

As required, create and configure ISA-NAT groups. See 30.3 “To configure an ISA-NAT group” (p. 1080) for more information. Additionally, perform the following, as required:

a. Configure statistics on an ISA-NAT group. See 30.15 “To configure statistics on an ISA-NAT group” (p. 1096) for more information.

b. Start or stop a NAT address-pool drain operation. See 30.13 “To start or stop a NAT address-pool drain operation” (p. 1094) for more information.

7

As required, configure ISA-Video groups. See 13.13 “To configure an ISA-Video group” (p. 427) for more information.

8

As required, configure WLAN GW groups. See 13.14 “To configure a WLAN GW group” (p. 428) for more information.

9

As required, configure IGH objects. See 13.15 “To create an IGH and add members” (p. 430) for more information.

10

As required, configure LAG objects:

a. Create and configure a LAG. See 13.16 “To create a LAG” (p. 431) and 13.17 “To modify a LAG” (p. 435) for more information.

b. Create and configure a LAG on an OmniSwitch. See 13.19 “To configure an OmniSwitch LAG” (p. 440) for more information.

c. Create and configure a dynamic LAG member on an OmniSwitch. See 13.20 “To configure OmniSwitch dynamic LAG members” (p. 442) for more information.

d. Create a LAG Link Mapping Profile. See 13.21 “To create a LAG link mapping profile” (p. 443) for more information.

13.3 Workflow to configure weighted per-link hashing on a LAG

13.3.1 Purpose

The following workflow describes the sequence of high-level tasks required to configure weighted per-link hashing on a LAG. This workflow assumes that the physical devices have been installed, commissioned, and discovered. See Chapter 8, “Device commissioning and management” for more information about device commissioning. See Chapter 9, “Device discovery” for more information about device discovery.

Note: LAG objects can be accessed using the equipment navigation tree. See Chapter 3, “NFM-P navigation tree” for more information about using the equipment navigation tree.

13.3.2 Stages

1

Configure a LAG object with weighted per-link hashing. See 13.16 “To create a LAG” (p. 431) or 13.17 “To modify a LAG” (p. 435) for more information. Configure the required service sites as LAG members.

2

If required, configure LAG weighted per-link hashing on a subscriber profile. See 64.4 “To configure a subscriber profile” (p. 1840) for more information.

3

As required, configure SAPs for weighted per-link hashing:

- Epipe and Ipipe L2 access interface. See 76.41 “To configure LAG per-link hashing on a VLL Epipe or Ipipe L2 access interface” (p. 2180) for more information.
- IES L3 access interface. See 78.29 “To configure LAG per-link hashing on an IES L3 access interface” (p. 2474) for more information.
- IES group interface SAP. See 78.22 “To configure LAG per-link hashing on an IES group interface SAP” (p. 2462) for more information.
- VPLS L2 access interface (B-VPLS, I-VPLS or M-VPLS). See 77.68 “To configure LAG per-link hashing on a VPLS L2 access interface” (p. 2339) for more information.
- VPRN L3 access interface. See 79.86 “To configure LAG per-link hashing on a VPRN L3 access interface” (p. 2660) for more information.
- VPRN group interface SAP. See 79.40 “To configure LAG per-link hashing on a VPRN group interface SAP” (p. 2599) for more information.

Logical group object configuration procedures

13.4 To configure a CCAG

13.4.1 Steps

1

On the Equipment tree, expand *NE*→Logical Groups→CCAGs.

2

Right-click on the CCAGs icon and choose Create CCAG, or right-click an existing CCAG object and choose Properties. The CCAG (Create|Edit) form opens.

3

Configure the required parameters.

4

Click Apply.

5

Click on the CCAG MDA Members tab to configure CCAG MDA members.

6

Click Create or select an existing CCAG MDA member and click Properties. The CCAG MDA Member (Create|Edit) form opens.

1. Select an MDA to add to the CCAG.
2. Save and close the form.

7

Click on the CCAG Paths tab to modify the internal paths for the CCAG. The Alpha and Beta paths are displayed.

1. Select a path and click Properties. The CCAG Internal Path (Edit) form opens.
2. Configure the required parameters.
3. Click on the Path Cross Connects tab to configure cross-connects for the CCAG internal path, as outlined in Step 8 .
4. Save your changes and close the form.

8

Click on the Path Cross Connects tab to modify the path cross-connects associated with the CCAG.

1. Select a cross-connect entry and click Properties. The Cross Connect (Edit) form opens.

2. Configure the required parameters.
3. Click on the Policies tab to specify non-default ingress and egress queue policy settings.
4. To specify an egress slope policy other than the default, click Clear in the Egress Slope Policy panel and select an alternate policy.
5. Configure the Egress Reserved CBS parameter.
6. To specify an ingress slope policy other than the default, click Clear in the Ingress Slope Policy panel and select an alternate policy.
7. Configure the Ingress Reserved CBS parameter.

9

Save your changes and close the forms.

END OF STEPS

13.5 To configure an ISA-AA group and ISA-AA partitions

13.5.1 Purpose

Perform this procedure to create an ISA-AA group that contains one or more partitions. ISA-AA partitions provide ISA-AA group functions that are limited to the partition scope.

Note: When you create an ISA-AA group or partition, a default AA policy is automatically created for the group or partition. When you delete a group or partition, the default policy is also deleted.

13.5.2 Steps

1

On the Equipment tree, expand *[NE]*→Logical Groups→ISA-AA Groups.

2

Right-click on the ISA-AA Groups icon and choose Create ISA-AA Group, or right-click an existing ISA-AA group object and choose Properties. The ISA-AA Group (Create|Edit) form opens.

3

Configure the required parameters.

If the ISA-AA group is to be added to an ISA-WLAN GW, you must set the Subscriber Scale parameter to Lightweight Internet.

If you are configuring an existing AA group and the associated AA group policy has SAP dependencies, you cannot modify the Partitions parameter until you remove the SAP dependencies on the group policy.

The following parameters are configurable when the Subscriber Scale parameter is set to something other than Lightweight Internet:

- Number of IPv4 Transit Prefix Entries
- Number of Remote IPv4 Transit Prefix Entries
- Number of IPv6 Transit Prefix Entries
- Number of Remote IPv6 Transit Prefix Entries

4

Click Apply.

5

Click on the AA Group Members tab to specify one or more AA group members for the ISA-AA group.

Note: The available group member type depends on the Subscriber Scale parameter: each subscriber scale model is applicable to either ISA or ESA only.

- To add an ISA-AA MDA as an AA group member, see Step 6.
- To add an ESA VM as an AA group member, see Step 7.

6

Click on the AA Group Members tab to specify one or more ISA-AA MDAs for the ISA-AA group.

1. Click Create or select an existing AA group member entry and click Properties. The AA Group Member (Create|Edit) form opens.
2. Configure the Role parameter.

   If the ISA-AA group is to be included for Distributed Subscriber Management in an ISA-WLAN GW group, you must set the Role parameter to Primary for each group member.
3. Select a member MDA.

   After a reboot, an NE rebalances the AA processing load. Because of this, the MDA slot number assigned to an AA subscriber or AA SAP on the AA Subscriber or AA SAP Summary form is displayed as Unassigned if the AA subscribers in the configuration file cannot be accommodated.
4. Save your changes and close the form.

Proceed to Step 8.

7

Click on the AA Group Members tab to specify one or more ESA VMs for the ISA-AA group.

1. Click Create or select an existing AA group member entry and click Properties. The AA Group Member (Create|Edit) form opens.
2. Select a member VM.

   The VM type of the selected member VM must be Application Assurance.
3. Save your changes and close the form.

Proceed to Step 8.

8

Click on the ISA-AA Group Diverted FCs tab to specify one or more traffic forwarding classes to divert to the ISA-AA group.

1. Click Create or select an existing ISA-AA group diverted forwarding class entry and click Properties.The ISA-AA Group Diverted FC (Create|Edit) form opens.
2. Configure the Forwarding Class Name parameter.
3. Save your changes and close the form.

9

Click on the QoS tab to configure QoS policy parameters for the ISA-AA group.

1. Configure the required parameters on the Egress From-Subscriber tab.

   You must deselect the Default check box before you can use a slider to specify a Reserved CBS or Buffer Utilization High Water Mark value.

   The value of the Buffer Utilization High Water Mark parameter must be higher than the value of the Buffer Utilization Low Water Mark parameter.
2. Select a slope policy in the Slope Policy panel.
3. Select a network queue policy in the Network Queue Policy panel.
4. Select a port scheduler policy in the Port Scheduler Policy panel.
5. Click on the Egress To-Subscriber tab and repeat Step 9 1 to 4 .

10

You can configure the following objects on the ISA-AA group if the Partitions parameter was disabled in Step 3 .

- AA subscriber statistics (13.6 “To configure AA subscriber statistics collection on an ISA-AA group or partition” (p. 418))
- AA special study objects (13.7 “To configure special study objects on an ISA-AA group or partition” (p. 419))
- AA subscriber policy override (13.8 “To configure an AA subscriber policy override on an ISA-AA group or partition” (p. 421))

11

To configure Cflowd on the ISA-AA group, click on the CFLOWD tab and perform 13.9 “To configure Cflowd collectors on an ISA-AA group or partition” (p. 422).

12

If the Partitions parameter on the General tab is enabled in Step 3 , click on the ISA-AA Partitions tab to configure AA partitions for the group.

1. Click Create or select an existing partition entry and click Properties. The ISA-AA Group Partition (Create|Edit) form opens.
2. Configure the required parameters.
3. Click on the CFLOWD tab to configure Cflowd on the partition (See 13.9 “To configure Cflowd collectors on an ISA-AA group or partition” (p. 422) .

4. The following objects are configurable on ISA-AA group partitions:
   - AA subscriber statistics (13.6 “To configure AA subscriber statistics collection on an ISA-AA group or partition” (p. 417))
   - AA special study objects (13.7 “To configure special study objects on an ISA-AA group or partition” (p. 419))
   - AA subscriber policy override (13.8 “To configure an AA subscriber policy override on an ISA-AA group or partition” (p. 421))

13

Save your changes and close the forms.

END OF STEPS

13.6 To configure AA subscriber statistics collection on an ISA-AA group or partition

13.6.1 Before you begin

If partitions are disabled on an ISA-AA group, subscriber statistics objects are configured directly on the group. If partitions are enabled on an ISA-AA group, subscriber statistics objects are configured on the individual partitions within the group.

13.6.2 Steps

1

If you are performing this procedure as part of the ISA-AA group or partition configuration described in 13.5 “To configure an ISA-AA group and ISA-AA partitions” (p. 415) , go to Step 4 .

2

On the Equipment tree, expand *[NE]*→Logical Groups→ISA-AA Groups→ISA-AA Group *n*.

3

Right-click on the ISA-AA Group *n* icon and choose Properties. The ISA-AA Group (Edit) form opens.

4

If you are configuring the subscriber statistics objects on an ISA-AA partition, perform the following steps.

1. Click on the ISA-AA Partitions tab.
2. Select a partition in the list and click Properties. The ISA-AA Group Partition (Edit) form opens.

5

Click on the AA Subscriber Stats Objects tab.

1. Click Add and choose one of the following options:
   - Application
   - Application Group
   - Charging Group
   - System Protocol
   - Custom Protocol

   The Select *object_type* form opens and lists the available objects of the chosen type.
2. Select an object and click OK. The Select *object_type* form closes and the AA Subscriber Stats Object Config form opens.
3. Configure the parameters in the Export Method Selection panel.

6

Save your changes and close the forms.

END OF STEPS

13.7 To configure special study objects on an ISA-AA group or partition

13.7.1 Before you begin

If partitions are disabled on an ISA-AA group, special study objects are configured directly on the group. If partitions are enabled on an ISA-AA group, special study objects are configured on the individual partitions within the group.

13.7.2 Steps

1

If you are performing this procedure as part of the ISA-AA group or partition configuration described in 13.5 “To configure an ISA-AA group and ISA-AA partitions” (p. 415) , go to Step 4 .

2

On the Equipment tree, expand *[NE]*→Logical Groups→ISA-AA Groups.

3

Right-click on the ISA-AA Group *n* icon and choose Properties. The ISA-AA Group (Edit) form opens.

4

If you are configuring the special study objects on an ISA-AA partition, perform the following steps.

1. Click on the ISA-AA Partitions tab.
2. Select a partition in the list and click Properties. The ISA-AA Group Partition (Edit) form opens.

3. Click on the AA Special Study tab.

5

To configure special study subscribers on the ISA-AA group or partition, click on the Subscribers sub-tab.

1. Click Create or select an existing special study subscriber and click Properties. The AA Special Study Subscriber Config (Create|Edit) form opens.
2. Configure the AA Subscriber Name and AA Stats Type parameters.
3. Save your changes and close the form.

6

To configure special study subscribers on the ISA-AA group or partition, click on the SAPs sub-tab.

Click on one or more of the following buttons and use the list form that opens to select one or more objects, as required:

- Add Per-SAP Protocols—to add a SAP for per-protocol monitoring
- Add Per-SAP Applications—to add a SAP for per-application monitoring

7

To configure special study spoke SDP bindings on the ISA-AA group or partition, click on the Spoke SDP Bindings sub-tab.

Click on one or more of the following buttons and use the list form that opens to add one or more objects, as required:

- Add Per-Spoke SDP Binding Protocols—to add a SAP for per-protocol monitoring
- Add Per-Spoke SDP Binding Applications—to add a SAP for per-application monitoring

8

To configure special study transit subscribers on the group or partition, click on the Transit Subscribers sub-tab.

1. Click Create or select an existing transit subscriber entry and click Properties. The AA Special Study Transit Subscriber Config (Create|Edit) form opens.
2. Select a transit subscriber.
3. Configure the AA Stats Type parameter.

9

To configure special study ESM subscribers on the ISA-AA group or partition, click on the ESM Subscriber Host sub-tab.

1. Click Create. The AA Special Study ESM Subscriber Host Config (Create) form opens.
2. Configure the AA ESM Subscriber Host Name and AA Stats Type parameters.
3. Save your changes and close the form.

10

Save your changes and close the forms.

END OF STEPS

13.8 To configure an AA subscriber policy override on an ISA-AA group or partition

13.8.1 Before you begin

If partitions are disabled on an ISA-AA group, subscriber policy overrides are configured directly on the group. If partitions are enabled on an ISA-AA group, subscriber policy overrides are configured on the individual partitions within the group.

The AA subscriber policy override is rejected if the subscriber does not have an application profile assigned. You can add an AA subscriber policy override to a SAP or Spoke SDP, but not to an ESM subscriber.

13.8.2 Steps

1

If you are performing this procedure as part of the ISA-AA group or partition configuration described in 13.5 “To configure an ISA-AA group and ISA-AA partitions” (p. 415) , go to Step 4 .

2

On the Equipment tree, expand *[NE]*→Logical Groups→ISA-AA Groups→ISA-AA Group *n*.

3

Right-click on the ISA-AA Group *n* icon and choose Properties. The ISA-AA Group (Edit) form opens.

4

If you are configuring the subscriber policy override on an ISA-AA partition, perform the following steps.

1. Click on the ISA-AA Partitions tab.
2. Select a partition in the list and click Properties. The ISA-AA Group Partition (Edit) form opens.

5

Click on the AA Subscriber Policy Overrides tab.

Note: An AA subscriber policy override is rejected if the subscriber does not have an assigned application profile.

6

Click Create or select an existing policy override entry and click Properties. The AA Subscriber Policy Override (Create|Edit) form opens.

7

Configure the AA Subscriber Type parameter.

8

Perform one of the following, based on the AA Subscriber Type parameter setting:

a. If it is SAP, select a SAP subscriber in the SAP Subscriber panel.

b. If it is Spoke SDP Binding, select a spoke SDP binding subscriber in the Spoke SDP Binding Subscriber panel.

c. If it is Transit, select a transit subscriber in the Transit Subscriber panel.

9

Click on the ASO Characteristics tab.

1. Click Create or select an existing policy override ASO characteristic entry and click Properties. The AA Subscriber Policy Override ASO Characteristic (Create|Edit) form opens.
2. Select an override ASO characteristic.
3. Select an override ASO characteristic value.

10

Save your changes and close the forms.

END OF STEPS

13.9 To configure Cflowd collectors on an ISA-AA group or partition

13.9.1 Before you begin

You can configure Cflowd collectors on an ISA-AA group, and on partitions within the group. The options differ, depending on whether you configure a group or partition.

13.9.2 Steps

1

If you are performing this procedure as part of the ISA-AA group or partition configuration described in 13.5 “To configure an ISA-AA group and ISA-AA partitions” (p. 415) , go to Step 4 .

2

On the Equipment tree, expand *[NE]*→Logical Groups→ISA-AA Groups→ISA-AA Group *n*.

3

Right-click on the ISA-AA Group *n* icon and choose Properties. The ISA-AA Group (Edit) form opens.

If you are configuring Cflowd on an ISA-AA partition, go to Step 7 .

4

Click on the CFLOWD tab and configure the required parameters on the General tab.

5

Click on the Collector tab.

1. Click Create or select an existing collector entry and click Properties. The Cflowd Collector (Create|Edit) form opens.
2. Configure the required parameters.
3. Save your changes and close the form

Note:

An ISA-AA group can contain a maximum of two Cflowd collectors.

6

Go to Step 11 .

7

Click on the ISA-AA Partitions tab.

8

Select a partition in the list and click Properties. The ISA-AA Group Partition (Edit) form opens.

9

Click on the CFLOWD tab.

10

To add an AA application or application group for Cflowd performance monitoring, click on the Performance tab. Otherwise, go to Step 13 .

11

To add an AA application for Cflowd performance monitoring:

1. Click Add Applications Comprehensive, or Add Applications TCP. The Select Applications form opens.
2. Select one or more applications and click OK.

12

To add an AA application group for Cflowd performance monitoring:

1. Click Add Application Groups Comprehensive, or Add Application Groups TCP. The Select Application Groups form opens.
2. Select one or more application groups and click OK.

13

To set the Cflowd sampling administrative states, click on the States tab and configure the required parameters.

14

Configure direct Cflowd export, if required.

1. Click on the Direct Export tab.
2. Configure the Direct Export VLAN parameter.
3. Click on the Collectors tab.
4. Click Create. The CFLOWD Direct Export Collector (Create) form opens.

   Note:

   You can create only one collector.
5. Configure the parameters.
6. Click Create. The CFLOWD Direct Export Collector Address (Create) form opens.

   Note:

   You can add a maximum of two host address entries.
7. Configure the parameters.
8. Click OK. The CFLOWD Direct Export Collector Address (Create) form closes.
9. Repeat Step 14 6 to 8 to create an additional host address, if required.

   You can view the statistics for a collector host on the Statistics tab of the collector host properties form.

15

Save your changes and close the forms.

END OF STEPS

13.10 To configure an ISA-tunnel group

13.10.1 Steps

1

On the Equipment tree, expand *[NE]*→Logical Groups→ISA-Tunnel Groups.

2

Right-click on the ISA-Tunnel Groups icon and choose Create ISA-Tunnel Group, or right-click an existing ISA-tunnel group object and choose Properties. The ISA-Tunnel Group (Create|Edit) form opens.

3

Configure the required parameters.

4

To associate a member-pool group to an ISA-tunnel group, configure the parameters under Member Pool Association panel.

5

Click Apply.

6

Click on the ISA Tunnel Group Members tab.

1. Click Create or select an existing tunnel group member entry and click Properties. The ISA Group Member (Create|Edit) form opens.
2. Select a daughter card.
3. Save your changes and close the form.
4. Repeat 1 to 3 to configure the backup ISA-Tunnel group member.

7

Save your changes and close the forms.

END OF STEPS

13.11 To configure an ISA-tunnel member-pool group

13.11.1 Steps

1

On the Equipment tree, expand *[NE]*→Logical Groups→ISA-Tunnel Member-Pool Groups.

2

Right-click on the ISA-Tunnel Member-Pool Groups icon and choose Create ISA-Tunnel Member-Pool Group, or right-click an existing ISA-tunnel member-pool group object and choose Properties. The ISA-Tunnel Member-Pool Group (Create|Edit) form opens.

3

Configure the required parameters.

4

Click Apply.

5

Click on the ISA Tunnel Member-Pool Group Members tab.

1. Click Create or select an existing tunnel member-pool group member entry and click Properties. The ISA Member-Pool Group Member (Create|Edit) form opens.
2. Select a daughter card.
3. Save your changes and close the form.
4. Repeat 1 to 3 to configure the backup ISA-Tunnel member-pool group member.

6

Click on the ESA Member-Pool Group Members tab.

1. Click Create or select an existing member-pool group member entry and click Properties. The ESA Member-Pool Group Member (Create|Edit) form opens.
2. Select a VM.
3. Save your changes and close the form.
4. Repeat 1 to 3 to configure the backup ESA member-pool group member.

7

Save your changes and close the forms.

END OF STEPS

13.12 To configure an ISA-LNS group

13.12.1 Before you begin

You can configure an IES or VPRN group interface to terminate LNS PPP sessions. See Chapter 78, “IES management” for information about configuring an IES group interface. See Chapter 79, “VPRN service management” for information about configuring a VPRN group interface.

13.12.2 Steps

1

On the Equipment tree, expand *[NE]*→Logical Groups→ISA-LNS Groups.

2

Right-click on the ISA-LNS Groups icon and choose Create ISA-LNS Group, or right-click an existing ISA-LNS group object and choose Properties. The ISA-LNS Group (Create|Edit) form opens.

3

Configure the required parameters.

4

Select a port policy.

5

Click Apply.

6

Click on the ISA-LNS Group Members tab.

1. Click Create or select an existing LNS group member entry and click Properties. The ISA-LNS Group Member (Create|Edit) form opens.

   Note:

   You can configure up to six ISA-LNS group members. For each group member, you must choose an ISA Broadband Applications MDA. An ISA Broadband Applications MDA can be configured only on an IOM3-XP module on a 7750 SR, Release 20.10 and earlier.
2. Select the LNS group member MDA.
3. Repeat 1 and 2 to configure additional LNS group members, if required.

7

Save your changes and close the forms.

END OF STEPS

13.13 To configure an ISA-Video group

13.13.1 Before you begin

An ISA-Video group supports ISA or ESA-VM video group members, and not a mix of group members under the same ISA-Video group.

13.13.2 Steps

1

On the Equipment tree, expand *[NE]*→Logical Groups→ISA-Video Groups.

2

Right-click on the ISA-Video Groups icon and choose Create ISA-Video Group, or right-click an existing ISA-video group object and choose Properties. The ISA-Video Group (Create|Edit) form opens.

3

Configure the required parameters.

4

Click Apply.

5

To specify ISA video group members:

1. Click on the Video Group Members tab.
2. Click Create or select an existing video group member entry and click Properties. The Video Group Member (Create|Edit) form opens.
3. Select the video group member card.
4. Repeat 2 and 3 to configure additional group members, if required.

6

To specify ESA-VM video group members:

1. Click on the ESA Video Group Members tab.
2. Click Create or select an ESA existing video group member entry and click Properties. The ESA Video Group Member (Create|Edit) form opens.
3. Select the video group member card.
4. Repeat 2 and 3 to configure additional group members, if required.

7

Save your changes and close the forms.

END OF STEPS

13.14 To configure a WLAN GW group

13.14.1 Steps

1

On the Equipment tree, expand Network→*NE*→Logical Groups→ISA-WLAN GW Groups.

2

Right-click on the ISA-WLAN GW Groups icon and choose Create ISA-WLAN GW Group, or right-click an existing ISA-WLAN GW Group object and choose Properties. The ISA-WLAN GW Groups (Create|Edit) form opens.

3

Configure the required parameters.

The LSN Support parameter in the NAT panel is only configurable when the ISA WLAN GW

group is in the Shut Down state.

4

Select a port policy.

5

Select a tunnel port policy.

6

Select a NAT RADIUS accounting policy in the NAT panel, if required.

7

Select an ISA-AA group in the Distributed Subscriber Management panel, if required.

8

Click Apply. The ISA-WLAN GW Group form refreshes with additional tabs.

9

Click on the ISA-IOMs tab.

1. Click Create or select an existing IOM entry and click Properties. The ISA-WLAN GW Group IOM (Create|Edit) form opens.
2. Select the ISA-WLAN GW group member IOM card.
3. Repeat 1 and 2 to configure additional LNS group members, if required.

10

Click on the Watermarks tab to configure high/low watermark entries for the ISA-WLAN GW group.

1. Click Create or select an existing watermark entry and click Properties. The WLAN-GW Group Watermark (Create|Edit) form opens.
2. Specify the entity type to monitor.
3. Configure the High Watermark and Low Watermark percentage for the entity type.

11

Save your changes and close the forms.

END OF STEPS

13.15 To create an IGH and add members

13.15.1 Steps

1

On the Equipment tree, expand *[NE]*→Logical Groups→IGHs.

2

Right-click on the IGHs icon and choose Create IGH. The Create IGH form opens with the Define General Properties step displayed.

3

Configure the required parameters.

4

Click Next. The Configure IGH Members step displays.

5

Click Create. The Create IGH Member form opens with the Select Ports step displayed.

Alternatively, you can create IGH members anytime by right-clicking on an existing IGH object and choosing Create IGH Members from the contextual menu.

6

Choose a port from the list and click Finish.

7

Repeat Step 5 and Step 6 to add more members, if required.

8

Click Finish.

9

Click Close. The Create IGH form closes.

END OF STEPS

LAG configuration procedures

13.16 To create a LAG

13.16.1 Before you begin

This procedure applies to various variants of the 7210 SAS, 7250 IXR, 7450 ESS, 7705 SAR, 7750 SR, and 7950 XRS. See 13.20 “To configure OmniSwitch dynamic LAG members” (p. 442) for information about configuring a LAG on an OmniSwitch. See the *NSP Wavence Device Support Guide* for information about configuring a LAG on a Wavence NE.

13.16.2 Steps

1

On the equipment navigation tree, expand *NE*→Logical Groups.

2

Right-click on LAGs and choose Create LAG. The Create LAG wizard opens.

Configure general properties

3

Configure the required parameters.

If you are creating a LAG for HSMDA, the Port Type parameter must be set to HSMDA. The Encapsulation Type must be either Dot1Q or QinQ. Setting Mode to network creates a network LAG, and setting it to access creates an access LAG.

If you are creating a LAG containing ports on an XMDA card on a 7705 SAR-18, the Encapsulation Type parameter must be either Dot1 Q or Null and the Mode must be set to Access.

The Weighted parameter is configurable only if the Per-Link Hashing parameter is enabled. The Auto Rebalance parameter is only configurable only if the Weighted parameter is enabled.

Consider the following when you configure the Enable DEI parameter on a hybrid LAG.

- When the Enable DEI parameter is selected, the Enable DEI parameter for the ports in the LAG must also be selected. See 16.24 “To configure Ethernet ports” (p. 599) .
- Network policies assigned to the ports in the LAG must be configured to use DEI as the profile. The Default FC Profile parameter and the Profile parameter on the Ingress Dot1p tab must be set to the DEI option. See 50.42 “To configure a 7210 and 1830 network policy” (p. 1571) .

4

If you are configuring Ethernet ports for MWA 1+0 on a 7705 SAR-8 or 7705 SAR-18:

1. Set the Mode parameter to Network and the Encapsulation Type parameter to Dot1Q.
2. Set the MWA port Auto-negotiation parameter to Limited.

3. Create an MWA 1+0 link and add the port to the link.
4. Add the MWA 1+0 port to the LAG.

You can configure up to four MW links per LAG group, with a mix of MW and non-MW links with the same port speed settings. The LAG interface must be configured on the LAG group ID, not on the MW link. 1+1 is not supported, the redundancy is for L2 LAG only.

5

If you are configuring a LAG on a 7210 SAS NE that supports split horizon groups, you can select an SHG in the Split Horizon Group panel. See 16.46 “To create a 7210 SAS SHG” (p. 638) for information about creating a 7210 SAS SHG.

Note: A LAG cannot be added to or deleted from an SHG if it has a SAP configured on it. A LAG cannot belong to more than one SHG; you must remove all SHGs from the LAG before you can add the LAG to a different SHG.

Configure LAG parameters

6

Click Next. The Configure LAG Parameters step displays.

7

Configure the required parameters.

You must set the Port Threshold parameter to 0 when the Standby Signalling parameter is set to Power Off in Step 12 .

8

Perform one of the following:

a. If you set the Mode parameter in Step 3 to Access or Hybrid, go to Step 9 .

b. If you set the Mode parameter in Step 3 to Network, or if you did not configure the Mode parameter, go to Step 11 .

Configure access parameters

9

Click Next. The Configure Access Parameters step displays.

10

Configure the required parameters.

If you are creating a LAG for HSMDA, the QoS Adaptation parameter must be set to Link, otherwise the LAG will not be created.

Configure LACP parameters

11

Click Next. The Configure LACP form opens.

12

Configure the required parameters.

The LACP Mode, LACP Transmit Interval, Actor Administration Key, LACP System ID, and LACP System Priority parameters are configurable when the LACP Enabled parameter is enabled.

When the Standby Signalling parameter is set to Power Off, you must set the Active Sub-Group Selection Criteria parameter to Best Port.

Configure LAG members

13

Click Next. The Configure LAG Members step displays.

14

Click Create. The Only Show Compatible Ports wizard opens.

15

Configure the Show Only Compatible Ports and Class parameters.

16

Click Next. The Select Ports step displays.

17

Choose compatible ports to construct the LAG:

1. Choose one or more ports. The maximum number of ports you can add to a LAG is 64. The number or ports you can choose depends on the NE type; see the NE documentation for more information.

   Note:

   If there are no compatible ports to choose from and you want to edit some of the existing ports to be compatible, disable the Show Only Compatible Ports parameter in Step 15 .

   For ports to appear as compatible ports, ensure no SAPs or services are configured on them.

   You must use the same load balance algorithm for the ports associated with the LAG.

   The dot1x configuration modification is allowed only on the primary member port. These changes will be propagated to other member ports. Any new port added to LAG must have the same dot1x configuration as primary port.

All ports added to a LAG must have the Enable DEI parameter set to the same configuration.

Add subports of the same type, otherwise a validation error appears.

For HSMDAv2 ports in a LAG, you must set the Auto-negotiate parameter to False or Limited. See 16.24 “To configure Ethernet ports” (p. 599) for more information on configuring Ethernet ports.

If you are creating a LAG containing ports on an XMDA card in the 7705 SAR-18, then the following conditions apply to the ports:

- The Encapsulation Type must be set to either Dot1Q or Null.
- The Mode parameter must be set to Access.
- The Auto-negotiate parameter must be set to False or Limited.

2. Click Next. The Specify the Member Properties step displays.
3. Configure the parameters.
4. If required, perform Step 42 of 16.24 “To configure Ethernet ports” (p. 599) to add Egress Secondary Shapers to a port member of an HSMDA LAG.

   The add/delete/modify functions for Egress Secondary Shapers apply only to the primary port.

   There can be a total of 64 egress secondary shapers per MDA, including the default shaper.

   The Egress Secondary Shapers on the primary port of the LAG are propagated to each non-primary port member of the LAG, with a maximum 8 ports per LAG. These propagated shapers cannot be deleted.

   For adding any new port to the LAG, the user must configure each Egress Secondary Shaper as per the primary port, otherwise the addition of the port is blocked.

   When adding a port member to a LAG, the primary port and each selected port (maximum 8 ports) secondary shapers must have the same name and rate.

   Ports with Egress Secondary Shapers cannot be added to a configured LAG which do not match the Egress Secondary Shapers of the primary port.

   Shapers are not removed from the port when the port is removed from a LAG.

   The SAP reference to the Egress Secondary Shapers within a LAG is supported. Only the primary port of the SAP on the LAG is used to determine the list of Egress Secondary Shapers for the SAP.

   Note:

   When port members are removed from the LAG, care must be taken to ensure that the last port member is not removed if the LAG is referenced to a SAP. Shapers must exist on a LAG to be referenced on a SAP. See Chapter 70, “Service management and QoS” to Chapter 85, “Composite service management” for more information.

18

Click Finish.

Configure BFD parameters

19

Click Next. The Configure BFD step displays.

20

Select the IPv4 or IPv6 entry and click Properties. The BFD Configuration on LAG form appears.

21

Configure the required parameters.

22

Save your changes and close the form.

23

Click Finish.

Configure Operational Group parameters

24

Click Next. The Configure Operational Group step displays.

25

Configure the required parameters.

26

Save your changes and close the form.

27

Click Finish. Save your changes and close the wizard.

END OF STEPS

13.17 To modify a LAG

13.17.1 Before you begin

This procedure applies to 7210 SAS, 7250 IXR, 7450 ESS, 7705 SAR, 7750 SR, and 7950 XRS NEs. See 13.20 “To configure OmniSwitch dynamic LAG members” (p. 442) for information about configuring a LAG on an OmniSwitch. See the *NSP Wavence Device Support Guide* for information about configuring a LAG on a Wavence NE.

13.17.2 Steps

1

On the equipment navigation tree, expand Network→*NE*→Logical Groups→LAGs→LAG *n*.

2

Right-click on the LAG *n* object and choose Properties. The LAG (Edit) form opens.

Configure general parameters

3

Configure the required parameters.

The Weighted parameter is configurable only if the Per-Link Hashing parameter is enabled, and the Auto Rebalance parameter is only configurable if the Weighted parameter is enabled.

Consider the following when you configure the Enable DEI parameter on a hybrid LAG.

- When the Enable DEI parameter is selected, the Enable DEI parameter for the ports in the LAG must also be selected. See 16.24 “To configure Ethernet ports” (p. 599) .
- Network policies assigned to the ports in the LAG must be configured to use DEI as the profile. The Default FC Profile parameter and the Profile parameter on the Ingress Dot1p tab must be set to the DEI option. See 16.45 “To assign QoS policies to a 7210 SAS Ethernet port” (p. 636) and 50.42 “To configure a 7210 and 1830 network policy” (p. 1571) .

4

If you are configuring a LAG on a 7210 SAS NE that supports split horizon groups, you can select an SHG in the Split Horizon Group panel. See 16.46 “To create a 7210 SAS SHG” (p. 638) for information about creating a 7210 SAS SHG.

Note: A LAG cannot be added to or deleted from an SHG if it has a SAP configured on it. A LAG cannot belong to more than one SHG; you must remove all SHGs from the LAG before you can add the LAG to a different SHG.

5

If you are configuring a LAG on a 7850 VSG, you can select a port profile and an operational group in the OperGroup and ServiceProfle panel.

Configure other LAG parameters

6

Click on the Link Aggregation Group tab and configure the required parameters.

You must set the Port Threshold parameter to zero when the Standby Signalling parameter is set to Power Off in Step 9 .

7

Click on the States tab and configure the Administrative State parameter.

8

If you are configuring a LAG in Access or Hybrid mode, click on the Access tab and configure the required parameters.

If you are configuring a LAG for HSMDA, the QoS Adaptation parameter must be set to Link.

9

Click on the LACP tab and configure the required parameters.

The LACP Mode, LACP Transmit Interval, and Actor Administration Key parameters are configurable when the LACP Enabled parameter is enabled.

When the Standby Signalling parameter is set to Power Off, you must set the Active Sub-Group Selection Criteria parameter to Best Port

10

Click on the LAG Members tab.

You can also add LAG members by right-clicking on an existing LAG object and choosing Create LAG Members from the contextual menu.

To add LAG members, perform Step 14 to Step 18 of 13.16 “To create a LAG” (p. 431) .

11

Perform one of the following steps:

a. If the LAG that you are configuring is in Network mode, the Network Interfaces tab is displayed. Click Create. The Create Network Interface form opens. See 27.17 “To create an L3 network interface on a routing instance” (p. 856) for information on creating a network interface. Otherwise go to Step 17 .

b. If the LAG that you are configuring is in access mode or hybrid mode with dot1q or QinQ encapsulation, or in network mode with dot1q encapsulation, the MEPs tab is displayed. Go to Step 12 .

12

Add a facility MEP to the LAG:

Note: Only one facility MEP can be configured on a LAG.

1. Click on the MEPs tab and click Create. The MEP (Create) form opens.
2. Select a global MEG.
3. Configure the required parameters.

   Note:

   You cannot enable the collection of LMM statistics on a facility MEP if a service MEP is already configured to collect the LMM statistics information.

   The CCM Padding Packet Size (Bytes) parameter cannot be configured when the CCM

interval parameter is set to 10 ms or 100 ms.

To enable fault propagation on a LAG facility MEP, the Facility Fault Notify parameter must be enabled.

4. If the MD for the MEP has a Name Type of None, the Y.1731 Tests tab is configurable; click on the Y.1731 Tests tab and configure the required parameters.

   The Eth Test Pattern parameter is configurable when the Eth Test Enabled parameter is enabled.

5. Save your changes and close the form.

13

To add a tunnel facility MEP to the LAG, perform the following steps.

The LAG that you are configuring must be in Access mode or Hybrid mode and must have an encapsulation type of QinQ.

1. Click on the MEPs tab.
2. Click Create. The MEP (Create) form opens.
3. Select a global MEG.
4. Configure the required parameters.

   Note:

   The CCM Padding Packet Size (Bytes) parameter cannot be configured when the CCM interval parameter is set to 10 ms or 100 ms.

   To enable the fault propagation on a tunnel facility MEP, Facility Fault Notify must be enabled.

   To link the tunnel facility status to the SAP, Facility VLAN ID must match the outer encapsulation value of the SAP.

   To accept the fault notification from a facility MEP on the site where the SAP is located and on the SAP, Tunnel Fault Management must be set to Accept.

5. If the MD for the MEP has a Name Type of None the Y.1731 Tests tab is configurable; click on the Y.1731 Tests tab and configure the required parameters.

   The Eth Test Pattern parameter is configurable when the Eth Test Enabled parameter is enabled.

6. Save your changes and close the form.

14

Configure Ethernet-CFM redundancy on a facility MEP.

You must enable Ethernet CFM redundancy globally on a device before it can function on child objects such as LAGs. See Chapter 12, “Device object configuration” for information about device object configuration.

The tunnel MEP must be part of an MC-LAG with Ethernet CFM redundancy configured.

1. Click on the MEPs tab.
2. Choose the facility MEP for which you need to configure Ethernet-CFM redundancy and click Properties. The MEP (Edit) form opens.

3. On the Facility MEPS panel, enable the Create Redundant MEP parameter.
4. Click OK to confirm. A redundant tunnel MEP with the same ID and Operational MAC address is created on the peer LAG. The redundant MEP has the same state as the MC-LAG in which that MEP resides.

15

Configure BFD parameters:

1. Select the IPv4 or IPv6 entry and click Properties. The BFD Configuration on LAG form appears.
2. Configure the required parameters.
3. Save your changes and close the form.

16

Configure Operational Group parameters:

1. Select the Oper Group and Monitor Oper Group value.
2. Save your changes.

17

Save your changes and close the form.

END OF STEPS

13.18 To manually re-balance LAG ports

13.18.1 Purpose

Perform this procedure to force a manual subscriber load balance function on a LAG that is configured for weighted per-link hashing, or to configure LAG adaptive load balancing to resolve a traffic imbalance between LAG member ports on FP-based SR family of NEs. Adaptive load balancing is mutually exclusive with per-link-hashing.

13.18.2 Steps

1

On the equipment navigation tree, expand Network→*NE*→Logical Groups→LAGs→LAG *n*.

2

Right-click on the LAG *n* object and choose Properties. The LAG (Edit) form opens.

3

To force a manual subscriber load balance, perform the following:

1. Enable the Per-link Hashing parameter.
2. Click the Load Balance button. The LAG Load Balance form opens.

3. Configure the Class ID parameter.
4. Click OK to perform the load balance function.

4

To configure LAG adaptive load balancing, perform the following:

1. Enable the Load Balance parameter.
2. Configure the required parameters.

5

Close the form.

END OF STEPS

13.19 To configure an OmniSwitch LAG

Note: You can configure MVRP fixed ports/LAGs, 802.1 Q ports/LAGs, aggregate ports/LAGs, and VLAN Stacking Network ports/LAGs.

When a port is assigned to a LAG member, you cannot modify the port properties using the NFM-P.

13.19.1 Steps

1

On the equipment navigation tree, expand *NE*→Logical Groups.

2

Right-click on LAGs and choose Create LAG. The Create LAG wizard opens.

Configure general parameters

3

Configure the required parameters.

The Automatic VLAN Binding parameter can only be configured for network LAGs and Stacked VLANs.

Configure LAG parameters

4

Click Next. The Create LAG - Configure LAG Parameters step displays.

5

Configure the required parameters.

6

Perform one of the following:

a. If you set the Type parameter to Static, go to Step 10 .

b. If you set the Type parameter to Dynamic, go to Step 7 .

Configure LACP parameters

7

Click Next. The Create LAG - Configure LACP step displays.

8

Configure the required parameters.

9

Go to Step 15 .

See 13.20 “To configure OmniSwitch dynamic LAG members” (p. 442) for more information about adding members to a dynamic LAG.

Configure LAG members

10

Click Next. The Create LAG - Configure LAG Members step displays.

11

Click Create to add ports to the LAG. The Create LAG Member - Only show compatible ports wizard opens.

12

Configure the Show Only Compatible Ports and Class parameters.

13

Click Next. The Create LAG Member - Select Ports step displays.

14

Choose up to the maximum number of ports you require from the list of ports to create the LAG. You can select more than one port at a time from the list.

Note: If there are no compatible ports to choose from and you want to edit some of the existing ports to be compatible, then disable the Show Only Compatible Ports parameter. Click Next. Choose ports to edit from the list and click Properties.
Mobile, UNI, and NNI ports cannot be members of a LAG.
Only network ports can be members of a network LAG and only access ports can be members of an access LAG.

15

Click Finish. Save your changes and close the forms.

END OF STEPS

13.20 To configure OmniSwitch dynamic LAG members

Note: LAG members are not added during the creation of the dynamic LAG, as they are with static LAGs. When a new dynamic LAG member is created it is placed into the Unassigned Dynamic LAG Members object. The new dynamic LAG members remain under the Unassigned Dynamic LAG Members object until the system identifies a LAG with matching properties. When an unassigned LAG member joins a LAG, the member is removed from the Unassigned Dynamic LAG Members object and added to the appropriate LAG object.

When a port is assigned to a LAG member, you cannot modify the port properties using the NFM-P.

13.20.1 Steps

1

On the equipment navigation tree, expand Network→*NE*→Logical Groups.

2

Right-click on the Unassigned Dynamic LAG Members object and choose Create LAG Members. The Create LAG Member wizard opens.

3

Configure the Show Only Compatible Ports and Class parameters.

4

Click Next. The Create LAG Member - Select Ports step displays.

5

Choose up to the maximum number of ports you require from the list of ports to create the LAG. You can select more than one port at a time from the list.

Note: If there are no compatible ports to choose from and you want to edit some of the existing ports to be compatible, then disable the Show Only Compatible Ports parameter. Click Next. Choose ports to edit from the list and click Properties.
For all ports in an LAG, you must disable auto-negotiation, configure the same speed, and set the ports to full duplex. Mobile ports cannot be part of a LAG.

6

Configure the required parameters.

7

Click Finish. Save your changes and close the form.

END OF STEPS

13.21 To create a LAG link mapping profile

Note: You can only use LAG link mapping profiles on an NE that is in chassis mode D or higher.

13.21.1 Steps

1

On the equipment navigation tree, expand Network→*NE*→Logical Groups→LAGs→LAG *n*.

2

Right-click on the LAG *n* object and choose Properties. The LAG (Edit) form opens.

The following table describes the required parameter values that must be set in order to use LAG link mapping profiles.

Table 13-1 LAG link mapping prerequisites

Tab	Parameter	Required values
General	Port Type	Access or Hybrid
Access	QoS Adaptation	Link
LAG Members	Sub-Group ID	All LAG members must be in the same sub-group.

3

Click on the Link Mapping Profiles tab and click Create. The Link Mapping Profile (New Instance) form opens.

Configure general profile parameters

4

Configure the required parameters on the General tab.

Create mapping profile links

5

Click on the Mapping Profile Links tab and click Create. The Link Mapping Profile Link (New Instance) form opens.

6

Click Select and specify a port. The selected port will be used for egress traffic for interfaces assigned to this LAG link mapping profile.

7

Configure the Type parameter.

8

Save your changes and close the form.

9

Configure a secondary port by repeating Step 5 to Step 8 , if required.

Assign the link mapping profile to an interface or MSAP policy, if required

10

Assign the LAG link mapping profile to a network interface, access interface, or SAP, if required:

1. Click on the Network Interface, L2 Access Interface, L3 Access Interface, or Service Access Points tab. A list of interfaces that terminate on the LAG appears.
2. Select an interface from the list and click Properties. The Interface (Edit) form appears.
3. Click on the Port tab.
4. Select a LAG link mapping profile.
5. Save your changes and close the form.

11

Assign the LAG link mapping profile to an MSAP policy, if required:

1. From the NFM-P main menu, select Policies→Residential Subscriber. The Residential Subscriber Policies form opens.
2. Select an MSAP policy from the list and click Properties. The MSAP Policy (Edit) form opens.
3. Click on the Local Definitions tab.
4. Select the local definition for the site where the LAG link mapping profile is configured, and click Properties. The MSAP Policy (Local Policy) form opens.
5. If the Distribution Mode parameter is set to Sync With Global, click Switch Mode.
6. Set the LAG Link Map Profile parameter to the ID of the LAG link mapping profile you need to assign to the MSAP policy.
7. Save your changes and close the forms.

END OF STEPS

13.22 To view micro-BFD sessions on a LAG

13.22.1 Steps

1

On the equipment navigation tree, navigate to the LAG object that you want to configure. The path is Network→*NE*→Logical Groups→LAGs→LAG *n*.

2

Right-click on the LAG *n* icon and choose Properties. The LAG (Edit) form opens.

3

Click on the BFD tab.

4

Select the IPv4 or IPv6 entry and click Properties. The BFD Configuration on LAG form opens.

5

Click on the Micro BFD Session tab.

6

Select a BFD session and click Properties to view information about the selected session.

END OF STEPS

14 ESA object configuration

Configuring ESA objects using the NFM-P

14.1 Overview

14.1.1 ESA objects in the NFM-P navigation tree

When the NFM-P discovers applicable 7750 SR chassis, Release 20.5 R1 and later, the ESAs group object appears automatically in the navigation tree. The ESA operates as a resource server that provides packet buffering and processing, and is connected to the 7750 SR using standard SR interface ports.

The ESAs group objects are children of 7750 SR device objects. They appear above logical group objects in the navigation tree. ESA objects are children of ESAs group objects, and as such appear below the ESAs group object in the navigation tree. The ESA hosts up to four Virtual Machine (VM) instances for multiservice processing. VM objects are created in the navigation tree as children of the ESA object.

See the *NSP NFM-P Network Element Compatibility Guide* for information about which SR devices support ESAs.

14.1.2 Working with ESA objects

An ESA hosts up to four VM instances for multiservice processing.

An ESA VM may use up to four host ports. Each physical port can be used to bring up each VM within an ESA. With four host ports, four VMs can be operationally up. ESA VMs can be different types or the same type.

ESA VMs are configured as a desired type and size (number of cores and amount of memory).

Multiple ESAs may be configured per IOM and per system as needed for scale. See the node documentation for more information.

14.2 Workflow to manage ESA objects

14.2.1 Purpose

The following workflow describes the sequence of high-level tasks required to create and configure ESA objects. This workflow assumes that the physical 7750 SR devices have been installed, commissioned, and discovered. See Chapter 8, “Device commissioning and management” for more information about device commissioning. See Chapter 9, “Device discovery” for more information about device discovery.

Note: ESAs group objects can be accessed using the equipment navigation tree. See Chapter 3, “NFM-P navigation tree” for more information about using the equipment navigation tree.

14.2.2 Stages

1

Create ESAs. See 14.3 “To create an ESA” (p. 449).

2

As required, create VMs. See 14.5 “To create a virtual machine on an ESA” (p. 450) .

3

As required, configure the ESAs. See 14.4 “To configure an ESA” (p. 449) .

4

As required, configure the VMs. See 14.6 “To configure a virtual machine on an ESA” (p. 451) .

5

As required, create and configure ISA-AA groups and ISA-AA partitions. See 13.5 “To configure an ISA-AA group and ISA-AA partitions” (p. 415) .

6

As required, create and configure ISA-NAT groups. See 30.3 “To configure an ISA-NAT group” (p. 1080).

7

As required, create and configure ISA Video groups. See 13.13 “To configure an ISA-Video group” (p. 427).

Procedures for ESA configuration

14.3 To create an ESA

14.3.1 Purpose

Perform this procedure to create an ESA on a supported 7750 SR system.

14.3.2 Steps

1

On the equipment tree, expand Network→*7750 SR*.

2

Right-click on the ESAs group object and choose Create ESA. The Extended Services Appliance (Create) form opens.

3

Configure the required parameters.

4

Associate a host port.

1. Click Create. The Host Port (Create) form opens.
2. Click Select. The Select Host Port form opens.
3. Select a port and click OK. The Select form closes.
4. Click OK. The Host Port (Create) form closes.

For applicable 7750 SR chassis, Release 21.2 R1 and later, you can associate two host ports.

5

Save your changes and close the form.

END OF STEPS

14.4 To configure an ESA

14.4.1 Purpose

Perform this procedure to configure an ESA.

14.4.2 Steps

1

On the equipment tree, expand Network→*7750 SR*→ESAs group.

2

Right-click on an ESA object and choose Properties. The Extended Services Appliance (Edit) form opens with the General tab displayed.

3

Configure the parameters, as required.

4

Click on the Virtual Machine tab to create, modify, or delete one or more virtual machines, as required.

5

Click on the Deployment tab to monitor the deployment status of the ESA, as required.

6

Click on the Faults tab to view alarm information, as required..

7

Save your changes and close the form.

END OF STEPS

14.5 To create a virtual machine on an ESA

14.5.1 Purpose

Perform this procedure to create an ESA VM.

14.5.2 Steps

1

On the equipment tree, expand Network→*7750 SR*→ESAs.

2

Right-click on an ESA object and choose Create VM. The Virtual Machine Extended (Create) form opens.

3

Configure the required parameters.

4

Save your changes and close the form.

END OF STEPS

14.6 To configure a virtual machine on an ESA

14.6.1 Purpose

Perform this procedure to configure an ESA VM.

14.6.2 Steps

1

On the equipment tree, expand Network→*7750 SR*→ESAs→ESA→VM.

2

Right-click on a VM object and choose Properties. The Virtual Machine (Edit) form opens with the General tab displayed.

3

Right-click on a VM and perform one of the following:

a. If the VM type has not yet been configured, choose Configure VM.

b. If the VM type has been configured, choose Properties.

The Virtual Machine (Edit) form opens with the General tab displayed.

4

Configure the parameters, as required.

5

Click on the VM Port tab to view VM port details, as required.

6

Click on the NAT VAAPs tab to view any associations to NAT groups, as required.

7

Click on the Statistics tab to view and collect statistics, as required.

8

Click on the TCA tab to apply a TCA policy to the VM, as required.

9

Click on the Deployment tab to monitor the deployment status of the VM, as required.

10

Click on the Faults tab to view alarm information, as required.

11

Save your changes and close the form.

END OF STEPS

14.7 To view virtual ports on an ESA

14.7.1 Before you begin

Perform this procedure to view ESA virtual port details.

14.7.2 Steps

1

On the equipment tree, expand Network→*7750 SR*→ESAs→ESA→VM.

2

Right-click on a VM port object and choose Properties. The VM Port (View) form opens with the General tab displayed.

3

Click on the Statistics tab to view performance statistical information about the virtual port, as required.

4

Click on the Deployment tab to monitor the deployment status of the virtual port, as required.

5

Click on the Faults tab to view alarm information, as required.

6

Save your changes and close the form.

END OF STEPS

15 Shelf and card object configuration

Configuring shelf objects using the NFM-P

15.1 Overview

15.1.1 Shelf objects in the NFM-P navigation tree

In the equipment navigation tree, shelf objects are children of device objects. They appear below logical group objects in the navigation tree. Card slot objects are children of shelf objects, and as such appear below the shelf object in the navigation tree. Daughter card slot objects are created in the navigation tree as children of the card slot object, after the card slot object is configured. APS bundle objects appear below the shelf object and Bundle objects appear below daughter card objects that are configured as channelized MDAs. See Chapter 38, “APS” for more information about APS bundles.

Shelf objects represent the hardware that is configured on a shelf. When you choose the shelf object in the navigation tree and click on Properties in the contextual menu, you can view the states and conditions of the shelf including:

- general information
- fan tray state and speed
- power supply tray statuses
- LED statuses
- card slots
- hardware environment information
- CCM properties
- PoE
- timing
- statistics
- dry contacts
- faults
- port segregation
- software control module
- software bank information
- cross connects

The Display tab displays a graphical representation of the device’s shelf and its equipment components, such as the empty card slots and the cards that are installed on the device. You can double-click on an object under this tab to open its Properties configuration form. Right-click on the object and you have full access to the contextual menus for the object and any child objects, for example the ports of a card (dynamic graphical representation only).

15.1.2 Chassis modes

The chassis mode of a device indicates the minimum IOM or IMM card type that is initialized by the device and determines the scaling numbers and features that are available to the system. See the appropriate device Release Notice for scaling information.

Note: Chassis modes are not supported on the 7950 XRS, and are not required for NEs using SR OS, Release 15.0 or later. After upgrading an NE to SR OS Release 15.0 or later, the chassis mode is displayed as D and cannot be modified.

15.1.3 Timing synchronization

The NFM-P supports the configuration of timing synchronization on supporting NEs. Configurations are typically performed on the shelf properties form. Additional configurations may be required on the NE properties form, for example, to configure specific timing protocols. See 15.6 “Workflow to manage shelf objects” (p. 457).

The NFM-P supports the following timing synchronization options. See the NE documentation for information about synchronization support for a specific NE.

- Synchronous Ethernet (SynchE), based on ITU-T G.8261, G8262, G8264, G8265, and G8275
- IEEE 1588 PTP clock
- BITS

See 15.20 “To configure timing synchronization” (p. 477) for more information about configuring timing synchronization.

Note: NTP and SNTP are also available for compatible devices but are configured separately from timing synchronization. See 15.34 “To configure NTP on supported devices” (p. 490) and 15.32 “To configure SNTP on a 7705 SAR” (p. 489).

15.1.4 IEEE 1588 PTP clock

The NFM-P supports IEEE 1588 PTP clocks and the ITU-T G.8265.1, G.8275.1, or G.8275.2 PTP profile, for packet-based timing synchronization on supporting NEs.

The IEC/IEEE 61850.9.3 PTP clock profile supports recovery of frequency as well as time/phase. PTP transport is based on Ethernet encapsulation with multicast addressing. Instead of the delay-request/response mechanism, the IEC/IEEE 61850.9.3 profile uses the peer delay mechanism.

The C37.238-2017 profile is an extension of IEC/IEEE 61850.9.3 profile with support of additional TLVs.

The IEC/IEEE 61850.9.3 and the C37.238-2017 profiles are supported on a 7705 SAR with a CSM clock ID.

The NFM-P supports IEC/IEEE 61850.9.3 and C37.238-2017 profiles on 7210 SAS-DXP 16 and 24 port variants.

Depending on the device, NEs can be configured with an ordinary master, ordinary slave, or boundary clock. The 7705 SAR-A, 7705 SAR-Ax, 7705 SAR-H, 7705 SAR-Hc, 7705 SAR-M/ME, 7705 SAR-W, and 7705 SAR-Wx can also be configured with a transparent clock.

The following satellites on 7450 ESS, 7750 SR and 7950 XRS nodes, Release 16.0 R5 and later support transparent clock functionality:

- 48-port 1-Gig Ethernet SFP satellite
- 64-port 10-Gig SFPP Ethernet satellite with 4 100-Gig CFP up-links
- 48-port 1-Gig Ethernet SFP satellite, LCS variant
- 64-port 10-Gig SFPP Ethernet satellite with 4 100-Gig QSFP28 up-links

For some NEs, PTP can operate in two modes. In PTP pure mode, PTP is selected as both the timing reference and frequency source. In PTP hybrid mode, PTP is selected as the timing reference, and SSU (for example, SyncE or BITS) is selected as the frequency source.

15.1.5 Synchronization management

You can use the NFM-P to manage synchronization domains and assign IP path monitors to PTP peers. See Chapter 46, “Synchronization management” for more information.

15.2 SCADA on the 7705 SAR

15.2.1 Overview

SCADA systems are used to monitor and maintain networks from remote monitoring locations. SCADA uses a controlling unit/RTU architecture with a single controlling unit that supports multiple RTUs.

The ISC supports software applications that specifically meet the requirements of TDM-based SCADA systems. The ISC is supported on the 7705 SAR-8 and the 7705 SAR-18.

The SCADA MDDB and PCM multidrop bridge applications feature similar architecture and functionality, with the main exception being that the MDDB application uses a serial RS-232 interface, while the PCM multidrop bridge application uses an E&M analog interface.

15.2.2 Multi-drop data bridge

The MDDB application provides a centralized digital bridging functionality that allows a SCADA bridge to be configured between a controlling unit and remote RTUs. The bridge allows a single data message stream to be broadcast from a controlling unit to multiple RTUs and allows a single RTU to communicate back to the controlling unit.

In a SCADA network, the 7705 SAR provides the communications infrastructure to connect the central controlling units to multiple RTUs at remote locations, where the controlling units and RTUs communicate over serial RS-232 links (synchronous or asynchronous). The 7705 SAR-8 or 7705 SAR-18 located at the controlling unit site contains the ISC, which provides the MDDB bridge functionality and acts as the MDDB controlling unit. Remote 7705 SAR nodes connected to RTUs are referred to as MDDB RTUs. See 6.8 “7705 SAR” (p. 222) for information about the ISC. See 15.36 “To configure SCADA on a 7705 SAR” (p. 495) for more information.

The remote nodes are connected to the SCADA bridge over an IP/MPLS network. The ISC supports up to 16 SCADA bridges. Each bridge supports 32 branches. Two branches (branch 1 and branch 2) are dedicated connections to the SCADA controlling units; the other 30 branches connect to the RTUs.

Note: Larger bridges can be built by cascading individual bridges internally within a single ISC and using the controlling unit output from one bridge as the RTU input to another bridge. Larger bridges can be cascaded across multiple ISCs by using an RS-232 link.

15.2.3 PCM multi-drop data bridge

The PCM multidrop bridge application provides multidrop bridging for SCADA systems that use 4-wire analog modems to connect remote RTUs to a controlling unit. Incoming analog signals from

the controlling unit are converted to PCM (Mu-Law or A-Law) for transport between a remote RTU and the controlling unit. The ISC broadcasts the controlling unit stream to all remote RTUs. Only the addressed remote unit will respond to the broadcast and the response must be transported through the bridge back to the controlling unit via an E&M interface. If the network RTUs support two SCADA systems over the same interface by separating them into high-frequency and low-frequency bands, the PCM multidrop bridge always selects the two loudest branches to be passed through the bridge for communication with the controlling unit.

15.2.4 Redundancy

Most SCADA systems have redundant controlling units where both monitor all traffic but only one controlling unit transmits at a time. The 7705 SAR SCADA system supports duplicated links - one to each controlling unit. Each bridge has two branches that connect to the controlling unit. The bridge supports two controlling unit links with only one being active. If redundancy is required, the second link can be manually configured and activated by forcing a switchover. Data from the bridge to the controlling unit is broadcast to both controlling units. The switchover allows only one controlling unit to access the bridge at a time. The 7705 SAR does not support automatic switchover capability.

15.2.5 Branch squelch

A condition may occur where a single RTU continues to send data to the controlling unit after the normal response period has expired. This condition locks up the bridge so that no other RTU can transmit data back to the controlling unit. To resolve this condition, the squelch command can be enabled on a bridge (it is disabled by default) by configuring a timeout period that, once expired, raises an alarm and triggers the squelching function. Squelching blocks the errant RTU so that other RTUs can continue to use the bridge. The squelch reset command is used to put the bridge back into a normal state. See 15.36 “To configure SCADA on a 7705 SAR” (p. 495) for more information about configuring a squelch reset.

15.3 Power management configuration

15.3.1 Overview

The NFM-P supports configuring power management zones on NEs with power supplies that support configuration, and power priority values on MDA cards installed on those nodes. Each MDA and APEQ provisioned on a node is associated with a power management zone. During startup, MDAs with higher power priority values are started first. You can view information and collect statistics about power availability and shedding using the NFM-P.

See 15.47 “To configure a power management zone” (p. 510) for information about configuring a power management zone. See 15.78 “To configure an MDA” (p. 536) for information about configuring power priority values on an MDA. See the *NSP NFM-P Statistics Management Guide* for information about gathering power statistics using the NFM-P.

Detailed information about power usage is available on the power management zone, shelf, card slot, and daughter card slot configuration forms. Use the Hardware Environment tab to view information about power usage.

15.4 Reboot hold

15.4.1 Functional description

The Reboot Hold option in a contextual menu instructs the selected standby SF or CPM module to gracefully shut down. The module remains shut down until instructed to reboot by another operation, such as the Reboot option.

15.5 Manual chassis reboot

15.5.1 Overview

There are two fields at the Shelf->General->Chassis Reboot level which indicate if and why a manual chassis reboot is required:

- “System Reboot Required”: Indicates if a configuration change has been made that requires an operator-driven reboot to fully activate.
- “Reboot Reason”: If a reboot is required, the reboot field checkbox will be checked with the respective reason for why the node requires a reboot.

To update these fields, a manual NE resync should be executed because the node does not send trap separately for each read-only property. The user can also update these fields through executing the clear command of “clear system reboot-required” on the NE; however, that NE does not send trap to NFM-P.

15.6 Workflow to manage shelf objects

15.6.1 Purpose

The following workflow describes the sequence of high-level tasks required to manage and configure shelf objects and shelf object children. This workflow assumes that the physical devices have been installed, commissioned, and discovered. See Chapter 8, “Device commissioning and management” for more information about device commissioning. See Chapter 9, “Device discovery” for more information about device discovery.

Note: Shelf objects and shelf object children can be accessed using the equipment navigation tree. See Chapter 3, “NFM-P navigation tree” for more information about using the equipment navigation tree.

15.6.2 Stages

1

As required, perform the following procedures to configure shelf objects.

a. Configure the chassis mode of a device. See 15.13 “To configure the device chassis mode” (p. 471) .

b. Configure a VWM shelf for a 7210 SAS device. See 15.14 “To configure a VWM shelf for a 7210 SAS” (p. 472) .

c. Configure dry contact sensor monitoring. See 15.15 “To configure dry contact sensors” (p. 473) .

d. Configure the IMM card type on a 7210 SAS-R. See 15.16 “To configure the IMM card type on a 7210 SAS-R” (p. 474) .

e. Configure switch fabric multicast ingress replication rates. See 15.17 “To configure switch fabric multicast ingress replication rates” (p. 475) .

f. Configure IMPM overrides. See 15.18 “To configure IMPM overrides” (p. 475) .

g. Enable mixed mode on a 7450 ESS or 7750 SR device. See 15.19 “To enable mixed mode” (p. 476) .

h. Configure an IEEE 1588 PTP port on a 7705 SAR. See 15.30 “To configure an IEEE 1588 PTP port on a 7705 SAR” (p. 487) .

i. Configure system time on a 7705 SAR. See 15.31 “To configure system time on a 7705 SAR” (p. 488) .

j. Configure SNTP on a 7705 SAR. See 15.32 “To configure SNTP on a 7705 SAR” (p. 489) .

k. Configure NTP on supported device types. See 15.34 “To configure NTP on supported devices” (p. 490) .

l. Configure the IEEE 1588 PTP clock on supported devices. See 15.21 “To configure the IEEE 1588 PTP clock on a 7210 SAS, 7250 IXR, 7450 ESS, or 7750 SR” (p. 478).

m. Configure the IEEE 1588 PTP peer on supported devices. See 15.22 “To configure the IEEE 1588 PTP peer of a 7210 SAS, 7250 IXR, 7450 ESS, or 7750 SR” (p. 480).

n. Configure the IEEE 1588 PTP port on supported devices. See 15.23 “To configure IEEE 1588 PTP ports on a 7210 SAS, 7250 IXR, 7450 ESS, 7750 SR, or 7950 XRS” (p. 481).

o. Manage OmniSwitch running configuration. See 15.41 “To manage an OmniSwitch running configuration” (p. 505) .

p. Configure OmniSwitch health monitoring. See 15.42 “To configure OmniSwitch health monitoring” (p. 506) .

q. Configure a CCM on a 7950 XRS-20. See 15.43 “To configure a CCM on a 7950 XRS-20” (p. 507) .

r. Configure power supply trays. See 15.46 “To configure a power supply tray” (p. 509) .

s. Configure power management zones. See 15.47 “To configure a power management zone” (p. 510) , 15.49 “To provision an APEQ” (p. 511) , and 15.50 “To configure a variable power supply APEQ” (p. 511) .

2

Assign a card type to a chassis slot. See 15.56 “To assign a card type” (p. 517) .

3

As required, configure the card and card slot objects as follows:

a. Configure an egress WRED queue control on an IOM 3 or IMM forwarding plane. See

15.62 “To configure egress WRED queue control on an XCM, IOM 3 or IMM forwarding plane” (p. 521) .

b. Configure IMPM on a 2 × XP MDA IOM 3 or IMM forwarding plane. See 15.64 “To configure IMPM on an XCM, 2 x XP MDA IOM 3, or IMM forwarding plane” (p. 522) .

c. Enable named pool mode. See 15.67 “To enable named pool mode” (p. 526) .

d. Configure OmniSwitch stacks. See 15.72 “To configure OmniSwitch stacks” (p. 530) .

e. Configure an OmniSwitch CPU temperature threshold. See 15.73 “To configure an OmniSwitch CPU temperature threshold” (p. 530) .

f. Configure a CPM on a 7950 XRS. See 15.74 “To configure a CPM” (p. 531) .

4

As required, configure daughter card objects as follows:

a. Configure an MDA. See 15.78 “To configure an MDA” (p. 536) .

b. Configure IMPM on an MDA. See 15.79 “To configure IMPM on an MDA” (p. 539) .

c. Specify an event action for a 7x50 MDA. See 15.81 “To specify an event action for a 7x50 MDA” (p. 541) .

d. View operational multicast channel properties on an MDA. See 15.82 “To view the operational multicast channel properties of an MDA” (p. 541) .

e. Configure a module card on the 7705 SAR-M/ME. See 15.83 “To configure a module card on a 7705 SAR-M/ME or 7705 SAR-H” (p. 543) .

5

As required, configure shelf objects that require daughter cards as follows:

a. Configure timing synchronization. See 15.20 “To configure timing synchronization” (p. 477) .

b. Configure an IEEE 1588 clock on a 7705 SAR. See 15.26 “To configure an IEEE 1588 PTP clock on a 7705 SAR” (p. 483) .

c. Configure SCADA on a 7705 SAR. See 15.36 “To configure SCADA on a 7705 SAR” (p. 495) .

d. Configure a 7705 SAR microwave link. See 15.38 “To configure a 7705 SAR MW link” (p. 499) .

e. Configure a 7705 SAR MW link member. See 15.39 “To configure a 7705 SAR MW link member” (p. 501) .

f. Configure auxiliary alarm definitions on a 7705 SAR. See 15.40 “To configure 7705 SAR auxiliary alarm definitions” (p. 504) .

6

As required, create or modify bundle objects as follows:

a. FR group bundle. See 15.86 “To create an FR group bundle” (p. 548) and 15.87 “To modify an FR group bundle” (p. 549) .

b. IMA group bundle. See 15.88 “To create an IMA group bundle” (p. 550) and 15.89 “To modify an IMA group bundle” (p. 551) .

c. MLPPP bundle. See 15.90 “To create an MLPPP bundle” (p. 551) and 15.91 “To modify an MLPPP bundle” (p. 553) .

d. MLPPP bundle for multiclass service transmission. See 15.92 “To configure an MLPPP bundle for multiclass service transmission” (p. 554) .

e. MLPPP bundle as a network interface on a channelized ASAP MDA. See 15.93 “To configure an MLPPP bundle as a network interface on a channelized ASAP MDA” (p. 555) .

Working with card and card slot objects

15.7 Overview

15.7.1 Functional description

When you expand a shelf object in the equipment navigation tree, the card slots of the shelf are displayed as child objects. A card slot object is shown as empty when no card is provisioned.

Card slots A and B are reserved for CPM or CSM cards. When you expand a CPM or CSM card object, the processor and flash memory objects are displayed.

Note: Some 7210 SAS and 7250 IXR devices are equipped with a USB flash memory. In the equipment tree and on Alarm Info forms, the NFM-P displays only Flash Memory. The display does not distinguish between compact flash memory and USB flash memory.

Card slot objects for the OS 6250, OS 6400, OS 6450, OS 6465, OS 6850, OS 6850E, OS 6855, OS 6860, OS 6860E, OS 6860N, and OS 6865 appear automatically when a physical device exists. This occurs because the entire device is represented by a card slot object and no daughter cards are associated with these devices.

When the NFM-P discovers a 7210 SAS or 7705 SAR-F, the integrated IOM and daughter card objects appear automatically in the navigation tree.

The 7250 IXR-R6 uses CPIOM cards that provide both CPM and IOM functionality. For information about the NFM-P equipment tree display of card slots and daughter card slots on the 7250 IXR-R6, see 6.6.1 “Overview” (p. 220).

The 7750 SR-s series of NEs allow for configuration of an IOM-s in a slot position of an XCM-s. This module is an Xiom-s. You can configure either XMA or Xiom-s on XCM-s, but not both. See 15.57 “To configure an Xiom-s card slot” (p. 518).

When the NFM-P discovers a supported PAC FP3 IMM in a card slot, the daughter cards and ports appear automatically in the navigation tree. Daughter cards and ports that are discovered in this way cannot be manually deleted.

Choose Configure Card from the contextual menu of the object and assign a supported card type for the slot. The Assigned Card Type parameter lists the card types that can be assigned to the card slots.

Some card types can be pre-provisioned in a slot before the card is installed in the chassis. A card and daughter card must be provisioned before a port can be configured.

When a card is first configured, the administrative state can be down. The resource is not operationally up until the card is equipped and the administrative state is up. A card can only be provisioned in a slot that is vacant, and no other card can be provisioned (configured) for that specific slot.

The Remove Card option in a contextual menu deletes the card from the slot when the slot and everything contained in the slot is changed to administratively down.

To reconfigure a slot position, delete the card currently in the slot and configure the new card type added to the slot. A card can only be provisioned in a slot when the card type is allowed in the slot.

Note: You can also reconfigure a slot position by changing the chassis mode. The chassis mode determines the minimum card requirements. See 15.1.1 “Shelf objects in the NFM-P navigation tree” (p. 453) for more information about chassis modes.

For example, if a 2 x 10-Gig MDA IOM 2 card is installed in the chassis that is running in chassis mode B, the card behaves as a 2 x 10-Gig MDA IOM Card, B. You can upgrade the chassis mode to C to make the IOM card behave as a 2 x 10-Gig MDA IOM 2 card.

You can configure forwarding plane properties on the properties forms for IOM 3, IMM, and XCM cards. IOM 3 and IMM cards support one forwarding plane, and XCM cards support two forwarding planes — one for each XMA card slot.

Note: You cannot configure a forwarding plane on an XCM card until you have provisioned the corresponding XMA card.

You cannot remove a provisioned XMA card when any of the following is true on the corresponding XCM forwarding plane:

- Egress WRED queue control is administratively enabled
- Access ingress queue groups are configured
- Network ingress queue groups are configured
- The Dynamic Enforcement Policer Pool Size parameter is configured with a nonzero value

15.7.2 PChip FCS Errors for cards

PChip FCS Error counts can be viewed from the IO Card tab of a Card Slot form. The Card Complex Statistics can be viewed from the Statistics tab of a Card Slot form. When frames of data are being corrupted during transmission, or duplex disparities between switch and the end device causes these errors, the NFM-P raises an alarm.

Note: The PChip alarm details, such as the alarms and statistics, cannot be differentiated whether raised against an MDA or IOM.

15.8 Card provisioning and chassis modes

15.8.1 Overview

The behavior of the installed card depends on the chassis mode that has been configured on the device. The following table describes the behavior of the provisioned (configured) card types and installed cards in each chassis mode.

Table 15-1 Behavior of installed IOM cards

Provisioned card type	Installed card type	Behavior
2 x 10-Gig MDA IOM	2 x 10-Gig MDA IOM	The IOM card appears and behaves at the scaling limits of the 2 x 10-Gig MDA IOM.
	2 x 10-Gig MDA IOM Card, B	The IOM card appears and behaves as a 2 x 10-Gig MDA IOM. The 2 x 10-Gig MDA IOM Card, B is fully backward-compatible with the 10-Gig MDA IOM.
	2 x 10-Gig MDA IOM 2	The IOM card appears and behaves as a 2 x 10-Gig MDA IOM. The 2 x 10-Gig MDA IOM 2 is fully backward-compatible with the 10-Gig MDA IOM.
	2 × XP MDA IOM 3 [1]	The IOM card appears and behaves as a 2 x 10-Gig MDA IOM. The 2 x XP MDA IOM is fully backward-compatible with the 10-Gig MDA IOM.
2 x 10-Gig MDA IOM Card, B	2 x 10-Gig MDA IOM	The IOM card fails because the minimum card requirements are not met.
	2 x 10-Gig MDA IOM Card, B	The IOM card appears and behaves at the scaling limits of the 2 x 10-Gig MDA IOM Card, B.
	2 x 10-Gig MDA IOM 2	The IOM card appears and behaves as a 2 x 10-Gig MDA IOM Card, B. The 2 x 10-Gig MDA IOM 2 is fully backward-compatible with the 10-Gig MDA IOM Card, B.
	2 × XP MDA IOM 3 [1]	The IOM card appears and behaves as a 2 x 10-Gig MDA IOM Card, B. The 2 x XP MDA IOM 3 is fully backward-compatible with the 10-Gig MDA IOM Card, B.
2 x 10-Gig MDA IOM 2	2 x 10-Gig MDA IOM	The IOM card fails because the minimum card requirements are not met.
	2 x 10-Gig MDA IOM Card, B	The IOM card fails because the minimum card requirements are not met.
	2 x 10-Gig MDA IOM 2	The behavior of the card depends on the operational chassis mode: • 2 x 10-Gig MDA IOM in chassis mode A • 2 x 10-Gig MDA IOM Card, B in chassis mode B • 2 x 10-Gig MDA IOM 2 in chassis mode C and D
	2 × XP MDA IOM 3 [1]	The behavior of the card depends on the operational chassis mode: • 2 x 10-Gig MDA IOM in chassis mode A • 2 x 10-Gig MDA IOM Card, B in chassis mode B • 2 x 10-Gig MDA IOM 2 in chassis mode C and D

Table 15-1 Behavior of installed IOM cards (continued)

Provisioned card type	Installed card type	Behavior
2 × XP MDA IOM 3 card [1]	2 x 10-Gig MDA IOM	The IOM card fails because the minimum card requirements are not met.
	2 x 10-Gig MDA IOM Card, B	The IOM card fails because the minimum card requirements are not met.
	2 x 10-Gig MDA IOM 2	The IOM card fails because the minimum card requirements are not met.
	2 × XP MDA IOM 3 [1]	The behavior of the card depends on the operational chassis mode: • 2 x 10-Gig MDA IOM in chassis mode A • 2 x 10-Gig MDA IOM Card, B in chassis mode B • 2 x 10-Gig MDA IOM 2 in chassis mode C • 2 x XP MDA IOM 3 in chassis mode D. With mixed mode enabled for 7750 SR, only the IPv6 features of the IOM3 card are enabled, but no other IOM3 features are available.
2 × XP MDA IOM 3, B card [1]	2 x 10-Gig MDA IOM	The IOM card fails because the minimum card requirements are not met.
	2 x 10-Gig MDA IOM Card, B	The IOM card fails because the minimum card requirements are not met.
	2 x 10-Gig MDA IOM 2	The IOM card fails because the minimum card requirements are not met.
	2 × XP MDA IOM 3 [1]	The behavior of the card depends on the operational chassis mode: • 2 x 10-Gig MDA IOM in chassis mode A • 2 x 10-Gig MDA IOM Card, B in chassis mode B • 2 x 10-Gig MDA IOM 2 in chassis mode C • 2 x XP MDA IOM 3 in chassis mode D. With mixed mode enabled for 7750 SR, only the IPv6 features of the IOM3 card are enabled, but no other IOM3 features are available.

Notes:

1. Also applies to any IMM

Working with daughter card objects

15.9 Overview

15.9.1 Daughter card objects

The NFM-P navigation tree displays daughter cards, or MDAs, as child objects of card objects.

An NFM-P license has a specific equipment management capacity. MDAs fall into two licensing categories: premium and standard. Premium MDAs consume more license capacity than standard MDAs. In general, non-high-performance MDA cards are considered standard. All IMM, HSMDA, XMDA, and XP MDA cards are premium.

Each IMM card is associated with a platform, and counts towards the licensed IMMs for that platform regardless of where it is installed. For example, a 7750 SR IMM installed on a 7450 ESS is counted as a premium 7750 SR MDA for the purposes of licensing. Enabling or disabling mixed mode does not change the associated platform type of a card.

FP4 cards on 7x50, Release 16.0 R1 and later, support license levels under card and MDA. The Licensing Details parameters appear on the Card Slot and Daughter Card Slot forms. You can set the Licensed Assigned Level that a card or daughter card slot can accept.

15.9.2 DCO daughter cards

CFP2-DCO daughter cards support DWDM channels, coherent optics, and optical transport channel unit (OTU). The 400 Gig QSFP-DD daughter cards and x2-1000g-wdm XMA support DWDM and coherent optics only. And other daughter cards support DWDM only. See the hardware documentation for more information about daughter card and XMA optical support.

On the NFM-P, DWDM channel and coherent optics are supported under connector ports and OTU is supported under breakout ports. See 16.23 “To configure connector ports and breakout ports” (p. 597) for more information about enabling coherent optics.

15.9.3 IMM daughter cards

The IMM card integrates IOM 3 and high bandwidth MDA functionality on a single card that fits into existing IOM slots. When you configure the IMM the integrated MDAs are automatically configured. The NFM-P equipment tree displays the IMM with two daughter cards, each having half of the total number of ports supported by the IMM.

Each daughter card object contains a number of ports that are specific to the type of service required. The port objects are created automatically under the daughter card but they must be configured based on the function served by the port; for example, as an access interface for a VPRN service.

You can associate policies to daughter cards. Network buffer policies are used to create and edit QoS buffer pool resources on egress network ports, channels, and ingress ports. Ingress and egress network ports and channels have a dedicated buffer pool for egress queuing. The ingress and egress network traffic is handled by a buffer pool at the ingress and a buffer pool at the egress.

You can also configure multicast path management on an IMM daughter card. See Chapter 52, “Multicast policies” for more information.

15.9.4 MDA modes for the 7705 SAR

The NFM-P allows you to configure the MDA mode of some MDA types on the 7705 SAR. The MDA mode on a channelized ASAP determines the capabilities that are available to the MDA. The MDA mode on an XMDA determines the number of ports that are available to the MDA. See the MDA Mode parameter description for more information.

Working with bundle objects

15.10 Overview

15.10.1 Bundle objects

Bundle objects can be configured as multilink PPP, IMA group, or FR group bundles. Multilink PPP, IMA group, and FR group bundles appear as Bundle objects under the daughter card object if the daughter card has been configured as a channelized MDA.

APS Bundle objects appear in the navigation tree as children of the shelf object. APS Bundle objects are configured to protect multilink PPP and IMA bundles on channelized ASAP MDAs. See Chapter 38, “APS” for more information on APS and APS bundles.

15.10.2 Multilink PPP bundles

You can create MLPPP bundles to:

- bundle DS0 channels together to be used as a SAP
- provide a mechanism to distribute data across multiple links to achieve higher bandwidth

The following general rules apply to multilink bundles.

- Table 15-2, “Multilink bundle configuration maximum” (p. 467) lists the maximum number of multilink bundles that can be created on each MDA.
- DS0 channels can be aggregated on a single MDA only.
- Up to 8 members can be added to a bundle.
- The Encap Type parameter of a member cannot be set to FR.
- A DS0 channel can host only one SAP.
- If a channel is being used as a SAP, it cannot be added to a bundle.

Table 15-2 Multilink bundle configuration maximum

MDA	Bundle maximum
4 x Channelized OC3/OC12 ASAP SFP MDA	32
All MDAs other than Channelized ASAP MDAs	56
• 1 x OC12 Deep Channel • 4 x OC3 Deep Channel • 12 x DS3/E3 Deep Channel • 4 x DS3/E3 Deep Channel	56
4 x Channelized DS3/E3 ASAP MDA	112
• 4 x Channelized OC3 ASAP • 1 x Channelized OC12 ASAP • 12 x Channelized DS3/E3 ASAP	256

See 15.90 “To create an MLPPP bundle” (p. 551) to create an MLPPP bundle.

15.10.3 IMA group bundles

IMA group bundles combine ATM-encapsulated DS0 channel groups into a single ATM interface. The following general rules apply to IMA group bundles.

- IMA group bundles can only be created on:
  - channelized ASAP MDAs with SDH or SONET framing the 7750 SR
  - channelized DS1/E1 ASAP daughter cards on the 7705 SAR
- The encapsulation type of the DS0 group channel must be ATM.
- The Clock Source parameter of the DS1 channel must be set to Node-Timed.
- Table 15-3, “IMA group bundle configuration maximums” (p. 467) lists the maximum number of IMA group bundles that can be created on each MDA.
- IMA group members must be on the same MDA.

Table 15-3 IMA group bundle configuration maximums

Device	MDA	Bundle maximum
7750 SR	All MDAs other than channelized ASAP MDAs	56
7750 SR	4 x Channelized DS3/E3 ASAP MDA	112
7750 SR	• 4 x Channelized OC3 ASAP • 1 x Channelized OC12 ASAP • 12 x Channelized DS3/E3 ASAP	256
7705 SAR	16 x Channelized DS1/E1 ASAP	8
7705 SAR	2 x Channelized OC3/STM1 ASAP	16

See 15.88 “To create an IMA group bundle” (p. 550) to create an IMA group bundle.

15.10.4 FR group bundles

FR group bundles are used to fragment lower priority DLCI frames to minimize jitter and delay on higher priority DLCI frames. The following general rules apply to FR group bundles.

- FR group bundles can only be created on channelized ASAP MDAs.
- FRF12 cannot be enabled on a SAP that is using an FR group bundle.
- DS0 channel groups must have all their timeslots selected and have their encapsulation type set to FR to be configured as bundle members.

Note: You can configure a maximum of 128 FR group bundles on an MDA.

See 15.86 “To create an FR group bundle” (p. 548) to create an FR group bundle.

Working with extension shelf objects

15.11 Extension shelves

15.11.1 Overview

An extension shelf is a virtual object that is modeled in the NFM-P as a shelf object. It can represent a variety of equipment connected to the NE by cables connected to uplink ports. This section describes the types of extension shelves supported by the NFM-P.

15.11.2 Ethernet satellite shelf

An Ethernet satellite shelf is a breakout box attached to a router that provides equipment support for additional gigabit Ethernet ports. These breakout boxes are modeled as virtual shelves on the host NE in the NFM-P. See 15.94 “To create a satellite shelf” (p. 557) for information about creating a satellite shelf on an NE. Each breakout box is connected to an NE through uplink ports; see 15.95 “To configure satellite shelf uplink port topology” (p. 557) for information about configuring the uplink.

You can specify the satellite file transfer protocol to be used for the boot process when transferring boot images and configuration files from the 7x50 host to the Ethernet satellite. See 12.42 “To configure satellite file transfer” (p. 375) for more information.

15.11.3 TDM satellite shelf

A TDM satellite shelf is a separate TDM chassis attached to a router that provides additional TDM ports. See 15.94 “To create a satellite shelf” (p. 557) for information about creating a satellite shelf on an NE. Each chassis is connected to an NE through uplink ports; see 15.95 “To configure satellite shelf uplink port topology” (p. 557) for information about configuring the uplink.

Software upgrade

You can upgrade the software on an optical extension shelf using the NFM-P. To perform an upgrade, you must associate the shelf with a software repository, then perform a reboot upgrade. See 15.101 “To perform a software upgrade on an extension shelf” (p. 562) for information about upgrading system software on a TDM satellite shelf.

Procedures for shelf object configuration

15.12 To configure an 1830 VWM shelf

15.12.1 Before you begin

The 1830 VWM manages passive devices SFD-96, SFD-44, BMU-P, and AMP as shelves. The following procedure may be used to configure passive devices as well as shelves.

15.12.2 Steps

1

On the equipment tree, expand Network→1830–VWM-OSU NE.

2

Right-click on the 1830–VWM-OSU NE object and choose Configure Shelf. The Shelf (Create) form opens.

3

Configure the parameters in the Shelf Details panel.

The following shelf types and passive devices can be configured:

1830 VWM-ITP4LCA	1830 VWM-PMU9UC	1830 VWM-SMMAI
1830 VWM-ITP4LCB	1830 VWM-PMU9LC	1830 VWM-SMMAO
1830 VWM-ITP4UCA	1830 VWM-PMU9UCM	1830 VWM-TLU9
1830 VWM-ITP4UCB	1830 VWM-PMU9LCM	1830 VWM-TLU9M
1830 VWM-OPS	1830 VWM-SFD44	1830 VWM-SFD44B
1830 VWM-SFD96	1830 VWM-BMUP	1830 VWM-PMUD21A
1830 VWM-PMUD21B	1830 VWM-PMUD21C	1830 VWM-PMUD21D
1830 VWM-SPLIT2	1830 VWM-OSCCPLR	1830 VWM-OAUNIDIR
1830 VWM-SFD10 and its variants A, B, C, and D	1830 VWM-SFD2 and its variants A, B, C, D, E, F, G , H, I, L, M, N, O, P, Q, and R	1830 VWM-SFD4 and its variants A, B, C, D, E, F, G, and H
1830 VWM-SFD8 and it variants A, B, C, and D	1830 VWM-SFC1 and its variants A, B, C, D, E, F, G, and H	1830 VWM-SFC2 and its variants AB, CD, EF and GH
1830 VWM-SFC4AD and SFC4EH	1830 VWM-SFC8U and SFC8L	1830 VWM-SARO2 and its variants A, B, C, D, E, F, G, and H

1830 VWM-SARO4 and its variants A, B, C, and D	1830 VWM-SARO8A and SARO8B	1830 VWM-LR4BOC
1830 VWM-TLU200	-	-

4

Save your changes and close the form.

END OF STEPS

15.13 To configure the device chassis mode

15.13.1 Before you begin

The device chassis mode must be set to indicate the minimum IOM or IMM card type that is initialized by the NE. This also determines other features available to the system. The behavior of the installed card depends on the chassis mode configured on the device. See 15.1.1 “Shelf objects in the NFM-P navigation tree” (p. 453) and “Working with card and card slot objects” (p. 461) for more information about chassis modes and card types.

15.13.2 Steps

1

On the equipment tree, expand Network→*NE*→Shelf.

2

Right-click on the Shelf object and choose Properties. The Shelf (Edit) form opens.

3

Configure the parameters:

- Administrative Mode

  If you downgrade the administrative chassis mode, the device must be rebooted to change the operational chassis mode.

- Force Mode

  Forcing a chassis mode change does not change the operational chassis mode unless there is a compatible card type equipped on the device. See 15.1.1 “Shelf objects in the NFM-P navigation tree” (p. 453) for more information about the minimum card type that must be installed for each chassis mode.

4

Save your changes and close the form.

END OF STEPS

15.14 To configure a VWM shelf for a 7210 SAS

15.14.1 Before you begin

The 1830 VWM is an add-on optical module that provides WDM capability to 7210 SAS devices. Support for 1830 VWM shelves varies depending on the 7210 SAS chassis type. See the NE documentation for more information.

15.14.2 Steps

1

On the equipment tree, expand Network→*NE*→VWM Shelves.

2

Right-click on VWM Shelves and choose Configure VWM Shelf. The VWM Shelf (Create) form opens.

3

Configure the required parameters.

Configure the Shelf ID parameter to match the hardware shelf ID value that is preset on the rotary dial of the 1830 VWM module. If the Shelf ID parameter does not match the hardware shelf ID, the correct manufacturer details will not appear on the VWM Shelf form.

Some chassis types support a value of zero for the Shelf ID parameter. When a value of zero is configured, the VWM Type parameter is set to DWDM-A (DWDM-active) by default and is not configurable.

4

On the equipment tree, expand the VWM Shelves object to the VWM Card Slot level.

5

Right-click on a VWM Card Slot object and choose Configure Card. The Configure VWM Card Slot form opens.

6

Configure the Assigned VWM Card Type parameter.

The Assigned VWM Card Type parameter provides a way to check if the equipped card type is acceptable. An alarm is raised when the equipped VWM card type in the module does not match the Assigned VWM Card Type.

7

Save your change and close the form.

8

Repeat Step 5 to Step 7 for each additional card slot that you need to configure.

9

You can view information about VWM controllers, such as Status and manufacturer details, by opening the VWM controller properties form. To open the form, right click on a VWM controller object in the navigation tree and choose Properties.

The Status parameter indicates whether a controller is operational or standing by. The Status parameter is available only for DWDM and DWDM-A shelf types.

10

Save your changes and close the form.

END OF STEPS

15.15 To configure dry contact sensors

15.15.1 Before you begin

You can enable dry contact sensors on the console port or alarm interface port of supported NEs. When an external alarm condition is present, the NE sends an alarm with a user-configured message to the NFM-P. See the NE documentation for more information about dry contact sensors.

15.15.2 Steps

1

If you are configuring a 7210 SAS-D or 7210 SAS-K, perform the following steps. Otherwise, go to Step 2 .

1. On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.
2. Enable the Console Alarm Input parameter.

   Note:

   The console port is not available for other purposes when the Console Alarm Input parameter is enabled.
3. Save your change and close the form.

2

On the equipment tree, expand Network→*NE*→Shelf.

3

Right-click on the Shelf object and choose Properties. The Shelf (Edit) form opens.

4

Click on the External Alarms tab. A list of dry contacts is displayed.

5

Choose one of the dry contacts and click Properties. The Dry Contact (Edit) form opens.

6

Configure the required parameters and click OK. The Dry Contact (Edit) form closes.

7

Repeat Step 5 and Step 6 as required to configure additional dry contacts.

Note: You can configure only one dry contact for the 7210 SAS-D and 7210 SAS-K.

8

Save your changes and close the form.

END OF STEPS

15.16 To configure the IMM card type on a 7210 SAS-R

15.16.1 Steps

1

On the equipment tree, expand Network→*NE*→Shelf.

2

Right-click on the Shelf object and choose Properties. The Shelf (Edit) form opens.

3

Configure the Allow IMM Family Type parameter.

The Allow IMM Family Type parameter requires an NE reboot to take effect. The Operational IMM Family Type parameter displays the card type currently in effect for the shelf.

When None is enabled for the Allow IMM Family Type parameter, the default IMM family type for the NE is applied. The default for the 7210 SAS-R6 is KT1. For the 7210 SAS-R12, the default is KT2.

4

Save your changes and close the form.

END OF STEPS

15.17 To configure switch fabric multicast ingress replication rates

15.17.1 Purpose

Perform this procedure to configure the total multicast replication rates for primary and secondary ingress paths for each switch fabric multicast plane.

15.17.2 Steps

1

On the equipment tree, expand Network→*NE*→Shelf.

2

Right-click on the Shelf object and choose Properties. The Shelf (Edit) form opens.

3

Click on the Multicast tab.

4

Configure the required parameters.

5

Save your changes and close the form.

END OF STEPS

15.18 To configure IMPM overrides

15.18.1 Before you begin

See 15.64 “To configure IMPM on an XCM, 2 x XP MDA IOM 3, or IMM forwarding plane” (p. 522) to configure IMPM on an IOM or XCM. See Chapter 52, “Multicast policies” for more information on multicast path management.

15.18.2 Steps

1

On the equipment tree, expand Network→*NE*→Shelf.

2

Right-click on the Shelf object and choose Properties. The Shelf (Edit) form opens.

3

Click on the Multicast tab.

4

Configure the required parameters in the MMRP Ingress Multicast Path Management Override panel.

Note: The Operational Mode parameter is not configurable. If the Administrative Mode parameter is changed, the value of the Operational Mode parameter changes to indicate the same as the Administrative Mode, after the system is rebooted.

5

Save your changes and close the form.

END OF STEPS

15.19 To enable mixed mode

15.19.1 Before you begin

Enabling mixed mode only applies to 7750 SR devices.

Mixed-mode is the default behavior for all 7450 ESS chassis, which allows the 7450 ESS chassis to support all 7750 SR functionality.

7750 SR-7 and 7750 SR-12 devices also support mixed mode, which allows you to enable IPv6 in chassis mode A or B, without having to upgrade an entire chassis. Slots with network ports, and ports that require IPv6 support, can then be selectively upgraded for IOM3-XPs (SROS Release 20.10 and earlier) or IMMs.

Note: You cannot enable mixed mode on a 7750 SR-7 or 7750 SR-12 that has a provisioned ISA TMS MDA.

15.19.2 Steps

1

On the equipment tree, expand Network→*NE*→Shelf.

2

Right-click on the Shelf object and choose Properties. The Shelf (Edit) form opens.

3

Enable the Mixed Mode State on Chassis Enabled parameter.

4

Save your change and close the form.

END OF STEPS

15.20 To configure timing synchronization

15.20.1 Purpose

The following procedure describes the sequence of tasks required to configure timing synchronization. This procedure assumes that the shelf and its daughter cards have been configured.

You must enable the Synchronous Ethernet parameter on the daughter card in order to configure the Timing Reference One and Timing Reference Two panels for SyncE. See 15.78 “To configure an MDA” (p. 536) .

You must configure an IEEE 1588 PTP clock on the device when you configure PTP as a timing reference; see 15.26 “To configure an IEEE 1588 PTP clock on a 7705 SAR” (p. 483) or 15.21 “To configure the IEEE 1588 PTP clock on a 7210 SAS, 7250 IXR, 7450 ESS, or 7750 SR” (p. 478).

15.20.2 Steps

1

On the equipment tree, expand Network→*NE*→Shelf.

2

Right-click on the Shelf object and choose Properties. The Shelf (Edit) form opens.

3

Click on the Timing tab and configure the required parameters.

When you select a port as a timing reference for SyncE, the Port Clock Mode parameter for the port must be set to Manual Slave. See 16.24 “To configure Ethernet ports” (p. 599) . Other restrictions may also apply for SyncE port selection, depending on the device. See the NE documentation for more information.

You can enable the Administrative State parameter in the PTP panel only when the Frequency Source and Oper Frequency Source parameters are both set to Ptp on the IEEE 1588 PTP Clock form; see 15.21 “To configure the IEEE 1588 PTP clock on a 7210 SAS, 7250 IXR, 7450 ESS, or 7750 SR” (p. 478) .

For the 7210 SAS-D ETR, 7210 SAS-M, and 7210 SAS-X, PTP and SyncE are mutually exclusive. Consider the following when configuring timing synchronization on these 7210 SAS NEs:

- You can only choose PTP as an option for First Timing Reference Input when the Administrative State parameter in the PTP panel is set to Up.
- You cannot configure the Second Timing Reference Input parameter when the First Timing Reference Input parameter is set to PTP.
- You can only set the Administrative State parameter in the PTP panel to Up when the Administrative State parameter in both the Timing Reference One and Timing Reference Two panels is set to Down.

- You can only set the Administrative State parameter in the Timing Reference One and Timing Reference Two panels to Up when the Administrative State parameter in the PTP panel is set to Down.

Note: The displayed parameters vary depending on the NE type, release, and the settings of other parameters.

4

Save your changes and close the form.

END OF STEPS

15.21 To configure the IEEE 1588 PTP clock on a 7210 SAS, 7250 IXR, 7450 ESS, or 7750 SR

15.21.1 Purpose

Perform this procedure to configure the IEEE 1588 PTP clock on a device that is configured as an IEEE 1588 PTP client. See 15.20 “To configure timing synchronization” (p. 477) for information about how to configure a device as a PTP client.

Depending on the PTP profile you are configuring, you may need to configure PTP peers or PTP ports; see 15.22 “To configure the IEEE 1588 PTP peer of a 7210 SAS, 7250 IXR, 7450 ESS, or 7750 SR” (p. 480) and 15.23 “To configure IEEE 1588 PTP ports on a 7210 SAS, 7250 IXR, 7450 ESS, 7750 SR, or 7950 XRS” (p. 481).

15.21.2 Steps

1

In the navigation tree equipment view, right-click on the required device and choose Properties. The Network Element (Edit) form opens.

2

Click on the IEEE PTP Clock tab.

3

Select an IEEE 1588 PTP Clock from the list and click Properties. The IEEE 1588 PTP Clock (Edit) form opens.

4

Configure the required parameters.

At least one IEEE PTP peer or port must be created before you can set the Admin State parameter to Enabled. See 15.22 “To configure the IEEE 1588 PTP peer of a 7210 SAS, 7250

IXR, 7450 ESS, or 7750 SR" (p. 481) and 15.23 "To configure IEEE 1588 PTP ports on a 7210 SAS, 7250 IXR, 7450 ESS, 7750 SR, or 7950 XRS" (p. 481).

When the Admin State parameter is set to Enabled, you cannot change the following parameters:

- Clock Type
- PTP Profile
- Domain
- Clock Announce Rx Timeout
- Clock Announce Interval
- Log sync interval

The PTSF Unusable Admin State parameter is only configurable when the PTP Profile is set to ITU-T G.8275.1.

For the 7210 SAS-D ETR, 7210 SAS-K, 7210 SAS-M, 7210 SAS-R, 7210 SAS-S/Sx VC, 7210 SAS-T, 7210 SAS-T ETR, and 7210 SAS-X: when the Clock Type parameter is set to Boundary, you must set the PTP Profile parameter to IEEE-1588-2008.

If you are configuring an ITU-T G.8275.1 profile on a supporting 7210 SAS NE, you must choose Boundary Clock for the Clock Type parameter and ITU-T G.8275.1 for the PTP Profile parameter.

If you are configuring an ITU-T G.8275.1 profile on a 7250 IXR, you must choose Boundary or Slave for the Clock Type parameter and ITU-T G.8275.1 for the PTP Profile parameter.

The ITU-T G.8265.1 profile only supports master slave clocks and PTP peers. For the 7250 IXR-e big/small, the ITU-T G.8265.1 profile only supports ordinary slave clocks and PTP peers.

Changes to the PTP Profile and Frequency Source parameters may require an NE reboot to take effect; see the NE documentation for more information. The currently effective frequency source is displayed as the Oper Frequency Source.

To make SSU the effective Oper Frequency Source, the timing reference must be qualified and the Status must be set to Master Locked on the Timing tab of the shelf properties form; see 15.20 "To configure timing synchronization" (p. 477). Also, the Admin State parameter on the General tab of the ptp clock tab must be set to enabled.

Note: The displayed parameters vary depending on the NE type, release, and the settings of other parameters.

5

Save and close the forms.

END OF STEPS

15.22 To configure the IEEE 1588 PTP peer of a 7210 SAS, 7250 IXR, 7450 ESS, or 7750 SR

15.22.1 Purpose

Perform this procedure to configure IEEE 1588 PTP peers for a device that has the IEEE 1588 PTP clock configured. See 15.21 “To configure the IEEE 1588 PTP clock on a 7210 SAS, 7250 IXR, 7450 ESS, or 7750 SR” (p. 478) for information about how to configure the IEEE 1588 PTP clock on a device.

For 7250 IXR-e CPM GNSS with the ITU-T G.8265.1 profile, PTP peer creation is only supported for the ordinary slave clock profile.

15.22.2 Steps

1

In the navigation tree equipment view, right-click on the required device and choose Properties. The Network Element (Edit) form opens.

2

Click on the IEEE PTP Clock tab.

3

Choose an entry from the list and click Properties. The IEEE 1588 PTP Clock (Edit) form opens.

4

Click on the IEEE PTP Peers tab.

5

Click Create, or choose an IEEE 1588 PTP peer from the list and click Properties. The IEEE 1588 PTP Peer (Create|Edit) form opens.

The number of peers that you can create varies depending on the NE. When the limit is reached, the Create button is not available.

Alternatively, you can create IEEE PTP peers by right-clicking on the Clock object in the navigation tree and choosing Create IEEE PTP Peer.

6

Configure the required parameters.

7

Save and close the forms.

END OF STEPS

15.23 To configure IEEE 1588 PTP ports on a 7210 SAS, 7250 IXR, 7450 ESS, 7750 SR, or 7950 XRS

15.23.1 Purpose

Perform this procedure to configure IEEE 1588 PTP ports for a supporting device that has the IEEE 1588 PTP clock and the ITU-T G.8275.1, ITU-T G.8275.2, or IEEE1588-2008 profile configured. See 15.21 “To configure the IEEE 1588 PTP clock on a 7210 SAS, 7250 IXR, 7450 ESS, or 7750 SR” (p. 478) for information about how to configure the IEEE 1588 PTP clock on a device.

You can configure multiple IEEE PTP ports on the same device.

15.23.2 Steps

1

In the navigation tree equipment view, right-click on the required device and choose Properties. The Network Element (Edit) form opens.

2

Click on the IEEE PTP Clock tab.

3

Choose an entry from the list and click Properties. The IEEE 1588 PTP Clock (Edit) form opens.

4

Click on the IEEE PTP Port tab.

5

Click Create, or choose an IEEE 1588 PTP port from the list and click Properties. The IEEE 1588 PTP Port (Create|Edit) form opens.

The number of ports that you can create varies depending on the NE. When the limit is reached, the Create button is not available.

Alternatively, you can create IEEE PTP ports by right-clicking on the Clock object in the navigation tree and choosing Create IEEE PTP Port.

6

Configure the required parameters.

When you configure a 7210 SAS-R NE as a Boundary clock, you must disable the Master Only parameter on at least one of the configured IEEE PTP ports.

7

If an NE with embedded GNSS receiver is configured as a PTP boundary with G8275.2 profile, the GNSS input is modeled as a virtual PTP port and the GNSS Port tab appears. The GNSS virtual ports are A/gnss or B/gnss.

Choose a virtual PTP port from the list and click Properties to display the IEEE 1588 GNSS Port (View) form.

8

Save and close the forms.

END OF STEPS

15.24 To configure alternate profiles under IEEE PTP Clock on a 7250 IXR, 7450 ESS, 7750 SR, or 7950 XRS

15.24.1 Before you begin

This procedure is not supported on 7250 IXR-s, 7250 IXR-e, 7250 IXR-e2, 7250 IXR-e2c, and 7250 IXR-ec.

An alternate profile can only be configured if the primary profile is either G.8275.1 or G.8275.2, and the clock type is either Master or Boundary. The initially-defined profile functions as a primary profile and up to six alternate profiles can be configured and assigned to desired PTP ports. If the PTP port is created without choosing any alternate profiles, then it will use the primary profile.

15.24.2 Steps

1

In the navigation tree equipment view, right-click on the required device and choose Properties. The Network Element (Edit) form opens.

2

Click on the IEEE PTP Clock tab.

3

Select an IEEE 1588 PTP Clock from the list and click Properties. The IEEE 1588 PTP Clock (Edit) form opens.

4

Click Create in the PTP Clock Alternate Profiles panel.

The PTP Clock Alternate Profile Inter Working (Create) form opens.

5

Configure the required parameters.

6

Save and close the forms.

END OF STEPS

15.25 To associate an alternate profile to an IEEE PTP Port on a 7250 IXR, 7450 ESS, 7750 SR, or 7950 XRS

15.25.1 Before you begin

This procedure is not supported on 7250 IXR-s, 7250 IXR-e, 7250 IXR-e2, 7250 IXR-e2c, and 7250 IXR-ec.

15.25.2 Steps

1

In the navigation tree equipment view, right-click on the required device and choose Properties. The Network Element (Edit) form opens.

2

Click on the IEEE PTP Clock tab.

3

Choose an entry from the list and click Properties. The IEEE 1588 PTP Clock (Edit) form opens.

4

Click on the IEEE PTP Port tab.

5

Click Create or choose a port entry and click Properties. The IEEE 1588 PTP Port (Create) form opens.

6

On the Alternate Profile panel, configure an alternate profile to be associated with the port.

7

Save and close the forms.

END OF STEPS

15.26 To configure an IEEE 1588 PTP clock on a 7705 SAR

15.26.1 Before you begin

You can only configure the IEEE 1588 PTP clock on a 7705 SAR that is configured as an IEEE 1588 PTP client. See 15.20 “To configure timing synchronization” (p. 477) for information about how to configure the NE as a PTP client.

15.26.2 Steps

1

On the equipment tree, expand Network→*NE*.

2

Right-click on the NE and choose Properties. The Network Element (Edit) form opens.

3

Click on the IEEE PTP Clock tab and click Create. The IEEE 1588 PTP Clock (Create) form opens.

4

Configure the required parameters.

If you set the PTP Profile to ITU-T G.8275.1 or ITU-T G.8275.2, the Clock Local Priority parameter is configurable.

You can configure the IEC/IEEE 61850.9.3 and the C37.238-2017 PTP clock only on a 7705 SAR with a CSM clock ID. Master clock is only supported for 7705 SAR devices with integrated GNSS. When you configure a 7705 SAR with the IEC/IEEE 61850.9.3 or the C37.238-2017 profile, the default settings are automatically applied.

5

Select a clock MDA for the PTP clock.

6

Select a source interface for the PTP clock.

7

If you are configuring a 7705 SAR-8 or 7705 SAR-18, you can view the properties of the local clocks, active or standby, in the Local Clock-Active/Standby panel.

8

If you set the Clock Type parameter to Boundary or Ordinary, Slave, you can view the Parent clock information in the Parent Clock panel.

9

Click Apply to save your changes.

10

To turn up PTP ports on the IEEE 1588 PTP clock:

1. Click on the IEEE PTP Port tab, and click Create. The IEEE 1588 PTP clock (Create) form opens.
2. Select a port and configure the required parameters.

The Cfg Sync Rate parameter is not supported if the Clock Type parameter was configured as Ordinary, Slave in Step 4 .

You can only configure the Local Priority and Master Only parameters if the PTP Profile parameter was configured as ITU-T G.8275.1 or ITU-T G.8275.2 in Step 4 .

3. Save your changes.

11

Save your changes and close the forms.

END OF STEPS

15.27 To configure an IEC/IEEE 61850-9-3 PTP clock on a 7705 SAR

15.27.1 Before you begin

You can only configure the IEC/IEEE 61850-9-3 PTP clock on a 7705 SAR with a CSM clock ID. Master clock is only supported for 7705 SAR devices with integrated GNSS. When you configure a 7705 SAR with the IEC/IEEE 61850-9-3 profile, the default settings are automatically applied.

15.27.2 Steps

1

On the equipment tree, expand Network→*NE*→ Shelf→Synchronization→Clock 32.

2

On the General tab, configure the PTP Profile parameter as IEC-61850.9.3.

3

Configure the Clock Type parameter, as required.

Note: Master clock is only supported for 7705 SAR devices with integrated GNSS.

4

Verify that the default values are correct for the following parameters: Domain, Network Type, Clock ID, Clock Announce Rx Timeout, and Clock Announce Interval.

5

To turn up PTP ports on the IEC-61850.9.3 PTP clock:

1. Click on the IEEE PTP Port tab. The IEEE 1588 PTP clock form opens.
2. Select a port and configure the required parameters.
3. Verify that the default values for the Cfg Sync Rate and Cfg Delay Req Rate parameters are configured as 1 pkt/sec.
4. Save your changes.

6

Save your changes and close the forms.

You can view the statistics for the PTP clock on the Statistics tab of the PTP clock form.

END OF STEPS

15.28 To configure alternate profiles under IEEE PTP Clock on a 7705 SAR

15.28.1 Before you begin

The 7705 SAR supports a number of PTP profiles. For networks deployed using specific profile, support to inter-work with other profiles is provided. Initially defined profile functions as a primary profile and alternate profiles can be configured to be assigned to desired PTP ports.

Note: Alternate profile configuration is supported only on a Master CSM clock and with primary clock profile type G.8275.1.

A maximum of 2 alternate profiles can be configured.

15.28.2 Steps

1

On the equipment tree, expand Network→*NE*→Shelf→Synchronization.

2

Right-click on the PTP Clock 32 and choose Properties. The ptp (Edit) form opens.

3

On the CSM Clock Alternate Profiles panel, click Create or choose a profile entry and click Properties. The PTP CSM clock Alternate Profile (Create|Edit) form opens.

4

Configure the required parameters on the General tab.

5

Save your changes and close the forms.

END OF STEPS

15.29 To associate an alternate profile to an IEEE PTP Port on a 7705 SAR

15.29.1 Steps

1

On the equipment tree, expand Network→*NE*→Shelf→Synchronization.

2

Right-click on the PTP Clock 32 and choose Properties. The ptp (Edit) form opens.

3

Click IEEE PTP Port tab.

4

Click Create or choose a port entry and click Properties. The IEEE 1588 PTP Port (Create|Edit) form opens.

5

Configure the required parameters.

6

On the Alternate Profile panel, configure an alternate profile to be associated with the port.

7

Save your changes and close the forms.

END OF STEPS

15.30 To configure an IEEE 1588 PTP port on a 7705 SAR

15.30.1 Before you begin

You can configure the IEEE 1588 PTP port on a 7705 SAR that is configured as an IEEE 1588 PTP client. See 15.20 “To configure timing synchronization” (p. 477) for information about how to configure a 7705 SAR as a PTP client.

15.30.2 Steps

1

Expand Network→*NE*→Shelf.

2

Right-click on the Shelf object and choose Properties. The Shelf (Edit) form opens.

3

Click on the Timing tab and click on PTP Port Properties. The PTP Port (Edit) form opens.

4

Configure the required parameters.

Note: The Master 1 and 2 clock recovery statistics are available on the Recovered Clock History Master tabs.

5

Save your changes and close the forms.

END OF STEPS

15.31 To configure system time on a 7705 SAR

15.31.1 Before you begin

You can configure system time updates, based on priority values. There are five system time reference types: PTP, GPS, GNSS, NTP, SNTP, and the default value, Holdover. PTP is supported on the 7705 SAR-8, 7705 SAR-18, 7705 SAR-A, 7705 SAR-A T1/E1, 7705 SAR-Ax, 7705 SAR-H, 7705 SAR-Hc, 7705 SAR-M, 7705 SAR-M ASAP, 7705 SAR-W, and 7705 SAR-Wx. GPS is supported on the 7705 SAR-H and 7705 SAR-Wx GPS variants. GNSS is supported on the 7705 SAR-8 CSMv2 with shelf v1 or v2, 7705 SAR-18, and 7705 SAR-Ax configured with a GNSS MDA.

Time references become qualified for use when they provide a valid input into system time. Of the qualified time references, the highest priority, which is the lowest numerical priority value, becomes the selected time reference. If all five time references are operationally up, the order of priority for the selected time reference is PTP or GPS, depending on which one has the lowest numerical priority value, then NTP, SNTP, and Holdover. When PTP or GPS are selected time references, the operational states of NTP and SNTP are automatically down.

15.31.2 Steps

1

In the navigation tree equipment view, right-click on the 7705 SAR on which you need to configure system time, and choose Properties.

2

Click on the Time tab and on the Input References tab.

3

Click Create. The Time References (Create) form opens.

4

Configure the required parameters.

If you configure the Ref Type parameter as PTP, a PTP clock and priority value must be assigned. If you configure GPS or GNSS, a GPS port or GNSS port and priority value must be assigned. See 15.26 “To configure an IEEE 1588 PTP clock on a 7705 SAR” (p. 483) for more information about configuring a PTP clock on a 7705 SAR.

5

Save your changes and close the form.

END OF STEPS

15.32 To configure SNTP on a 7705 SAR

15.32.1 Before you begin

SNTP is a compact, client-only version of NTP. The 7705 SAR supports SNTP in both unicast client modes and broadcast client modes. SNTP can only receive the time from SNTP or NTP servers and cannot be used to provide time services to other systems.

15.32.2 Steps

1

In the navigation tree equipment view, right-click on the 7705 SAR on which you need to configure SNTP, and choose Properties.

2

Click on the SNTP tab and configure the required parameters on the General tab.

3

Configure an SNTP server.

1. Click on the Server tab.
2. Click Create or select a server and click Properties. The SNTP Server (Create|Edit) form opens.
3. Configure the required parameters.

4

Save your changes and close the form.

END OF STEPS

15.33 To configure VPLS scalability on a 7705 SAR

15.33.1 Before you begin

The VPLS scalability can be configured only on 7705 SAR-8 and 7705 SAR-18 nodes. This configuration applies to SAR nodes from Release 21.4 R2 onwards.

15.33.2 Steps

1

On the equipment tree, choose Network→*NE* where *NE* is the object on which you need to configure VPLS scaling.

2

Right-click on the NE and choose Properties. The Network Element (Edit) form opens.

3

Click the System Forwarding Path Option tab and configure the Admin State parameter.

Note: By default, the Oper and Admin state parameters are set to Down. You must reboot the NE for the configured Admin State value to take effect. The Oper State parameter is updated when the NE is rebooted.

Once the Admin State is turned up, a total of 255 VPLS instances can be configured on the node.

4

Save your changes and close the form.

END OF STEPS

15.34 To configure NTP on supported devices

15.34.1 Before you begin

NEs can act as NTP servers, clients, or peers.

The 7705 SAR acts as an NTP client as well as an NTP server. The 7705 SAR as an NTP server, and the support for NTP on a VPRN service is supported from Release 21.4 R1 and later.

Note: For the Wavence SM, if the main and spare NTP servers are defined with the same IP address in NEtO, only the IP address for the main server will be displayed in the NFM-P. Main and primary NTP servers with the same IP address should be avoided.

For any failed operation related to NTP server addition or modification, you must close the current GUI session on the NTP tab and reopen it before proceeding. This action removes the failed entry from the GUI cache so that it is not applied again.

The tabs and parameters that are configurable vary depending on the NE.

15.34.2 Steps

1

On the equipment tree, choose Network→*NE* where *NE* is the object on which you need to configure NTP.

2

Right-click on the NE and choose Properties. The Network Element (Edit) form opens.

3

If you are configuring a 7705 SAR, Release 6.2 R1 or earlier, or a Wavence SM, click on the NTP tab and configure the NTP State parameter, and go to Step 6 . If you are configuring a 7705 SAR, Release 7.0 or later, go to Step 4 .

You must set the NTP State parameter to Enabled in order to configure the remaining NTP parameters.

4

Configure the NTP State parameter on the General tab.

You must set the NTP State parameter to Enabled in order to configure the remaining NTP parameters.

When you change the NTP State parameter from Disabled to Enabled, you must click Apply and confirm the action in order to activate the NTP tab.

5

Click on the NTP tab. The General tab is displayed.

6

Configure the required parameters.

7

If you are configuring NTP on an 1830 VWM, OS 6250 or OS 6450 device, go to Step 9. Otherwise, continue to Step 8.

8

Configure Authentication:

1. Click on the Authentication tab and click Create. The Network Time Protocol Authentication (Create) form opens.
2. Configure the required parameters.

   The values of the Authentication Key Id and Authentication Key parameters must be the same on the reference clock server and the NE.
3. Save your changes.
4. Go to Step 10.

9

Configure Authentication:

1. Click on the Authentication tab and click Load Authentication Keys. A dialog box appears. Click Yes.
2. Choose Resync→Resync All MIBs. A dialog box appears. Click Yes. The Authentication Keys are loaded.
3. Save your changes.

10

Configure an NTP server:

1. Click on the Server tab and click Create. The NTP Server (Create) form opens.
2. Configure the required parameters.

   Note:

   When the PTP Server parameter is enabled, the IP Address parameter becomes non-configurable. The address that is displayed in the field is not the PTP server address, it is an internal reference.

   The Authentication Key Id and NTP Version parameters are only displayed when the PTP Server parameter is not enabled.

   For 7705 SAR, NTP Version parameter supports version 2, version 3, and version 4 for IPv4 and only version 4 is supported for IPv6.

   If you are configuring NTP Server on an OS 6900 or OS 6860 or OS 6860E or OS 6860N or OS 6865 or OS 6465 or OS 6560 device, select Host mode as client.
3. Save your changes.

   If you are configuring Wavence SM, go to Step 21 .

11

If you are configuring NTP Peer on an OS 6900 or OS 6860 or OS 6860E or OS 6860N or OS 6865 or OS 6465 or OS 6560 device, continue to Step 12. Otherwise, go to Step 13.

12

Configure an NTP peer:

1. Click on the Server tab and click Create. The NTP Server (Create) form opens. Select Host mode as active.
2. Save your changes.
3. Go to Step 14.

13

Configure an NTP peer:

1. Click on the Peer tab and click Create. The NTP Peer (Create) form opens.
2. Configure the required parameters.

   Note:

For 7705 SAR, NTP Version parameter supports version 2, version 3, and version 4 for IPv4 and only version 4 is supported for IPv6.

3. Save your changes.

14

If you are configuring NTP Broadcast on an OS 6900 or OS 6860 or OS 6860E or OS 6860N or OS 6865 or OS 6465 or OS 6560 device, continue to Step 15. Otherwise, go to Step 16.

15

Configure NTP broadcast:

1. Click on the Server tab and click Create. The NTP Server (Create) form opens. Select Host mode as broadcast.
2. Save your changes.
3. Go to Step 17.

16

Configure NTP broadcast:

1. Click on the Broadcast tab and click Create. The NTP Broadcast (Create) form opens.
2. Configure the Router Instance parameter.
3. Select a source interface.
4. Configure the required parameters.

   A warning message is displayed if the Direction parameter is set to transmit when the NTP Server parameter is not enabled in Step 6 .

   When the value of the Direction parameter is set to transmit, the Authentication Key Id, NTP Version, and Time to Live parameters are displayed.
5. Save your changes.

17

Configure NTP multicast:

1. Click on the Multicast tab and click Create. The NTP Multicast (Create) form opens.
2. Configure the required parameters.

   When the value of the Direction parameter is set to transmit, the Authentication Key Id and NTP Version parameters are displayed.
3. Save your changes.

18

Click on the Associations tab and perform the following to view the properties of the NTP associations, if required:

1. Click Search. A list of NTP-associated NEs appears.
2. Choose an NE and click Properties. The Network Time Protocol Associations (View) form opens. You can view information about the status and mode of the NTP server.

3. Close the form.

19

Click on the Clients tab and perform the following to view the properties of the NTP clients, if required:

1. Click Search. A list of NTP clients appears.
2. Choose an NTP client and click Properties. The Network Time Protocol Clients (View) form opens. You can view information about the status and mode of the NTP client.
3. Close the form.

20

Configure an NTP Disabled interfaces:

1. Click on the Disabled Interfaces tab and click Create. The NTP Disabled interfaces (New instance) (create) form opens.
2. Add IP Address.
3. Save your changes.

21

Save and close the forms.

END OF STEPS

15.35 To configure NTP on 1830 VWM OSU devices

15.35.1 NTP on 1830 VWM devices

The 1830 VWM OSU has three NTP servers and the RMUs (Remote Managed Units include TLUs and PMUs) have one NTP server. You can configure the NTP parameters only on the 1830 VWM OSU device. The parameters are read-only on the other 1830 VWM devices.

15.35.2 Steps

1

On the equipment tree, expand Network→1830 VWM OSU→1830 VWM OSU Shelf .

2

Right-click on the 1830 VWM OSU Shelf object and choose Properties. The Shelf (Edit) form opens.

3

Click on the NTP tab and configure the required parameters in the General sub-tab.

4

Click on the Server tab, choose an NTP server, and click Properties. The NTP Server (Edit) form opens.

5

Configure the IP Address parameter.

6

Save and close the forms.

END OF STEPS

15.36 To configure SCADA on a 7705 SAR

15.36.1 Purpose

Perform this procedure to configure SCADA on a 7705 SAR-8 or 7705 SAR-18, Release 6.1 R1 or later. To configure SCADA, an ISC must be installed in the daughter card slot. See 6.8 “7705 SAR” (p. 222) for more information about the ISC.

15.36.2 Steps

1

In the navigation tree equipment view, navigate to the shelf object on which you want to configure SCADA. The path is Network→*NE*→Shelf.

2

Right-click on the Shelf object and choose Properties. The Shelf (Edit) form opens.

3

Click on the SCADA tab.

4

Select one or more ports that you want to configure as a SCADA bridge, and click Properties. The SCADA Bridge - MDDB (Edit) form opens.

All of the ports have the bridge type as MDDB by default. If you want to configure PCM, you must change the MDA mode on the ISC. See 15.78 “To configure an MDA” (p. 536).

5

Perform one of the following:

a. If you set the MDA mode of the ISC to MDDB, configure the general parameters and parameters in the MDDB panel.

b. If you set the MDA mode of the ISC to PCM, configure the general parameters and

parameters in the PCM panel.

The Squelch Reset Timeout (seconds) parameter only appears if you set the Squelch Reset Mode parameter to Auto.

The Force Active Master parameter only appears if the Redundant Mode parameter is set to Manual.

Note: The MDA mode of the ISC can be configured for VCB. See 15.37 “To configure voice conference bridging on a 7705 SAR” (p. 496) for more information.

6

Configure SCADA branches. You can create up to 32 branches per bridge.

1. Click on the Branches tab.
2. Click Create. The SCADA Branch (Create) form opens.
3. Configure the required parameters.
4. Click OK and confirm to close the form.
5. Configure more SCADA branches, as required.

   You can add SCADA MDDB and PCM branches as SAPs on an L2 access interface on a VLL Cpipe or Epipe service site. See 76.40 “To create a VLL L2 access interface on a terminating site” (p. 2174) for more information.

7

Click OK to save the configuration.

8

To activate or deactivate a SCADA bridge, select one or more SCADA bridges listed on the Shelf (Edit) form.

a. Click Turn Up and confirm to activate the SCADA bridge.

b. Click Shut Down and confirm to deactivate the SCADA bridge.

9

Save and close the form.

END OF STEPS

15.37 To configure voice conference bridging on a 7705 SAR

15.37.1 Purpose

Perform this procedure to configure VCB on a 7705 SAR-8 or 7705 SAR-18. To support VCB, the NE must be configured with an ISC.

The VCB application provides a simultaneous communication path between two or more voice circuits. VCBs are deployed in a central location with remote devices connected to the bridge via an NE over an IP/MPLS or TDM network.

VCBs can be used as a conference bridge with any-to-any connectivity (all branches participate) or as a bridge in broadcast mode where one branch broadcasts to the other branches that are in listen-only mode.

VCB can be configured in one of four applications. These applications are set at the card level. Each application uses a bridging algorithm that determines which branches control the management of the bridge and transmission of signals:

- VCB — One branch talks and all other branches on the bridge can hear.
- Broadcast — Only one branch on the bridge (fixed as branch 1) has control of the bridge to transmit, and all other branches are in listen-only mode.
- VCB Branch Initiate — Branches on the bridge are only enabled (unmuted) when the attached base station signals its presence by grounding the M-lead on the interface connected to the bridge. Upon receiving the grounded M-lead via T1/E1 ABCD bits or TDM PW signaling, the bridge unmutes the associated branch. When the ground is removed, the branch is muted again.
- Teleprotection — Each teleprotection relay transmits state information on discrete frequencies so that each relay can both hear what the other relays are transmitting as well as transmit its own information to the other relays.

15.37.2 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

On the NE navigation tree, expand Shelf→Card Slot n.

3

Click the Daughter Card Slot with the Integrated Services card. The Daughter Card Slot form opens.

4

Click on the Daughter Card tab and configure the MDA Mode parameter as VCB.

5

Configure the VCB Application parameter. Choose one of the following options:

a. Broadcast

b. Tele-Protection

c. VCB

d. VCB Branch Initiate

6

In the Voice panel, configure the Companding Law and Signalling Type parameters. By default, the companding law is set to Mu-Law.

For information about which adapter cards support A-Law or Mu-Law, and which signalling types are configurable for each card, see the node documentation.

Note: Mu-Law encoding is used for North America, and provides up to 16 bridges per ISC, up to 24 branches per bridge, and up to 384 total branches per ISC. A-Law is used for the rest of the world. A-Law encoding provides up to 16 bridges per ISC, up to 32 branches per bridge, and up to 512 total branches per ISC.

7

Click OK and confirm the changes.

8

On the NE navigation tree, right-click on the Shelf and choose Properties. The Shelf (Edit) form opens.

9

Click on the SCADA tab.

10

Select one or more VCBs and set the Bridge Admin Status parameter to Up.

11

Click Turn Up.

12

Click on Properties. The SCADA Bridge - VCB form opens.

13

If you are configuring a VCB branch initiate, configure the VCB Idle Code and VCB Seized Code parameters as required.

14

Click on the Branches tab and click Create to create a SCADA branch. The SCADA Branch (Create) form opens

15

On the General tab of the SCADA branch, set the Administrative State parameter to Up, and configure the Description, Gain Input (dB) and Gain Output (dB) parameters.

16

Click OK and confirm the changes.

17

Configure more SCADA VCB branches as required. You can add SCADA VCB branches as SAPs on an L2 access interface on a VLL Epipe or Cpipe service site. See 76.40 “To create a VLL L2 access interface on a terminating site” (p. 2174) for more information.

END OF STEPS

15.38 To configure a 7705 SAR MW link

15.38.1 Purpose

Perform this procedure to configure a microwave link on a 7705 SAR-8 or 7705 SAR-18. To support an MW link, the NE must be configured with 4 × MWA Gig Ethernet (2 TX, 2 SFP) + 4 × Gig Ethernet SFP daughter cards. See 15.78 “To configure an MDA” (p. 536) for information about how to configure daughter cards.

Note: The NFM-P supports the creation of an MW link in 1+0 protection mode and 1+1 protection mode. You can only configure 1+1 protection on an NE in network mode.

15.38.2 Steps

1

In the navigation tree equipment view, choose Network→NE→*Shelf* where *Shelf* is the 7705 SAR shelf object on which you need to create an MW link.

2

Click on the shelf object to expand the tree view.

3

Right-click on the MW Links item and choose Create MW Link. The Create MW Link (Create) form opens, with the General tab displayed.

4

Configure the Description parameter, if required.

5

Click on the MW Link tab.

6

Configure the required parameters in the Hold Time panel.

7

Click on the States tab and configure the Administrative State parameter.

8

Click on the Protection tab and configure the Protection Scheme parameter.

If you choose the value One Plus One Hsb, the Protection form displays additional panels.

9

To configure 1+1 radio protection, configure the required parameters in the Equipment Protection Scheme, Radio Protection Scheme, and Transmission Protection Scheme panels.

10

Click OK. The MW Link (Create) form closes and the new MW link appears under the MW Links item in the navigation tree.

11

To modify the MW Link properties, right-click on the MW link and choose Properties. The MW Link (Edit) form appears with the General tab displayed.

12

Click on the MW Link tab and configure the required parameters in the Hold Time panel.

Note: The Peer IP Address parameter in the Peer Info panel is read-only and is displayed as follows:

- When a Wavence SA is in standalone mode, the Peer IP Address displays 0.0.0.0.
- When the Wavence SA is in single NE mode, the Peer IP Address displays the IP address of the other end Wavence SA if the other end of the radio link terminates on a Wavence SA in standalone mode.
- When the Wavence SA is in single NE mode, the Peer IP Address displays the IP address of the other end 7705 SAR if the other end of the radio link terminates on a Wavence SA in single NE mode.
- The Peer IP Address changes only when the 7705 SAR discovers a new peer after the radio link is operationally up between both Wavence SAs or when the 7705 SAR reboots.

13

Configure the Peer Discovery parameter in the Peer Discovery panel.

14

Click on the Statistics tab to view statistical information, if required.

15

Save and close the form.

END OF STEPS

15.39 To configure a 7705 SAR MW link member

15.39.1 Purpose

Perform this procedure to configure a 7705 SAR MW link member on the 7705 SAR-8 or 7705 SAR-18. To support an MW link and an MW link member, the NE must be configured with 4 × MWA Gig Ethernet (2 TX, 2 SFP) + 4 × Gig Ethernet SFP daughter cards. See 15.78 “To configure an MDA” (p. 536) for information about how to configure daughter cards.

If you configured 1+1 HSB protection in 15.38 “To configure a 7705 SAR MW link” (p. 499) , you can configure a main radio and a spare radio for each MW link. By default, the main radio assumes the active status and the spare radio assumes the standby status.

If you configured 1+1 HSB protection and you want to revert back to 1+0 protection, you must delete the spare radio. You cannot delete the main radio.

1+1 HSB protection is displayed on the NFM-P physical topology map. The protection state is shown on the links, and 1+1 links are grouped in a common link group. The expansion of links on the physical map displays eight links. See 4.1 “Topology map types” (p. 169) for more information about the NFM-P physical topology maps.

15.39.2 Steps

1

Choose Network→NE→Shelf→Card Slot n→Daughter Card Slot n→Port n/n/n where the port object is the port that you need to use for the MW link.

Note: Only the first four ports on the MDA are microwave-aware.
If a port is associated with an MW link, the port cannot be used as a timing reference. Also, if a port is already being used as a timing reference, the port cannot be associated with an MW link member.

2

Right-click on a port and choose Properties. The Physical Port (Edit) form opens.

3

Configure the Encapsulation Type parameter to be Dot1 Q.

4

Configure the Mode parameter.

Note: Setting the Mode parameter to Access allows you to later associate the MW link with an L2 or L3 access interface for services. Setting the Mode parameter to Access is the typical setting. Setting the parameter to Network allows you to associate the MW link with a network interface.
1+1 HSB radio protection can only be configured on a port in Network mode.

5

Click OK and confirm to close the form.

6

Create an MW link member:

a. If you configured 1+0 radio protection in 15.38 “To configure a 7705 SAR MW link” (p. 499) , right-click on the MW link you created and choose Create MW Link Member. The Create MW Link Member step form opens.

b. If you configured 1+1 HSB radio protection in 15.38 “To configure a 7705 SAR MW link” (p. 499) , right-click on the MW link you created and choose Create MW Link Main Radio. The Create MW Link Member step form opens.

7

Configure the required parameters on the Specify the Member Properties form.

The Database Filename parameter must be the same name as the database file in the config file of the cflash directory and must be in a *.tar format.

8

Click Next. The Select Ports form opens.

9

Choose the port from the list and click Finish. Only eligible ports are displayed in the list and only one port per link is supported.

To configure a main radio, you must choose a port in an odd numbered slot.

10

Select the View the newly created Port Termination check box if you need to view the MW link member properties, and click Close.

11

To configure a spare radio, right-click on the MW link where you created the main radio, and choose Create MW Link Spare Radio. Repeat Step 7 to Step 10 .

To configure a spare radio, you must choose a port in an even numbered slot.

12

Click on the Radio tab. The tab displays information about MPT hardware and the software state of the connected radio. You can enable PM statistics for G.826, ACM, and Power. Enable the checkboxes as required.

13

Associate the MW link with an L2/L3 access interface or a network interface, if required.

1. If you set the MW Link Member port Mode to Access in Step 4 , you can associate the MW link with a service, if required.

   The MW links can be used in the L2 Access Interfaces of the following service types:
   - VLL Epipe (see 76.40 “To create a VLL L2 access interface on a terminating site” (p. 2174))
   - VLL Ipipe (see 76.40 “To create a VLL L2 access interface on a terminating site” (p. 2174))
   - VPLS (see 77.67 “To create a VPLS or MVPLS L2 access interface” (p. 2332))
   - MVPLS (see 77.67 “To create a VPLS or MVPLS L2 access interface” (p. 2332))

   The MW links can also be used in the L3 Access Interfaces of the following service types:
   - VPRN (see 79.83 “To configure an L3 access interface on a VPRN site” (p. 2656))
   - IES (see 78.28 “To configure an L3 access interface on an IES site” (p. 2472))

   The created access interface appears in the list on the L2 Access Interface or L3 Access Interface tab of the MW Link (Edit) form, as appropriate.

   See the specific service chapter and forms when you create the required L2 or L3 access interfaces. Specify the MW Link Member as the Terminating Port.
2. If you set the MW Link Member port Mode setting to Network in Step 4 , the Network Interface tab is displayed. Click on the tab and then the Create button to create a network interface. The network interface that you create appears in the list. See 27.17 “To create an L3 network interface on a routing instance” (p. 856) for more information.

14

Click on the Statistics tab to view radio analog statistical information, if required.

15

Click on the Faults tab to view alarm information, if required.

16

To modify the MW Link Member properties, right-click on the MW link member and choose Properties. The MW Link Member (Edit) form appears with the General tab displayed.

17

Configure the required parameters.

18

Save and close the form.

END OF STEPS

15.40 To configure 7705 SAR auxiliary alarm definitions

15.40.1 Purpose

Perform this procedure to configure auxiliary alarm definitions for the auxiliary alarms daughter card on a 7705 SAR.

15.40.2 Steps

1

In the navigation tree equipment view, navigate to the shelf object on which you want to configure auxiliary alarm definitions. The path is Network→*NE*→Shelf.

2

Right-click on the Shelf object and choose Properties. The Shelf (Edit) form opens.

3

Click on the External Alarms tab.

4

As required, configure auxiliary alarm digital inputs.

1. Click on the Auxiliary Alarm Digital Inputs tab.
2. Select a digital input from the list and click Properties. The Auxiliary Alarm Digital (Edit) form opens.
3. Configure the required parameters.
4. Click OK. The Auxiliary Alarm Digital (Edit) form closes.
5. Repeat 1 to 4 to configure more auxiliary alarm digital inputs, as required.

5

As required, configure auxiliary alarm port inputs.

1. Click on the Auxiliary Alarm Port Inputs tab.
2. Click Create. The Auxiliary Alarm Ports (Create) form opens.
3. Click Select beside the CLI Name parameter and select a port reference. Only Ethernet ports can be selected.
4. Configure the required parameters.
5. Click OK and confirm to close the form.
6. Repeat 1 to 5 to configure more auxiliary alarm port inputs, as required.

6

Click on the Auxiliary Alarm Definitions tab on the Shelf (Edit) form.

7

Click Create. The Auxiliary Alarm Definition (Create) form opens.

8

Configure the required parameters.

9

Click on the Inputs tab and configure the required parameters.

10

Click on the Outputs tab and configure the required parameters.

11

Save and close the forms.

END OF STEPS

15.41 To manage an OmniSwitch running configuration

CAUTION

Service Disruption

When you reboot an OmniSwitch that is in service, it is service-affecting.

Ensure that the reboot activity occurs during a maintenance window.

15.41.1 Steps

1

In the navigation tree equipment view, expand the OmniSwitch object.

2

Right-click on a device and choose Properties. The Network Element (Edit) form opens.

3

Click on a shelf object. The Shelf (Edit) form opens.

4

Click on the Software Control Module tab.

5

Configure the Command to Apply parameter.

a. If you specify Copy certified to working, configure the Active Timeout parameter.

b. If you specify Reload from working, configure the Delayed Activation Timer parameter.

6

Save and close the form.

END OF STEPS

15.42 To configure OmniSwitch health monitoring

15.42.1 Before you begin

The health monitoring function monitors the consumable resources, such as bandwidth and CPU usage of the OmniSwitch at fixed intervals and collects the current values for each resource being monitored. You can specify the resource threshold limits. If a resource value is greater or less than the threshold, traps are sent to the NFM-P.

15.42.2 Steps

1

On the equipment tree, right-click on the OmniSwitch device for which you want to configure health monitoring and choose Properties. The Network Element (Edit) form opens.

2

On the Network Element (Edit) form navigation tree, click on a shelf object. The Shelf (Edit) form opens.

3

Click on the Health Monitoring tab and configure the required parameters.

4

Click on the Statistics tab and search for Card Health Stats (Physical Equipment) or Device Health Stats (Physical Equipment) to view card statistics or chassis statistics. Statistics can also be viewed from the card-level statistics tab.

5

Click on the Faults tab to view alarm information.

6

Save your changes and close the forms.

END OF STEPS

15.43 To configure a CCM on a 7950 XRS-20

15.43.1 Steps

1

On the equipment tree, right-click on the 7950 XRS-20 device for which you want to configure CCM properties and choose Properties. The Network Element (Edit) form opens.

2

On the Network Element (Edit) form navigation tree, expand the Shelf object.

3

Right-click on a CCM object and choose Properties. The CCM (Edit) form opens.

Alternatively, you can open a CCM properties form by right-clicking on the associated CPM object and choosing View CCM from the contextual menu.

4

To configure a flash memory module:

1. Click on the Flash Memory Modules tab.
2. Select a flash memory module in the list and click Properties. The Flash Memory (Edit) form opens.
3. Configure the Administrative State parameter.
4. Save your changes and close the form.

5

On the CCM Shelf (Edit) form, click View CPM to open the properties form of the associated CPM.

See 15.74 “To configure a CPM” (p. 531) for more information about the CPM properties form.

6

Close the forms.

END OF STEPS

15.44 To manage the internal fan on a 7210 SAS-D

15.44.1 Purpose

Perform this procedure to change the administration mode and view the fan operational state for the 7210 SAS-D 128 Mbyte variant.

15.44.2 Steps

1

On the equipment tree, expand Network→*NE*→Shelf→Fans→Fan Tray.

2

Right-click on Fan Tray and choose Properties. The Fan Tray (Edit) form opens.

3

Click on the Fans tab. A list form opens.

4

Choose a fan from the list. The Fan (Edit) form opens.

5

Configure the Admin Mode parameter. The operational state of the fan (On or Off) is displayed in the Oper Mode field.

6

Save your changes and close the forms.

END OF STEPS

15.45 To enable fan speed monitoring on a 7x50 device

15.45.1 Steps

1

On the equipment tree, expand Network→*NE*→Shelf→Fans→Fan Tray.

2

Right-click on Fan Tray and choose Properties. The Fan Tray (Edit) form opens.

3

Enable the Monitor Fan Speed parameter.

4

Save your changes and close the form.

TCA and MIB statistics are created.

Alarms will be generated if fan speed exceeds threshold limits (Minor - 75%, Major - 80%, Critical - 100%).

End of steps

15.46 To configure a power supply tray

15.46.1 Steps

1

On the equipment tree, expand Network→*NE*→Shelf→Power Supplies→Power Supply Tray.

2

Right-click on a power supply tray and choose Properties. The Power Supply Tray (Edit) form opens.

3

Configure the required parameters.

4

Configure the Power Supply Type parameter from the drop-down menu.

Note: If you are configuring for OS 6465-P6 and OS 6465-P12, depending on the power supply unit type (Third Party, ALE, or Phoenix Contact) the form displays different options. Select one of the following, as appropriate:

- Third Party - The Power (Watts) ranges from 50W to 200W.
- ALE - Select the Power Supply Input Type parameter from the drop-down menu. The default values for Power (Watts) are LO-AC = 75W, HI-AC = 240W, 24VDC = 240W, and 48VDC = 240W.
- Phoenix Contact - Select the Power Supply Input Type parameter from the drop-down menu. The default values for Power (Watts) are 24VDC = 240W, 48VDC = 240W.

5

Save your changes and close the form.

End of steps

15.47 To configure a power management zone

15.47.1 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Power Management Zones tab. A list of power management zones is displayed.

3

Select a power management zone and click Properties. The Power Management Zone (Edit) form opens.

4

Configure the power management parameters.

5

Click on the Utilization and Requirements tab to view information about power usage in the power management zone. Click on the ellipsis button (...) for detailed information about each entry.

6

Save your changes and close the forms.

END OF STEPS

15.48 To configure a PCM tray

15.48.1 Steps

1

On the equipment tree, expand Network→*NE*→Shelf→Power Connection Modules→PCM Tray.

2

Configure one or more PCM trays.

a. To configure one PCM tray, right-click on a PCM tray and choose Configure PCM. The PCM Tray (Edit) form opens.

b. To configure multiple PCM trays in bulk, right-click on empty PCM tray slots and choose Configure PCM. The PCM Tray (Multiple Instances) (Edit) form opens.

3

Configure the required parameters.

4

Save your changes and close the form.

END OF STEPS

15.49 To provision an APEQ

15.49.1 Steps

1

On the equipment tree, expand Network→*NE*→Shelf→Power Supplies→Power Supply Tray.

2

Right-click on a power supply tray and choose Configure PEQ. The Power Supply Tray (Create) form opens with the General tab displayed.

3

Configure the required parameters.

4

Save your changes and close the form.

END OF STEPS

15.50 To configure a variable power supply APEQ

15.50.1 Steps

1

On the equipment tree, expand Network→*NE*→Shelf→Power Supplies→Power Supply Tray.

2

Right-click on a power supply tray and choose Properties. The Power Supply Tray form opens with the General tab displayed.

3

Click on the Power Supply tab and configure the Input Power Mode in the Power Details panel.

4

Save your changes and close the form.

END OF STEPS

15.51 To restart an 1830 VWM shelf

15.51.1 Before you begin

Ensure that the:

- 1830 VWM device is managed by the NFM-P.
- value of the Connection State parameter in the Shelf Specifics tab of the Shelf (Edit) form is Connected for all of the 1830 VWM devices except 1830 VWM OSU.

15.51.2 Steps

NOTICE

Service affecting

Cold restart is service-affecting.

Ensure that you perform cold restart only during a scheduled maintenance period.

1

On the equipment tree, expand Network→1830 VWM.

2

Right-click on the Shelf object and click Properties. The Shelf (Edit) form opens.

3

Click on the Shelf Specifics tab and configure the parameters in the Shelf Restart panel.

4

Save your changes and close the form.

END OF STEPS

15.52 To configure optical protection switching on an 1830 VWM OPS shelf

15.52.1 Steps

1

On the equipment tree, expand Network→1830 VWM OSU→1830 VWM OPS shelf.

2

Right-click on the OPS OSM card slot object and choose Properties. The Card Slot (Edit) form opens.

3

Click on the Card Specifics tab, then on the Protection Switch Management tab, and configure the Switch Command parameter.

Note: The OPS shelf supports the following external switch commands:

- Clear - clears all current external switch requests
- Forced Switch to Worker
- Forced Switch to Protection

4

Configure the remaining parameters.

5

Save your changes and close the form.

END OF STEPS

15.53 To configure bi-directional protection switching on an 1830 VWM OPS shelf

15.53.1 Steps

1

Configure an OPS OSM-DSV card on an 1830 VWM OPS shelf:

1. On the equipment tree, expand Network→*NE*→Shelf→Card Slot *n*.
2. Assign the OPS OSM-DSV card, see 15.56 “To assign a card type” (p. 517).
3. On the Card Slot (Edit) form, click on the Card Specifics tab and configure the Assigned Status parameter as Assigned.
4. Click Apply and confirm your actions.

5. Configure the required parameters in the OPS OSM-DSV Specifics panel.
6. Save your changes and close the form.

2

Configure bi-directional protection switching for the PSE-R:

1. On the equipment tree, right-click on the 1830 VWM-OSU NE and choose Properties. The NE (Edit) form opens.
2. Click on the PSE-R PMU-D group tab and click Create. The PSE-R PMU-D group (Create) form opens.
3. Configure the PMUD Group parameter.
4. Select one to four PMUD in the PMUD panels.
5. Click on the OPS PSE-R tab and click Create. The OPS PSE-R (Create) form opens.
6. Configure the required parameters.

   Note: You must select a PMUD Group.
7. Click Apply. The OPS OSM PSE-R (Edit) form appears with the OPS OSM PSE-R protection switch management tab.
8. Configure the Activate parameter as True and configure the required parameters, if applicable.
9. Click Apply and confirm you actions.

3

Configure bi-directional protection switching for the PSE-L:

1. Click on the OPS PSE-L tab and click Create. The OPS PSE-L (Create) form opens.
2. Configure the Description parameter.
3. Select an OPS OSM-DSV card for the Slot parameter.
4. In the Worker Loop Monitor Interface panel, configure the port as OSC1.
5. In the Protection Loop Monitor Interface, configure the port as OSC2.
6. Click Apply. The OPS OSM PSE-L (Edit) form appears with the OPS OSM PSE-L protection switch management tab.
7. Configure the Activate parameter as True and configure the required parameters, if applicable.
8. Click Apply and confirm your actions.

4

Save your changes and close the forms.

END OF STEPS

15.54 To configure an OPS protection audit entity on an 1830 VWM OSU shelf

15.54.1 Steps

1

On the equipment tree, expand Network.

2

Right-click on the 1830 VWM OSU object and choose Properties. The Network Element (Edit) form opens.

3

Click on the OPS Protection Audit Entity tab and click Create. The OPS Protection Audit Entity (Create) form opens.

4

Choose the near-end and far-end 1830 VWM OPS OSM cards in Slot A and Slot Z. The shelf and card details are populated automatically.

5

Configure the remaining parameters.

6

Save your changes and close the forms.

END OF STEPS

15.55 To activate or deactivate a PAE

15.55.1 Steps

1

Configure a PAE. See 15.54 “To configure an OPS protection audit entity on an 1830 VWM OSU shelf” (p. 515).

2

On the equipment tree, expand Network.

3

Right-click on the 1830 VWM OSU object and choose Properties. The Network Element (Edit) form opens.

4

Click on the OPS Protection Audit Entity tab, choose an entry, and click Properties. The OPS Protection Audit Entity (Edit) form opens.

5

Set the Activate Parameter to True or False depending on whether you need to activate or deactivate the PAE.

6

Save your changes and close the forms.

END OF STEPS

Procedures for card and card slot object configuration

15.56 To assign a card type

15.56.1 Purpose

Perform this procedure to assign a card type to an empty card slot or SFM slot.

The available configurations vary depending on the device; not all NEs support all configurations.

15.56.2 Steps

1

On the equipment tree, right-click on the device where you want to assign a card type and choose Properties. The Network Element (Edit) form opens.

2

On the Network Element (Edit) form navigation tree, expand the Shelf object.

3

Right-click on an empty Card Slot object or SFM Slot object and choose Configure Card. The Card Slot (Create) or SFM Slot (Create) form opens.

4

Configure the required parameters.

Note: The correct chassis mode must be configured for the assigned card types. The chassis mode determines the behavior of the card and establishes the scaling limits and available features. See 15.13 “To configure the device chassis mode” (p. 471) and 15.19 “To enable mixed mode” (p. 476) for more information.

5

Configure the required parameters in the Virtual Scheduler panel.

6

Save your changes and close the form.

The card and slot appear in the navigation tree and in the equipment inventory list.

END OF STEPS

15.57 To configure an Xiom-s card slot

15.57.1 Purpose

Perform this procedure to configure an Xiom-s card slot on a 7750 SR-s series NE. Each Xiom-s supports up to two MDA-s.

Xiom-s card slots are indicated in the equipment tree using the index of ‘x1’ or ‘x2’. The MDA-s in an Xiom-s uses an index ‘x1/1’, ‘x1/2’, ‘x2/1’, or ‘x2/2’ reflecting the fact that these are contained in Xiom-s ‘x1’ or ‘x2’.

15.57.2 Steps

1

On the equipment tree, expand Network→*NE*→Shelf→Card Slot.

2

Perform one of the following:

a. To configure a new Xiom-s, right-click on the Xiom Card Slot object and choose Configure Card. The Xiom Card Slot (Create) form opens.

b. To modify an existing Xiom-s, right-click on the Xiom Card Slot object and choose Properties. The Xiom Card Slot (Edit) form opens.

3

Configure the required parameters.

4

Save your changes and close the form.

END OF STEPS

15.58 To assign a network queue policy to a forwarding plane

15.58.1 Before you begin

Perform this procedure to assign network queue policies to forwarding planes on 7450 ESS, 7750 SR, and 7950 XRS NEs.

15.58.2 Steps

1

On the equipment tree, expand Network→*NE*→Shelf→Card Slot *n*.

2

Right-click on the Card Slot object and choose Properties. The Card Slot form opens.

3

Click on the Forwarding Plane tab, choose an entry in the list, and click Properties. The Forwarding Plane form opens.

4

On the General tab, select a network queue policy in the Network Queue Policy panel.

5

Save your changes and close the forms.

END OF STEPS

15.59 To assign an FP Resource policy to a forwarding plane

15.59.1 Before you begin

Forwarding Plane Resource policies allow custom allocation of card slot resources to queues. See 50.72 “To configure an FP Resource policy” (p. 1615).

15.59.2 Steps

1

On the equipment tree, expand Network→*NE*→Shelf→Card Slot *n*.

2

Right-click on the Card Slot object and choose Properties. The Card Slot form opens.

3

Click on the Forwarding Plane tab, choose an entry in the list, and click Properties. The Forwarding Plane form opens.

4

On the General tab, select an FP Resource policy in the FP Resource Policy panel.

The FP Resource Policy panel is available only when FP Resource policies are supported on the NE.

5

Save your changes and close the forms.

END OF STEPS

15.60 To configure a network ingress pool on a forwarding plane

15.60.1 Before you begin

Perform this procedure to configure network ingress pools on forwarding planes on 7450 ESS, 7750 SR, and 7950 XRS NEs.

15.60.2 Steps

1

On the equipment tree, expand Network→*NE*→Shelf→Card Slot *n*.

2

Right-click on the Card Slot object and choose Properties. The Card Slot form opens.

3

Click on the Forwarding Plane tab, choose an entry in the list, and click Properties. The Forwarding Plane form opens.

4

Click on the QoS Pool tab, choose a network ingress pool in the list, and click Properties. The QoS Pool form opens.

5

Configure the required general parameters.

6

Save your changes and close the forms.

END OF STEPS

15.61 To view the operational MC path management properties of a forwarding plane

15.61.1 Before you begin

MC path management properties are not configurable. However, you can perform this procedure to view the default operational MC path management properties of forwarding planes on 7450 ESS, 7750 SR, and 7950 XRS NEs.

15.61.2 Steps

1

On the equipment tree, expand Network→*NE*→Shelf→Card Slot *n*.

2

Right-click on the Card Slot object and choose Properties. The Card Slot form opens.

3

Click on the Forwarding Plane tab, choose an entry in the list, and click Properties. The Forwarding Plane form opens.

4

Click on the QoS Pool tab, choose an MC path management pool in the list, and click Properties. The QoS Pool form opens.

5

View the default settings. MC path management properties are not configurable.

6

Save your changes and close the forms.

END OF STEPS

15.62 To configure egress WRED queue control on an XCM, IOM 3 or IMM forwarding plane

Note: You cannot configure a forwarding plane on an XCM card until you have provisioned the corresponding XMA card.

15.62.1 Steps

1

On the equipment tree, expand Network→*NE*→Shelf→Card Slot *n*.

2

Right-click on the Card Slot object and choose Properties. The Card Slot (Edit) form opens.

3

Click on the Forwarding Plane tab.

4

Choose an entry in the list and click Properties. The Forwarding Plane (Edit) form opens.

5

Configure the required parameters in the Egress WRED Queue Control panel.

6

Select a slope policy for the forwarding plane.

7

Save your changes and close the forms.

END OF STEPS

15.63 To configure ingress policy accounting policer limits on a forwarding plane

15.63.1 Steps

1

On the equipment tree, expand Network→*NE*→Shelf→Card Slot *n*.

2

Right-click on the Card Slot object and choose Properties. The Card Slot form opens.

3

Click on the Forwarding Plane tab, choose an entry in the list, and click Properties. The Forwarding Plane form opens.

4

On the General tab, configure the Policer Limit parameter (under Ingress Policy Accounting).

The value for the Policer Limit parameter must not exceed the value configured for the Stats Pool limit parameter (under Policy Accounting).

5

Save your changes and close the forms.

END OF STEPS

15.64 To configure IMPM on an XCM, 2 x XP MDA IOM 3, or IMM forwarding plane

Note: See 15.79 “To configure IMPM on an MDA” (p. 539) for information about configuring IMPM on an MDA that is not installed in an XCM, 2 × XP MDA IOM 3, or in an IMM.

You cannot configure a forwarding plane on an XCM card until you have provisioned the corresponding XMA card.

15.64.1 Steps

1

On the equipment tree, expand Network→*NE*→Shelf→Card Slot *n*.

2

Right-click on the Card Slot object and choose Properties. The Card Slot (Edit) form opens.

3

Click on the Forwarding Plane tab.

4

Choose an entry in the list and click Properties. The Forwarding Plane (Edit) form opens.

5

Click Clear in the Ingress Multicast Path Management panel to remove the selected BW policy. The Select button is enabled.

6

Select a BW policy.

7

Configure the Administrative State parameter.

8

Configure the required bandwidth parameters.

9

Save your changes and close the forms.

END OF STEPS

15.65 To configure an ingress queue group on a forwarding plane

Note: You can configure ingress queue groups only on the forwarding planes of XCM, IOM3, and IMM cards.

You cannot configure a forwarding plane on an XCM card until you have provisioned the corresponding XMA card.

15.65.1 Steps

1

On the equipment tree, expand Network→*NE*→Shelf→Card Slot *n*.

2

Right-click on the Card Slot object and choose Properties. The Card Slot (Edit) form opens.

3

Click on the Forwarding Plane tab.

4

Choose an entry in the list and click Properties. The Forwarding Plane (Edit) form opens with the General tab displayed.

5

Perform one of the following:

a. Click on the Access Ingress Queue Group tab.

b. Click on the Network Ingress Queue Group tab.

6

Click Create. The Forwarding Plane Access|Ingress Queue Group (Create) form opens.

7

Select a Queue Group Template Policy in the Queue Group Instance panel.

Note: If you select a policy that contains queues, a configuration error message appears when you try to apply the changes.

8

Configure the Instance ID and Description parameters.

9

Select an Accounting Policy in the Accounting Policy panel.

Note: Only accounting policies with Queue Group Packets as record type are supported. You can also choose to create an accounting policy from this form by clicking the Create button instead of the Search button. See 87.37 “To configure an AA accounting policy” (p. 2849) for information on creating an accounting policy and the *NSP NFM-P Statistics Management Guide* for general information about configuring and collecting accounting statistics.

10

Configure the Collect Accounting Statistics parameter.

11

Select a Policer Control Policy in the Policer Control Policy panel.

12

Click Create in the Ingress Policer Control Override panel. The Ingress Policer Control Override (Create) form opens, with the General tab displayed.

13

Configure the required parameters and save your changes.

14

Click on the Level Override Policy Items tab.

15

Select an item from the list and click OK. The FP Ingress Policer Level Override form opens, with the General tab displayed.

16

Click on the Override tab and configure the Maximum Cumulative Buffer Space (bytes) parameter.

17

Save your changes.

18

Click on the Override Policy Items tab and click Create. The Forwarding Plane Ingress Queue Group Policer Override (Create) form opens.

19

Select a policer.

20

Click on the Override tab and configure the required parameters in the Overridden Queue Group Template Policer panel.

The parameters are configurable when the associated override check box is enabled.

21

Save your changes and close the forms.

END OF STEPS

15.66 To configure NE DDoS protection on a forwarding plane

15.66.1 Purpose

Perform this procedure to configure the maximum number of enforcement policers for a DDoS protection configuration on a forwarding plane. See the section on DDoS protection in the *NSP*

System Administrator Guide for more information.

Note: You cannot configure a forwarding plane on an XCM card until you have provisioned the corresponding XMA card.

15.66.2 Steps

1

On the equipment tree, expand Network→*NE*→Shelf→Card Slot *n*.

2

Right-click on the Card Slot object and choose Properties. The Card Slot form opens.

3

Click on the Forwarding Plane tab, choose an entry in the list, and click Properties. The Forwarding Plane form opens.

4

Configure the NE DDoS Protection - Dynamic Enforcement Policer Pool Size parameter. Enable the Default check box to specify a default value.

5

Save your changes and close the forms.

END OF STEPS

15.67 To enable named pool mode

15.67.1 Purpose

Perform this procedure to allow named pools to be created for an MDA. Set the Pool Mode parameter when you are configuring the card. Enabling the Named Pool mode is mutually exclusive with enabling Stable Pool sizing.

CAUTION

Service Disruption

The Pool Mode parameter can be enabled and disabled at anytime, however changing the pool mode resets the IOM when MDAs are provisioned on the slot.

If MDAs are not provisioned the IOM is not reset.

15.67.2 Steps

1

On the equipment tree, expand Network→*NE*→Shelf→Card Slot *n*.

2

Right-click on the Card Slot object and choose Properties. The Card Slot form opens.

3

Click on the IO Card tab and configure the Pool Mode parameter.

4

Click OK and confirm your actions. The form closes.

END OF STEPS

15.68 To enable Stable Pool Sizing

15.68.1 Purpose

Perform this procedure to enable an even split of buffering amongst all possible MDAs.

When Stable Pool sizing is enabled, then for each MDA, the buffering is split between all ports based on the port maximum bandwidth and adjusted by the port's modify buffer allocation rate percentages. You cannot enable Stable Pool Sizing on any forwarding plane on a card while the card is either administratively or operationally in Named Pool mode.

15.68.2 Steps

1

On the equipment tree, expand Network→*NE*→Shelf→Card Slot *n*.

2

Right-click on the Card Slot object and choose Properties. The Card Slot form opens.

3

Click on the Forwarding Plane tab, select a forwarding plane, and click Properties. The Forwarding Plane form opens.

4

Configure the Stable Pool Sizing parameter and click OK. The form closes.

5

Save your changes and close the forms.

END OF STEPS

15.69 To enable Ingress Buffer Allocation

15.69.1 Purpose

Perform this procedure to enable the allocation of an ingress buffer percentage on a given forwarding plane. The allocation you specify will be set aside for use only by the ingress pools.

15.69.2 Steps

1

On the equipment tree, expand Network→*NE*→Shelf→Card Slot *n*.

2

Right-click on the Card Slot object and choose Properties. The Card Slot form opens.

3

Click on the Forwarding Plane tab, select a forwarding plane, and click Properties. The Forwarding Plane form opens.

4

Configure the Ingress Buffer Allocation (%) parameter and click OK. The form closes.

5

Save your changes and close the forms.

END OF STEPS

15.70 To initialize drop priority mode on card forwarding plane

15.70.1 Purpose

Perform this procedure to initialize the drop priority mode on card forwarding plane.

15.70.2 Steps

1

On the equipment tree, expand Network→*NE*→Shelf→Card Slot *n*.

2

Right-click on the Card Slot object and choose Properties. The Card Slot form opens.

3

Click on the Forwarding Plane tab, select a forwarding plane, and click Properties. The Forwarding Plane form opens.

4

Configure the Initialize drop priority mode parameter, save your changes and close the form.

5

Save your changes and close the forms.

END OF STEPS

15.71 To select system resource profile policies for the 7210 SAS-R or 7210 SAS-S/Sx VC

15.71.1 Purpose

For the 7210 SAS-R or 7210 SAS-S/Sx VC, system resource allocations are configured in a system resource profile policy. See 12.51 “To configure a system resource profile policy for the 7210 SAS-R/T/Mxp, 7210 SAS-S/Sx, or 7210 SAS-S/Sx VC” (p. 382) .

Perform the following procedure to assign a policy to the card slot of a 7210 SAS-R or 7210 SAS-S/Sx VC. You must distribute the policy to the device first.

Note: When the policy is assigned to a card slot and the SAP Aggregate Meter parameter is modified, you must reboot the card or the node for the modified value to take effect.

15.71.2 Steps

1

On the equipment tree, expand Network→7210 SAS-R or 7210 SAS-S/Sx VC→Shelf→Card Slot *n*.

2

Right-click on the card slot object and choose Properties. The Card Slot form opens.

3

Click on the IO Card tab and select a policy in the System Resource Profile Policy panel.

4

To view the currently effective resource profile for the card slot, click on the Active Resource Profile tab.

5

Click OK and confirm your changes. The form closes.

END OF STEPS

15.72 To configure OmniSwitch stacks

15.72.1 Steps

1

On the equipment tree, expand Network→OmniSwitch object.

2

Right-click on the OmniSwitch object and choose Properties. The Network Element form opens.

3

On the Network Element tree, expand the Shelf object.

4

Click on a slot object. The Card Slot form opens.

5

Click on the Stack Configuration tab and configure the required parameters.

6

Save your changes and close the forms.

END OF STEPS

15.73 To configure an OmniSwitch CPU temperature threshold

15.73.1 Steps

1

On the equipment tree, expand Network→OmniSwitch object.

2

Right-click on the OmniSwitch object and choose Properties. The Network Element form opens.

3

On the Network Element tree, expand the Shelf object.

4

Click on a slot object. The Card Slot form opens.

5

Click on the Hardware Environment tab and configure the Temperature Threshold (Celsius) parameter.

6

Save your changes and close the forms.

END OF STEPS

15.74 To configure a CPM

15.74.1 Purpose

Perform this procedure to configure CPM, CPM-s, CPM2, or CPM2-s objects.

15.74.2 Steps

1

On the equipment tree, right-click on the NE and choose Properties. The Network Element form opens.

2

On the Network Element tree, expand the Shelf object.

3

Right-click on Card Slot A or Card Slot B and choose Properties. The Card Slot form opens.

Alternatively, for the 7950 XRS, you can open a CPM Card Slot properties form by right-clicking on the associated CCM object and choosing View CPM from the contextual menu.

Note: Card Slot A and Card Slot B are automatically configured with CPMs. The CPMs cannot be removed, and they cannot be configured in any other card slot.

4

Configure the required parameters.

5

If the Flash Memory Module tab is available, you can perform the following steps. Depending on the device, only certain flash memory modules may be supported.

1. Click on the Flash Memory Modules tab, select a flash memory module, and click Properties. The Flash Memory form opens.
2. Configure the Administrative State parameter and click OK. The form closes.

Note:

You can configure flash memory modules on the 7950 XRS-20 from the CCM properties form. See 15.43 “To configure a CCM on a 7950 XRS-20” (p. 507) for more information.

6

If you are configuring a CPM on a 7950 XRS-20, the View CCM button is available. If required, click View CCM to open the properties form of the associated CCM.

See 15.43 “To configure a CCM on a 7950 XRS-20” (p. 507) for more information about the CCM properties form.

7

Save your changes and close the forms.

END OF STEPS

15.75 To configure a CPRI rate and channel management for a CDR channel on an 1830 VWM TLU or ITP card slot

15.75.1 Steps

1

On the equipment tree, expand Network→1830–VWM-OSU NE→1830–VWM-TLU shelf→Card Slot 1 TLU or Card Slot 1 ITP.

2

Right-click on the Card Slot 1 TLU or Card Slot 1 ITP object and choose Properties. The Card Slot (Edit) form opens.

3

Choose a CDR channel interface and click Properties. The CDR Channel (Edit) form opens.

4

Configure the CDR Channel Rate parameter.

5

Configure the CDR Channel Used For Mgmt parameter. The parameter is set to Disabled by default.

When the CDR Channel Used For Mgmt parameter is set to Enabled, the following configurations changes appear:

- The CDR Channel Rate parameter is set to 1 GBE.
- The port Administrative State parameter is set to UP.

- The LOS Propagation Mode parameter is set to Laser off.

Editing of the following parameters is not supported:

- Administrative State
- AINS mode
- Loopback, PRBS and monitoring settings
- CDR Channel Rate
- DWDM frequency

6

Save your changes and close the forms.

END OF STEPS

15.76 To modify the SFP profile and SFP profile rate on the 1830 VWM

15.76.1 Purpose

Perform this procedure to modify SFP profile or SFP profile rate associated with the CDR channel on the 1830 VWM TLU–9, 9M, and ITP devices.

15.76.2 Steps

1

Perform one of the following:

a. From the device:
   1. On the equipment tree, right-click on the 1830 VWM device object and choose Properties. The Network Element (Edit) form opens.
   2. Click on the SFP Profiles tab. A list of 32 default SFP profiles are displayed.
   3. Double-click on the SFP profile. The VWM SFP Profiles window opens with the General tab displayed.

      If required, edit the SFP Profile Name.

b. From the shelf:
   1. On the equipment tree, expand Network→1830 VWM.
   2. Right-click on the shelf object and choose Properties. The Shelf (Edit) form opens.
   3. Click on the Shelf Specifics tab.
   4. Go to Shelf SFP Profile section.

      If required, edit the SFP Profile Name. By default, Profile1 is assigned.
   5. Click Select. A list of 32 default SFP profiles are displayed.

2

Click on the SFP Profiles Rates tab to display the list of supported SFP rates.

3

Double-click on the selected SFP profile rate. The VWM SFP Profile Rate window opens.

4

Configure the SFP Profile Rate parameter from the drop-down menu..

5

Save your changes and close the form.

END OF STEPS

15.77 To upgrade a license path on an IOM-1, IOM5-e, and XIOM-s

15.77.1 Purpose

Perform this procedure to upgrade the license-level for IOM-1 or IOM5-e on 7750 SR platforms, Release 16.0 R4 and later, and for XIOM-s on 7750 SR-s platforms, Release 20.2 R1 and later.

Before you perform a license level upgrade, the NE bof should be pointed to the latest license file, and then you execute admin system license validate and admin system license activate.

15.77.2 Steps

1

On the equipment tree:

For IOM-1 or IOM5-e, expand Network→*NE*→Shelf→Card Slot.

For XIOM-s, expand Network→*NE*→Shelf→Card Slot→Xiom Card Slot.

2

Right-click on the IOM-1, IOM5-e, or XIOM-s and choose Properties. The Card Slot form opens.

3

Click on the Licenses tab. The Upgrade Path and Available Path tabs appear.

4

Click on the Upgrade Path tab and click Create. The Upgrade License Path (Create) form opens.

5

Click on Select beside the Assigned Level Upgrade ID parameters, and choose an ID.

6

Save your changes and close the forms.

END OF STEPS

Procedures for daughter card slot object configuration

15.78 To configure an MDA

15.78.1 Steps

1

On the equipment tree, right-click on a device and choose Properties. The Network Element form opens.

2

On the Network Element tree, expand the Shelf object→Card Slot object.

3

Perform one of the following:

a. To add a daughter card to an empty daughter card slot, right-click on the daughter card slot and choose Configure Daughter Card. The Daughter Card Slot form opens.

b. To modify an existing daughter card, click on the daughter card slot. The Daughter Card Slot (Edit) form opens.

Note: If a daughter card in your configuration is managed by NFM-P but becomes no longer supported by NFM-P (for instance, an obsoleted MDA), it will be displayed under the equipment tree as type Unspecified. To delete such a card from NFM-P, you must remove the MDA from the device. Once a card is removed from the device, it is also automatically deleted from NFM-P.

4

Configure the required parameters.

The Clock Mode parameter value must be set to Differential in order to configure the Differential Timestamp Frequency (kHz) parameter.

The Assigned Daughter Card Type and In MDA Carrier Module Slot parameters are configurable only during daughter-card creation.

Note: The ATM Mode parameter must be set to a value of max16k-vc for PPPoA and PPPoEoA to be supported.

5

Click on the Daughter Card tab and configure the required parameters.

Note: Before you configure the MDA Mode parameter, you must shut down all of the ports and remove all of the subchannels and bundles from the MDA.

6

To configure named buffer pools:

Note: You must enable pool mode on the parent I/O card to enable named buffer pool support. See 15.67 “To enable named pool mode” (p. 526) for more information.

1. Select a policy in the Ingress Pool Policy panel.
2. If you are configuring an HSMDA daughter card, go to Step 10 .

   Note:

   HSMDA daughter cards support only ingress named buffer pool policies, and not egress named buffer pool policies.
3. Select a policy in the Egress Pool Policy panel.

7

If required, select a policy in the Network Queue Policy panel.

For 7450 ESS, 7750 SR, and 7950 XRS NEs, network queue policies are assigned to forwarding planes; see 15.58 “To assign a network queue policy to a forwarding plane” (p. 518).

8

If required, select a Network Ingress Fabric Profile and an Access Ingress Fabric Profile in the Fabric Profiles panel.

9

If required, select a Network Ingress Security Queue and an Access Ingress Security Queue in the Security Queue Policies panel.

10

If required, select a policy in the Egress HSMDA Pool Policy panel.

Note: You must enable pool mode on the parent I/O card to enable HSMDA pool support. See 15.67 “To enable named pool mode” (p. 526) for more information.

11

Configure the required parameters in the HSMDA Aggregate Queue Burst panel.

12

To assign a network queue policy and network policy of ring type to a 7705 SAR:

1. Select a network queue policy (also called an add-drop queue policy) in the Ring Policies panel.
2. Select a network policy in the Network Policy panel.

   Note:

To assign a network policy of ring type to a 7705 SAR-8 or 7705 SAR-18 MDA, you must set the Network Policy Type for 7705 parameter to Ring when you configure a network policy on the MDA. See 50.41 “To configure a QoS network policy” (p. 1568) for more information.

13

Select an Access Ingress Shaper policy in the Shaper Policies panel.

Note: The Shaper policy is supported on all Ethernet MDAs on the 7705 SAR-8 and 7705 SAR-18 except the following:

- 2 × 10-Gig Bridged Ethernet + 1 × 2.5G Virtual Ethernet MDA
- 6 × 10/100 Ethernet + 2 × 10/100/1000 Ethernet SFP v2
  The Shaper policy is supported on all integrated MDAs on all 7705 SAR variants except the following:
- 7705 SAR-M — 2 × 10-Gig Bridged Ethernet XFP + 1 × 2.5G Virtual Ethernet
- 7705 SAR-H — 4 × 10/100 MDA

14

To configure MAC management:

1. Click on the MAC Operation tab and configure the required parameters.
2. To create an FDB Mac entry, click on the FDB Entries tab. The MDA MAC FDB Management form opens.
3. Configure the required parameters.
4. Select a port in the Port panel.

   Note:

   You can only bind a ring port to an FDB Mac entry.
5. Click OK.

15

To configure the cellular MDA on 7705 SAR-Hm, click on the Cellular tab and configure the required parameters.

When the 7705 SAR-Hm is operating in dual SIM mode, you can configure the SIM switchover behavior to be automatic based on specified failover criteria. When you set the Active SIM Card parameter to Automatic, you can configure the Down Recovery Interval (Min) and Down Recovery Criteria parameters for each SIM card. These parameters specify failover criteria to determine when to automatically switch to the backup SIM.

If you set the Down Recovery Interval (Min) parameter to be less than the Fail Duration (Min) value set on the cellular port, a node reboot happens instead of a SIM switchover.

16

If required, click on the Wlan Radio tab and configure the parameters.

17

If required, click on the Network Interfaces tab to add a network interface card.

18

Click Add. The Create Network Interface - Routing Instance form opens. See 27.17 “To create an L3 network interface on a routing instance” (p. 856) for information on creating a network interface.

19

If required, perform 15.79 “To configure IMPM on an MDA” (p. 539) to configure IMPM on the daughter card.

20

For 7450 ESS, 7750 SR, and 7950 XRS NEs, network ingress pools are configured on forwarding planes; see 15.60 “To configure a network ingress pool on a forwarding plane” (p. 520).

21

To configure ATM:

1. Click on the ATM tab, select an ATM configuration, and click Properties. The ATM Configuration form opens.
2. Click on the VP Shaping tab and click Create. The ATM VP Shaper form opens.
3. Configure the VP ID parameter.
4. Select an ATM QoS Policy in the ATM QoS Policy panel.
5. Click on the QoS tab and configure the VP Shaping Weight parameter.
6. Save your changes and close the forms.
7. If required, repeat 1 to 6 to create additional ATM VP shapers.

22

Save your changes and close the forms.

END OF STEPS

15.79 To configure IMPM on an MDA

15.79.1 Purpose

Perform this procedure to configure IMPM on an MDA that is not installed in an XCM, 2 x XP MDA IOM 3 or an IMM.

Note: See 15.64 “To configure IMPM on an XCM, 2 x XP MDA IOM 3, or IMM forwarding plane” (p. 522) for information about configuring IMPM on an XCM, 2 × XP MDA IOM 3 or IMM.

15.79.2 Steps

1

Perform Step 1 to Step 6 of 15.78 “To configure an MDA” (p. 536) .

2

Configure the required parameters.

3

Select a policy in the BW policy panel.

Note: The multicast bandwidth policy named “default” cannot be modified or deleted.

4

Click OK and confirm your actions. The form closes.

END OF STEPS

15.80 To upgrade a license path on an FP4 MDA

15.80.1 Before you begin

Before you perform a license level upgrade, the NE bof should be pointed to the latest license file, and then you execute admin system license validate and admin system license activate.

15.80.2 Steps

1

On the equipment tree, expand Network→*NE*→Shelf→Card Slot→Daughter Card Slot.

2

Right-click on the MDA and choose Properties. The Card Slot form opens.

3

Click on the Licenses tab. The Upgrade Path and Available Path tabs appear.

4

Click on the Upgrade Path tab and click Create. The Upgrade License Path (Create) form opens.

5

Click on Select beside the Assigned Level Upgrade ID parameters, and choose an ID.

6

Save your changes and close the forms.

Note: If a higher upgrade path is deleted, then the Licensed Level reverts to the previous level.

END OF STEPS

15.81 To specify an event action for a 7x50 MDA

15.81.1 Purpose

Perform this procedure to specify the action to happen on the MDA when a specified event occurs. Supported event actions send a trap that is received by the NFM-P and will be raised as an alarm in NFM-P.

15.81.2 Steps

1

On the equipment tree, expand Network→*NE*→Shelf→Card Slot→Daughter Card Slot.

2

Right-click on the MDA and choose Properties. The Card Slot form opens.

3

Click on the Events tab and click Create. The Events (Create) form opens.

4

Configure the event type and the associated event action.

5

Save your changes and close the form.

END OF STEPS

15.82 To view the operational multicast channel properties of an MDA

15.82.1 Purpose

Perform this procedure to view specific information about an operational multicast channel on an MDA that is configured to use an Ingress Multicast Bandwidth policy.

For 7450 ESS, 7750 SR, and 7950 XRS NEs, the operational MC path management properties are available for viewing on forwarding planes; see 15.61 “To view the operational MC path management properties of a forwarding plane” (p. 520).

Note: You can also view operational multicast channel information in the following locations:

- the Mcast Path Mgmt tab on the properties form of a VPLS or VPRN service site
- the Mcast Path Mgmt Channels tab on the properties form of a routing instance.

Each properties form contains information about the ingress MDA of each operational channel.

15.82.2 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

On the NE navigation tree, expand Shelf→Card Slot n.

3

Click the Daughter Card Slot object. The Daughter Card Slot form opens.

4

Click on the Mcast Path Mgmt Channels tab.

5

Search for channels, choose a channel from the list and click Properties.

6

View the channel information, which includes the service site or routing instance associated with the channel, and the following properties:

Note: Channel information is displayed only when the MDA receives multicast traffic for a previously configured multicast group.

- Group Address—the operational channel multicast group address
- Source Address—the operational channel multicast source address
- Bandwidth—the operational bandwidth of the channel
- Administrative Bandwidth—the administrative bandwidth of the channel
- Last Highest Bandwidth—the value of the multicast bandwidth that is currently allocated to the channel forwarding path on the MDA. This value is calculated based on periodic statistics polls and represents the highest recorded bandwidth value since the most recent restart of the bandwidth update timer for the channel.
- Second Highest Bandwidth—the second-highest recorded bandwidth value for the channel since the most recent restart of the bandwidth update timer. The value is calculated based on periodic statistics polls and is reset to zero every time the bandwidth update timer for the channel is restarted.

- BW Update Timer expiration—the time that remains before the bandwidth update timer for the channel expires
- Current Path—the path that the channel traffic uses to reach the switching fabric; the path value is primary, secondary, or ancillary
- Explicit Path—indicates whether the current path is explicitly specified by a Multicast Info Policy
- Preference Level—the preference level of the channel
- Black-Hole—whether the channel is in the Black-Hole state
- Black-Hole Rate—specifies the bandwidth rate, in kb/s, at which the channel enters the Black-Hole state

7

Close the form.

END OF STEPS

15.83 To configure a module card on a 7705 SAR-M/ME or 7705 SAR-H

15.83.1 Steps

1

On the equipment tree, right-click on a 7705 SAR-M/ME or 7705 SAR-H NE and choose Properties. The Network Element (Edit) form opens.

2

On the NE navigation tree, expand Shelf→Card Slot *n*, right-click on the applicable Daughter Card Slot object and choose Configure Daughter Card. The Daughter Card Slot (Create) form opens.

Note: For the 7705 SAR-M and 7705 SAR-ME, only the third daughter card slot can be configured with module cards. The first two daughter card slots are configured with integrated cards.
For the 7705 SAR-H, only the second and third daughter card slots can be configured with module cards. The first daughter card slot is configured with an integrated card.

3

Configure the Assigned Daughter Card Type parameter.

4

Click Apply. The Daughter Card Slot form refreshes.

5

Click on the Daughter Card tab and configure the required parameters.

6

To add a fabric profile:

1. Select a fabric profile in the Network Ingress Fabric Profile panel.
2. Select a fabric profile in the Access Ingress Fabric Profile panel.

   If you are configuring a 1 Colour Optical Add/Drop Mux card, go to Step 21 .

7

Select a network queue policy in the Network Policy Queue panel, if required.

8

Click on the Ports tab.

9

Click on a port and choose Properties. The Physical Port (Edit) form opens.

Note: The first port on the DCM includes four SHDSL lines. The second port includes two XDSL lines.

10

Configure the required parameters.

11

Click on the States tab and configure the Administrative State parameter. If you are configuring a DSL or DCM module, go to Step 13 .

12

Click on the GPON tab and configure the required parameters. Go to Step 21 .

13

Click on the DSL tab and configure the required parameters.

14

To configure XDSL or SHDSL lines:

1. Click on the XDSL or SHDSL tab, as required.
2. Choose an XDSL or SHDSL line and click Properties. The XDSL Line (Edit) or SHDSL Line (Edit) form opens.
3. Configure the Administrative State parameter.
4. Save the configuration and close the form.
5. To configure more lines, repeat 1 to 4 .

15

Click on the Ethernet tab and configure the required parameters on the General tab.

16

Click on the EFM-OAM tab. To configure the parameters on this tab, perform the steps provided in 90.49 “To configure an 802.3ah EFM OAM diagnostic test from an NE Properties form” (p. 3069) .

17

Click on the LLDP tab and configure the required parameters on the Nearest Bridge, Nearest Customer, and Nearest Non TPMR tabs.

18

Click on the Remote Peers tab under the LLDP tab to search for and display LLDP remote peers associated with the port. These remote peers are used to determine the physical topology of the network.

19

Click on the 802.1x Port and 802.1x Port Authenticator tabs, and configure the required parameters.

20

If you are configuring a 6 port Ethernet module card, click on the PoE tab and configure the required parameters.

21

Save your changes and close the forms.

END OF STEPS

15.84 To configure GNSS receiver functions on a 7705 SAR-Hm

15.84.1 Purpose

Perform this procedure to enable NMEA data streaming, view GNSS location information, and view satellite information for 7705 SAR-Hm, Release 16.0 R4 and later and 7705 SAR-Hmc, Release 20.5 R1 and later.

15.84.2 Steps

1

On the equipment tree, right-click on the NE and choose Properties. The Network Element (Edit) form opens.

2

On the NE navigation tree, expand Shelf→Card Slot 1.

3

Click the Daughter Card Slot object and click Properties. The Daughter Card Slot form opens.

4

Click on the GNSS tab and configure the required parameters.

5

To enable NMEA, set the Sentence Streaming parameter to In Service and configure the Sentences and Sentence Interval (seconds) parameters, as required.

6

The form also displays GNSS location information.

7

Click on the Visible Satellites tab to display satellite information.

8

Close the form.

END OF STEPS

15.85 To perform a manual SIM switchover on a 7705 SAR-Hm

15.85.1 Purpose

Perform this procedure to manually switch from one SIM card to the other on a 7705 SAR-Hm in dual SIM mode.

15.85.2 Steps

1

On the equipment tree, right-click on a 7705 SAR-Hm and choose Properties. The Network Element (Edit) form opens.

2

On the NE navigation tree, expand Shelf→Card Slot 1.

3

Click the Daughter Card Slot object and click Properties. The Daughter Card Slot form opens.

4

Click on the Cellular tab.

5

On the Cellular tab, configure the Active SIM Card to the other SIM

6

Click OK in the confirmation dialog.

The 7705 SAR-Hm changes cellular connection to the other carrier.

7

Close the form.

END OF STEPS

Procedures for bundle configuration

15.86 To create an FR group bundle

15.86.1 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

On the NE navigation tree, expand Shelf→Card Slot n→Daughter Card Slot n, right-click on the Bundles object and choose Create Bundle. The Create Multilink Bundle window opens.

3

Configure the general property parameters and click Next. The Configure Bundle Parameters form opens.

4

Set the Bundle Type parameter to FR and configure the rest of the required parameters, then click Next. The Configure Bundle Members form opens.

Note: To create a PPP group bundle, perform 15.90 “To create an MLPPP bundle” (p. 551) .
To create an IMA group bundle, perform 15.88 “To create an IMA group bundle” (p. 550)

5

Perform one of the following:

a. To create the multilink bundle without adding any members, go to Step 6 .

b. To add DS0 channel groups to the bundle:

1. Click Create. The Add Bundle Member form opens.
2. Configure the Show Only Compatible Channels parameter, as required.
3. Click Next. The Select Channels configuration form opens.
4. Search for channels, and then choose up to 8 channel groups from the list of channels to construct the bundle.

   Note:

   The channel group with the lowest Port ID is chosen as the primary member for the bundle. The Encap Type of the primary member is used for all other members. When adding members to a bundle at a later time, choose members with the same Encap Type as the primary member.
5. Click Finish. The form closes and the Create Multilink Bundle form reappears.

6

Click Finish to close the form.

END OF STEPS

15.87 To modify an FR group bundle

15.87.1 Purpose

Perform the following procedure to modify an FR group bundle already configured on a channelized MDA in the NE.

15.87.2 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

On the NE navigation tree, expand Shelf→Card Slot n→Daughter Card Slot n→Bundles, right-click on an FR group bundle object and choose Properties. The Multilink Bundle (Edit) form opens.

3

Configure the required parameters on the following tabs:

- General
- Multilink Bundle
- States
- MLFR
- Bundle Members (where you can create and add new bundle members)

4

To configure the FR interface:

1. Click Edit FR. The FR Interface Bundle form opens.
2. Configure the required parameters.
3. Save your changes and close the form.

5

Save your changes and close the form.

END OF STEPS

15.88 To create an IMA group bundle

15.88.1 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

On the NE navigation tree, expand Shelf→Card Slot n→Daughter Card Slot n, right-click on the Bundles object and choose Create Bundle. The Create Multilink Bundle form opens.

3

Configure the general property parameters and click Next. The Configure Bundle Parameters form opens.

4

Set the Bundle Type parameter to IMA and configure the rest of the required parameters, then click Next. The Configure Bundle Members form opens.

Note: To create a PPP group bundle, perform 15.90 “To create an MLPPP bundle” (p. 551) .
To create an FR group bundle, perform 15.86 “To create an FR group bundle” (p. 548) .

5

Perform one of the following:

a. To create the multilink bundle without adding any members, go to Step 6 .

b. To add DS0 channel groups to the bundle:

1. Click Create. The Add Bundle Member form opens.
2. Configure the Show Only Compatible Channels parameter, as required.
3. Click Next. The Select Channels configuration form opens.
4. Search for channels, and then choose up to 8 channel groups from the list of channels to construct the bundle.

   Note:

   The channel group with the lowest Port ID is chosen as the primary member for the bundle. The Encap Type of the primary member is used for all other members. When adding members to a bundle at a later time, choose members with the same Encap Type as the primary member.
5. Click Finish. The form closes and the Create Multilink Bundle form reappears.

6

Click Finish to close the form.

END OF STEPS

15.89 To modify an IMA group bundle

15.89.1 Purpose

Perform the following procedure to modify an IMA group bundle already configured on a channelized MDA in the NE.

15.89.2 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

On the NE navigation tree, expand Shelf→Card Slot n→Daughter Card Slot n→Bundles, right-click on an IMA group bundle object and choose Properties. The Multilink Bundle (Edit) form opens.

3

Configure the required parameters on the following form tabs:

- General
- Multilink Bundle
- States
- Bundle Members (where you can create and add new bundle members)

4

Save your changes and close the form.

END OF STEPS

15.90 To create an MLPPP bundle

15.90.1 Steps

1

On the equipment tree, right-click on the NE on which you need to create an MLPP group bundle and choose Properties. The Network Element (Edit) form opens.

2

On the NE navigation tree, expand Shelf→Card Slot n→Daughter Card Slot n, right-click on the Bundles object and choose Create Bundle. The Create Multilink Bundle form opens.

3

Configure the general property parameters and click Next. The Configure Bundle Parameters form opens.

4

Set the Bundle Type parameter to PPP and configure the rest of the required parameters, then click Next. The Configure Bundle Members form opens.

Note: To create an FR group bundle, perform 15.86 “To create an FR group bundle” (p. 548)
To create an IMA group bundle, perform 15.88 “To create an IMA group bundle” (p. 550) .
If you create an MLPPP bundle and the DS1 BER exceeds a threshold, the PPP link is automatically removed from the MLPPP bundle.

5

Perform one of the following:

a. To create the multilink bundle without adding any members, go to Step 6 .

Note: If you need to configure the MLPPP group bundle for multiclass service transmission, do not add any bundle members. See 15.92 “To configure an MLPPP bundle for multiclass service transmission” (p. 554) for information about how to configure the MLPPP bundle for multiclass service transmission.

b. To add DS0 channel groups to the bundle:

1. Click Create. The Add Bundle Member form opens.
2. Configure the Show Only Compatible Channels parameter, as required.
3. Click Next. The Select Channels configuration form opens.
4. Search for channels, and then choose up to 8 compatible channel groups from the list of channels to construct the bundle.

   Note:

   If there are no compatible channels to choose from, edit some of the existing channels that are not compatible to make them compatible:
   - Click Back and disable the Show Only Compatible Channels parameter. Click Next.
   - Choose channels to edit from the list and click Properties.

   The channel group with the lowest Port ID is chosen as the primary member for the bundle. The Encap Type of the primary member is used for all other members. When adding members to a bundle at a later time, choose members with the same Encap Type as the primary member.
5. Click Finish. The form closes and the Create Multilink Bundle form reappears.

6

Save your changes and close the form.

END OF STEPS

15.91 To modify an MLPPP bundle

15.91.1 Purpose

Perform the following procedure to modify an MLPPP group bundle already configured on a channelized MDA in the NE.

15.91.2 Steps

1

In the Equipment view of the navigation tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

On the NE navigation tree, expand Shelf→Card Slot n→Daughter Card Slot n→Bundles.

3

Right-click on an MLPPP group bundle object and choose Properties. The Multilink Bundle (Edit) form opens.

4

Configure the required parameters on the following form tabs:

- General
- Multilink Bundle
- States
- MLPPP
- Bundle Members (where you can create and add new bundle members)

  Note:

  If you need to configure the MLPPP group bundle for multiclass service transmission, do not add any bundle members. See 15.92 “To configure an MLPPP bundle for multiclass service transmission” (p. 554) for information about how to configure the MLPPP bundle for multiclass service transmission.

5

Save your changes and close the form.

END OF STEPS

15.92 To configure an MLPPP bundle for multiclass service transmission

15.92.1 Purpose

Perform the following procedure to configure an existing MLPPP group bundle for multiclass service transmission.

Consider the following before you start to configure an MLPPP bundle for multiclass service transmission.

- Only channelized ASAP MDAs on the 7705 SAR and 7750 SR support multiclass MLPPP.
- You need to configure multiclass MLPPP before you add bundle members to the multilink bundle.
- Ports configured in network mode do not support multiclass MLPPP.
- Multiclass MLPPP is not supported when LFI is enabled.

15.92.2 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

On the NE navigation tree, expand Shelf→Card Slot n→Daughter Card Slot n→Bundles.

3

Right-click on an MLPPP group bundle object and choose Properties. The Multilink Bundle (Edit) form opens.

4

Click on the MLPPP tab and configure the required parameters.

Note: The Magic Number parameter is configurable only on channelized ASAP MDAs on 7750 SR NEs.
You can apply QoS profiles to an MLPPP bundle only if the Class Count parameter is set to 4.

5

Save your changes and close the form.

END OF STEPS

15.93 To configure an MLPPP bundle as a network interface on a channelized ASAP MDA

15.93.1 Purpose

Perform the following procedure if you need to configure an existing MLPPP group bundle as a network interface; see 15.90 “To create an MLPPP bundle” (p. 551) for details.

Consider the following when configuring an MLPPP as a network interface.

- Only channelized ASAP MDAs on the 7705 SAR and 7750 SR support MLPPP group bundles.
- The MLPPP network interfaces do not support LFI.
- The MLPPP network interfaces do not support MC MLPPP.
- IPv6 network interfaces are not supported.

15.93.2 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

On the NE navigation tree, expand Shelf→Card Slot n→Daughter Card Slot n→Bundles.

3

Right-click on an MLPPP group bundle object and choose Properties. The Multilink Bundle (Edit) form opens.

4

Click on the Bundle Members tab and configure the port mode:

1. Search for bundle members, choose a member from the list and click Properties. The Bundle Member (Edit) form opens.
2. Click on the Port tab.
3. Click Properties beside the port name. The DS0 Channel Group (Edit) form opens.
4. Set the Mode parameter to Network.
5. Save your changes and close the form.

5

Save your changes and close the form. The form refreshes with new tabs.

6

Click on the Network Interfaces tab and configure a network interface:

1. Click Create. The Create Network Interface - Routing Instance form opens.

2. See 27.17 “To create an L3 network interface on a routing instance” (p. 856) for information about creating a network interface on the DS0 channel.

   Note:

   The port in Step 5 of 27.17 “To create an L3 network interface on a routing instance” (p. 856) is set to the DS0 channel by default. Go to Step 8 of 27.17 “To create an L3 network interface on a routing instance” (p. 856) .

   The L3 interface appears on the Network Interfaces tab.

7

Save your changes and close the form.

END OF STEPS

Procedures for extension shelf configuration

15.94 To create a satellite shelf

15.94.1 Steps

1

On the equipment tree, right-click on the NE where you need to create a satellite shelf and choose Create Satellite.

2

Configure the required parameters.

Configure the Dynamic Uplink and Uplink Distribution parameters to dynamically enable satellite port mapping.

3

Save your changes and close the form.

END OF STEPS

15.95 To configure satellite shelf uplink port topology

15.95.1 Overview

Use this procedure to configure uplink port topology between the connection ports on an NE and the uplink ports on a satellite shelf.

15.95.2 Steps

1

Perform one of the following:

a. To configure uplink port topology from the NFM-P main menu:
   1. From the NFM-P main menu, select Create→Equipment→Satellite Port Link.

b. To configure uplink port topology from the NE level:
   1. On the equipment tree, right-click on the NE and choose Properties.
   2. Click on the Physical Links tab, and then on the Satellite Port Topology tab. Click Create.

c. To configure uplink port topology from the port level:
   1. On the equipment tree, click on an uplink port on the satellite shelf.
   2. Hold the Ctrl key and click on the port on the NE to which the satellite shelf is connected.
   3. Right-click on one of the ports and select Create Satellite Port Link.
   4. Go to Step 4.

2

In the End Pointer A Port panel, click on the Select button and choose an uplink port on the satellite shelf.

3

In the End Pointer B Port panel, click on the Select button and choose the port on the NE to which the satellite shelf is connected.

4

Save your changes and close the forms.

END OF STEPS

15.96 To configure flexible satellite port mapping for Ethernet satellites

15.96.1 Overview

Use this procedure to configure any number of primary uplinks to be used between the 7x50 host, Release 15.0 R3 or later, and the Ethernet satellites to achieve uplink resiliency. You can also configure any number of secondary uplinks to be used between the 7x50 host, Release 15.0 R8 or later, and the Ethernet satellites to achieve uplink resiliency.

Note: For node versions prior to Release 16.0 R4, primary and secondary uplink ports of satellite access ports cannot be mapped to host ports of same MDA/Card in 7x50 nodes.

Note: The administrator must ensure that the new uplink port has sufficient resources to handle the re-assigned satellite ports and associated services.

Note: The satellite port mapping requires a manual refresh to get the updated information on the host port.

15.96.2 Steps

1

On the equipment tree, right-click on the Ethernet satellite and choose Properties.

2

Click on the Flexible Satellite Port Mapping tab, and then on the satellite port. Click Properties. The Flexible Satellite Port Mapping form opens.

3

Click Select beside the Primary Up Link Port - Port Name parameter and select a port from the list and click OK.

Note: The uplink association can only be changed if there are no services configured against any of the satellite client ports.

4

Click Select beside the Secondary Up Link Port - Port Name parameter and select a port from the list and click OK.

5

Repeat to configure multiple ports and then click Apply on the Flexible Satellite Port Mapping form.

6

To revert to the primary uplink click Clear beside the Secondary Up Link Port - Port Name parameter and click OK.

7

Save your changes and close the forms.

END OF STEPS

15.97 To configure tunable optics for Ethernet satellites

15.97.1 Before you begin

You must create a 64-port 10-Gig SFPP Ethernet Satellite with 4 100-Gig QSFP28 up-links or 64-port 10-Gig SFPP Ethernet Satellite with 4 100-Gig CFP up-links on the 7750 SR, 7450 ESS, and 7950 XRS, Release 16.0 R4 and later.

The tabs and parameters that display vary depending on the type of Ethernet Satellite, and the NE and release.

15.97.2 Steps

1

On the equipment tree, right-click on the esat port of the Ethernet satellite and choose Properties.

2

Perform one of the following:

a. Click Select beside the DWDM Channel parameter and choose the available channel. The other DWDM parameters are populated.

b. Click the DWDM Optics tab and configure the required parameters.

   You cannot configure the center frequency if the DWDM channel parameter is configured.

3

Save your changes and close the form.

END OF STEPS

15.98 To associate a port template on an Ethernet satellite shelf

15.98.1 Before you begin

You must create a port template before you can associate the port template on a satellite shelf. See 12.43 “To create a port template” (p. 375).

15.98.2 Steps

1

On the equipment tree, navigate to the Ethernet satellite shelf and choose Properties. The Satellite Configure Shelf form opens.

2

Set the Assigned Type parameter to a satellite that contains a port template.

3

Click Select beside Template Name and then choose a port template.

4

Save your changes and close the forms.

END OF STEPS

15.99 To configure local forward on Ethernet satellite shelf

15.99.1 Steps

1

On the equipment tree, navigate to the Ethernet satellite shelf and choose Properties. The Satellite Configure Shelf form opens.

2

Enable the Local Forward parameter.

3

On the equipment tree, right-click on the NE with the Ethernet satellite shelf and choose Properties.

4

Click on the Local Forwards tab and click Create. The Satellite Local Forward Create form opens.

5

Configure the required parameters on the General tab.

6

Click on the SAP tab and click Create. The Satellite Local Forward Sap Create form opens.

7

Configure the required parameters. A maximum of two SAP entries can be created.

8

Save your changes and close the forms.

END OF STEPS

15.100 To enable transparent clock functionality on an Ethernet satellite

15.100.1 Before you begin

You must create one of the following satellites on a 7450 ESS, 7750 SR or 7950 XRS, Release 16.0 R5 and later:

- 48-port 1-Gig Ethernet SFP satellite
- 64-port 10-Gig SFPP Ethernet satellite with 4 100-Gig CFP up-links
- 48-port 1-Gig Ethernet SFP satellite, LCS variant
- 64-port 10-Gig SFPP Ethernet satellite with 4 100-Gig QSFP28 up-links

See 15.94 “To create a satellite shelf” (p. 557).

15.100.2 Steps

1

On the equipment tree, navigate to the Ethernet satellite shelf and choose Properties. The Satellite Configure Shelf form opens.

2

Enable the Synchronous Ethernet and Ptp Transparent Clock parameters under Shelf Details, and the Ptp Transparent Clock parameter under Feature.

3

On the equipment tree, right-click on the NE with the Ethernet satellite shelf and choose Properties.

4

Click on the Clock item under the IEEE PTP and Synchronization items in the navigation tree.

5

Set the PTP Profile parameter on the General tab to IEEE1588-2008.

6

Associate the IEEE PTP ports. See 15.23 “To configure IEEE 1588 PTP ports on a 7210 SAS, 7250 IXR, 7450 ESS, 7750 SR, or 7950 XRS” (p. 481).

7

Save your changes and close the forms.

END OF STEPS

15.101 To perform a software upgrade on an extension shelf

15.101.1 Steps

1

If required, create a software repository policy for the upgrade files.

1. Choose Administration→NE Maintenance→Software Repository from the main menu.
2. Click on the Create button.
3. Configure the Primary Location parameter, and any other required parameters.
4. Save and close the form.

2

In the equipment tree, navigate to the host node for the extension shelf you need to upgrade.

3

Right-click on the node and choose Properties.

4

In the Software Repository panel, click on the Select button and select the software repository policy for the upgrade files.

5

Save your changes and close the form.

6

In the equipment tree, navigate to the extension shelf you need to upgrade.

7

Right-click on the shelf, and select Reboot Upgrade to perform the upgrade.

END OF STEPS

Procedures for power shelf configuration

15.102 To configure power shelves

15.102.1 Steps

1

On the equipment tree, navigate to the power shelf and choose Configure Power Shelf. The Power Shelf form opens.

2

Configure the required parameters.

3

Save your changes and close the form.

END OF STEPS

15.103 To configure power modules

15.103.1 Steps

1

On the equipment tree, navigate to the power module and choose Configure Power Module. The Power Module form opens.

2

Configure the required parameters.

3

Save your changes and close the form.

END OF STEPS

16 Port and channel object configuration

Configuring port and channel objects

16.1 Overview

16.1.1 Port and channel objects

Port objects are children of daughter card slot objects. They appear below the daughter card slot after the daughter card is configured. Channel objects are children of port objects. They appear on the navigation tree below the port object after the channel is configured.

Properties forms for port objects and channel objects are accessed using the NFM-P navigation tree.

This chapter contains the procedures to configure devices using the navigation tree. See Chapter 3, “NFM-P navigation tree” for more information about using the navigation tree.

16.1.2 Working with port and channel objects

The types of ports that are available depend on the daughter cards that are configured in the chassis. For some OmniSwitch devices, the ports that are available depend on the chassis type, for others the type of card that is configured for the card slot. Ethernet ports cannot be channelized. SONET/SDH and TDM ports can be channelized.

The port syntax for most devices that support daughter cards is card slot/daughtercard/port. For example, Port 1/1/1 represents port 1 of daughter card 1 in slot 1. Connector ports are indicated in the equipment tree by the letter c preceding the port number; for example, 1/1/c1/1. The port syntax for the OmniSwitch is card slot/port.

In most cases, ports are created automatically when the daughter card is created. You must select one port object at a time and configure the properties of the port for the service that you need the port to provide. The properties vary depending on the port type. Channel objects are created on SONET/SDH or TDM ports for any type of channelization on the port whether it is a clear channel application or a sub-channel application.

Use the properties forms from the contextual menus in the navigation tree to configure port and channel parameters. You can configure the port mode as network, access, or hybrid.

- Network ports pass network-level traffic.
- Access ports are customer-facing and pass service-level traffic.
- Hybrid ports can pass network-level and access-level traffic.

Note: By default, a port is in network mode.
See 16.29 “To change the port mode” (p. 611) to change the port mode.

Clear channel ports (OC-192/OC-48c/OC-12c/OC-3c) are network or access ports. Channelized ports (CHOC-12/CHOC-3c/ DS3/E3) are always in access mode, however, the ASAP CHOC-3 supports both access and network modes. The ASAP DS1/E1 ports support:

- access mode for ATM/IMA and TDM

- network mode for PPP/MLPPP

Network ports are used in the service provider transport or infrastructure network, such as an IP/MPLS-enabled backbone network or uplink ports for rings using L2 Ethernet switches. A port that is in network mode can be assigned an IP address and host an L3 interface that can perform IP routing functions.

Access ports are associated with a SAP, a subscriber, and a service to provide connectivity. Access ports and channels are configured with encapsulation values to differentiate the service on the port or channel. When a port is access mode, one or more services can be configured on the port. A channelized port that is to act as an endpoint must be in access mode. You can convert access ports to hybrid ports and migrate any existing SAPs. See 16.30 “To migrate SAPs from access mode to hybrid mode” (p. 612) for more information.

Hybrid ports are ports that can host SAPs and network interfaces simultaneously. This enables a customer to use one uplink port for enterprise and end-user traffic. A hybrid port preserves the existing network and access port functionality, and uses the same QoS, scheduler, and port scheduler resources as other ports, but requires the configuration of weight values that allocate buffer percentages to the access and network traffic on the port.

The NFM-P supports hybrid mode configuration on Ethernet ports. Support for hybrid ports varies depending on the NE chassis, card, and release; see the NE documentation for information.

Note: Single-slot chassis such as the 7450 ESS-1 and 7750 SR-1 do not support hybrid port mode.

You can configure a hybrid port on an Ethernet MDA in an IOM-3XP, or on a CMA in an IOM-XP. The 7750 SR supports hybrid port configuration on an IMM in addition to an IOM-3XP.

Note: Hybrid port configuration is not supported on an HSMDA or a VSM MDA.

A hybrid port supports dot1q and QinQ encapsulation, but does not support null encapsulation, in order to accommodate single-SAP operation. The available VLAN tags are shared among the VLAN SAPs and VLAN network IP interfaces. When you create a SAP or L3 interface on a hybrid port, the outer VLAN tag must not be in use by another SAP or L3 interface on the port.

By default, the MTU of a hybrid port is set to the larger of the network and access MTUs to accommodate the creation of L3 interfaces and SAPs.

Note: A hybrid port can participate in a single-chassis LAG.
A hybrid port cannot participate in an MC-LAG or MC ring.

See the appropriate device documentation for more information about hybrid ports.

When working with a TDM port, you must specify the Line Buildout as either short or long. That is, for a DS3 port the Line Buildout parameter must be configured. If the TDM port is in the context of a SONET STS-1 sub-channel, for example, the DS3 channel is built on the STS-1 channel of a SONET port, the line buildout parameter is not required.

At the connection termination points, you are required to configure the Encap Type as required, the MTU size as required, and the configured MAC address as required when configuring the port or channel.

Policies can be added or deleted as required using the manage policy forms.

You can associate policies to ingress and egress access and network ports. Buffer policies are used to create and edit QoS buffer pool resources on network ports, access ports, and access channels. Egress network ports, access ports, and access channels have a dedicated buffer pool for queuing. The traffic is handled by a single buffer pool, one at the ingress, and one at the egress.

You can configure the amount of egress buffer space to be allocated to the port or channel. By default, all egress buffers are allocated fairly among the egress ports and channels based on their relative egress bandwidth.

The egress buffers for egress network ports and channels are put into per-port or per-channel egress buffer pools and are used by the egress network forwarding class queues on that port or channel. The ingress buffers allocated to network ports and channels are summed into a single pool and are used by the ingress network forwarding class queues (defined by the network ingress buffer policy).

The egress and ingress buffers allocated to access ports and channels are put into an egress buffer pool and ingress buffer pool for the port or channel. The access buffer pools are used by egress and ingress service queues created by the SAP-egress and SAP-ingress policies in use by services on the port or channel.

Changing the size of an egress buffer pool should be carefully planned. By default, there are no free buffers to increase the size of a pool. In order to increase a pool on one port or channel, the same amount of buffers must be freed from other egress buffer pools on the same daughter card.

16.2 Digital diagnostics monitoring

16.2.1 Overview

The NFM-P displays the following digital diagnostics monitoring data and alarm and warning information for ports on CFPs, QSFPs, SFPs and XFPs optical modular transceivers:

- temperature
- supply voltage (SFP)
- TX bias
- TX output power
- RX received optical power
- external calibration

The transceiver is programmed with warning and alarm thresholds for low and high conditions that can generate system events. The thresholds for CFPs, QSFPs, SFPs, and XFPs are programmed by the transceiver manufacturer. The NFM-P raises an alarm when these thresholds are exceeded.

You can view digital diagnostics monitoring information from the DDM tab and the Lane DDM tab on the property form of supported ports. The External Calibration tab is available if the ports on CFPs, QSFPs, SFPs, and XFPs optical modular transceivers support the external calibration functionality.

16.2.2 1830 VWM − DDM data retrieval

The NFM-P supports DDM data retrieval from each optical SFP in the data and control plane. See 16.77 “To retrieve 1830 VWM DDM data” (p. 680) for more information about how to retrieve 1830 VWM DDM data.

The following DDM data is retrieved from the local 1830 VWM devices or from the 1830 VWM RMUs:

- DDM received power
- DDM transmitted power
- DDM laser bias current
- DDM temperature
- DDM voltage

16.3 Remote fiber link monitoring in 1830 VWM devices

16.3.1 Overview

Passive WDM devices in remote radio sites cannot communicate with 1830 VWM OSU devices. You can still monitor and detect signal failures using RFLM ports.

16.3.2 RFLM

Perform the following to monitor and detect a signal failure in a passive WDM device:

1. Transmit an RFLM wave, that is, a 1627 nm signal, from an optical OSC port of an 1830 VWM OSU device to a passive WDM device in the remote radio site.
2. Loop the signal at the remote end back to the 1830 VWM OSU device. An alarm is generated if a signal path failure is detected.

NFM-P supports the configuration of an 1830 VWM OSU optical OSC port to operate as an RFLM port. The Interface Role parameter of the 1830 VWM OSU optical OSC port participating in the remote fiber link monitoring is set as RFLM after setting the administrative state to down. You can associate a label with the signal by entering relevant information in the RFLM Label text field. When a signal failure occurs, the text appears in the generated alarm and helps in identifying the RFLM alarm.

See 16.78 “To configure an OSC port of an 1830 VWM OSU as a RFLM port” (p. 680) for more information about configuring the OSC port as an RFLM port.

16.4 Tagged and untagged VLAN ports

16.4.1 Overview

The NFM-P supports tagged and untagged ports as VLAN access ports. The following table describes the behavior when ingress tagged or untagged traffic enters and then exits a VLAN.

Table 16-1 Tagged and untagged traffic behavior

Ingress traffic configuration	Ingress VLAN port configuration	Action	Egress VLAN port configuration and action
Untagged	Untagged	The VLAN allows the traffic and passes it based on the default VLAN ID. The MAC address of the destination is learned.	If the egress VLAN port is untagged, the traffic remains untagged.
			If the egress VLAN port is tagged, a tag is added to the traffic.
	Tagged		If the egress VLAN port is untagged, the traffic remains untagged.
			If the egress VLAN port is tagged, a tag is added to the traffic.
Tagged	Untagged	The VLAN allows the traffic if the tag matches the default VLAN ID. The MAC address of the destination is learned. If the tag does not match the default VLAN ID, the traffic is dropped.	If the egress VLAN port is untagged, the tag of the traffic is removed.
			If the egress VLAN port is tagged, the traffic remains tagged.
	Tagged	The VLAN allows the traffic: • if the tag matches the default VLAN ID • if the tag matches another VLAN ID The MAC address of the destination is learned. If the tag does not meet either condition, the traffic is dropped.	If the egress VLAN port is untagged, the tag of the traffic is removed.
			If the egress VLAN port is tagged, the traffic remains tagged.

The following figures show how tagged and untagged traffic is handled on the devices, based on the VLAN ID.

Figure 16-1 Untagged traffic and VLANs

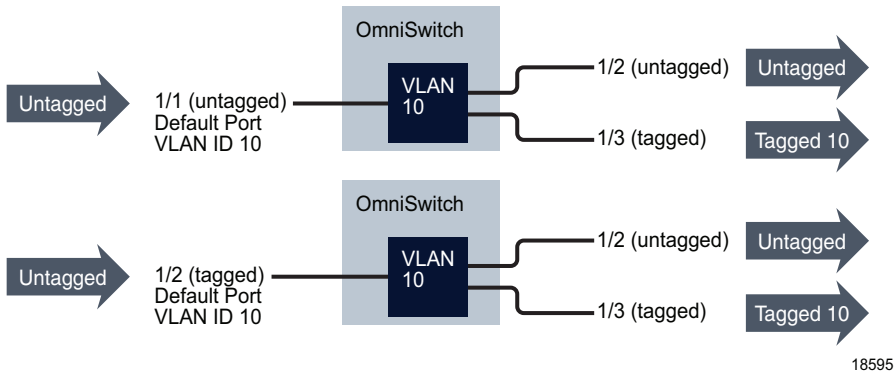


Figure 16-2 Tagged traffic and VLANs

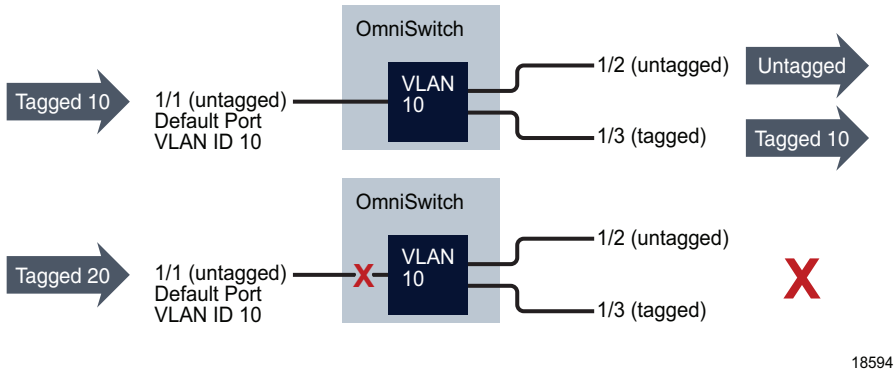


16.5 Connection termination points for services and interfaces

16.5.1 Overview

Connection termination points are objects that represent terminating endpoints for a service, for example the endpoint of a VLL service. Connection termination points can be Layer 2 or Layer 3 interfaces, depending on the type of service being created. At the connection termination points you must configure the mode as Access or Network, the Encap Type as required, the MTU size as required, and the configured MAC address as required when configuring the port or channel. The following objects can be used for connection termination points:

- STS-3 to STS-192 clear channels
- DS3 clear channel
- DS0 groups
- ports
- bundle

16.5.2 STS-3 to STS-192 clear channel

STS-3 to STS-192 clear channel SONET/SDH ports can be used to create SAPs or IP interfaces with one clear channel on each port that operates at the rate of the parent object. Clear channel SONET applications can be performed on any OC-*n* card. SONET channel termination for 1 × 10-Gig MDAs are not supported. See 16.9 “SONET clear channel applications” (p. 578) in this section for more information.

16.5.3 DS3 clear channel

A DS3 clear channel can be a connection termination point when it is explicitly configured as unchannelized, that is, when the Configuration Type is set to None, which is the default setting for a DS3. DS3 clear channel connections cannot be channelized to a lower level than the one full DS3 channel. See 16.10 “TDM channelization and clear channel applications” (p. 579) in this section for more information.

16.5.4 DS0 channel groups

A TDM channel group connects a group of DS0s by allocating a specific number of spans or interfaces and channels to a group of channels. The DS0 channel group defines the incoming and outgoing parameters for a group of channels such as IP profiles, routing tables, and translation tables to be assigned during the configuration of the specific channel group.

To use a DS1 or E1, you must create at least one DS0 group for the DS1 or E1. The NFM-P supports the automatic configuration of sub-channels and assignment of timeslots on the ports within DS0 groups. Depending on the TDM port selected, the NFM-P automatically creates the DS0 channel groups with the appropriate type of timeslots. For example, you can assign timeslots to a DS0 channel group as follows:

- For DS1 channel types: Use four timeslots per channel group, which results in six DS0 channel groups with IDs from 1 to 6. Each contains four timeslots.
- For E1 channel types: Use five timeslots per channel group, which results in six DS0 channel groups with IDs from 1 to 6. Each contains five timeslots, with one timeslot not assigned.

You can view the channels that are assigned in DS0 groups using the associate properties form. You can also disable, enable, or reassign the assignment of timeslots as required, in a DS0 group.

See 16.10 “TDM channelization and clear channel applications” (p. 579) in this section for more information about DS0 channel groups. See 16.61 “To perform a bulk channel creation on ports that support multiple sub-channels” (p. 654) for information about creating channels on ports for card types that support multiple sub-channels. See 16.66 “To configure TDM DS1 or E1 channels” (p. 663) for information about creating TDM DS1 or E1 channels and DS0 channel groups.

SONET STS-1 sub-channels

Only the DS0 group level can be used as a connection termination point for SONET STS-1 sub-channels. Channelization on the 1 × OC12 can be used to create up to 12 SONET STS-1 sub-channels. Each STS-1 channel can be used to create a DS3 frame on which you can build DS1 or E1 channels that can be configured to the DS0 channel group level. You can configure the DS0s of a DS0 group in any sequence and you do not need to use all DSOs. For example, you can use DS0 1, 3, 5, and 9. See 16.13.3 “SONET VT1.5 and VT2 payloads” (p. 587) in this section for more information.

Only the DS0 group level can be used as an endpoint on the channelized 12 × DS3 card. Channelization can be used on each DS3 port of the card to create independent TDM channels in the form of DS1 or E1 data channels that handle DS0 groups. The DS0s of a DS0 group can be configured in any sequence and you do not need to use all DS0s. For example, you can use DS0 1, 3, 5, and 9. See “SONET and SDH sub-channel applications and structure” (p. 586) in this section for more information.

16.5.5 Ethernet ports

Ethernet ports can be configured as connection termination points in SAPs and IP interfaces. They cannot be channelized.

You must configure the class of port, such as fast Ethernet, GigE, or 10G Ethernet. You must also configure the port encapsulation at the connection termination point. Ethernet access ports use:

- dot1q—supports multiple services on the port; the outer encapsulation value that distinguishes services is the VLAN ID in the IEEE 802.1Q header

- QinQ—supports multiple services on the port/channel; the inner and outer encapsulation values that distinguish services is the VLAN ID in the IEEE 802.1Q header
- null—supports a single service on the port

You must configure the duplex parameter from the Ethernet tab if the port is to be added to a LAG. Configure the Dot1 Q Ethertype and Q in Q Ethertype parameters from the Ethernet tab, if required. The range is 1536 to 65 535.

You must also configure the speed parameter from the General tab. The options are 10, 100, 1000, or 10 000, depending on the speed of the Ethernet interface.

Most OmniSwitch chassis offer four hybrid or combo ports. These ports consist of four paired 10/100/1000Base-T ports and four 1000 SFP ports. Preferences for these ports are configurable and, depending on the configuration, redundancy can be provided if a link fails.

16.5.6 PXC loopback ports

You can place a port in an internal loopback mode called a port cross-connect (PXC). Each PXC is associated with a single physical port, and contains two logical PXC sub-ports. One PXC sub-port is created per upstream or downstream path. PXC ports can be added to hybrid LAGs, and associated with the following interfaces:

- Base routing network interfaces
- VPRN network interfaces
- Epipe L2 access interfaces
- Ipipe L2 access interfaces
- VPLS L2 access interfaces
- VPRN L3 access interfaces
- VPRN tunnel interfaces
- IES L3 access interfaces
- IES IPsec interfaces

Supported breakout ports can be associated to a PXC. The PXC ports can be added to either a LAG or FPE. The LAG with the PXC can be associated to the FPE. See 12.41 “To create an FPE” (p. 374) for information about configuring FPE.

PXC ports are configured in the Equipment tree. See 16.59 “To configure PXC loopback ports” (p. 652) for information about configuring a PXC port.

16.5.7 Xconnect anchor ports

The PXC functionality uses the loopback mechanism of anchor ports to feed traffic from egress forwarding context into the ingress forwarding context on the same line card utilizing the E-chip functionality.

The Xconnect object appears automatically in the navigation tree under daughter cards supported NEs. After you create MAC on the Xconnect, you can create up to 2 loopbacks. Each loopback creates respective anchor ports in the navigation tree (Port 1/1/m1/1). The anchor ports can be associated to a PXC.

See 16.58 “To create and configure Xconnect anchor ports” (p. 650) for information about configuring anchor ports.

16.5.8 OmniSwitch learned port security

LPS provides a mechanism to control network device access on one or more OmniSwitch ports. Configurable LPS parameters allow you to restrict the source learning of host MAC addresses to:

- a specific amount of time in which the switch allows source learning to occur on all LPS ports
- a maximum number of learned MAC addresses allowed on the port
- a list of configured authorized source MAC addresses allowed on the port

The following options allow you to specify how the LPS port handles unauthorized traffic.

- Block only traffic that violates LPS port restrictions; authorized traffic is forwarded on the port.
- Disable the LPS port when unauthorized traffic is received; all traffic is stopped and a port reset is required to return the port to normal operation.

See 28.128 “To configure bridging on an OmniSwitch” (p. 1043) for information about enabling LPS on Ethernet ports and configuring LPS properties. See 16.56 “To configure OmniSwitch Ethernet ports” (p. 647) for information about configuring static MAC addresses on LPS enabled Ethernet ports.

Note: A deployment error is displayed in NFM-P while creating a LAG with ports. This deployment failure occurs if there is an LPS/VLAN configuration done on a specific port, using CLI.

16.5.9 MTU size and port configuration

You must specify the MTU size for an Ethernet port using the MTU (bytes) parameter on the General tab at the connection termination endpoint.

Consider the following when you configure MTU parameters.

- The managed devices must handle MTU limitations at many service points. The physical (access and network) ports, service, and service tunnel MTU values must be individually defined.
- The ports to be designated as network ports and the ports to be designated as access ports intended to carry service traffic must be identified.
- MTU values should not be frequently modified.
- Service MTU values must be less than or equal to the service tunnel MTU.
- Service MTU values must be less than or equal to the access port MTU.
- The MTU value for an in-band management port should be less than or equal to the MTU value for the peer port connected to the in-band management port.

See the device specific documentation for end-to-end considerations for configuring maximum MTU size throughout the managed network.

The Ethernet port MTU parameter indirectly defines the largest physical packet that the port can transmit or that the far-end Ethernet port can receive. Packets received that are larger than the MTU are discarded. Packets that cannot be fragmented at egress and that exceed the MTU are discarded.

The parameters for MTU configuration include the destination MAC address, source MAC address, Ethernet encapsulation type, length field, and complete Ethernet payload.

The MTU value for a port is associated with the port mode, such as access or network, and the port encapsulation type. If you change the mode or encapsulation type value for a port, the NFM-P adjusts the MTU value to a default value. If you do not want the MTU values for ports to revert to the defaults, you can configure the NFM-P to retain the currently configured MTU values for ports regardless of a mode or encapsulation type change. See 16.31 “To configure the NFM-P to retain non-default port MTU values” (p. 613) for more information.

16.5.10 HSMDA Egress Secondary Shapers

The egress port scheduler combines all subscriber queues of the same scheduling class and services the queues in a byte fair round robin fashion. This results in more packets being forwarded into the aggregation network towards a DSLAM than the DSLAM can accept. If the HSMDA egress port is congested, the egress bandwidth represented by the downstream discarded packets to the DSLAM may be allocated packets destined to other DSLAMs.

The HSMDA supports egress secondary shapers to provide a control mechanism to prevent downstream overruns without affecting the class-based scheduling behavior on the port. All subscribers destined to the same DSLAM have their queue groups mapped to the same egress secondary shaper. As the scheduler services the queues within the groups according to scheduler class, the destination shaper is updated.

After the shapers rate threshold is exceeded, scheduling for all queues associated with the shaper is stopped. When the dynamic rate drops below the threshold, the queues are allowed to be placed back on the scheduler service lists. By removing the queues from their scheduling context for a downstream congested DSLAM, the port scheduler is allowed to fill the egress port with packets destined to other DSLAMs without affecting class behavior on the port.

Egress secondary shapers are configured per port.

16.5.11 PoE

PoE provides power directly from the Ethernet ports. Powered devices such as IP phones, wireless LAN stations, Ethernet hubs, and other access points can be plugged directly into PoE-enabled Ethernet ports. The NFM-P supports PoE and PoE+ on supporting devices. See the following procedures:

- 16.49 “To configure PoE ports on a 7210 SAS” (p. 641)
- 16.52 “To configure PoE ports on a 7705 SAR” (p. 644)
- 16.57 “To configure OmniSwitch PoE Ports” (p. 650)

16.6 Copying and moving SAPs

16.6.1 Overview

You can copy and move SAPs between physical Ethernet ports, logical ports, or ports and LAGs.

You can also copy and move SAPs between endpoints configured with ATM encapsulation. For example, you can move a SAP on an IMA bundle to another bundle or to a TDM channel configured with ATM encapsulation. The function is typically used in redundancy scenarios, or to recover from a hardware failure.

Consider the following before you attempt to copy or move a SAP:

- Ports:
  - The source and destination ports can be on the same or on a different chassis. Inter-chassis copy or move is supported only when both NEs are of the same type, in the same chassis mode or from a lower chassis mode (source NE) to a higher chassis mode (destination NE), and at the same major software release.
  - The source and destination ports can be the same. This configuration allows you to change the encapsulation values for a group of SAPs on the same port using outer and inner encapsulation offset values. These values can be positive or negative, depending on whether the encapsulation values must increase or decrease.
  - The physical Ethernet ports can be of different types; for example, Fast Ethernet (10/100/1000 Base-T), Gigabit Ethernet (1000 Base-T), and 10 Gigabit Ethernet (10 GBase-T).
  - The source and destination ports must be configured as access ports.
  - The encapsulation type must be the same on the source and destination ports.
  - You cannot copy or move a SAP between an HSMDA port and a non-HSMDA port.
  - The copy and move operations fail if the encapsulation value for a SAP on the source port is used by a SAP on the destination port. You can modify the SAP encapsulation values used on the destination port, if required.
  - The selected L2 access interface SAPs on the source port can be moved only to another service, and not within the same service.
  - If a SAP on the source port belongs to a service not supported on the destination port, the SAP is not copied or moved.
  - The maximum number of SAPs varies for ports and MDAs. The SAP copy or move operation fails if the SAP capacity is exceeded for the destination port.
  - For L2 and L3 access interfaces, you can move all SAPs or a subset of the SAPs on a port. You can also copy all SAPs or a subset of the SAPs on a port for L2 access interfaces.
  - All SAPs associated with a specific port within a group interface contained in an L3 subscriber interface can be moved at the same time.
- LAGs:
  - LAG to SAP copy and move works on all services that support SAP to SAP copy and move. There are no restrictions.
  - LAG specific attributes such as lag-per-link-has are dropped during the copy or move.
  - The target can be a port or a LAG. The target LAG or port can be on the same or a different NE for L2 Services. For L3 Services the target must be the same NE.
  - Both the mode and the encap-type must match to be copied. The NFM-P only displays LAGs or ports that have matching mode and encap-type. You can copy from an Access LAG or port to a Hybrid LAG or port and vice versa.
  - Port speed is not checked. You must verify that the target of the copy or move has enough capacity.
- SAPs:
  - SAPs can be associated with either L2 access interfaces on services such as Apipes, Cpipes,

Epipes, Hpipes, Fpipes, Ipipes, VPLS, and MVPLS, or L3 access interfaces or subscriber interfaces that are associated with services such as IES and VPRN.

- L2 access interface SAPs can be copied or moved from one service to another service of the same service type. The source and target service must be on the same site, and the source and destination service site types must be the same, for example B-site, I-site.
- MEPs are copied or moved with the L2 SAP copy/move operation only if the Follow Service Topology Changes parameter is not enabled on the global MEG service. If the Follow Service Topology Changes parameter is enabled, the MEPs are automatically created by the OAM framework when the new SAP is created. See 91.15 “To configure an Ethernet CFM MD policy and subordinate objects” (p. 3109).
- For an L2 SAP copy/move operation, only MEP CFM tests that are manually created are moved to the new SAP. MEP CFM tests created by Test Suite are not moved to the new SAP.
- For a SAP copy, the MEP ID is auto-assigned. For a SAP move, the MEP ID is copied only if the Node Wide MEP ID is not set on the destination NE. Otherwise the MEP ID will be auto-assigned based on the configured MEP ID. See 91.14 “To configure an automatic MEP ID assignment on an NE” (p. 3108).
- Endpoints associated with the specified SAPs are copied during an L2 SAP copy/move operation, but other objects associated with the endpoints such as other SAPs or spokes are not copied/moved. If the destination already has an endpoint with the same name, the endpoint associated with the source SAP will not be copied/moved with the source SAP.
- You cannot change SAP encapsulation from bridged to routed if ARP and DHCP options have been configured.

- SAP attributes:
  - VPLS and MVPLS dynamic FIB entries that are associated with copied or moved SAPs are discarded. Static FIB entries are transferred to the destination port after a successful SAP copy or move.
  - All SAP redundancy relationships at the source port, such as those provided by an MVPLS, are discarded during a copy or move operation.
  - All alarms, statistics, or OAM test results that are associated with a copied or moved SAP are discarded.
  - When a source SAP belongs to an SHG, the NFM-P attempts to preserve the SHG membership. The destination SHG must have the same name as the source SHG, and must have the same residential SHG status. If an SHG with the same name does not exist on the destination service site, the NFM-P creates it.
  - When a source SAP uses an aggregation scheduler, the scheduler is copied to the destination. The aggregation scheduler must be unique to the destination NE and must have the same scope, for example, MDA or port.
- MEPs
  - MEPs and associated CFM tests are included in SAP copy/move operations for L3 Access Interface and Subscriber Interface SAPs.

See 16.32 “To copy or move L2 SAPs between ports” (p. 614) , 16.33 “To copy or move L2 access interface SAPs between services” (p. 619) , 16.34 “To move L3 SAPs within or between ports or LAGs on the same NE” (p. 620) , and 16.35 “To move L3 subscriber interface SAPs between ports on the same NE” (p. 623) to move access interface SAPs between services or ports.

16.7 Configuring access SAP bandwidth CAC

16.7.1 Overview

You can configure the bandwidth CAC function on a port or LAG, based on the admin bandwidth configured on a SAP and on an associate port or LAG. In addition, a booking factor is provided to allow over/under booking of the sum of the SAP bandwidth compared to the port/LAG bandwidth. See 16.36 “To configure bandwidth CAC on an access SAP for services or a LAG” (p. 625).

The goal of the CAC function is to ensure that the sum of the admin SAP bandwidth on a port or LAG does not exceed the admin bandwidth configured on that port or LAG. This ensures there is sufficient bandwidth available on the associated port or LAG before a SAP is operationally up.

This feature is supported for SAPs on all 7x50 platforms with FP2-and higher hardware on the following service sites:

- VPLS
- VPRN
- MVPLS
- EPIPE
- IPIPE
- IES

The admin bandwidth is an abstract value which could represent either the ingress or egress bandwidth; the bandwidth is a statically configured value; there is no attempt to use any dynamic bandwidth information associated with a SAP, port or LAG.

An admin bandwidth can only be configured on a SAP connected to a port or LAG which itself has an admin bandwidth configured. When a LAG is configured, the admin bandwidth and booking factor on its constituent ports are ignored.

The NFM-P tracks the requested and available bandwidth per port or LAG; where the available bandwidth is equal to the admin bandwidth on the port or LAG, with the booking factor applied, minus the sum of admin bandwidth configured on its SAPs. The SAP bandwidth CAC state is maintained on a port or LAG basis as long as the NFM-P can associate a SAP to the port or LAG. The NFM-P will perform a server validation to make sure the booking bandwidth is not more than the available bandwidth.

16.8 SONET/SDH and TDM port encapsulation

16.8.1 Overview

SONET/SDH and TDM ports can be configured as connection termination points in SAPs and IP interfaces. They can be channelized.

An access port is used for customer-facing traffic on which services are configured. SAPs can only use an access port. When a port is configured for access mode, the appropriate encapsulation type must be specified to distinguish the services on the port.

You must configure the Encap Type parameter from the General tab at the connection termination point. SONET/SDH or TDM ports or channels support the following encapsulation types, depending on the MDA type:

- BCP Null
- IPCP
- BCP Dot1 Q
- FR — Support multiple services using the DLCI header to distinguish services
- ATM — Support multiple services using the VCI or VPI of the PVC
- PPP Auto
- CEM

MTU size considerations apply to SONET/SDH and TDM channels. See 16.5.9 “MTU size and port configuration” (p. 573) in 16.1.2 “Working with port and channel objects” (p. 565) for more information.

16.9 SONET clear channel applications

16.9.1 Overview

Ports on OC-*n* cards can be used for SONET clear channel applications. SONET or TDM clear channel applications allow you to create a full channel on a port which can be configured as access or network mode for SONET and access only for TDM. For example, when you create a 16 × OC3 SFP card, 16 ports are created. You can create one full channel on each of these ports. For more information about the 4 × OC3/STM1 ASAP SFP and 4 × Channelized OC3/OC12 ASAP SFP adapter cards for clear channel support, see 16.9.2 “OC3/STM1 clear channel support on the 7705 SAR-8 and 7705 SAR-18” (p. 579) in this section.

STS-192/48/12/3 clear channel applications use the following syntax:

```
card slot/daughtercard/port.STSType
```

For example, the clear channel STS-12 on slot 4, MDA 1, port 1 is named 4/1/1.sts12

The following table lists available SONET channel applications and parameters for clear channel, sub-channel, and TDM applications.

Table 16-2 SONET channel parameters

Applications	Channel ranges								
	STS-192	STS-48	STS-3	STS-1	DS3	DS1	DS0	E1	DS0
SONET Clear channel	1	1	1		1				
SONET Sub channel			1 to 4	1 to 3	1	1 to 28	1 to 24	1 to 21	2 to 32
TDM					1	1 to 28	1 to 24	1 to 21	2 to 32

16.9.2 OC3/STM1 clear channel support on the 7705 SAR-8 and 7705 SAR-18

The 7705 SAR-8 and 7705 SAR-18 support the 4 × OC3/STM1 ASAP SFP card. The 4 × OC3/STM1 ASAP SFP card has four SFP-based ports that can be independently configured for ATM in access mode or for Packet over SONET/SDH (POS) in network mode. Each port can be independently configured to be SONET (OC3) or SDH (STM1) framing. See 16.11 “ATM encapsulation” (p. 581) in this section for more information. The interface must be configured as UNI. The transmit clock rate for a port can be device- or loop-timed.

Note: Channels on the 4 × OC3/STM1 ASAP SFP adapter card cannot be configured as IES SAPs.

The section trace (J0) byte can be configured by the operator to check the physical cabling. The port can activate and deactivate local line and internal loopbacks. The MTU size for a 4-port OC3/STM1 ASAP SFP access port is fixed at 1572 for ATM encapsulation.

CSM activity switches for a 4-port OC3/STM1 ASAP SFP card on the 7705 SAR-8 and 7705 SAR-18 are hitless on the data path.

The 7705 SAR-8 and 7705 SAR-18 support the 4 × Channelized OC3/OC12 ASAP SFP adapter card. In OC3 mode, the card supports path sts3 under SONET and path sts3 with payload sts3 under SDH for clear channel POS and network APS. In OC12 mode, the card supports sts3 and sts12 under SONET and SDH for clear channel POS and network APS.

The 7705 SAR-8 and 7705 SAR-18 support the 2-port OC3/STM1 ASAP SFP card. The 2-port OC3/STM1 ASAP SFTP card has two SFP-based ports (optical or electrical) that can be configured for ATM/IMA or TDM in access mode or for MLPPP in access or network mode. The port type must be configured to be either SONET (OC3) or SDH (STM1).

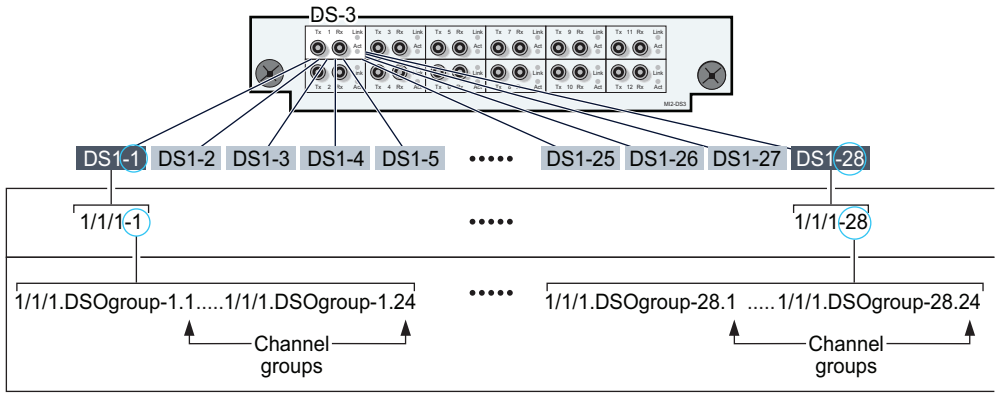
16.10 TDM channelization and clear channel applications

16.10.1 Overview

When you create a 4 or 12 × DS3/E3 card, 4 or 12 DS3/E3 ports are created. You can then create DS3/E3 channels using the NFM-P, one per port. Each DS3/E3 channel can be channelized into 28 independent DS1 or 21 independent E1 data channels or, in clear channel applications, the DS3 can be the connection termination point. For channelized DS3 connections, each DS1 channel can be channelized to 24 DS0 groups and each E1 channel can be channelized to 31 DS0 groups. To use a DS1 or E1, you must create at least one DS0 group for the DS1 or E1.

By default, DS3 ports are automatically created for clear channel connections. To create a channelized DS3, you must configure the DS3 channel type as E3 or DS3 on the port. To channelize the DS3 to the DS0 level, you must set the Channelization Type to Channelized DS1 or E1. The following figure shows the channelized DS3 port structure for DS1 channels.

Figure 16-3 Channelized 12 × DS3 port structure for DS1 Channels



The channelized DS3 port structure for E1 channels has the following parameter values:

- each DS3 port supports 21 E1 channels
- each E1 channel supports 31 DS0 channel groups

TDM-based DS3 channelization uses the following syntax:

DS3 channel configured for TDM:

```
card slot/daughtercard/port.DS3-
```

DS1 channel from a TDM-based DS3 channel:

```
slot/daughtercard/port.DS1-[DS3#].[DS1#]
```

E1 channel from a TDM-based DS3 channel:

```
slot/daughtercard/port.DS1-[DS3#].[E1#]
```

DS0 group channel from the DS1 channel:

```
slot/daughtercard/port.DS0Grp-[STS3#].[STS1#].[DS1#/E1#].[Group#]
```

The following table provides an example of the naming conventions for a 12 × DS3 port.

Table 16-3 Example of TDM channel naming convention

Syntax	Description	Additional information
Channel 1/1/1.ds3	1/1/1 is the slot number/daughtercard number/port number .ds3 identifies the channel as DS3	Because DS3s are unchannelized by default, you must configure the Channelization Type as Channelized.

Table 16-3 Example of TDM channel naming convention (continued)

Syntax	Description	Additional information
Channel 1/1/1.ds1-1.2	.ds1 identifies the channel as DS1 1 is the DS3 number .2 is the DS1 number (1 to 28)	Identifies the DS1 channel and shows how the DS3 level acts as a place holder for the DS1s.
Channel 1/1/1.e1-1.2	.e1 identifies the channel as E1 1 is the DS3 number .2 is the E1 number (1 to 21)	Identifies the E1 channel and shows how the DS3 level acts as a place holder for the E1s.
Channel 1/1/1.ds0Grp-1.2.23	.ds0Grp- identifies the channel as a DS0 group 1 is the DS3 number .2 is the DS1 number (1 to 28) or E1 number (1 to 21) .23 identifies the DS0 channel group (1 to 24) on the DS1 or (2 to 32) on the E1	The DS0 group is configured on the DS1 or E1 channel. Only a DS0 can be used as a CTP.

16.11 ATM encapsulation

16.11.1 Overview

SONET/SDH clear channels can be provisioned so that ATM cells are encapsulated in SONET/SDH frames. The entire SONET/SDH path of the port is then used to carry ATM cells. The channel of the port becomes the ATM interface. ATM encapsulation is supported on the following daughter cards:

- 16 × ATM OC3 SFP
- 16 × ATM OC3 SFP B
- 4 × ATM OC12/OC3 SFP
- 4 × ATM OC12/OC3 SFP B
- 4 × OC3/STM1 ASAP SFP
- 4 × Any Service Channelized OC3
- 16 × Any Service Channelized DS1/E1

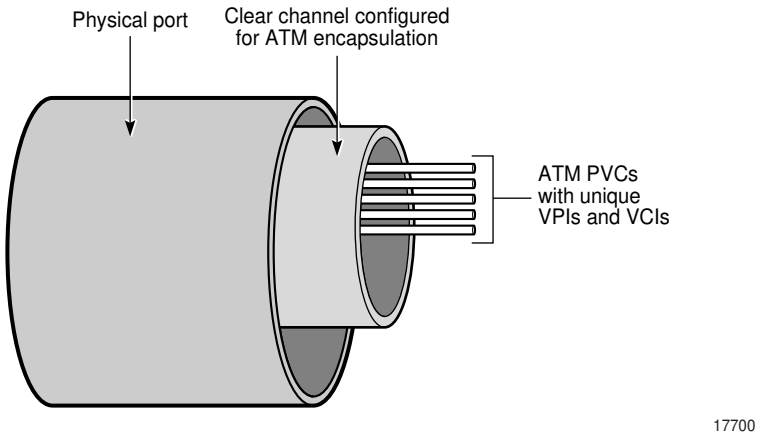
SONET/SDH clear channel applications with ATM encapsulation use the following syntax:

```
Daughter Card Slot - 3 (16 × ATMOC3), OK
Port 3/1/1 - Speed: OC3, State: OK
Channel 3/1/1.sts3, Mode: Access, Encap: ATM, State: Ok
```

Customer devices with ATM interfaces are connected directly or using the ATM access network to a 7750 SR that offers IES or VPRN services.

A SONET/SDH clear channel with ATM encapsulation can carry multiple ATM PVCs. ATM PVCs cannot be created from the NFM-P. They are created automatically by the router when a new Layer 3 interface over ATM is created. The following figure shows an example of ATM PVCs on a SONET/SDH clear channel.

Figure 16-4 ATM PVCs on a SONET/SDH clear channel



16.11.2 ILMI links between ATM interfaces

ILMI links can be configured between ATM interfaces. ILMI is a protocol that sets and sends physical layer, ATM layer, virtual path, and virtual channel parameters that are exchanged by ATM interfaces.

When ILMI is run between two ATM interfaces, the interfaces exchange ILMI packets that consist of SNMP messages across the physical connection. An ILMI link allows ILMI to run on an available virtual channel. When an ILMI link is created to carry ILMI messages, a PVC is automatically created with default PVC attributes. The PVC is deleted when the ILMI link is removed.

16.11.3 IMA

IMA is supported on channelized ASAP MDAs on the 7750 SR, 7705 SAR. For Wavence device IMA support, see the *NSP Wavence Device Support Guide*.

IMA group bundles aggregate E1 or DS1 ATM paths into a single logical ATM interface. Each IMA group bundle can have from 1 to 8 members, or links. Up to 56 IMA group bundles can be configured on a single 7750 SR MDA. Up to 8 IMA group bundles can be configured on a single 7705 SAR daughter card.

Each ATM Interface supports up to 48 VP/VC connection points. Each 16 × E1 ASAP Access (ETSI) board supports up to 128 VP/VC connection points.

An IMA group bundle has the following common interface properties:

- ATM encapsulation type is displayed on the ATM Interface properties form by clicking on the “Edit ATM button”.
- MTU value (of the primary link)

Member links inherit the common properties of the IMA group to which they belong. Only the properties of the primary link can be changed. The primary link is the member with the lowest interface index or initialization sequence. The primary link may change as member links are added and deleted from the IMA group.

Consider the following when you create a multilink IMA group bundle.

- When a path becomes a member of an IMA group bundle, it is no longer a physical ATM path interface.
- The members of the IMA group bundle inherit all of the properties of the primary link, such as the SONET configuration and MTU. If you modify the configuration of the primary link, the configuration of the bundle members is also modified.
- Member links that are added after the primary link has been added to the IMA group bundle must match the configuration of the primary link.
- You cannot configure services on a member link.

16.12 Workflow to manage port objects

16.12.1 Purpose

The following workflow describes the sequence of high-level tasks required to manage and configure port objects. This workflow assumes that the physical devices have been installed, commissioned, and discovered. See Chapter 8, “Device commissioning and management” for more information about device commissioning. See Chapter 9, “Device discovery” for more information about device discovery.

Note: After they are configured, port objects can be accessed using the equipment navigation tree. See Chapter 3, “NFM-P navigation tree” for more information about using the equipment navigation tree. for more information.

16.12.2 Stages

1

As required, configure Ethernet ports; see 16.24 “To configure Ethernet ports” (p. 599) .

2

As required, change the port mode; see 16.29 “To change the port mode” (p. 611) .

3

As required, migrate SAPs from access mode to hybrid mode; see 16.30 “To migrate SAPs from access mode to hybrid mode” (p. 612) .

4

As required, configure the NFM-P to retain non-default port MTU values; see 16.31 “To configure the NFM-P to retain non-default port MTU values” (p. 613) .

5

As required, copy or move L2 access interface SAPs between ports; see 16.32 “To copy or move L2 SAPs between ports” (p. 614) .

6

As required, move L3 access interface SAPs within or between ports on the same NE; see 16.34 “To move L3 SAPs within or between ports or LAGs on the same NE” (p. 620) .

7

As required, move L3 subscriber interface SAPs between ports on the same NE; see 16.35 “To move L3 subscriber interface SAPs between ports on the same NE” (p. 623) .

8

As required, configure the bandwidth CAC function on a port or LAG; see 16.36 “To configure bandwidth CAC on an access SAP for services or a LAG” (p. 625) .

9

As required, add a queue group to an Ethernet port; see 16.37 “To add a queue group to an Ethernet port” (p. 627) .

10

As required, configure SONET ports; see 16.39 “To configure SONET ports” (p. 631) .

11

As required, configure an HSMDA port scheduler override; see 16.40 “To configure an HSMDA override” (p. 632) .

12

As required, configure TDM DS3 ports; see 16.41 “To configure TDM DS3 ports” (p. 633) .

13

As required, configure serial ports; see 16.42 “To configure serial ports” (p. 634) .

14

As required, configure PW ports; see 16.43 “To configure PW ports” (p. 634) .

15

As required, configure ports on 7210 SAS devices, as follows:

a. Configure a 7210 SAS-M channelized TDM DS1 or E1 port; see 16.44 “To configure a 7210 SAS-M channelized TDM DS1 or E1 port” (p. 635) .

b. Assign policies to a 7210 SAS Ethernet port; see 16.45 “To assign QoS policies to a 7210 SAS Ethernet port” (p. 636) .

c. Configure an SHG for 7210 SAS NEs; see 16.46 “To create a 7210 SAS SHG” (p. 638) .

d. Configure PoE ports on supporting 7210 SAS NEs; see 16.49 “To configure PoE ports on a 7210 SAS” (p. 641) .

16

As required, configure ports on 7705 SAR devices, as follows:

a. virtual Ethernet ports on a 7705 SAR 2-port ring MDA; see 16.47 “To configure a virtual Ethernet port on a 7705 SAR 2-port ring MDA” (p. 639) .

b. PoE ports on a 7705 SAR; see 16.52 “To configure PoE ports on a 7705 SAR” (p. 644) .

c. GPS on a 7705 SAR; see 16.53 “To configure GPS on a 7705 SAR” (p. 645) .

d. 7705 SAR ASAP channelized TDM port; see 16.54 “To configure a 7705 SAR ASAP channelized TDM port” (p. 646) .

17

As required, configure the following on OmniSwitch devices:

a. OmniSwitch Ethernet ports; see 16.56 “To configure OmniSwitch Ethernet ports” (p. 647) .

b. OmniSwitch PoE ports; see 16.57 “To configure OmniSwitch PoE Ports” (p. 650) .

SONET and SDH sub-channel applications and structure

16.13 Overview

16.13.1 SONET sub-channel applications

SONET sub-channel applications allow you to create multiple STS-1 channels on deep channelized OC-12 and OC-3 ports, and to configure multiple DS0 connection termination points.

An STS-1 sub-channel is configured, or channelized, to carry one of the following payload types:

- DS3
- VT1.5
- VT2

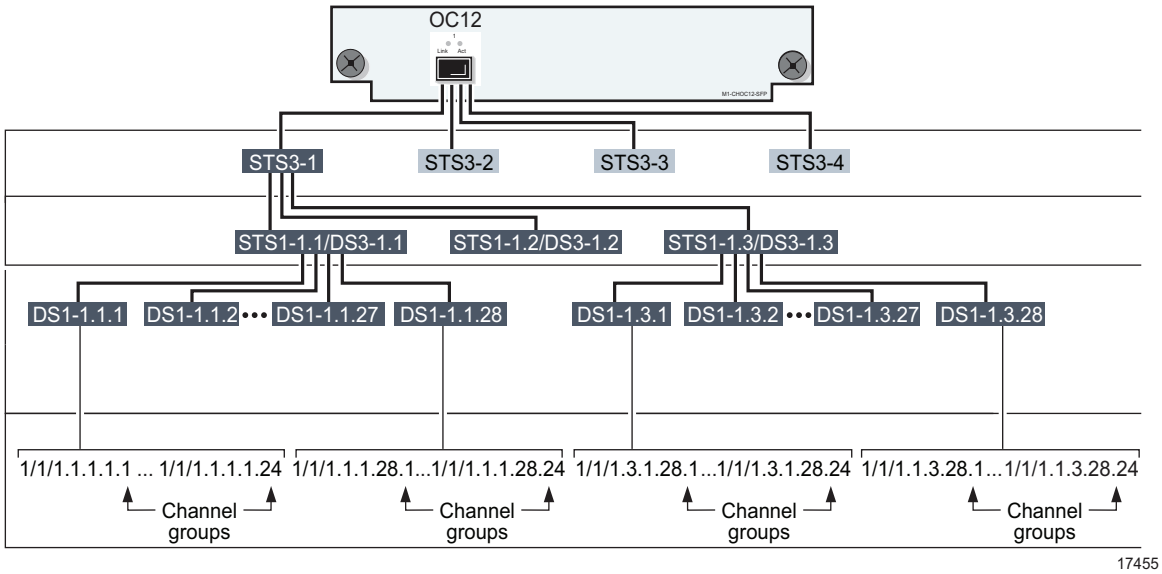
Because of the differences between SONET and SDH in multiplexing and mapping of tributary payloads into higher digital levels, some building blocks of SDH have no SONET equivalent and therefore the containment hierarchy and terminology for SDH is different from SONET. See 16.15 “Comparison of SONET and SDH hierarchies” (p. 589) and 16.16 “SDH AU-4 and AU-3 sub-channel applications” (p. 590) in this section.

16.13.2 SONET DS3 payload

The following example, illustrated in Figure 16-5, “Channelized 1 × OC-12 port structure using STS-1/DS3 sub-channels” (p. 587) , shows the channelization sequence for a DS3 payload on a 1 × OC12 Deep Channel card.

1. One OC-12 port is created when you create a channelized 1 × OC12 Deep Channel card.
2. This port can be channelized into 12 SONET STS-1 sub-channels from the four STS-3s available on the port.
3. You can then configure each of these STS-1s to carry a DS3 frame
4. Each DS3 frame can be channelized into 28 independent DS1 data channels or 21 independent E1 data channels. Each channel must be created one at a time.

Figure 16-5 Channelized 1 × OC-12 port structure using STS-1/DS3 sub-channels

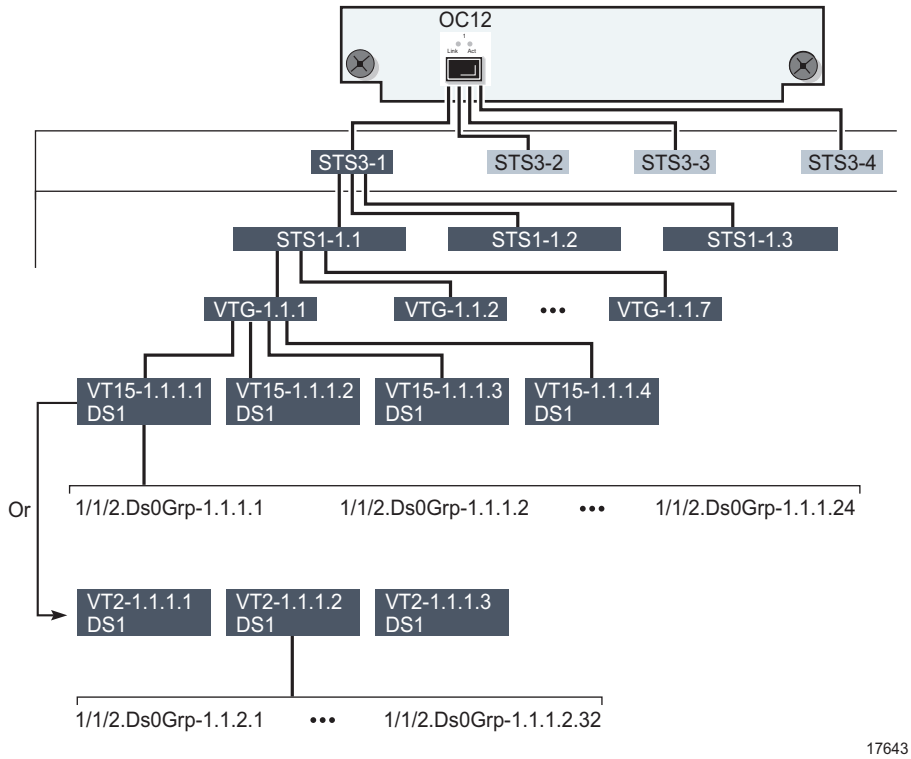


16.13.3 SONET VT1.5 and VT2 payloads

The following example, illustrated in Figure 16-6, “Channelized 4 × OC-3 port structure using VT sub-channels” (p. 588) , shows the channelization sequence for a VT1.5 or VT2 payload on a 1 × OC12 Deep Channel card.

1. One OC-12 port is created when you create a channelized 1 × OC12 Deep Channel card.
2. This port can be channelized into 12 SONET STS-1 sub-channels from the four STS-3s available on the port.
3. You can then configure each of these STS-1s to be channelized to carry up to 28 DS1. For SONET sub-channel configuration you must select payload type VT1.5 or VT2. When you choose VT1.5 payload type, seven VTG are implicitly created.
4. Each VTG is channelized into four independent VT1.5 channels or three VT2 channels, each of which can carry an independent DS1 data channel. Each channel must be created one at a time.
5. Each VT1.5 DS1 channel can be configured to handle up to 24 DS0 groups. Each VT2 DS1 channel can be configured to handle up to 32 DS0 groups. To use a DS1, you must create at least one DS0 group for the DS1 or E1.

Figure 16-6 Channelized 4 × OC-3 port structure using VT sub-channels



16.14 SONET sub-channel syntax

16.14.1 Syntax examples

The NFM-P uses the following SONET syntax for the STS-1 sub-channel:

```
card slot/daughtercard/port.STS1-[STS3#].[STS1#]
```

DS3 channels from an STS-1 sub-channel use the following syntax:

```
slot/daughtercard/port.DS3-[STS3#].[STS1#]
```

DS1 channels from a DS3 channel use the following syntax:

```
slot/daughtercard/port.DS1-[STS3#].[STS1#].[DS1#]
```

E1 channels from a DS3 channel use the following syntax:

```
slot/daughtercard/port.DS1-[STS3#].[STS1#].[E1#]
```

VT15 or VT2 from a VT group use the following syntax:

```
slot/daughtercard/port.VTG#-[STS3#].[STS1#]
```

DS1 channels from a VT15 or VT2 use the following syntax:

```
slot/daughtercard/port.DS1-[STS3#].[STS1#].[VT15#] or [VT2#}.[VTG#].[DS1#]
```

Table 16-4 Example of SONET sub-channel syntax for an OC-12 port

Syntax	Description	Additional information
Channel 1/1/1.sts1-2.2	1/1/1 is the slot number/daughtercard number/port number 2 is the STS-3 number (1 to 4) .2 is the STS-1 number (1 to 3)	The sts1 parameter is 2.2 which means that it is the fifth STS-1. There are four STS-3s for an OC-12 and each STS-3 has three STS-1s such that the fifth STS-1 is the second STS-1 of the second STS-3.
Channel 1/1/1.ds3-2.2	.ds3-2 is the STS3 number (1 to 4) .2 identifies the STS-1 number (1 to 3)	Identifies the DS3 channel and shows how the sts1 level acts as a place holder for the DS3
Channel 1/1/1.ds1 2.2.25	.ds1-2.2.25 identifies a DS1 channel (1 to 28) on the DS3	The DS1 is configured on the DS3.
Channel 1/1/1.e1 2.2.21	.e1-2.2.21 identifies a E1 channel (1 to 21) on the DS3	The E1 is configured on the DS3.
Channel 1/1/1.DS0Grp-2.2.20.5	.DS0Grp-2.2.20.5 identifies one of the DS0 channel groups: 1 to 28 for DS1; 2 to 32 for E1	The DS0 is configured on the DS1 or E1 channel.
Channel 1/1/1.ds1 2.2.3.18	ds1 2.2.3.18 identifies a DS1 channel on the VT15 or VT2 payload, where 3 is the VT group.	—

16.15 Comparison of SONET and SDH hierarchies

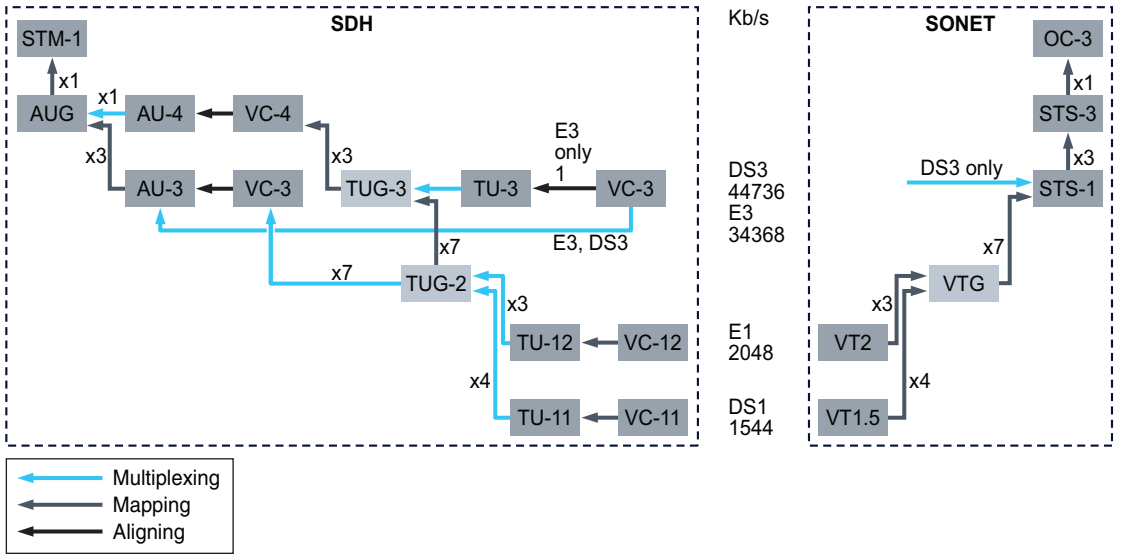
16.15.1 Overview

SONET and SDH are compatible digital hierarchies that support identical transmission rates with similar framing structures. However, SONET and SDH standards differ in the way they multiplex and map tributary payloads into higher digital levels. Because of these differences, some SDH framing blocks do not have equivalent blocks in SONET.

SONET provides one STS sub-channel, the STS-1, for mapping lower-capacity, deep-channel payloads while SDH provides two alternative sub-channels, the AU3 and the AU4. After an AU3 sub-channel is created, an AU4 cannot be created on that port in the case where the port is an OC-3 (STM-1). Conversely, if an AU4 sub-channel is created, an AU3 cannot be created on that port in the case where the port is an OC-3 (STM-1).

SONET and SDH transmission rates converge at 155.520 Mb/s where the SONET STS-3c is equivalent to the SDH STM-1 bit rate. For lower-capacity payloads, such as DS1, E1, DS3, and E3, SONET provides one unique mapping path for each payload while SDH permits two alternative paths for each payload as shown in the following figure.

Figure 16-7 Supported SONET/SDH multiplexing structures



17610

16.16 SDH AU-4 and AU-3 sub-channel applications

16.16.1 Overview

SDH sub-channel applications allow you to create AU4 or AU3 channels on deep channelized OC-12 (STM-4) and OC-3 (STM-1) ports, and to configure multiple DS0 connection termination points.

After an AU4 sub-channel is created, it implicitly contains three TUG-3 groups. A TUG-3 is channelized to carry one of the following payload types:

- TU3
- TU11
- TU12

After an AU-3 sub-channel is created, it is channelized to carry one of the following payload types:

- DS3, E3
- TU11
- TU12

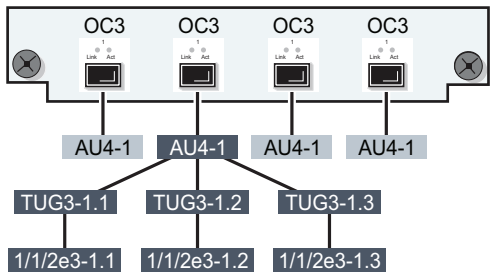
16.17 SDH TU3 payload

16.17.1 Overview

The following example, illustrated in Figure 16-8, “Channelized 4 × OC-3 port structure using AU4/TU3 sub-channels” (p. 590) , shows the channelization sequence for a TU3 payload on a 4 × OC3 Deep Channel card.

1. Four OC-3 ports are created when you create a channelized 4 × OC3 Deep Channel card.
2. The user creates each required AU4 sub-channel.
3. Each AU4 sub-channel implicitly contains three TUG3 groups.
4. You can then configure each TUG3 to carry a TU3 frame
5. Each TU3 frame is channelized into an independent E3 data channel and cannot be changed.

Figure 16-8 Channelized 4 × OC-3 port structure using AU4/TU3 sub-channels



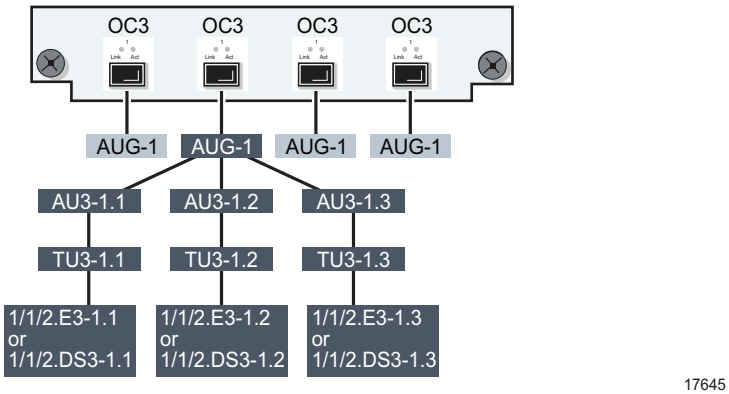
16.18 SDH E3 or DS3 payload

16.18.1 Overview

The following example, illustrated in Figure 16-9, “Channelized 4 × OC-3 port structure using AU3/E3 sub-channels” (p. 592) , shows the channelization sequence for an E3 or DS3 payload on a 4 × OC3 Deep Channel card using AU3 sub-channels.

1. Four OC-3 ports are created when you create a channelized 4 × OC3 Deep Channel card.
2. Each port can be channelized into up to three AU3 sub-channel.
3. Each AU3 frame can be channelized into an independent E3 or DS3 data channel.

Figure 16-9 Channelized 4 × OC-3 port structure using AU3/E3 sub-channels



16.19 SDH TU11 and TU12 payloads

16.19.1 Overview

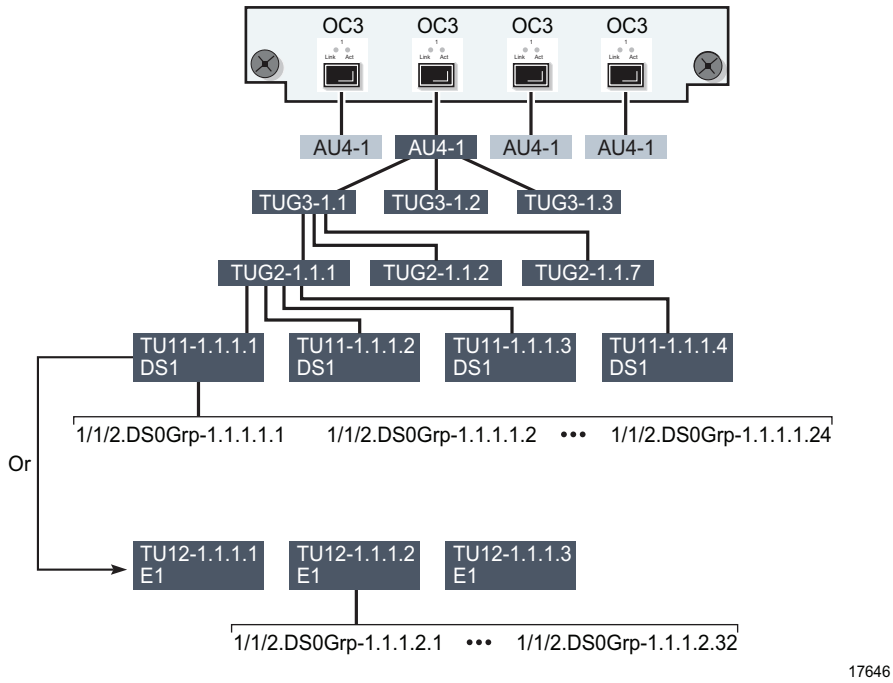
TU11 and TU12 payloads can be channelized using an AU4 sub-channel or an AU-3 sub-channel. An AU4 sub-channel implicitly contains three TUG3 groups. A TUG3 and an AU3 channelized to carry TU11 or TU12 payloads implicitly contain seven TUG2 tributary groups.

The following example, illustrated in Figure 16-10, “Channelized 4 × OC-3 port structure using AU4/TU sub-channels” (p. 593) , shows the channelization sequence for a TU11or a TU12 payload on a 4 × OC3 Deep Channel card.

1. Four OC-3 ports are created when you create a channelized 4 × OC3 Deep Channel card.
2. Each port can be channelized into one AU4 sub-channel or three AU3 sub-channels.
3. Each AU4 sub-channel implicitly contains three TUG3 groups.
4. You can then configure each TUG3 group or each AU3 sub-channel to carry a TU11 or TU12 payload.
5. Each TUG3 group or AU3 sub-channel implicitly contains seven TUG2 tributary groups.
6. Each TUG2 group can be channelized into three independent TU12 channels or four independent TU11 channels.
7. Each TU12 can contain an E1 or DS1 data signal. Each TU11 can contain a DS1 data signal. Each E1 can be configured to handle up to 31 DS0 groups. Each DS1 can be configured to handle up to 24 DS0 groups. To use an E1 or a DS1, you must create at least one DS0 group for the DS1 or E1.

Note: On the same TUG3 or AU3, you cannot mix TU-1*X* with DS1 and E1 payload types. Every TU-1*X* on the same TUG3 or AU3 must use the same payload type, either E1 or DS1, not a mix of both. The mix is shown in for illustrating the structure.

Figure 16-10 Channelized 4 × OC-3 port structure using AU4/TU sub-channels



16.20 Workflow to manage channel objects

16.20.1 Purpose

The following workflow describes the sequence of high-level tasks required to manage and configure channel objects. This workflow assumes that the physical devices have been installed, commissioned, and discovered, and that the port objects have been configured. See Chapter 8, “Device commissioning and management” for more information about device commissioning. See Chapter 9, “Device discovery” for more information about device discovery.

Note: After they are configured, channel objects can be accessed using the equipment navigation tree. See Chapter 3, “NFM-P navigation tree” for more information about using the equipment navigation tree.

16.20.2 Stages

1

As required, configure SONET clear channels; see 16.60 “To configure SONET clear channels” (p. 653) .

2

As required, create channels on ports for card types that support multiple sub-channels; see 16.61 “To perform a bulk channel creation on ports that support multiple sub-channels” (p. 654) .

3

As required, configure SONET sub-channels; see 16.62 “To configure SONET sub-channels” (p. 655) .

4

As required, configure SDH sub-channels; see 16.63 “To configure SDH sub-channels” (p. 657) .

5

As required, create VT15 (TU11) or VT2 (TU12) sub-channels; see 16.64 “To create VT15 (TU11) or VT2 (TU12) sub-channels” (p. 660) .

6

As required, create TDM DS1 channels; see 16.67 “To create serial channels” (p. 665) .

7

As required, configure TDM DS1 or E1 channels; see 16.66 “To configure TDM DS1 or E1 channels” (p. 663) .

8

As required, configure serial channels; see 16.67 “To create serial channels” (p. 665) .

9

As required, create TDM DS3 channels; see 16.68 “To create TDM DS3 channels” (p. 666) .

10

As required, configure TDM DS3 channels; see 16.69 “To configure TDM DS3 channels” (p. 668) .

11

As required, configure a DS3 or E3 channel as a network interface on a channelized ASAP MDA; see 16.70 “To configure a DS3/E3 channel as a network interface on a channelized ASAP MDA” (p. 671) .

12

As required, configure an L3 interface on a DS3 or E3 channel on a channelized ASAP MDA; see 16.72 “To configure an L3 interface on a DS3/E3 channel on a channelized ASAP MDA” (p. 674) .

13

As required, configure a PVC; see 16.73 “To configure a PVC” (p. 676) .

14

As required, create an ILMI link; see 16.74 “To create an ILMI link” (p. 677) .

15

As required, modify an ILMI link; see 16.75 “To configure an ILMI link” (p. 678) .

Procedures for port configuration

16.21 To configure 1830 VWM ports

16.21.1 Steps

1

On the equipment tree, expand Network→1830–VWM-OSU NE→Shelf→Card Slot→Port object and choose Properties. The Physical Port (Edit) form opens.

2

Configure the Description parameters on the General tab.

3

Click on the States tab and configure the Administrative State parameter.

4

Click on the Media Adaptor tab and view the parameters listed. You can verify the parameters using the device CLI.

5

Click on the Port Specifics tab, and configure the required parameters.

- Configure the Topology String 1 and Topology String 2 parameters.
- Configure the AINS timer parameter.

  The AINS timer can be configured at the system level or at the port level. By default, all ports are AINS enabled and align to the AINS timer set by the system timer.

If you are configuring for the 1830 VWM TLU–200, configure the TLU–200 Specifics parameters.

6

Save your changes and close the form.

END OF STEPS

16.22 To configure Ethernet LAN ports on the 1830 VWM OSU and 1830 VWM SMM

16.22.1 Steps

1

On the equipment tree, expand Network→1830–VWM NE→Shelf→Card Slot→Port object and choose Properties. The Physical Port (Edit) form opens.

2

Configure the Description parameters on the General tab.

3

Click on the States tab and configure the Administrative State parameter.

4

Click on the Media Adaptor tab and view the parameters. You can verify the parameters using the device CLI.

5

Click on the Port Specifics tab and configure the required parameters.

The AINS timer can be configured at the system level or at the port level. By default, all ports are AINS enabled and align to the AINS timer set by the system timer.

6

Perform one of the following:

a. For an 1830 VWM OSU, configure the Interface role from the drop-down menu.

   If Userdata is selected as the Interface Role, the TPID parameter is enabled. The TPID parameter is not available if you set the Interface Role parameter to Normal.

b. For an 1830 VWM SMM, configure the MAU and Userdata parameters.

7

Save your changes and close the form.

END OF STEPS

16.23 To configure connector ports and breakout ports

16.23.1 Before you begin

Connector ports are indicated in the equipment tree by the letter c preceding the port number; for example, 10/1/c1/. Each connector port has the capability to support multiple Ethernet breakout ports.

DWDM channel and coherent optics are supported under connector ports and OTU is supported under breakout ports.

Depending on the NE and release, the tabs and parameters displayed may vary.

16.23.2 Steps

1

On the equipment tree, expand Network→*NE*→Shelf→Card Slot *n*→Daughter Card Slot *n*→Port *n/n/n*.

For XIOM-s, expand Network→*NE*→Shelf→Card Slot *n*→Xiom Card Slot *n*→Daughter Card Slot *n*→Port *n/n/n/n*.

2

Right-click on the Port icon and choose Properties. The Connector Port (Edit) form opens.

3

Configure the required parameters.

Use the Connector Breakout Type parameter to configure the number and class of Ethernet ports to be housed by the connector port. For example, c4-10g indicates four 10 GB Ethernet ports.

For FP4-based QSFP28 MDAs on 7x50 NEs, the configuration of breakout connector types c1-10g and c1-25g (or just c1-10g for E4 platforms) implies you will be installing an adapter with a SFP+ or SFP28 optical module.

When you enable the CFP2-DCO parameter, the Coherent Optics tab becomes enabled and the Optical Transport Channel Unit tab becomes enabled under breakout port.

You can only set the DWDM channel after you enable the CFP2-DCO parameter. After you select the DWDM channel the wavelength and frequency associated with the channel are automatically populated. You cannot configure the DWDM channel under the General tab if frequency is configured under the DWDM Optics tab.

For 400G ZR optical module support, DWDM must be configured on 400G ZR QSFP-DD and DCO must be enabled on the transceiver before NFM-P DWDM and coherent optical configuration.

For the x2-1000g-wdm XMA, the CFP2-DCO parameter does not appear, as DWDM and coherent optics are supported by default.

4

To configure the center frequency and view the minimum/maximum frequencies and supported frequency grid for a particular optical module, click the DWDM Optics tab and configure the required parameters.

You cannot configure the frequency here if the DWDM channel is configured under the General tab. DWDM channel and frequency configuration are mutually exclusive.

5

As required, configure the breakout ports.

1. Right-click on the port icon for the breakout port on the equipment tree and choose Properties. The Physical Port (Edit) form opens.
2. Configure the required parameters.
3. Save your changes and close the form.

6

To view information about the SFP, click on the Media Adaptor tab.

7

To enable coherent optics, click on the Coherent Optics tab and configure the required parameters.

8

Save your changes and close the form.

END OF STEPS

16.24 To configure Ethernet ports

16.24.1 Note

Before you can configure 802.1X on an Ethernet access port, 802.1X must be enabled on the device and an 802.1X policy must be created and distributed to the device.

See 12.17 “To enable or disable 802.1X” (p. 353) for information about enabling 802.1X on a device. See Chapter 59, “802.1x policies” for information about creating and distributing 802.1X policies.

Depending on the NE and release, the navigation to the Physical Port form or the tabs and parameters displayed may vary.

16.24.2 Steps

1

On the equipment tree, expand Network→*NE*→Shelf→Card Slot *n*→Daughter Card Slot *n*→Port *n/n/n*.

2

Right-click on the Port icon and choose Properties. The Physical Port (Edit) form opens.

3

Configure the required general parameters.

Only one MAC address can be assigned to a port. When a new MAC address is configured while the port is operational, IP issues an ARP, if appropriate, and BPDUs are sent with the new MAC address. A default MAC address is assigned by the system.

If the port is a LAG member, the Hold Time Up (seconds) parameter is configurable only if the port is the primary member. The Hold Time Down (seconds) parameter is not configurable when the port is a LAG member.

When you set a DWDM Channel, the other DWDM parameters are populated. You cannot configure the DWDM channel if frequency is configured under the DWDM Optics tab. DWDM channel and frequency configuration are mutually exclusive.

The DDM Event Suppression parameter is configurable only on ports on SFPs and XFPs optical modular transceivers.

You cannot change the Mode parameter when the Enable DEI parameter is selected.

When you set the Mode parameter to Hybrid, you cannot set the Encapsulation Type parameter to Null.

The MTU value for a port is associated with the port mode and the port encapsulation type. By default, the MTU of a hybrid port is set to the larger of the network and access MTUs.

You cannot deselect the Enable DEI parameter on a port when SAPs on that port are configured with color-aware meters. If you deselect the Enable DEI parameter, the ingress policies assigned to SAPs on the port must be configured with meters whose Color Mode parameter is set to Color Blind. See 50.29 “To configure a 7210, 7250, and 1830 SAP Access Ingress policy” (p. 1544) .

Consider the following when you configure the Enable DEI parameter on a hybrid port.

- When the Enable DEI parameter is selected, the network policy assigned to the port must be configured to use DEI as the profile. The Default FC Profile parameter and the Profile parameter on the Ingress Dot1p tab in the policy must be set to the DEI option. See 50.42 “To configure a 7210 and 1830 network policy” (p. 1571) .
- You cannot select Enable DEI and assign a DEI-configured network policy in the same configuration process. You must first assign the network policy with the Default FC Profile and Profile parameters set to the DEI option, and apply the change. Then you can subsequently select the Enable DEI parameter.

4

If you set the Mode parameter to Hybrid, configure the required parameters in the Hybrid Ingress Buffer Allocation and the Hybrid Egress Buffer Allocation panels, as required.

5

If you change the Mode parameter from Access to Hybrid and there are SAPs on the port, perform 16.30 “To migrate SAPs from access mode to hybrid mode” (p. 612) to migrate the SAPs.

6

If you are configuring a 7210 SAS Ethernet port, you can add the port to an SHG on supporting NEs. See 16.46 “To create a 7210 SAS SHG” (p. 638) for information about creating an SHG.

Note: A port cannot be added to or deleted from an SHG if it has a SAP configured on it or is a member of a LAG.
A port cannot belong to more than one SHG; you must remove any SHGs from the port before you can add the port to a different SHG.

7

Configure the Named Pool Buffer Policy for the port in the Named Buffer Pool panel.

1. Select an Ingress Pool Policy.
2. Select an Egress Pool Policy.
3. Configure the required parameters.

   Note:

Ensure that the named pool mode is enabled. See 15.67 “To enable named pool mode” (p. 526) in Chapter 15, “Shelf and card object configuration” for more information.

8

Click on the States tab and configure the required parameters.

9

Click on the Policies tab.

Note: The types of policies that you can choose depend on the type of NE, daughter card, and the mode type of the port you are configuring.

- The Network Queue and Accounting Policies panel are only displayed for network and hybrid ports.
- The Port Scheduler panel is only displayed for ports on non-HSMDA daughter cards.
- The HSMDA Egress Scheduler panel is only displayed for ports on HSMDA daughter cards. HSMDA is only supported on 7750 SR-7/12/12e and 7450 ESS-7/12, Release 20.10 and earlier.

10

Select an accounting policy for the port, if applicable.

11

Configure the Collect Accounting Statistics parameter, if required.

12

If you are configuring an access port on a 7210 SAS-E for the collection of packet forwarding statistics on egress queues, configure the required parameters in the Egress Packets Forwarding panel.

For the 7210 SAS-E, access ports always contain eight queues. You can enable up to eight queues on any port for the collection of packet forwarding statistics. However, only eight counters can be enabled for each 7210 SAS-E device. If no queues are enabled on a port, no accounting statistics are collected for that port.

13

If you are configuring a 7210 SAS Ethernet port, perform 16.45 “To assign QoS policies to a 7210 SAS Ethernet port” (p. 636) , then go to Step 20 .

14

Select a network queue policy for the port, if applicable.

15

Select a 7250 SROS Port QoS policy for the port, if applicable.

16

Select a port scheduler policy for the port, if applicable.

17

Select a port scheduler policy override for the port, if applicable.

1. Click Create in the Port Scheduler Policy Override panel. The Port Scheduler Policy Override form opens.
2. Click on the Override tab.
3. Configure the Override, MAX, CIR, and PIR parameters for each required level.
4. Save your changes and close the form.

18

Configure the Collect Stats parameter in the Port Scheduler Monitor panel, if required.

19

Select a scheduler policy for the port, if applicable.

20

Click on the DDM tab to view digital diagnostics monitoring information, if required.

21

Click on the Media Adaptor tab to view information about the SFP, if required.

22

If you are configuring a 7705 SAR-Wx and the port supports DSL, the DSL tab is displayed. Configure DSL.

1. Click on the DSL tab.
2. Configure the required parameters.
3. Click on the XDSL Line tab.
4. Choose an XDSL line and click Properties. The XDSL Line (Edit) form opens.
5. Configure the Administrative State parameter.
6. Save your changes and close the form.
7. Repeat 2 to 6 to configure more lines, if required.

23

Click on the Ethernet tab.

24

Configure the required parameters.

For access or hybrid ports on the 7210 SAS-X, configure the SAP QoS Marking parameter to enable or disable SAP-based remarking.

For hybrid ports on the 7210 SAS-K12 and 7210 SAS-K30, configure the Egress Network Aggregate Shaper Rate parameter.

The RS-FEC Mode parameter is configurable in the NFM-P for supported physical ports and breakout ports. The RS-FEC Mode is configurable for physical ports under the Ethernet tab. For breakout ports, the RS-FEC Mode parameter is configurable either under the Ethernet tab of the breakout port or under the General tab of its connector port. After the RS-FEC Mode is configured, the RS-FEC Oper Mode can be viewed in the General tab.

On the 7210 SAS-X, configure the Egress Scheduler Mode parameter to choose FC-based or SAP-based scheduling for access ports.

For access ports on supporting 7210 SAS NEs, configure overrides for queues in the Port Access Egress policy assigned to the port; see50.100 “To configure QoS policy overrides on port access egress queues for a 7210 SAS” (p. 1660).

For 7210 SAS NEs, ports can forward multicast data packets to either L2 or L3 interfaces, but not both. Configure the Multicast Ingress parameter according to your forwarding requirements.

Management connectivity between the NFM-P and the 7705 SAR may be lost if a line loopback is applied to an Ethernet port that is carrying in-band management traffic. The line loopback remains in effect until the timer expires and the 7705 SAR removes the loopback.

Statistics are collected for IEEE 1588 PTP timestamps only when the Timestamp Capable parameter is enabled on the 7705 SAR-A, 7705 SAR-Ax, and the 7705 SAR-W.

If you are configuring a 7705 SAR-Wx and the port supports DSL, the EFM-OAM tab appears. Perform the required steps in 90.49 “To configure an 802.3ah EFM OAM diagnostic test from an NE Properties form” (p. 3069) to configure the EFM-OAM tab.

On the 7250 IXR, the Timed Loopback Type parameter must be configured while enabling Swap Mac Address. Internal loopback is only supported in access or hybrid mode, and line loopback is supported in access or network mode. You cannot configure the Timed Loopback Type parameter when the Received Remote Loopback Requests parameter is set to Processed.

Select the Hardware Aggregate Shaper Scheduler policy.

25

Configure a port loopback on a 7210 SAS device.

1. If you are configuring a port loopback with MAC swap, you must first configure a no-service loopback port. See 12.46 “To configure a no-service loopback port on the 7210 SAS” (p. 378) .
2. Set the Type parameter to Internal. See Step 24 .
3. Select a SAP in the SAP panel.
4. In the MAC panel, configure the required parameters.

26

For supported 7210 SAS devices, associate the port with an operational group. See 12.9 “To configure a 7210 SAS operational group” (p. 346) for information about 7210 SAS operational groups.

Perform one of the following:

a. For an L2 uplink port, assign the port to an operational group. Select an operational group in the Oper Group panel.

b. For an access port, choose an operational group to monitor. Select an operational group in the Oper Group panel.

27

If you are configuring an Ethernet port on a 2-port ring MDA on a 7705 SAR-8 or 7705 SAR-18, select a VLAN filter.

28

If you are configuring a 7705 SAR Ethernet port, select a Shaper policy in the Shaper Policy panel as required.

Note: When the port mode is access, the Shaper policy can be associated with the access egress of the port. When the port mode is hybrid, the Shaper policy can be associated with the access egress and network egress.

29

If you are configuring a 7705 SAR Ethernet port, configure Ethernet Bandwidth Notification as required. See 16.48 “To configure Ethernet Bandwidth Notification on a 7705 SAR Ethernet port” (p. 640) for more information.

Note: ETH-BN can only be enabled if the egress rate is configured.

30

To transparently forward LACP packets, enable the LACP Tunnel parameter, as required.

31

Configure the Dot1x Tunneling Enabled parameter, as required.

32

In the Synchronous Ethernet panel, configure the required parameters.

33

In the E-LMI panel, configure the required parameters.

34

In the CRC Failure panel, configure the required parameters.

35

In the Oper Group panel, configure the required parameters.

36

Select the sFlow check box to enable sFlow on the Ethernet port. See 12.29 “To configure sFlow on an NE” (p. 364) for more information.

37

If the port is an access or hybrid port with QinQ or dot1q encapsulation, or a network port with dot1q encapsulation, the MEPs tab is displayed. Add a facility MEP, if required.

Note: Only one facility MEP can be configured on a port.

1. Click on the MEPs tab.
2. Click Create. The MEP (Create) form opens.
3. Select a global MEG for the MEP.

   Note:

   For port-based facility MEPs, the Maintenance Domain must be set for a Level of 0 or 1. See 91.15 “To configure an Ethernet CFM MD policy and subordinate objects” (p. 3109) for information on creating the MD.
4. Configure the required parameters.

   Only the parameters that are supported on the NE, daughter card, or port are displayed.

   You cannot enable the collection of LMM statistics on a LAG facility MEP or on a tunnel facility MEP if a service MEP is already configured to collect the LMM statistics information.

   To enable fault propagation on a LAG facility MEP or on a tunnel facility MEP, the Facility Fault Notify parameter must be enabled.

   To link the facility tunnel status to the SAP, the Facility VLAN ID parameter must match the outer encapsulation value of the SAP.

   The CCM Padding Packet Size (Bytes) parameter cannot be configured when the CCM interval parameter is set to 10 ms or 100 ms.
5. If the MD for the MEP has a Name Type of none the Y.1731 Tests tab is configurable. Click on the Y.1731 Tests tab and configure the required parameters.
6. Save your changes and close the form.

38

Click on the EFM-OAM tab to configure and initiate the 802.3ah EFM OAM diagnostic as described in 90.49 “To configure an 802.3ah EFM OAM diagnostic test from an NE Properties form” (p. 3069) . Otherwise, continue to Step 40 .

39

To configure Ethernet link monitoring on the port, perform 90.53 “To configure link monitoring on an Ethernet port” (p. 3080) .

40

Click on the 802.1x Port and 802.1x Port Authenticator tabs, and configure the required parameters.

You can enable the Tunneling parameter only when:

- the port is in access mode
- the Controlled Port Control parameter is set to Force Authorized
- the port is not used as a SAP (except in an Epipe service)

Configure the RADIUS Server Policy Authentication and RADIUS Server Policy Accounting parameters to associate a RADIUS server policy to the Ethernet port.

For 7250 IXR-x1/xs/x3 NEs, Release 21.5.R1 and later, and for 7250 IXR-6d/6dl NEs, Release 22.7.R1 and later, you can only enable the Per Host Authentication State parameter when the forwarding path options for Ethernet 802.1x host authentication are enabled on the NE Properties form. See 12.57 “To configure forwarding path options or resource allocation on a 7250 IXR” (p. 388) .

You can click on the Per Host Authentication sub-tab to configure Allowed Source MACs and view authenticated hosts. The configured MAC addresses do not take part in authentication and are always allowed.

41

Go to 16.37 “To add a queue group to an Ethernet port” (p. 627) to add a queue group to the port.

42

If the port is an HSMDA access port, the Egress Secondary Shapers tab is present. Add an egress secondary shaper, if required.

Note: An HSMDA port is initially created with a default egress secondary shaper. The default shaper cannot be deleted, but it can be modified.
Non-default egress secondary shapers can only be created if the port’s Mode parameter is not set to the network option.
You cannot switch the Mode of an HSMDA port to network if there are non-default egress secondary shapers on that port. An error message will be issued. You must delete any non-default egress secondary shapers from the port before switching its Mode to network.

1. Click on the Egress Secondary Shapers tab.
2. Click Create. The HSMDA Egress Secondary Shaper (Create) form opens.
3. Configure the required parameters.
4. Click on the Classes tab.
5. Configure the Class Rate (kbps), Class Monitor Threshold (Kbytes) and Class Burst Threshold (bytes) parameters for Classes 1 through 8, as required.
6. Save your changes and close the form.

43

Click on the LLDP tab and configure the required parameters on the Nearest Bridge, Nearest Customer, and Nearest Non TPMR sub-tabs.

Care must be taken when configuring the Port ID SubType parameter, as the setting may affect the ability to build the Layer 2 topology map using LLDP. See the NE documentation for more information.

44

Click on the Remote Peers sub-tab under the LLDP tab to search for and display LLDP remote peers associated with the port. These remote peers are used to determine the physical topology of the network.

45

Configure a QoS pool, if required.

1. Click on the QoS Pool tab.
2. Choose a QoS pool from the list and click Properties. The QoS Pool (Edit) form opens.
3. Select a slope policy for the QoS pool.
4. Configure the required parameters.
5. Save your changes and close the form.

46

Click on the Override Policy Items tab to configure HSMDA overrides, if required. See 16.40 “To configure an HSMDA override” (p. 632) for more information.

47

To configure the center frequency and view the minimum/maximum frequencies and supported frequency grid for a particular optical module, click the DWDM Optics tab and configure the required parameters.

You cannot configure the frequency here if the DWDM channel is configured under the General tab. DWDM channel and frequency configuration are mutually exclusive.

48

To configure a tunable optic DWDM MDA or IMM on a 7750 SR or 7450 ESS, click on the Optical Transport Channel Unit tab and configure the required parameters.

49

Click on the OTU Alarms tab and select the OTU alarms for the Configured Alarms parameter.

50

Select a DWDM channel. The tabs and parameters that appear depend on the supported NE.

51

Click on the Optical tab and configure the required parameters.

52

Click on the Optical Amplifier tab and configure the Configured Alarms parameter.

53

Click on the Optical Tunable Dispersion Compensation Module tab and configure the required parameters.

54

Save your changes and close the form.

55

To configure coherent optics options for a 1-Port 100GE OTU4 DWDM tunable optic IMM on a 7750 SR or 7450 ESS, click on the Coherent Optics tab and configure the required parameters.

56

Click on the Operational Status tab to view information about the state of the optical port.

57

Save your changes and close the form.

END OF STEPS

16.25 To configure LLDP-MED

16.25.1 Before you begin

LLDP-MED (Media Endpoint Discovery) is an extension to LLDP to support interoperability between VoIP endpoint devices and other networking end-devices. LLDP-MED is focused mainly on discovery running between network devices and endpoints such as IP phones.

LLDP-MED configuration is supported only on 7210 SAS-S/Sx from Release 20.9 R1 onwards and on 7210 SAS-Dxp from Release 22.3 R1 onwards.

16.25.2 Steps

1

On the equipment tree, expand Network→NE→Shelf→Card Slot n→Daughter Card Slotn→Port n/n/n.

2

Right-click on the Port icon and choose Properties. The Physical Port (Edit) form opens.

3

Click on the LLDP tab and then on Nearest Bridge tab.

4

Click on the LLDP MED sub-tab and configure the required parameters.

Associate LLDP network policies. To create LLDP MED Network Policy, See 16.26 “To configure LLDP MED Network Policy” (p. 608)

5

Save your changes and close the forms.

END OF STEPS

16.26 To configure LLDP MED Network Policy

16.26.1 Steps

1

Choose Administration→LLDP MED Network Policy from the NFM-P main menu. The LLDP MED Network Policy form opens.

2

Configure the required parameters.

3

Save your changes and close the form.

END OF STEPS

16.27 To configure a cellular port on a 7705 SAR-Hm

16.27.1 Before you begin

SIM cards must be installed in the 7705 SAR-Hm before the cellular ports can be configured.

16.27.2 Steps

1

On the equipment tree, expand Network→7705 SAR-Hm→Shelf→Card Slot 1→Daughter Card Slot 1→Port 1/1/1.

2

Right-click on the Port icon and choose Properties. The Physical Port (Edit) form opens.

3

Configure the required general parameters.

The Mode and Encapsulation Type parameters are set to Network and Cellular, respectively, by default. These parameters cannot be changed.

4

Click on the States tab and configure the required parameters.

5

Click on the Cellular tab and configure the required parameters.

1. A PDN profile must be configured. See Chapter 69, “PDN profile policies” for more information.
2. To configure SIM switchover behaviour, click on the SIM Cards tab and configure the required parameters.

   The length of time configured for the Fail Duration (Min) parameter specifies when to perform an automatic failover from one SIM to the other. Set the Fail Duration (Min) parameter to a value lower than the Down Recovery Interval (Min) parameter on the cellular MDA, or a node reboot will happen instead of a SIM switchover.
3. View port bearer and port traffic flow template details by performing the following:
   - Click on the PortBearer tab, select a bearer in the list, and click Properties. The Cellular Port Bearer form opens.
   - Click on the PortTFT tab, select a traffic flow template from the available list, and click Properties. The Port Traffic flow Template (TFT) form opens.
4. To enable the 7705 SAR-Hmc to operate as a CBSD category A/B device in the CBRS spectrum band, click on the CBSD tab and configure the required parameters.

6

Click on the Statistics tab and perform one of the following:

a. Click Collect to collect performance statistics data on demand. The collected statistics are listed on the form.

b. Click Collect All to collect one on-demand statistics record for each statistic type that the object supports. The collected statistics are listed on the form.

7

Save your changes and close the form.

END OF STEPS

16.28 To configure a WLAN port on a 7705 SAR-Hm

16.28.1 Steps

1

On the equipment tree, expand Network→7705 SAR-Hm→Shelf→Card Slot 1→Daughter Card Slot 4→Port 1/4/1.

2

Right-click on the Port icon and choose Properties. The Physical Port (Edit) form opens.

3

Configure the required general parameters.

4

Click on the WLAN tab and then click on the Network tab.

5

Click Create. The Wlan Network (Edit) form opens.

Configure the required parameters and click OK. The Access Point is created.

6

If required, configure the Access Point parameters:

1. Select the Access Point and click Properties.
2. Configure the parameters and click OK.
3. Click Apply.

7

If required, configure the Station parameters.

8

Save your changes and close the forms.

END OF STEPS

16.29 To change the port mode

Note: Save the device configuration before you perform this procedure. See the appropriate NE documentation for more information.

16.29.1 Steps

1

On the equipment tree, expand Network→*NE*→Shelf→Card Slot *n*→Daughter Card Slot *n*→Port *n/n/n*.

2

Right-click on the Port icon and choose Properties. The Physical Port (Edit) form opens.

3

Change the Mode parameter as required and click Apply.

4

If you are changing the mode from Access to Network and services are configured on the port, warnings are displayed in a dialog box, depending on the permissions that are associated with your user role. Perform one of the following:

a. The default warning dialog indicates that the object has dependencies that will be deleted if you apply the port mode change.
   1. Click on View Dependencies button to see the dependencies (services and interfaces) associated with the port.
   2. Click OK to confirm the configuration change.

      Any services and interfaces associated with the port, including SAPs, are deleted, and the mode for the port is changed to Network.

      Note:

      Changing the port mode from Access to Network without first removing the dependencies results in a TopologyMisconfigured alarm.

b. For users who have the port.RestrictNodeConfigModify permission associated with their role, a warning form appears, indicating that the object has dependencies that must be removed before proceeding.
   1. Click on View Dependencies button to see the dependencies (services and interfaces) associated with the port.
   2. Click OK to confirm the configuration change.
   3. Remove the services or interfaces associated with the port. You can manually delete them or move them to other ports as described in this chapter.
   4. Repeat Step 2 and Step 3 to change the port mode to Network.

5

Save your changes and close the form.

END OF STEPS

16.30 To migrate SAPs from access mode to hybrid mode

Note: Save the device configuration before you perform this procedure. See the appropriate NE documentation for more information.

16.30.1 Steps

1

On the equipment tree, expand Network→*NE*→Shelf→Card Slot *n*→Daughter Card Slot *n*→Port *n/n/n*.

2

Right-click on an Ethernet port or SC-LAG port icon and choose Properties. The Physical Port (Edit) form opens.

3

Change the Mode parameter from Access to Hybrid. A dialog box opens.

4

Click OK to confirm the configuration change.

5

Perform an admin save.

6

Save your changes and close the form.

End of steps

16.31 To configure the NFM-P to retain non-default port MTU values

16.31.1 Before you begin

The MTU value for a port is associated with the port mode, such as access or network, and the port encapsulation type. If you change the mode or encapsulation type of a port, the MTU value changes to the associated default. If you do not want the port MTU values to change, you can use this procedure to configure the NFM-P to retain each port MTU value, regardless of a mode or encapsulation type change.

Note: You must perform this procedure on each main server in a redundant NFM-P deployment.

16.31.2 Steps

1

Log in to the NFM-P main server station as the nsp user.

2

Navigate to the /opt/nsp/nfmp/server/nms/config directory.

3

CAUTION

Service Disruption

Contact your Nokia technical support representative before you attempt to modify the nms-server.xml file. Modifying the nms-server.xml file can have serious consequences that can include service disruption.

Open the nms-server.xml file using a plain-text editor.

4

Add the following line to the end of the file:

```
<customMTURefresh refresh="true"/>
```

5

Save and close the nms-server.xml file.

6

Open a console window.

7

Navigate to the /opt/nsp/nfmp/server/nms/bin directory.

8

If the main server is a standalone server, or the primary server in a redundant deployment, enter the following:

```
bash$ ./nmsserver.bash read_config ↲
```

The main server reads the nms-server.xml file and puts the configuration change into effect.

9

If the main server is the standby server in a redundant deployment, enter the following:

```
bash$ ./nmsserver.bash force_restart ↲
```

The main server restarts and puts the configuration change into effect.

10

Close the console window.

END OF STEPS

16.32 To copy or move L2 SAPs between ports

16.32.1 Before you begin

Note: If the source SAP has an MEP configured, and a CFM test is running on the service that has the new MEP, the test must be stopped and executed again to make the new MEP active.

Before you perform a SAP move operation, archive all existing test results associated with the source SAP MEP.

You can also use the NFM-P clipboard to copy or move SAPs. See Chapter 1, “NFM-P GUI” for information about using the NFM-P clipboard.

16.32.2 Steps

1

For the source NE, disable automatic configuration backup if it is enabled in the backup policy assigned to the NE. Configure the Auto Backup Scheme parameter appropriately. See 23.4 “To configure a backup policy” (p. 746) for configuration information.

2

CAUTION

Service Disruption

An unsuccessful SAP copy or move may result in the deletion of one or more source SAPs from the source NE. The backed-up configuration file is required to restore the configuration on the source NE if a SAP copy or move operation fails.

On the source NE, use a CLI to back up the device configuration to a file. Ensure that you use a unique name for the backup file to ensure that it is not accidentally overwritten. Enter the following at the CLI prompt:

`admin save file_name` ↵

where *file_name* is a name that differs from the existing configuration file names on the NE and identifies this as the configuration in effect before the copy or move operation

See the appropriate device documentation for more information about saving the device configuration to a file.

3

For the destination NE, disable automatic configuration backup if it is enabled in the backup policy assigned to the NE. Configure the Auto Backup Scheme parameter appropriately. See 23.4 “To configure a backup policy” (p. 746) for configuration information.

4

On the destination NE, use a CLI to back up the device configuration to a file. Ensure that you use a unique name for the backup file to ensure that it is not accidentally overwritten. Enter the following at the CLI prompt:

`admin save file_name` ↵

where *file_name* is a name that differs from the existing configuration file names on the NE and identifies this as the configuration in effect before the copy or move operation

See the appropriate device documentation for more information about saving the device configuration to a file.

5

CAUTION

Service Disruption

Nokia strongly recommends that you monitor the NE deployments and the alarm window during a SAP copy or move operation to ensure that faults that may arise during the operation are immediately detected.

The Incomplete Deployments tab of the Deployment form notifies the NFM-P operator of configuration changes that are not successfully deployed to the NE, and the NFM-P alarm window alerts the operator to object failures on the NE that are related to the copy or move operation.

Open the Deployment form to monitor deployments as they occur during the SAP copy or move operation. Choose Administration→NE Maintenance→Deployment from the NFM-P main menu. The Incomplete Deployments tab is displayed.

6

Choose Tools→Copy/Move→SAP. The SAP Copy/Move form opens.

7

Arrange the forms on the GUI so that the SAP Copy/Move form, the Deployment form, and the alarm window are all shown.

8

On the SAP Copy/Move form, click on the Result tab and then click Result Export Path. The Result Export Path form opens.

9

Specify the file name and location in which to save a text file that contains the results of the SAP copy or move operation.

10

Click Set. The Result Export Path form closes.

11

On the SAP Copy/Move form, click on the General tab.

12

Configure the Current Mode parameter as L2 Access Interface.

13

Configure the Service Type parameter.

14

Select a source node and a source port in the Source panel.

15

Configure the Outer Encap Value Start and Outer Encap Value End parameters, and the Inner Encap Value Start and Inner Encap Value End parameters, if applicable.

16

Select a destination node and a destination port in the Destination panel.

17

Configure the required parameters in the Execution Details panel.

18

Click Execute to begin the copy or move operation. The Execution Result panel displays the execution state of the copy or move operation and the number of successful and failed operations based on the input criteria.

Note: When you copy or move a SAP on an L2 interface and there is a non-zero value assigned to the PIM Snooping parameter Maximum Number of Groups, the value is not copied or moved to the new location. You must manually configure the Maximum Number of Groups parameter in the new location.
The Succeeded state only specifies that the SAP copy or move operation is successfully committed to the database. After the SAP copy or move operation is executed, you must monitor the Deployment form for any deployment errors.

19

Monitor the Deployments form and the alarm window for any deployment failures and faults related to the SAP copy or move operation. Click Refresh on the Deployments form to update the list, if required.

20

Click on the Result tab to view a list of the successful and failed operations as identified by the NFM-P.

You can double click the result to open it in a new window and view the details.

21

Click Refresh Result to view the most recent results.

22

To view the information for an individual SAP copy or move operation, move the mouse pointer over the Message field of the operation.

23

If a copy or move operation fails, you can restore the previous source NE configuration using the backup configuration file created in Step 2 .

1. Open a CLI on the source NE.
2. Enter the following at the command prompt to load the saved configuration file:

   exec *file_name* ↵

   where *file_name* is the name of the configuration file that was specified in Step 2

   The SAPs that were deleted during the unsuccessful copy or move operation are restored on the NE.
3. Enter the following at the command prompt to save the NE configuration:

   admin save ↵

24

If a copy or move operation partially fails, you can restore the previous destination NE configuration using one of the following methods.

Note: If the copy or move operation fails completely, there is no need to restore the previous configuration because no SAPs are created on the destination NE.

a. Restore the backed-up configuration file.
   1. Open a CLI on the destination NE.
   2. Enter the following at the command prompt to load the saved configuration file:

      exec *file_name* ↵

      where *file_name* is the name of the configuration file specified in Step 4

      The previous configuration is restored on the NE.
   3. Enter the following at the command prompt to save the NE configuration:

      admin save ↵

b. Manually delete the SAPs that the copy or move operation created on the destination NE.

25

Restore the previous automatic configuration backup setting in the backup policy of the source NE by configuring the Auto Backup Scheme parameter appropriately. See 23.4 “To configure a backup policy” (p. 746) for configuration information.

26

Restore the previous automatic configuration backup setting in the backup policy of the destination NE by configuring the Auto Backup Scheme parameter appropriately. See 23.4 “To configure a backup policy” (p. 746) for configuration information.

27

Close the form.

END OF STEPS

16.33 To copy or move L2 access interface SAPs between services

16.33.1 Before you begin

You can move L2 access interface SAPs between VPLS, MVPLS and VLL services.

Note the following:

- You can move the source SAP only to another service, and not within the same service. You cannot move the source SAP to a different site; it can be moved only to a different service on the same site.
- The source and destination service types must be the same. The source and destination site types (Site, B-Site or I-Site) must be the same.
- The source and destination services must have the same Customer ID.

VPLS L2 access interfaces can be used for MSAPs, access interfaces for SPB in control mode, and throughput tests. When you move an L2 interface, the NFM-P deletes the SAP from the source site. The NFM-P does not check that the source site has consistent configuration after the move, and for example, a throughput test might reference nonexistent SAPs.

16.33.2 Steps

1

Choose Manage→Services→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS, MVPLS, or VLL service and click Properties. The *Service_Type* Service (Edit) form opens.

3

On the service tree, expand Sites→Site→L2 Access Interfaces.

4

Right-click on the L2 access interface that you want to move and choose Move to Another Service. The Select Services form opens with a list of eligible target services.

5

Select a service. The NFM-P moves the L2 access interface SAP to the selected service and removes the service from the from the source service.

6

Close the forms.

END OF STEPS

16.34 To move L3 SAPs within or between ports or LAGs on the same NE

16.34.1 Before you begin

You can also use the NFM-P clipboard functionality to move SAPs. See Chapter 1, “NFM-P GUI” for information about using the NFM-P clipboard.

Note: L3 access interfaces are not bound to a port; for example, loopback interfaces cannot be moved.

16.34.2 Steps

1

For the NE, disable automatic configuration backup if it is enabled in the backup policy assigned to the NE. Configure the Auto Backup Scheme parameter appropriately. See 23.4 “To configure a backup policy” (p. 746) for configuration information.

2

On the NE, use a CLI to back up the device configuration to a file. Ensure that you use a unique name for the backup file to ensure that it is not accidentally overwritten. Enter the following at the CLI prompt:

`admin save` ***`file_name`*** ↵

where *file_name* is a name that differs from the existing configuration file names on the NE and identifies this as the configuration in effect before the move operation

See the appropriate device documentation for more information about saving the device configuration to a file.

3

CAUTION

Service Disruption

Nokia strongly recommends that you monitor the NE deployments and the alarm window during a SAP move operation to ensure that faults that may arise during the operation are immediately detected.

The Incomplete Deployments tab of the Deployment form notifies the NFM-P operator of configuration changes that are not successfully deployed to the NE, and the NFM-P alarm window alerts the operator to object failures on the NE that are related to the move operation.

Open the Deployment form to monitor deployments as they occur during the SAP move operation. Choose Administration→NE Maintenance→Deployment from the NFM-P main menu. The Incomplete Deployments tab is displayed.

4

Choose Tools→Copy/Move→SAP. The SAP Copy/Move form opens.

5

Arrange the forms on the GUI so that the SAP Copy/Move form, the Deployment form, and the alarm window are all shown.

6

Click on the Result Export Path tab.

7

Specify the file name and location in which to save a text file that contains the results of the SAP move operation.

8

Click Set. The Result Export Path form closes.

9

Configure the Current Mode parameter as L3 Access Interface.

10

Configure the Service Type parameter.

11

Select a source node and a source port in the Source panel.

12

Configure the Outer Encap Value Start and Outer Encap Value End parameters, and the Inner Encap Value Start and Inner Encap Value End parameters, if applicable.

13

Select a destination port in the Destination panel.

14

Configure the required parameters in the Execution Details panel.

15

Click Execute to start the move operation. The Execution Result panel displays the execution state of the move operation and the number of successful and failed operations based on the input criteria.

16

Monitor the Deployments form and the alarm window for any deployment failures and faults related to the SAP move operation. Click Refresh on the Deployments form to update the list, if required.

17

Click on the Result tab to view a list of the successful and failed operations as identified by the NFM-P.

You can double click the result to open it in a new window and view the details.

18

Click Refresh Result to view the most recent results.

19

To view the information for an individual SAP move operation, move the mouse pointer over the Message field of the operation.

20

If a move operation fails, you can restore the previous NE configuration using the backup configuration file created in Step 2 .

1. Open a CLI on the NE.
2. Enter the following at the command prompt to load the saved configuration file:

   `exec file_name` ↵

   where *file_name* is the name of the configuration file specified in Step 2

   The SAPs that were deleted during the unsuccessful move operation are restored on the NE.
3. Enter the following at the command prompt to save the NE configuration:

   `admin save` ↵

21

Restore the previous automatic configuration backup setting in the backup policy of the NE by configuring the Auto Backup Scheme parameter appropriately. See 23.4 “To configure a backup policy” (p. 746) for configuration information.

22

Close the forms.

END OF STEPS

16.35 To move L3 subscriber interface SAPs between ports on the same NE

16.35.1 Before you begin

You can also use the NFM-P clipboard functionality to move SAPs. However, you can only move all of the SAPs in a group interface; you cannot move a subset of SAPs. See Chapter 1, “NFM-P GUI” for information about using the NFM-P clipboard.

16.35.2 Steps

1

For the NE, disable automatic configuration backup if it is enabled in the backup policy assigned to the NE. Configure the Auto Backup Scheme parameter appropriately. See 23.4 “To configure a backup policy” (p. 746) for configuration information.

2

On the NE, use a CLI to back up the device configuration to a file. Ensure that you use a unique name for the backup file to ensure that it is not accidentally overwritten. Enter the following at the CLI prompt:

`admin save file_name` ↵

where *file_name* is a name that differs from the existing configuration file names on the NE and identifies this as the configuration in effect before the move operation

See the appropriate device documentation for more information about saving the device configuration to a file.

3

CAUTION

Service Disruption

Nokia strongly recommends that you monitor the NE deployments and the alarm window during a SAP move operation to ensure that any faults that arise during the operation are immediately detected.

The Incomplete Deployments tab of the Deployment form notifies the NFM-P operator of configuration changes that are not successfully deployed to the NE, and the NFM-P alarm window alerts the operator to object failures on the NE that are related to the move operation.

Open the Deployment form to monitor deployments as they occur during the SAP move operation. Choose Administration→NE Maintenance→Deployment from the NFM-P main menu. The Incomplete Deployments tab is displayed.

4

Choose Tools→Copy/Move→SAP. The SAP Copy/Move form opens.

5

Arrange the forms on the GUI so that you can view the entire SAP Copy/Move form, the Deployment form, and the alarm window.

6

Click on the Result Export Path tab. The Result Export Path form opens.

7

Specify the file name and location in which to save a text file that contains the results of the SAP move operation.

8

Click Set. The Result Export Path form closes.

9

Configure the Current Mode parameter as L3 Subscriber Interface SAP.

10

Configure the Service Type parameter.

11

Select a source node and a source port in the Source panel.

12

Select a destination port in the Destination panel.

13

Configure the required parameters in the Execution Details panel.

14

Click Execute to start the move operation. The Execution Result panel displays the state of the move operation, and the number of successful and failed operations based on the input criteria.

15

Monitor the Deployments form and the alarm window for any deployment failures and faults related to the SAP move operation. Click Refresh on the Deployments form to update the list, if required.

16

Click on the Result tab to view a list of the successful and failed operations, as identified by the NFM-P.

You can double click the result to open it in a new window and view the details.

17

Click Refresh Result to view the most recent results.

Note: If one SAP fails, all SAPs under the same group interface fail because the SAPs can only move together. In this case, there is insufficient information to determine which SAP caused the problem using the NFM-P.

18

To view information about an individual SAP move operation, move the mouse pointer over the Message field of the operation.

19

If a move operation fails, you can restore the previous NE configuration using the backup configuration file created in Step 2 .

1. Open a CLI on the source NE.
2. Enter the following at the command prompt to load the saved configuration file:

   exec *file_name* ↵

   where *file_name* is the name of the configuration file specified in Step 2

   The SAPs that were deleted during the unsuccessful move operation are restored on the NE.
3. Enter the following at the command prompt to save the NE configuration:

   admin save ↵

20

Restore the previous automatic configuration backup setting in the backup policy of the NE by configuring the Auto Backup Scheme parameter appropriately. See 23.4 “To configure a backup policy” (p. 746) for configuration information.

21

Close the forms.

End of steps

16.36 To configure bandwidth CAC on an access SAP for services or a LAG

16.36.1 Before you begin

You can configure the bandwidth CAC function on a port or LAG, based on the admin bandwidth configured on a SAP and on an associate port or LAG. In addition, a booking factor is provided to allow over/under booking of the sum of the SAP bandwidth compared to the port/LAG bandwidth. See 16.7 “Configuring access SAP bandwidth CAC” (p. 577) for more information.

16.36.2 Steps

To configure bandwidth CAC for services

1

Choose Manage→Services→Services from the NFM-P main menu. The Manage Services form opens.

2

Click Search and choose a VPLS, VPRN, MVPLS, EPIPE, IPIPE, or IES service and click Properties. The *Service_Type* Service (Edit) form opens.

3

On the service tree, expand Sites→Site→L2 Access Interface or L3 Access Interface.

4

Right-click on the L2 access interface or L3 Access Interface that you want to configure the bandwidth CAC for and click Properties. The *Service_Type* L2 or L3 Access Interface form opens.

5

Click on the Port tab and configure the Mode parameter to Access or Hybrid mode to view the Access Bandwidth panel.

Note: By default, the No Bandwidth parameter is configured in the Access Bandwidth panel which excluded the port from the CAC function.

6

As required, configure the Bandwidth (kbps) and Book Factor (Percentage) parameters.

7

Save your changes and close the forms.

To configure bandwidth CAC for LAGs

8

Choose Equipment from the navigation tree view selector.

9

On the equipment navigation tree, expand Network→*NE*→Logical Groups→LAGs→LAG *n*.

10

Right-click on the LAG *n* object that you want to configure the bandwidth CAC for and choose Properties. The LAG (Edit) form opens.

11

On the General tab, configure the Mode parameter to Access or Hybrid mode to access the bandwidth CAC panel.

12

Click on the Access tab, and as required, configure the Bandwidth (kbps) and Book Factor (Percentage) parameters.

Note: By default, the No Bandwidth parameter is configured in the Access Bandwidth panel which excluded the LAG from the CAC function.

Note: When a LAG is configured, the admin bandwidth and booking factor on its constituent ports are ignored.

13

Save your changes and close the forms.

END OF STEPS

16.37 To add a queue group to an Ethernet port

16.37.1 Before you begin

You can create a port queue group on an Ethernet port after creating an Ingress/Egress Queue Group Template policy.

Note: You must use the same name for the port queue group and Ingress/Egress Queue Group Template policy.

16.37.2 Steps

1

On the equipment tree, navigate to the port object where you need to add a queue group. The path is Network→*NE*→Shelf→Card Slot *n*→Daughter Card Slot *n*→Port *n/n/n*.

2

Right-click on the required Ethernet port icon and choose Properties. The Physical Port (Edit) form opens.

3

Click on the Ethernet tab.

4

Perform one of the following:

a. Click on the Network Egress Queue Group tab.

b. Click on the Access Ingress Queue Group tab.

c. Click on the Access Egress Queue Group tab.

Note: The Network Egress Queue Group tab is available if queue groups are supported on the port, depending on the NE release and IOM type. See 71.1.3 “Port queue groups” (p. 1963) in Chapter 71, “Queue groups” for more information about supported devices and IOM types.

5

Click Create. The Queue Group (Create) form opens.

6

Select a queue group template policy.

7

Configure the required parameters.

8

If you are adding a network egress queue group, go to Step 9 . Otherwise, continue to Step 10.

9

Select a policer control policy.

10

Select an accounting policy.

Note: Only the accounting policies with the Type parameter configured to one of the following options are listed:

- Queue Group Octets
- Queue Group Packets
- Combined Queue Group

11

Configure the Collect Accounting Statistics parameter, if required.

12

Select a scheduler policy.

13

If you are adding an access ingress queue group, go to Step 20 . Otherwise, continue to Step 14 .

14

Configure the required parameters.

The Aggregate Rate Limit (kbps) and Frame-Based Accounting parameters are configurable only if you did not select a scheduler policy. The Frame-Based Accounting parameter is configurable only if you configure the Aggregate Rate Limit (kbps) parameter.

15

If you are adding a network egress queue group (including queue groups for HSMDA), go to Step 20 . Otherwise, continue to Step 16 .

16

Click on the Host Matching tab.

Note: The Host Matching tab is available only if the Instance ID is set to 1.

17

Click Create. The Host String (Create) form opens.

18

Configure the Host String parameter.

19

Click OK. The Host String (Create) form closes and the information on the Host Matching tab is updated.

20

Click on the Overrides: *Type* Queue tab, where *Type* will be Network Egress, Access Egress, or Access Ingress, depending on your selection in Step 4 .

21

Click Create. The Queue Override (Create) form opens.

22

Select a Queue ID.

23

Click on the Override tab.

24

If you are configuring an access egress queue group queue override for HSMDA, then go to Step 28 .

25

Configure the required override parameters.

The Weight and CIR Weight parameters are only applicable to access egress queue group overrides.

The parameters are configurable when the Override check box is enabled.

26

In the Stats panel, configure queue depth monitoring. For more information, see 50.21 “Queue depth monitoring” (p. 1527).

27

Go to Step 30 .

28

Configure the required parameters.

The parameters are configurable when the associated Override check box is enabled.

29

If you need to configure an override for a Slope Policy, enable the associated Override check box and select a slope policy.

30

Save your changes and close the forms.

END OF STEPS

16.38 To configure queue group scheduler overrides

16.38.1 Before you begin

Perform this procedure to override the scheduler values for access ingress or access egress queue groups. The queue groups must already exist. To create queue groups, see 16.37 “To add a queue group to an Ethernet port” (p. 627).

16.38.2 Steps

1

On the equipment tree, navigate to the port object where you need to override the queue group scheduler values. The path is Network→*NE*→Shelf→Card Slot *n*→Daughter Card Slot *n*→Port *n/n/n*.

2

Right-click on the required Ethernet port icon and choose Properties. The Physical Port (Edit) form opens.

3

Click on the Ethernet tab.

4

Perform one of the following:

a. Click on the Access Ingress Queue Group tab.

b. Click on the Access Egress Queue Group tab.

5

Choose a queue group and click Properties. The Queue Group (Edit) form opens.

6

Click on the Overrides: Ingress Scheduler tab or Overrides: Egress Scheduler tab, depending on your selection in Step 4 .

7

Choose a scheduler and click Create Override. The Access Ingress (or Access Egress) Queue Group Scheduler Override (Create) form opens.

8

Click on the Override tab and configure the required parameters.

9

Save your changes and close the forms.

END OF STEPS

16.39 To configure SONET ports

16.39.1 Steps

1

On the equipment tree, navigate to the port object where you want to configure a SONET port. The path is Network→*NE*→Shelf→Card Slot *n*→Daughter Card Slot *n*→Port *n/n/n*.

2

Right-click on a port icon and choose Properties. The Physical Port (Edit) form opens.

3

Configure the required parameters.

The DDM Event Suppression parameter is configurable only on ports on SFPs and XFPs optical modular transceivers.

4

Click on the States tab and configure the Administrative State parameter.

5

Click on the Channels tab to configure the SONET/SDH channel.

a. Click Create to create a new channel.

b. Choose a channel from the list and click Properties to view and edit the channel parameters.

c. Choose a channel from the list and click Delete to remove a channel from the port.

6

Click on the SONET tab and configure the required parameters.

7

Click on the SONET Monitoring tab and configure the required parameters.

8

Click on the SONET Overhead tab and configure the required parameters.

Enter a J0 byte that identifies the circuit. This byte is inserted continuously at source. This can be checked against the expected value by the receiver. If no byte is entered, then null is used. The parameter is configurable when the SONET Section Trace Mode is set to Byte.

The J0 String parameter is configurable when the SONET Section Trace Mode is set to String.

9

Save your changes and close the form.

END OF STEPS

16.40 To configure an HSMDA override

16.40.1 Steps

1

On the equipment tree, navigate to the port object where you want to configure a SONET port. The path is Network→*NE*→Shelf→Card Slot *n*→Daughter Card Slot *n*→Port *n/n/n*.

Select an HSMDA card. HSMDA is only supported on 7750 SR-7/12/12e and 7450 ESS-7/12, Release 20.10 and earlier.

2

Click on the Override Policy Items tab.

3

Click Create. The Port Egress HSMDA Scheduler Policy Override (Create) form opens.

4

Click on the Override tab and configure the required parameters.

The Rate (Mbps) parameter is configurable when a Group is not specified for the applied HSMDA scheduler policy. The Weight in Group parameter is only configurable when Group 1 or Group 2 is specified for the HSMDA scheduler policy.

5

Save your changes and close the forms.

END OF STEPS

16.41 To configure TDM DS3 ports

16.41.1 Steps

1

On the equipment tree, navigate to the port object where you want to configure a TDM DS3 port. The path is Network→*NE*→Shelf→Card Slot *n*→Daughter Card Slot *n*→Port *n/n/n*.

2

Right-click on a port icon and choose Properties. The Physical Port (Edit) form opens.

3

Configure the required parameters on the General tab.

4

Click on the States tab and configure the Administrative State parameter.

5

Click on the DS3/E3 tab and configure the required parameters.

6

Save your changes and close the form.

END OF STEPS

16.42 To configure serial ports

16.42.1 Purpose

Perform this procedure to configure serial ports on a 12 × Serial Data card on the 7705 SAR.

16.42.2 Steps

1

On the equipment tree, navigate to the port object where you want to configure a serial port. The path is Network→*NE*→Shelf→Card Slot *n*→Daughter Card Slot *n*→Port *n/n/n*.

2

Right-click on a port icon and choose Properties. The Physical Port (Edit) form opens.

3

Configure the required parameters.

4

Click on the States tab and configure the Administrative State parameter.

5

Save your changes and close the form.

END OF STEPS

16.43 To configure PW ports

16.43.1 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the PW Ports tab. A list of existing PW ports is displayed.

3

Click Create to create a PW port or choose a port and click Properties. The PW Port (Create|Edit) form opens.

4

Configure the required general parameters.

5

Configure node redundancy for the PW port, if required.

1. Click Node Redundancy. The Manage Node Redundancy form appears, preconfigured for MC peer groups.
2. Click Search and configure an existing MC peer group, or click Create and configure a new MC peer group. See 40.4 “To configure an MC peer group” (p. 1330) .

   The Node Redundancy button allows you to access the MC sync group configuration within the MC peer group in order to add PW port sync tags.

6

Save the changes and close the forms.

END OF STEPS

16.44 To configure a 7210 SAS-M channelized TDM DS1 or E1 port

16.44.1 Steps

1

On the equipment tree, navigate to the port object where you want to configure a 7210 SAS-M channelized TDM DS1 or E1 port. The path is Network→*NE*→Shelf→Card Slot *n*→Daughter Card Slot *n*→Port *n/n/n*.

2

Right-click on a 7210 SAS-M port object that contains a channelized DS1 or E1 and choose Properties. The Physical Port (Edit) form opens.

3

Configure the required parameters.

4

Select a split horizon group.

Note: To create or delete a 7210 SAS SHG, see 16.46 “To create a 7210 SAS SHG” (p. 638) .

5

Click on the DS1/E1 tab and configure the required parameters.

The Line Impedance parameter only appears when the Port Type parameter is set to E1.

6

Click on the QoS Pool tab.

7

Choose a QoS pool from the list and click Properties. The QoS Pool (Edit) form opens.

8

Select a slope policy.

9

Save your changes and close the form.

10

Click on the States tab and configure the Administrative State parameter.

11

Save your changes and close the forms.

END OF STEPS

16.45 To assign QoS policies to a 7210 SAS Ethernet port

16.45.1 Before you begin

Perform this procedure to assign QoS policies to a 7210 SAS Ethernet port, or to enable table-based ingress classification on the port for supporting 7210 SAS NEs.

The policies that can be assigned to a 7210 SAS Ethernet port vary depending on the port mode.

Table 16-5 7210 SAS QoS policies and port modes

7210 SAS QoS policy	Supported port mode
Port scheduler policy	All port modes
Port access egress policy	Access
Network policy (of port type)	L2 uplink, network, hybrid
Network queue policy	L2 uplink, network, hybrid
7210/7250 DSCP classification policy	Access

Support for port modes and policies also varies depending on the chassis type. For more information, see 50.23 “7210 SAS QoS policies” (p. 1528) and the NE documentation.

Slope policies for Ethernet ports are assigned to QoS pools (buffer pools) on the port; see 16.24 “To configure Ethernet ports” (p. 599) .

Network policies of network interface type are assigned to L3 network interfaces; see 27.17 “To create an L3 network interface on a routing instance” (p. 856) and 27.18 “To configure L3 network interfaces” (p. 863) .

When you assign a 7210 and 1830 network policy that has an associated MPLS LSP-EXP classification policy, the port must be in network mode.

For ports on 7210 SAS-K12 NEs, when you assign a 7210 and 1830 network policy that has an associated remarking policy, the port must be in network mode if the remarking policy is one of the following types:

- DOT1P-LSP-EXP
- DOT1P-LSP-EXP-DSCP
- DSCP-LSP-EXP
- LSP-EXP

16.45.2 Steps

1

On the equipment tree, navigate to a configured Ethernet port object on a 7210 SAS device. The path is Network→*NE*→Shelf→Card Slot *n*→Daughter Card Slot *n*→Port *n/n/n*.

2

Right-click on a configured Ethernet port object and choose Properties. The Physical Port (Edit) form opens.

3

Click on the Policies tab, then click on the 7210 Specific tab.

Note: The policies that can be assigned vary depending on the chassis type and port mode.

4

Select a port scheduler policy.

For information about how to create a 7210 and 1830 Port Scheduler policy, see 50.60 “To configure a 7210, 7250 and 1830 Port Scheduler policy” (p. 1601) .

5

Select an access egress policy.

For information about how to create a 7210 and 1830 Port Access Egress policy, see 50.31 “To configure a 7210 and 1830 port access egress policy” (p. 1556) .

6

Configure table-based ingress classification for the port. Perform the following:

1. Configure the parameters in the Ingress Classification Policy panel.
2. Select a 7210/7250 DSCP classification policy in the DSCP Classification Policy panel.

   The selected policy is effective only when the Enable Table Classification parameter is enabled.

For information about how to create a 7210/7250 DSCP classification policy, see 50.85 “To configure a 7210/7250 DSCP classification policy” (p. 1638).

7

Select a network policy.

For information about how to create a 7210 and 1830 Network policy, see 50.42 “To configure a 7210 and 1830 network policy” (p. 1571) .

When the Enable DEI parameter is selected on a hybrid port, the network policy assigned to the port must be configured to use DEI as the profile. The Default FC Profile parameter and the Profile parameter on the Ingress Dot1p tab in the policy must be set to the DEI option. See 50.42 “To configure a 7210 and 1830 network policy” (p. 1571) .

8

Select a network queue policy.

For information about how to create a 7210 and 1830 Network Queue policy, see 50.47 “To configure a 7210 and 1830 network queue policy” (p. 1583) .

9

Save your changes and close the forms.

END OF STEPS

16.46 To create a 7210 SAS SHG

16.46.1 Before you begin

Traffic that arrives on a access or access uplink port or LAG within an SHG is not copied to other ports and LAGs in the same SHG; the traffic is copied to ports and LAGs in other SHGs if they exist within the same VPLS. Ports and LAGs are added to an SHG when you configure a port or LAG on a 7210 SAS. SHGs are not supported for a VPLS instance.

Note: SHG creation is only supported on specific 7210 SAS variants; see the NE documentation for more information.

16.46.2 Steps

1

On the equipment tree, right-click on the device where you want to configure the SHG and select Properties. The Network Element (Edit) form opens.

2

Click on the Split Horizon Groups tab.

3

Click Create. The Split Horizon Group (Create) form opens.

4

Configure the required parameters and click OK.

Note: Only one SHG can be configured per service.
A SHG and a Mesh SDP Binding cannot exist simultaneously on a single service.

5

Repeat Step 3 to Step 4 to add another SHG, if required.

6

Save your changes and close the form.

END OF STEPS

16.47 To configure a virtual Ethernet port on a 7705 SAR 2-port ring MDA

16.47.1 Purpose

Perform this procedure to configure a virtual Ethernet port on a 7705 SAR 2 × 10-Gig Bridged Ethernet XFP + 1 × 2.5G Virtual Ethernet card on a 7705 SAR-8 and 7705 SAR-18. See 50.41 “To configure a QoS network policy” (p. 1568) for information about configuring a network policy of ring type for a 7705 SAR. See 15.78 “To configure an MDA” (p. 536) for information about configuring a ring port on a 7705 SAR 2 × 10-Gig Bridged Ethernet XFP + 1 × 2.5G Virtual Ethernet card.

16.47.2 Steps

1

On the equipment tree, choose Network→*NE*→Shelf→Card Slot *n*→Daughter Card Slot *n*→Virtual Port *n/n/n*, where the virtual port is the port object you need to configure.

2

Right-click on the Virtual Port icon and choose Properties. The Virtual Port (Edit) form opens.

3

Configure the required parameters.

4

Click on the States tab and configure the Administrative State parameter.

5

Click on the Policies tab.

6

Select a network queue policy.

7

Click on the Ethernet tab and configure the required parameters.

You must configure the Down When Looped parameter value as Enabled to see the Down When Looped Configuration panel parameters.

8

Click on the Network Interfaces tab to create a network interface on the virtual Ethernet port.

9

Click Add. The Create Network Interface - Routing Instance form opens. See 27.17 “To create an L3 network interface on a routing instance” (p. 856) for information on creating a network interface.

Note: You can only bind a virtual Ethernet port to a network interface.

10

Save your changes and close the form.

END OF STEPS

16.48 To configure Ethernet Bandwidth Notification on a 7705 SAR Ethernet port

16.48.1 Before you begin

The 7705 SAR can interop with ETH-BN communication from the Wavence SM over Ethernet links (without MWA). ETH-BN is supported on the following ports:

- 8p GigE v1/v2/v3
- XMDA v1/v2
- 8p PMC
- 6p 10GigE/GigE
- Ethernet modules in the 7705 SAR-H and 7705 SAR-M
- Virtual port of Ring MDA and 7705 SAR-M module
- all Ethernet ports for the 7705 SAR-A, 7705 SAR-Ax, 7705 SAR-H, 7705 SAR-Hc, 7705 SAR-M, 7705 SAR-W and 7705 SAR-Wx

ETH-BN enables the detection and extraction of ETH-BN messages to the CSM. If the ETH-BN indicates a new throughput value, the CSM programs the new value into the egress-rate of the port.

The 7705 SAR only supports the client side of ETH-BN. When enabled on a port, the egress rate that previously was a fixed bandwidth, may be dynamically altered based on the available bandwidth indicated by the ETH-BN server.

16.48.2 Steps

1

On the equipment tree, navigate to the port object on the required 7705 SAR NE. The path is Network→*NE*→Shelf→Card Slot *n*→Daughter Card Slot *n*→Port *n/n/n*.

2

Right-click on the required port and choose Properties. The Physical Port (Edit) form opens.

3

Click on the Ethernet tab and enable the Bandwidth Rate Change Notification parameter.

Note: ETH-BN notification can only be enabled if the Egress Rate (kbps) parameter is configured. The maximum egress rate is the native port rate, e.g. 1 Gbit/s, and the minimum egress rate for the port can be as low as 1 kbit/s. Any rate request outside of this range, including 0, cannot be followed. The egress rate setting has a +/- 1% accuracy, as rate conversion to the hardware is necessary. Any request to change less than 1% is ignored.

Note: The bandwidth indicated in the Bandwidth Notification Message from the Wavence SM includes the FCS. You must enable the Egress Rate Include FCS parameter in the Egress Rate panel or the bandwidth will not match the intended rate.

4

To reduce the number of bandwidth changes, configure the Bandwidth Rate Hold Time (seconds) parameter.

Note: Any Bandwidth Notification Message received before the hold-timer expires, after the last bandwidth change, is ignored (not stored).

5

Save your changes and close the forms.

Operational information on the number of BN changes, messages statistics, previous bandwidth value etc. is displayed in the Egress Rate panel and the Ethernet Bandwidth Notification Counters panel.

END OF STEPS

16.49 To configure PoE ports on a 7210 SAS

16.49.1 Before you begin

Some 7210 SAS chassis variants support PoE on specific ports. See the NE documentation for more information about 7210 SAS support of PoE.

You can view information about power consumption and availability on the PoE tab of the shelf properties form for supporting 7210 SAS NEs.

16.49.2 Steps

1

On the equipment tree, navigate to the port object on the required 7210 SAS NE. The path is Network→*NE*→Shelf→Card Slot *n*→Daughter Card Slot *n*→Port *n/n/n*.

2

Right-click on the required port and choose Properties. The Physical Port (Edit) form opens.

3

Click on the PoE tab and configure the PoE Mode parameter.

4

View the information about the PoE connection.

5

Save your changes and close the form.

END OF STEPS

16.50 To enable or disable hardware timestamps for ports on the 7210 SAS

16.50.1 When to use

For ports on the supported 7210 SAS, perform the following to enable or disable hardware timestamps for ingress and egress PTP packets.

16.50.2 Steps

1

On the equipment tree, navigate to the port object on the required 7210 SAS NE. The path is Network→*NE*→Shelf→Card Slot *n*→Daughter Card Slot *n*→Port *n/n/n*.

2

Right-click on the required port and choose Properties. The Physical Port (Edit) form opens.

3

On the General tab, in the PTP panel, configure the Enable PTP Hardware Timestamp parameter.

4

Save your changes and close the form.

END OF STEPS

16.51 To configure MAC or VLAN authentication

16.51.1 Before you begin

Consider the following before you configure MAC or VLAN authentication:

- You cannot configure MAC authentication and VLAN authentication simultaneously on the same port.
- VLAN authentication is supported only on dot1q ports.
- Before you can configure MAC authentication, the system resource profile for the NE must be appropriately configured. See 12.50 “To configure the global system resource profile on a 7210 SAS or 7250 IXR” (p. 380) and 12.51 “To configure a system resource profile policy for the 7210 SAS-R/T/Mxp, 7210 SAS-S/Sx, or 7210 SAS-S/Sx VC” (p. 382).

16.51.2 Steps

1

On the equipment tree, navigate to the port object where you want to configure MAC or VLAN authentication. The path is Network→*NE*→Shelf→Card Slot *n*→Daughter Card Slot *n*→Port *n/n/n*.

2

Right-click on the required port and choose Properties. The Physical Port (Edit) form opens.

3

Click on the 802.1x Port Authenticator tab.

4

Set the Controlled Port Control parameter to Auto.

5

Perform one of the following:

a. To enable MAC authentication, set the MAC Auth Enabled parameter to True.

   Configure MAC Auth Wait parameter.

b. To enable VLAN authentication, set the VLAN Auth Enabled parameter to True.

6

Save your changes and close the forms.

END OF STEPS

16.52 To configure PoE ports on a 7705 SAR

16.52.1 Before you begin

You can configure PoE on a 7705 SAR-H, 7705 SAR-Hc, 7705 SAR-W, and 7705 SAR-Wx.

Note: You can view information about power consumption and availability on the PoE tab of the shelf properties form.

16.52.2 Steps

1

On the equipment tree, navigate to the port object where you want to configure PoE. The path is Network→NE→Shelf→Card Slot→Daughter Card Slot→Port *n/n/n*.

2

Right-click on the port on which you want to configure PoE and choose Properties. The Physical Port (Edit) form opens.

3

Click on the PoE tab and configure the PoE Mode parameter.

4

Save your changes and close the form.

5

If you are configuring a 7705 SAR-H, perform the following steps to configure the PoE power supply source.

1. On the equipment tree, right-click on the 7705 SAR-H device on which you want to configure PoE and choose Properties. The Network Element (Edit) form opens.
2. On the Network Element (Edit) form navigation tree, expand the Shelf object and the Card Slot object.
3. If you are configuring a 7705 SAR-H, Release 6.1 or later, right-click on the Daughter Card Slot object and choose Properties. The Daughter Card Slot (Edit) form opens.

   If you are configuring an earlier release 7705 SAR-H, right-click on the Shelf object and choose Properties. The Shelf (Edit) form opens.
4. Configure the PoE Power Supply Source parameter in the PoE panel.

5. Save your changes and close the form.

End of steps

16.53 To configure GPS on a 7705 SAR

16.53.1 Before you begin

You can configure GPS on the 7705 SAR-8 CSMv2 with shelf v1 and v2, 7705 SAR-18, 7705 SAR-H, and on the following 7705 SAR-Wx variants:

- 4 GigE 4-port xDSL GPS Rx
- 5 GigE GPS Rx
- 5 GigE PoE+ GPS Rx

Only the 7705 SAR-8 CSMv2 with shelf v1 and v2, 7705 SAR-18, and 7705 SAR-Ax support a GPS MDA with a port type that is configurable for GPS, GLONASS, or GPS plus GLONASS.

GLONASS can be enabled on GPS ports of the p1 × GPS Rx module on the 7705 SAR-H and on the i1 × GPS Rx module on the 7705 SAR-Wx (5 GigE PoE+ GPS Rx).

From 7705 SAR Release 8.0 R1 or later, the GNSS MDA can be configured for GPS only mode or both GPS and GLONASS mode, simultaneously. The GLONASS only mode is not supported.

16.53.2 Steps

1

Ensure that the 7705 SAR NE is configured with the appropriate GPS MDA. See 15.78 “To configure an MDA” (p. 536) for more information about configuring an MDA.

2

On the equipment tree, navigate to the port object where you want to configure GPS. The path is Network→NE→Shelf→Card Slot→Daughter Card Slot→Port *n/n/n*.

3

Right-click on the port on which you want to configure GPS and choose Properties. The Physical Port (Edit) form opens.

4

Click on the GPS tab and configure the required parameters.

For the 7705 SAR-8 CSMv2 with shelf v1 and v2, 7705 SAR-18, and 7705 SAR-Ax, Release 8.0 R1 or later, you can configure the Type parameter as GPS only or both GPS and GLONASS, simultaneously. The GLONASS only mode is not supported.

5

Save your changes and close the form.

END OF STEPS

16.54 To configure a 7705 SAR ASAP channelized TDM port

16.54.1 Before you begin

This procedure applies to 7705 SAR channelized TDM DS1/E1 ports and channelized TDM DS3/E3 ports.

16.54.2 Steps

1

On the equipment tree, navigate to the port object where you want to configure a 7705 SAR ASAP channelized TDM port. The path is Network→*NE*→Shelf→Card Slot *n*→Daughter Card Slot *n*→Port *n/n/n*.

2

Right-click on a port object that contains a channelized port (DS1/E1 or DS3/E3) and choose Properties. The Physical Port (Edit) form opens.

3

Configure the required parameters.

4

Click on the DS1/E1 or DS3/E3 tab and configure the required parameters.

All ports of the ASAP daughter card are automatically configured to the same port type when the first port is configured. A mix of DS1 and E1 ports or DS3 and E3 ports is not supported. The Port Type parameter can only be modified when no channels are configured on any port of the daughter card. If all of the channels are deleted on the daughter card, the port type is automatically set to DS1 or DS3 for all ports.

5

Click on the States tab and configure the Administrative State parameter.

6

Save your changes and close the form.

END OF STEPS

16.55 To configure a channelized TDM DS1 or E1 port

16.55.1 Steps

1

On the equipment tree, right-click on the device where you need to configure a channelized TDM DS1 or E1 port and select Properties. The Network Element (Edit) form opens.

2

On the Network Element (Edit) form navigation tree, expand to the port level and click on a port object that contains a channelized DS1 or E1. The Physical Port (Edit) form opens.

3

Configure the required parameters.

4

Click on the DS1/E1 tab and configure the required parameters.

All ports are automatically configured to the same port type when the first port is configured. A mix of DS1 and E1 ports is not supported.

5

Click on the States tab and configure the Administrative State parameter.

6

Save your changes and close the form.

END OF STEPS

16.56 To configure OmniSwitch Ethernet ports

Note: You can configure MVRP fixed ports, 802.1 Q ports, aggregate ports, and VLAN Stacking Network ports.

16.56.1 Steps

1

On the equipment tree, navigate to the port object where you want to configure an OmniSwitch Ethernet port. The path is Network→*NE*→Shelf→Card Slot *n*→Port *n/n/n*.

2

Right-click on a port object and choose Properties. The Physical Port (Edit) form opens.

3

Configure the required parameters.

An access port is used for customer-facing VLAN service traffic.

A network port or channel is used for network access in the service provider transport or infrastructure network. Typically, only one OmniSwitch network port is required for tree topology; ring topology requires two ports.

The Automatic VLAN Binding parameter is only supported on Stacked VLANs.

The Automatic VLAN Binding parameter is only supported on Stacked VLANs.

4

Click on the States tab and configure the Administrative State parameter.

5

Click on the Policies tab.

Note: A port must have a service access point associated with it before you can apply a UNI policy to the port.

6

Select a UNI policy.

7

Click on the Ethernet tab and configure the required parameters.

The Inter-Frame Gap (bytes) parameter is only configurable on Gigabit Ethernet ports.

The Default VLAN Restore, Default VLAN Enable, Ignore BPDU, Authenticate, and Ingress Filtering parameters are only configurable when the Enable Port Mobility parameter is set to Enable.

8

Click on the LLDP tab and configure the required parameters.

9

Click on the Remote Peers sub-tab under the LLDP tab to search for and display LLDP remote peers that are associated with the port. The remote peers are used to determine the physical topology of the network.

10

Click on the MVRP tab and configure the required parameters.

11

Configure VLAN restrictions, if required.

1. Click on the VLAN Restrictions tab.

2. Click Create. The MVRP VLAN Registration form appears.
3. Configure the required parameters.
4. Save your changes and close the form.

12

Click on the QoS tab, and configure the required parameters.

The Servicing Mode parameter does not apply to OS 6900 and OS 10K devices.

13

If you are configuring a port on an OS 6900 or OS 10K device, click on the Queue tab and configure the required parameters.

14

Click on the DHCP/DHCPv6 Snooping tab, and configure the required parameters. The tab is only available when the port is associated with a VLAN that has DHCP/DHCPv6 snooping enabled or DHCP/DHCPv6 snooping is enabled at the switch level.

15

Click on the Ethernet Hybrid tab, and configure the required parameters. The tab is only available for hybrid Ethernet ports.

16

Click on the PoE tab, and configure the required parameters. The tab is only available for PoE ports.

17

Click on the LPS Learned MAC Entries tab to view the MAC addresses learned on the port. LPS must be enabled on the port. See 28.128 “To configure bridging on an OmniSwitch” (p. 1043) for information about configuring LPS on an Ethernet port.

18

Click Create to add static MAC address entries, if required. The MAC Entries (Create) form opens.

Note: A port must be LPS-enabled and belong to a VLAN before you can add static MAC addresses to the port.

19

Select a VLAN Site.

20

Configure the MAC Address parameter.

21

Save your changes and close the form.

22

Repeat Step 18 to Step 21 to add another MAC address, if required.

23

Save your changes and close the forms.

END OF STEPS

16.57 To configure OmniSwitch PoE Ports

16.57.1 Steps

1

On the equipment tree, navigate to the card object where you want to configure an OmniSwitch PoE port. The path is Network→*NE*→Shelf→Card Slot *n*. The Card Slot (Edit) form opens.

2

Click on the PoE tab and configure the required parameters.

3

Save your changes and close the forms.

END OF STEPS

16.58 To create and configure Xconnect anchor ports

16.58.1 Purpose

Perform this procedure to create and configure anchor ports on FP4 daughter cards on 7750 SR and 7950 XRS NE variants, Release 21.5 and later. These anchor ports can be associated to a PXC; see 16.59 “To configure PXC loopback ports” (p. 652).

16.58.2 Steps

1

On the equipment tree, navigate to the Xconnect object under the FP4 daughter card where you need to configure an anchor port.

Right-click on Xconnect and choose Create Xconnect Mac. The Create MDA Xconnect MAC wizard opens.

2

Configure the MDA Xconnect MAC Properties.

Configure the required parameters and click Next. The Xconnect Mac object appears under the Xconnect object in the equipment tree.

3

Configure the MDA Xconnect Loopback.

1. Click Create.
2. Configure the required parameters and click Finish.

The Anchor Port object appears under the Xconnect Mac object in the equipment tree (Port 1/1/m1/1).

4

Close the wizard forms.

5

Create a second anchor port, if required.

1. Right-click on Xconnect Mac and choose Create Xconnect Loopback.
2. Configure the required parameters and click Finish.

The Anchor Port object appears under the first created anchor port in the equipment tree (Port 1/1/m1/2).

6

Close the wizard forms.

7

To view details for Xconnect Mac, right-click the Xconnect Mac and choose Properties.

8

Configure the anchor ports.

1. Right-click on Anchor Port and choose Properties.
2. Configure the required parameters.
3. Save and close the forms.

END OF STEPS

16.59 To configure PXC loopback ports

16.59.1 Steps

1

On the equipment tree, navigate to the node where you need to configure a PXC port. The path is Network→*NE*→Logical Groups. Right-click on PXCs and choose Create PXC. The Port Cross Connect configuration form opens.

2

Select a physical port to host the port cross-connect in the PXC Port panel.

Note: The port must be in shutdown state.

Note: A maximum of eight PXCs can be associated to each anchor port.

3

Save your changes and close the form.

END OF STEPS

Procedures for channel and framing link configuration

16.60 To configure SONET clear channels

16.60.1 Purpose

Perform this procedure to configure SONET clear channels on OC3 to OC192 ports that provide clear channel services. Each port supports one clear channel.

16.60.2 Steps

1

Choose Equipment from the navigation tree view selector.

2

Right-click on the device on which you want to create a clear channel port and select Properties. The Network Element (Edit) form opens.

3

On the Network Element (Edit) form navigation tree, expand the Shelf icon.

4

Expand to the port level and click on a clear channel port object. The Physical Port (Edit) form opens. SONET is the default framing scheme.

Note: A clear channel port is a port on a card that is not designated Deep Channelized.

5

Configure the required parameters and click Apply.

6

In the navigation tree, right-click on the port and choose Create Channel. The Channel Type Selection form opens.

7

Choose the channel type. The Sts*n* SONET Channel (Create) form opens with the General tab displayed.

If you are configuring a 4 x Channelized OC3/OC12 ASAP SFP adapter card on a 7705 SAR, Release 7.0 R5 or later:

- If the MDA mode is configured as OC3, the NFM-P supports channel type Sts3 under SONET, and channel type Sts3 with payload type Sts3 (non-channelized) under SDH for clear channel POS and Network APS.
- If the MDA mode is configured as OC12, the NFM-P supports channel types Sts3 and Sts12 under SONET or SDH for clear channel POS and network APS.

You can create an SC APS or MC APS group to enable automatic protection switching. See 38.14 “To create an SC APS group” (p. 1302) and 38.15 “To create an MC APS group” (p. 1305) .

8

Configure the required parameters.

The Encapsulation Type parameter is configurable when the Mode parameter is set to Access.

If you configure the Payload Type parameter as Sts3 (non-channelized), you must configure the Mode parameter as Network and the Encap Type as PPP Auto.

9

Click Apply.

a. If the Encapsulation Type parameter of the port is ATM, the form is refreshed.

b. If the Encapsulation Type parameter of the port is not ATM, go to Step 12 .

10

If required, configure an ATM interface. Click Edit ATM. The ATM interface form opens.

11

Configure the required parameters.

12

If required, create an ILMI link, see 16.74 “To create an ILMI link” (p. 677) .

13

Click OK and close the forms.

END OF STEPS

16.61 To perform a bulk channel creation on ports that support multiple sub-channels

16.61.1 Purpose

Perform this procedure to create the maximum number of channels on ports that support multiple sub-channels. The following table lists the port types that support bulk channel creation.

Table 16-6 Bulk channel creation support

Node	OC3	OC12	DS3 ASAP	E3 ASAP	APS common port	APS SONET VTG
7450 ESS	X	X	X	X	X	X

Table 16-6 Bulk channel creation support (continued)

Node	OC3	OC12	DS3 ASAP	E3 ASAP	APS common port	APS SONET VTG
7705 SAR-8 7705 SAR-8v2 7705 SAR-18	X	X	—	—	—	—

Note: This procedure assumes you have preconfigured an NE with an appropriate daughter card that supports multiple sub-channels.

16.61.2 Steps

1

Choose Equipment from the view selector in the navigation tree.

2

Locate and expand the device on which you need to perform a bulk channel creation.

3

Perform one of the following:

a. For OC3, OC12, DS3 ASAP, and E3 ASAP ports, right-click on a port icon and choose Create Maximum # of Channels. The Create Maximum # of Channels form opens.

b. For APS common ports and APS SONET VTGs, right click on an APS Common Config SONET channel icon and choose Create Maximum # of Channels. The Create Maximum # of Channels form opens.

Note: APS common ports and APS SONET VTGs are created when you create APS groups. See 38.14 “To create an SC APS group” (p. 1302) for more information.

4

Configure the required parameters.

5

Click Execute.

END OF STEPS

16.62 To configure SONET sub-channels

16.62.1 Before you begin

SONET sub-channels are available on deep channelized OC12 and OC3 ports. SONET STS1 channels support the following payload types:

- DS3

- VT15
- VT2

16.62.2 Steps

1

Choose Equipment from the navigation tree view selector.

2

Right-click on the device on which you want to configure SONET sub-channels and select Properties. The Network Element (Edit) form opens.

3

On the Network Element (Edit) form navigation tree, expand the Shelf icon.

4

Expand to the port level, right-click on a port object, and choose Create Channel. The Channel Type Selection form opens.

5

Choose the channel type. The Sts*n* SONET Channel (Create) form opens with the General tab displayed.

If you are configuring a 4 x Channelized OC3/OC12 ASAP SFP adapter card on a 7705 SAR, Release 7.0 R5 or later, when the MDA Mode is OC12 with SONET framing, you can create an Sts1 channel with a DS1 channel.

6

Configure the required parameters.

For an OC3 port, use a value from 1 to 3. For an OC12 port, use a value in the format <1 to 4>.<1 to 3>.

The DDM Event Suppression parameter is configurable only on ports on SFPs and XFPs optical modular transceivers.

7

Click Apply.

8

Create the STS1 (AU3) sub-channels according to the payload type configured:

a. To create VT15 (Sdh TU11) sub-channels, go to 16.64 “To create VT15 (TU11) or VT2 (TU12) sub-channels” (p. 660) .

b. To create VT2 (Sdh TU12) sub-channels, go to 16.64 “To create VT15 (TU11) or VT2 (TU12) sub-channels” (p. 660) .

c. To create a DS3 or E3 (SDH framing only) clear channel, go to Step 9 .

9

To create a DS3 or E3 clear channel, perform the following steps:

1. From the navigation tree, select an STS1 or AU3 channel and choose Create Channel. The DS3/E3 Channel (Create) form opens.
   - For AU3 channels, DS3 and E3 channelization is available.
   - For STS1 channels, only DS3 channelization is available.
2. Configure the Description parameter.
3. Configure the Channelized parameter.
   - Choose Ds1 to channelize the DS3 to carry up to 28 DS1 channelized to the DS0 level.
   - Choose E1 to channelize the DS3 to carry up to 21 E1 channelized to the DS0 level.
   - Choose None to create a DS3 or E3 clear channel. Configure the required parameters.
4. Click OK.

   If you set the Channelized parameter to None, a DS3 clear channel in Access mode is created under the STS1 or the AU3 in the navigation tree.

   If you set the Channelized parameter to DS1, a DS3 channelized for DS1 is created under the STS1 (AU3). Go to Step 10 in 16.68 “To create TDM DS3 channels” (p. 666) to create the DS1 channels.

   If you set the Channelized parameter to E1, a DS3 channelized for E1 is created under the STS1 (AU3) in the navigation tree. Go to Step 10 in 16.68 “To create TDM DS3 channels” (p. 666) to create the E1 channels.

END OF STEPS

16.63 To configure SDH sub-channels

16.63.1 Purpose

SDH sub-channels are available on deep channelized OC12 and OC3 ports. SDH AU4 channels support the following payload types:

- TU3
- TU11
- TU12

SDH AU3 channels support the following payload types:

- DS3
- E3
- TU11
- TU12

Perform this procedure to configure SDH sub-channels on ports that provide channelized services. You must first configure port framing to SDH since default framing on SONET/SDH ports is SONET.

16.63.2 Steps

1

Choose Equipment from the navigation tree view selector.

2

Right-click on the device on which you want to configure SDH sub-channels and select Properties. The Network Element (Edit) form opens.

3

On the Network Element (Edit) form navigation tree, expand the Shelf icon.

4

Expand to the port level and click on a channelized port. The Physical Port (Edit) form opens.

5

Click on the SONET tab and set the Framing parameter to SDH.

6

Click OK.

7

Right-click on the port again and choose Create Channel. The Channel Type Selection form opens.

8

Choose one of the following channel types and click OK. The Sts*n* SONET channel (Create) form opens.

a. SONET Sts1 channelization and SDH Au3 channelization are equivalent. Go to Step 6 of 16.62 “To configure SONET sub-channels” (p. 655) .

b. If you choose SONET Sts3 (Sdh Stm1), the Sts3 SONET Channel (Create) form opens. Go to Step 9 .

The Payload Type parameter for SDH STM1 (AU4) is set to TUG3. There is no SONET framing equivalent. Go to Step 9 .

If you are configuring a 4 x Channelized OC3/OC12 ASAP SFP adapter card on a 7705 SAR, Release 7.0 R5 or later, when the MDA Mode is OC12 with SDH framing, you can create an Sts1 and Sts3 channel type with a DS1 or an E1 channel.

9

Configure the required parameters.

10

Click on the States tab and configure the Administrative State.

11

Click OK. The STM1 (AU4) channel appears in the navigation tree under the port of the daughter card. It contains three TUG3 groups.

12

Right-click on a TUG3 group and choose Properties. The Sdh Tug3 (Edit) form opens.

13

Choose one of the following options to configure the Payload Type parameter:

a. PDH Tu3. Click Cancel and go to Step 14 to create a TU3 channel.

b. SONET VT15 (SDH Tu11). Click Apply and go to 16.64 “To create VT15 (TU11) or VT2 (TU12) sub-channels” (p. 660) .

c. SONET VT2 (SDH Tu12). Click Apply and go to 16.64 “To create VT15 (TU11) or VT2 (TU12) sub-channels” (p. 660) .

14

To create a TU channel, right-click on the TUG3 group and choose Create Channel. The TU3 Channel (Create) form opens.

15

Configure the required parameters.

16

Click on the States tab and configure the Administrative State.

17

Click OK. A TU3 channel is created under the TUG3 group in the navigation tree.

18

Right-click on the Tu3 and choose Create Channel. The DS3/E3 Channel (Create) form opens.

The E3 is the only payload type available.

19

Configure the required parameters.

20

Click on the States tab and configure the Administrative State.

21

Click OK. An E3 clear channel is created under the AU4/TUG3 in the navigation tree.

END OF STEPS

16.64 To create VT15 (TU11) or VT2 (TU12) sub-channels

16.64.1 Before you begin

A SONET VTG and an SDH TUG2 are equivalent groups. A VTG contains four VT15 channels or three VT2. A TUG2 contains four TU11 channels or three TU12. An SDH TUG 3 has no SONET equivalent, however, it contains seven TUG2. (An STM1/AU4 contains three TUG3). See 16.15 “Comparison of SONET and SDH hierarchies” (p. 589) in “SONET and SDH sub-channel applications and structure” (p. 586) .

An STS1 channelized to carry a VT15 or VT2 payload type contains seven VTG. An AU3 or a TUG3 channelized to carry a TU11 or TU12 payload type contain seven TUG2.

Each VTG (TUG2) supports up to four VT15 (TU11) channels or three VT2 (TU12) channels.

16.64.2 Steps

1

Complete 16.62 “To configure SONET sub-channels” (p. 655) or 16.63 “To configure SDH sub-channels” (p. 657) to carry a VT15 (TU11) or VT2 (TU12) payload type.

2

To create a VT15 (TU11) channel, perform the following steps:

1. Choose Equipment from the navigation tree view selector.
2. Right-click on the device where you want to create a VT15 (TU11) channel and select Properties. The Network Element (Edit) form opens.
3. On the Network Element (Edit) form navigation tree, expand the Shelf icon.
4. Expand to the channel level, right-click on a VTG or TUG2 channel group that is to carry a VT15 (TU11) payload and choose Create Channel. The SONET VT (SDH Tu) Channel (Create) form opens.
5. Configure the required parameters.

   Set the Local Channel ID to a value in the range 1 to 4 since there are four VT15 (TU11) in a VTG (TU2).

   The default payload type for a VT15 (TU11) channel is PDH DS1. There is no other available payload type.
6. Click OK. A VT15 channel is created under the VTG or a TU11 channel is created under the TUG2 in the navigation tree.
7. Right-click on a VT15 or TU11 channel and choose Create Channel. The DS1/E1 Channel (Create) form opens.

The Local Channel ID is equal to the VT15 channel Local Channel ID parameter and the channel type is set to DS1 since a VT15 or TU11 channel supports one DS1.

8. Click OK A DS1 channel is created under the VT15 or the TU11 in the navigation tree.

   You can create up to 28 VT15 (TU11) channels on a VTG (TUG2).

9. Repeat Step 1 and Step 2 for each VT15 (TU11) channel that you want to create.
10. Since a DS1 channel is not used as a SAP, create a DS0 group for each DS1 channel created. Go to Step 11 of 16.68 “To create TDM DS3 channels” (p. 666) .

3

To create a VT2/TU12 channel, complete these steps:

1. From the navigation tree, select a VTG or TUG2 channel group to carry a VT2 (TU12) payload and choose Create Channel. The SONET VT (SDH Tu) Channel (Create) form opens.
2. Configure the required parameters.

   Set the Local Channel ID to a value in the range 1 to 3 since there are three VT2 (TU12) in a VTG (TUG2).

   PDH E1 is not available for SONET framing.

3. Click OK. A VT2 channel is created under the VTG, or a TU12 channel is created under the TUG2 in the navigation tree.
4. Right-click on the VT2 or TU12 channel and choose Create Channel. The DS1/E1 Channel (Create) form opens.

   The Local Channel ID is equal to the VT2 channel Local Channel ID parameter, since a VT2 channel supports one E1 or DS1.

5. Click on the States tab and configure the Administrative State parameter.
6. Click OK. A DS1 channel is created under the VT2 in the navigation tree. An E1 or DS1 is created under the TU12. You can create up to 21 VT2 (TU12) channels on a VTG (TUG2).
7. Repeat Step 1 and Step 2 for each VT2 (TU12) that you want to create.
8. Since a DS1/E1 channel is not used as a SAP, create a DS0 group for each DS1 or E1 channel created. Go to Step 11 of 16.68 “To create TDM DS3 channels” (p. 666) .

END OF STEPS

16.65 To create TDM DS1 or E1 channels

16.65.1 Purpose

Perform this procedure to create DS1/E1 channels and child objects on a channelized DS1/E1 port.

Note: If you are using the XML API to create a DS1 or E1 channel, the create request creates a channel with a G704 CRC framing type for E1 channels and ESF for DS1 channels. To modify the channel framing type requires a second request.

16.65.2 Steps

1

On the equipment tree, right-click on the device where you want to configure TDM DS1 or E1 channels and select Properties. The Network Element (Edit) form opens.

2

On the Network Element navigation tree, expand to the port level.

3

Click on a port. The Port form opens.

4

Configure the required general parameters.

5

Click on the DS1/E1 tab and configure the required parameters.

6

Click OK.

7

Right-click on the port and choose Create Channel. The DS1/E1 Channel (Create) form opens. If there are no channels available on that port, the Create Channel menu option is dimmed.

8

Click OK.

9

To create DS0 channel groups:

1. On the navigation tree, right-click on a DS1 or E1 channel under the required port and choose Create Channel. The DS0 Channel Group (Create) form opens.
2. Configure the required parameters.

   For the Local Channel ID parameter, for a DS0 group from a DS1 channel, choose from 1 to 24. For a DS0 group from an E1 channel, choose from 2 to 32.

   Note:

   All channel groups on a 7705 SAR ASAP port must have the same mode configured. When the first channel group is configured, all other channel groups on the port must be set to the same mode.

   The default encapsulation type for the 7705 SAR is N/A. The encapsulation type must be changed from N/A to a valid type. For instance, to support CAS signaling, the encapsulation type must be set to CEM. After a valid encapsulation type is configured for a channel group,

the encapsulation type cannot be changed for that channel group. To change the encapsulation type, the channel group must be deleted and recreated.

On a 16/32x Channelized ASAP, you must configure the MDA mode in order to use certain encapsulation types. See 15.78 “To configure an MDA” (p. 536) for more information on configuring the MDA mode.

3. Click on the Channel Group tab and configure the required parameters.

10

Save your changes and close the forms.

END OF STEPS

16.66 To configure TDM DS1 or E1 channels

16.66.1 Purpose

Perform this procedure to configure DS1/E1 channel parameters and child objects on a channelized DS1/E1 port, add a DS0 channel group, collect and view performance statistics, or view alarm information.

16.66.2 Steps

1

In the navigation tree equipment view, right-click on the device you need to configure TDM DS1 or E1 channels and choose Properties. The Network Element (Edit) form opens.

2

Expand the Shelf icon to the channel level and choose a DS1 or E1 channel. The DS1/E1 Channel (Edit) form opens.

3

Click on the States tab and configure the Administrative State parameter.

4

Click on the Channel tab. The DS1/E1 Channel (Edit) form opens.

5

Configure the required parameters.

The Synchronous Status Messages, E1 Tx DUS/DNU, and E1 SSM-Bit parameters are configurable only on E1 channels on a 7705 SAR.

The Channel Framing parameter must be set to E1-unframed to create a DS0 channel under the E1 channel.

The Clock Source parameter value Differential is only supported on the following 7705 SAR cards:

- 16/32 × Channelized DS1/E1 ASAP v2 on a 7705 SAR-8, 7705 SAR-8 v2, or 7705 SAR-18
- 4 × Channelized DS3/E3 ASAP on a 7705 SAR-8, 7705 SAR-8 v2, or 7705 SAR-18, Release 6.1 R3 or later
- 4 × Channelized OC3/OC12 ASAP SFP on a DS1/E1 channel, on a 7705 SAR-8, 7705 SAR-8 v2, or 7705 SAR-18, Release 6.2 R1 or later
- ASAP channelized card on a 7705 SAR-A

Note: If you create an MLPPP bundle and the DS1 BER exceeds a threshold, the PPP link is automatically removed from the MLPPP bundle.

6

Add a DS0 channel group, if required.

Note: For the 7250 IXR-R6, you can only create a DS0 channel under the E1 channel (not the DS1 channel) of a 32-port Any Service Channelized DS1/E1 Multi-Sync MDA.

1. Click on the SubChannels tab.
2. Click on the Create Cha... tab. The DS0 Channel Group (Create) form opens.
3. Configure the required parameters.

   Note:

   On a 16/32x Channelized ASAP, you must configure the MDA mode in order to specify the encapsulation type. See 15.78 “To configure an MDA” (p. 536) for more information about configuring the MDA mode.

   You must set the value of the Encapsulation Type parameter to CEM if you are configuring an MDA card of type 16 × Channelized DS1/E1 ASAP v2 or 32 × Channelized DS1/E1 ASAP v2 on a 7705 SAR-8 or 7705 SAR-18.
4. Click OK.
5. Click OK.

7

Perform one of the following:

a. Click Collect to collect performance statistics data on demand. The collected statistics are listed on the form.

b. Click Collect All to collect one on-demand statistics record for each statistic type that the object supports. The collected statistics are listed on the form.

8

Click on the Faults tab to view alarm information, if required.

Note: If are configuring a 7705 SAR and selected a clock source of adaptive, you can click on the Adaptive Clock History tab to view channel adaptive clock performance data for the preceding 15 min.

9

Save your changes and close the forms.

END OF STEPS

16.67 To create serial channels

16.67.1 Purpose

Perform this procedure to create serial channels and child objects from a Serial Data Interface port.

16.67.2 Steps

1

Choose Equipment from the navigation tree view selector.

2

Navigate to the device where you want to configure serial channels and expand to the port level.

3

Right-click on the port and choose Create Channel. The Serial Channel (Create) form opens. If there are no channels available on that port, the Create Channel menu option is dimmed.

4

Click on the States tab and configure the Administrative State parameter. Click Apply.

5

Click on the Channel tab and configure the required parameters.

Depending on the serial type of the configured port, different parameters are configurable in the Control Leads panel.

6

Create DS0 channel groups:

1. Click on the SubChannels tab.
2. Click on the Create Cha... button. The DS0 Channel Group (Create) form opens.
3. Configure the required parameters.

   Note:

   The default encapsulation type for the 7705 SAR is N/A. The encapsulation type must be changed from N/A to a valid type. After a valid encapsulation type is configured for a channel group, the encapsulation type cannot be changed for the channel group. To change the encapsulation type, the channel group must be deleted and re-created.

On an SDI MDA, you must configure the serial type to X.21 or V.35 to use the IPCP, FR, HDLC, or Cisco HDLC encapsulation types. See 16.42 “To configure serial ports” (p. 634) for more information.

4. Click OK.

7

Configure the DS0 channel according to the encapsulation type, if required:

a. For an IPCP channel, click Edit PPP and configure the required parameters.

b. For an FR channel, click Edit FR and configure the required parameters.

c. For a Cisco HDLC channel, click on the CISCO HDLC tab and configure the required parameters.

8

Save your changes and close the form.

END OF STEPS

16.68 To create TDM DS3 channels

16.68.1 Purpose

Perform this procedure to create DS3 channel and children objects from a channelized DS3 port.

16.68.2 Steps

1

Choose Equipment from the navigation tree view selector.

2

Right-click on the device on which you want to create a TDM DS3 channel and select Properties. The Network Element (Edit) form opens.

3

On the Network Element (Edit) form navigation tree, expand the Shelf icon.

4

Expand to the port level and click on a port. The Physical Port (Edit) form opens.

5

Configure the required parameters.

6

Choose the DS3/E3 tab and configure the required parameters. Click OK.

7

Right-click on the port again and choose Create Channel. The DS3/E3 Channel (Create) form opens. If there are no channels available on that port, the Create Channel menu option is dimmed.

8

To create the DS3/E3 channel, complete these steps:

a. Configure the Channelized parameter to DS1 or E1, if you want to channelize to the DS0 level.

b. Configure the Channelized parameter to None if this is a clear channel application.

Configure the required parameters.

The Local Channel ID parameter is configured automatically and the Mode parameter is always Access for TDM.

Note: On a 4x Channelized ASAP, you must configure the MDA mode in order to use certain encapsulation types. See 15.78 “To configure an MDA” (p. 536) for more information on configuring the MDA mode.
If you want to configure a DS3/E3 channel as a network interface on a channelized ASAP MDA, see 16.70 “To configure a DS3/E3 channel as a network interface on a channelized ASAP MDA” (p. 671) .

9

Click OK.

If this is a Channelized DS1 or E1 application, continue to Step 10 .

10

To create DS1 or E1 channels, complete these steps:

1. From the navigation tree, select a DS3 channel and choose Create Channel. The Create DS1/E1 Channel form opens.
2. Configure the Local Channel ID parameter.
   - For DS1 choose from 1 to 28.
   - For E1 choose from 1 to 21.
3. Click OK. The DS1 or E1 channels are created under the DS3 in the navigation tree.

11

To create DS0 channel groups, complete these steps:

1. From the navigation tree, select a DS1 or E1 channel and choose Create Channel from the contextual menu to create DS0 groups. The DS0 Channel (Create) form opens.
2. Configure the required parameters.

   For a DS0 group from a DS1 choose from 1 to 24 for the Local Channel ID parameter. For a DS0 group from an E1, choose from 2 to 32.

   Note:

On a 4x Channelized ASAP, you must configure the MDA mode in order to use certain encapsulation types. See 15.78 “To configure an MDA” (p. 536) for more information on configuring the MDA mode.

3. Click on the Channel Group tab and configure the required parameters.
4. Click OK. The timeslot is assigned to the DS0 channel group in the navigation tree.

END OF STEPS

16.69 To configure TDM DS3 channels

16.69.1 Purpose

Perform this procedure to configure DS3 channels and children objects from a channelized DS3 port.

16.69.2 Steps

1

Choose Equipment from the navigation tree view selector.

2

Right-click on the device where you want to configure TDM DS3 channels and select Properties. The Network Element (Edit) form opens.

3

On the Network Element (Edit) form navigation tree, expand the Shelf icon.

4

Expand to the channel level and click on a DS3 channel. The DS3/E3 Channel (Edit) form opens. Configure the required parameters.

5

Configure the Channelized parameter and click Apply.

If you choose DS1 or E1, perform Step 10 to Step 21 .

6

Configure the Encapsulation Type parameter and click Apply.

a. If you choose BCP Null, BCP DOT1 Q, or IPCP, go to Step 7 .

b. If you choose FR, go to Step 8 .

c. If you choose Cisco HDLC, go to Step 9 .

d. If you choose WAN Mirror, perform Step 11 to Step 14 .

7

Configure the PPP interface for the channel, if required.

1. Click Edit PPP. The PPP Interface form opens. Configure the required parameters.
2. Click OK.
3. Perform Step 11 to Step 14 .

8

Configure the FR interface, if required.

1. Click Edit FR. The FR Interface form opens. Configure the required parameters.
2. Click on the Frf12 tab and configure the required parameters. Set the Mode parameter to Enabled.
3. Click Select beside the MCFR Egress QoS Profile parameter. The Select MCFR Egress Qos Profile - FR Configuration form opens.
4. Choose a profile from the list and click OK. The Select MCFR Egress Qos Profile - FR Configuration form closes and the FR Interface form is refreshed with the MCFR Egress QoS Profile information.
5. Click OK.
6. Perform Step 11 to Step 14 .

9

Configure the Cisco HDLC information.

1. Click on the Cisco HDLC tab and configure the required parameters.
2. Perform Step 11 to Step 14 .

10

Configure the DS1 and DS0 channels. Perform the following steps:

1. Click on the SubChannels tab.
2. Click Create. The DS1/E1 Channel (Create) form opens. Configure the required parameters.
3. Click on the States tab and configure the required parameters.
4. Click OK.

11

Click on the States tab and configure the required parameters.

12

Click on the Channel tab. The DS3/E3 Channel (Edit) form opens. Configure the required parameters.

The Clock Source parameter value Differential is supported on a 4 × channelized DS3/E3 ASAP MDA for a DS3/E3 channel, on a 7705 SAR-8, 7705 SAR-8 v2, or 7705 SAR-18, Release 7.0 R1 or later.

13

Click on the Message Data Link tab and configure the required parameters.

The MDL Message Type parameter specifies the Line Message Data Link message for a DS3 and specifies the transmission method of a message over a channelized interface. The parameter is only applicable if the DS3 is using C-bit framing. The default is disabled. Click on the check boxes to enable transmission methods and enter text strings to choose the message options for this parameter as required. The transmission options are:

- Test Signal
- DS3 Path
- Idle Signal

Table 16-7 MDL message options

Option	String Length	Description
Port Number String	0 to 38 characters	specifies the port ID code
Generator Number String	0 to 38 characters	specifies the generator number to send in the MDL test signal message
Equipment ID Code	0 to 10 characters	specifies the Equipment ID code
Location ID Code	0 to 11 characters	specifies the Location ID code
Frame ID Code	0 to 10 characters	specifies the Frame ID code
Unit ID Code	0 to 6 characters	specifies the unit ID code
Facility ID Code	0 to 38 characters	specifies the facility ID code

14

Click OK.

15

Right-click on a DS1 channel in the navigation tree and choose Properties. The property form for the channel opens.

16

Click on the States tab and configure the required parameters.

17

Add a DS0 channel group, if required. Perform the following steps:

1. Click on the SubChannels tab.
2. Click Create. The DS0 Channel Group (Create) form opens.
3. Configure the required parameters.

   Note:

On a 4x Channelized ASAP, you must configure the MDA mode in order to use certain encapsulation types. See 15.78 “To configure an MDA” (p. 536) for more information on configuring the MDA mode.

4. Click OK.

18

Click on the Channel tab and configure the required parameters.

19

Click OK.

20

Configure timeslots for the DS0 channel group. Perform the following steps.

1. Choose a DS0 channel in the navigation tree and choose Properties. The property form for the channel opens.
2. Configure the required parameters.
3. Click on the States tab and configure the required parameters.
4. Click on the Channel Group tab and configure the required parameters.

   Choose one or more timeslots. You can use the Select All and Deselect All buttons.
5. If you set the Encapsulation Type parameter to BCP Null, BCP DOT1 Q, or IPCP in 2 , you can configure the PPP for the timeslot on the Channel Groups tab.
   - Click Edit PPP. The PPP Interface form opens. Configure the required parameters.

     The Compression parameter is configurable when the DS1 or E1 channel group is on an ASAP MDA in a 7750 SR.
   - Click OK.

21

Click OK.

END OF STEPS

16.70 To configure a DS3/E3 channel as a network interface on a channelized ASAP MDA

16.70.1 Steps

1

Choose Equipment from the navigation tree view selector.

2

Right-click on the device where you want to configure a DS3/E3 channel and select Properties. The Network Element (Edit) form opens.

3

On the Network Element (Edit) form navigation tree, expand the Shelf icon to the port level.

4

Perform one of the following.

a. If you are configuring an OC-*n* channelized ASAP MDA, right-click on an available port and choose Create Channel. The Sts SONET Channel (Create) form opens; go to Step 5 .

b. If you are configuring a DS3/E3 channelized ASAP MDA, right-click on an available port and choose Create Channel. The DS3/E3 Channel (Create) form opens; go to Step 9 .

5

Configure the required parameters.

6

Click on the States tab and configure the required parameters.

7

Click OK.The Sts SONET Channel (Create) form closes and the STS1 channel appears in the navigation tree under the port of the channelized ASAP daughter card.

8

Right-click on the STS1 channel and choose Create Channel. The DS3/E3 Channel (Create) form opens.

9

Configure the required parameters.

10

Click on the States tab and configure the required parameters.

11

Click Apply. The form displays additional tabs.

12

Click on the Channel tab and configure the required parameters.

13

Click on the Message Data Link tab and configure the required parameters.

The MDL Message Type parameter specifies the Line Message Data Link message for a DS3 and specifies the transmission method of a message over a channelized interface. The parameter is only applicable if the DS3 is using C-bit framing. The default is disabled. Click on

the check boxes to enable transmission methods and enter text strings to choose the message options for this parameter as required. The transmission options are:

- Test Signal
- DS3 Path
- Idle Signal

Table 16-8 MDL message options

Option	String Length	Description
Port Number String	0 to 38 characters	specifies the port ID code
Generator Number String	0 to 38 characters	specifies the generator number to send in the MDL test signal message
Equipment ID Code	0 to 10 characters	specifies the Equipment ID code
Location ID Code	0 to 11 characters	specifies the Location ID code
Frame ID Code	0 to 10 characters	specifies the Frame ID code
Unit ID Code	0 to 6 characters	specifies the unit ID code
Facility ID Code	0 to 38 characters	specifies the facility ID code

14

Click OK. The DS3/E3 channel appears in the navigation tree under the port on the channelized ASAP MDA.

END OF STEPS

16.71 To configure data framing on a 7705 SAR

16.71.1 Purpose

Perform this procedure to configure data framing on a 7705 SAR-8 or 7705 SAR-18. Data framing is supported on TPIF channels on an 8 × C37.94 Teleprotection Interface MDA or TPIF ports on an 8 × Voice Teleprotection Interface MDA. See 15.78 “To configure an MDA” (p. 536) for information about how to configure daughter cards.

Note: Data framing can be configured as Unframed only on odd numbered ports of the 8 × C37.94 Teleprotection Interface MDA and TPIF ports on an 8 × Voice Teleprotection Interface MDA. For example, ports 1,3,5 and 7 on the C37.94 MDA and port 1 on the VT MDA can be used in Unframed mode.

Data framing can be configured as Framed on all ports of the 8 × C37.94 Teleprotection Interface MDA and TPIF ports on an 8 × Voice Teleprotection Interface MDA.

16.71.2 Steps

1

Choose Network→NE→Shelf→Card Slot n→Daughter Card Slot n→Port n/n/n→Channel where the channel object is the channel that you need to configure for data framing.

2

Right-click on the channel and choose Create. The Data Channel (Edit) form opens.

3

Click on the Channel tab.

4

Configure the Data Framing Mode parameter.

Note: In Unframed mode, all 32 timeslots will be selected for DS0 channels. The channels can be added as SAPs on a Cpipe service that has the VC Type parameter configured as SAToP Tpif.
In Framed mode, TPIF ports can be added as SAPs on a Cpipe service that has the VC Type parameter configured as CESoPSN.

5

Click OK and confirm to close the form.

6

Add the channels or TPIF ports as SAPs on a CPipe service, if required.

See 76.34 “To configure a spoke SDP binding on a VLL site” (p. 2161).

END OF STEPS

16.72 To configure an L3 interface on a DS3/E3 channel on a channelized ASAP MDA

16.72.1 Steps

1

Choose Equipment from the navigation tree view selector.

2

Right-click on the device on which you want to configure an L3 interface and select Properties. The Network Element (Edit) form opens.

3

On the Network Element (Edit) form navigation tree, expand the Shelf icon.

4

Expand to the channel level and click on a DS3/E3 channel on a channelized ASAP MDA port. The DS3/E3 Channel (Edit) form opens.

5

Click on the Policies tab to configure the policies for the DS3/E3 channel. Perform the following steps.

1. Click Select beside the Network Queue Policy Name parameter. The Select Network Queue Policy - DS3/E3 Channel list form opens.
2. Select a network queue policy from the list and click OK. The Select Network Queue Policy - DS3/E3 Channel list form closes and the DS3/E3 Channel (Edit) form reappears.
3. Click Select beside the ID parameter in the Accounting Policy panel. The Select Accounting Policy - DS3/E3 Channel list form opens.
4. Select an accounting policy from the list and click Ok. The Select Accounting Policy - DS3/E3 Channel list form closes and the DS3/E3 Channel (Edit) form refreshes with the accounting policy information.
5. Configure the Collect Accounting Statistics parameter.
6. Click Select in the Port Scheduler Policy panel to assign a port scheduler policy to the port. The Select Port Scheduler Policy - Physical Port form opens.
7. Select a port scheduler policy from the list and click OK. The Select Port Scheduler Policy - Physical Port form closes.

6

Click on the Network Interfaces tab.

7

Click Create. The Create Network Interface - Routing Instance form opens.

8

See 27.17 “To create an L3 network interface on a routing instance” (p. 856) to create a network interface on the DS3/E3 channel.

The port is set to the DS3/E3 channel by default.

9

The L3 interface appears on the Network Interfaces tab. Close the DS3/E3 Channel (Edit) form.

END OF STEPS

16.73 To configure a PVC

16.73.1 Before you begin

PVCs are automatically created by the device when a new L3 interface over ATM is created on the NFM-P, and when a new ILMI link is created between ATM interfaces. See 16.74 “To create an ILMI link” (p. 677) for more information about creating ILMI links.

16.73.2 Steps

1

Choose Equipment from the navigation tree view selector.

2

Right-click on the device where you want to configure a PVC and select Properties. The Network Element (Edit) form opens.

3

On the Network Element (Edit) form navigation tree, expand the Shelf icon.

4

Expand to the channel level and click on a SONET/SDH ATM clear channel. The property form for the channel opens.

5

Click on the L3 Interfaces tab. Choose the appropriate interface from the list and click Properties. The L3 Interface form opens.

6

Click on the ATM tab and configure the required parameters.

7

Click Apply.

8

To view more information about the PVC:

1. Click View PVC Connection. The ATM PVC Connection form opens.
2. Click on the tabs to view information for the ATM PVC connection.

9

Click Cancel to close the ATM PVC Connection form, the L3 Interface form, and the channel form.

END OF STEPS

16.74 To create an ILMI link

16.74.1 Purpose

Perform this procedure to create an ILMI link between device ATM interfaces. This functionality is supported on the 7750 SR. Ensure that ATM QoS policies are configured before you create the ILMI link. See Chapter 49, “Policies overview” for more information about creating ATM QoS policies.

16.74.2 Steps

1

Perform one of the following to open the ATM interface properties form.

a. Use the navigation tree

1. Choose Equipment from the navigation tree view selector.
2. Right-click on the device on which you want to create an ILMI link and select Properties. The Network Element (Edit) form opens.
3. On the Network Element (Edit) form navigation tree, expand the Shelf icon.
4. Expand to the port level and click on a clear channel port. The Physical Port (Edit) form opens.

   Note:

   A clear channel port is a port on a card that is not designated Deep Channelized.
5. Click on the Channels tab.
6. Choose the appropriate channel from the list and click Properties. The Channel (Edit) form opens.
7. Click Edit ATM. The ATM Interface form opens.

b. Use the Manage Equipment list form to search for a clear channel port with an ATM interface.

1. Choose Manage→Equipment→Equipment from the NFM-P main menu. The Manage Equipment form opens.
2. Choose Port.
3. Configure the filter criteria to search for ATM encapsulation types.
4. Click Search and select an entry by double-clicking. Alternatively, select an entry and click Properties. The Select form closes and the Channel (Edit) form opens.
5. Click Edit ATM. The ATM Configuration (Edit) form opens.

2

Click Create ILMI Link. The Configure ILMI Link form opens.

3

Configure the required parameters.

The Restore Keep-Alive Defaults parameter restores the default values of the Keep-Alive Polling Frequency (seconds), Keep-Alive Polling Count, and Keep-Alive Test Frequency (seconds) parameters.

The Keep-Alive Test Frequency (seconds) parameter is configurable when the Protocol Version parameter is set to 4.0.

4

Choose an ingress ATM QoS policy by clicking Select. The Select ATM Policy - ATM ILMI Link Configuration list form opens. Click Search and choose an ingress ATM policy from the list to associate with the ILMI link. Click OK. The Select ATM Policy - ATM ILMI Link Configuration list form closes.

5

Choose an egress ATM QoS policy by clicking Select. The Select ATM Policy - ATM ILMI Link Configuration list form opens. Click Search and choose an egress ATM policy from the list to associate with the ILMI link. Click OK. The Select ATM Policy - ATM ILMI Link Configuration list form closes.

6

Click Finish and close the forms.

END OF STEPS

16.75 To configure an ILMI link

16.75.1 Steps

1

Perform Step 1 of 16.74 “To create an ILMI link” (p. 677) to open the ATM Configuration (Edit) form.

2

Click Edit ILMI Link. The ILMI Link form opens.

3

Configure the required parameters.

The Restore Keep-Alive Defaults parameter restores the default values of the Keep-Alive Polling Frequency (seconds), Keep-Alive Polling Count, and Keep-Alive Test Frequency (seconds) parameters.

The Keep-Alive Test Frequency (seconds) parameter is configurable when the Protocol Version parameter is set to 4.0.

4

Choose an ingress ATM QoS policy by clicking Select. The Select ATM Policy - ATM ILMI Link Configuration list form opens. Click Search and choose an ingress ATM policy from the list to associate with the ILMI link. Click OK. The Select ATM Policy - ATM ILMI Link Configuration list form closes.

5

Choose an egress ATM QoS policy by clicking Select. The Select ATM Policy - ATM ILMI Link Configuration list form opens. Click Search and choose an egress ATM policy from the list to associate with the ILMI link. Click OK. The Select ATM Policy - ATM ILMI Link Configuration list form closes.

6

Click on the Peer Interface Configuration tab to view ILMI properties of the peer interface of the link.

7

Click OK to close the Configure ILMI Link form. The ATM Configuration (Edit) form opens.

8

To remove an ILMI link, click Remove ILMI Link. Removing the ILMI link also removes the PVC.

Note: An ILMI link can be removed only if its Administrative Status parameter is set to Disabled.

9

Click Cancel to close the forms.

END OF STEPS

16.76 To view the channels associated with a 1830 VWM TLU port

16.76.1 Steps

1

On the equipment tree, expand Network→1830–VWM-OSU NE→1830–VWM-TLU shelf→Card Slot 1 TLU→Port.

2

Right-click on the Port object and choose Properties. The Physical Port (Edit) form opens.

3

Click on the CDR Channel tab, choose the CDR channel interface, and click Properties. The CDR Channel (Edit) form opens.

Result: The mapping of the port to the CDR channel appears.

End of steps

16.77 To retrieve 1830 VWM DDM data

16.77.1 Steps

1

On the equipment tree, expand Network→1830 VWM→Shelf→Card.

2

Right-click on the port object and choose Properties. The Physical Port (Edit) form opens.

3

Click on the Statistics tab, choose DDM Statistics (On Demand) (VWM) from the object drop-down menu, and click Collect. The DDM data is listed.

4

Close the form.

End of steps

16.78 To configure an OSC port of an 1830 VWM OSU as a RFLM port

16.78.1 Steps

1

On the equipment tree, expand Network→1830 VWM OSU→Shelf→Card.

2

Right-click on the OSC port and choose Properties. The Physical Port (Edit) form opens.

3

Click on the States tab and set the Administrative State parameter to Down.

4

Click on the Port Specifics tab and set the Interface Role parameter to RFLM.

5

Enter suitable text in the RFLM Label field.

6

Save your changes and close the form.

END OF STEPS

16.79 To perform CPRI monitoring using 1830 VWM TLU 9M MON ports

16.79.1 Before you begin

Ensure that the States parameter of the target ports (client and its corresponding line port, for example, if the target port is C1, its corresponding line port is L1) are configured as Maintenance, if you need the monitoring mode to be configured as tap Insert or terminate.

16.79.2 Steps

1

On the equipment tree, expand Network→1830 VWM OSU→Shelf (TLU 9M)→Card (TLU 9M).

2

Right-click on the MON port and choose Properties. The Physical Port (Edit) form opens.

3

Click on the Interface Monitor tab.

4

Configure the Monitor Mode parameter.

5

Click Select in the Interface Monitor Details panel and the Select Target Port form opens.

6

Select the target port and click OK. The port details are updated in the Interface Monitor Details panel.

Note:

If...	then...
you configure the Monitoring Mode parameter as Listen in Step 4,	the target ports can be in up, down, or maintenance state.
you configure the Monitoring Mode parameter as Tap Inset or Terminate in Step 4,	only the target ports that have the States Parameter configured as Maintenance are listed for selection in the Select Target Port form.

7

Click Apply.

8

Click on the States tab and configure the Administrative State parameter as Up.

9

Save your changes and close the form.

END OF STEPS

16.80 To configure OTDR on 1830 VWM

16.80.1 Purpose

Perform this procedure to configure Optical Time Domain Reflectometer (OTDR) on the supported 1830 VWM. OTDR functionality is used as a diagnosis to detect fiber breaks and open connectors in the network, eliminating the delay in fault detection.

16.80.2 Steps

1

On the equipment tree, expand Network→1830–VWM-OSU NE→Shelf→Card Slot→Port object and choose Properties. The Physical Port (Edit) form opens.

2

Click on the OTDR tab, and then on the OTDR Specifics tab.

3

Configure the OTDR Mode in the OTDR panel.

4

Configure the Execution Measurement parameter in the OTDR Measurement panel.

Execution details are populated under the Execution Details panel.

5

Click on the OTDR Results tab. The results are displayed in a tabular format. Click Resync to display the latest OTDR results.

END OF STEPS

17 Inventory management

Managing inventory

17.1 Overview

17.1.1 Functional description

You can use an NFM-P GUI or OSS client to inventory the managed network equipment. The inventory information is available to GUI clients on equipment list, properties, and management forms. For information about using the XML API interface to perform inventory management, see the “Inventory management” chapter of the *NSP NFM-P XML API Developer Guide*.

Inventory information may be required for the following purposes:

- spare equipment management
- SLA audits
- license capacity tracking

17.1.2 License capacity tracking

An NFM-P license has one overall capacity value for managed equipment; each licensed equipment object consumes a number of license points based on the equipment type. You can use inventory management to anticipate the need for additional license capacity as the managed network grows.

For licensed equipment types, an inventory list includes the following fields:

- Licensed Product—whether the equipment consumes NFM-P license points
- License Points Consumed—the number of NFM-P license points that the equipment consumes

Creating a license points inventory

You can use the License Points Inventory button on the NFM-P License form to generate an inventory of the license point consumption for managed objects and subscriber types. The inventory entries are saved in a file and listed by device site ID or subscriber type; the information for each includes the following:

- object FDN, for equipment
- associated site ID, for equipment
- licensed product name or subscriber type
- number of license points that the object consumes

See the section on software and license configuration procedures in the *NSP System Administrator Guide* for information about creating a license point inventory.

17.1.3 Viewing inventory information in the GUI

Using the NFM-P Equipment Manager, you can list the license information for the following object types:

- cards, using Card (Physical Equipment) as the search criterion
- card child objects:
  - Blade
  - IO Card
  - IO Card→Base Card
  - IO Card→Daughter Card
  - IO Card→MCM Card
  - Processor Card
- chassis, using Network Element (Network) as the search criterion
- VWM shelves, using VWM Shelf (Physical Equipment) as the search criterion

You can use a GUI client to retrieve the inventory information for equipment objects in the following contexts:

- one managed NE
- entire managed network

Note: Not all columns in an inventory list apply to all equipment types. For example, not all card types have an associated CLEI code. In such a case, an inventory list column displays N/A.

Figure 17-1 Generating inventory data for all managed NEs

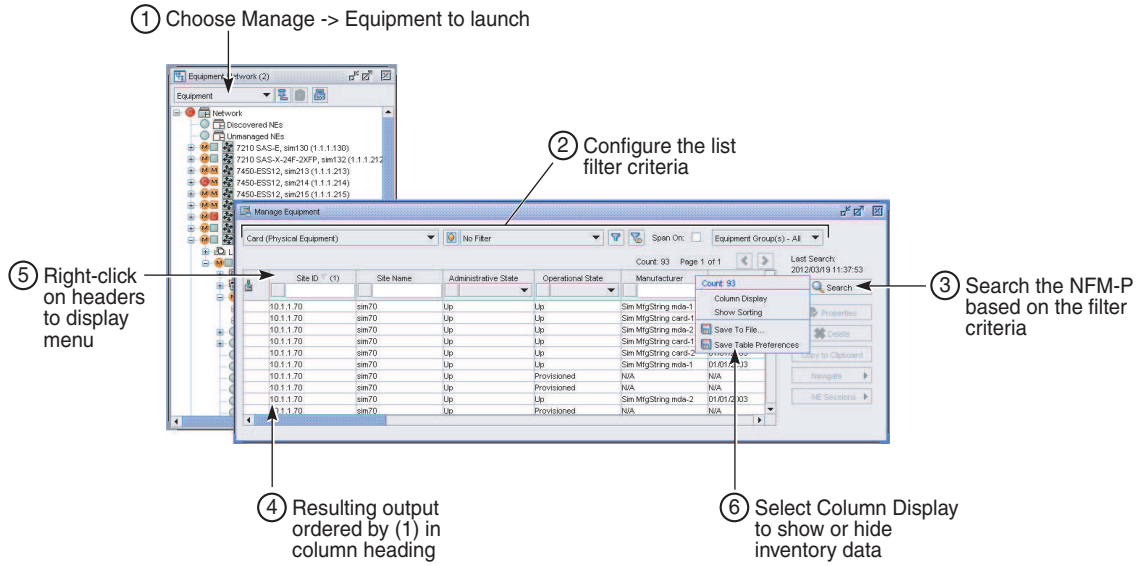


Figure 17-2 Generating inventory data for a managed NE

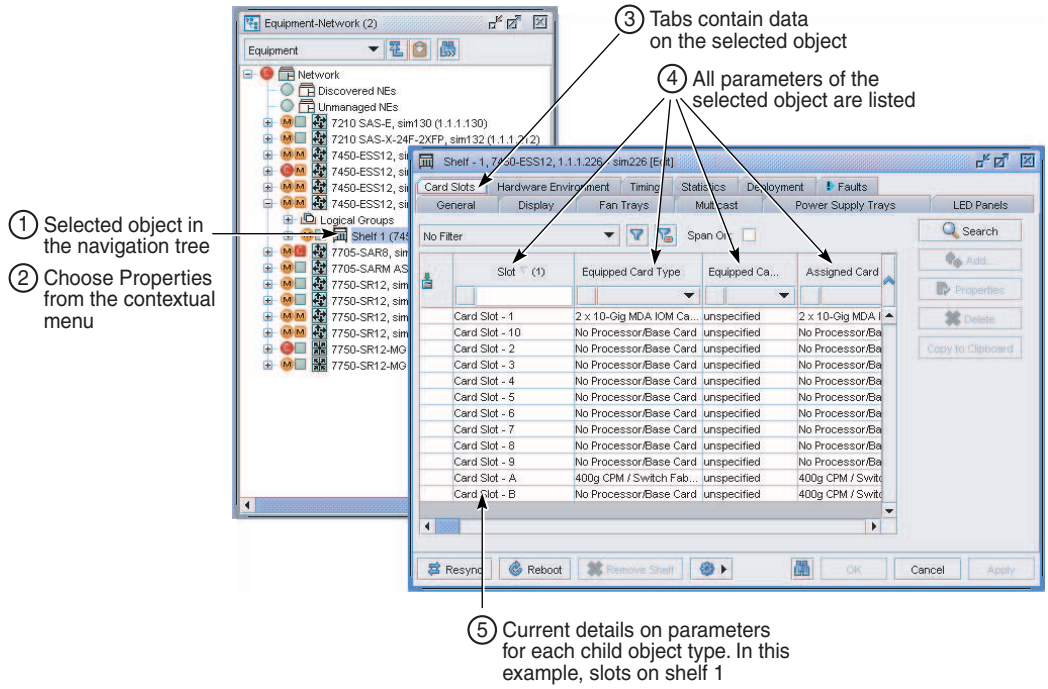

22864

You can save the inventory data in various formats, for example, CSV and HTML.

Figure 17-3 CSV inventory output

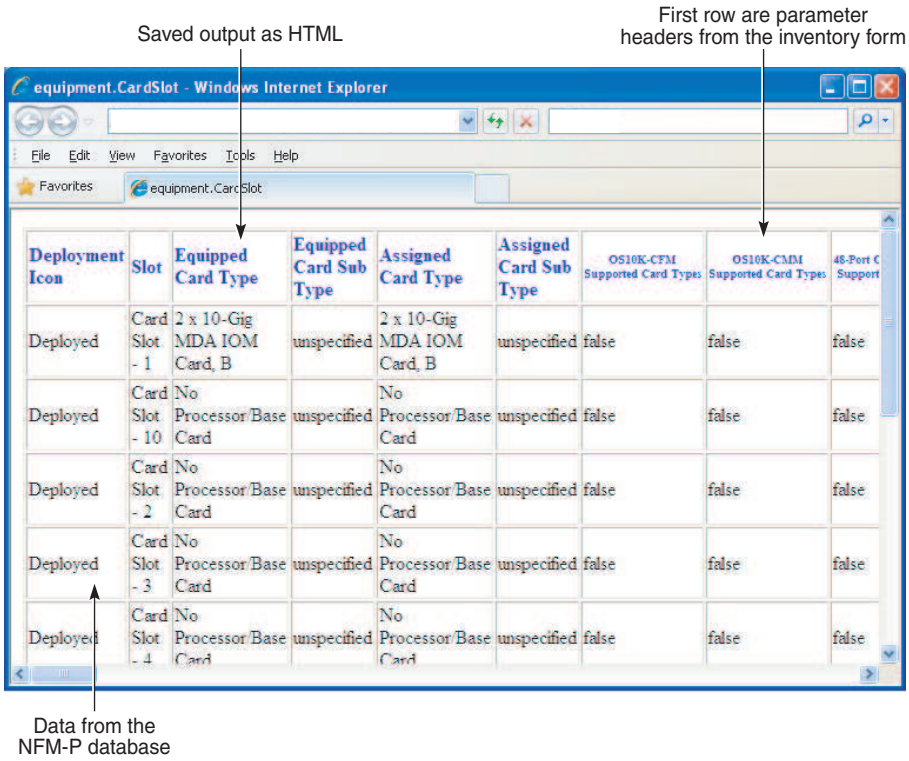

Figure 17-4 HTML inventory output

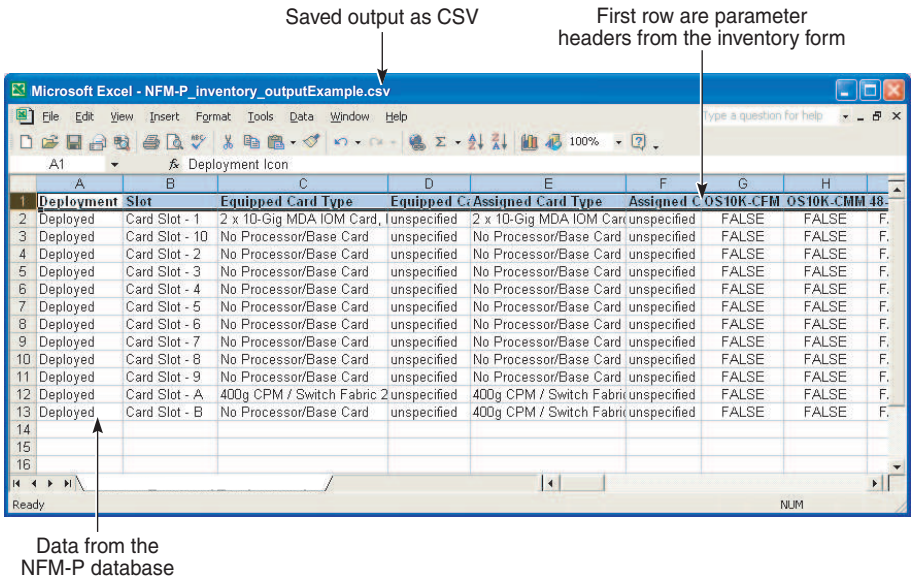


17.1.4 Exporting a network inventory file for adaptor modules and license details

Using the NFM-P Equipment Manager, you can export a zipped network inventory file that contains inventory files for NEs, shelves, cards, media adaptors, and license information for all NFM-P-managed NEs. See 17.12 “To export a network inventory file for adaptor modules and license details” (p. 697).

17.2 Sample inventory management workflow

17.2.1 Stages

1

Determine the part needs based on business requirements and network growth.

2

Based on the business requirements, use the NFM-P to generate one or more filtered inventory lists that contain only the objects for which spare parts may be required.

3

Save the lists of required spare parts in a format that is compatible with your back-office systems; for example, CSV or HTML. Move the lists to another system, for example, an order management or data management system, for processing.

4

Correlate inventory lists with data from other back-office systems.

17.3 Workflow to manage inventory

17.3.1 Stages

1

Determine the inventory management requirements.

2

Provide inventory list requirements to NOC operators.

3

As required, list and sort inventory data for a managed NE or the entire network; see 17.4 “To list and sort equipment information” (p. 689) .

4

As required, save an inventory list to a file; see 17.5 “To save an inventory list” (p. 690) .

5

As required, save search filters; see 1.33 “To save search filters” (p. 132) .

6

As required, generate an inventory of objects on one managed NE:

- CLEI codes; see 17.6 “To inventory the CLEI codes of NE objects” (p. 690)
- card software versions; see 17.7 “To inventory the card software versions of one NE” (p. 691)
- port types; see 17.8 “To inventory the port types of one NE” (p. 692)
- shelf data; see 17.9 “To inventory the shelf data for one NE” (p. 693)

7

As required, generate a network-wide inventory of all managed objects, see 17.10 “To generate a network-wide inventory of managed objects” (p. 693).

8

Generate an inventory list for NE SLA audits; see 17.11 “To collect inventory data for NE SLA audits” (p. 696) .

9

As required, export a zipped network inventory file for adaptor modules and license details; see 17.12 “To export a network inventory file for adaptor modules and license details” (p. 697).

10

Move inventory lists to other systems for further processing, as required.

17.4 To list and sort equipment information

17.4.1 Steps

1

Choose Manage→Equipment→Equipment from the NFM-P main menu. The Manage Equipment form opens.

2

Perform one of the following to generate a list of equipment.

a. List the equipment on one NE.
   1. Choose Network Element (Network) from the object drop-down menu and click Search. A list of NEs is displayed.
   2. Select an NE and click Properties. The Network Element (Edit) form opens.
   3. Click on the Inventory tab and choose an object type from the object drop-down menu. A list of objects is displayed.

b. List the equipment in the entire network.
   1. Choose an object type from the object drop-down menu.
   2. Configure the filter criteria and click Search. A list of objects is displayed.

3

Perform one or more of the following to format the results.

a. To display the number of items in the list, right-click on the list heading and view the Count value.

b. To sort the list, click on a column heading. The column heading displays an arrow that indicates the sort order.

c. To move a column, drag and drop the column to a different position.

d. To remove a column:
   1. Right-click on the column heading and choose Column Display. The Column Display form opens.
   2. Select the columns to remove in the Displayed on Table list, and then click on the left arrow. The columns move to the Available for Table list.
   3. Click OK. The columns are removed from the table.

e. To sort multiple columns:
   1. Right-click on a column heading and choose Show Sorting. The Show Sorting form opens.

2. Select one or more properties in the Available for Sorting panel, and then click on the right arrow button. The properties move to the Used for Sorting panel.
3. Click Sort Ascending or Sort Descending, as required.
4. Close the Show Sorting form.

4

Save the inventory output, as required. see 17.5 “To save an inventory list” (p. 689) .

5

Close the form.

END OF STEPS

17.5 To save an inventory list

17.5.1 Steps

1

Right-click on a column heading of the inventory output and choose Save to File. The Save As file browser form opens.

2

Navigate to the directory in which you want save the file.

3

Configure the File Name and Files of Type parameters.

4

Click Save. The NFM-P saves the inventory list.

END OF STEPS

17.6 To inventory the CLEI codes of NE objects

17.6.1 Steps

1

Choose Manage→Equipment→Equipment from the NFM-P main menu. The Manage Equipment form opens.

2

Perform one of the following to generate a list of network objects.

a. List the CLEI codes for objects on one NE.
   1. Choose Network Element (Network) from the object drop-down menu and click Search. A list of NEs is displayed.
   2. Select an NE and click Properties. The Network Element (Edit) form opens.
   3. Click on the Inventory tab and choose a network object. The form displays a list of network objects.

b. List the CLEI codes for all network objects of a specific type. Choose a network object.

3

Remove all columns from the list except for object ID, object type, and CLEI code. See 17.4 “To list and sort equipment information” (p. 689) for information.

4

Save the information to a file. See 17.5 “To save an inventory list” (p. 690) .

5

Close the forms.

END OF STEPS

17.7 To inventory the card software versions of one NE

17.7.1 Steps

1

Choose Manage→Equipment→Equipment from the NFM-P main menu. The Manage Equipment form opens.

2

Choose Network Element (Network) from the object drop-down menu and click Search. A list of NEs is displayed.

3

Select an NE in the list and click Properties. The Network Element (Edit) form opens.

4

Click on the Inventory tab and choose Card (Physical Equipment) from the object drop-down menu. A list of cards is displayed.

5

Remove all columns from the list except for Slot ID and Software Version. See 17.4 “To list and sort equipment information” (p. 689) .

6

Save the inventory output. See 17.5 “To save an inventory list” (p. 690) .

7

Close the forms.

End of steps

17.8 To inventory the port types of one NE

17.8.1 Steps

1

Choose Manage→Equipment→Equipment from the NFM-P main menu. The Manage Equipment form opens.

2

Choose Network Element (Network) from the object drop-down menu and click Search. A list of NEs is displayed.

3

Select an NE in the list and click Properties. The Network Element (Edit) form opens.

4

Click on the Inventory tab and choose Port (Physical Equipment) from the object drop-down menu. A list of ports is displayed.

5

To display more detailed port inventory information, expand the Port (Physical Equipment) object and choose from the available objects.

6

Sort the inventory output. See 17.4 “To list and sort equipment information” (p. 689) .

7

Save the inventory output. See 17.5 “To save an inventory list” (p. 690) .

8

Close the forms.

End of steps

17.9 To inventory the shelf data for one NE

Note: You can also generate an inventory of shelf data for all NEs in a managed network; see 17.10 “To generate a network-wide inventory of managed objects” (p. 693) for more information.

17.9.1 Steps

1

Choose Manage→Equipment→Equipment from the NFM-P main menu. The Manage Equipment form opens.

2

Choose Network Element (Network) from the object drop-down menu and click Search. A list of NEs is displayed.

3

Select an NE in the list and click Properties. The Network Element (Edit) form opens.

4

Click on the Inventory tab and choose Shelf (Physical Equipment) from the object drop-down menu. A list of shelf objects is displayed.

5

Select a shelf in the list and click Properties. The Shelf (Edit) form opens.

6

Click on the Display tab. A picture of the selected shelf is displayed.

7

Use screen capture software to record the screen image, or otherwise copy the shelf information to a file for further processing.

8

Close the open forms, as required.

END OF STEPS

17.10 To generate a network-wide inventory of managed objects

17.10.1 Purpose

Perform this procedure to inventory all equipment of one object type, for example, all cards. The table below describes the columns to include in the inventory list for each equipment type.

Table 17-1 Inventory columns for managed objects

Equipment	Columns to include in inventory list
Cards	• Manufacture Date • Part Number • Serial Number • CLEI Code
CCMs	• Manufacture Date • Part Number • Serial Number • CLEI Code • CCM Index • CCM Equipped Type
Fan trays	• Operational State • Administrative State • Device State
Flash memory units	• Serial Number • Firmware Revision • Model Number • Capacity (sectors) • Amount Used (sectors)
Physical links	• Endpoint A Type • Endpoint A — Port • Endpoint B Type • Endpoint B — Port
Ports	• Name • CLI Name • MTU (bytes) • State
Power supply trays	• Administrative State • Operational State • AC Voltage Status • DC Voltage Status • Assigned Type

Table 17-1 Inventory columns for managed objects (continued)

Equipment	Columns to include in inventory list
Processors	• Operational State • Administrative State • CLEI Code • Manufacturer • Manufacture Date • Part Number • Serial Number
Shelves	• Operational State • Administrative State • CLEI Code • Manufacturer • Manufacture Date • CLLI Code • Part Number • Serial Number (Manufacturer Details)
Management ports	• System ID • Management IP Address • Location • Chassis Type • Sys Object ID • Software Version • Descriptor Version (software release) • Resource Group ID

17.10.2 Steps

1

Choose Manage→Equipment→Equipment from the NFM-P main menu. The Manage Equipment form opens.

2

Choose Card (Physical Equipment) from the object drop-down menu.

3

Remove all columns from the list except the required columns shown in the table above. See 17.4 “To list and sort equipment information” (p. 689) for information.

4

Save the inventory output. See 17.5 “To save an inventory list” (p. 690) .

5

Close the form.

End of steps

17.11 To collect inventory data for NE SLA audits

Note: SLA inventory collection requirements differ. Ensure that you collect the required data for your SLA.

Inventory data collection can be resource-intensive; perform inventory collection during a maintenance period or a period of low network activity.

17.11.1 Steps

1

Choose Manage→Equipment→Equipment from the NFM-P main menu. The Manage Equipment form opens.

2

To collect the required SLA audit data, choose the required object type from the object drop-down menu.

a. For card SLA audits, choose Card (equipment).

b. For shelf SLA audits, choose Shelf (equipment).

c. For power supply tray SLA audits, choose Power Supply Tray (equipment).

3

Click Search. The SLA audit information is listed.

4

Typically, only a subset of data is required for SLA audits. Remove all columns from the list except for the required columns. See 17.4 “To list and sort equipment information” (p. 689) for information.

Required information typically includes the following:

- Identification information, such as Site ID, Site Name, Slot ID, and Slot Name
- SLA audit and ordering information, such as Manufacture Date, Part Number, Serial Number, CLEI Code, and Card Type

5

Save the inventory output. See 17.5 “To save an inventory list” (p. 690) .

6

Close the form.

END OF STEPS

17.12 To export a network inventory file for adaptor modules and license details

17.12.1 Purpose

Perform this procedure to export a zipped network inventory file that contains the following network inventory files:

- Network_MediaAdaptor.csv
- Network_LicenseInformation.csv
- Network_NetworkElement.csv
- Network_Shelf.csv
- Network_Card.csv

Note: Only one export request can be handled at a time; the Export Inventory button is disabled until the file export completes.

17.12.2 Steps

1

Choose Manage→Equipment→Equipment from the NFM-P main menu. The Manage Equipment form opens.

2

Click Export Inventory. A dialogue box opens with a reminder that the network inventory file generation and export is a time consuming activity.

3

Click OK.

4

Navigate to where you want to save the exported inventory file and click Save. A download status pop-up displays when the inventory file is downloaded.

5

Click OK.

6

Close the form.

END OF STEPS

18 Card migration

Card migration management

18.1 Overview

18.1.1 NFM-P Card Migration Event Manager

You can use an NFM-P GUI utility called the Card Migration Event Manager to facilitate the transition to an IOM 3 on one or more 7450 ESS or 7750 SR NEs. The Card Migration Event Manager transfers the existing IOM and MDA configurations to new modules with minimal service interruption.

The NFM-P Card Migration Event Manager can do the following:

- Upgrade from an IOM 1 or IOM 2 to an IOM3 while retaining the same MDAs.
- Upgrade from one MDA type to a newer MDA type that has compatible features.
- Upgrade an IOM and the associated MDAs in one operation.

You can perform an immediate migration, or preconfigure one or more migration events for later execution. A migration event can include an NE reboot to put the new hardware configuration into effect immediately after the migration. You can upgrade multiple IOMs and MDAs in one operation to limit the number of required NE reboots to one.

During a migration event, the NFM-P identifies the configured objects that are bound to the IOM or MDA, deletes the objects, and then creates the objects on the new IOM or MDA. The old and new configurations are saved in the NFM-P database until the migration completes successfully. The NFM-P preserves the statistics data and alarm information that is associated with each object.

18.1.2 Restrictions

The following restrictions apply to NFM-P card migration event management:

- **General**
  - Only the NFM-P admin user, or a user with an assigned administrator scope of command role, can create, modify, or execute a migration event.
  - The migration functions are not available to NFM-P OSS clients.
  - You may need to re-enable SNMP on an NE after the NE reboots following a migration event.
  - The description of a SAP associated with the card cannot contain a numerical value.
- **IOM-specific**
  - An IOM downgrade, for example, a migration from an IOM 3 to an IOM 2, is not supported.
- **MDA-specific:**
  - You cannot migrate an empty MDA slot to an MDA.
  - MDA migration is limited to MDAs of the same physical transmission type; for example, migration from a SONET MDA to an Ethernet MDA is not supported.
  - You cannot upgrade an MDA that is integrated with an IOM, for example, an IMM.
  - For MDAs, you can migrate only to an MDA of similar capacity that has the same or a greater number of ports.

The NFM-P raises an alarm during a migration event if a target NE is unreachable. After a migration event, the NFM-P raises an alarm to indicate migration success or failure.

Table 18-1 Supported MDA migration types

Current MDA	MDAs supported by migration
10 x 1-Gig Ethernet SFP	10 x 1Gig Extended Performance SFP 20 x 10/100/1000 Ethernet Extended Performance SFP 20 x 10/100/1000 Ethernet Extended Performance TX
5 x 1-Gig Ethernet SFP	10 x 1Gig Extended Performance SFP 20 x 10/100/1000 Ethernet Extended Performance SFP 20 x 10/100/1000 Ethernet Extended Performance TX
1 x 10-Gig Ethernet	4 x 10Gig Extended Performance XFP 2 x 10Gig Extended Performance XFP 1 x 10Gig Extended Performance SFP
20 x 100 Ethernet Fx	20 x 10/100/1000 Ethernet Extended Performance SFP 20 x 10/100/1000 Ethernet Extended Performance TX
20 x 10/100/1000 Ethernet Tx	20 x 10/100/1000 Ethernet Extended Performance SFP 20 x 10/100/1000 Ethernet Extended Performance TX
2 x 10-Gig Ethernet XFP	2 x 10Gig Extended Performance XFP 4 x 10Gig Extended Performance XFP
20 x 10/100/1000 Ethernet SFP	20 x 10/100/1000 Ethernet Extended Performance SFP 20 x 10/100/1000 Ethernet Extended Performance TX
1 x 10-gig Ethernet XFP	4 x 10GigExtended Performance XFP 2 x 10Gig Extended Performance XFP 1 x 10Gig Extended Performance XFP
5 x 10/100/1000	10 x 1Gig Extended Performance SFP 20 x 10/100/1000 Ethernet Extended Performance SFP 20 x 10/100/1000 Ethernet Extended Performance TX
10 x 10/100/1000 Ethernet SFP	10 x 1Gig Extended Performance SFP 20 x 10/100/1000 Ethernet Extended Performance SFP 20 x 10/100/1000 Ethernet Extended Performance TX
60 x 10/100 Ethernet	48 x 10/100/1000 Ethernet Extended Performance TX

18.2 Workflow to manage card migration

18.2.1 Stages

Note: When you attempt a migration on an NE that does not have a recent configuration backup in the NFM-P database, the NFM-P raises an alarm and the migration fails.

Note: A recent configuration backup is a backup that occurs after the latest configuration save on the NE.

Note: Use the NFM-P to back up the device configuration of each target NE. See Chapter 23, “NE backup and restore” for information about performing NE backups.

1

Create a card migration event and execute or save it, as required. See 18.3 “To create a card migration event” (p. 700) for more information.

2

Execute a saved card migration event, as required. See 18.4 “To execute a saved card migration event” (p. 703) for more information.

18.3 To create a card migration event

18.3.1 Steps

1

Choose Tools→Card Migration Event Manager from the NFM-P main menu. The Card Migration Event Manager form opens.

2

Click Create. The Card Migration Event (Create) form opens with the General tab displayed.

3

Configure the general parameters.

4

Click on the NE Migration Candidates tab and click Add. The Select Network Elements - Card Migration Event form opens.

5

Select one or more NEs and click OK. The Select Network Elements - Card Migration Event form closes and the NEs are listed on the Card Migration Event (Create) form.

6

Select one or more NEs and click Properties. The Network Element Migration Candidates form opens.

7

Configure the Auto Reboot parameter and click OK.

8

Click on the Card Migration Candidates tab and click Add. The Select Cards - Card Migration Event form opens.

9

Select one or more cards and click OK. The Select Cards - Card Migration Event form closes and the cards are listed on the Card Migration Event (Create) form.

10

Select one or more cards and click Properties. The Migration Details (Create) form opens.

11

Configure the New Type parameter in the IOM, MDA 1, or MDA 2 panels, as required, and click OK.

12

To execute the migration event immediately, perform the following steps. Otherwise, you can execute the migration later by performing 18.4 “To execute a saved card migration event” (p. 703) .

1. Use the NFM-P to back up the device configuration of each target NE.

   Note:

   When you attempt a migration on an NE that does not have a recent configuration backup in the NFM-P database, the NFM-P raises an alarm and the migration fails.

   A recent configuration backup is a backup that occurs after the latest configuration save on the NE.
2. Click Apply. The NFM-P saves the card migration event configuration.
3. Click on the General tab to display the Status indicator.
4. Click Initiate Migration and click Yes. The NFM-P starts to migrate the specified cards.
5. Monitor the card migration as it progresses by viewing the Status indicator on the form. The status can be one of the following:
   - Awaiting manual reboot to complete migration
   - Failed - Latest configuration not available
   - Failed - Unable to migrate configuration
   - Failed - Unable to reboot network element
   - Failed - Unable to transfer migrated configuration
   - Migration completed
   - Not Started
   - Rebooted network element
   - Started
   - Swap failed
   - Swap failed on some network elements

13

Save your changes and close the form.

END OF STEPS

18.4 To execute a saved card migration event

18.4.1 Steps

1

Use the NFM-P to back up the device configuration of each target NE.

Note: When you attempt a migration on an NE that does not have a recent configuration backup in the NFM-P database, the NFM-P raises an alarm and the migration fails. A recent configuration backup is a backup that occurs after the latest configuration save on the NE.

2

Choose Tools→Card Migration Event Manager from the NFM-P main menu. The Card Migration Event Manager form opens.

3

Select a card migration event and click Properties. The Card Migration Event (Edit) form opens with the General tab displayed.

4

Click Initiate Migration and click Yes. The NFM-P starts to migrate the specified cards.

5

Monitor the card migration as it progresses by viewing the Status indicator on the form. The status can be one of the following:

- Awaiting manual reboot to complete migration
- Failed - Latest configuration not available
- Failed - Unable to migrate configuration
- Failed - Unable to reboot network element
- Failed - Unable to transfer migrated configuration
- Migration completed
- Not Started
- Rebooted network element
- Started
- Swap failed
- Swap failed on some network elements

6

Save your changes and close the form.

END OF STEPS

19 TCA

TCA management using the NFM-P

19.1 Overview

19.1.1 Functional description

You can create policies to raise NFM-P alarms based on managed-object statistics. When a statistic counter of an object such as an interface reaches a specified threshold, the NFM-P alerts GUI operators using a threshold-crossing alarm, or TCA, based on policy specifications.

A TCA policy includes the following:

- a list of objects to monitor
- a traffic flow direction to monitor
- rules that define the rising and falling thresholds, and the alarm severity
- optional custom rules to monitor statistics based on user-defined formulas

Note: A TCA is not self-clearing. The NFM-P clears a TCA only when the TCA policy contains a falling-threshold rule in addition to a rising-threshold rule, and the alarm severity in the falling-threshold rule is set to cleared.

19.1.2 TCA operation

To enable TCA on an object, you must enable performance statistics collection on the object. See the *NSP NFM-P Statistics Management Guide* for information about enabling performance statistics collection.

The NFM-P compares the object counter values at each statistics collection to the threshold values in the associated TCA policy. When a value initially crosses a threshold, the NFM-P raises an alarm. Rather than raise new alarms for successive threshold-crossing events associated with the policy, the NFM-P adjusts the alarm severity based on the policy rules.

Note: If required, you can use a parameter on the TCA policy properties form to disable the alarm-severity demotion defined in a TCA policy. For example, an operator may want a critical alarm associated with an object to persist and be visible to other operators until the fault condition is cleared.

Using the NFM-P client GUI, you can associate a TCA policy with a managed object from the TCA policy configuration form, or from the object properties form. You can associate one TCA policy with multiple objects.

19.1.3 TCA policy rules

Depending on the object type, you can use rules to monitor the following:

- object utilization
- errored packets

- dropped packets
- custom values; see 19.1.4 “Custom profile TCAs” (p. 705)

A rule can apply to an absolute counter value or to a delta value, which is the difference between the current value and the previous value.

In a TCA policy rule, you can specify whether the rule raises alarms. Disabling the raising of alarms according to a policy rule may be required, for example, when the rule raises excessive alarms because of a fault that causes frequent threshold crossing. You can disable the raising of alarms while the fault is being resolved, and then re-enable the raising of alarms when the affected object returns to normal operation.

19.1.4 Custom profile TCAs

You can optionally create custom profile TCAs that define the TCA rules using one or more of the following in a mathematical formula:

- monitored object statistics counters
- monitored object properties
- numerical constants
- mathematical operators

Note: For monitored object property values in a formula, the current and previous values are the same. If a monitored object property value changes between collections, the new property value is used as the current and previous values.

After you create a custom profile TCA, you associate the custom profile TCA with a TCA policy to put the TCA into effect.

19.1.5 TCA configuration example

The following example describes the NFM-P configuration required to raise a TCA, adjust the alarm severity, and clear the alarm, based on the following utilization specifications:

- Raise a minor alarm if utilization is between 60% and 69%.
- Change the alarm severity to major if utilization rises to between 70% and 79%.
- Change the alarm severity to critical if utilization rises to 80% or higher.
- Change the alarm severity to major if utilization falls below 80%.
- Change the alarm severity to minor if utilization falls below 70%.
- Clear the alarm if utilization falls below 60%.

The following are the TCA rules and associated parameter values required to implement the example alarm behavior:

Rule to raise minor alarm for 60% or higher utilization:

- Alarm Severity—minor
- Threshold (%)—60
- Threshold Direction—Rising Above

Rule to change alarm severity to major for 70% or higher utilization:

- Alarm Severity—major
- Threshold (%)—70
- Threshold Direction—Rising Above

Rule to change alarm severity to critical for 80% or higher utilization:

- Alarm Severity—critical
- Threshold (%)—80
- Threshold Direction—Rising Above

Rule to change alarm severity to major if utilization falls below 80%:

- Alarm Severity—major
- Threshold (%)—80
- Threshold Direction—Falling Below

Rule to change alarm severity to minor if utilization falls below 70%:

- Alarm Severity—minor
- Threshold (%)—70
- Threshold Direction—Falling Below

Rule to clear alarm if utilization falls below 60%:

- Alarm Severity—cleared
- Threshold (%)—60
- Threshold Direction—Falling Below

19.2 Workflow to configure TCA

19.2.1 Purpose

The following is the sequence of high-level actions required to configure TCA and enable the TCA function on a monitored object.

19.2.2 Stages

1

Enable performance statistics collection on the object to monitor. Table 19-1, “Port statistics policy objects for TCA” (p. 707) lists the port statistics policy objects required to enable TCA on a network interface or physical link.

Table 19-1 Port statistics policy objects for TCA

Statistics policy type	MIB	MIB entry	Monitored class
NE MIB	IF-MIB	ifEntry	—
Specific MIB			equipment.PhysicalPort
Interface Additional Stats		ifXEntry	lag.Interface

2

If you require custom TCA rules, configure a custom profile TCA; see 19.3 “To configure a custom profile TCA” (p. 707) .

3

Configure a TCA policy; see 19.4 “To configure a TCA policy” (p. 709) .

1. Configure utilization, error, and drop TCA rules.
2. Optionally, associate a custom profile TCA with the policy.

4

Apply the TCA policy to an object; see 19.5 “To apply a TCA policy to objects using the object properties forms” (p. 711) .

5

If required, customize the TCA system preferences, such as specifying the default TCA severity or the maximum TCA limit; see the section on system preferences configuration procedures in the *NSP System Administrator Guide*.

19.3 To configure a custom profile TCA

19.3.1 Steps

1

Choose Tools→TCA Policies from the NFM-P main menu. The TCA Policies form opens.

2

Choose Custom Profile TCA (TCA Policy) and click Create. The Custom Profile TCA (Create) form opens.

3

Configure the general parameters.

4

Select a monitored object type.

5

Configure the Stats Type parameter.

6

Click Build Formula. The Build Formula form opens.

7

Choose a statistic counter from the Counter Field drop-down menu and click Add.

8

Add one or more values and operators to the formula, as required.

Note: To enclose an expression in parentheses, select the expression and click on the ( ) operator.

a. Add a statistic counter for the monitored object.
   1. Click on a mathematical operator.
   2. Choose a counter from the Counter Field drop-down menu and click Add.

b. Add a property of the monitored object.
   1. Click on a mathematical operator.
   2. Choose a property from the Class Field drop-down menu and click Add.

c. Add a constant value.
   1. Click on a mathematical operator.
   2. Enter a number in the Constant Value field and click Add.

9

Click OK to save your changes and close the Build Formula form.

10

Click OK to save your changes and close the Custom Profile TCA (Create) form.

11

Close the TCA Policies form.

END OF STEPS

19.4 To configure a TCA policy

19.4.1 Steps

1

Choose Tools→TCA Policies from the NFM-P main menu. The TCA Policies form opens.

2

Choose TCA Policy (TCA Policy) and click Create. The TCA Policy (Create) form opens.

3

Configure the general parameters.

4

Select a monitored object and click Apply.

Note: The panels displayed on the General tab vary, depending on the type of monitored object. If the monitored object type you need does not appear in the list, you may need to create a custom TCA profile first; see 19.3 “To configure a custom profile TCA” (p. 708).

5

To configure utilization TCA rules:

1. Configure the parameters in the Utilization panel.
2. Click Create in the Rules panel. The PercentageTCARule, tca.UtilizationTCA-0 (Create) form opens.
3. Configure the parameters and click OK.

   Note:

   You cannot create two rules that have the same Threshold (%) and Threshold Direction values.

6

To configure error TCA rules:

1. Configure the parameters in the Error panel.
2. Click Create in the Rules panel. The PercentageTCARule, tca.ErrorTCA-0 (Create) form opens.
3. Configure the parameters and click OK.

   Note:

   You cannot create two rules that have the same Threshold (%) and Threshold Direction values.

7

To configure drop TCA rules:

1. Configure the parameters in the Drop panel.
2. Click Create in the Rules subpanel. The PercentageTCARule, tca.DropTCA-0 (Create) form opens.
3. Configure the parameters and click OK.

   Note:

   You cannot create two rules that have the same Threshold (%) and Threshold Direction values.

8

To configure custom TCA rules:

1. In the Custom panel, click Create. The CustomTCA (Create) form opens.
2. Configure the parameters.

3. Select a Custom TCA Profile.
4. Click Create in the Rules panel. The CustomTCARule, tca.CustomTCA-0 (Create) form opens.
5. Configure the parameters and click OK.

9

Apply the TCA Policy to one or more monitored objects:

1. Click on the Monitored Objects tab.
2. Click Add. The Select form opens.
3. Select the required objects and click OK.

10

Click OK to save your changes and close the TCA Policy (Edit) form.

11

Close the TCA Policies form.

END OF STEPS

19.5 To apply a TCA policy to objects using the object properties forms

19.5.1 Steps

1

Choose Manage→Equipment→Equipment from the NFM-P main menu. The Manage Equipment form opens.

2

Select an object type and click Search. A list of equipment objects is displayed.

3

Select an object and click Properties. The object properties form opens.

4

If the object is a Physical Link, assign a TCA policy to End Point A and End Point B. Go to Step 7 .

5

Click on the TCA tab and click Assign. The Select TCAPolicy form opens.

6

Select a TCA policy and click OK

7

Click OK to save your changes and close the object properties form.

8

Close the Manage Equipment form.

END OF STEPS

20 Bulk operations

Bulk operations using the NFM-P

20.1 Overview

20.1.1 Functional description

The NFM-P bulk operations function allows you to create bulk changes to modify a large amount of information. Bulk changes may be deployed to NEs or restricted to the NFM-P.

A bulk change can contain thousands of target objects. These objects, referred to as batch items, are grouped into batches for efficient bulk change execution. An operator can execute an entire bulk change or individual batches.

You should regenerate batches each time you execute a bulk change to ensure that each target object that matches the bulk change filter is modified.

If one or more of the batch items fail to change during a bulk change operation, the Batch Status and the Batch Status Summary parameters help identify the items. You can also use the Task Manager to view information about a batch.

The NFM-P displays a confirmation message before executing bulk change operations. You can configure user preferences to disable confirmation messages for bulk change operations; see 1.23 “To configure NFM-P user preferences” (p. 116) .

20.2 Workflow to manage bulk operations

20.2.1 Stages

1

Create a bulk change. See 20.3 “To create a bulk change” (p. 714) .

2

Generate batches for a bulk change. See 20.5 “To execute a bulk change” (p. 716) .

3

Execute one or more batches in a bulk change. See 20.5 “To execute a bulk change” (p. 716) .

4

As required, stop a bulk change. See 20.7 “To stop one or more bulk changes” (p. 718) .

5

View the bulk change execution results to verify that the bulk change was successful and to identify any items that failed to change. See 20.6 “To view executed batch information” (p. 717) .

20.3 To create a bulk change

20.3.1 Steps

1

Choose Tools→Bulk Operations from the NFM-P main menu. The Bulk Operations form opens.

2

Open the Create Bulk Change form by performing one of the following steps.

a. Click Create.

b. To create a bulk change by copying values from an existing bulk change:
   1. Choose an existing bulk change and click Properties. The Bulk Change (Edit) form opens.
   2. Click Copy.

3

Configure the general parameters and click Next. The Specify the filter form opens.

4

To specify a filter, perform one of the following.

a. Create a filter.
   1. Click on the Attribute drop-down menu and select an option.
   2. Click on the Function drop-down menu and select an option.
   3. Click on the Value drop-down menu and select or enter an option.
   4. Click Add. The options are displayed in the filter panel.
   5. Select AND or OR from the Operators drop-down menu. Repeat 1 to 4 to add more options.
   6. Click Save. The Save Filter form opens.
   7. Configure the general parameters.
   8. Click Save. The Save Filter form closes.

b. Load a filter.
   1. Click Saved Filters. The Saved Filters form opens.
   2. Select a saved filter and click Load. The Saved Filters form closes and the loaded filter is displayed in the filter panel.

5

Configure the filter criteria. Creating a filter that contains the attributes that you want to change can limit the number of objects generated for the bulk change.

6

Click Count to determine the number of network objects that are affected, based on the filter.

7

Click View to list the target objects. The Filtered List form opens.

8

Click Search. A list of target objects is displayed.

9

Click Next. The Specify the attributes form opens.

10

Double-click on the attribute or attribute group in the attribute tree panel that you want to include in the bulk change. The attribute or attribute group appears in the display panel.

If you included an attribute or attribute group that you want to exclude from the bulk change, you can remove it by clicking the Remove X icon in the display panel.

11

Perform one of the following for each listed attribute, as required.

a. Enter a value in the attribute field. The drop-down menu changes from Unchanged to Set, which means that the attribute changes to the new value when you execute the bulk change.

b. Choose Default from the drop-down menu to specify that the attribute is to change to the default value when you execute the bulk change.

c. Choose Clear from the drop-down menu. Depending on the object type, the attribute value is cleared or set to the default value when you execute the bulk change.

12

Click Next. The Change review form opens.

13

Configure the required parameters and click Finish.

14

Select the View the newly created Bulk Change check box to view the bulk change after closing the form, if required.

15

Click Close.

16

To create more Bulk Changes, repeat Step 2 to Step 15 .

END OF STEPS

20.4 To modify a bulk change

20.4.1 Steps

1

Choose Tools→Bulk Operations from the NFM-P main menu. The Bulk Operations form opens.

2

Choose a bulk change and click Properties. The Bulk Change (Edit) form opens with the General tab displayed.

3

Modify the required parameters.

4

Click on the Spans tab and specify a span, if required.

5

Save your changes and close the form.

END OF STEPS

20.5 To execute a bulk change

Note: You can only execute one bulk change at a time. All other bulk changes are queued.
You can only generate batches for one bulk change at a time.
You cannot generate batches when a bulk change is executing.

20.5.1 Steps

1

Choose Tools→Bulk Operations from the NFM-P main menu. The Bulk Operations form opens.

2

Choose a bulk change from the list and perform one of the following.

a. If the bulk change contains batches, click Execute to execute all of the batches.

Note: Changes made to the network after the batches are generated are not affected by the bulk change batches.

b. If the bulk change does not contain batches, or you want to regenerate the batches, perform the following.

1. Click Properties. The Bulk Change (Edit) form opens with the General tab displayed.

2. Click on the Batch Control tab.

   If the Generate Batches button is dimmed, set the Admin State parameter on the General tab to Enable.
3. Click Generate Batches. The batches are generated and listed on the form.
4. To execute only specific batches, choose one or more batches and click Execute Selected.
5. To execute all of the batches, click Execute All.

3

Click Yes. The NFM-P executes the bulk change.

4

Close the forms.

END OF STEPS

20.6 To view executed batch information

Note: You can also use the NFM-P Task Manager to view information about a batch.

20.6.1 Steps

1

Choose Tools→Bulk Operations from the NFM-P main menu. The Bulk Operations form opens.

2

Choose a bulk change and click Properties. The Bulk Change (Edit) form opens with the General tab displayed.

3

Click on the Batch Control tab.

4

Choose a batch and click Properties. The Bulk Change Batch form opens with the General tab displayed. View general information about the executed batch.

5

Click on the Batch Items tab and click Search. A list of items that were changed in the batch appears with the status of each batch item.

6

To view the parameters for each batch item, choose a batch item and click Properties.

7

Close the forms.

END OF STEPS

20.7 To stop one or more bulk changes

20.7.1 Steps

1

Choose Tools→Bulk Operations from the NFM-P main menu. The Bulk Operations form opens.

2

Perform one of the following:

a. Choose one or more bulk change to stop.

b. Choose one or more batches to stop by performing the following:

1. Choose a bulk change from the list and click Properties. The Bulk Change (Edit) form opens with the Batch Control tab displayed.
2. Choose one or more batches.

3

Click Stop and click Yes. The bulk change execution stops.

4

Close the forms.

END OF STEPS

21 Serial raw sockets for IP transport services

Creating serial raw sockets for IP transport services using the NFM-P

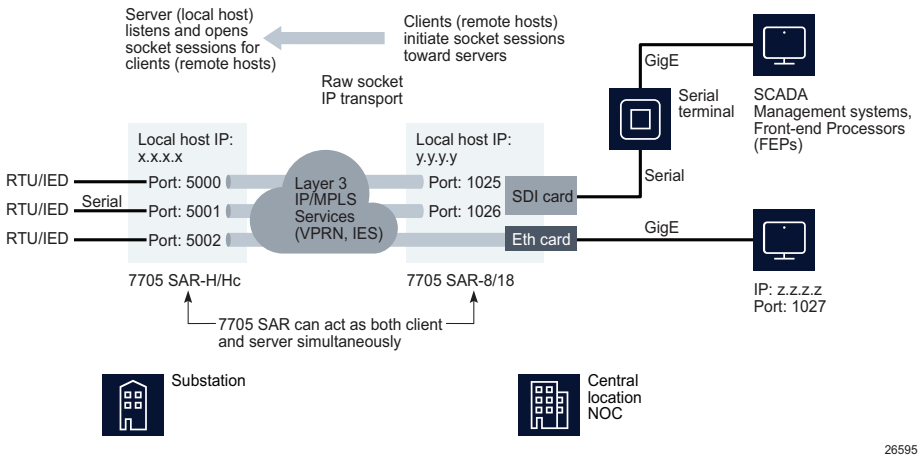
21.1 Serial socket and IP transport services

21.1.1 Overview

Raw socket for serial data transport is a method of transporting serial data over an IP network using L3-based services (IES or VPRN). A raw socket allows direct sending and receiving of IP packets between network devices without any protocol-specific transport layer formatting.

Through local-host and remote-host configurations on an NE, the serial socket IP transport sessions are established to carry serial data over an IP/MPLS network. Incoming serial data is packetized into L3 TCP/UDP packets which ingress IES or VPRN L3 SAPs and are forwarded across an IP/MPLS network. These packets belong to individual sessions between an RTU and SCADA management system/FEP, and are transported as an IP transport sub-service within an IES or VPRN context. The IP transport sub-service uses the local host and remote host details, and port numbers (session parameters) to establish TCP/UDP sessions.

Figure 21-1 Sample serial data transport configuration



For example, SCADA data from RTUs can be transported to FEPs or SCADA controlling units. The serial port-facing RTU is configured as both server and client. Unsolicited messages are communicated by the RTU as a client to the FEPs. When the FEPs request data, the RTUs respond as a server. This transport method is an alternative to C-pipes where the transport medium is an L3 IP/MPLS service instead of L2. For more information about SCADA, see 15.2 “SCADA on the 7705 SAR” (p. 455).

This functionality is supported on the 7705 SAR-8, 7705 SAR-18, 7705 SAR-H and 7705 SAR-Hc, release 8.0 R4 or later, and the 7705 SAR-Hm, Release 15.0 R4 or later.

The benefits of serial sockets are:

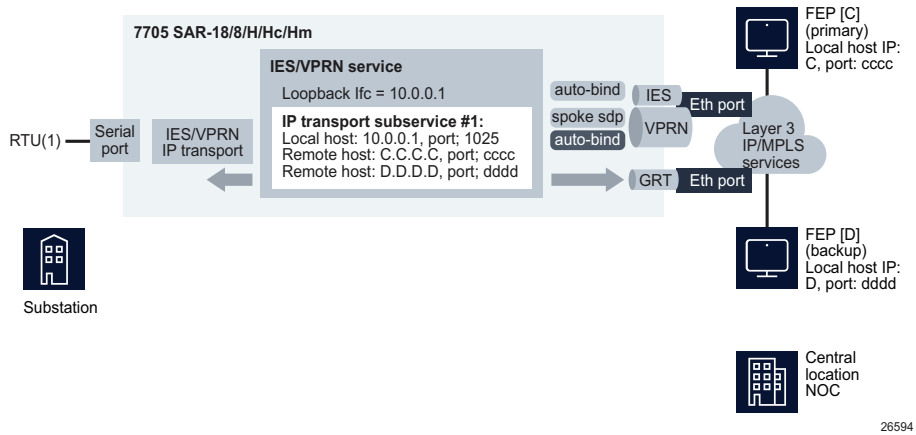
- Lower bandwidth consumption - serial sockets only send data when needed.
- Multiple head end FEPs can poll RTUs at the same time which avoids serial data collisions from both FEPs at the RTU serial link. Serial sockets can be used to queue and manage data streams and respond back to each at once.
- A single RTU can send a single data stream to multiple FEPs for unsolicited polls that originate from the RTU.
- There is no requirement for terminal servers at the FEP locations to convert IP to serial data and back. SCADA controlling units can connect to the head end router via Ethernet to send and receive serial data to and from the RTU.

Serial socket and IP transport configuration setup

1. A 7705 SAR NE with a serial port is connected to local hosts (RTUs) through serial ports acting either as client, server, or both client and server.
2. Serial data over an IES or VPRN L3 interface is carried from the 7705 SAR NEs through another 7705 SAR over IP/MPLS cloud.
3. The remote hosts (SCADA management systems/FEPs) can be connected in one of two ways:
   - Through serial ports of a serial data card on a 7705 SAR-8 and 7705 SAR-18 connected to serial terminals, which is then connected to FEPs/SCADA management systems through GigE interfaces.
   - Through direct TCP/UDP sessions from RTU servers to FEPs/SCADA management systems through GigE interfaces with no serial terminal in between.

   The source and destination IP addresses and port numbers for the IP transport sessions are derived from the local/remote-host configurations associated with each serial port.

Figure 21-2 Sample IES/VPRN IP transport configuration



Serial raw socket squelch

A condition may occur where the end device connected to the serial port sends out a continuous stream of data, stopping the far end raw socket or controlling unit from receiving data from other end devices in the network. To resolve this condition, enable the squelch command on the raw socket at the port level (disabled by default) to suppress the socket from receiving any more data from the device connected to the port.

The squelch function is enabled by configuring a delay period that specifies the delay between when the start of a constant character stream begins (e.g. a new packet) and when to start the squelch function. When a constant character stream occurs for the delay timer value, the port is considered locked up, an alarm is raised indicating the lock-up, and the squelching function is triggered. The range of the delay between the alarm and the squelching function is from one to 120s.

To recover from squelch, there are two methods:

1. Manually clear the squelch function for the serial port and put the port in a normal state.
2. Automatically clear the squelch function after a configurable amount of time (one to 120 s) after the squelch function was instantiated to put the serial port back into a normal state.

Socket profile mismatch

A socket profile mismatch occurs when the local properties of a serial raw socket on a 7705 SAR-Hm node with an assigned socket profile no longer match the values defined in the profile. The Socket Profile Mismatch parameter on the RS-232 Socket tab of the port configuration form becomes enabled, and the ReApply button is available. To resolve the mismatch, click on the ReApply button in the Socket Profile panel. The mismatched parameters on the port are configured with the values from the profile.

21.2 Workflow to configure serial raw sockets for IP transport services

21.2.1 Stages

The following workflow describes the sequence of high-level tasks required to configure serial raw sockets for IP transport. This workflow assumes that the physical devices have been installed, commissioned, and discovered.

1

Create a socket profile and optionally, associate the Socket profile to a physical port on a 7705 SAR-Hm node. See 21.4 “To create a socket profile” (p. 723).

2

Configure the port level socket which includes serial link parameters and socket level configurations such as end-of-packet checking parameters and the inter-sessions delay for transmitting sessions data out of the serial link. See 21.5 “To configure a serial raw socket on a 7705 SAR” (p. 724).

3

As required, configure the remote-hosts for IP transport using the Local Host Entity Manager. See 21.6 “To configure a global entry using the Local Host Entity Manager” (p. 725) and 21.7 “To modify a global entry” (p. 726).

4

Configure IP transport services to associate the serial port within either an IES or VPRN SAP allowing TCP/UDP encapsulated serial data to be routed within the corresponding Layer 3 service. This includes a loopback interface for IP transport local-hosts (servers), IP transport local-host and remote-hosts configuration, and the associated serial port SAP. See 21.8 “To configure IP transport on an IES site” (p. 727) or 21.9 “To configure IP transport on a VPRN site” (p. 729).

5

If required, you can use the Check TCP Connection tool to test the health of a TCP connection from the client to the server. See 21.8 “To configure IP transport on an IES site” (p. 727) or 21.9 “To configure IP transport on a VPRN site” (p. 729).

21.3 Serial IP transport using the Local Host Entity Manager

21.3.1 Overview

Serial transport over raw sockets can be either between two 7705 SAR NEs (one at an RTU and one at the controlling unit), or between a 7705 SAR NE and another NE such as a 7750 SR. These types of local-hosts do not require a 7705 SAR NE or any IP transport services to be configured. These would typically be 3rd party devices such as FEPs, SCADA controlling units, other terminal servers, or other devices not managed by the NFM-P.

For IP transport, the remote-host can be one of the following:

1. For a 7705 SAR NE, the remote-host can be another local-host IP that belongs to a different site in the same service.
2. For a non-7705 SAR NE, the remote-host can be another IP address that is globally reachable to the NE (via routing), but does not belong to the same service.

To facilitate adding remote-hosts to an IP transport, the Local Host Entity Manager is used. The Local Host Entity Manager lists the following:

- All local-hosts from all services/sites managed by the NFM-P, called discovered entries.
- A list of user-created global host entries called global entries.

When an NE is managed by the NFM-P, it checks the NE for all configured IP transports. The local-host details (IP Address and Port Number parameters) from all of the IP transports are populated in the Local Host Entity Manager. The remote-host details are not populated.

When the local-host entries are populated in the Local Host Entity Manager, you can click the Add Remote Hosts button on the IP Transport Remote Host Properties form which will list all possible entries from the Local Host Entity Manager that are valid remote-hosts for a particular local-host.

Serial raw socket and IP transport procedures

21.4 To create a socket profile

21.4.1 Purpose

You can use the Tools→Socket Profile menu on the NFM-P GUI to create a reusable template to configure serial port parameters for raw sockets such as parity, character size, start-stop bits, squelch delay, and EOP (end-of-packet) length, timeout, and special characters.

21.4.2 Steps

1

Choose Tools→Socket Profile from the NFM-P main menu. The Socket Profile form opens.

2

Click Create, or select an existing socket profile and click Properties. The Socket Profile (Create | Edit) form opens.

3

Configure the parameters on the General tab as required.

4

Click on the Socket Specifics tab and configure the parameters as required.

5

Save your changes and close the form.

6

Optionally, associate the socket profile to a physical port on a 7705 SAR-Hm node:

1. In the navigation tree equipment view, navigate to a port on a 7705 SAR-Hm node (Shelf→Card Slot→Daughter Card→[Supported] Port) and choose Properties. The Physical Port (Edit) form opens.
2. On the RS-232 Socket tab, select a socket profile to associate with the 7705 SAR-Hm port and click OK. The parameters in the Serial RS-232 and Serial Socket panels automatically update with the parameter settings defined in the socket profile.

   Note: If the socket profile properties are changed after you associate the socket profile to the port, the Socket Profile Mismatch parameter located on the RS-232 Socket tab, Socket Profile panel, is enabled to indicate the socket profile parameters have been modified without the changes being applied to the port. Also, if the serial port/raw socket parameters are changed without changing the socket profile properties, a mismatch will occur between the socket profile and the actual configuration. Clicking on the ReApply button updates the parameter settings for the port to match the socket profile.

3. Save your changes and close the form.

End of steps

21.5 To configure a serial raw socket on a 7705 SAR

21.5.1 Before you begin

A raw socket IP transport interface can be configured for each RS-232 serial port on an NE. IP transport interfaces are only supported on RS-232 serial ports with the Encap Type parameter configured as RAW. This allows the serial port to receive TCP connections or UDP session packets from multiple remote-hosts when operating as a server, or to create new multiple sessions to remote-hosts in order to send and receive serial data when operating as a client.

Configuration of serial raw sockets is supported on the 7705 SAR-8, 7705 SAR-18, 7705 SAR-H, and 7705 SAR-Hc, Release 8.0 R4 or later.

There are two main configurations required for a serial raw socket to be operational and support sending/receiving serial data in either server mode, client mode, or both:

1. Port level socket configuration - This includes serial link parameters such as baud rate, start/stop, bits, etc. Socket level configurations are required such as end-of-packet checking parameters and the inter-sessions delay for transmitting sessions data out of the serial link.
2. IP transport services configuration – Creating an IP transport service is required to associate the serial port within either an IES or VPRN so that TCP/UDP encapsulated serial data can be routed within the corresponding Layer 3 service. This configuration includes IP transport local-host items (local servers) and remote host configurations, TCP timers and sessions control, etc. See 21.8 “To configure IP transport on an IES site” (p. 727) and 21.9 “To configure IP transport on a VPRN site” (p. 729) for more information.

21.5.2 Steps

1

Configure the applicable MDA for the 7705 SAR NE. See 15.78 “To configure an MDA” (p. 536) for more information.

The 7705 SAR-8 and 7705 SAR-18 must be configured with a 12-port Serial Data v2 or v3 MDA.

The 7705 SAR-H must be configure with a 2 × Serial Data + 2 × Channelized DS1/E1 MDA.

The 7705 SAR-Hc has fixed MDAs that cannot be modified.

2

In the navigation tree Equipment view, right-click on the port and choose Create Channel/Socket. The Serial Channel (Create) form opens.

3

Click on the States tab and configure the Administrative State parameter as Up.

4

Click Apply and confirm your action.

5

Click on the General tab and enable the Serial Socket Enabled parameter.

Note: When you enable the Serial Socket Enabled parameter, the Channel tab is no longer available and the RS-232/Socket tab appears. The NFM-P will automatically set the Device Mode parameter as Asynchronous and the Gender parameter as DCE, on the RS-232/Socket tab.

6

Select a Socket Profile ID in the Socket Profile panel and click Apply.

7

Click on the RS-232/Socket tab and configure the required parameters.

8

Save your changes and close the form.

You can click on the IP Transports tab to view the IP Transport to which this serial raw socket is associated.

END OF STEPS

21.6 To configure a global entry using the Local Host Entity Manager

21.6.1 Before you begin

Consider the following regarding global and discovered entries:

- You can modify the Name and Description parameters for both global and discovered entries.
- You can modify the IP Address and Port Number parameters for global entries, but not for discovered entries. The modification of the IP Address and Port Number parameters of a global entry is propagated to all matching remote-hosts in the network. These matching remote-hosts can be viewed on the IP Transport tab of the Global Entry properties form.
- Discovered entries cannot be deleted. They will automatically disappear when the corresponding local-host is deleted.
- Whenever the IP Address and Port Number of an IP transport local-host is modified using CLI or the NFM-P, the old discovered entry with the old IP Address and Port Number is deleted and a new discovered entry is added automatically, with a modified IP Address and Port Number.
- All discovered entries from an NE are automatically deleted if the node is unmanaged/deleted from the NFM-P.

21.6.2 Steps

1

Choose Tools→Local Host Entity Manager from the NFM-P main menu. The Local Host Entity Manager form opens.

2

Click Create. The Network Wide Local Host (Create) form opens.

3

Configure the required parameters on the General tab and click Apply. The global entry is listed on the Local Host Entity Manager form.

Once you have added remote-hosts to an IP transport, you can click on the IP Transports tab to view the associations of the IP transports and their remote-hosts. Associations can be seen for both global and discovered entries. Associations are dynamic; the association is automatically removed if an entry is deleted as a remote-host for its IP Transport.

4

Close the forms.

END OF STEPS

21.7 To modify a global entry

21.7.1 Before you begin

Global entries are user-created entries in the Local Host Entity Manager. These entries (IP Address and Port Number) are generally those of either third party servers, or NEs that are un-managed in the NFM-P. The NFM-P allows modification of global entries. When the IP Address and Port Number parameters of a global entry are modified, these parameters are modified correspondingly across all matching remote-hosts in the network. This would allow seamless migration among third part servers.

Consider the following:

- This procedure is applicable only to global entries. The IP Address and Port Number parameters of discovered entries cannot be modified.
- Modification of the IP Address and Port Number parameters of a global entry is propagated to all matching remote-hosts in the network. These “matching” remote-hosts can be viewed on the IP Transports tab of the Global Entry properties form.
- Modification of the Name and Description parameters remains a local change in the global/discovered entry and they are not propagated across matching remote-hosts in the network.
- Deletion of a global entry will only delete the entry from the NFM-P. It will not delete matching remote-hosts in the network.

21.7.2 Steps

1

Choose Tools→Local Host Entity Manager from the NFM-P main menu. The Local Host Entity Manager form opens.

2

Select a global entry in the list and click Properties. The Network Wide Local Host (Edit) form opens.

3

On the General tab, configure the IP Address and Port Number parameters.

4

Click OK to confirm your actions.

5

Close the form.

END OF STEPS

21.8 To configure IP transport on an IES site

21.8.1 Purpose

IP transport service configurations are required to associate a serial port within either an IES or VPRN SAP, allowing TCP/UDP encapsulated serial data to be routed within the corresponding Layer 3 service.

Before you begin, ensure that you configure the port level serial socket on the serial data card of the applicable 7705 SAR NE. See 21.5 “To configure a serial raw socket on a 7705 SAR” (p. 724) for more information.

The 7705 SAR-Hm uses serial ports instead of raw sockets. The serial ports are 1/3/1 and 1/3/2. The 7705 SAR-Hm supports IP transport with a serial port or GNSS. One IP transport with GNSS can be configured per 7705 SAR-Hm. Multiple IP transports with serial ports and GNSS can exist within the same service.

For information about configuring IP transport on a VPRN site, see 21.9 “To configure IP transport on a VPRN site” (p. 729).

Note: When an IES IP transport is operationally down with an existing IP Transport Down Reason, a second IP Transport Down Reason is not automatically updated in the NFM-P. When this occurs, the IP transport requires a manual resynchronization.

21.8.2 Steps

1

Create an IES site. See 78.5 “To configure an IES site” (p. 2431).

2

Click on the IP Transports tab and click Create. The IES IP Transport (Create) form opens.

3

Configure the general parameters as required.

4

Select a transport port in the Transport Port panel.

Note: You must configure a serial socket on the 7705 SAR SDI MDA port in order to choose a transport port. See 21.5 “To configure a serial raw socket on a 7705 SAR” (p. 724) for more information.
For a 7705 SAR-Hm NE, choose one of the serial ports, 1/3/1 and 1/3/2, or choose GNSS.

5

Configure the IP address for the local host in the Local Host panel.

6

Configure the required parameters in the Session Details and TCP panels.

7

Click on the Remote Host tab and click Create. The IP Transport Remote Host (Create) form opens.

8

Configure the required parameters and click OK.

9

Click on Add Remote Hosts. The Select Network Wide Local Host form opens. All applicable remote-host entries from the Local Host Entity Manager are listed.

10

Select one or more entries that you want to add as remote-hosts. Click Apply and then OK.

The remote-host IDs are auto-assigned by the NFM-P.

11

Click OK to save your changes.

12

If required, use the Check TCP Connection tool to test the health of a TCP connection from the client to the server.

1. Click on the Remote Host tab.
2. Select a remote-host in the list and click Properties. The IP Transport Remote Host (Edit) form opens with the General tab displayed.
3. Configure the Check TCP Connection parameter in the TCP Test panel and click OK. The Result parameter shows if the TCP test failed or succeeded.

Note: When you perform a TCP connection test on a remote-host, the result is not updated automatically. You must perform a manual resynchronization of the remote-host in order to update the result.

13

Save your changes and close the forms.

END OF STEPS

21.9 To configure IP transport on a VPRN site

21.9.1 Purpose

IP transport services configurations are required to associate a serial port within either an IES or VPRN SAP allowing TCP/UDP encapsulated serial data to be routed within the corresponding Layer 3 service.

Before you begin, ensure that you configure the port level serial socket on the serial data card of the applicable 7705 SAR NE. See 21.5 “To configure a serial raw socket on a 7705 SAR” (p. 724).

The 7705 SAR-Hm uses serial ports instead of raw sockets. The serial ports are 1/3/1 and 1/3/2. The 7705 SAR-Hm supports IP transport with a serial port or GNSS. One IP transport with GNSS can be configured per 7705 SAR-Hm. Multiple IP transports with serial ports and GNSS can exist within the same service.

See 21.8 “To configure IP transport on an IES site” (p. 727) for information about configuring IP transport on an IES site.

Note: When a VPRN IP transport is operationally down with an existing IP Transport Down Reason, a second IP Transport Down Reason is not automatically updated in the NFM-P. When this occurs, the IP transport requires a manual resynchronization.

21.9.2 Steps

1

Create a VPRN site. See 79.11 “To configure a VPRN site” (p. 2545).

2

Click on the IP Transports tab and click Create. The VPRN IP Transport (Create) form opens.

3

Configure the general parameters as required.

4

Select a transport port in the Transport Port panel.

Note: You must configure a serial socket on the 7705 SAR serial data MDA port in order to choose a transport port. See 21.5 “To configure a serial raw socket on a 7705 SAR” (p. 724) for more information.
For a 7705 SAR-Hm NE, choose one of the serial ports, 1/3/1 and 1/3/2, or choose GNSS.

5

Configure the IP address for the local host in the Local Host panel.

6

Configure the required parameters in the Session Details and TCP panels.

7

Click on the Remote Host tab and click Create. The IP Transport Remote Host (Create) form opens.

8

Configure the required parameters and click OK.

9

Click on Add Remote Hosts. The Select Network Wide Local Host form opens. All applicable remote-host entries from the Local Host Entity Manager are listed.

10

Select one or more entries that you want to add as remote-hosts. Click Apply and then OK.

The remote-host IDs are auto-assigned by the NFM-P.

11

Click OK to save your changes.

12

If required, use the Check TCP Connection tool to test the health of a TCP connection from the client to the server.

1. Click on the Remote Host tab.

2. Select a remote-host in the list and click Properties. The IP Transport Remote Host (Edit) form opens with the General tab displayed.
3. Configure the Check TCP Connection parameter in the TCP Test panel and click OK. The Result parameter shows if the TCP test failed or succeeded.

Note: When you perform a TCP connection test on a remote-host, the result is not updated automatically. You must perform a manual resynchronization of the remote-host in order to update the result.

13

Save your changes and close the forms.

END OF STEPS

Part III: NE maintenance

Overview

Purpose

This part provides information about NE maintenance using the NFM-P.

Contents

22 NE maintenance overview

Maintaining NEs using the NFM-P

22.1 Overview

22.1.1 NE maintenance

The NFM-P has policies and functions that facilitate the maintenance of managed NEs. You can use the NFM-P to do the following:

- configure how and when to deploy NE configuration changes—see Chapter 25, “NE deployment”
- back up device configurations on demand, or using a schedule—see Chapter 23, “NE backup and restore”
- restore device configurations—see Chapter 23, “NE backup and restore”
- perform device configuration rollbacks—see Chapter 24, “NE configuration rollback”
- upgrade device software on demand, or using a schedule—see Chapter 24, “NE configuration rollback”
- monitor and troubleshoot operations in progress
- browse NE file systems—see 22.5 “To view an NE file system using an FTP file browser” (p. 739) and 22.2 “To view an NE file system using an SSH file browser” (p. 736)

You can also view the accounting statistics collection status of an NE using 22.3 “To view the accounting statistics collection status of an NE” (p. 737) , and view the SNMP trap metrics of an NE using 22.6 “To view NE trap metrics information” (p. 740) .

22.1.2 NE file system browsing

An NFM-P operator can browse the file system of a managed NE to list the contents of the compact flash devices. You can browse the file system of a 7210 SAS, 7450 ESS, 7705 SAR, 7750 SR, 7950 XRS, or OmniSwitch using simple FTP or a CLI session using SSH. The NFM-P GUI is used to browse the different types of files.

Note: Some 7210 SAS devices are equipped with a USB flash memory (uf1). In the equipment tree and on Alarm Info forms, the NFM-P displays only Flash Memory. The display does not distinguish between compact flash memory (cf) and USB flash memory (uf).

Browsing an NE file system using the NFM-P is a convenient way to confirm that operations such as the following occur as planned by verifying the sizes and time stamps of local NE files:

- NE configuration saves
- NE software image transfers and upgrades
- NE configuration restores
- NE accounting-statistics collection

FTP file browsing on an NE requires FTP user account access on the NE. SSH file browsing requires console user-account access and the configuration of SSH security on the NE. See

Chapter 8, “Device commissioning and management” for information about enabling FTP and console access for an NE user and configuring SSH on an NE.

Note: A 7705 SAR may become temporarily unreachable while enabling SSH and starting the device SSH server.

See 22.5 “To view an NE file system using an FTP file browser” (p. 739) for information about browsing an NE file system using an FTP file browser, and 22.2 “To view an NE file system using an SSH file browser” (p. 735) for information about browsing an NE file system using an SSH file browser.

22.2 To view an NE file system using an SSH file browser

22.2.1 Prerequisites

Perform this procedure to browse and list the contents of a managed NE using a secure file browser. You need console and SSH user-account privileges on the NE for access to the NE file system, and an SSH server must be configured on the NE. See Chapter 8, “Device commissioning and management” for information about enabling console or SSH access for an NE user and configuring the SSH server on an NE.

22.2.2 Steps

1

Initiate an SSH file browser session using one of the following methods:

a. Use the NFM-P main menu.
   1. Choose Tools→Network Elements→NE Sessions→SSH File Browser. The SSH File Browser form opens.
   2. Enter the IP address of the NE that you need to browse in the field at the top of the form.
   3. Click Connect. The Enter the Username and Password form opens.

b. Use the contextual menu for an NE.
   1. Select an NE icon in the NFM-P network navigation tree or topology map.
   2. Right-click on the NE icon and choose NE Sessions→File Browser. The SSH File Browser form opens, then displays the Enter the Username and Password form.

c. Use the NE alarm contextual menu.
   1. Select an NE alarm in the NFM-P alarm window.
   2. Right-click on the alarm item and choose NE Sessions→File Browser. The SSH File Browser form opens, then displays the Enter the Username and Password form.

Note: When you use the NFM-P main menu to open a file-browser session, you are not restricted to the original NE; you can use the same form to connect to other NEs. This is useful when you need to browse several NEs in succession.

2

Enter the user name and password of a user account with FTP and SSH access privileges on the NE and click OK. If the NE accepts the credentials, the form lists the contents of the NE.

<DIR> in the Type column indicates a directory. The file path to the current directory is displayed in the Path field.

On an NE with redundant CPMs, the form lists the contents of the cf3 device on the active CPM. You can browse the cf3 device on the standby CPM by specifying cf3-B:\ in the Path field.

3

Navigate the file system as required. Perform one of the following actions to open a directory and list the contents:

a. Double-click on the directory row in the list.

b. Select the directory row and press Ctrl-O.

c. Type the path to the directory in the Path field and click Go.

4

If you opened the browser using the NFM-P main menu or from the Software Upgrade form, you can browse another NE file system using the same form, if required.

1. Click Disconnect to end the browsing session.
2. Enter the IP address of the NE that you need to browse in the field at the top of the form and click Connect.

5

Close the form.

END OF STEPS

22.3 To view the accounting statistics collection status of an NE

22.3.1 Steps

1

Choose Tools→Statistics→Accounting Retrieval Status from the NFM-P menu. The Accounting Retrieval Status form opens with a list of managed NEs displayed.

2

Select an NE in the list and click Properties.

3

View the statistics collection information for the NE.

4

Close the forms.

END OF STEPS

22.4 To configure an event log policy

22.4.1 Purpose

Perform this procedure to specify the amount of time that log records are kept in the NFM-P database and enable or disable the saving of log records in the database.

Event log policies control the retention time and administrative state of each log type across the managed network.

Note: You must have a user account with access to the “event” permission to perform this procedure. This permission is included by default in the “NFM-P Management and Operations” scope of command role.

Note: You can also edit an event log policy by clicking Edit Policy in the Events tab after selecting a log type.

22.4.2 Steps

1

Choose Tools→Events→Event Policies from the NFM-P main menu. The Manage Event Policies form opens.

2

Select an entry and click Properties. The Event Policy (Edit) form opens.

3

Configure the required parameters.

Note: The Administrative State parameter enables or disables saving the event type in the NFM-P database.

4

Click OK. The changes to the policy are saved.

END OF STEPS

22.5 To view an NE file system using an FTP file browser

22.5.1 Prerequisites

Perform this procedure to browse and list the files on a managed NE. You need FTP user-account privileges on the NE for access to the NE file system. See Chapter 8, “Device commissioning and management” for information about enabling FTP access for an NE user.

22.5.2 Steps

1

Initiate an FTP file browser session using one of the following methods:

a. Use the NFM-P main menu.

1. Choose Tools→Network Elements→NE Sessions→FTP File Browser. The FTP File Browser form opens.
2. Enter the IP address of the NE that you need to browse in the field at the top of the form.
3. Click Connect. The Enter the Username and Password form opens.

b. Use the contextual menu for an NE.

1. Select an NE icon in the NFM-P network navigation tree or topology map.
2. Right-click on the NE icon and choose NE Sessions→File Browser. The FTP File Browser form opens, then displays the Enter the Username and Password form.

c. Use the NE alarm contextual menu.

1. Select an NE alarm in the NFM-P alarm window.
2. Right-click on the alarm item and choose NE Sessions→File Browser. The FTP File Browser form opens, then displays the Enter the Username and Password form.

Note: When you use the NFM-P main menu to open a file-browser session, you are not restricted to the original NE; you can use the same form to connect to other NEs. This is useful when you need to browse several NEs in succession.

2

Enter the user name and password of a user account with FTP access privileges on the NE and click OK. If the NE accepts the credentials, the form lists the contents of the NE.

<DIR> in the Type column indicates a directory. The file path to the current directory is displayed in the Path field.

On an NE with redundant CPMs, the form lists the contents of the cf3 device on the active CPM. You can browse the cf3 device on the standby CPM by specifying cf3-B:\ in the Path field.

3

Navigate the file system as required. Perform one of the following actions to open a directory and list the contents.

a. Double-click on the directory row in the list.

b. Select the directory row and press Ctrl-O.

c. Type the path to the directory in the Path field and click Go.

4

If you opened the browser using the NFM-P main menu, you can browse another NE file system using the same form, if required.

1. Click Disconnect to end the browsing session.
2. Enter the IP address of the NE that you need to browse in the field at the top of the form and click Connect.

5

Close the form.

END OF STEPS

22.6 To view NE trap metrics information

22.6.1 Steps

1

Choose Tools→Statistics→Trap Metrics Information from the NFM-P main menu. The Trap Metrics Information form opens.

The form lists the NEs that send the most traps during the most recent collection interval. The collection interval is indicated by the Start Collection Period and End Collection Period values.

2

View the trap metrics information for one or more NEs.

3

Click Search to refresh the information, as required.

4

Close the form.

END OF STEPS

23 NE backup and restore

NE backup and restore overview

23.1 NE backups and restores

23.1.1 Backup policies

An NFM-P backup policy specifies the conditions under which the NFM-P performs device configuration backups. The NFM-P stores the backups, which can quickly be restored in the event of an NE failure. Each managed NE that is not associated with a policy is assigned to a default policy, but you can create multiple additional policies and assign NEs to the policies according to your requirements.

A backup policy specifies settings that include the following:

- the backup schedule
- the files that a backup is to retrieve
- the type of file compression to use, if any
- the age and number of backup files that the NFM-P retains

An NFM-P operator that has the network element software management scope of command role can perform device configuration save, backup, and restore operations.

Note: An NFM-P user that has the lawful intercept management scope of command role can back up and restore an LI configuration. Backup data is saved only when the LI Local Save Allowed parameter on the Polling tab of the NE properties form is selected.

Note: An on-demand backup takes priority over scheduled backup operations, and is processed as soon as the NFM-P has the required resources.

You can export backup files from the NFM-P to a GUI client file system, and can import NE backup file sets to the NFM-P. In a redundant NFM-P system, the backup files are synchronized between the primary and standby main servers.

You can configure the NFM-P to automatically delete device backup files after the associated NE is unmanaged; see the chapter on NFM-P database management in the *NSP System Administrator Guide* for more information.

When a device configuration requires replacement, for example, when it is corrupt, you can restore a previous configuration. Unless otherwise specified, the NFM-P restores the most recent configuration backup. See 23.5 “To perform an on-demand backup, restore, or configuration save” (p. 748) and 23.8 “To restore a device configuration other than the most recent” (p. 752) for information about restoring device backups.

A restore works implicitly with a backup policy; there is no explicit restore policy. An operator must manually restore a device backup.

Before you can delete a backup policy, you must remove from the policy all NEs that are assigned to the policy.

GNE backups

The NFM-P NE backup function is supported for GNEs, depending on the device type and release. Backing up a GNE configuration requires a valid NFM-P GNE driver that supports the function.

Note: Some GNE devices may have specific backup requirements. Before you attempt to perform a GNE backup operation, see the appropriate domain user guide for information about driver capabilities and driver-specific information, including backup requirements.

GNE backups are configured and performed using the policy-based mechanism that is used for natively managed devices; the type of backup policy required for GNEs is Generic NE Node. In a Generic NE Node backup policy, you must specify the transfer protocol and user credentials, and a directory on the main server that is used for transferring the backup files from the GNEs.

Note: GNE backups have the following special requirements.

- FTP, SFTP, or TFTP must be enabled on each main server, depending on which protocol you use.
- If a firewall is used, the required FTP, SFTP, or TFTP ports must be open.
- The FTP, SFTP,or TFTP user that you specify in a backup policy must be a valid FTP, SFTP, or TFTP user on each main server station, and must belong to the sam user group on each main server station.
- The nsp user requires read, write, and execute access to the directory that you specify in the policy.

23.2 Backup policy configuration example

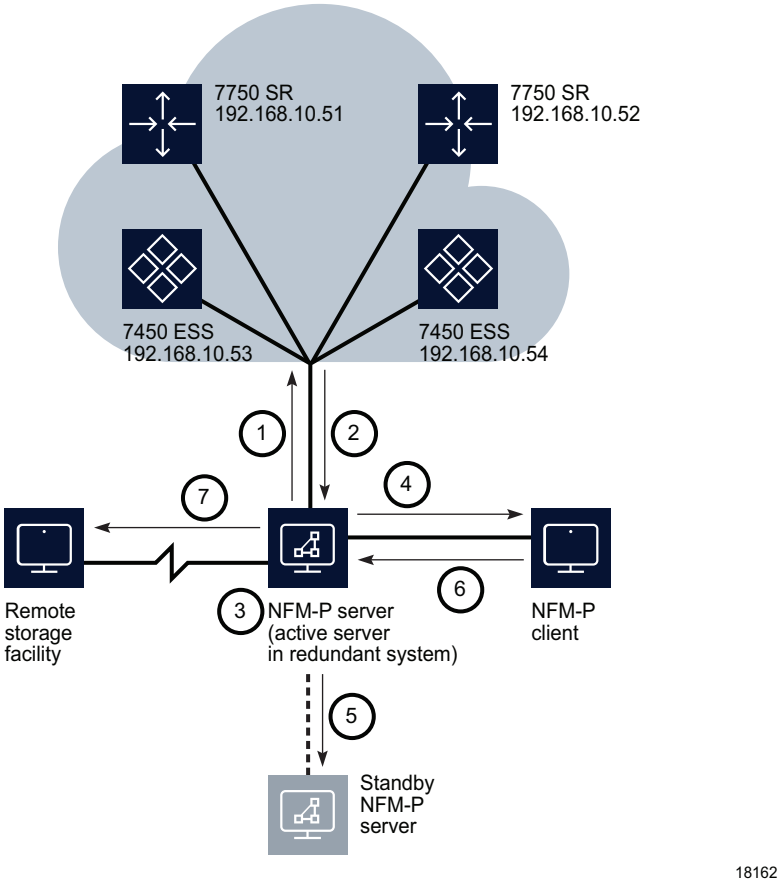
23.2.1 Example details

The following example describes an NFM-P backup policy configuration using appropriate parameter values for most scenarios. The Backup Policy form contains the parameters in the example; see 23.4 “To configure a backup policy” (p. 746) for the configuration information.

The sample backup policy specifies that the NFM-P obtains the backup files by FTP from the NE once every hour regardless of configuration activity, and after every 25 configuration changes. The policy also specifies that the NFM-P backs up the device configuration file, license file, and boot options file, or BOF, only when a newer file is present, and uses gzip file compression. The NFM-P is to retain at most 30 backup versions, and purge versions that are more than 30 days old.

The following figure illustrates the activities of the NFM-P backup and restore process.

Figure 23-1 NFM-P backup process



The labels in Figure 23-1, “NFM-P backup process” (p. 743) correspond to events in the following sequence:

1. At the interval specified, which is every hour in the example, the NFM-P issues a request to all NEs for a backup.
2. The NEs send the BOF, configuration files, and license file to the NFM-P.
3. The NFM-P stores the new versions of the received files.
4. A GUI client operator views the backup status on the Backup/Restore Status tab of the Backup Policy form.
5. If the NFM-P system is redundant, the active and standby main servers synchronize the backup files.
6. An NFM-P operator uses the Backup/Restore form to perform on-demand and scheduled backups, restores, and configuration saves, as required.

7. A third-party application periodically sends a copy of the backup files from the NFM-P to a remote storage location for safekeeping.

The policy parameters and values are the following:

- Enable Backup—enabled
- Auto Reboot After Successful Restore—enabled
- Scheduled Backup Scheme—Every Scheduled Interval
- Scheduled Backup Interval—1 hour
- Scheduled Backup Sync Time — 00:00
- Scheduled Backup Threshold (operations)—5
- Auto Backup Scheme—Every Nth NFM-P Server Initiated Save
- Auto Backup Threshold (operations)—50
- CLI Config File Mode—New Version Only
- CLI Config Save Details—disabled
- CLI Debug Save Config File Mode—disabled
- Boot Option File Mode—New Version Only
- File Compression—GZIP
- Backup 7705 Radio Database—disabled
- Auto-Purge Scheme—By Age But Retain A Minimum Number Of Backups
- Number of Backups—30
- Maximum Backup Age (days)—30

23.3 Workflow to perform NE backups and restores

23.3.1 Stages

1

For secure backups and restores, verify that SSH2 is configured and enabled on each NE, and that the NFM-P mediation policy for the NEs is configured to use secure FTP.

2

Configure device backup policies; see 23.4 “To configure a backup policy” (p. 746) .

3

Perform an on-demand backup, restore, or configuration save; see 23.5 “To perform an on-demand backup, restore, or configuration save” (p. 748) .

4

Perform an on-demand OmniSwitch backup or configuration save; see 23.6 “To perform an on-demand OmniSwitch backup or configuration save” (p. 749) .

5

Restore an OmniSwitch device backup; see 23.7 “To restore an OmniSwitch configuration” (p. 751) .

6

Restore a device backup other than the most recent; see 23.8 “To restore a device configuration other than the most recent” (p. 752) .

7

View the backup, restore, or configuration save status; see 23.9 “To view the backup, restore, or configuration save status of an NE” (p. 753) .

8

Import a device backup file set to the NFM-P; see 23.11 “To import a device configuration backup” (p. 755) .

9

Export a device backup file set from the NFM-P; see 23.10 “To export a device configuration backup” (p. 754) .

NE backup and restore procedures

23.4 To configure a backup policy

23.4.1 Steps

Note: All NFM-P-managed NEs that are not assigned to a backup policy are automatically assigned to a default backup policy upon device discovery.

Note: Beginning in NSP 23.11, the backup policy with settings “CLI Config File Mode” and “Boot Option File Mode” set to “New Version only” will only allow the second backup or consecutive backup operation to be successful if there is a change in the config or bof file. Optional files like rollback, tech-support and certificate backup will not happen even if selected in the policy unless there is a “New Version” in BOF or Config file. This behavior is the same for both manual backups and scheduled backup operations.

1

Choose Administration→NE Maintenance→Backup/Restore from the NFM-P main menu. The Backup/Restore form opens.

2

Click on the Backup/Restore Policy tab.

3

Click Create, or select an existing policy and click Properties. The Backup Policy (Create | Edit) form opens.

4

Configure the Enable Backup parameter. If you disable the Enable Backup parameter, go to Step 9 .

5

If you are creating a policy, configure the Policy Type parameter.

Note: For 7210 SAS, 7450 ESS, 7705 SAR, 7750 SR, 7950 XRS, or Wavence NEs, choose the SR Based Node option.

Note: For a GNE, choose the Generic NE Node option.

6

If the Policy Type is set to SR Based Node, you can perform a reboot after the configuration is restored on the NE by specifying the Auto-Reboot After Successful Restore parameter.

Note: When you use an NFM-P GUI client to restore a configuration, and the Auto-Reboot After Successful Restore parameter is unselected, the BOF is overwritten by a subsequent “bof save” command on the NE.

Note: When a reboot does not immediately follow a restore, use a CLI to view the BOF and ensure that it has not changed since the restore.

Note: For Wavence NEs, you must enable the Auto-Reboot After Successful Restore parameter in order for the restored configuration to be activated on the NE. Otherwise, the restored configuration is not activated on the NE during a later reboot.

7

Configure the parameters in the Backup Triggering, Backup Settings, and Backup Purging panels. You can schedule backups based on a time interval, or based on the number of configuration saves initiated by the NFM-P.

Backup purge parameters allow you to specify the number of backup files that are retained. The purge settings eliminate the need for manual backup file deletion. The purge criteria can be the number of files, the age of the files, or both.

Note: The Backup roll back files and Backup tech-support files parameters appear and are enabled by default for SR Based Node type. Once Backup is successful on NFM-P for a node, these files as well as node bof, config files and other files, are saved on NFMP-server under NE Backup location (/opt/nsp/nfmp/nebackup).

Note: If the Policy Type parameter is set to SR Based Node, in order to enable the CLI Debug Save Config File Mode parameter, you must specify the location of the debug configuration files in the NFM-P configuration. See the chapter on NFM-P component configuration in the *NSP System Administrator Guide* for information about setting the parameter.

Note: For an OmniSwitch, the NFM-P can back up only files in the certified directory. If you need to back up configuration files in the working directory, you must ensure that the files in the certified and working directories are identical. See 26.23 “To certify or synchronize OmniSwitch software” (p. 812) for information about issuing a Certify and Synchro command to synchronize the files.
For supporting OmniSwitch NEs, you can configure the Restore Directory parameter to specify the directory on the node that the backup files are restored to. To specify a user-defined directory, enter a text string that matches the name of the user-defined directory on the node.

Note: If the Backup 7705 Radio Database parameter is enabled, the Wavence MPT radio databases are backed up with the configuration file, depending on the CLI Config File Mode setting. Only the 7705 SAR-8 and 7705 SAR-18 support the backup of the Wavence MPT radio databases.

8

If the Policy Type is Generic NE Node, configure the Transfer Protocol parameter, and then the FTP or SFTP user credentials in the Generic NE Backup Settings panel.

Note: You must ensure that the following conditions are met before you attempt to use the backup policy.

- FTP, SFTP, or TFTP is enabled on each main server, depending on which protocol you use.
- If a firewall is used, the required FTP, SFTP, or TFTP ports are open.
- The FTP, SFTP, or TFTP user that you specify is a valid FTP, SFTP, or TFTP user on each main server station, and belongs to the sam user group on each main server station.
- The nsp user has read, write, and execute access to the Root Directory that you specify.

9

Click Apply.

10

Click on the Backup/Restore Policy Assignment tab and assign one or more NEs to the policy, as required.

11

Close the form.

END OF STEPS

23.5 To perform an on-demand backup, restore, or configuration save

23.5.1 Prerequisites

Note: To perform an on-demand backup or configuration save on an OmniSwitch, see 23.6 “To perform an on-demand OmniSwitch backup or configuration save” (p. 749) . To restore an OmniSwitch configuration, see 23.7 “To restore an OmniSwitch configuration” (p. 751) .

When you perform an on-demand backup, the device configuration is backed up based on the backup policy to which the NE is assigned.

A restore operation uses the most recent backup file unless otherwise specified; see 23.8 “To restore a device configuration other than the most recent” (p. 752) for information about restoring a backup file other than the most recent.

The following must be true in order for you to perform this procedure:

- You have an NFM-P user account with an administrator or network element software management scope of command role, or a scope of command role with write access to the mediation package.
- FTP or secure FTP is configured in the NE mediation policy.
- BOF persistence is enabled on each NE that supports BOF persistence.

23.5.2 Steps

1

Choose Administration→NE Maintenance→Backup/Restore from the NFM-P main menu. The Backup/Restore form opens.

2

Click on the Backup/Restore Status tab. The managed NEs are listed.

3

Select an NE and click Backup, Restore, or Save Config, as required.

4

Click Yes. The operation begins, and the current operation state is indicated in the appropriate column.

5

You can resynchronize an NE with the NFM-P, if required, by clicking Resync.

6

Close the form.

END OF STEPS

23.6 To perform an on-demand OmniSwitch backup or configuration save

23.6.1 Steps

Note: The following limitations apply to an OmniSwitch virtual chassis node, depending on how the node is managed:

- If the NE is managed using the out-of-band management IP address, and is a single-shelf node, vcboot.cfg and vcsetup.cfg files are backed up from primary.
- If the NE is managed using out-of-band management IP address and is a multi-shelf node, the following are backed up:

–vcboot.cfg file from primary

–vcsetup.cfg file from the primary and all secondary NEs

If any of the NE is unreachable from the NFM-P server, the backup operation fails.

- If the NE is managed using a VLAN-based management IP address or an in-band management IP address, the vcboot.cfg file is backed up from primary.

1

On the Equipment tree, expand an OmniSwitch object, right-click on a shelf object, and choose Properties. The Shelf (Edit) form opens.

2

Click on the Software Control Module tab and set the Command to Apply parameter to Certified.

3

Click Resync.

Note: You must resynchronize the NE to ensure the /flash/working and /flash/certified directory contents are the same, even though the Certified Status displays Certified.

4

Save your changes and close the form.

5

Choose Administration→NE Maintenance→Backup/Restore from the NFM-P main menu. The Backup/Restore form opens.

6

Click on the Backup/Restore Policy tab. The backup policies are listed.

7

Select a policy and Click Properties. The Backup Policy (Edit) form opens.

8

Click on the Backup/Restore Status tab. The tab lists NEs of the type specified by the Policy Type parameter setting on the General tab.

9

Select an NE and click Backup or Save Config, depending on the operation that you need to perform.

10

The operation begins; the Last Operation Details column displays the operation status.

11

When the operation is complete, close the forms.

END OF STEPS

23.7 To restore an OmniSwitch configuration

Note: You can import the locally available backup file for the same NE to the NFM-P which can be restored. Ensure the backup policy remains the same as was in place during the backup procedure. This will prevent the NFM-P from generating an error while importing the file.

The restored configuration is typically stored in a working directory. Supporting OmniSwitch devices allow you to configure a user-defined directory for the restored files; see 23.4 “To configure a backup policy” (p. 746).

The NFM-P indicates when the file is successfully transferred to the appropriate NEs. However, the file will not become active until the device(s) have been reloaded from the specified working or user-defined directory.

23.7.1 Steps

1

Choose Administration→NE Maintenance→Backup/Restore from the NFM-P main menu. The Backup/Restore form opens.

2

Click on the Backup/Restore Status tab. The NEs for which a backup is available are displayed.

3

Select an NE and click Restore. The restore begins, and the Last Operation Details column displays the operation status.

4

On the Equipment tree, expand the OmniSwitch icon, right-click on an OmniSwitch shelf object, and choose Properties. The Shelf (Edit) form opens.

5

Click on the Software Control Module tab.

6

Set the Command to Apply parameter to Reload.

7

If required, configure the Delayed Activation Timer and Redundancy Time (seconds) parameters.

8

Configure the Image Files Directory parameter.

9

Save your changes and close the form.

10

After reboot, on the Shelf (Edit) form, click on the Software Control Module tab and verify that the Command to Apply parameter is set to Certified.

11

When the operation is complete, close the forms.

END OF STEPS

23.8 To restore a device configuration other than the most recent

23.8.1 Purpose

You can choose to restore an older version of the device configuration to meet special network requirements.

CAUTION

Service Disruption

Older backups may not have the most recent network information.

Restoring an older configuration may be service-affecting.

23.8.2 Steps

1

Back up the current device configuration as a safeguard; see 23.4 “To configure a backup policy” (p. 746) .

2

Choose Administration→NE Maintenance→Backup/Restore from the NFM-P menu. The Backup/Restore form opens.

3

Click on the Backup/Restore Status tab. The managed NEs are listed.

4

Select an NE and click Properties. The Backup/Restore Status form for the NE opens.

5

Click on the Backups tab, which lists the available configuration backups for the NE, ordered from the oldest to the most recent.

6

Select a backup and click Restore. The NFM-P begins to restore the device configuration.

7

Click Resync to ensure that the latest network information is available to the NFM-P.

8

Close the form.

END OF STEPS

23.9 To view the backup, restore, or configuration save status of an NE

23.9.1 Steps

1

Choose Administration→NE Maintenance→Backup/Restore from the NFM-P main menu. The Backup/Restore form opens.

2

Click on the Backup/Restore Status tab. Depending on the operation type, the Backup State, Restore State, or Config Save State column displays the current operation status for each listed NE, which is one of the following:

- Not Attempted—The operation has not begun.
- Saving Config—The NE is saving the configuration.
- Transferring Files—A file transfer is in progress.
- Success—The operation is complete and successful.
- Failure—The operation is complete but unsuccessful.
- CPM Sync and Pending Reboot—The device configuration is restored and the NE is synchronizing the CPMs before a reboot.
- CPM Sync and Pending Reboot Standby—The NFM-P awaits the reboot of the standby CPM.
- Standby Reboot and Pending Redundant Switch-over—The NFM-P awaits the switchover to the standby CPM.
- MPR reboot pending—The NFM-P awaits the reboot of a Wavence NE.

Note: During a backup, if an NE is unresponsive to the NFM-P because SNMP on the NE is disabled, the Backup State column entry for the NE does not immediately display the

correct value of Failed. This latency is caused by the inability of the NFM-P to communicate with the unresponsive NE. In such a situation, the Backup State column displays the Saving Config status until three 10-minute SNMP polling periods, or 30 minutes, have elapsed, after which the Backup State changes to Failed if SNMP remains disabled.

3

To view more information about the operations performed on an NE, select the NE and click Properties. The NE Backup/Restore Status form opens. The Last Operation Details indicator describes the most recent operation type.

4

Click on the Backups tab to display a list of the recent device backups, if required.

5

Click on the Configuration Saves tab to view information about recent configuration saves, if required.

6

Close the forms.

END OF STEPS

23.10 To export a device configuration backup

23.10.1 Steps

Perform this procedure to export a backup file set from the NFM-P to a GUI client file system.

1

Choose Administration→NE Maintenance→Backup/Restore from the NFM-P main menu. The Backup/Restore form opens.

2

Click on the Backup/Restore Status tab.

3

Select the NE for which you are exporting a backup and click Properties. The NE Backup/Restore Status form opens.

4

Click on the Backups tab. A list of backups for the NE is displayed.

5

Select a backup and click Export. A file browser form opens.

6

Specify the local directory that is to contain the exported file set and click OK. The backup file set is saved in the directory.

7

Close the forms.

END OF STEPS

23.11 To import a device configuration backup

23.11.1 Steps

Perform this procedure to import a backup file set from a GUI client file system to the NFM-P.

1

Choose Administration→NE Maintenance→Backup/Restore from the NFM-P main menu. The Backup/Restore form opens.

2

Click on the Backup/Restore Status tab.

3

Select the NE for which you are importing a backup and click Properties. The NE Backup/Restore Status form opens.

4

Click Import. A file browser form opens.

5

Specify the directory that contains the backup file set and click OK. The NFM-P imports and stores the backup file set.

6

Close the forms.

END OF STEPS

24 NE configuration rollback

NE configuration rollback overview

24.1 Comparing configuration files

24.1.1 Using the compare function

A compare function allows you to display NE configuration changes between selected checkpoints, a selected checkpoint and the active configuration, a selected checkpoint and the rescue file, or the active configuration and the rescue file. This is useful for troubleshooting NE configurations.

Note: In order to use the compare function, valid SSH or Telnet credentials must be specified in the applicable mediation policy.

When you choose one of the compare NE configuration rollback file options, the Checkpoint Compare window opens listing differences between the selected configuration files. The window title displays the names of the NE configuration files that are compared. For example, the title “Index 0 and rescue” indicates that the first NE configuration checkpoint file listed on the Checkpoint Files tab is compared with the NE configuration rescue file.

Differences in the configuration files are noted as follows:

- A plus sign (+) indicates that the configuration is in the first NE configuration file listed in the window title but not in the second NE configuration file. In this case, the configuration is in the checkpoint file index 0.
- A minus sign (–) indicates that the configuration is in the second NE configuration listed file in the window title but not in the first NE configuration file. In this case, the configuration is in the rescue file.
- Configurations that are in both NE configuration files are not listed in the Checkpoint Compare window.

24.2 Workflow to configure NE configuration rollback

24.2.1 Stages

1

Configure the storage location for the NE configuration rollback rescue file and checkpoint files; see 24.3 “To configure NE configuration rollback file storage” (p. 759) .

2

Create the NE configuration rollback rescue file; see 24.4 “To create an NE configuration rollback rescue file” (p. 760) .

3

As required, perform one or both of the following:

a. Create the NE configuration rollback checkpoint files manually; see 24.5 “To create NE configuration rollback checkpoint files” (p. 760) .

b. Configure scheduled checkpoint file creation; see 24.6 “To configure scheduled checkpoint file creation” (p. 762) .

4

As required, compare NE configuration rollback files with each other, or with the current NE configuration file; see 24.7 “To compare NE configuration rollback files” (p. 763) .

5

As required, view the configuration files to verify the content; see 24.9 “To view NE configuration files” (p. 764) .

6

As required, perform one or both of the following:

a. Revert to a previous NE configuration manually; see 24.8 “To revert to a previous NE configuration” (p. 764) .

b. Configure scheduled reversion to an NE configuration rollback checkpoint file; see 24.6 “To configure scheduled checkpoint file creation” (p. 762) .

NE configuration rollback procedures

24.3 To configure NE configuration rollback file storage

24.3.1 Purpose

Perform this procedure to configure the storage location for the NE configuration rollback rescue file or checkpoint files. To configure NE configuration rollback file storage locations, FTP must be configured on the device.

24.3.2 Steps

1

Choose Administration→NE Maintenance→NE Configuration Rollback from the NFM-P main menu. The NE Configuration Rollback form opens.

2

Click on the NE Rollback tab. The NE Rollback list form opens.

3

Choose a device and click Properties. The NE Rollback (Edit) form opens.

4

To configure the storage location for the NE configuration rollback rescue file:

1. In the Rescue File panel, configure the Rescue File Location Type parameter.
   - If you specified FTP, in the Rescue File — Remote Location panel, configure the required parameters.
   - If you specified CFLASH, in the Rescue File — CFLASH panel, configure the required parameters.
2. Save your changes.

5

To configure the storage location for the NE configuration rollback checkpoint files:

1. In the Checkpoint File Storage panel, configure the required parameters.
2. Configure the Rollback Location Type parameter.
   - If you specified FTP, in the Checkpoint File Storage — Remote Location panel, configure the required parameters.
   - If you specified CFLASH, in the Checkpoint File Storage — CFLASH panel, configure the required parameters.
3. Save your changes. The Checkpoint Files tab lists the checkpoint files.

6

Close the forms.

END OF STEPS

24.4 To create an NE configuration rollback rescue file

24.4.1 Prerequisite

The rollback rescue file storage location must be configured before you can create the NE configuration rollback rescue file; see 24.3 “To configure NE configuration rollback file storage” (p. 759) .

24.4.2 Steps

1

Choose Administration→NE Maintenance→NE Configuration Rollback from the NFM-P main menu. The NE Configuration Rollback form opens.

2

Click on the NE Rollback tab. The NE Rollback list form opens.

3

Choose a device from the list and click Properties. The NE Rollback (Edit) form opens.

4

Click Create Rescue File and confirm the action. The rescue file is saved to the specified file location. The Delete Rescue File, View Rescue File, and Revert to Rescue File buttons are enabled.

Note: If a rescue file exists, the Rescue File Exists parameter is enabled, and the dialog box prompts you to confirm that you need to overwrite the existing rescue file.

5

Close the forms.

END OF STEPS

24.5 To create NE configuration rollback checkpoint files

24.5.1 Prerequisite

The checkpoint file storage location must be configured before you can create NE configuration rollback checkpoint files; see 24.3 “To configure NE configuration rollback file storage” (p. 759) .

You can also automate NE configuration rollback checkpoint file creation; see 24.6 “To configure scheduled checkpoint file creation” (p. 762) .

24.5.2 Steps

1

Choose Administration→NE Maintenance→NE Configuration Rollback from the NFM-P main menu. The NE Configuration Rollback form opens.

2

To create a checkpoint file:

1. Click on the NE Rollback tab.
2. Choose a device and click Properties. The NE Rollback (Edit) form opens.
3. Click on the Checkpoint Files tab.
4. Click Create and confirm. The Create Checkpoint form opens.
5. If required, add a comment to the checkpoint file. Click OK. The comment dialog box closes.
6. Click OK. The Create Checkpoint form opens and the checkpoint is added to the list form on Checkpoint Files tab.

3

Note: You can enable redundant rollback synchronization only when the following conditions are met.

- The rollback file location is CFLASH.
- The device has a standby CPM.

To enable redundant rollback synchronization between the active and standby CPMs:

1. Click on the General tab.
2. Perform one of the following:
   - To configure automated redundant rollback synchronization, select the Redundant Rollback Synchronization check box.
   - To perform manual redundant rollback synchronization, click Rollback-Sync Now.

4

Save your changes and close the form.

END OF STEPS

24.6 To configure scheduled checkpoint file creation

24.6.1 Additional resources

See Chapter 5, “NFM-P-based schedules” for information about creating schedules. You can also create NE configuration rollback checkpoint files manually; see 24.5 “To create NE configuration rollback checkpoint files” (p. 760) .

24.6.2 Steps

1

Choose Administration→NE Maintenance→NE Configuration Rollback from the NFM-P main menu. The NE Configuration Rollback form opens.

2

Choose a rollback policy and click Properties. The Rollback Policy (Edit) form opens.

3

In the Checkpoint File Creation panel, click Create. The Checkpoint Create Scheduled Task (Create) form opens.

4

Configure the required parameters.

5

Click Select beside the ID parameter. The Select Schedule - Checkpoint Create Scheduled Task form opens.

6

Perform one of the following:

a. Click Create to create a schedule. The NFM-P Schedule (Create) form opens.

   1. Configure the required parameters.
   2. Click OK. The schedule is saved.
   3. Choose the schedule in the Select Schedule list and click OK.

b. Choose an existing schedule and click OK.

7

Click OK in the Checkpoint Create Scheduled Task (Create) form. The policy is updated with the selected scheduled task.

END OF STEPS

24.7 To compare NE configuration rollback files

24.7.1 Purpose

Perform this procedure to compare NE configuration rollback files with each other or with the current NE configuration file.

24.7.2 Steps

1

Choose Administration→NE Maintenance→NE Configuration Rollback from the NFM-P main menu. The NE Configuration Rollback form opens.

2

Click on the NE Rollback tab.

3

Choose a device and click Properties. The NE Rollback (Edit) form opens.

4

Click on the Checkpoint Files tab.

5

Perform one of the following:

a. To compare the NE configurations of two checkpoint files:
   1. Choose two checkpoint files.
   2. Click Compare File and choose Checkpoint Vs Checkpoint.

b. To compare the NE configurations of a checkpoint file and the active configuration:
   1. Choose a checkpoint file.
   2. Click Compare File and choose Checkpoint Vs Active-Configuration.

c. To compare the NE configurations of a checkpoint file and the rescue file:
   1. Choose a checkpoint file.
   2. Click Compare File and choose Checkpoint Vs Rescue.

d. To compare the NE configuration of the current configuration and the rescue file, click Compare File and choose Active-Configuration Vs Rescue.

The Checkpoint Compare window opens listing differences between the selected configuration files; see 24.1 “Comparing configuration files” (p. 757) for information.

END OF STEPS

24.8 To revert to a previous NE configuration

24.8.1 Purpose

Use this procedure to revert to a previous device configuration without rebooting an NE. You can automate NE configuration reversion for NE configuration rollback checkpoint files; see 24.6 “To configure scheduled checkpoint file creation” (p. 762) .

24.8.2 Steps

1

Choose Administration→NE Maintenance→NE Configuration Rollback from the NFM-P main menu. The NE Configuration Rollback form opens.

2

Click on the NE Rollback tab.

3

Choose a device and click Properties. The NE Rollback (Edit) form opens.

4

Perform one of the following:

a. To revert to the NE configuration rollback rescue file:
   1. Click Revert to Rescue File. A dialog box appears.
   2. Click OK to acknowledge the warning and perform the reversion.

b. To revert to a NE configuration rollback checkpoint file:
   1. Click on the Checkpoint Files tab.
   2. Choose a checkpoint file and click Revert Checkpoint File. A dialog box appears.
   3. Click OK to acknowledge the warning and perform the reversion.

END OF STEPS

24.9 To view NE configuration files

24.9.1 Purpose

Use this procedure to view NE configuration rollback rescue files and checkpoint files, or the current NE configuration file.

24.9.2 Steps

1

Choose Administration→NE Maintenance→NE Configuration Rollback from the NFM-P main menu. The NE Configuration Rollback form opens.

2

Click on the NE Rollback tab.

3

Choose a device and click Properties. The NE Rollback (Edit) form opens.

4

Perform one of the following:

a. To view the NE configuration rollback rescue file:
   1. Click View Rescue File. The Rescue View window opens and the NFM-P loads the file data.
   2. View the file contents and close the form.

b. To view the NE configuration rollback checkpoint files or the active configuration file:
   1. Click on the Checkpoint Files tab.
   2. Click View File and choose an option. The View window for the chosen option opens.
   3. View the file contents and close the form.

5

Close the NE Configuration Rollback form.

END OF STEPS

25 NE deployment

Using the NFM-P to deploy NEs

25.1 NE deployment overview

25.1.1 Overview

When you use the NFM-P to apply an NE configuration change, for example, by clicking OK or Apply after setting a service parameter, the NFM-P deploys the change to the NE according to the NFM-P deployment policy. The NFM-P deployment policy also specifies the conditions under which each managed NE performs a configuration save.

The information in a deployment policy includes the following:

- number and frequency of NFM-P deployment retries
- NE configuration save settings, such as the following:
  - save frequency
  - level of configuration detail to save
  - delay between consecutive saves

In a lab or testing environment, it is sometimes necessary to disable NFM-P deployment. See the *NSP NFM-P XML API Developer Guide*for information about disabling NFM-P deployment.

Note: The Deployment tab on an object properties form lists the failed deployments and deployments that are in progress. In addition, a deployment icon is displayed on the configuration form beside the parameter associated with the failed or attempted deployment, beside the NE object in the navigation tree, in list tables, and in map info tables.

25.2 Sample deployment policy configuration

25.2.1 Example details and settings

The following example describes the configuration and operation of an NFM-P deployment policy. See 25.4 “To configure the NFM-P deployment policy” (p. 768) for deployment policy configuration information.

The example policy settings are as follows:

- Auto Save Scheme—Every Nth Successful Deployment
  Initiate a device configuration save after the number of configuration changes specified by Auto Save Threshold.
- Auto Save Threshold—3
  Initiate a configuration save after every three successful deployments, if Auto Save Scheme is set to Every Nth Successful Deployment.
- Scheduled Save Scheme—None
  Do not perform a scheduled configuration save on any NE.

- Scheduled Save Interval—1 hour
  If scheduled saves are enabled, perform a save every hour.
- Save Details—disabled
  Save only non-default parameter values.
- Configuration Save Interval—30 seconds
  Delay consecutive configuration save requests for an NE that are less than 30 seconds apart.
- Interval Repeat Limit—5
  Wait up to five Configuration Save Interval periods before performing a configuration save.
- Retry Scheme—Retry Number Of Times
  Retry each deployment the number of times specified by Retry Interval.
- Retry Interval—5 minutes
  Wait five minutes before retrying a failed deployment.
- Retry Threshold—3
  Retry each failed deployment three times.

25.3 Workflow to configure and manage NE deployment

25.3.1 Stages

1

Configure the NFM-P deployment policy to specify how and when the NFM-P deploys configuration changes to the managed NEs; see 25.4 “To configure the NFM-P deployment policy” (p. 768) .

2

As required, view the deployment status and troubleshoot failed configuration deployments; see 25.5 “To view and manage failed deployments” (p. 769) .

25.4 To configure the NFM-P deployment policy

25.4.1 Steps

1

Choose Administration→NE Maintenance→Deployment from the NFM-P main menu. The Deployment form opens.

2

Click on the Deployment Policy tab.

3

Configure the required parameters.

4

Save your changes and close the form.

END OF STEPS

25.5 To view and manage failed deployments

25.5.1 Failed deployment scenarios

The NFM-P continues to retry a deployment after a failed or incomplete attempt, based on the NFM-P deployment policy.

When a deployment error occurs, a number of problems can result. For example:

- The NFM-P database may lose synchronization with the device database.
- Configuration changes requested using the client GUI may conflict with configuration changes, retries, and recovery applications developed by an OSS system, or by an operator using a CLI.

When a deployment fails, a Problems Encountered form displays error information about the failure.

Note: The Request Id and Task Name values on the form can be used as troubleshooting references in the NFM-P Task Manager.

The Problems Encountered form is also displayed for non-deployment errors.

25.5.2 Steps

1

If a Problems Encountered form opens and you want to navigate directly to the object of the deployment failure, click View Affected Object. The object properties form opens.

The current failed deployments are listed on the Deployment tab, from which you can select an entry and click Properties to view the deployment information.

2

Perform one of the following.

a. Open the list of failed deployments from a Problems Encountered form; click Deployment.

b. Open the list of failed deployments by choosing Administration→NE Maintenance→Deployment from the NFM-P main menu.

The Deployment form opens.

3

Review the deployment information. The State value indicates the cause of the deployment failure.

4

Select a deployment and click Properties. The properties form for the deployment opens. The objects of the deployment failure are shown in the Objects list.

5

Select an Objects list entry and click Properties. The Object Change form that describes the attempted configuration change opens.

6

Select an entry in the Attributes list and click Properties. The Attribute Change form opens and displays the following object attribute information:

- NE attribute to be modified
- previous attribute value
- new attribute value that the deployment fails to assign

7

Close the forms.

8

Perform one or more of the following, depending on the result of the investigation into the deployment failure.

a. Click Suspend Retries to override the deployment policy setting and prevent further deployment retries.

b. Click Resume Retries to override a previous Suspend Retries action performed on the deployment.

c. Click Clear to clear the deployment.

Note: Clearing a failed deployment may result in a loss of data synchronization between the NFM-P database and the NE. Nokia recommends that you resynchronize the NE objects associated with a failed deployment after you clear the deployment.

d. Click Force Submit to force the NFM-P to immediately reattempt the deployment.

9

Click Refresh to update the failed deployment list.

10

Close the form.

END OF STEPS

26 NE software upgrades

NE software upgrade overview

26.1 Software upgrades

26.1.1 Software upgrade requirements

CAUTION

Service Degradation

Ensure that you regularly remove from the NFM-P the device software images that are no longer required, for example, by deleting the images.

An accumulation of device software images can dramatically increase the length of an operation such as an NFM-P database backup, restore, or reinstantiation.

A software upgrade requires a software upgrade policy that specifies the device family, software image and image backup locations, and the actions to perform; for example, image download, activation, or ISSU. Depending on the device family, the activation function supports the reboot and reboot upgrade options. See 26.3 “Reboot and reboot upgrade” (p. 773) in this section for more information.

Using software upgrade policies

Using a software upgrade policy, an NFM-P operator can independently perform the image download, upgrade, and activation tasks. For example, you can configure a policy to perform the time-consuming software image downloads only, and then schedule the image activations as a separate task. When the images are downloaded in advance, the NFM-P can perform more activations in a maintenance period.

Nokia recommends that you plan the image download tasks independent of upgrade and activation tasks. The download tasks can be time-consuming depending on the software image size, network bandwidth, and number of NEs the image is being downloaded to.

Note: The NFM-P limits the software image download to 10 NEs at a time.

Software compatibility and upgrades

During a software upgrade, the NFM-P verifies that the new software is compatible with the device and that the required files are present; otherwise, the upgrade is not attempted. You can use the NFM-P to roll back a software upgrade in the event of an upgrade failure.

You cannot upgrade an NE to a chronologically older release, regardless of the release identifier; for example, the R1 revision of a release may predate the R9 revision of the previous release. See the *NSP NFM-P Network Element Compatibility Guide* for information about the supported device upgrade paths.

VSR-a software (SROS) upgrade is not supported in NFM-P.

Nokia recommends that you import all of the images that are bundled for a release. All 7x50 NEs use the same bundle. When downloading the software, the NFM-P automatically chooses the required files for a specific NE variant.

For SR NEs, the NFM-P downloads a complete list of software bundles regardless of chassis type.

For IXR NEs, the NFM-P downloads only the required list of image files based on the chassis type.

GNE software upgrades

The NFM-P NE software upgrade function is supported for GNEs, depending on the device type and release. Upgrading a GNE requires a valid NFM-P GNE driver that supports the function.

Note: Some GNE devices may have specific upgrade requirements. Before you attempt to perform a GNE upgrade, see the appropriate domain user guide for information about driver capabilities and driver-specific information.

GNE software upgrades are configured and performed using the policy-based mechanism that is used for natively managed devices; the type of upgrade policy required for GNEs is Generic NE Node. In a Generic NE Node upgrade policy, you must specify FTP or SFTP user credentials and a directory on the main server that is used for transferring the software image files to and from the GNEs.

Note: GNE software upgrades have the following special requirements.

- FTP or SFTP must be enabled on each main server, depending on which protocol you use.
- If a firewall is used, the required FTP or SFTP ports must be open.
- The FTP or SFTP user that you specify in a software upgrade policy must be a valid FTP or SFTP user on each main server station, and must belong to the sam user group on each main server station.
- The nsp user requires read, write, and execute access to the directory that you specify in the policy.

26.2 ISSUs

26.2.1 Upgrading in-service NEs

CAUTION

Service Disruption

Before you attempt an ISSU, see the appropriate device release notice and the *NSP NFM-P Network Element Compatibility Guide* for information about the following:

- device releases that support ISSU
- supported upgrade paths

The software upgrade information in the device documentation takes precedence over the information in this chapter.

You can use the NFM-P to perform an in-service software upgrade, or ISSU, on a managed NE that has dual CPMs. An ISSU allows an NE to provide uninterrupted service during the upgrade process.

A device software upgrade requires a CPM restart, which causes a temporary NE outage. When an NE has dual CPMs, however, one CPM can remain active while the other restarts using the upgraded software. The alternate CPM restarts mean that the NE remains fully in service during an upgrade. If the upgrade of a CPM fails, the CPM reports the failure and an alarm is raised.

Note: ISSUs are restricted to device maintenance releases only. See the device documentation for the supported release transitions.

Some 7210 SAS chassis types do not support ISSUs; see the device documentation for more information.

26.3 Reboot and reboot upgrade

26.3.1 Manual or automatic reboots

You can perform a manual or an automatic NE reboot during an on-demand software upgrade, and can configure an automatic reboot in a software upgrade policy. See 26.5 “To configure a software upgrade policy” (p. 776) for information about configuring an automatic reboot in a software upgrade policy, or 26.9 “To perform an ISSU or on-demand software upgrade” (p. 783) for information about performing a manual reboot during an on-demand software upgrade.

The NFM-P supports the 7210 SAS and 7705 SAR reboot upgrade option, which upgrades the system firmware. You can manually perform a reboot upgrade on an NE, or configure an automatic reboot upgrade in a software upgrade policy. See 26.5 “To configure a software upgrade policy” (p. 776) for information about configuring an automatic reboot upgrade, and 26.9 “To perform an ISSU or on-demand software upgrade” (p. 783) for information about performing a manual reboot upgrade during an on-demand software upgrade.

26.3.2 Preventing unwanted NE reboots

Only an operator with the admin or Network Element Software Management scope of command role can perform an NE software upgrade. The Network Element Software Management role includes a permission that you can enable to allow the configuration of NE reboots in a software upgrade policy.

If the mediation.SoftwareUpgradePolicy.property_autoRebootType permission is enabled in the Network Element Software Management scope of command role of an operator, the operator can enable or disable the NE reboot function in a software upgrade policy, and perform an NE reboot as part of a software upgrade. NE upgrade operators for whom the permission is disabled cannot configure an NE reboot in an upgrade policy or perform an NE reboot during a software upgrade.

26.3.3 Log Last Reboot

The Log Last Reboot indicator on the Shelf properties form shows the time of the previous chassis reboot and the user that performed the reboot..

NE software upgrade workflow and procedures

26.4 Workflow to manage NE software upgrades

26.4.1 Purpose

The following is the sequence of high-level actions required to perform and manage NE software upgrades for the following device types:

- 210 WBX
- 7210 SAS
- 7250 IXR
- 7450 ESS
- 7705 SAR
- 7705 SAR-Hm
- 7750 SR
- 7950 XRS
- OmniSwitch

26.4.2 Stages

1

Perform the following pre-upgrade checks.

1. It is the user responsibility to keep the valid checksum file before import.
2. Verify that the device supports the new software.
3. Verify that there is sufficient space on the NE compact flash drives for the new software image files and a backup of the current image.
4. For NEs that have redundant CPMs, use a CLI to verify that the boot environments are synchronized.

2

Configure a software upgrade policy; see 26.5 “To configure a software upgrade policy” (p. 776) .

3

Import the required device software image to the NFM-P; see 26.6 “To import device software files to the NFM-P” (p. 779) .

4

Back up the device configuration.

5

Schedule an upgrade of one or more NEs, as required; see 26.7 “To schedule an NE software upgrade” (p. 781) for node upgrades and 26.10 “To schedule an extension shelf software upgrade” (p. 787) for extension shelf upgrades.

6

Turn up, shut down, or delete a scheduled upgrade task; see 26.8 “To manage scheduled software upgrades” (p. 782) .

7

Perform an on-demand upgrade or an ISSU, as required.

See 26.9 “To perform an ISSU or on-demand software upgrade” (p. 783) for 7210 SAS, 7250 IXR, 7450 ESS, 7705 SAR, 7750 SR, or 7950 XRS upgrade information.

See 26.12 “To upgrade 7705 SAR-Hm radio card firmware” (p. 790) for 7705 SAR-Hm upgrade information.

See 26.21 “To perform an OmniSwitch on-demand software upgrade or ISSU” (p. 803) and 26.22 “To perform an OS 6400, OS 6850E, or OS 6855 ISSU” (p. 809) for OmniSwitch upgrade information.

See 26.11 “To perform an extension shelf on-demand software upgrade” (p. 788) for extension shelf upgrade information.

8

Monitor the upgrade progress; see 26.17 “To monitor the status of a software upgrade” (p. 799) .

9

Activate a software image on an NE, if required; see 26.18 “To activate a device software image” (p. 799) .

10

After the upgrade, verify the boot environment synchronization for NEs that have dual CPMs.

11

For an OS 6250SME or OS 6450, perform a software license upgrade to enable the Ethernet Metro functions; see 26.20 “To upgrade OS 6250SME and OS 6450 NE software licenses for an Ethernet (Metro) role” (p. 801) .

12

Certify or synchronize the OmniSwitch software on an NE; see 26.23 “To certify or synchronize OmniSwitch software” (p. 812) .

13

If required, reboot the NE.

14

Resynchronize the NE.

15

As required, perform upgrade verification tests.

16

Remove outdated software images from the device and from the NFM-P.

NOTE:: Ensure that you regularly remove from the NFM-P device software images that are no longer required, for example, by deleting the images or by exporting to a remote file system. An accumulation of device software images can greatly increase the length of an NFM-P database operation such as a backup, restore, or reinstantiation.

26.5 To configure a software upgrade policy

26.5.1 Purpose

Perform this procedure to configure a policy that you can use to perform an on-demand device software upgrade, ISSU, or a scheduled device software upgrade.

Note: For information about device software downgrades, contact Nokia technical support.

26.5.2 Steps

1

Ensure that the following conditions are present.

- An FTP account is configured and available on each device.
- The device configuration is backed up.

2

Choose Administration→NE Maintenance→Software Upgrade from the NFM-P main menu. The Software Upgrade form opens.

3

Click Create. The Software Upgrade Policy (Create) form opens.

4

If you are creating a policy, configure the Policy Type parameter. Perform one of the following:

a. For a 210 WBX, 7210 SAS, 7250 IXR, 7450 ESS, 7705 SAR, 7705 SAR-Hm, or 7950 XRS, choose the SR Based Node option.

b. For a GNE, choose the Generic NE Node option.

c. For an 1830 VWM, choose 1830 VWM OSU Node and go to Step 7.

5

If the Policy Type is SR Based Node, configure the Software Download, Activate Image, and Software Upgrade parameters to specify the actions that the NFM-P is to perform using the

policy. Configure the parameters in the Extension Shelf Settings panel to specify the actions performed on extension shelves that are connected to the node. Configure the Firmware Settings, see 26.12 “To upgrade 7705 SAR-Hm radio card firmware” (p. 790).

Note: The Activate Image parameter does not apply to the 210 WBX.

To check the disk space, perform one of the following:

- Enable the Validate Disk Space parameter in the Disk Space Validation Settings panel. Configure the Expected free disk space after upgrade (%) parameter to determine the expected free disk space as a percentage of the total disk space. The validation checks the available space in the target file system against the size of the image to be uploaded. If the NE file system does not have sufficient capacity, the NFM-P raises an alarm and does not complete the software upgrade for the specific NE. If the NE has two CPMs, the NFM-P checks for free space for both the active and standby CPMs. For 7705 SAR NEs, the disk space validation is only supported on the 7705 SAR-8 and 7705 SAR-18.
- On the supported NE, click Software Images, click Import and click Inspect Disk Space. This inspects the node disk space on the selected NE before performing an upgrade. The success or failure log message is displayed in the log viewer.

If the Software Download parameter is selected, the NFM-P downloads a software image to the NE when performing an activation, regardless of whether the image is already present on the NE.

If the Software Upgrade parameter is selected, perform one of the following to configure the Software Upgrade Options parameter.

Note: Depending on the permissions in your scope of command profile, the Software Upgrade Options parameter may not be configurable.

a. Select Reboot if you want the NE to reboot after the upgrade.

b. To specify an out-of-service upgrade for a 7210 SAS or 7705 SAR that includes an NE reboot with firmware upgrade, select Reboot with Firmware Upgrade.

   Note: Depending on the device configuration, a 7210 SAS or 7705 SAR determines whether a firmware upgrade is required, and may override the parameter setting.

c. To specify an ISSU for a device with dual CPMs, select ISSU (In Service Software Upgrade).

   Note: ISSUs are restricted to device maintenance releases only. See the device documentation for the supported ISSU release transitions.

d. To specify a hypervisor upgrade for a 210 WBX that includes an NE reboot after the hypervisor upgrade, select 210 WBX Reboot with Hypervisor Upgrade.

   Note: The option 210 WBX Reboot with Hypervisor Upgrade is applicable only to 210 WBX NEs. The options Reboot, ISSU (In Service Software Upgrade), and Reboot with Firmware Upgrade do not apply to the 210 WBX. However, the 210 WBX NE can be rebooted from the shelf properties form.

6

If the Policy Type is Generic NE Node, configure the Transfer Protocol parameter and the parameters in the FTP Settings or SFTP Settings panel.

Note: You must ensure that the following conditions are met before you attempt to use the software upgrade policy.

- FTP or SFTP is enabled on each main server, depending on which protocol you use.
- If a firewall is used, the required FTP or SFTP ports are open.
- The FTP or SFTP user that you specify is a valid FTP or SFTP user on each main server station, and belongs to the sam user group on each main server station.
- The nsp user has read, write, and execute access to the Root Directory that you specify.

7

If the Policy Type is 1830 VWM OSU Node, perform the following:

1. Configure the SFTP user ID and password in the 1830 Based Setting panel.
2. Configure the Server IP parameter by providing the remote server IP address required to import 1830 VWM software from a remote location. See 26.24 “To perform an 1830 VWM on-demand software upgrade” (p. 812) for more information about performing an 1830 VWM software upgrade.
3. Configure the remaining parameters.
4. Go to Step 11.

8

Click Apply.

9

Depending on the Transfer Protocol parameter value you specified, configure the FTP or SFTP parameters.

10

Configure the remaining parameters.

Note: The default value for the CFlash Image Root Path and CFlash Backup Root Path parameters specifies compact flash drive cf3, which may not exist on some devices. To check the drive availability and capacity on an NE, click FTP Browser or SSH File Browser; see 22.5 “To view an NE file system using an FTP file browser” (p. 739) and 22.2 “To view an NE file system using an SSH file browser” (p. 736) for browser usage information.
Some 7210 SAS devices are equipped with a USB flash memory (uf1). The NFM-P display does not distinguish between compact flash memory (cf) and USB flash memory (uf).

To avoid file transfer failures, Nokia recommends that you equip 7210 SAS-X NEs with a USB flash drive, and configure the CFlash Backup Root Path parameter with a file path on the USB drive (uf1:).

11

Click Apply.

12

Click on the Software Upgrade Policy Assignment tab and assign one or more NEs to the policy, as required.

13

Close the form.

END OF STEPS

26.6 To import device software files to the NFM-P

26.6.1 Purpose

Perform this procedure to import a set of device software image files or software description files to the NFM-P for use during an NE software upgrade.

Note: The Wavence SM and Wavence SA require software description files, which identify the files that require an upgrade. A software description file has a .DSC file extension.

Note: For releases prior to NFM-P 21.11, NFM-P supports 210 WBX image import only when the files onie-installer-x86_64 and md5sums.txt are present in the package. The md5sum.txt must be renamed to md5sums.txt. No additional files or folder must be present.

The NFM-P supports 210 WBX image import with all the files in Nauge-210-wbx-x package except MIBs folder. Before importing the image MIBs folder must be removed from the package.

26.6.2 Steps

1

Make the new device software files available to the NFM-P.

1. If the device software files are compressed in an archive, for example, a TiMOS ZIP file, extract the archive files to an empty directory. The directory structure in a device software archive depends on the device type and release, and must have one of the following structures:
   - flat—all files are in one directory, and there are no subdirectories

- tiered—the directory contains a boot loader file, and a subdirectory contains the software image files

For example, if you extract a set of 7750 SR files to */ExtractDir*, the directory structure is tiered:

- */ExtractDir/cflash* contains the boot.ldr file.
- */ExtractDir/cflash/R.r.Rn* (where *R.r.Rn* is the software release identifier) contains the software image files, both.tim and cpm.tim

Note:

The 7450 ESS and 7750 SR use a common software image with a Target Product name of Alcatel-SR/ESS-7XXX.

2. Copy the files to a location that is accessible to the NFM-P.

Note:

Nokia recommends that all OmniSwitch software image files, including optional and boot files, be made available.

The Wavence SM requires only the software description files.

2

Choose Administration→NE Maintenance→Software Upgrade from the NFM-P main menu. The Software Upgrade form opens.

3

Click on the Software Images tab.

4

Click on the tab that corresponds to the type of NE to be upgraded.

5

Click on the Inspect Disk Space.

6

Click Import. One of the following happens:

a. The Open form opens.

b. If upgrading 7705 SAR-Hm firmware, the Import Firmware Image form opens. After you set the Image Version and click Select, the Open form opens.

7

Navigate to the directory that contains the software files and click Open.

Note: If the directory structure is tiered, you must navigate to the directory that contains the boot loader file, then to the subdirectory that contains the software files. For the example in Step 1 , this directory is the *cflash/R.r.RN* directory for the software image files (where *R.r.RN* is the release identifier).

Some 7210 SAS devices are equipped with a USB flash memory (uf1). The NFM-P display does not distinguish between compact flash memory (cf) and USB flash memory (uf).

The NFM-P verifies the file set, imports the files, and lists an entry for the imported image.

8

If the directory does not contain only the required files, a message is displayed. Perform the following steps.

1. Click OK.
2. Copy or move files, as required, to ensure that the directory contains only the files required for the upgrade.
3. Go to Step 6 .

9

Close the Software Upgrade form.

END OF STEPS

26.7 To schedule an NE software upgrade

26.7.1 Purpose

Perform this procedure to schedule a device software upgrade on one or more managed NEs according to a software upgrade policy and an NFM-P schedule. See Chapter 5, “NFM-P-based schedules” for information about NFM-P schedules.

Note: A new NFM-P scheduled task is shut down by default and must be turned up before it can be executed, with one exception: Scheduled software upgrade tasks associated with all NE types are automatically enabled by default.

You must perform 26.6 “To import device software files to the NFM-P” (p. 779) to import the required device software image before you perform this procedure.

26.7.2 Steps

1

Choose Administration→NE Maintenance→Software Upgrade from the NFM-P main menu. The Software Upgrade form opens.

2

Select the required software upgrade policy.

Note: The NFM-P performs the upgrade according to the configuration in the software upgrade policy that you select.

3

Click on the Software Images tab.

4

Select a software image and click Schedule Upgrades. The Select Sites form opens.

5

Select one or more NEs and click OK. The Select Schedule form opens.

Note: You cannot use a schedule in which the Ongoing parameter is enabled.

6

Select a schedule and click OK.

7

Click Yes. The NFM-P schedules the upgrade.

8

Close the form.

END OF STEPS

26.8 To manage scheduled software upgrades

Note: You cannot reuse a completed scheduled task.
The NFM-P does not delete a scheduled task after it runs; you must delete it manually.

26.8.1 Steps

1

Choose Administration→NE Maintenance→Software Upgrade from the NFM-P main menu. The Software Upgrade form opens.

2

Click on the Software Upgrade Status tab.

3

Click Scheduled Task. The Scheduled Task form opens.

4

Select a scheduled software upgrade entry and click Properties. The Software Upgrade Scheduled Task form opens.

1. Administratively enable or disable the scheduled software upgrade, if required, by configuring the Administrative State parameter.
2. Click Properties in the Schedule panel to view the schedule information, if required.
3. Click Properties in the Task panel to view the NFM-P task information, if required.
4. Save your changes and close the form.

5

To turn up, shut down, or execute the task, click Task Action and select the appropriate option.

6

Delete the scheduled task, if required.

1. Click Task Action and choose Shut Down.
2. Click Delete. The scheduled task is deleted.

7

Close the forms.

END OF STEPS

26.9 To perform an ISSU or on-demand software upgrade

26.9.1 Purpose

Perform this procedure to upgrade the device software on one or more NEs.

The following must be true before you attempt a device software upgrade.

- You have an NFM-P user account with an administrator or network element software management scope of command role, or a scope of command role with write access to the mediation package.
- The FTP or SFTP credentials are configured in the NE mediation policy.

CAUTION

Service Disruption

A device may require a firmware upgrade before a software upgrade.

To avoid a service outage, ensure that the device firmware version supports the software release. See the device software Release Notes for information about firmware and software compatibility, and about the firmware upgrade procedure.

CAUTION

Service Disruption

Nokia recommends that you open a physical console session on the NE that you need to upgrade so that you can monitor the upgrade and recover in the event of an upgrade failure.

Read the software upgrade information in the device documentation before you perform a software upgrade.

Before you attempt an ISSU, see the appropriate device release notice and the NSP NFM-P Network Element Compatibility Guide for information about the supported upgrade paths.

You cannot upgrade an NE to a chronologically older release, regardless of the release identifier; for example, the R1 revision of a release may predate the R9 revision of the previous release. See the NSP NFM-P Network Element Compatibility Guide for information about the supported device upgrade paths.

Note: ISSUs are restricted to device maintenance releases only. See the device documentation for the supported release transitions.

Some 7210 SAS chassis types do not support ISSUs; see the device documentation for more information.

Before you downgrade a device, you must unmanage and delete the device from the NFM-P. Contact Nokia technical support for information about device downgrades.

If the NFM-P raises a NodeVersionMismatch alarm, manually unmanage and remanage the device after performing the upgrade or downgrade.

The NFM-P does not support an upgrade of the 7705 SAR-H from Release 5.0 to Release 6.1. You must first unmanage the device and then perform the upgrade using a CLI, after which you can again use the NFM-P to manage the NE.

26.9.2 Steps

1

Choose Administration→NE Maintenance→Software Upgrade from the NFM-P main menu. The Software Upgrade form opens.

2

Click on the Software Images tab.

3

Select a software image and click Import. The Open window appears.

4

Navigate to the directory that contains the software image, select the image, and click Open.

Note: The directory must contain only the files required for the upgrade.
The 7450 ESS, 7750 SR, and 7950 XRS use a common software image with a Product Name of Nokia-SR/ESS-7XXX.

If you are upgrading a 7705 SAR-8 or 7705 SAR-18, two images are required: One image contains the boot.ldr and both.tim files, and the second contains the MWA files in the pkgs/MPT folder. If the image folder contains the MPT files, the MPT Image Software Version is displayed on the Software Image form. If the image folder does not contain MPT packages, the MPT Image Software Version shows N/A.

5

If the directory contains only the required files, the NFM-P imports the files, and an entry for the image is listed on the Software Upgrade form. Go to Step 7 .

6

If the directory does not contain only the required files, a message is displayed.

Perform the following steps.

1. Click OK.
2. Copy or move files, as required, to ensure that the directory contains only the files required for the upgrade.
3. Go to Step 3 .

7

Click Upgrade Sites. A list of NEs is displayed. Only the devices that support the software image are listed.

8

Select one or more NEs and click OK. The software upgrade begins.

9

Click on the Software Upgrade Status tab to view the upgrade progress.

10

CAUTION

Service Disruption

Rebooting an NE that is in service is service-affecting.

Ensure that you perform the reboot only during a scheduled maintenance period.

If the Software Upgrade parameter in the software upgrade policy is not selected, you must activate the image on each NE and then reboot each NE.

Note: Some device software upgrades, for example, ISSUs, do not require a reboot. See the device documentation for more information.
When you perform an ISSU, you can manually soft reset or hard reboot the IOMs or IMMs after the upgrade. A soft reset results in minimal downtime, but has limited support. See

26.14 “To perform an IOM, IMM, or XCM soft reset” (p. 793) to perform a manual soft reset, or 26.15 “To perform an IOM or XCM hard reboot” (p. 794) to perform a manual hard reboot.
When the IOMs are not manually soft reset or hard rebooted, the device performs a soft reset, if supported, after two hours; otherwise, the device performs a hard reboot after two hours.

1. Select the NEs that are to be upgraded.
2. Click on the Software Images tab. A list of software images on the selected NEs is displayed.
3. Select the required software image and click Activate Image. A confirmation message is displayed.
4. Click Yes. The software image is activated.

   When the NFM-P activates an NE software image, it does the following:
   - backs up the original boot.ldr at the location specified by the CFlash Backup Root Path parameter
   - synchronizes the CPMs on NEs that have redundant CPMs
   - updates the BOF with the new software image location
5. Click on the Software Upgrade Status tab to monitor the activation progress. The Last Operation column displays each operation as it completes, and the Upgrade Status column displays the overall activation status.
6. Wait until the image activation completes.
7. In the navigation tree equipment view, navigate to the shelf object. The path is Network→*NE*→Shelf.
8. Right-click the shelf icon and choose Reboot or Reboot Upgrade. A dialog box appears.

   Note:

   Only the 7210 SAS and 7705 SAR support the Reboot Upgrade option.
9. Click Yes. The NE reboots.

11

Click on the Software Upgrade Status tab to monitor the upgrade progress. The Upgrade State column displays the current upgrade status.

12

Use the NFM-P FTP or SSH file browser to verify that the transferred files and configuration are on each upgraded NE. See 22.5 “To view an NE file system using an FTP file browser” (p. 739) for information about using the FTP file browser, and 22.2 “To view an NE file system using an SSH file browser” (p. 736) for information about using the SSH file browser.

13

Resynchronize each upgraded NE.

END OF STEPS

26.10 To schedule an extension shelf software upgrade

26.10.1 Purpose

Perform this procedure to schedule a device software upgrade on one or more extension shelves, according to a software upgrade policy and an NFM-P schedule. See Chapter 5, “NFM-P-based schedules” for information about NFM-P schedules.

Note: A new NFM-P scheduled task is shut down by default and must be turned up before it can be executed, with one exception: scheduled software upgrade tasks associated with all NE types are automatically enabled by default.

You must perform 26.6 “To import device software files to the NFM-P” (p. 779) to import the required device software image before you perform this procedure.

The NFM-P automatically creates software repositories for use with extension shelf upgrades. To manually create a software repository, see 26.13 “To create a software repository” (p. 793).

26.10.2 Steps

1

Choose Administration→NE Maintenance→Software Upgrade from the NFM-P main menu. The Software Upgrade form opens.

2

Select the required software upgrade policy.

Note: The NFM-P performs the upgrade according to the configuration in the software upgrade policy that you select.

3

Click on the Software Images tab, and then on the SR Extended Shelf Software Images tab.

4

Select a software image and click Schedule Upgrades. The Select NE form opens.

5

Select an NE and click OK. The Select Extended Shelf form opens.

6

Select one or more extended shelves and click OK. The Select Software Repository form opens.

7

A software repository is automatically created for the upgrade. To manually specify a software repository, click on the Properties button and select a software repository. Click OK. The Select Schedule form opens.

8

Select a schedule and click OK.

Note: You cannot use a schedule in which the Ongoing parameter is enabled.

9

Click Yes. The NFM-P schedules the upgrade.

10

Close the form.

END OF STEPS

26.11 To perform an extension shelf on-demand software upgrade

26.11.1 Purpose

Perform this procedure to upgrade the device software on one or more extension shelves.

The following must be true before you attempt a device software upgrade.

- You have an NFM-P user account with an administrator or network element software management scope of command role, or a scope of command role with write access to the mediation package.
- The FTP or SFTP credentials are configured in the NE mediation policy.

CAUTION

Service Disruption

A device may require a firmware upgrade before a software upgrade.

To avoid a service outage, ensure that the device firmware version supports the software release. See the device software Release Notes for information about firmware and software compatibility, and about the firmware upgrade procedure.

CAUTION

Service Disruption

Nokia recommends that you open a physical console session on the NE that you need to upgrade so that you can monitor the upgrade and recover in the event of an upgrade failure.

Read the software upgrade information in the device documentation before you perform a software upgrade.

You cannot upgrade an NE to a chronologically older release, regardless of the release identifier; for example, the R1 revision of a release may predate the R9 revision of the previous release. See the NSP NFM-P Network Element Compatibility Guide for information about the supported device upgrade paths.

Note: Before you downgrade a device, you must unmanage and delete the device from the NFM-P. Contact Nokia technical support for information about device downgrades.

The NFM-P automatically creates software repositories for use with extension shelf upgrades. To manually create a software repository, see 26.13 “To create a software repository” (p. 793).

26.11.2 Steps

1

Choose Administration→NE Maintenance→Software Upgrade from the NFM-P main menu. The Software Upgrade form opens.

2

Click on the Software Images tab, then on the SR Extended Shelf Software Images tab.

3

Select a software image and click Import. The Open window appears.

4

Navigate to the directory that contains the software image, select the image, and click Open.

Note: The directory must contain only the files required for the upgrade.

5

If the directory contains only the required files, the NFM-P imports the files, and an entry for the image is listed on the Software Upgrade form. Go to Step 7 .

6

If the directory does not contain only the required files, a message is displayed.

Perform the following steps.

1. Click OK.

2. Copy or move files, as required, to ensure that the directory contains only the files required for the upgrade.
3. Go to Step 3 .

7

Click Upgrade Shelves. A list of NEs is displayed. Only the devices that support the software image are listed.

8

Select an NE and click OK. The Select Extended Shelf form opens.

9

Select one or more extended shelves and click OK. The Select Software Repository form opens.

10

A software repository is automatically created for the upgrade. To manually specify a software repository, click on the Properties button and select a software repository. Click OK. The software upgrade begins.

11

Click on the Software Upgrade Status tab to view the upgrade progress. The Upgrade State column displays the current upgrade status.

12

Use the NFM-P FTP or SSH file browser to verify that the transferred files and configuration are on each upgraded NE. See 22.5 “To view an NE file system using an FTP file browser” (p. 739) for information about using the FTP file browser, and 22.2 “To view an NE file system using an SSH file browser” (p. 736) for information about using the SSH file browser.

13

Resynchronize each upgraded NE.

END OF STEPS

26.12 To upgrade 7705 SAR-Hm radio card firmware

26.12.1 Purpose

The Sierra Wireless cellular radio card firmware is not bundled with the SAR-Hm SROS image. Instead, an operator must download a specific RHEL firmware file (Linux Version) from Sierra Wireless to the NSP host server.

For the 7705 SAR-Hm, the firmware is a zip file. For 7705 SAR-Hmc, the firmware is a tim file.

The 7705 SAR-Hm SROS software must be upgraded to Release 15.0 R6 or later before a firmware upgrade is possible.

The 7705 SAR-Hmc supports both ADP and non-ADP radio card firmware upgrade.

When ADP upgrades the 7705 SAR-Hm software, ADP also upgrades the 7705 SAR-Hm firmware if a new firmware version is available for the new 7705 SAR-Hm release.

26.12.2 Steps

1

Choose Administration→NE Maintenance→Software Upgrade from the NFM-P main menu. The Software Upgrade form opens.

2

Click Create. The Software Upgrade Policy (Create) form opens.

3

Set the Policy Type parameter to the SR Based Node option and configure the parameters.

For Non-ADP, enable the Firmware Download and Firmware Activate parameters and set the Firmware Upgrade Options parameter to Reboot.

For ADP, enable the Firmware Download and Firmware Activate parameters and set the Firmware Upgrade Options parameter to None.

Note: Depending on the permissions in your scope of command profile, the Software Upgrade Options parameter may not be configurable.

4

Click Apply.

5

Click on the Software Upgrade Policy Assignment tab and assign a 7705 SAR-Hm to the policy.

6

Close the form.

7

On the Software Upgrade form, click on the Software Images tab.

8

Click on the SAR-Hm/Hmc Firmware Images tab and click Import. The Import Firmware Image form opens.

9

Specify the Image Version and click Select.

For the 7705 SAR-Hm, use a format that is aligned with the Sierra Wireless web portal, [VENDOR NAME]<space>[FIRMWARE_SUFFIX]<space>[PRI]. For example: GENERIC 02.24.03.00 002.026_000

For the 7705 SAR-Hmc, use a format such as this example: 7705_SAR-Hmc_FW_CAT4_GS_BYPASS_0.3.3.9_V1.7.tim

The Open window appears.

10

Navigate to the directory that contains the firmware image, select the image, and click Open.

Note: The directory must contain only the firmware file.

11

If the directory contains only the required files, the NFM-P imports the files, and an entry for the image is listed on the Software Upgrade form. Go to Step 13 .

12

If the directory does not contain only the required files, a message is displayed.

Perform the following steps.

1. Click OK.
2. Copy or move files, as required, to ensure that the directory contains only the files required for the upgrade.
3. Go to Step 9 .

13

Select the imported image and click Upgrade Sites. The Select NE For Firmware Upgrade page opens.

14

Select an NE and click Next.

15

Set the Upgrade Sim parameter and click Finish. A confirmation pop-up opens.

16

Click Yes to begin the firmware upgrade.

17

To view the upgrade progress, click on the Software Upgrade Status tab and then on the Firmware Upgrade Status tab. For additional information, select the NE and click Properties.

When the firmware version is upgraded on the node, the NFM-P raises an alarm.

END OF STEPS

26.13 To create a software repository

26.13.1 Purpose

Perform this procedure to create a software repository for use with an extension shelf. A software repository defines a location where system upgrade files for the extension shelf are stored.

26.13.2 Steps

1

Choose Administration→NE Maintenance→Software Repository from the main menu.

2

Click on the Create button.

3

Configure the Primary Location parameter, and any other required parameters.

4

Save and close the form.

END OF STEPS

26.14 To perform an IOM, IMM, or XCM soft reset

26.14.1 Purpose and prerequisities

Perform this procedure to perform a manual soft reset on an IOM, IMM or XCM.

Soft reset is supported only under the following conditions:

- The IOM or XCM is operationally up.
- The IOM, IMM, or XCM is supported. The IOM, IMM, or XCM supports soft reset when the Soft Reset menu item is selectable after you right click on the object. The Soft Reset menu is greyed out if it is not supported.
- The MDAs or XMAs are provisioned, and are Ethernet, but not HSMDA.

MDAs that do not support soft reset are hard rebooted during a soft reset operation.

For more information about soft reset support, see the appropriate node documentation.

26.14.2 Steps

1

On the Equipment tree, locate a card slot object by expanding Network→*NE*→Shelf→Card Slot *n*.

2

Right-click on the object and choose Soft Reset. A Warning form opens.

3

Click View Dependencies to view the dependency information, if required.

4

Select the check box and click Yes. The NFM-P resets the IO card; the operational state of the IO card displays the soft reset progress.

END OF STEPS

26.15 To perform an IOM or XCM hard reboot

26.15.1 Steps

1

On the Equipment tree, locate an IOM or XCM card slot object by expanding Network→*NE*→Shelf→Card Slot *n*.

2

Right-click on the object and choose Properties. The Card Slot (Edit) form opens.

3

Click on the IO Card tab and click Reboot. A Warning form opens.

4

Click View Dependencies to view the dependency information, if required.

5

Select the check box and click Yes. The NFM-P resets the IO card; the operational state of the IO card displays the hard reboot status.

END OF STEPS

26.16 To upgrade the ISA-AA MDA software

26.16.1 Purpose and prerequisites

Perform this procedure to upgrade only the ISA-AA MDA software on an NE, for example, when the new software includes new AA protocol signatures.

Note: You cannot use the procedure to upgrade between major releases; only minor-release ISA-AA upgrades within the same major release are supported.

An ISA-AA MDA software upgrade is an in-service upgrade that does not require an NE reboot. Although the Software Upgrade parameter in the associated software upgrade policy must be selected for the image activation and upgrade to occur, the Software Upgrade Options in the policy do not apply to an ISA-AA MDA software upgrade.

The 7450 ESS and 7750 SR support ISA-AA MDA upgrades.

The following must be true before you attempt an ISA-AA software upgrade.

- You have an NFM-P user account with an administrator or network element software management scope of command role or a scope of command role with write access to the mediation package.
- The FTP or secure FTP credentials are configured in the NE mediation policy.

CAUTION

Service Disruption

Nokia recommends that you open a physical console session on the device that you need to upgrade. The console session allows you to monitor the upgrade and recover in the event of an upgrade failure.

Read the software upgrade information in the device documentation before you perform a software upgrade.

Before you attempt an ISA-AA MDA software upgrade, see the appropriate device release notice and the NSP NFM-P Network Element Compatibility Guide for information about the supported upgrade paths. See "NE software upgrade overview" (p. 771) for general ISSU information.

26.16.2 Steps

1

Perform the following steps.

1. Verify that the device supports the new ISA-AA software.
2. Extract the isa-aa.tim and md5sums.txt files from the Nokia software package to a directory that is reachable by the NFM-P. Ensure that there are no other files in the directory.
3. Manually verify the software image file checksum against the file checksum listed in the md5sums.txt file.
4. Verify that the device file system has space for the software image file.

5. For NEs with redundant CPMs, verify that the boot environments are synchronized by using the appropriate CLI command.
6. Configure the appropriate software upgrade policy, as described in 26.5 “To configure a software upgrade policy” (p. 776) ; apply the policy to the NEs that you need to upgrade.

2

Back up the device configuration.

3

Choose Administration→NE Maintenance→Software Upgrade from the NFM-P main menu. The Software Upgrade form opens.

4

Click on the Software Images tab and click Import. The Open window appears.

5

Navigate to the directory that contains the software image, select the directory, and click Open.

Note: The directory must contain only the isa-aa.tim and md5sums.txt files.

6

The NFM-P verifies the isa-aa.tim checksum and imports the file to the NFM-P database. An entry for the image is listed on the Software Upgrade form.

7

Select the required ISA-AA image.

8

Click Upgrade Sites. A list of NEs is displayed. Only the devices that support the software image are listed.

9

Select one or more NEs.

10

Click OK. A dialog box appears.

11

Ensure that the conditions described in the dialog box are met, and then click Yes. The software upgrade begins.

12

Click on the Software Upgrade Status tab to monitor the upgrade progress.

The following Upgrade State value is displayed:

- Transferring Image Files—The NFM-P imports the image file from the specified directory to the NFM-P database.

Note: Each upgrade stage also has one or more specific failure values.

If the Software Upgrade parameter in the software upgrade policy is selected, the NFM-P activates the new software image and displays the following sequence of Upgrade State values during the activation:

- Backing Up ISA-AA File—The NFM-P makes a backup copy of the isa-aa.tim file in the primary-image location specified by the BOF.
- Updating ISA-AA File—The new isa-aa.tim file is downloaded to the primary-image location specified by the BOF, and the appropriate ISA-AA upgrade command is issued on each NE.
- Pending ISA MDA Reboot—A reboot of the ISA-AA MDA is required.

13

If the Software Upgrade parameter in the software upgrade policy is unselected, you must activate the software image.

Note: Alternatively, you can select the required ISA-AA image on the Software Images tab and click Activate Image.

Perform the following steps.

1. Edit the following software upgrade policy settings, as described in 26.5 “To configure a software upgrade policy” (p. 776) :
   - Deselect the Software Download parameter.
   - Select the Software Upgrade parameter.
2. Select the required software image and click Upgrade Sites. The Select Sites form opens.
3. Use the form to select the required NEs, and then click OK. A dialog box appears.
4. Ensure that the conditions described in the dialog box are met, and then click Yes. The software image upgrade begins.
5. Click on the Software Upgrade Status tab to monitor the upgrade progress. The Upgrade State displays the following sequence of values:
   - Backing Up ISA-AA File—The NFM-P makes a backup copy of the isa-aa.tim file in the primary-image location specified by the BOF.
   - Updating ISA-AA File—The new isa-aa.tim file is downloaded to the primary-image location specified by the BOF, and the appropriate ISA-AA upgrade command is issued on each NE.
   - Pending ISA MDA Reboot—A reboot of the ISA-AA MDA is required.

14

Perform the following steps on each upgraded ISA-AA MDA to shut down and reboot the MDA.

1. In the navigation tree equipment view, navigate to the upgraded ISA-AA MDA. The path is Network→*NE*→Shelf→Card Slot *n*→Daughter Card Slot *n*.
2. Right-click on the Daughter Card Slot object and choose Shut Down. A dialog box appears.
3. Click View Dependencies. A dialog box displays the number of objects that shutting down the ISA-AA MDA may affect.
4. Click OK.
5. When you are certain that shutting down the MDA has no unintended effects, select the check box and click Yes. The NFM-P shuts down the ISA-AA MDA.
6. Right-click on the Daughter Card Slot object and choose Reboot. A dialog box appears.
7. Click View Dependencies. A dialog box displays the number of objects that rebooting the ISA-AA MDA may affect.
8. Click OK.
9. When you are certain that rebooting the MDA has no unintended effects, select the check box and click Yes. The NFM-P reboots the ISA-AA MDA.
10. After the MDA reboots, right-click on the Daughter Card Slot object and choose Turn Up. A dialog box appears.
11. Click Yes. The NFM-P turns up the ISA-AA MDA.

15

Click on the Software Upgrade Status tab to monitor the upgrade progress.

The Upgrade State column displays the current upgrade status, which is one of the following:

- Success—The new image is successfully loaded on each ISA-AA MDA.
- Failed to upgrade ISA—The upgrade is a failure on at least one ISA-AA MDA.

16

If required, use the NFM-P FTP or SSH file browser to verify that the transferred file and configuration are on each upgraded NE. See 22.5 “To view an NE file system using an FTP file browser” (p. 739) for information about using the FTP file browser, and 22.2 “To view an NE file system using an SSH file browser” (p. 736) for information about using the SSH file browser.

17

Update each ISA-AA policy, as required, to enable the new protocol signatures. See Chapter 87, “Application assurance” for information about configuring AA policies.

END OF STEPS

26.17 To monitor the status of a software upgrade

26.17.1 Steps

1

Choose Administration→NE Maintenance→Software Upgrade from the NFM-P main menu. The Software Upgrade form opens.

2

Click on the Software Upgrade Status tab.

3

Click Search. A list of NEs is displayed.

4

Select an NE and click Properties. The Software Upgrade Status (View) form opens.

5

Click on the Software Upgrade tab to view status information about the upgrade.

6

Close the forms.

END OF STEPS

26.18 To activate a device software image

26.18.1 Purpose

Perform this procedure to activate a device software image on an NE.

Note: If the BOF update fails, the original boot.ldr file is put in place to align with the BOF specification.

The NFM-P ensures that the software image is present on the NE and valid for the device before it updates the BOF.

26.18.2 Steps

1

Choose Administration→NE Maintenance→Software Upgrade from the NFM-P main menu. The Software Upgrade form opens.

2

Click on the Software Upgrade Status tab.

3

Select an NE.

4

Click on the Software Images tab. The software images on the NE are listed.

5

Select a software image and click Activate Image; a confirmation message is displayed.

6

Click Yes. The software image is activated.

When the NFM-P activates an NE software image, it does the following:

- backs up the original boot.ldr at the location specified by the CFlash Backup Root Path parameter
- synchronizes the CPMs on NEs that have redundant CPMs
- updates the BOF with the new software image location

7

Click on the Software Upgrade Status tab to monitor the activation progress. The Last Operation column displays each operation as it completes, and the Upgrade Status column displays the overall activation status.

8

Close the form.

END OF STEPS

26.19 To export a device software image from the NFM-P to a GUI client file system

26.19.1 Steps

1

Choose Administration→NE Maintenance→Software Upgrade from the NFM-P main menu. The Software Upgrade form opens.

2

Click on the Software Images tab.

3

Click on the appropriate tab for the device type, select a software image and click Export. A file browser form opens.

4

Navigate to the directory that is to contain the exported software image and click OK. The software image is saved as files in the specified directory.

5

Close the form.

END OF STEPS

26.20 To upgrade OS 6250SME and OS 6450 NE software licenses for an Ethernet (Metro) role

26.20.1 Purpose

Perform this software license upgrade to allow OS 6250SME and OS 6450 NEs to perform in the Ethernet (Metro) role and support the OmniSwitch Ethernet (Metro) features such as ERP, SAA/OAM, stacking/IPM Enterprise VLANs, Dying Gasp, Link OAM, CPE Test-Head profiles, and group profiles. This procedure is not applicable OS 6250 Ethernet (Metro) nodes.

After you upgrade the OS 6250SME and OS 6450 NEs for an Ethernet (Metro) role, perform 26.21 “To perform an OmniSwitch on-demand software upgrade or ISSU” (p. 803) to perform any future software license upgrades on these NEs.

26.20.2 OmniSwitch restrictions and prerequisites

CAUTION

Service Disruption

This procedure is service-affecting because the OS 6250SME and OS 6450 NEs will reboot.

Ensure that the license upgrade activity occurs during a maintenance window.

The following prerequisites are required before you can perform an upgrade:

- You need a new license key for each OS 6250 and OS 6450 OmniSwitch to be upgraded. Contact your Nokia sales representative if you need a new software license.
- You must copy the new license key to a text file and position the file in a folder in the node file system so the file can be imported into the NFM-P. Record the path to the folder where the license key text file is located.

26.20.3 Steps

1

Choose Administration→NE Maintenance→License Upgrade from the NFM-P main menu. The License Upgrade form opens with the License Upgrade Policy tab selected.

2

Optionally, click on the License Upgrade Status tab to confirm the software version and license policy that is currently applied to the NE being upgraded. Otherwise, go to Step 3 .

1. Select an NE and click Properties. The License Upgrade Status - [Policy Name] [Router ID] [View] form appears.
2. Confirm the software version that is installed and the license policy that is applied to the NE.
3. Click Cancel to close the form.
4. Click on the License Upgrade Policy tab.

3

Perform one of the following:

a. To create a new AOS license policy, go to Step 4 .

b. To modify the default AOS default license policy, go to Step 7 .

4

Click Create. The License Upgrade Policy [Create] form opens.

5

Configure the required parameters:

- Policy ID
- Auto-Assign ID
- Name
- Root Path

6

Click OK to save the changes and close the License Upgrade Policy [Create] form. The new AOS default license policy appears on the License Upgrade form. Go to Step 10 .

7

Select the AOS default license policy on the License Upgrade form, and click Properties. The License Upgrade Policy - AOS Default Policy [Edit] form opens.

8

As required, modify the Root Path parameter to specify the license text file location.

9

Click OK to save the changes and close the License Upgrade Policy [Edit] form. The modified AOS Default License policy appears on the License Upgrade form.

10

Click on the Licenses tab on the License Upgrade form.

11

Click Import. The Open form appears.

12

Locate the license key text file in the appropriate folder in the node file system and click Open. The license_key.txt file appears on the Licenses tab on the License Upgrade form.

13

Optionally, review the license key information before the installation by double-clicking on the license_key.txt file. The License Info form appears. Click Cancel to close the form and return to the License Upgrade form.

14

Select a license to install and click Install License. The Select Sites-Select Sites form appears.

15

Select one or more NEs to upgrade and click OK.

16

Click Yes to proceed.

17

Optionally, click on the License Upgrade Status tab on the License Upgrade form to confirm whether the upgrade on the NEs was successful. The status is displayed in the Upgrade State column.

18

Click Close to close the License Upgrade form.

END OF STEPS

26.21 To perform an OmniSwitch on-demand software upgrade or ISSU

26.21.1 Purpose

Perform this procedure to upgrade the device software on an OmniSwitch.

On-demand software upgrades are supported on all OmniSwitch variants.

Not all OmniSwitch variants support ISSU. This procedure describes how to perform an ISSU on the OS 6860, OS 6860E, OS 6860N, OS 6900, OS 9700E, OS 9800E, and OS 10K. For

information about performing an ISSU on an OS 6400, OS 6850E, or OS 6855, see 26.22 “To perform an OS 6400, OS 6850E, or OS 6855 ISSU” (p. 809) .

You can perform the following types of software upgrades:

- Image file
- Boot files
- CPLD/FPGA files (OS 6250 and OS 6450, Release 6.6.3-453R01 and later only)

26.21.2 OmniSwitch restrictions

CAUTION

Service Disruption

An OmniSwitch may require a firmware upgrade before a device software upgrade.

To avoid a service outage, ensure that the device firmware version supports the software upgrade. See the device software Release Notes for information about firmware and software version compatibility.

CAUTION

Service Disruption

Nokia recommends that you establish a physical console session on the device that you need to upgrade.

This console session will allow you to monitor the upgrade and recover the device in the event of an upgrade failure.

The following conditions must be true before you can perform a device software upgrade on an OmniSwitch:

- You have an NFM-P user account with an administrator or network element software management scope of command role or a scope of command role with write access to the mediation package.
- FTP is configured in the NE mediation policy.

The following are the OmniSwitch software upgrade restrictions and requirements.

- You can perform an ISSU on the OS 6860, OS 6860E, OS 6860N, and OS 6900, when stacked in virtual chassis mode.
- The OS 9700E, OS 9800E, and OS 10K NE platforms must be fully synchronized and certified.
- Target images must be loaded to the /flash/issu directory.
- Sufficient flash memory must be available for upgrade images.
- OS 9700E and OS 9800E NEs running an ‘R##’ build, such as 6.4.1.123.R01 do not support ISSU patches. The NE must first be upgraded to an ‘S##’ build such as 6.4.1.123.S01. This does not apply to OS 10K NE platforms.
- The directory structure that stores the image and configuration files is divided into two parts:

- The certified directory contains files that have been certified by an authorized user as the default files for the switch.
- The working directory contains files that may or may not be modified from the certified directory. The working directory is a holding place for new files. Files in the working directory must be tested before you commit them to the certified directory.

Note: To perform an ISSU, use the software upgrade window only.

The OS 6400, OS 6850E, OS 9700E, OS 9800E, and OS 10K support standard software upgrades in addition to ISSU. On an OmniSwitch, the introduction of new images requires a system reload which disrupts all data traffic during the reload process. Data traffic loss is limited to L3 base routing instance traffic; no loss of Layer 2 data traffic should occur.

26.21.3 Steps

1

Choose Administration→NE Maintenance→Software Upgrade from the NFM-P main menu. The Software Upgrade form opens.

2

Perform one of the following:

a. If you need to upgrade the image files or the image and boot files, go to Step 3 .

b. If you need to upgrade the boot files, go to Step 17 .

c. If you need to upgrade the FPGA files, go to Step 30 .

3

Select the appropriate software upgrade policy.

Note: The NFM-P performs the upgrade according to the configuration in the software upgrade policy that is assigned to the NE.

4

Click on the Software Images and AOS Software tabs.

5

Select a software image.

If you are performing an ISSU on an OS 6860, OS 6860E, OS 6860N, or OS 6900, in virtual chassis mode, the ISSU package is identified in the list on the AOS Software tab by the word “present” in the AOS Software ISSU file column. The NFM-P will not validate the ISSU software package; it assumes that the ISSU software package is valid and contains the required files and image. During an ISSU, the NFM-P upgrades the secondary shelves and automatically switches one secondary shelf to become the primary shelf, then upgrades the former primary shelf, which becomes a secondary shelf.

6

Click Transfer to Sites. A list of NEs opens. The list is filtered to display only the device type that is appropriate for the selected software image.

7

Select one or more NEs.

8

Click OK. The selected software image file is uploaded to the working directory of the selected NEs.

9

Click on the Software Upgrade Status tab to view the status of the upgrade as it progresses. Wait until the files have been successfully transferred before going to Step 10 .

10

Click Reload working Sites. A list of NEs opens.

11

Select one or more NEs.

12

CAUTION

Service Disruption

Rebooting an NE that is in service is service-affecting.

Ensure that the reboot activity occurs during a maintenance window.

Click OK. The selected NEs reboots using the new software image that was uploaded to the working directory.

Note: Nokia recommends monitoring the switch to ensure that the reboot completes successfully.

13

Click Certify Sites. A list of NEs opens.

Note: Only software that is thoroughly validated as viable and reliable software should be copied to the certified directory. After you copy the software to the certified directory, you cannot recover a previous version of the image or configuration files.

14

Select one or more NEs.

15

Click OK. The software image stored in the NE working directory is copied to the certified directory. The working directory and the certified directory are synchronized so that the same files are in both directories.

16

Perform one of the following:

a. If you need to upgrade the boot files, go to Step 24 .

b. If you need to upgrade the FPGA files, go to Step 31 .

c. If you are upgrading only the image files, go to Step 35 .

17

Select the appropriate software upgrade policy.

Note: The NFM-P performs the upgrade according to the configuration in the software upgrade policy that is assigned to the NE.

18

Click on the Software Images and AOS Software tabs.

19

Select a software image.

20

Click Transfer to Sites. A list of NEs opens. The list is filtered to display only the device type that is appropriate for the selected software image.

21

Select one or more NEs.

22

Click OK. The boot files are uploaded to the root directory of the selected NEs.

23

Click on the Software Upgrade Status tab to view the status of the upgrade as it progresses. Wait until the files have been successfully transferred before going to Step 24 .

24

Click Upgrade Boot files. A list of NEs opens. The list is filtered to display only the device type that is appropriate for the selected files.

25

Select one or more NEs.

26

Click OK. The boot files are upgraded on the selected NEs.

27

Click on the Software Upgrade Status tab to view the status of the upgrade as it progresses. Wait until the files have been successfully transferred before going to Step 28 .

28

Click Delete boot files.

29

Perform one of the following:

a. If you need to upgrade the FPGA files, go to Step 31 .

b. If you do not need to upgrade the FPGA files, go to Step 35 .

30

Click on the Software Images and AOS Software tabs.

31

Select a software image.

32

Click Upgrade FPGA files. A list of NEs opens. The list is filtered to display only the device type that is appropriate for the selected file type.

33

Select one or more NEs.

34

Click OK. The selected FPGA files are uploaded to the root directory of the selected NEs.

35

Click on the Software Upgrade Status tab to monitor the upgrade progress. The Upgrade State column displays the current upgrade status.

After the FPGA files are successfully transferred, the selected NEs are rebooted.

END OF STEPS

26.22 To perform an OS 6400, OS 6850E, or OS 6855 ISSU

26.22.1 Prerequisites

This procedure applies to the following OmniSwitch NEs, in stacked configuration:

- OS 6400, Release 6.4.5 R02 or later
- OS 6850E, Release 6.4.5 R02 or later
- OS 6855, Release 6.4.5 R02 or later

ISSU cannot be used to upgrade from one major release to another.

26.22.2 Steps

1

In the navigation tree equipment view, expand the icon of the OmniSwitch to upgrade, right-click on an OmniSwitch shelf object in the equipment view, and click Properties. The Shelf (Edit) form opens.

2

Click on the Software Control Module tab.

3

Click Resynch and click Yes to clear the dialog box.

4

Ensure that one of the following is true:

- The Certify Status is Need Certify and the Synchronization Status is Not Synchronized.
- The Certify Status is Certified and the Synchronization Status is Synchronized.

5

Click OK to apply the changes. A dialog box appears. Click Yes. The Shelf (Edit) form closes.

6

Choose Administration→NE Maintenance→Software Upgrade from the NFM-P main menu. The Software Upgrade form opens.

7

Select the ISSU software upgrade policy for an AOS Based Node.

Note: For stacked NEs, the ISSU directory should be created automatically under /flash/issu. If the ISSU directory does not exist, it can be created by setting the File Transfer Type parameter to Secure on the NE being upgraded. See 9.17 “To configure device mediation” (p. 301) for information.

8

Click on the Software Images and AOS Software tabs.

9

Select a software image.

Note: ISSU software images should not contain Kencrypt image files. If the ISSU software image contains a Kencrypt image file, it will transfer the image to the working directory and perform an on-demand software upgrade.
For OS 6400, ISSU software images should not contain Gdiag image files. If the ISSU software image contains a Gdiag image file, it will transfer the image to the working directory and perform an on-demand software upgrade.

10

Click Transfer to Sites. A list of NEs opens. The list is filtered to display only the device type that is appropriate for the selected software image.

11

Select one or more NEs.

12

Click OK in the dialog boxes that appear and click Yes. The boot files are uploaded to the root directory of the selected NEs.

13

Click on the Software Upgrade Status tab to view the status of the upgrade as it progresses. Once the files have been successfully transferred, continue to Step 14 .

14

Click on the Software Images tab.

15

Click Certify Sites. A list of NEs opens.

Note: Only software that is thoroughly validated as viable and reliable software should be copied to the certified directory. After you copy the software to the certified directory, you cannot recover a previous version of the image or configuration files.

16

Select one or more NEs.

17

Click OK. A dialog box appears.

18

Click Yes. The software image stored in the NE working directory is copied to the certified directory. The working directory and the certified directory are synchronized so that the same files are in both directories.

19

Click on the Software Upgrade Status tab to view the status of the upgrade as it progresses. Once the sites have been successfully certified, continue to Step 20 .

Note: After the desired sites have been certified, the Command to Apply parameter should be set to Flash Synchro on each affected shelf; see 15.41 “To manage an OmniSwitch running configuration” (p. 505) for configuration information.

20

Click on the Software Images tab.

21

Click Reload Sites. A list of NEs opens.

22

Select one or more NEs and click OK. A dialog box appears.

23

CAUTION

Service Disruption

Rebooting an NE that is in service is service-affecting.

Ensure that the reboot occurs only during a scheduled maintenance period.

Click Yes. The selected NEs reboot using the new software image that was uploaded to the working directory.

24

Click on the Software Upgrade Status tab to view the upgrade status.

END OF STEPS

26.23 To certify or synchronize OmniSwitch software

26.23.1 Steps

1

Choose Administration→NE Maintenance→OMNI Software Maintenance from the NFM-P main menu. The OMNI Software Maintenance form opens.

2

Select one or more NEs and perform one of the following:

a. Click Certify. Go to Step 5 .

b. Click Certify and Synchronize. Go to Step 5 .

c. Click Flash Synchronization. Go to Step 5 .

d. Click Properties. The Software Control Module (Edit) form opens.

3

Configure the Command to Apply parameter.

4

If the Command to Apply parameter is set to Reload, configure the Delayed Activation Timer parameter.

5

Save your changes and close the forms.

END OF STEPS

26.24 To perform an 1830 VWM on-demand software upgrade

26.24.1 Before you begin

Configure a software upgrade policy or use the default “VWM OSU Default Policy”.

See 26.5 “To configure a software upgrade policy” (p. 776) for more information about configuring a software upgrade policy.

26.24.2 Steps

1

Choose Administration→NE Maintenance→Software Upgrade from the NFM-P main menu. The Software Upgrade form opens.

2

Click on the Software Images tab and then on the 1830 VWM OSU Software Images tab.

3

Note: NFM-P requires only CATALOG and osu.isd files to be present in the specified folder to import the image. Copy the CATALOG and osu.isd files to a separate folder or remove all other files from the folder before you begin with import operation.

Perform one of the following:

a. Import image files from the NFM-P main server file system:

1. Click Import. The Select Import VWM Software form opens.
2. Select a software image and click OK. The NFM-P saves the image in a directory below /opt/nsp/nfmp/nesoftware/SAM/VWMOSU/.

   When the import is complete, an entry for the image file appears in the list.

b. Import 1830 VWM software from a remote location.

Note: The remote system address is the server IP address that is configured in the software upgrade policy. See Step 7 of the 26.5 “To configure a software upgrade policy” (p. 776) for more information.

1. Click Remote Path. A Remote Path notification box appears.
2. Click Yes. The Software Directory Path form opens.
3. Enter the remote software path, which is an absolute path in the following format:

   /directory/device-software_version

   For example:

   /root/Desktop/1830VWMOSU-8.5-0

When the remote path import is complete, an entry for the image file is listed on the form.

4

Choose an appropriate 1830 VWM software image and click Audit. The Confirm Audit Settings dialog box opens.

5

Configure the Audit Settings parameter, choose an 1830 VWM device and click OK.

6

Click Load and choose the 1830 VWM device.

7

Click Activate and choose the 1830 VWM device.

8

Click Revert and choose an 1830 VWM device to revert to a previously committed software release, if required.

9

Click Commit and choose the 1830 VWM device.

10

Save your changes and close the forms.

END OF STEPS

Part IV: Network management

Overview

Purpose

This part provides information about network management using the NFM-P.

Contents

27 NE routing and forwarding

27.1 NE routing and forwarding

27.1.1 NE routing and forwarding objects

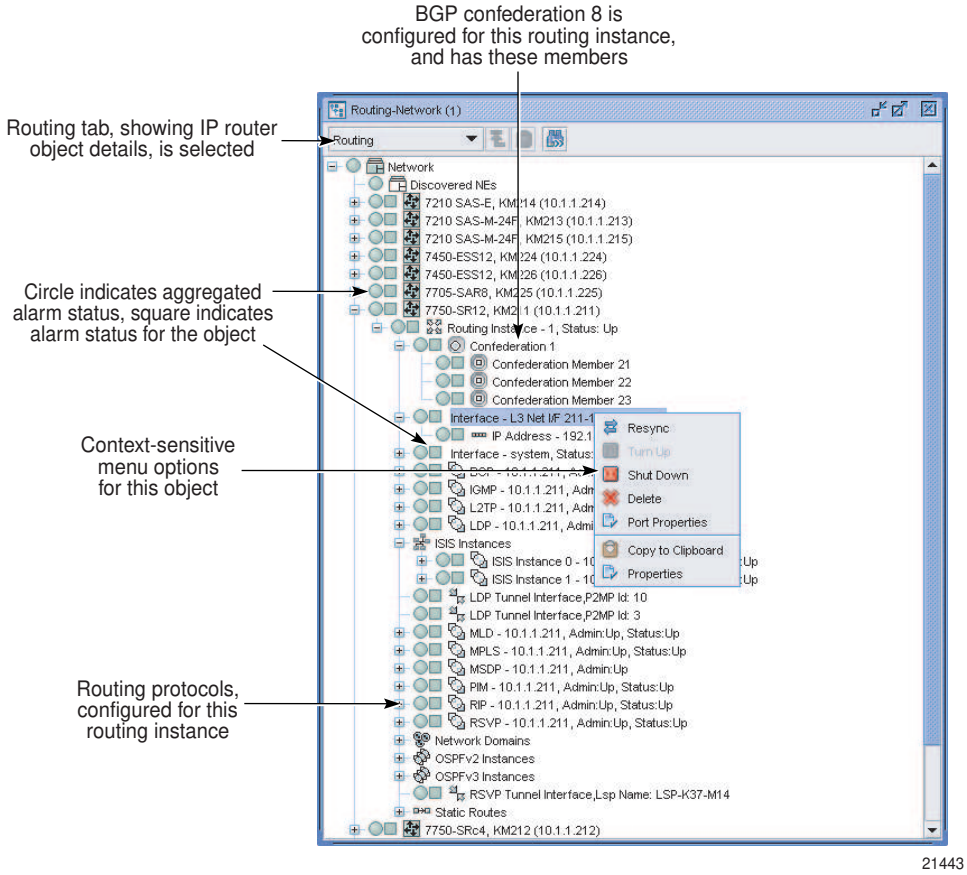
You can configure and manage the following routing and forwarding objects on managed NEs using the NFM-P navigation tree routing view:

- routing instances
- VRF instances
- web portal routing instances
- IS-IS instances
- OSPFv2 and OSPFv3 instances
- static routes
- L3 interfaces
- network domains

You can also configure the routing protocols assigned to routing and forwarding objects such as BGP, L2TP, MPLS, and LDP. The supported protocols are device-dependent and are displayed in the navigation tree routing view as child objects of the routing instance. See Chapter 28, “Routing protocol configuration” for more information about configuring routing protocols.

The following figure shows an example of the various routing objects that can be displayed in the routing view of the navigation tree.

Figure 27-1 Routing and forwarding objects



27.1.2 Routing instances

Routing instances are virtual routers. A routing instance in routing navigation tree is a representation of all of the characteristics/objects assigned to the router such as the interfaces, protocols, static routes, network domains, and other instance types (IS-IS, OSPF) being managed by the NFM-P. The supported objects are displayed in the navigation tree as child objects of the routing instance.

Routing instances contain their own dedicated interfaces and routing tables that are used to deploy multiple logical devices in one physical chassis.

27.1.3 DHCP relay and snooping on OmniSwitch routing instances

A DHCP relay agent is a BOOTP relay agent that relays DHCP messages between DHCP clients and DHCP servers on different IP networks. The Omniswitch supports global or per-VLAN BOOTP/DHCP relay service and per-VLAN UDP port relay services.

DHCP Option 82 and DHCP snooping provide security for a DHCP relay service. The DHCP Option 82 switch-level feature allows the relay agent to insert identifying information into client-originated DHCP packets before the packets are forwarded to the DHCP server. DHCP Snooping, at the switch or VLAN level, improves network security by filtering DHCP messages received from devices outside the network and building and maintaining a binding table to track access information for each device. DHCP relay Option 82 and snooping cannot be run on the switch at the same time.

DHCP relay and snooping is configured at the default routing instance level, see 27.12 “To configure UDP relay, DHCP snooping, and DHCP Option 82 on OmniSwitch routing instances” (p. 850) . In addition, per-VLAN DHCP snooping can be enabled on a VLAN site. See 75.7 “To create a standard VLAN service on OmniSwitch devices” (p. 2075) , 75.8 “To create an OmniSwitch L2 VPN TLS VLAN service” (p. 2076) , and 75.9 “To create an OmniSwitch BTV VLAN service” (p. 2078) for more information.

It is necessary to configure ports connected to DHCP servers within the network and/or firewall as trusted ports so that necessary DHCP traffic to/from the server is not blocked. Configuring the port mode as trusted also identifies the device connected to that port as a trusted device within the network. See 16.56 “To configure OmniSwitch Ethernet ports” (p. 647) for more information.

27.1.4 Web portal routing instances

You can use a web port routing instance to configure the WPP protocol running between a BRAS/BNG and a Web portal server. WPP is used for web portal authentication of WLAN users (DHCP Host). A web portal routing instances can be configured on a base routing instance or a VPRN routing instance. See 28.19 “WPP” (p. 907) in Chapter 28, “Routing protocol configuration” for more information.

27.1.5 VRF instances

Virtual routing and forwarding (VRF) allows multiple instances of a routing table to co-exist within the same router at the same time. This increases functionality by allowing network paths to be segmented without using multiple devices. Because traffic is automatically segregated, VRF also increases network security and can eliminate the need for encryption and authentication. Because the routing instances are independent, the same or overlapping IP addresses can be used without conflicting with each other.

27.1.6 IS-IS and OSPF instances

You can use IS-IS and OSPF non-forwarding instances to separate a very large network into smaller administrative entities. Instead of configuring a large number of filters, non-forwarding instances can be used to filter routes, thereby instantiating policies. Non-forwarding instances can be used to reduce the amount of routing information advertised throughout all components of a network. Routing information associated with a particular instance can be announced where required, instead of being advertised to the whole network.

27.1.7 Static routes

Static routing uses a manually-configured routing entry, rather than information from a dynamic routing protocol to forward traffic and never change unless you explicitly update them. Additionally, all traffic destined for a static address is routed through the same router and are automatically imported into the routing table when a router comes online.

Static routing is useful for networks with customers whose traffic must always flow through the same routers. Static routing avoids the bandwidth cost and route import latency of dynamic routing.

27.1.8 L3 network interfaces

An L3 network interface is a logical IP object that is defined on a physical port, such as an Ethernet port. An L3 interface:

- associates an IP address and subnet mask with a physical port or channel
- has a physical port or channel cabled to another device
- requires QoS policy configuration
- requires routing protocol configuration

The physical connection of one device to another device is through a port or channel. However, the L3 network interface determines its IP connectivity. The L3 network interface passes both routing information and IP traffic.

You can configure the following L3 network interface types on routing instances with the NFM-P:

- ICMP interface
- system interface
- management interface
- IGMP interface
- PIM interface
- MLD interface
- RSVP tunnel interface
- LDP tunnel interface
- multi-homing interface
- IS-IS interface

27.1.9 DoS protection on L3 network interfaces

In a subscriber aggregation network, an NE typically receives few control-plane packets from a specific subscriber. If one or more subscribers generate excessive control-plane traffic, DoS protection policies can help to ensure that NEs do not become overburdened by these unwanted packets. Global DoS protection controls the arrival rate for unprovisioned link-layer protocol packets from CE devices.

You can use the NFM-P to create DoS protection policies and apply them to L3 network interfaces. A DoS protection policy limits the number of control-plane protocol packets that are received each second from a subscriber host, and optionally logs a violation notification if a policy limit is exceeded. The interface drops the excessive packets before they are queued or processed by the NE. You can use the NE System Security form to view the violations for a specific NE.

You can apply DoS protection policies to control the following on L3 network interfaces:

- the control-plane packet arrival rate per subscriber host
- the overall control-plane packet arrival rate for the interface
- whether an NE sends a notification trap if a policy limit is exceeded

An NE that supports DoS protection automatically assigns a default DoS protection policy to each L3 network interface. The default policy limits only the overall packet arrival rate for the interface, and cannot be deleted or modified.

You can also apply DoS protection policies to certain L2 and L3 access interfaces. See the appropriate service chapter for information about applying DoS protection policies to access interfaces.

You can configure a global NE DoS protection policy and distribute it to NEs by choosing Administration→Security→NE DoS Protection from the NFM-P main menu. See the procedure to configure an NE DoS protection policy in the *NSP System Administrator Guide* for more information about configuring and applying NE DoS protection policies.

27.1.10 DDoS protection on network and access interfaces

You can configure a global NE DDoS protection policy and distribute it to NEs by choosing Administration→Security→NE DDoS Protection from the NFM-P main menu. You can configure a DDoS protection policy on an L2 and L3 network interface. See the procedure to configure an NE DDoS protection policy in the *NSP System Administrator Guide* for information about configuring a DDoS protection policy.

You can also apply DDoS protection policies to certain L2 and L3 access interfaces and SAPs. See the appropriate service chapter for information about applying DDoS protection policies to access interfaces.

27.1.11 System interfaces

The system interface is associated with a network entity, such as a specific device, not a specific interface.The system interface is also referred to as the loopback interface.

The system interface is used to preserve connectivity when an interface fails or is removed. A system interface must have an IP address and a 32-bit subnet mask. The system interface is used as the device identifier by higher-level protocols such as OSPF and BGP. The system interface is associated during the configuration of the following entities:

- the termination point of service tunnels
- the hops when configuring MPLS paths and LSPs
- the addresses on a target device for BGP and LDP peering

27.1.12 NE routing policies

Policy-based routing (PBR) gives you a flexible means of routing packets over devices using the NFM-P by allowing you to configure a defined policy that override default routing protocol decisions on the router for traffic flows, and lessening reliance on routes derived from routing protocols. PBR gives you more control over routing by extending and complementing the existing mechanisms provided by routing protocols. PBR allows you to set the IP precedence. It also allows you to specify a path for certain traffic, such as priority traffic over a high-cost link.

You can set up PBR as a way to route packets based on configured policies. For example, you can implement routing policies to allow or deny paths based on the identity of a particular end system, an application protocol, or the size of packets.

There are no default routing policies on the NFM-P. Each policy must be created and applied to a routing object, a routing protocol, or the forwarding table. Each set of rules that is associated with controlling routes are called routing policy statement entries on the client GUI. See Chapter 54, “Routing policies” for more information on routing policies.

27.1.13 Self-generated traffic and QoS

The NFM-P supports QoS configuration for self-generated traffic (SGT) on routing instances and VPRN sites. NEs produce SGT for various applications, such as Telnet, SNMP, SSH, and others. For each application, you can configure the DSCP or dot1p value for the traffic generated by that application. You can also map DSCP values to forwarding classes. See 27.15 “To configure QoS for self-generated traffic on a routing instance” (p. 854) and 79.13 “To configure QoS for self-generated traffic on a VPRN site” (p. 2546).

27.1.14 Network domains

You can use the navigation tree Routing view to configure and manage network domains and to associate network interfaces or service tunnels with the network domain. For supported devices, there is a default Network Domain that is assigned to the associate Routing Instance. The default network domain cannot be deleted but the properties associated with it can be changed.

By default, all network interfaces in a routing instance belong to the default network domain. You can associate an interface to any user defined network domain. The loopback and system interfaces cannot be associated with user defined network domains.

Network domains help determine which network ports are eligible to transport traffic of individual SDPs. This information is used for the SAP-ingress queue allocation which is applied to VPLS SAPs. No SAP-ingress queues are allocated if a given port does not belong to the network domain used in a VPLS.

Note: A maximum of four network domains are supported in any VPLS.

If an SDP is used for E-PIPE, I-PIPE or A-PIPE bindings, the network domain configuration is not considered.

Network domains are not applicable to loopback and system interfaces.

An SDP can be assigned to only one network domain. If no user defined network domain is created, an SDP will be assigned to the default network domain. All SAPs in VPLS will have a queue reaching all fwd complexes serving interfaces belonging to the same network domains as the SDPs. You can assign or remove a network domain association of the interface or SDP without deleting the respective object.

27.1.15 TCP MSS adjustment for PPPoE sessions

The NFM-P supports ISA-based TCP MSS adjustment for PPPoE sessions. The functionality allows a BNG to adjust TCP MSS values, preventing PPP clients from sending large packets which could be dropped in an access network.

In the NFM-P, TCP SYN-flagged packets are matched by an IP filter policy configured with a filter action of TCP MSS Adjust, and forwarded through an internal LAG SAP to an ISA-BB provisioned on the routing instance. Base and VPRN routing instances are associated with an ISA-BB through an ISA NAT group containing multiple ISA-BBs. The ISA-BB adjusts the TCP MSS value if:

- the MSS option is not present, in which case MSS field is inserted into the packet with the MSS value configured on the routing instance.
- the MSS value is larger than the value configured on the routing instance, in which case the packet MSS value is changed to the configured value.

27.1.16 Workflow to configure TCP MSS adjustment

1

Configure an ISA NAT group to be used for MSS adjustment; see 30.3 “To configure an ISA-NAT group” (p. 1080).

2

Associate the ISA-NAT group with a base routing instance or VPRN routing instance and configure the MSS value on the routing instance; see 27.2 “To configure a routing instance or a VRF instance” (p. 826) or 79.36 “To configure TCP MSS adjustment on a VPRN site” (p. 2586).

3

Create an IPv4 or IPv6 filter policy with a filter action of TCP MSS Adjust to match TCP packets requiring MSS adjustment; see 51.5 “To configure an ACL IP filter policy” (p. 1671) or 51.6 “To configure an ACL IPv6 filter policy” (p. 1677).

4

Apply the IPv4 or IPv6 filter policy to an SLA profile or L3 network interface; see 64.5 “To configure an SLA profile” (p. 1845) or 27.18 “To configure L3 network interfaces” (p. 863).

27.1.17 Workflow to configure NE routing and forwarding

1

Configure a base routing instance or VRF instance on a device; see 27.2 “To configure a routing instance or a VRF instance” (p. 826) .

2

Enable the routing protocols to be supported on the device or routing instance. The supported protocols are device dependent. See the “Routing protocol configuration workflow and procedures” (p. 909) in Chapter 28, “Routing protocol configuration” for more information about configuring routing protocols.

3

Perform the following actions on the base routing instances as required:

- configure a local DHCPv4 or DHCPv6 server; see 27.5 “To configure a local DHCPv4 server on a routing instance” (p. 839) or 27.6 “To configure a local DHCPv6 server on a routing instance” (p. 842).
- perform a Force Partner Down action on a local DHCP server failover; see 27.7 “To perform a Force Partner Down action on a local DHCP server failover” (p. 845).
- configure a RADIUS server; see 27.8 “To configure a RADIUS server on a routing instance” (p. 846).
- configure a RADIUS proxy server; see 27.9 “To configure a RADIUS proxy server on a routing instance” (p. 847).

- configure UDP relay/DHCP snooping on an OmniSwitch; see 27.12 “To configure UDP relay, DHCP snooping, and DHCP Option 82 on OmniSwitch routing instances” (p. 850).
- configure static routes; see 27.13 “To configure a static route on a routing instance” (p. 852).
- configure QoS for self-generated traffic; see 27.15 “To configure QoS for self-generated traffic on a routing instance” (p. 854).
- configure LSP entries with indirect static routes; see 27.16 “To configure LSP entries with indirect static routes” (p. 855).
- configure a BGP confederation; see 28.30 “To configure a BGP confederation” (p. 916) .
- configure an LDP peer or LDP targeted peer; see 28.54 “To configure an LDP peer” (p. 946) or 28.53 “To configure an LDP targeted peer” (p. 945) .
- configure ECMP for LDP routing; see 28.55 “To configure ECMP for LDP routing” (p. 948) .
- configure an IS-IS link group, or an IS-IS NET address; see 28.60 “To configure IS-IS on a routing instance” (p. 953) or 28.61 “To configure an IS-IS link group on a routing instance” (p. 956) .
- configure Web Portal routing instances; see 28.134 “To create a web portal routing instance” (p. 1051) .
- configure NAT; see 30.9 “To configure NAT on a routing instance” (p. 1086) .

4

Configure L3 network interfaces as required:

a. For the following L3 network interfaces; see 27.17 “To create an L3 network interface on a routing instance” (p. 856) and 27.18 “To configure L3 network interfaces” (p. 863) .

- ICMP interface
- system interface
- management interface
- IGMP interface
- control tunnel
- PIM interface
- MLD interface

Perform the following steps:

1. Associate a network port with the L3 interface.
2. Enable the multicast routing protocols on the interfaces as required. See Chapter 28, “Routing protocol configuration” for more information about multicast configuration and parameters.
3. Enable bridging on the interfaces as required. The NFM-P supports bridging on OmniSwitch devices. See Chapter 28, “Routing protocol configuration” for more information about bridging.
4. Assign a DoS protection policy to the interface, as required; see 27.18 “To configure L3 network interfaces” (p. 863) .
5. If you enabled OSPF on the device, add a L3 network interface or create an OSPF area range as required; see 28.69 “To add a Layer 3 interface to an OSPF router” (p. 965) or 28.70 “To create an OSPF area range” (p. 967) .

6. Assign an IES or network interface to a virtual router as a VRRP instance. See Chapter 37, “VRRP” for more information about VRRP configuration and parameters.

b. RSVP tunnel interfaces; see 27.2 “To configure a routing instance or a VRF instance” (p. 826)

c. Multi-homing interfaces; see 27.2 “To configure a routing instance or a VRF instance” (p. 826)

d. LDP tunnel interfaces; see 28.52 “To configure an LDP interface” (p. 944) .

e. IS-IS interfaces; see 28.63 “To configure an IS-IS interface” (p. 958) .

f. PIM interfaces; see 28.101 “To create a PIM interface on a base routing instance or VPRN routing instance” (p. 1013) .

g. IGMP interfaces; see 28.106 “To configure an IGMP interface” (p. 1019) .

h. MLD interfaces; see 28.123 “To configure an MLD interface on a base routing instance or VPRN routing instance” (p. 1035) .

5

Configure CPM virtual routing instances as required:

- Configure a CPM virtual routing instance; see 27.3 “To configure a CPM virtual routing instance ” (p. 837).
- Configure network interfaces on the CPM virtual routing instance as required; see 27.19 “To create a network interface on a CPM virtual routing instance” (p. 865) and 27.20 “To configure network interfaces on a CPM virtual routing instance” (p. 866).
- Configure static routes on the CPM virtual routing instance as required; see 27.13 “To configure a static route on a routing instance” (p. 852)

6

Cable the network ports on the devices to the network ports on other devices.

7

Configure the appropriate routing policies as required; see Chapter 54, “Routing policies” .

8

Create a network domain as required; see 27.21 “To create a network domain” (p. 867) .

a. Associate a network interface or service tunnel with a network domain; see 27.22 “To associate a network interface or service tunnel with a network domain” (p. 868) .

b. Delete a network interface or remove a service tunnel from a network domain; see 27.23 “To remove a network interface or service tunnel from a network domain” (p. 869)

9

View or list the following NE routing and forwarding related objects, as required:

- routing instances and child objects; see 27.24 “To list and view routing instances and child objects” (p. 869) .
- DHCP leases or prefixes assigned to routing instances; see 27.25 “To view and clear DHCP leases or prefixes assigned to a routing instance” (p. 870) .
- DHCPv6 log events; see 27.26 “To view DHCPv6 log events” (p. 872) .
- MVPN Extranet objects for a NE; see 27.28 “To list MVPN Extranet objects for a NE” (p. 873) .
- IOM/IMM label, next hop, and outgoing interface information for BGP, LDP and RSVP tunnels; see 27.29 “To display show router fp-tunnel information for a routing instance” (p. 874) .
- LDP session information; see 28.56 “To view the LDP session information” (p. 949) .
- LSN subscriber host statistics data; see 30.16 “To plot LSN subscriber host statistics” (p. 1097) .
- policy variable usage in a routing policy statement; see 54.20 “To view policy variable usage in a routing policy statement” (p. 1766) .
- routing policy usage; see 54.21 “To view routing policy usage” (p. 1767) .
- routing policies from a CLI session; see 54.22 “To show a routing policy CLI configuration in the client GUI” (p. 1768) .

27.2 To configure a routing instance or a VRF instance

27.2.1 Purpose

This procedure describes the base configuration of a routing instance or VRF instance.

Note: The functionalities described in this procedure are device-dependent. Not all functionalities described in this procedure are supported by all devices.

27.2.2 Steps

1

In the navigation tree routing view, expand Network→*NE*→Routing Instance.

2

Perform one of the following:

a. If you are configuring a VRF instance on the following OmniSwitch NEs, go to Step 3 .

- OS 6850E
- OS 6855-U24X
- OS 6860
- OS 6860E
- OS 6860N
- OS 6865
- OS 6900
- OS 9700E
- OS 9800E
- OS 10K

Note: SNMPv3 must be used to manage supported OmniSwitch devices when configuring a VRF routing instance.

b. If you are configuring a routing instance on all other devices, go to Step 5 .

3

Right-click on an OmniSwitch routing instance icon and choose Create VRF Instance. The Routing Instance (Create) form opens.

4

Configure the VRF Name parameter and click Apply. The Routing Instance (Edit) form opens. Go to Step 6 .

5

Right-click on a routing instance icon and choose Properties. The Routing Instance (Edit) form opens.

6

Edit or view the base routing policies associated with the routing instance if required:

Perform the following steps:

1. Click Edit Routing Policies. The Routing Policy Manager - Site (Edit) form opens.
2. Configure the parameters if required.
3. Click Show Policy. A Routing Policy Show Policy form opens and a CLI session is initiated.

   The Show Policy button only displays if a routing policy has been distributed to the device.
4. View the policy as required.
5. Close the form. The Routing Policy Manager - Site (Edit) form reappears.
6. Click OK if required or close the form. The Routing Instance (Edit) form reappears.

7

Configure the parameters on the General tab as required.

1. Select a reassembly group, if required.
2. If the routing instance is part of a TCP MSS adjustment configuration, select an ISA-BB group and configure the Segment Size parameter.
3. If the routing instance is part of a home LAN extension configuration, place a check mark in the Enable Home LAN Extension check box.

4. If the routing instance is part of an ISA service chaining configuration, place a check mark in the Enable ISA Service Chaining check box.

8

If GRT route leaking is required for VPRN, configure the parameters on the Leak Export Policies tab.

9

Click on the Protocols tab or Multicast tab to modify the default routing or multicast protocols assigned to the routing instance.

1. Configure the parameters as required. See Chapter 28, “Routing protocol configuration” for more information about routing protocol configuration using the GUI.
2. Click Apply to save the changes.

10

Click on the OAM tab and perform the following as required:

a. Assign a test generation option to the routing instance by configuring the Test Generation Options parameters on the Configuration tab as required.

b. Configure a TWAMP Light Reflector on the routing instance:

Note: A TWAMP Light reflector is required to conduct a TWAMP Light Test Session. See 92.11 “To configure a TWAMP Light reflector” (p. 3153) for more information about TWAMP Light reflectors.
The 7705 SAR does not initiate TWAMP Light Test sessions, but only acts as a TWAMP Light Reflector. The 7705 SAR does not support PM sessions.
The 7705 SAR-Hm supports TWAMP Light Test sessions and PM sessions.

Perform the following steps:

1. Click the TWAMP Light Reflector tab and click Create or select an existing TWAMP Light Reflector and click Properties.The TWAMP Light Reflector (Create|Edit) form opens.
2. Configure the parameters on the General tab as required.
3. Click Create in the Reflector Prefixes panel. The Prefix TWAMP Light Reflector (New Instance) form opens.
4. Configure the parameters as required and click OK. The TWAMP Light Reflector (Create) form reappears.

   Prefixes are added to the reflector to determine which PM Sessions can target the reflector. You should specify the prefix address and length if you require masking. Only those TWAMP Light test sessions with a Source IP matching a prefix will be valid. A maximum of 50 prefixes can be added to a reflector. TWAMP Light sessions without a matching prefix will cause an alarm to be generated.
5. Close the form. The Routing Instance (Edit) form reappears.

c. Add a TWAMP Light Session to the routing instance:

Perform the following steps:

1. Click on the TWAMP Light Sessions tab and click Add.The TWAMP Light Session (Create) form opens.
2. Perform 92.12 “To configure a TWAMP Light session OAM diagnostic test from the STM” (p. 3154) to complete the configuration of the TWAMP-Light Session.

d. Add a PM Session to the routing instance:

Perform the following steps:

1. Click on the PM Sessions tab and click Add. The PM Session, New Create form opens.
2. Perform 92.6 “To configure a PM session OAM diagnostic test from the STM” (p. 3146) to complete the configuration of the PM Session.

11

Click on the Routing tab and perform the following as required:

Perform the following steps:

1. Configure the required general parameters.

   For 7210 SAS NEs, the value for the Maximum Number of Equal Cost Routes parameter cannot be greater than the value of the Max ECMP Route Destinations (Active) parameter in the system resource profile. See 12.50 “To configure the global system resource profile on a 7210 SAS or 7250 IXR” (p. 380) .

   For 7250 IXR NEs, you must configure the system resource profile appropriately. Create ECMP Profiles to provide both an LDP and an IP profile type; see 12.50 “To configure the global system resource profile on a 7210 SAS or 7250 IXR” (p. 380).

   See Chapter 28, “Routing protocol configuration” for more information about AS and confederation AS parameters for BGP using the GUI.
2. Configure the Enable Entropy Label parameter, as required.
3. Configure the required parameters in the LDP Shortcut Enabled panel.
4. Configure the required parameters in the Maximum Number of Multicast Routes panel.
5. Assign an ingress multicast information policy to the routing instance in the Multicast Path Management Info Policy panel.

   See 52.13 “To configure an ingress multicast information policy” (p. 1720) for information about how to configure an ingress multicast information policy. See Step 37 in this procedure to view the data from the operational channels after actual traffic passes through the virtual router/routing instance from a specific multicast source for a specific multicast group.
6. Configure the required parameters in the TTL Propagate panel.
7. Configure the required parameters in the LSP BFD panel.
8. Configure the Single SFM Overload Admin State parameter in the Single SFM Overload panel.
9. Configure the parameters in the Static Route Hold-Down Time panel.

The Initial Hold-Down Time, Hold-Down Time Multiplier, and Maximum Hold-Down Time parameters are configurable when you enable the Enable Hold-Down Time parameter.

10. Configure the IPv4 Max Size and IPv6 Max Size parameters in the Flowspec panel, as required.

12

Click on the WLAN GW tab as required to view or configure WLAN gateway functionality on 7750 SR devices routing instances.

Note: Prior to completing this step, verify that the WLAN GW parameter on the General tab on the Routing Instance (Create|Edit) form is enabled.

Perform the following steps:

1. Configure the parameters on the General tab as required.

   The Interim Update parameter must be enabled if the Include Counters and Hold Down Time parameters are to be configured.

2. Click on the Mobile GW Address Map tab and click Create or select an existing mobile gateway address map. The Mobile Gateway Address Map (Create|Edit) form opens.
3. Configure the parameters as required.
4. Click on the Select button to specify a mobile gateway/peer profile policy.
5. Click Create or choose an existing mobile gateway/peer profile and click Properties. The Mobile Gateway/Peer Profile (Create|Edit) form opens. See 64.20 “To configure a mobile gateway/peer profile” (p. 1862) for information about how to create a Mobile Gateway/Peer Profile. See Step 26 in this procedure to view WLAN GW Tunnel information from the operational channels after actual traffic passes through the routing instance.
6. If the WLAN GW is intended for a home LAN extension configuration, click on the Cross Connect tab.

   Configure the required parameters and select a WLAN GW group.

7. Save your changes and close the form. The Routing Instance (Edit) form reappears.

13

To configure home LAN extension functionality on the routing instance, click on the Home LAN Extension tab.

Select an ISA WLAN GW group and configure the other parameters.

14

To configure home ISA service chaining functionality on the routing instance, click on the ISA Service Chaining tab.

1. On the ISA Groups tab click Create or choose an existing ISA group and click Properties. The Service Chaining ISA Group (Create|Edit) form opens.
2. Select an ISA-NAT or ISA-WLAN GW group and click OK to close the form.
3. Click on the VTEP tab and configure the VXLAN VTEP Range, Start and End parameters.

15

Click on the Interfaces tab if required, to view or configure L3 interfaces assigned to the routing instance. See 27.17 “To create an L3 network interface on a routing instance” (p. 856) to complete the configuration of L3 interface.

16

Click on the Address tab if required, to configure an IP address for the L3 interfaces.

Perform the following steps:

1. Choose an address in the list and click Click Properties. The IP Address form opens.
2. Configure the parameters as required.
3. Save your changes and close the form. The Routing Instance form reappears.

   Note:

   The IP Address, Prefix Length, and Broadcast Address Format cannot be changed for the System interface.

17

Click on the Static Routes tab if required, to view or configure static routes assigned to the routing instance. See 27.13 “To configure a static route on a routing instance” (p. 852) to complete the configuration of the static route.

18

Click on the Static Route Prefixes tab if required, to view or configure static route prefixes.

Perform the following steps:

1. Click Create. The Static Route Prefix form opens.
2. Configure the parameters.

   Routing instances that support BGP large communities can configure up to 12 communities in a static route prefix.
3. Save your changes and close the form. The Routing Instance form reappears.

19

Click on the NAT tab if required, to view or configure NAT configurations assigned to the routing instance. See 30.9 “To configure NAT on a routing instance” (p. 1086) to complete the NAT configuration.

20

Click on the RSVP Tunnel Interfaces tab if required, to view or configure tunnel interface entries assigned to the routing instance.

Perform the following steps:

1. Click Create to configure a new entry or select an existing RSVP Interface and click Properties. The RSVP Tunnel Interface (Create|Edit) form opens.

Note:

You can alternatively create a RSVP tunnel interface by right-clicking on a routing instance icon in the navigation tree routing view, and choose Create RSVP Tunnel Interface from the menu.

2. Click Select to choose a Point-to-Multipoint LSP. The Select - RSVP Tunnel Interface form opens. See 31.18 “To create a Point-to-Multipoint LSP” (p. 1137) for information about how to configure a Point-to-Multipoint LSP.
3. Choose an RSVP tunnel interface and click OK. The RSVP Tunnel Interface (Create) form reappears.
4. Configure all other parameters as required.
5. Save your changes and close the form. The Routing Instance form reappears.

21

Click on the LDP Tunnel Interfaces tab if required, to view or configure LDP Tunnel Interfaces assigned to the routing instance. Perform the following as required:

a. Configure a new interface.

Perform the following steps:

1. Click Create or select an existing LDP tunnel interface and click Properties. The LDP Tunnel Interface (Create|Edit) form opens.

   Note:

   You can alternatively create a LDP tunnel interface by right-clicking on a routing instance icon in the navigation tree routing view, and choose Create LDP Tunnel Interface from the menu.

   LDP tunnel interfaces can be created using the system address or any local interface address on the root node.

   An LDP tunnel can be created on intermediate nodes (that is, between direct and indirect nodes).

2. Configure the parameters as required.

   Note:

   When the Root Node parameter is enabled, the LDP tunnel interface you are creating is associated with a root node, and you must specify a unique P2MP ID and Sender Address.

   When the Root Node parameter is not enabled, the LDP tunnel interface you are creating is associated with a leaf node, and you must specify the same P2MP ID and Sender Address as the root node.

   The 7450 ESS only supports LDP tunnel interfaces in Mixed Mode.

   You must enable the OAM Test Root Node parameter to add an interface to an OAM test suite or to create a P2MP LSP Ping test.

3. Click Apply. The LDP Tunnel Interface (Create) form is refreshed.
4. Save and close the form or proceed to the next sub-step if required.

b. Add the interface to an OAM test suite if required.

Perform the following steps:

1. Click on the OAM tab and click Add on the Test Suite tab to assign the interface to an OAM test suite. The Select Test Suite form opens.
2. Click Search and choose the appropriate test suite. See 89.12 “To create an STM test suite” (p. 2951) for information about how to configure an OAM test suite.
3. Save the form or proceed to the next sub-step if required.

c. Create a P2MP LSP Ping test if required.

Perform the following steps:

1. Click on the P2MP LSP Ping tab and click Create or select an existing P2MP LSP Ping test and click Properties. The P2MP LSP Ping form is displayed. See 90.28 “To create and run a MPLS P2MP LSP ping OAM diagnostic test from the STM” (p. 3033) to complete the P2MP LSP Ping test configuration.
2. Save and close the form or proceed to the next sub-step if required.

d. Click on the Test Entity Results tab and click Search to view the results of the OAM test suite or P2MP LSP Ping test execution if required.

22

Click on the Multi-Homing Interface tab if required, to view or create multi-homing interface entries assigned to the routing instance. The Multi-Homing Interface is a loopback interface used in multi-homing resiliency for a pair of protected routers. When active, the Primary interface can be used to advertise reachability information of the alternate router to the rest of the network. The Secondary interface is used to resolve routes advertised by the alternate router in the event that router becomes unavailable. This mechanism applies to both IP and VPN traffic.

Note: You can alternatively create a multi-homing interface by right-clicking on a routing instance icon in the navigation tree routing view and choose Create Multi-homing Interface from the menu.
Multi-homing interfaces are not supported on 7705 SAR-Hm.
Only one Primary and one Secondary multi-homing interface can be created for a router.

You can configure a multi-homing interface on the 7950 XRS, 7750 SR, and 7450 ESS (in mixed mode) network elements. Chassis mode “D” must be enabled.

1. Click Create or select an existing Mult-Homing Interface and click Properties. The Mult-Homing Interface, (Create|Edit) form opens.
2. Configure the parameters as required.
3. Click on the Addresses tab and Click Create or select an existing IP address and click Properties. The IP Address, Routing Instance (Create|Edit) form opens.
4. Configure the IP Address parameter.

   Note:

   Only IPv4 addresses are supported when creating the multi-homing interface.
5. Save and close the forms. The Routing Instance form reappears.

23

Click on the Route Aggregation tab if required, to view or configure route aggregates that can be generated into the virtual router on the routing instance.

Perform the following steps:

1. Click Create or select an existing route aggregation and click Properties. The Aggregation (Create|Edit) form opens.
2. Configure the parameters as required.
3. Save your changes and close the form.

24

Click on the BGP Confederations tab, if required to view or create BGP confederations on the routing instance. See 28.30 “To configure a BGP confederation” (p. 916) to complete the BGP confederation configuration.

25

Click on the GTP tab to configure S11 and uplink interfaces on the routing instance; see 27.14 “To configure GTP on a routing instance” (p. 853).

26

Click on the WLAN GW Tunnels tab, if required to display WLAN GW Tunnel information from the operational channels after actual traffic passes through the routing instance. The tunnel is dynamically created by the NE to carry traffic from the access point to the WLAN-GW and terminates on the WLAN-GW ISA. The tunnel can be a GRE or VLAN type.

Perform the following steps:

1. Click Resync WLAN GW Tunnels to retrieve the up-to-date tunnel information from the NE. A warning message displays.
2. Acknowledge the warning message as required.
3. Click Search to refresh the data.

27

Click on the Source Address tab, if required to view or configure an override source IP address or L3 interface for use by a selected IP application on the routing instance.

Perform the following steps:

1. Click Create or select an existing Source Address and click Properties. The Source Address, (Create|Edit) form opens.
2. Configure the parameters as required.

   Note:

   If you choose the Interface Index option for the Source Address Termination parameter, the router must have a L3 network interface or an IES L3 access interface previously created on the routing instance to proceed. Click Select to choose an interface. See 27.17 “To create an L3 network interface on a routing instance” (p. 856) for information about how to

configure a L3 network interface; see 78.28 “To configure an L3 access interface on an IES site” (p. 2472) for information about how to configure an IES L3 access interface.

If you choose the IP Address option for the Source Address Termination parameter, you must enter a IPv6 address for the Source IP Address.

3. Save your changes and close the form. The Routing Instance form reappears.

28

Click on the Advertisement tab to configure RDNSS advertisement options, if required.

Perform the following steps:

1. Click Create or select an existing entry and click Properties. The DNS Options form opens.
2. Configure the required parameters.
3. Save your changes and close the form.

29

Click on the Local DHCP server tab if required, to view a list of DHCPv4 or DHCPv6 servers assigned to the routing instance or click Create to configure a new server. See 27.5 “To configure a local DHCPv4 server on a routing instance” (p. 839) or 27.6 “To configure a local DHCPv6 server on a routing instance” (p. 842) to complete the configuration.

30

Click on the RADIUS tab and the appropriate sub-tab as required, to view or create a new RADIUS server or a RADIUS proxy server assigned to the routing instance. See 27.8 “To configure a RADIUS server on a routing instance” (p. 846) or 27.9 “To configure a RADIUS proxy server on a routing instance” (p. 847) to complete the configuration.

31

Click on the PCP Servers tab if required, to view or create a PCP server assigned to the routing instance. See 67.4 “To configure a NAT PCP server on a base routing instance” (p. 1886) to complete the configuration.

32

Click on the PCEP PCC tab if required, to view or configure PCEP PCC attributes. See 27.10 “To configure a PCEP PCC” (p. 849) to complete the configuration.

33

Click on the SR Prefix SID tab if required, to configure a node SID.

Perform the following steps:

1. Click Create or select an prefix SID and click Properties. The Segment Routing Prefix SID (Create|Edit) form opens.
2. Configure the required parameters.
3. Save your changes and close the form.

34

Click on the Seamless BFD tab if required, to view or configure Seamless BFD peers. See 28.26 “To configure Seamless BFD ” (p. 912) to complete the configuration.

35

Click on the IPSec Security Policies tab if required, to view or create VSR or 7705 SAR-Hm IPSec Security Policies.

Perform the following steps:

1. Click Create or select an existing IPSec Security policy and click Properties. The IPSec Security policy (Create|Edit) form opens.
2. Configure the required parameters.
3. Click on the IPsec Security Policy Entries tab, and add one or more security policy entries.

   Use the following steps:

   a. Click Create. The Security Policy Entry (Create) form opens.
   b. Configure the Entry ID parameter.
   c. Configure the parameters in the Local IP Address panel.
   d. Configure the parameters in the Local IPv6 Address panel.
   e. Configure the parameters in the Remote IP Address panel.
   f. Configure the parameters in the Remote IPv6 Address panel.
   g. Save your changes and close the form.

36

Click on the Origin Validation tab if required, to view or create a new RPKI session for BGP SIDR prefix origin validation assigned to the routing instance. See 28.34 “To configure BGP SIDR prefix origin validation” (p. 930) for additional information about configuring BGP SIDR prefix origin validation.

Perform the following steps:

1. Click Create or select an existing RPKI Session and click Properties. The RPKI Session, Site (Create|Edit) form opens.
2. Configure the parameters as required.
3. Click on the Static Routes tab to assign a cache server IP address and click Create. The Origin Validation Static Route Entry form opens

   Note:

   A static VRP entry is only configurable on a base router instance.
4. Configure the parameters as required.
5. Save your changes and close the form. The Routing Instance form reappears.

37

Click on the Mcast Path Mgmt Channel tab if required, to display the data from the operational channels after actual traffic passes through the virtual router/routing instance from a specific

multicast source for a specific multicast group. You must click Search to refresh the data. See 15.82 “To view the operational multicast channel properties of an MDA” (p. 541) for additional information about how to view the operational multicast channel properties of an MDA.

38

Click on the Self Generated Traffic tab if required, to configure QoS for SGT. See 27.15 “To configure QoS for self-generated traffic on a routing instance” (p. 854).

39

Click on the Statistics tab if required, to collect and view performance statistical information about the routing instance for example, routing, DHCPv6 drop, or virtual router ICMPv6 in/out statistics. See the *NSP NFM-P Statistics Management Guide* for general information about configuring and collecting statistics.

40

Click on the Deployment tab if required, to monitor the deployment status of the routing instance. See 11.5 “To monitor the deployment status of a network object” (p. 336) for information about monitoring the deployment status of a network object.

41

Click on the Faults tab if required, to view the routing instance alarm information such as the object alarms, affecting alarms, aggregated alarms, and related object alarms.

42

Click on the Delay Metric tab if required, to associate a link measurement template.

43

Save your changes and close the form.

END OF STEPS

27.3 To configure a CPM virtual routing instance

27.3.1 Purpose

This procedure describes the configuration of a virtual routing instance on a 7450 ESS, 7750 SR, 7850 VSA, or 7950 XRS NE.

27.3.2 Steps

1

In the navigation tree routing view, expand Network→*NE*.

2

Right-click on the NE and choose Create CPM Virtual Routing Instance. The Routing Instance (Create) form opens.

3

Configure the VRF/Routing Instance Name parameter and click Apply. The Routing Instance (Edit) form opens.

4

Right-click on a routing instance icon and choose Properties. The Routing Instance (Edit) form opens.

5

Configure the parameters as required.

6

Click on the Interfaces tab if required, to view or configure network interfaces assigned to the routing instance. See 27.19 “To create a network interface on a CPM virtual routing instance” (p. 865) to complete the configuration of the interface.

7

Click on the Address tab if required, to modify the IP address for the network interfaces.

8

Click on the Static Routes tab if required, to view or configure static routes assigned to the routing instance. See 27.13 “To configure a static route on a routing instance” (p. 852) to complete the configuration of the static route.

9

Click on the Deployment tab if required, to monitor the deployment status of the routing instance. See 11.5 “To monitor the deployment status of a network object” (p. 336) for information about monitoring the deployment status of a network object.

10

Click on the Faults tab if required, to view the routing instance alarm information such as the object alarms, affecting alarms, aggregated alarms, and related object alarms.

11

Save your changes and close the form.

END OF STEPS

27.4 To configure a cellular interface on a 7705 SAR-Hm

27.4.1 Steps

1

In the navigation tree routing view, expand Network→7705 SAR-Hm→Routing Instance.

2

Right-click on the routing instance and choose Create Interface. The Create Network Interface step form opens.

3

Configure the required general properties. Select PDN for the Domain parameter.

4

Configure the remaining parameters as required.

Choose the cellular port in the Select Port step.

5

Save your changes and close the form.

END OF STEPS

27.5 To configure a local DHCPv4 server on a routing instance

27.5.1 Steps

1

In the navigation tree routing view, expand Network→*NE*→Routing Instance.

2

Right-click on a routing instance icon and choose Properties. The Routing Instance (Edit) form opens.

3

Click on the Local DHCP Servers tab and click Create or select an existing DHCPv4 server and click Properties. The Local DHCP Server (Create|Edit) form opens.

4

Configure the parameters on the General tab as required.

5

Click Select in the Local User Database panel if required to choose a local database to provided local authentication. The Local User Db - Local DHCP Server, Routing Instance form opens.

Perform the following steps:

1. Click Search to list the available databases. See 74.9 “To configure a local user database for subscriber host authentication” (p. 2025) for information about configuring a local user database.
2. Select a database and click OK. The Local DHCP Server (Create|Edit) form reappears.

6

Click on the Failover tab to configure DHCP server failover support.

Perform the following steps:

1. Configure the parameters on the General tab as required.

   The Administrative State parameter must be configured to Down if you are configuring a failover DHCP server peer.
2. Click on the Peer tab to configure a failover DHCP server peer.
3. Click Create or select an existing failover peer and click Properties. The Failover Peer (Create|Edit) form opens.
4. Click Select to choose a MC peer group and click OK. See 40.4 “To configure an MC peer group” (p. 1330) for information on configuring an MC peer group.
5. Configure the Sync Tag parameter.The Sync Tag parameter setting must be the same on both failover servers.
6. Click Node Redundancy to configure node redundancy for the failover peer if required. The Manage Node Redundancy form opens, preconfigured for MC peer groups. The Node Redundancy button allows you to access the MC sync group configuration within the MC peer group in order to add failover peer sync tags.
7. Click Create or select an existing MC peer group and click Properties. The MC Peer Group (Create|Edit) form opens. See 40.4 “To configure an MC peer group” (p. 1330) to complete the MC peer group configuration.
8. Save your changes and close the forms. The Local DHCP Server (Create|Edit) form reappears.

7

Click on the IP Address Pools tab to configure address pools for the local DHCPv4 server.

Perform the following steps:

1. Click Create or select an existing IP address pool and click Properties. The IP Address Pool (Create|Edit) form opens.
2. Configure the parameters on the General tab as required.

8

Click on the Failover tab and repeat Step 6 to configure DHCP server failover support.

9

Click on the Subnets tab and click Create to add a subnet to the IP address pool or select an existing subnet and click Properties. The Subnet (Create|Edit) form opens.

Perform the following steps:

1. Configure the parameters on the General tab as required.
2. Click on the Address Ranges tab and click Create or select an existing address range and click Properties. The Subnet Address Range (Create|Edit) form opens.
3. Configure the parameters as required. You must exclude static IP addresses from the subnet address range because static IP addresses are dedicated.
4. Save your changes and close form. The Subnet (Create|Edit) form reappears.

10

Click on the Options tab.

Perform the following steps:

1. Click Create or select an existing option entry and click Properties. The IP Address Pool Option (Create|Edit) form opens.
2. Configure the parameters as required.

   The Value parameter is configurable when the Type parameter is set to ASCII String or Hex String.

   The IP Address 1, IP Address 2, IP Address 3, and IP Address 4 parameters are configurable when the Type parameter is set to IP Address.
3. Save your changes and close the form. The IP Address Pool (Create|Edit) form reappears.

11

Click on the Free Addresses tab and click Search to observe the minimum number of free addresses in the pool. If the actual number of free addresses in the pool falls below this configured minimum, an alarm is generated. A value of 0 specifies No Minimum.

12

Click on the Declined Addresses tab and click Search to observe the number of declined addresses in the pool.

13

Save your changes and close the IP Address Pool form.

14

To add a sticky lease to an IP address pool, perform the following steps:

1. Click on an IP address pool entry and click Create Sticky Lease. The Sticky Lease Action (Create) form opens.
2. Configure the required parameters.

   The Host Name parameter value must be unique. The MAC Address can be duplicated across multiple sticky lease objects, provided that each has a different corresponding Circuit ID value. Similarly, the Circuit ID value can be duplicated across multiple sticky lease objects, provided that each has a different corresponding MAC Address.

15

Save your changes and close the forms.

END OF STEPS

27.6 To configure a local DHCPv6 server on a routing instance

Note: The tabs and parameters that are configurable vary depending on the NE.

27.6.1 Steps

1

In the navigation tree routing view, expand Network→*NE*→Routing Instance.

2

Right-click on a routing instance icon and choose Properties. The Routing Instance form opens.

3

Click on the Local DHCP Servers tab, then the DHCPv6 tab.

4

Click Create or select an existing DHCPv6 server and click Properties. The Local DHCP Server (Create|Edit) form opens.

5

Configure the parameters on the General tab as required.

The ID Type and Value parameters are configurable only if the Server ID Type parameter is set to Enterprise.

6

Configure DHCP server failover support, if applicable.

Perform the following steps:

1. Click on the Failover tab and configure the parameters on the General tab as required.

   The Administrative State parameter must be configured to Down if you are configuring a failover DHCP server peer.
2. Click on the Peer tab to configure a failover DHCP server peer.
3. Click Create or select an existing failover peer and click Properties. The Failover Peer (Create|Edit) form opens.
4. Click Select to choose a MC peer group and click OK. See 40.4 “To configure an MC peer group” (p. 1330) for information on configuring an MC peer group.
5. Configure the Sync Tag parameter.The Sync Tag parameter setting must be the same on both failover servers.
6. Click Node Redundancy to configure node redundancy for the failover peer if required. The Manage Node Redundancy form opens, preconfigured for MC peer groups. The Node Redundancy button allows you to access the MC sync group configuration within the MC peer group in order to add failover peer sync tags.
7. Click Create or select an existing MC peer group and click Properties. The MC Peer Group (Create|Edit) form opens. See 40.4 “To configure an MC peer group” (p. 1330) to complete the MC peer group configuration.
8. Save your changes and close the forms. The Local DHCP Server (Create|Edit) form reappears.

7

Click on the IPv6 Address Pools tab.

Perform the following steps:

1. Click Create or select an existing entry and click Properties. The IPv6 Address Pool (Create|Edit) form opens.
2. Configure the parameters on the General tab.

8

Click on the Excluded Prefixes tab, if applicable.

Perform the following steps:

1. Click Create or select an entry and click Properties. The Excluded Prefix Address Pool (Create|Edit) form opens.
2. Configure the parameters.

9

Click on the Failover tab and repeat Step 6 to configure DHCP server failover support, if applicable.

10

Click on the Prefixes tab to add prefixes to the IPv6 address pool, if applicable.

Perform the following steps:

1. Click Create or select an existing prefix entry and click Properties. The Prefix (Create|Edit) form opens.
2. Configure the parameters on the General tab as required.
3. Click on the Options tab.
4. Click Create or select an existing option entry and click Properties. The Prefix Option (Create|Edit) form opens.
5. Configure the required parameters.

   The Number parameter is configurable when the Option parameter is set to Custom Option.

   The Value parameter is configurable when the Type parameter is set to ASCII String, Hex String, or Domain.

   The IP Address 1, IP Address 2, IP Address 3, and IP Address 4 parameters are configurable when the Type parameter is set to IP Address.
6. Save your changes and close the form.
7. Click on the Minimum Free Thresholds tab, if applicable.
8. Click Create or select an existing minimum free threshold entry and click Properties. The Prefix Minimum Free Threshold (Create|Edit) form opens.
9. Configure the required parameters.

   The Minimum Threshold and Minimum Number parameters are mutually exclusive. They cannot both be configured at the same time.
10. Save your changes and close the forms.

11

On the IPv6 Address Pool form, click on the Options tab and click Create or select an existing option entry and click Properties. The IP Address Pool Option (Create|Edit) form opens.

Perform the following steps:

1. Configure the parameters as required.

   The Number parameter is configurable when the Option parameter is set to Custom Option.

   The Value parameter is configurable when the Type parameter is set to ASCII String, Hex String, or Domain.

   The IP Address 1, IP Address 2, IP Address 3, and IP Address 4 parameters are configurable when the Type parameter is set to IP Address.
2. Save your changes and close the form.

12

Click on the Minimum Free Thresholds tab, if applicable.

Perform the following steps:

1. Click Create or select an existing minimum free threshold entry and click Properties. The Address Pool Minimum Free Threshold (Create|Edit) form opens.
2. Configure the required parameters.
3. Save your changes and close the forms.

END OF STEPS

27.7 To perform a Force Partner Down action on a local DHCP server failover

27.7.1 Purpose

The Force Partner Down action attempts to force a transition of the local DHCP server failover facility from a noCommunication state to a partnerDown state.

27.7.2 Steps

1

In the navigation tree routing view, expand Network→*NE*→Routing Instance.

2

Right-click on the routing instance icon and choose Properties. The Routing Instance form opens.

3

Click on the Local DHCP Servers tab, then Click on the DHCPv4 or DHCPv6 t

4

Click on the DHCPv4 or DHCPv6 tab.

5

Select the DHCP server on which you want to perform a Force Partner Down action and click Properties. The Local DHCP Server form opens.

6

Click on the Failover tab.

7

Click Force Partner Down in the Force Partner Down Action panel.

The fields in the Force Partner Down Action panel are updated to reflect the result of the Force Partner Down action.

8

Save your changes and close the forms.

END OF STEPS

27.8 To configure a RADIUS server on a routing instance

27.8.1 Steps

1

In the navigation tree routing view, expand Network→*NE*→Routing Instance.

2

Right-click on the routing instance icon and choose Properties. The Routing Instance (Edit) form opens.

3

Click on the RADIUS tab.

4

Click Create or select an existing RADIUS server and click Properties. The RADIUS Server (Create|Edit) form opens.

5

Configure the parameters as required.

6

Click Select to assign a Python Policy if required. The Select Python Policy forms opens.

Perform the following steps:

1. Click Search to list the available policies or click Create. See 58.3 “To configure a Python policy” (p. 1808) to complete the Python policy configuration.
2. Select a policy and click OK. The RADIUS Server (Create|Edit) form reappears.

7

Click Select in the RADIUS Script Policy panel to assign a RADIUS script policy, if required. The Select Script Policy - RADIUS Server form opens.

Perform the following steps:

1. Click Search to list the available policies or Click. See 64.23 “To configure a RADIUS script policy” (p. 1865) to complete the RADIUS Script policy configuration.
2. Select a policy and click OK. The RADIUS Server (Create|Edit) form reappears.

8

Save your changes and close the forms.

END OF STEPS

27.9 To configure a RADIUS proxy server on a routing instance

27.9.1 Steps

1

In the navigation tree routing view, expand Network→*NE*→Routing Instance.

2

Right-click on the routing instance icon and choose Properties. The Routing Instance (Edit) form opens.

3

Click on the RADIUS tab, then the RADIUS Proxy Servers tab.

4

Click Create or select an existing RADIUS proxy server and click Properties. The RADIUS Proxy Server (Create|Edit) form opens.

5

Configure the parameters as required.

6

Select a Python Policy, if required.

If you intend to configure a WLAN GW group with a distributed Python policy in Step 7, the Python policy you select in this step must be the same Python policy that is distributed to the WLAN GW group.

7

Click Select in the WLAN GW panel to assign a ISA-WLAN GW Group, if required.

8

Configure default RADIUS policies:

Perform the following steps:

1. Select a RADIUS authentication policy.
2. Select a RADIUS accounting policy.

   Note:

   If you configure a ISA-WLAN GW group in Step 7, the default RADIUS policies must be a ISA RADIUS policy.

9

Click on the Caching tab and configure the parameters as required.

10

Click on the Interfaces tab and click Create or select an existing network Interface and click Properties. The RADIUS Proxy Interface form opens.

Perform the following steps:

1. Click Select and choose an interface from the Select Interface form.
2. Select an interface and click OK. The RADIUS Proxy Server (Create|Edit) form reappears.

11

Click on the Attribute Matching/Users tab to configure RADIUS attribute matching type and matching entries for RADIUS policies.

Perform the following steps:

1. On the Type tab, configure the Type and Vendor ID parameters.
2. Click on the Entry tab.
3. Click Create to create a new RADIUS attribute matching entry, or select an existing entry in the list and click Properties. The Attribute Matching Entry form appears.
4. Configure the Entry ID, Prefix Match String, and Suffix Match String parameters as required.
5. Select a RADIUS authentication policy and a RADIUS accounting policy.
6. Save your changes and close the form.

12

Save your changes and close the forms.

END OF STEPS

27.10 To configure a PCEP PCC

27.10.1 Purpose

Use this procedure to create a PCC client and PCC Peer if needed. Each router acting as a PCC instantiates a PCEP session to the PCE in its domain.

PCEP session information and statistics are supported.

27.10.2 Steps

1

In the navigation tree routing view, expand Network→*NE*→Routing Instance.

2

Right-click on the routing instance icon and choose Properties. The Routing Instance (Edit) form opens.

3

Click on the PCEP PCC tab and click Create.

4

Configure the parameters as needed.

5

To create a peer, click Create in the Peer panel and configure the parameters.

END OF STEPS

27.11 To configure a PCE Association

27.11.1 Steps

1

In the navigation tree routing view, expand Network→*NE*→Routing Instance.

2

Right-click on the routing instance icon and choose Properties. The Routing Instance (Edit) form opens.

3

Click on the PCEP PCC tab and click Create. The PCEP-PCC (Edit) form opens.

4

Click on the PCE-Associations tab.

5

To configure diversity association:

1. Click on the Diversity sub-tab.
2. Click Create. The PCEP-PCC PCE-Association Diversity (Edit) form opens.
3. Configure the parameters and click OK.

6

To configure policy association:

1. Click on the Policy sub-tab.
2. Click Create. The PCEP-PCC PCE-Association Policy (Edit) form opens.
3. Configure the parameters and click OK.

7

Save your changes and close the forms.

END OF STEPS

27.12 To configure UDP relay, DHCP snooping, and DHCP Option 82 on OmniSwitch routing instances

Note: DHCPv6 snooping is supported only for standard VLAN on the OS 6450.

Note: The routing instance must be the default routing instance.
UDP Server Statistics/UDP Service Statistics will be lost as part of the parent change from Bridge Instance to Routing Instance.

27.12.1 Steps

1

In the navigation tree routing view, expand Network→OmniSwitch→Routing Instance.

2

Right-click on the routing instance icon and choose Properties. The Routing Instance (Edit) form opens.

3

Click on the UDP Relay tab to configure UDP relay if required.

4

Configure the required parameters in the UDP BOOTP/DHCP Relay General Configuration panel.

5

Configure the parameters in the Relay Information Configuration panel if you need to use the DHCP Option 82 functionality.

6

Configure the PXE Support parameter if you need support for PXE devices.

7

Click on the DHCP Snooping tab to configure DHCP snooping.

In the DHCPv6 Snooping Configuration panel, configure the DHCPv6 Snooping Mode parameter from the drop-down menu.

8

Configure the parameters as required.

9

Click on the Relay Services tab to configure UDP port relay services if required.

Perform the following steps:

1. Click Create.
2. Configure the UDP Relay Service parameter.

   If you selected the Other option, configure the Relay Service Port and Relay Service Description parameters.
3. Save your changes and close the form. The Routing Instance (Edit) form reappears.

10

Click on the Relay Destinations tab and click Create. The Create UDP Service Destinations form opens.

11

Click Select. The Select UDP Service - UDP Relay Service Destination form opens.

Perform the following steps:

1. Choose a UDP relay service and click OK.
2. Configure the Forwarding Address parameter, if required.
3. Click Next. The Select VLANs step is displayed.
4. Configure the search filter and click Search. The Select VLANs form displays the VLANs that match the search criteria.

5. Choose one or more VLANs to be used to forward the UDP traffic.
6. Click Finish. The selected VLANs appear in the relay destinations list and the Routing Instance (Edit) form reappears.

12

Save your and close the form.

END OF STEPS

27.13 To configure a static route on a routing instance

27.13.1 Steps

1

In the navigation tree routing view, expand Network→*NE*→Routing Instance.

2

Right-click on the routing instance icon and choose Properties. The Routing Instance (Edit) form opens.

3

Click on the Static Routes tab and click Create or select an existing static route and click Properties. The Static Route (Create|Edit) form opens.

Note: You can alternatively create a static route by right-clicking on a static route icon in the navigation tree routing view, and choose Create Static Route from the menu.

4

Configure the required general parameters.

5

Configure the required parameters in the Destination panel.

To create an indirect static route, see 27.16 “To configure LSP entries with indirect static routes” (p. 855) .

6

To assign a network interface for the static route if IPv6 is enabled on the routing instance, select an interface in the Destination panel. See 27.17 “To create an L3 network interface on a routing instance” (p. 856) for information about how to configure a network Interface.

7

Configure the required parameters in the Other panel.

8

Configure the required parameters in the CPE Check panel.

9

To assign a prefix list policy to the static route, select a prefix list policy in the Prefix panel. See 54.7 “To configure a prefix list policy” (p. 1752) for information about how to configure a Prefix List policy.

You cannot specify a Prefix List policy if the BFD Enabled or Enable CPE Check parameters are enabled for the static route.

10

Configure the parameters in the Source/Destination Class Index panel.

11

Save your changes and close the form.

END OF STEPS

27.14 To configure GTP on a routing instance

27.14.1 Steps

1

In the navigation tree routing view, expand Network→*NE*→Routing Instance.

2

Right-click on the routing instance icon and choose Properties. The Routing Instance (Edit) form opens.

3

On the General tab, set the Enable GTP Uplink parameter to Enabled.

4

Click on the GTP tab to configure S11 and uplink interfaces.

5

Click on the On the S11 tab to configure S11 interfaces and peer profile mappings:

1. On the Interfaces tab, click Create. The S11 Interface (Create) form opens.
2. Select an interface and an APN policy.
3. Save the changes and close the form.
4. Click on the Peer Profile Mapping tab and click Create. The S11 Peer Profile Mapping (Create) form opens.

5. Configure the Address Prefix and Prefix Length parameters.
6. Select a Peer Profile.
7. Save the changes and close the form.

6

Click on the On the Uplink tab to configure an uplink interface and peer profile mappings:

1. On the General tab, configure the APN Network Identifier and PDN Type parameters.
2. Click on the Peer Profile Mapping tab and click Create. The Uplink Peer Profile Mapping (Create) form opens.
3. Configure the Address Prefix and Prefix Length parameters.
4. Select a Peer Profile.
5. Save the changes and close the form.

7

Save your changes and close the form.

END OF STEPS

27.15 To configure QoS for self-generated traffic on a routing instance

27.15.1 Before you begin

NEs produce SGT for various applications, for example Telnet, SNMP, SSH. For each application, you can configure the DSCP or dot1p value for the traffic generated by that application. You can also map DSCP values to forwarding classes.

27.15.2 Steps

1

In the navigation tree routing view, expand Network→*NE*→Routing Instance.

2

Right-click on the routing instance icon and choose Properties. The Routing Instance (Edit) form opens.

3

Click on the Self Generated Traffic tab and perform the following as required:

a. Configure DSCP values for the required SGT applications.
   1. Click on the DSCP Marking tab and select an application in the list, then click Properties. The Application DSCP Marking form opens.
   2. Configure the DSCP parameter.
   3. Save your changes and close the form.

b. Map DSCP names to forwarding classes.
   1. Click on the DSCP Mapping tab and select a DSCP name in the list, then click Properties. The Application DCSP Mapping form opens.
   2. Configure the Forwarding Class parameter.
   3. Save your changes and close the form.

c. Configure dot1p values for the required SGT applications.
   1. Click on the Dot1p Marking tab and select an application in the list, then click Properties. The Application Dot1p Marking form opens.
   2. Configure the Dot1p parameter.
   3. Save your changes and close the form.

4

Save your changes and close the Routing Instance (Edit) form.

END OF STEPS

27.16 To configure LSP entries with indirect static routes

27.16.1 Steps

1

In the navigation tree routing view, expand Network→*NE*→Routing Instance.

2

Right-click on the routing instance icon and choose Properties. The Routing Instance (Edit) form opens.

3

Click on the Static Routes tab and select an existing static route and click Properties. The Static Route (Edit) form opens.

4

In the Destination panel, set the Type parameter to Indirect.

5

In the Destination panel, configure the IP Address parameter.

6

In the IGP Shortcut panel, set one of the following parameters to true.

- RSVP-TE
- SR-ISIS

- SR-TE
- SR-OSPF

The LSP Entries panel appears.

7

Click Create. The Indirect LSP Entry (Create) form opens.

8

Configure the LSP Name parameter or select an LSP Name that exists on the NE in the LSP panel.

9

Save your changes and close the forms.

END OF STEPS

27.17 To create an L3 network interface on a routing instance

27.17.1 Purpose

Perform this procedure to create L3 network interfaces on a routing instance. This procedure provides an example for configuring a network interface on a 7950 XRS with IPv6 enabled.

Note: The steps in this procedure depend on the device type, device version, and the parameter options that are selected during configuration. If a step in this procedure does not apply to the interface type that you are configuring on your device, proceed to the next applicable step.

An L3 interface on an OmniSwitch enables IP routing on a VLAN. Without an L3 interface, traffic is bridged within the VLAN or across connections to the same VLAN on other switches.

See 27.18 “To configure L3 network interfaces” (p. 863) to re-configure a L3 network interface after it is created. See 27.1.17 “Workflow to configure NE routing and forwarding” (p. 823) for information about how to configure other L3 network interfaces on routing instances.

You can create the following L3 interface types:

- ICMP interface
- system interface
- unnumbered interface
- management interface
- control tunnel
- IGMP interface
- PIM interface
- MLD interface

27.17.2 Steps

1

In the navigation tree routing view, expand Network→*NE*→Routing Instance.

2

Right-click on the routing instance icon and choose Create Interface. The Create Network Interface step form opens.

3

Configure the parameters on the Define General Properties form as required.

When you create an unnumbered MPLS-TP instance, you must configure a Static ARP in Step 11 before you can turn the Administrative State parameter to Up.

4

Click Next. Perform one of the following as required:

a. If you chose the Numbered option for the Class parameter in Step 3 , the Configure IP Address form opens.

   On supporting NEs, you can create multiple IP addresses. For each address you need to create, perform the following:

   1. Click Create to associate an IP address for the interface. The IP Address, Routing Instance (Create) form opens,
   2. Configure the parameters as required.

      The Broadcast Address Format parameter only appears if the IP Address parameter is set to an IPv4 address.

      The parameters in the IPv6 panel only appear if the IP Address parameter is set to an IPv6 address.
   3. Select a Track SRRP Instance, if required.
   4. Save the changes and close the form.

b. If you chose the Unnumbered option for the Class parameter in Step 3 , the Configure Unnumbered Interface form opens. Configure the parameters as required.

5

Click Next to associate the L3 interface with a physical port. The Select Port form open.

Perform the following steps:

1. Select a port.
2. Select a LAG link mapping profile, if required to assign a specific LAG egress port to a SAP or interface, and control how egress traffic is handled if the specified port fails. See 13.21 “To create a LAG link mapping profile” (p. 443) for more information about creating a LAG link mapping profile.

6

Click Next to associate a network policy for the interface. The Select Network Policy form opens. Network policies are used to determine QoS settings based on the packet CoS bits on the ingress and egress of the network.

Note: The form name and policy selection options vary depending on the NE. See Chapter 50, “QoS policies” for information about network policies.

Perform the following steps:

1. Select a network policy in the Network Policy panel. See 50.41 “To configure a QoS network policy” (p. 1568) for information about configuring a network policy.

   Note:

   If the network policy you selected has Port Redirect Groups on its Ingress or Egress Forwarding Classes, you must specify both an Ingress or egress queue group template policy and Instance ID.

   If you select a network policy with a forwarding class mapped to a queue group queue ID, you must ensure that the mapping queue group queue ID is in the selected queue group template policy.

2. Select a queue group template policy in the Ingress Forwarding Plane Redirect and Egress Port Redirect panels. Queue group template policies allow SAP or IP interface forwarding classes to be redirected from the typical queue mapping to a shared queue. See 50.74 “To configure a queue group ingress template policy” (p. 1617) or 50.75 “To configure a queue group egress template policy” (p. 1619) for information about configuring an ingress/egress queue group template policies.

   Note:

   You must ensure that the port you selected has a network egress queue group with the same name as the queue group template policy created on it.

   Queue group template policies are not applicable to L3 interfaces associated with HSMDA ports.

3. Configure the Queue Group Instance ID parameter or click Select to associate a queue group instance for the interface.

If you are configuring an L3 access interface for 7210 SAS or 7250 IXR nodes, go to Step 7 . Otherwise, go to Step 8.

7

Click Next to configure accounting statistics collection for the interface. The Select Accounting Policy form opens. Select an accounting policy and configure the required parameters.

8

Click Next to assign ACL filters to the interface. The Select ACL Filters form opens. ACL filters are used to filter out IP traffic that matches user-defined criteria defined in ACL IP filter or ACL IPv6 policies.

Perform the following steps:

1. Select an ingress/egress ACL IP filter policy. See 51.5 “To configure an ACL IP filter policy” (p. 1671) for information about configuring an ACL IP filter policy.
2. Select an ingress/egress ACL IPv6 filter policy. See 51.6 “To configure an ACL IPv6 filter policy” (p. 1677) for information about configuring an ACL IPv6 filter policy

9

Click Next. The Configure ICMP form opens. Configure the ICMP parameters.

10

Click Next. If the IPv6 Allowed parameter is enabled on the Define General Properties form, the Configure ICMPv6 form opens. Configure the IPv6 parameters as required.

11

Click Next. The Configure ARP form opens.

Perform the following steps:

1. Configure the parameters as required.
2. Click Create to statically associate an IP or MAC address to the interface. The Static ARP (Create) form opens.
3. Configure the parameters as required.
4. Save your changes and close the form.

12

Click Next. The Configure Proxy ARP form opens. Configure the parameters as required.

Proxy ARP allows a device, such as a router, to answer ARP requests that are intended for another device. This allows a device to reach a remote subnet without configuring routes to the subnet or a default gateway device.

13

Click Next. The Configure Proxy ARP Policies form opens. Configure the parameters as required.

Note: You must not leave an empty policy parameter between two configured policy parameters. For example, do not configure the Policy 1 and Policy 3 parameters and leave the Policy 2 parameter unconfigured. The NFM-P reorders the policies and moves the policy entered for the Policy 3 parameter to the Policy 2 parameter.

14

Click Next. If the IPv6 Allowed parameter is enabled on the Define General Properties form, the Configure Neighbor Discovery form opens.

Perform the following steps:

1. Click Create to configure a neighbor. The Neighbor Discovery (Create) form opens.
2. Configure the parameters as required.
3. Save your changes and close the form.

15

Click Next. The Configure Proxy Neighbor Discovery form opens.

Perform the following steps:

1. Configure the parameters as required.
2. Click Select to associate a routing policy statement to the interface. You can associate up to five routing policy statements for each interface. See 54.5 “To configure a routing policy statement” (p. 1745) to create a routing policy statement.

16

Click Next. The Configure Secure Neighbor Discovery form opens. Configure the parameters as required.

17

Click Next. If NTP or SNTP is enabled on the NE, the Configure NTP form opens. Configure the Broadcast parameter.

Note: When the Broadcast parameter is enabled, a time protocol such as NTP or SNTP must be enabled and configured on the device, or the device ignores broadcast time packets received on the interface. See Chapter 8, “Device commissioning and management” for information about configuring NTP or SNTP on a device.

18

Click Next. The Configure DHCP - General form opens. To configure IPv4 DHCP for the interface:

Perform the following steps:

1. Configure the required parameters.

   The Remote ID String parameter is configurable when the Remote ID parameter is set to Remote IDString.
2. Select a Python policy, if required.
3. Click Next. The Configure DHCP - Server form opens.
4. Configure the Server 1 through Server 8 parameters.

19

Click Next. The Configure VRRP form opens. Click Create to add a VPPR instance. See 37.4 “To create and configure a VRRP instance” (p. 1283) to create a VRRP instance.

VRRP instances are members of a virtual router that provide backup if a router fails in a statically configured LAN. VRRP instances are created from network interfaces on a router, either as a master owner through which IP packets are routed before a failover, or as a backup non-owner that assumes the packet-forwarding (master) role after a failover. Before you create or add a VRRP instance to a virtual router, ensure that the master and backup interfaces have the same VRID and occupy the same subnet. See 37.4 “To create and configure a VRRP instance” (p. 1283) to create a VRRP instance.

20

Click Next. If the IPv6 Allowed parameter is enabled on the Define General Properties form, the Configure IPv6 VRRP form opens. Click Create to add a VPPR IPv6 instance. See 37.4 “To create and configure a VRRP instance” (p. 1283) to create a VRRP instance.

21

Click Next. The Configure Router Advertisement form opens.

Perform the following steps:

1. Click Create to add a router advertisement entry. The Router Advertisement (Create) form opens.
2. Configure the parameters on the General tab as required.

   If you are configuring the L3 interface for an IPv6 VRRP instance, then the Send Advertisement and Use Virtual MAC Address parameters must both be enabled.
3. Click on the DNS Options tab and click Create. The DNS Options form opens.
4. Configure the parameters as required.
5. Click on the Prefix tab and click Create. The Router Advertisement Prefix (Create) form opens.
6. Configure the parameters as required.

   Note:

   Each Lifetime (seconds) parameter is configurable when the associated No Expiry parameter is disabled.
7. Save the changes and close the forms.

22

Click Next. The Unicast RPF form opens. Configure the parameters as required.

The URPF Check State IPv6 and URPF Check Mode IPv6 parameters are only configurable when the IPv6 Allowed parameter is enabled is enabled on the Define General Properties form.

23

Click Next. The Configure DHCP - General form opens. Configure the parameters as required to configure IPv4 DHCP for the interface.

Note: The Remote ID String parameter is configurable when the Remote ID parameter is set to Remote IDString.

24

Click Next. The Configure DHCP - Server form opens. Configure the Server 1 through Server 8 parameters.

25

Click Next. The Configure Network Domain form opens. Click Add Network Domain to add a network domain to a network interface. See 27.21 “To create a network domain” (p. 867) to create a network domain.

26

Click Next. The Configure BFD form opens. To configure Bidirectional Forwarding Detection for the interface:

Perform the following steps:

1. Set the Administration Status parameter to Up.
2. Configure the parameters as required.
3. Click OK.

   Note:

   You cannot enable BFD on an interface, if BFD is not configured on the interface. You cannot set the administrative status of an interface to disabled, when protocols using the interface have BFD enabled. See Chapter 28, “Routing protocol configuration” for information about enabling and disabling BFD for routing protocols.

27

Click Next. If the IPv6 Allowed parameter is enabled on the Define General Properties form, the Configure IPv6 BFD form opens. Configure the parameters as required.

28

Click Next. The Select Security form opens. Click Select to assign a DoS protection policy or DDoS protection policy to a network interface. See 27.1.9 “DoS protection on L3 network interfaces” (p. 820) or 27.1.10 “DDoS protection on network and access interfaces” (p. 821) in this chapter for more information.

29

Click Next. The Configure Cflowd Sampling form opens.

Note: You must enable cflowd globally on an NE before you can configure cflowd collectors; see 12.10 “To enable and configure global Cflowd sampling on an NE” (p. 347)
.
You can configure cflowd sampling for unicast and multicast traffic on a routing network interface; up to two cflowd sampling objects can be configured under the parent interface, one for unicast and one for multicast.

Perform the following steps:

1. Click Create. The Cflowd Sampling (Create) form opens.
2. Configure the required parameters and click OK.

30

Click Finish. The Summary form opens.

31

Enable the View the newly created Network Interface parameter to view the interface configuration after closing the form.

32

Save your changes and close the form.

END OF STEPS

27.18 To configure L3 network interfaces

27.18.1 Purpose

Perform this procedure to re-configure L3 network interfaces created in 27.17 “To create an L3 network interface on a routing instance” (p. 856) or to configure interfaces that are associated with a routing instance but not previously configured.

27.18.2 Steps

1

In the navigation tree routing view, expand Network→*NE*→Routing Instance→*Interface type*.

2

Right-click on the interface that you want to configure and choose Properties. The Network Interface (Edit) form opens.

3

Click on the appropriate tab and configure the parameters as required. Table 27-1, “Network interface form tabs” (p. 863) describes the tabs you can use to modify an existing routing interface.

Note: The network interface form tabs listed in Table 27-1, “Network interface form tabs” (p. 863) depend on the device type, device version, and the parameter options that were initially configured for the network interface. If a tab does not apply to the interface type that you are configuring on your device, proceed to the next applicable tab that applies.

Table 27-1 Network interface form tabs

Tab	Description
General	To configure the general parameters associated with the network interface.

Table 27-1 Network interface form tabs (continued)

Tab	Description
Port	To create an association between the network interface and a physical port or channel. The system interface is not associated with a port.
Policies	To assign QoS policies, ingress or egress IP ACL filter policies, and accounting template policies to the network interface.
Protocols	To view a list of protocols that are enabled on the interface, and to apply protocols.
Multicast	To view a list of multicast protocols that are enabled on the interface, and to apply protocols.
Security	To assign a DoS protection policy or DDoS protection policy to a network interface. See 27.1.9 “DoS protection on L3 network interfaces” (p. 820) or 27.1.10 “DDoS protection on network and access interfaces” (p. 821) in this chapter for more information.
BFD	To configure BFD parameters to a network interface.
Addresses	To assign IP addresses, and subnet and broadcast address formats to a network interface. To assign Track SRRP Instance to IP addresses, if required.
ARP	To configure or view ARP and proxy ARP parameters on the network interface.
ICMP	To configure ICMP parameters on the network interface.
ICMPv6	To configure ICMPv6 parameters on the network interface if IPv6 is enabled.
Neighbor Discovery	To configure neighbor discovery and proxy neighbor discovery for static routes on the network interface.
DHCP	To configure DHCP Relay parameters or select a Python policy.
Local DHCP	To assign local DHCP servers to the network interface. To associate a local DHCPv6 server, the IPv6 Allowed parameter must be enabled on the General tab.
DHCP Client	To enable DHCP and configure a DHCP client.
Administrative Groups	To assign administrative group policies to a network interface. See 54.13 “To configure an administrative group policy” (p. 1758) to create an administrative group policy.
Shared Risk Link Groups	To assign shared risk link group policies to a network interface. See 54.14 “To configure a Shared Risk Link Group policy” (p. 1759) to create a shared risk link group policy.
Network Domain	To add a network domain to a network interface. See 27.21 “To create a network domain” (p. 867) to create a network domain.
VRRP	To add a VRRP instance to an existing virtual router that assumes routing responsibilities from a failed router in a statically configured LAN. See 37.4 “To create and configure a VRRP instance” (p. 1283) to create a VRRP instance.
MEPs	To add network interface facility MEPs to the network interface. Each network interface can support one facility MEP.
Advertisement	To configure router advertisement on the network interface.
NTP	To enable SNTP broadcasts on the network interface.
RCA Result	To view the results of RCA activities on the network interface.
Zone	To assign a 7705 SAR security zone policy to a network interface. See 68.9 “To configure a security zone policy for a 7705 SAR” (p. 1894) to create a security zone policy.

Table 27-1 Network interface form tabs (continued)

Tab	Description
QoS	To assign an egress network queue policy to a network interface. See 50.46 “To configure a network queue policy” (p. 1581) or 50.47 “To configure a 7210 and 1830 network queue policy” (p. 1583) to create a network queue policy.
Deployment	To monitor the deployment status of the interface such as any warnings when a configuration change is not fully deployed to an NE.
Clear Statistics Status	To view the status of all clear requests on the network interface.
RP Statement Actions items	To view the routing policy statement associated with the network interface. See 54.5 “To configure a routing policy statement” (p. 1745) to create a routing policy statement.
Statistics	To view the statistics associated with the network interface.
TCA	To assign a TCA policy to a network interface. See 19.4 “To configure a TCA policy” (p. 709) to create a TCA policy.
Faults	To view alarms that are raised against the network interface, or related alarms that affect the network interface.

4

Save your changes and close the form.

END OF STEPS

27.19 To create a network interface on a CPM virtual routing instance

27.19.1 Purpose

Perform this procedure to create network interfaces on a CPM virtual routing instance. Up to two network interfaces can be created on the virtual routing instance with up to two ports each. A limited number of attributes are supported on the interface.

See 27.20 “To configure network interfaces on a CPM virtual routing instance” (p. 866) to re-configure a network interface after it is created. See 27.1.17 “Workflow to configure NE routing and forwarding” (p. 823) for information about how to configure other L3 network interfaces on routing instances.

27.19.2 Steps

1

In the navigation tree routing view, expand Network→*NE*→Routing Instance.

2

Right-click on the routing instance icon and choose Create Interface. The Create Network Interface step form opens.

3

Configure the parameters on the Define General Properties form as required.

4

Click Next. The Configure IP Address form opens.

Perform the following steps:

1. Click Create to associate a IP address for the interface. The IP Address, Routing Instance (Create) form opens.
2. Configure the parameters as required.
3. Save the changes and close the form.

5

Click Next to associate the interface with a physical port. The Select Port form opens.

Select a port. Only A/4 or B/4 ports can be associated with the interface.

6

Save your changes and close the form.

END OF STEPS

27.20 To configure network interfaces on a CPM virtual routing instance

27.20.1 Purpose

Perform this procedure to re-configure network interfaces created in 27.19 “To create a network interface on a CPM virtual routing instance” (p. 865) or to configure interfaces that are associated with a CPM virtual routing instance but not previously configured.

27.20.2 Steps

1

In the navigation tree routing view, expand Network→*NE*→Routing Instance→*Interface*.

2

Right-click on the interface that you want to configure and choose Properties. The Network Interface (Edit) form opens.

3

Click on the appropriate tab and configure the parameters as required. Table 27-2, “CPM virtual routing instance network interface form tabs” (p. 867) describes the tabs you can use to modify an existing routing interface.

Table 27-2 CPM virtual routing instance network interface form tabs

Tab	Description
General	To configure the general parameters associated with the network interface.
Port	To create an association between the network interface and a physical port or channel. The system interface is not associated with a port.
Addresses	To assign an IP address and subnet to a network interface. Only one primary IP address can be associated with a network interface.
Statistics	To view the statistics associated with the network interface.
TCA	To assign a TCA policy to a network interface. See 19.4 “To configure a TCA policy” (p. 709) to create a TCA policy.
Deployment	To monitor the deployment status of the interface such as any warnings when a configuration change is not fully deployed to an NE.
Faults	To view alarms that are raised against the network interface, or related alarms that affect the network interface.

4

Save your changes and close the form.

END OF STEPS

27.21 To create a network domain

27.21.1 Steps

1

In the navigation tree routing view, expand Network→*NE*→Routing Instance→Network Domains.

2

Right-click on the network domains icon and choose Create Network Domain. The Network Domain (Create) form opens.

3

Configure the parameters as required.

4

Click OK. The Domain Network (Create) form closes and a network domain displays in the navigation tree routing view.

END OF STEPS

27.22 To associate a network interface or service tunnel with a network domain

27.22.1 Steps

1

In the navigation tree routing view, expand Network→*NE*→Routing Instance→Network Domains→domain-*user defined domain*.

2

Right-click on the domain-*user defined domain* icon and choose Properties. The Network Domain - domain-*user defined domain* (Edit) form opens.

3

Associate a network interface with a network domain.

Perform the following steps:

1. Click on the Network Interfaces tab and click on Add Network Interface. The Add Network Interface form opens
2. Click on Search to display all the Network Interfaces.
3. Choose a network interface and click OK. The selected network interface is displayed on the Network Domain form.

4

Associate a service tunnel with a network domain.

Perform the following steps:

1. Click on the Service Tunnels tab and click on Add Tunnel. The Add Tunnel form opens.
2. Click on Search to display all service tunnels.
3. Choose a service tunnel and click OK. The selected service tunnel is displayed on the Network Domain form.

5

Save your changes and close the form.

END OF STEPS

27.23 To remove a network interface or service tunnel from a network domain

27.23.1 Steps

1

In the navigation tree routing view, expand Network→*NE*→Routing Instance→Network Domains→domain-*user defined domain*.

2

Right-click on the domain-*user defined domain* icon and choose Properties. The Network Domain - domain-*user defined domain* (Edit) form opens.

3

Remove a network interface from a network domain.

Perform the following steps:

1. Click on the Network Interfaces tab and click Remove Network Interface. The Remove Network Interface form opens.
2. Click on Search to display all network interfaces associated with the network domain.
3. Choose a network interface and click OK. The selected network interface is remove from the network domain.

4

Remove a service tunnel from a network domain.

Perform the following steps:

1. Click on the Service Tunnel tab and click Remove Tunnel. The Remove Tunnel form opens.
2. Click on Search to display all service tunnels associated with the network domain.
3. Choose a service tunnel and click OK. The selected service tunnel is remove from the network domain.

5

Save the network domain and close all open forms.

END OF STEPS

27.24 To list and view routing instances and child objects

27.24.1 Purpose

Perform this procedure to list and view the properties associated with routing instances and child objects such as IP and source addresses, assigned interfaces, protocol and site assignments, statistics, and faults.

27.24.2 Steps

1

Choose Manage→Networking→Routing Instances from the NFM-P main menu. The Manage Routing Instances form opens.

2

Choose an object from the Select Object Type drop-down menu.

3

Configure the search fields as required, and click Search. The search results display showing the selected object general properties associated with the routing instances and child objects.

4

As required, choose an object and click Properties to get additional information on the selected object. The selected object properties form opens.

5

Select the appropriate tab on the form to view the current parameter settings, deployment information, or fault information.

6

Save your changes and close the form.

END OF STEPS

27.25 To view and clear DHCP leases or prefixes assigned to a routing instance

27.25.1 Purpose

Depending on the device being queried, you can view DHCPv4 or DHCPv6 leases or prefixes, or both types may be supported by the device.

27.25.2 Steps

1

In the navigation tree routing view, expand Network→*NE*→Routing Instance.

2

Right-click on the routing instance icon and choose Properties. The Routing Instance (Edit) form opens.

3

Click on the Local DHCP Servers tab, then the appropriate DHCPv4 or DHCPv6 sub-tab. The list of associate DHCP servers is displayed.

4

Choose a DHCP server and click Properties. The Local DHCP Server (Edit) form opens.

5

Perform one of the following:

a. View DHCPv4 leases or prefixes.

   Perform the following steps:

   1. Click on the Leases tabs.
   2. Click Search on the General tab to refresh the data.
   3. Choose a lease and click Properties. The Local DHCP Server Leases form opens.
   4. View the lease information on the form.

b. View DHCPv6 leases or prefixes.

   Perform the following steps:

   1. Click Show Leases. The Local DHCPv6 Server Show Leases form opens.
   2. To view all active leases on the server, click OK.
   3. To view the lease information for a specific prefix, enter an IP address in the Prefix parameter and click OK.
   4. To view the detailed lease information for a specific prefix, enter the IP address in the Prefix parameter, select the Detail check box, and click OK. The form displays the CLI details for the specific prefix.

c. Clear DHCPv4 leases.

   Perform the following steps:

   1. Click on the Leases tab.
   2. Click on the Regular tab to clear DHCP leases.
   3. Click Search to refresh the data.
   4. Select the DHCP lease you want to clear and click Clear DHCP Lease.

      If you want to clear all of the leases on the local DHCPv4 server, click Clear All DHCP Leases.
   5. Click on the Sticky tab to clear sticky leases.
   6. Select the sticky lease you want to clear and click Clear Sticky Lease.
   7. If you want to clear all sticky leases with a specific host name prefix, click Clear Sticky Lease With Host Name Prefix.

      Specify a host name prefix and click Ok.
   8. Click on the Clear Status tab to check the progress/success of the lease clear command.

6

Save your changes and close the form.

END OF STEPS

27.26 To view DHCPv6 log events

27.26.1 Purpose

This procedure describes how to view the following log events on a DHCPv6 server:

- host conflict log
- lease not owner log
- pool unknown log

27.26.2 Steps

1

In the navigation tree routing view, expand Network→*NE*→Routing Instance.

2

Right-click on the routing instance icon and choose Properties. The Routing Instance (Edit) form opens.

3

Click on the Local DHCP Servers tab, then the Local DHCPv6 tab. The list of associate DHCPv6 servers displays.

4

Choose a DHCPv6 server and click Properties. The Local DHCPv6 Server (Edit) form opens.

5

Click on the Logs tab, then the appropriate sub-tab for the type of log that you wish to display.

6

Configure the filter criteria and click Search. A list of event logs appears.

7

Choose a log entry and click Properties. The Log form opens.

8

View the log entry and close the form.

END OF STEPS

27.27 To configure DHCP clients on SAR devices

27.27.1 Overview

The SAR-Hm can be configured to support IP/MPLS services over WLAN. This requires that the SAR-Hm act as a WLAN station, and alternatively act as both an AP and station concurrently to create a WLAN topology as necessary.

You can configure DHCP clients on a network interface with WLAN or an Ethernet port.

The 7705 SAR-Hmc can be configured to support IP/MPLS services on Network Interface with Ethernet Port.

27.27.2 Steps

1

In the navigation tree routing view, expand Network→*NE*→Routing Instance→Interface.

2

Right-click on the interface that you want to configure and choose Properties. The Network Interface (Edit) form opens.

3

Click on the DHCP Client tab.

4

Click Create, or select a DHCP client and click Properties. The DHCP Client form opens.

5

Configure the required parameters.

6

Save your changes and close the forms.

END OF STEPS

27.28 To list MVPN Extranet objects for a NE

27.28.1 Purpose

Perform this procedure to display a list of MVPN extranet objects that exchange route information through a given NE. The Show MVPN-Extranet menu command issues a show router mvpn-extranet CLI command to the selected NE, and returns a list of subscriber VRF IP addresses. The command can be issued from a base routing instance, or from a VPRN site.

27.28.2 Steps

1

Perform one of the following:

a. In the navigation tree routing view, expand Network→*NE*→Routing Instance.

b. Run the Show MVPN-Extranet command from a VPRN site.

Perform the following steps:

1. Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.
2. Configure the filter criteria. A list of services appears at the bottom of the Manage Services form.
3. Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.
4. In the navigation tree, expand Network→*NE*→Routing Instance.

2

Right-click on the Routing Instance icon and choose Show MVPN-Extranet from the menu. The Show MVPN-Extranet form opens.

3

In the Parameters field, you can type filter arguments for the show router mvpn-extranet CLI command. For example:

- mvpn-extranet [detail] [srcmvpn <*source_service_id*>] [recvmvpn <*reciever_service_id*>]

where

[detail] provides a detailed route table in the command output.

[srcmvpn <*source_service_id*>] filters the output route table to a source VRF, based on the service ID of the source VRF. The variable range is 0 to 4294967295.

[recvmvpn <*reciever_service_id*>] filters the output route table to a destination VRF, based on the service ID of the destination VRF. The variable range is 0 to 4294967295.

4

Click OK. The Show MVPN-Extranet form displays table of MVPN extranet objects.

END OF STEPS

27.29 To display show router fp-tunnel information for a routing instance

27.29.1 Purpose

Perform this procedure to display show router fp-tunnel information for a routing instance including the IOM/IMM label, next hop, and outgoing interface information for BGP, LDP and RSVP tunnels.

27.29.2 Steps

1

In the navigation tree routing view, expand Network→*NE*→Routing Instance.

2

Right-click on the Routing Instance icon and choose Show FP Tunnel Table from the menu. The FP RTR Show FP Tunnel Table form appears.

3

Configure the parameters as required.

4

Click OK. The fp rtr Show FP Tunnel table opens and a CLI session is initiated.The FP tunnel table information for a routing instance is displayed.

END OF STEPS

27.30 To configure a Multi-Chassis shunt interface on a base routing instance or VPRN routing instance

27.30.1 Steps

1

Perform one of the following:

1. Configure a Multi-Chassis shunt interface on a base routing instance.

   Perform the following steps:

   a. In the navigation tree routing view, expand Network→*NE*→Routing Instance.
   b. Right-click on the routing instance icon and choose Properties. The Routing Instance (Edit) form opens.

2. Configure a Multi-Chassis shunt interface on a VPRN routing instance.

   Perform the following steps:

   a. Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.
   b. Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.
   c. On the VPRN Service tree, click on the site to which you need to configure a Multi-Chassis shunt interface.
   d. Right-click on the routing instance icon and choose Properties. The Routing Instance (Edit) form opens.

2

Click on the IPSec tab, then on the MC Shunt Interface tab.

3

Create or select an entry and click Properties. The Multi-Chassis Shunt Interface (Create/Edit) form opens.

4

Configure the required parameters.

5

Save your changes and close the form.

END OF STEPS

27.31 To configure a Multi-Chassis shunting profile on a base routing instance or VPRN routing instance

27.31.1 Steps

1

Perform one of the following:

1. Configure a Multi-Chassis shunting profile on a base routing instance.

   Perform the following steps:

   a. In the navigation tree routing view, expand Network→*NE*→Routing Instance.
   b. Right-click on the routing instance icon and choose Properties. The Routing Instance (Edit) form opens.

2. Configure a Multi-Chassis shunting profile on a VPRN routing instance.

   Perform the following steps:

   a. Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.
   b. Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.
   c. On the VPRN Service tree, click on the site to which you need to configure a Multi-Chassis shunt interface.
   d. Right-click on the routing instance icon and choose Properties. The Routing Instance (Edit) form opens.

2

Click on the IPSec tab, then on the MC Shunting Profile tab.

3

Create or select an entry and click Properties. The Multi-Chassis Shunting Profile (Create/Edit) form opens.

4

Configure the required parameters.

5

Click on the MC Peer tab.

6

Create or select an entry and click Properties. The Multi-Chassis Shunting Profile Peer (Create/Edit) form opens.

7

Configure the required parameters.

8

Configure the Shunt Interface parameter.

9

Save your changes and close the forms.

END OF STEPS

28 Routing protocol configuration

Routing protocol configuration overview

28.1 Routing protocol configuration overview

28.1.1 Overview

A routing protocol specifies how routers communicate with each other and enables them to select routes between any two nodes in a network. Routing protocols typically determine the specific choice of a route based on the following metrics:

- number of network-layer devices along a path (hop count)
- bandwidth
- load
- delay
- MTU
- reachable addresses
- cost

Routing protocols store the results of these metrics in a routing table. Routing protocols use the information and path parameters to compile a network topology. The information about routes that is used to update routing tables can be modified using routing policies. Some devices also support a RIB API with read and write access to their routing tables.

Each router has a prior knowledge only of networks attached to it directly. A routing protocol shares this information first among immediate neighbors, and then throughout the network. This way, routers gain knowledge of the topology of the network.

You can use the network, routing, IS-IS, and OSPF views in the NFM-P GUI navigation tree to view and configure the device routing protocol support. The supported protocols are displayed in the navigation tree as child objects to the routing instance.

A device can support multiple routing protocols. The supported protocols are device dependent. The NFM-P only displays the protocols that can be configured on each device type. Supported routing protocols on the NFM-P include:

- 28.3 “IPv6” (p. 881)
- 28.5 “BGP” (p. 883) and 28.5.2 “MP-BGP” (p. 886)
- 28.7 “RIP and RIPng” (p. 888)
- 28.8 “LDP” (p. 888)
- 28.9 “IS-IS” (p. 891)
- 28.10 “OSPFv2 and OSPv3” (p. 893)
- 28.12 “RSVP” (p. 896) (enabled by default)
- 28.13 “L2TP” (p. 898) (enabled by default)
- 28.19 “WPP” (p. 907)
- MPLS
- MPLS-TP
- Multicast routing
  - 28.14 “PIM” (p. 901)
  - 28.15 “IGMP” (p. 905)
  - 28.16 “MSDP” (p. 905)
  - 28.17 “MLD” (p. 906)
- 28.18 “Bridging” (p. 907)
- 28.19 “WPP” (p. 907)
- 28.20 “BIER” (p. 908)
- 28.21 “IPSec” (p. 908)

Note: For an OmniSwitch, the NFM-P supports viewing the status of routing protocols that are enabled using the CLI.

L2TP is enabled by default on a base routing instance, but not on a VPRN routing instance.

Routing protocols can be configured to import or export routes from other routing protocols using routing policies. See 27.1.12 “NE routing policies” (p. 821) in 27.1 “NE routing and forwarding” (p. 817) .

28.2 Area-based routing considerations with protocol usage

28.2.1 Overview

When you configure a device, you configure the routing protocols used to determine how routers communicate with each other and the topology of packet handling between different devices in the network.

Networks can be grouped into areas for a number of reasons including scaling, administrative convenience, equipment compatibility, or business structure, For example, an area can be a collection of network segments within an AS that have been administratively assigned to the same group.

Area topology is concealed from the rest of the AS. This means a significant reduction in routing traffic. Routing in the AS takes place on three levels, depending on whether the source and destination of a packet reside in:

- the entire path is limited to a single area (known as intra-area routing)
- the path spans multiple areas all owned by the same carrier (known as inter-area routing)
- the path spans multiple carriers (known as inter-carrier routing)

In intra-area routing, the packet is routed based on information found within the area; no routing information from outside the area is used. This protects intra-area routing from the injection of bad routing information. Two devices, which are not area border routers, and belonging to the same area, have identical topological databases.

Devices that are aware of more than one area are called area border routers. In this case, all devices in an AS do not have an identical topological database. An area border router has a

separate topological database for each area it is connected to. ASs share routing information, such as routes to each destination and information about the route or AS path, with other ASs using BGP.

28.3 IPv6

28.3.1 Overview

The NFM-P supports IPv6 for control-plane addressing on IPv6-enabled devices.

Although the implementation of IPv6 is driven by the diminishing IPv4 address space, it is increasingly necessary to use a protocol that is designed to handle more complex network applications, such as broadband voice and video transmission, IP transit, Internet exchange peering, and other large enterprise applications.

28.3.2 Transition from IPv4 to IPv6

The transition from IPv4 to IPv6 is occurring in stages as network providers, service providers, and end users migrate existing applications and equipment to the new version. Control-plane forwarding of IPv6 packets is an important part of this transition; it allows isolated IPv6 hosts and smaller IPv6 networks to peer across an IPv4 network, using a mechanism such as 6over4 tunneling.

With 6over4 tunneling, a host encapsulates IPv6 packets in IPv4 packets for transport across an IPv4 network. Routers that identify 6over4 encapsulation remove the IPv4 encapsulation before they forward the packets to other native IPv6 hosts. The 6over4 mechanism uses the IPv4 multicast infrastructure for neighbor discovery.

28.3.3 IPv6 benefits

The general benefits of IPv6 include:

- **simplified header format and fixed header length**
  An IPv6 header contains fewer fields than an IPv4 header. IPv6 excludes obsolete IPv4 header fields and processes option fields only when they contain values. IPv6 also standardizes the size of the packet header to 40 bytes to streamline packet processing. These features reduce packet-processing overhead and make routing more efficient.
- **addressing enhancements**
  IPv6 increases the IP address size from 32 bits to 128 bits to support a greater number of NEs and to provide a more versatile addressing hierarchy. IPv6 also supports address auto-configuration.
  The scalability of multicast routing is improved by the presence of a Scope field. IPv6 introduces anycast addressing, which designates a group of disparate NEs as the recipient of a specific data stream.
- **improved scalability and extensibility**
  Built-in traffic optimization makes IPv6 highly scalable, and IPv6 supports future routing technology enhancements using protocol extensions.
- **flow-labeling capability**
  IPv6 features packet prioritization which allows the labeling of packets that require special handling, such as real-time service for VoIP conferences.

- **improved privacy and security**
  Authentication, encryption, and data integrity features are mandatory components for which IPv6 supports standardized extensions.

28.3.4 IPv6 support on the NFM-P

The NFM-P entities that support IPv6 configuration include the following:

- BGP for base routing instances and VPRN services
- MVPN IPv6 for BGP routing instances
- MVPN IPv6 for BGP policy statements
- IS-IS adjacencies
- multicast routing
- static routes
- ICMP
- routing policies
- access ingress and egress policies
- CPM filter policies
- PPP
- IES and VPRN SAPs
- IES and VPRN bidirectional forwarding detection
- VLL Ipipe
- PIM-SSM
- PIMv6 on VPRN routing instances and interfaces
- MLD under IES and VPRN

An NFM-P operator enables IPv6 on an interface during interface creation.

The benefits of the NFM-P IPv6 implementation include:

- integration with existing IPv4 configurations on many property and configuration forms
- automatic validation of IP addresses on the client GUI, regardless of the IP version
- support of compressed IPv6 addresses when repeated address octets are present
- support for IPv6 statistics
- simultaneous IPv4 and IPv6 support by routing protocols
- separate IPv4 and IPv6 administrative and operational states on an interface

28.3.5 Accepted IPv6 address formats

The NFM-P accepts IPv6 addresses in the following formats:

- colon-hexadecimal, or *x:x:x:x:x:x:x:x*
  where *x* is a 16-bit hexadecimal number from 0 to FFFF
- a combination of colon-hexadecimal and dotted-decimal, or *x:x:x:x:x:x:d.d.d.d*
  where
  x is a 16-bit hexadecimal number from 0 to FFFF
  d is an 8-bit decimal number from 0 to 255

Using a combination of colon-hexadecimal and dotted-decimal formats may be convenient in an environment that supports the use of IPv4 and IPv6 addresses.

The NFM-P allows IPv6 address compression for an address that contains repeated zero values. You can use two adjacent colons to represent any group of repeated zero values in an IPv6 address. For example:

2001:DB8::

expands to

2001:0DB8:0000:0000:0000:0000:0000:0000

It is not necessary to supply the leading zeros for a number in an IPv6 address. For example, 2001:DB8::3C:5 is a valid IPv6 address.

28.4 BFD

28.4.1 Overview

Bidirectional Forwarding Detection (BFD) is a communication error detection protocol. BFD can provide failure detection on any kind of bidirectional path or link between systems, including physical links, virtual circuits, LAGs, and MPLS LSPs. When BFD is in use, switches periodically exchange BFD Hello packets over each path between them. If a switch stops receiving BFD Hello packets after a configured interval, the neighboring switch, or the path hop, is assumed to have failed.

BFD global configuration is performed in the NE properties.

BFD sessions are enabled at the path or interface level, for example, in the properties of an LSP.

Seamless BFD

Seamless BFD (SBFD) offers a streamlined version of BFD. An SBFD module allocates SBFD session discriminators to local entities and distributes them to remote entities. The advertised discriminator information allows remote entities to more quickly initiate and perform BFD connectivity testing.

28.5 BGP

28.5.1 Overview

BGP is an inter-AS routing protocol. An AS is a network or a group of devices logically organized and controlled by a common network administration. BGP enables devices to exchange network reachability information. AS paths are the routes to each destination. There are two types of BGP: IBGP and EBGP.

- IBGP is used to communicate with peer devices in the same AS. Routes received from a device in the same AS are not advertised to other devices in the same AS but can be advertised to an EBGP peer.
- EBGP is used to communicate with peers in a different AS. Routes received from a device in a different AS can be advertised to both EBGP and IBGP peers.

See 79.1.6 “Inter-AS connections” (p. 2517) in “VPRN service management” (p. 2513) for more information about connecting ASs in a VPRN.

You can use the NFM-P to enable BGP on the device and perform the following functions:

- set the AS values for the routing instance
- create confederations of group-managed devices

- create BGP peer groups
- create neighbors (peers) within the BGP peer groups

The NFM-P supports the configuration of IPv6 addresses for BGP peering on the base routing instance of supporting devices.

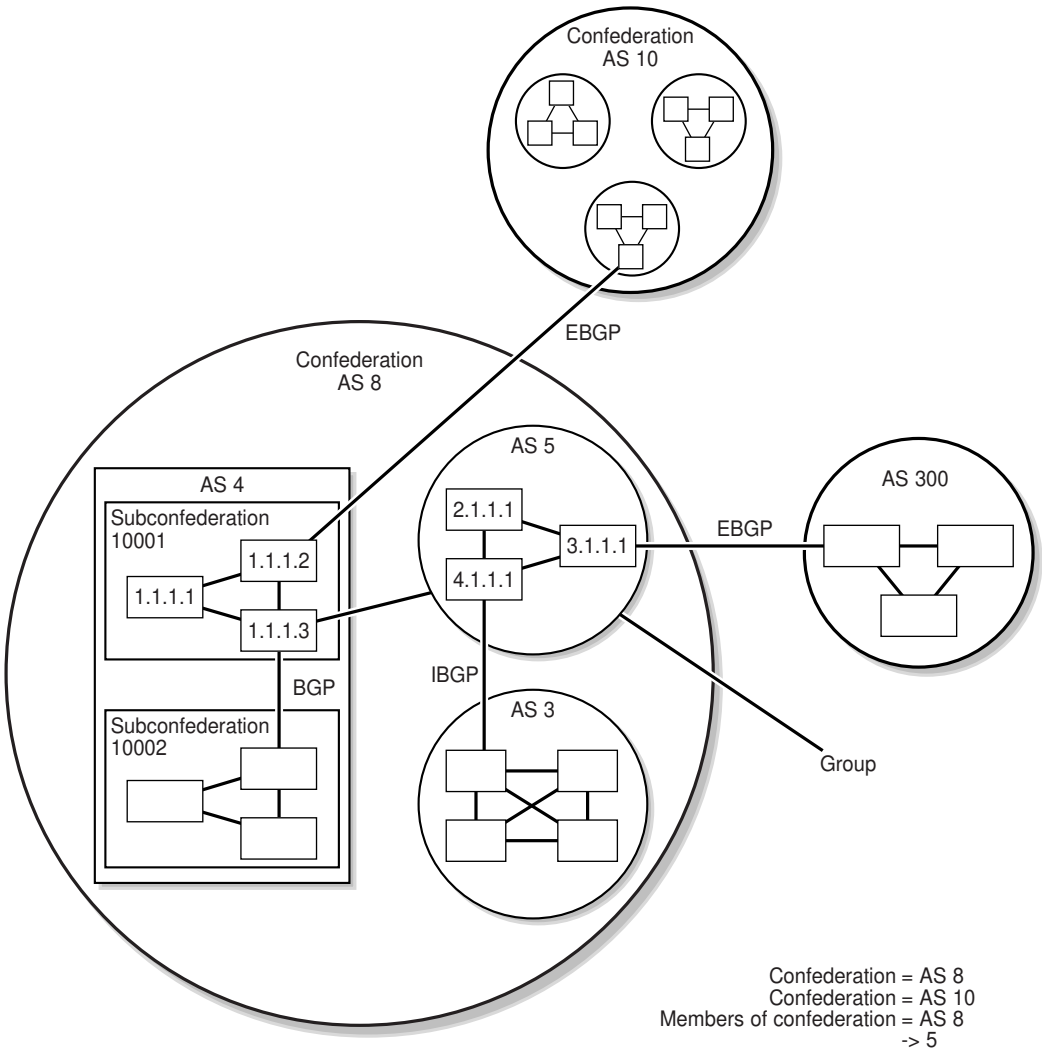
The base BGP routing instance and the policy statement support MVPN IPv6 on supporting devices.

The NFM-P supports IPv4 and IPv6 routes with and without implementation labels. The base router maintains separate BGP RIBs for each of the following types of routes: IPv4, label-IPv4, IPv6 and label-IPv6. Each VPRN maintains separate BGP RIBs for each of the following types of routes: IPv4, label-IPv4 (if CSC is enabled), IPv6 and label-IPv6.

A device can only belong to one AS. After the neighbor relationship is established between devices, they exchange BGP open messages, which contain information such as AS numbers, BGP versions, router IDs, hold-time values, and keepalive messages. This information determines the status of the BGP session. Peer relationships are defined by configuring the IP addresses of the devices that are peers of the local BGP system.

The following figure shows a simple BGP example using groups, subconfederations, and confederations.

Figure 28-1 BGP example



In a standard BGP configuration, all BGP-enabled devices within an AS have a full mesh of BGP peerings to ensure all externally learned routes are redistributed through the entire AS. This is needed because IBGP does not re-advertise routes learned from one IBGP peer to another IBGP peer. However, as more devices are added, scaling the IBGP mesh can become an issue. You can use the following subdividing methods to solve this scaling issue:

- BGP confederations: subdivides a large AS into smaller ASs yet still advertise as a single AS to external peers. The intent is to reduce IBGP mesh size.
- Subconfederations: further subdivide ASs; within each smaller AS, or confederation, IBGP is still used, however EBGP is used between subconfederations. This means less meshing between peers is required.
- Route reflector: ASs are divided into groups called clusters. Each cluster contains at least one route reflector. The route reflector redistributes routing updates to all devices in its cluster. Because the route reflector provides all the routing updates, the other devices in the cluster do not maintain a BGP mesh.
- BGP Optimal Route Reflection (BGP-ORR): BGP-ORR uses IGP on a route reflector to advertise the best path to the BGP-ORR client groups.

  Client groups sharing the same or similar IGP topology can be grouped as one BGP peer group, with BGP-ORR enabled. You can configure one of the client NEs as the primary NE for BGP-ORR so that the IGP metric from that NE is used to select the best path and advertise it to the clients in the same BGP peer group. Optionally, you can also select other NEs as secondary or tertiary backup NEs, to be used when the primary NE goes down or is unreachable.

By default, BGP routers will advertise only the best path to other BGP peers. When the best path fails or a better path is discovered, the old routing information is overwritten. If BGP PIC Add-Path is enabled, peers will advertise multiple paths for the same destination, all of which will be retained in their routing tables. In the event of a failure or path withdrawal message, the router is able to update its forwarding entry for that destination without having to receive new path advertisements. This results in faster convergence after path failure.

28.5.2 MP-BGP

MP-BGP is an extension to BGP that allows different types of addresses (known as address families) to be distributed in parallel. Standard BGP only supports IPv4 Unicast addresses; MP-BGP supports both IPv4 and IPv6 addresses and supports Unicast and Multicast variants of each. MP-BGP allows information about the topology of IP multicast-capable routers to be exchanged separately from the topology of normal IPv4 Unicast routers. The routes associated with multicast routing are used by PIM to build multicast data distribution trees.

BGP distributes IP routing information between networks. The distribution of IP routing information between VPRNs requires MP-BGP. MP-BGP addressing uses an 8-byte RD with a 4-byte or 16-byte IP address, depending on whether IPv4 or IPv6 is used. The requirements for MP-BGP configuration are the following.

- MP-BGP must be enabled on the participating PE devices.
- All PE devices must be configured as BGP peers.

When PE devices learn routing information from the CE devices in a VPRN configuration, the routing information is shared using MP-BGP. The RD is used to associate the new routing information with a VPRN instance.

The PE devices distribute the route information to the other CE devices in the VPRN. Each learned route is assigned an MPLS label that is distributed to the devices.

When customer packets arrive at a PE device, the packets are encapsulated with the MPLS label that corresponds to the learned route for the packet destination.

The MP-BGP multicast extension can be applied to build separate routing tables for multicast paths. IGPs such as OSPF and IS-IS can import multicast and Unicast routing information to the multicast and Unicast routing tables. The multicast routing information can subsequently be used by PIM to perform RPF lookups.

28.5.3 BGP SIDR prefix origin validation

BGP SIDR prefix origin validation can help prevent BGP prefix spoofing. BGP speakers access cryptographically secured information about the AS numbers that are authorized to originate routes for different prefixes.

If a BGP speaker that supports SIDR prefix origin validation receives a route from an EBGP peer and the origin AS of the route is incorrect for the advertised prefix, the route is considered invalid and may be given a lower preference or not propagated further. When a device is configured with RPKI router sessions, the device stores the information it receives from cache servers in a local database called the origin validation database. The entries in this database are called VRP (Validated ROA Payload) entries.

See 28.34 “To configure BGP SIDR prefix origin validation” (p. 930) for information about configuring BGP SIDR prefix origin validation.

28.6 BMP

28.6.1 Overview

BMP is a protocol used for monitoring BGP sessions. BMP allows a BGP router (BMP client) to advertise unprocessed routing information it has received from its peers to a monitoring station. The peer can be configured to send pre policy route information, post policy information, or both. The monitoring station can then monitor routing table size, identify issues and monitor trends in table size and update and withdraw frequency.

A BMP client is configured to create monitoring sessions using TCP with one or more monitoring stations.

The following are some of the messages provided by BMP during a monitoring session:

- Route Monitoring: the initial dump of all routes received from a peer and ongoing updates to the list of paths advertised by a peer
- Statistics Reports: output of statistics sent periodically to the monitoring station
- Peer Up Notification: sent whenever a peering session is established
- Peer Down Notification: sent whenever a peering session is terminated, including reasons for termination

28.7 RIP and RIPng

28.7.1 Overview

RIP is an IGP that uses a distance-vector algorithm to determine the best route to a destination, using hop count as the deciding factor. In order for the protocol to provide complete information about routing, every device in the domain must participate in the protocol. RIP, a UDP-based protocol, updates its neighbors, and the neighbors update their neighbors. RIP advertises IPv4 routing information, and RIPng advertises IPv6 routing information.

Unlike OSPF and other link-state protocols, RIP directly advertises reachability information to its neighbors. RIP advertises reachability information by sending prefix, mask, and either hop count or cost metric data. Each device running the RIP protocol advertises all RIP devices periodically by sending RIP update PDUs. The route with the lowest metric is advertised as the best route.

The NFM-P supports the configuration of RIPv1 and RIPv2 on network and access interfaces, as well as on IES and VPRN subscriber interfaces and group interfaces.

The NFM-P supports the configuration of IPv6 addresses for RIP on the base routing instance of the 7750 SR (chassis modes C and D, and chassis modes A and B with mixed mode enabled) and the 7705 SAR-Hm.

28.8 LDP

28.8.1 Overview

LDP is used to distribute labels in non-traffic-engineered MPLS applications. Routers can establish LSPs across a network by mapping network-layer routing information directly to the data link layer switched paths. After the LDP distributes the labels to the LSR, the LSR assigns the label to an FEC, and then informs all other LSRs in the path about the label and how the label switches data accordingly.

An FEC is a collection of common actions associated with a class of packets. LDP helps establish the LSP by providing a set of procedures that LSRs can use to distribute labels.

When a service tunnel is configured on managed routers using LDP signaling in an MPLS environment, LDP sessions are set up based on the configured hello and other PDU values. If another service tunnel is created to the same destination, the LDP session is reused.

The LDP sessions between LSRs:

- find and establish LDP peers in the managed network
- exchange label mappings for each LSR
- exchange label bindings

After all the LSRs are LDP-aware and the LSP is created, forwarding can occur as follows:

1. An FEC is associated with the LSP.
2. The FEC maps the packets to the LSP.

3. The next LSR that is part of the LSP splices incoming FEC labels to the outgoing FEC label of the next hop.

There are three types of LDP:

- T-LDP
- LDP DU
- LDP DoD

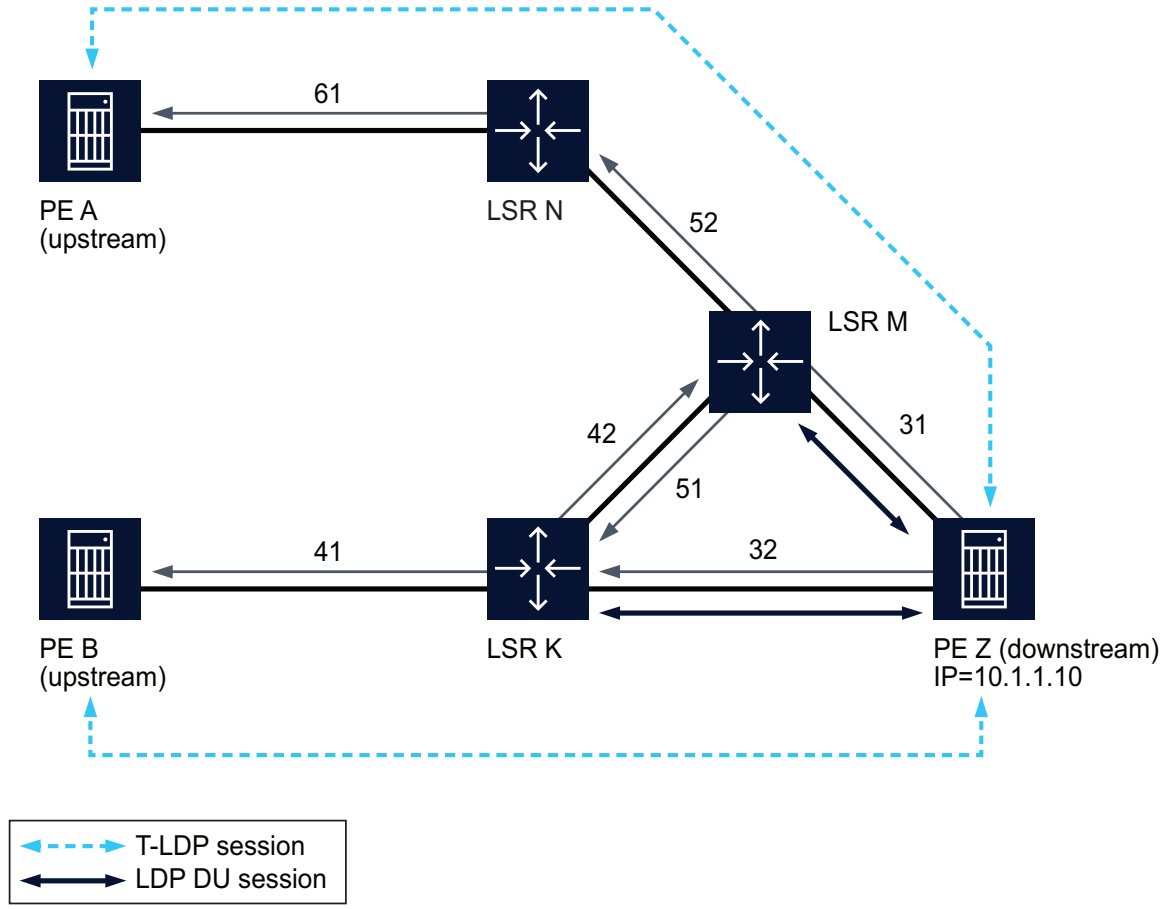
T-LDP is used to distribute labels for VLL and VPLS. T-LDP allows the targeting of remote devices that are not directly connected as targeted peers.

LDP DU can be used to create tunnels between PEs for IP-VPN services.

LDP DoD allows LDP peers to request label bindings for specific FECs.

The following figure shows an example of LDPs that are used in a simple Layer 2 and Layer 3 service provider network.

Figure 28-2 LDP sample network



- The solid straight lines between the devices indicate IP connectivity. These are directly connected peers.
- The dotted bidirectional curved lines indicate T-LDP sessions. These are targeted peers that are not directly connected.
- The solid bidirectional curved lines indicate LDP DU sessions. This example only shows two instances, between M and Z, and Z and K. If there is IP connectivity between all the devices, then all of the devices have LDP DU sessions.

Provider edge router Z advertises the labels for its address 1.1.1.10 to adjacent link state devices M and K. Routers M and K distribute the labels for that address to the rest of the network.

If provider edge router A wants to send a VPN-labeled packet to router Z, it uses label 61 as the outer label. When the packet reaches router N, outer label 61 is swapped for outer label 52 and the packet continues downstream to router M. Router M then swaps out label 52 for either outer label 31 or 42, depending on the router M label selection algorithm. If outer label 31 is selected, the packet reaches router Z directly, which then continues to route the packet to the customer site based on the VPN label.

If a router receives more than one request for an IP address, and the router does not support ECMP, it selects the first label it receives. If the router supports ECMP, it selects the label with the lowest cost path, or selects both labels if the cost paths are identical.

When a router supports ECMP, LSRs can have multiple equal cost paths to an IP address. ECMP LDP retains all labels it receives from multiple next hop peers. The forwarding plane contains multiple next hops for an FEC and as a result, provides load balancing for LDP-based LSPs.

When a router supports ECMP LDP and a device configured as the next hop is no longer valid, for example a session between peers is lost or the peer withdraws its label, a new valid LDP next hop peer is selected and the forwarding plane is updated.

Load balancing across LSPs for LDP over RSVP is also supported. When ECMP is enabled, all equal cost LSP endpoints are installed in the routing table by the IGP for consideration by LDP. LDP selects the LSP with the lowest LSP metric to determine the next hop. If multiple LSPs are available with equal cost, then ECMP is utilized until the ECMP count is exhausted. An LDP tree is created by sending LSP Trace messages along an ECMP path to downstream LSR NEs.

Weighted ECMP is supported for fine control of load balancing, especially where capacity of local links is unequal or variable.

28.8.2 LDP for P2MP

LDP support for P2MP can be enabled on an LDP interface. You can configure an LDP interface for multicast traffic forwarding towards a downstream NE. LDP configuration allows an exchange of P2MP FEC via an established session to a peer, and the use of next hops over an interface.

LDP configuration is supported on a tunnel interface under a base routing instance and under protocols such as PIM and IGMP. A P2MP ID is used as an index for LDP-based tunneling instead of an LSP ID.

Note: BFD and source redundancy are only supported on an RSVP tunnel interface.

28.9 IS-IS

28.9.1 Overview

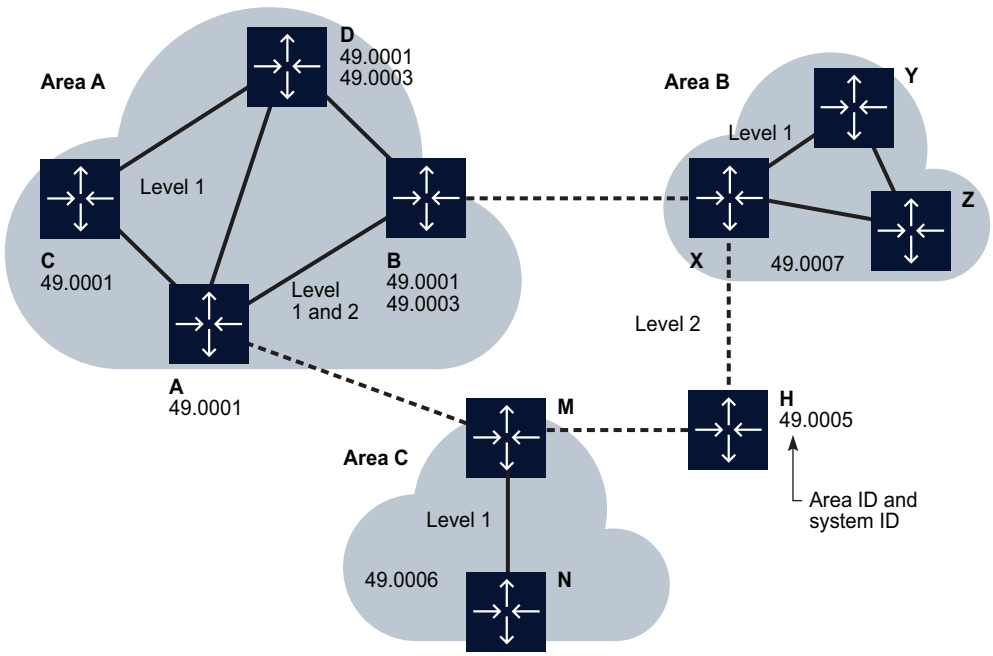
IS-IS is a link-state interior gateway protocol that uses the shortest path first algorithm to determine a route. Routing decisions are made using the link-state information. IS-IS entities include:

- networks, which are autonomous system routing domains
- intermediate systems, which are routers
- end systems, which are network devices that send and receive PDUs

End systems and intermediate system protocols allow devices and NEs to identify each other. The IS-IS protocol sends link state updates periodically through the network, so each device can maintain current network topology information.

Large networks, or autonomous systems, are supported by IS-IS using a two-level hierarchy. This divides a large area into more manageable, smaller areas. The first level (level 1) of routing is performed within an area. The second level (level 2) of routing is performed between areas, as shown in the following figure.

Figure 28-3 IS-IS routing areas example



Level 2 areas are also called backbones, similar to an OSPF backbone area. All traffic traversing different areas must traverse the backbone. A device can be configured as level 1, level 2, or both level 1 and 2. In this example, routers A, B, M, H, and X form the level 2 IS-IS backbone. The connection between routers A and B carries both level 1 and level 2 link-state PDUs (LSPs).

However, level 1 devices are only aware of their own area's topology, and must forward traffic to a level 1/2 device to forward the data to another area.

Two devices are in the same level 1 area when they have level 1 adjacency. Level 1 adjacency occurs when the area IDs are common and there is a level 1 connection between the devices. Level 2 adjacency occurs when it has at least one level 1 and 2, or one level 2 interface configured.

The NFM-P supports the configuration of IPv6 addresses for IS-IS adjacencies.

Note: If two neighboring devices in the same level 1 area run both level 1 and 2, they establish both a level 1 and a level 2 adjacency.

When LDP over RSVP is enabled for IS-IS, LSPs can be used by the IGP to calculate its SPF tree. The IGP then provides LDP with all of the ECMP IDP next-hops and tunnel endpoints that the IGP identifies as the lowest cost path to the destination. If an IGP calculation and an LDP over RSVP have the same cost, LDP chooses an LDP over RSVP tunnel over an IGP route and ECMP between the two types is not considered. The type and number of tunnels that are to be considered by LDP depend on the IGP costs, where the lowest cost between the tunnel endpoint and the target is selected.

After IS-IS is configured, routing occurs as follows:

1. Hello PDUs are sent to IS-IS-enabled interfaces to discover neighbors and establish adjacencies.
2. IS-IS neighbor relationships are formed.
3. Link-state PDUs (LSPs) are created based on local interfaces and prefixes that are learned from adjacent devices.
4. The devices flood LSPs to adjacent neighbors, and build a link-state database.
5. A shortest path tree is calculated by the IS-IS and the routing table is built.

28.9.2 Flexible Algorithm support

Flexible IGP algorithms allow IGPs to compute constraint-based paths over the network. A flexible algorithm definition can be configured for each NE in the global NE properties. The flexible algorithm definition provides topology constraints on a per-NE basis. A flexible algorithm definition requires an administrative group; see 54.13 "To configure an administrative group policy" (p. 1758).

A set of flexible algorithm definitions creates a flexible algorithm topology. If flexible participation has been configured on an ISIS instance, the IGP uses constraint-based shortest path first and the flexible algorithm definitions to find the best paths through the flexible algorithm topology.

28.9.3 IPv6 Traffic Engineering support

The NFM-P supports IPv6 Traffic Engineering (TE) extensions for IS-IS.

In addition, ISIS supports advertising which protocol is enabled on a given TE-link (SR-TE, RSVP-TE, or both) via the Application Specific Link Attributes sub-TLV. This allows the advertising router to send potentially different Link TE attributes for RSVP-TE and SR-TE applications.

To enable this feature, in summary, you must:

- configure the Interface Name parameter in the routing instance. The IP address of the specified interface is used as the IPv6 Traffic Engineering Router ID.
- configure traffic engineering on the ISIS Site.

28.10 OSPFv2 and OSPv3

28.10.1 Overview

OSPF is a hierarchical link-state interior gateway protocol that operates within ASs and is used in IP networks. OSPFv2 applies to IPv4 addressing whereas OSPFv3 applies to IPv6 addressing. OSPFv2 is defined in RFC 2328; OSPFv3 is defined in RFC 5340.

OSPF packets are routed based on the destination IP address of the IP packets. Each OSPF router collects link-state information to build a network topology based on OSPF areas. This topology is used to apply the Dijkstra algorithm to calculate the shortest path to each destination in the network.

OSPFv3 can run in Sparse or Only mode. In Sparse mode OSPFv3 uses Legacy LSAs to compute the shortest path and extended LSA is used by segment routing. In Only mode OSPFv3 uses extended LSA for SPF computation. See the appropriate device documentation for more information about OSPF.

When LDP over RSVP is enabled for OSPF, LSP can be used by the IGP to calculate its SPF tree. The IGP then provides LDP with all of the ECMP IDP next-hops and tunnel endpoints that the IGP identifies as the lowest cost path to the destination. If an IGP calculation and an LDP over RSVP have the same cost, LDP chooses an LDP over RSVP tunnel over an IGP route and ECMP between the two types is not considered. The type and number of tunnels that are to be considered by LDP depend on the IGP costs, where the lowest cost between the tunnel endpoint and the target is selected.

28.10.2 Flexible Algorithm support

Flexible IGP algorithms allow IGPs to compute constraint-based paths over the network. A flexible algorithm definition can be configured for each NE in the global NE properties. The flexible algorithm definition provides topology constraints on a per-NE basis. A flexible algorithm definition requires an administrative group; see 54.13 “To configure an administrative group policy” (p. 1758).

A set of flexible algorithm definitions creates a flexible algorithm topology. If flexible participation has been configured on an OSPF instance, the IGP uses constraint-based shortest path first and the flexible algorithm definitions to find the best paths through the flexible algorithm topology.

28.10.3 OSPF areas

The hierarchical design of OSPF allows a collection of networks to be grouped into a logical OSPF area. The topology of the area is hidden from the rest of the AS, which significantly reduces OSPF protocol traffic. Routing in the AS takes place on two levels, depending on whether the source and

destination of a packet reside in the same area (intra-area routing) or different areas (inter-area routing). In intra-area routing, the packet is routed solely on information obtained within the area; routing information obtained from outside the area is not used. Routers that belong to more than one area called an ABR. An ABR maintains a separate topological database for each area it is connected to. Every router that belongs to the same area has an identical topological database for that area.

28.10.4 OSPF neighbors

Routers in the same broadcast domain or at each end of a point-to-point telecommunications link form adjacencies when they detect each other. The detection occurs when a router identifies itself in a hello OSPF protocol packet. This is called a two-way state and is the most basic relationship. The routers in an Ethernet or frame relay network select a designated router and a backup designated router which act as a hub to reduce traffic between routers. OSPF uses both Unicast and multicast to send hello packets and link state updates.

The OSPF protocol establishes and maintains neighbor relationships in order to exchange routing updates with other routers. The neighbor relationship table is called an adjacency database in OSPF. Provided that OSPF is configured correctly, OSPF forms neighbor relationships only with the routers directly connected to it. In order to form a neighbor relationship between two routers, the interfaces used to form the relationship must be in the same area. An interface can only belong to a single area.

28.10.5 OSPF super-backbone

The OSPF super-backbone provides an additional layer of hierarchy in OSPF. The OSPF super-backbone functions include:

- loop prevention
- handling LSAs received from the CE
- managing VPN IPv4 routes received by BGP

The PE routers that connect OSPF areas to the super-backbone function as ABRs in the OSPF areas to which they are attached. To achieve full compatibility, the PE routers can also serve as ASBRs in non-stub areas.

PE routers insert inter-area routes from other areas into the area in which the CE router is present. The CE routers are not involved at any level and are not aware of the super-backbone or other OSPF areas that exist outside of the super-backbone.

When you configure the super-backbone, all destinations that are learned by PEs with matching domain IDs become inter-area routes.

See the appropriate device documentation for more information about the OSPF super-backbone.

28.11 Segment routing

28.11.1 Overview

Segment routing enables an IGP to perform shortest path routing and source routing using segments. A segment can represent a local prefix of an NE, a specific adjacency of the NE, a

service context, or a specific explicit path over the network. For each segment, the IGP advertises a segment identifier, or SID. The SID can be used to resolve forwarding in several contexts, such as BGP labelled routes, VPRN and EVPN auto-binding of tunnels, and remote loop-free alternate.

When segment routing is used together with MPLS, the segment identifier is a standard MPLS label. An NE forwarding a packet using segment routing pushes one or more MPLS labels. See 31.6 “To configure an MPLS instance” (p. 1116) for more information about how to configure the segment routing label range.

Each prefix SID represents a network global IP address. Therefore the SID index for a prefix must be unique in the network. All routers in the network are expected to configure and advertise the same prefix SID index range for an IGP instance. However, the label value used by each router to represent this prefix can be local to that router with the use of a start label.

Two mutually exclusive prefix SID types can be configured: global and local.

With the global prefix SID type, the IGP instance assumes the start label value is the lowest label value in the SRGB and the prefix SID index range size is equal to the range size of the SRGB. If the global option has been selected for one IGP instance, all IGP instances on the system will be restricted to do the same.

With the local prefix SID type, the user configures a subset of the SRGB by specifying the start label value and the prefix SID index range size. Note that all resulting net label values (start-label + index) must be within the SRGB or the configuration will fail. Also, the NFM-P checks for overlaps of the resulting net label value range across IGP instances and will strictly enforce that the ranges do not overlap.

You can use the NFM-P to configure segment routing and to assign an SID index or label to ISIS and OSPF instances; see 28.79 “To configure IS-IS segment routing” (p. 978) and 28.80 “To configure OSPF segment routing” (p. 980).

28.11.2 Segment routing policy

A segment routing policy specifies a source-routed path from a head-end router to an end-point, and it specifies the traffic flows that should be steered into that source-routed path. An SR policy can be explicitly configured or learned from a protocol such as BGP or PCEP. For information about configuring a BGP site to learn segment routing policies, see 28.78 “To enable SR policy support on a BGP site, peer, or peer group” (p. 977). For information about creating a segment routing policy, see 28.77 “To create a segment routing policy” (p. 976).

28.11.3 Segment routing tree

A segment routing tree is an SID based multicast tree. It is very similar to a P2MP LSP.

An SR tree policy can be used in the same manner as a P2MP RSVP-TE or mLDP, for example, it can be used as a provider tunnel under an MVPN.

An SR tree policy represents a multicast tree from a root to a set of leaves. The SR tree policy can contain redundant trees, each with its own preference. This redundancy is presented via candidate paths. Each candidate path represents a P2MP tree with its own traffic engineering constraints. These candidate paths can be optimized based on link failures or IGP optimizations. As such each candidate path can contain multiple P2MP LSPs represented by path Instance IDs. The candidate path can perform make before break between these path instances. The candidate path with the highest preference becomes the active candidate path.

An SR tree policy is relevant only on the root node where the segment routing tree is instantiated. An SR tree policy does not have any forwarding information for the P2MP LSP. It only contains root and leaf information and the traffic engineering information for the tree to be set up from the root to the leaves. The forwarding information is part of the replication policy. Therefore the transit and leaf nodes only contain the replication policy.

For information about creating a segment routing tree, see 28.81 “To create a segment routing tree” (p. 981).

Replication segments

A replication segment is a forwarding instruction for a P2MP LSP. It contains the incoming replication SID and a set of outgoing interfaces and their corresponding set of outgoing labels. A replication policy consists of a treeID, rootID and path-instanceID (LSP-ID). If a replication segment is shared between multiple roots or P2MP LSPs, it does not have a rootID. A shared replication segment has a replication segment identifier denoted in the treeID. This type of replication segment can be used for FRR.

28.11.4 Segment Routing with IPv6

SR-IPv6 allows Segment Routing to be deployed over non-MPLS networks and/or in areas of the network where MPLS is not present. An IPv6 packet consists of an IPv6 header, extension headers, and payload. The Segment Routing header (SRH) is an extension header added to IPv6 packets to implement Segment Routing IPv6 (SRv6) based on the IPv6 forwarding plane. It specifies an IPv6 explicit path and stores IPv6 segment lists that function in the same way as segment lists in SR-MPLS.

The segment lists in an SRv6 SRH are processed from the bottom up, which is different from SR-MPLS processing. Another difference between SRv6 and SR-MPLS is that segments in SRv6 SRHs are not removed after being processed by nodes.

SRv6 segments are identified using segment identifiers (SIDs) encoded as IPv6 addresses. An SRv6 SID consists of two parts: Locator and Function. The Locator part provides the location function. The Function part identifies an instruction bound to the node that generates the SRv6 SID.

Each SRv6-capable node keeps a local SID table containing all SRv6 SIDs generated on the node. The destination SID identifies a destination node. It is similar to a node SID in SR-MPLS. In shortest path routing, the destination SID is encoded in the Destination Address (DA) field of the outer IPv6 header. Unlike usual segment routing, SID value is derived from the locator prefix configured and the end function.

SRv6 is supported from NFM-P Release, 22.2 R1 onwards.

28.12 RSVP

28.12.1 Overview

RSVP is a network control protocol that hosts use to request specific qualities of service from the network for specific data streams. RSVP is also used to deliver QoS requests to all devices in a data path and to establish and maintain the state information required to provide the requested service quality.

RSVP is not a routing protocol. RSVP operates using Unicast and multicast routing protocols.

RSVP consults local routing tables to relay RSVP messages. By default, RSVP is enabled on all devices that support it.

RSVP requests typically result in the reservation of resources on each device in the data path. MPLS use this RSVP mechanism to set up traffic-engineered LSPs. RSVP requests resources for unidirectional flows only. RSVP treats a sender as logically distinct from a receiver, although the same application process may act as both a sender and a receiver.

The RSVP hello protocol detects the loss of a neighbor NE or the reset of a neighbor RSVP state information. In standard RSVP, neighbor monitoring occurs as part of the RSVP soft-state model. The reservation state is maintained as cached information that is first installed and then periodically refreshed by the ingress and egress LSRs.

If the state is not refreshed within a specified time interval, the LSR discards the state because it assumes that either the neighbor NE has been lost or its RSVP state information has been reset.

28.12.2 Diff-Serv Traffic Engineering support

The NFM-P supports Diff-Serv Traffic Engineering, or TE, extensions for RSVP. Diff-Serv TE extensions provide the ability to manage bandwidth in an MPLS network on a per-TE-class basis. With Diff-Serv TE, an LER can perform this on a per-class basis. Therefore, you can set different limits for admission control of LSPs in each TE class over each link in the network.

You do this by setting a bandwidth constraint, which configures the percentage of the RSVP interface bandwidth that each CT shares. The absolute value of the CT share of the interface bandwidth is derived as the percentage of the bandwidth advertised by IGP in the Maximum Reservable link bandwidth TE parameter, that is, the link bandwidth multiplied by the RSVP interface subscription parameter.

This configuration also exists at the RSVP interface level and the value specifically configured for the interface overrides the globally-configured value. The bandwidth constraint value can be changed on the fly. You are also allowed to specify the bandwidth constraint for a CT which is not used in any of the TE class definitions and which is not used by any LSP originating or transiting this NE.

To enable this feature, in summary, you must:

- configure Diff-Serv Classes on the router RSVP Routing Instances
- configure protocol properties to allow Diff-Serv Classes on the required router RSVP Interfaces
- configure traffic engineering and specify the Class Type that the required dynamic LSPs belongs to
- configure the Diff-Serv Class Type that the required LSP Paths belongs to. This overrides the value set at the LSP level.
- configure Diff-Serv to LSP FC mappings on the required service tunnels (SDPs). User-entered mappings of FC to LSP name are validated automatically (to avoid configuration conflicts) by checking with the RSVP module.

28.12.3 Dark bandwidth accounting support

The bandwidth availability advertised by IGP in a TE network accounts for RSVP-TE LSP bandwidth requirements. However, other types of labeled traffic may exists on the same links. The bandwidth used by this traffic is called dark bandwidth. You can configure accounting for MPLS-SR related dark bandwidth.

To enable this feature, you must:

- enable collection of Aux Stats, that is, statistics for dark bandwidth, on the MPLS routing instance
- enable and configure dark bandwidth accounting on the required router RSVP Interfaces

28.13 L2TP

28.13.1 Overview

L2TP is a session-layer protocol that extends the PPP model by allowing L2 and PPP endpoints to reside on different devices that are interconnected by a PSN. L2TP extends the PPP sessions between the CPE and PPP/L2TP termination point on the L2TP network server (LNS), via an intermediate L2TP access concentrator (LAC). The LAC is the initiator of session-generated L2TP tunnels; the LNS is the server that waits for new tunnels. Manually configured and initiated L2TP tunnels can be initiated and stopped from either the LNS or LAC.

After an L2TP tunnel is established, the network traffic between the peers is bidirectional. If a tunnel carrying a session fails, another tunnel from the same tunnel group re-establishes the session. Within each L2TP tunnel, one or more L2TP sessions can exist. Each L2TP session transports PPP packets.

The NFM-P supports the configuration and management of the following:

- ISA-LNS groups
- L2TP sites
- L2TP tunnel group profiles
- L2TP tunnel profiles

28.13.2 ISA-LNS groups

The NFM-P supports the creation and configuration of ISA-LNS groups on the 7750 SR. ISA-LNS groups provide LNS PPP session termination. An ISA-LNS group is associated with specific L2TP inbound peers and groups. Session traffic is automatically balanced across the available active ISA broadband application MDAs in the group.

The following operations can be performed on an ISA-LNS group member:

- drain MDA—prevents new sessions from being accepted
- stop drain—allows new sessions to be established
- stop MDA sessions—terminates the active sessions

See 13.12 “To configure an ISA-LNS group” (p. 426) for information about creating and configuring an ISA-LNS group.

28.13.3 L2TP sites

By default, L2TP is enabled on a base routing instance, and an L2TP site is created. An L2TP icon appears in the Routing view of the navigation tree. An L2TP site does not exist by default on the base routing instance of a 7450 ESS in non-mixed mode.

Certain LAC parameter values can be configured on an L2TP site which can, in turn, be inherited by any child L2TP tunnel group profiles of the site. The Tunnel Session Limit parameter value can only be inherited by an L2TP tunnel group profile.

A tunnel selection blacklist function provides a means to temporarily suspend (or blacklist) tunnels that return one or more specified return codes, indicating that the tunnel is inoperative. The user can specify the manner in which blacklisted tunnels are handled:

- how many tunnels can be blacklisted at any given time
- how long a tunnel can remain blacklisted
- action taken on a blacklisted tunnel when the maximum blacklist period expires

See 28.89 “To configure L2TP on a routing instance” (p. 989) for information about managing L2TP sites.

L2TP is not enabled by default on a VPRN site. To enable L2TP on a VPRN site, see 79.11 “To configure a VPRN site” (p. 2545) .

28.13.4 L2TP tunnel group profiles

An L2TP tunnel group profile represents the configuration for a group of L2TP tunnels. L2TP tunnel group profiles must be configured on the LNS NE. If a local user database is used on the LAC for session authentication, an L2TP tunnel group profile must be configured on the LAC. When you create an L2TP tunnel group profile, you can configure certain LAC parameter values to be inherited from the parent L2TP site. In turn, the profile can be used by its child L2TP tunnel profile to inherit certain parameter values. The inherited parameter values are used as the default values during L2TP tunnel profile configuration.

The following operations can be performed on an L2TP tunnel group profile that has a configured L2TP tunnel profile:

- drain—prevents new sessions from being accepted
- stop drain—allows new sessions to be established
- stop—closes tunnel instances and terminates the active sessions

See 28.89 “To configure L2TP on a routing instance” (p. 989) for information about managing L2TP tunnel group profiles.

28.13.5 L2TP tunnel profiles

You can create and manage L2TP tunnel profiles from the Tunnel Group Profile properties form. When you create an L2TP tunnel profile, you can configure certain LAC parameter values to be inherited from the parent L2TP tunnel group profile and L2TP site.

The following operations can be performed on an L2TP tunnel profile:

- start instance—attempts to create new tunnels

- stop instance—attempts to close the tunnels
- drain—prevents new sessions from being accepted
- stop drain—accepts new sessions

See 28.89 “To configure L2TP on a routing instance” (p. 989) for information about managing L2TP tunnel profiles.

28.13.6 L2TP tunnel instance endpoints

The endpoints of an operational L2TP tunnel are represented by tunnel instance endpoints. You can view tunnel instance endpoints from the Tunnel Instance Endpoints tab on the L2TP Site (Edit) form, and from the Tunnel Group Profile or Tunnel Profile properties form if the endpoint is created using the profile configuration.

An L2TP tunnel instance endpoint is automatically created when:

- a start operation is performed on an L2TP tunnel profile
- an incoming L2TP session is established using group and tunnel profiles
- RADIUS authentication returns a configuration for the tunnel when an incoming L2TP session is authenticated and PPP session authentication determines that L2TP is used, at which point an L2TP session is established.

The following operations can be performed on an L2TP tunnel instance endpoint:

- drain—prevents new sessions from being accepted
- stop drain—allows new sessions to be established
- stop—closes the tunnel instances and terminates the active sessions
- resync tunnel instance endpoints—updates all L2TP tunnel status objects on a routing instance to the current state

See 28.92 “To view L2TP tunnel instance endpoints on a subscriber instance” (p. 994) for information about viewing L2TP tunnel instance endpoints.

28.13.7 L2TP peers

An L2TP site can have none or multiple L2TP peers. L2TP peer information is available on the Peers tab of the L2TP Site form. Information about L2TP tunnels for a specific L2TP peer is available on the Tunnels tab of the L2TP Peer properties form.

The following operations can be performed on an L2TP peer:

- drain—prevents new sessions from being accepted
- stop drain—accepts new sessions

28.13.8 L2TP tunnels and tunnel endpoints

You can view information about L2TP tunnels and tunnel endpoints from the L2TP Tunnel - Endpoint A - Endpoint B form.

28.13.9 L2TP sessions

You can view information about L2TP sessions from the L2TP Session (View) form. You can access the form from the following places in the GUI:

- Manage Residential Subscribers form
- Sessions tab on the L2TP Site (Edit) form
- Sessions tab on the L2TP Tunnel Instance Endpoint (View) form
- L2TP panel on the PPPoE Session form (LAC only)
- L2TP Session button on the Subscriber Host form (LAC only)

See 28.93 “To view L2TP sessions” (p. 994) for information about viewing L2TP sessions from the Manage Residential Subscribers form.

28.13.10 PPP sessions

You can view information about PPP sessions from the PPP Session, PPPoE Session, and PPPoA Session forms. You can access the forms from the following places in the GUI:

- Manage Residential Subscribers form
- LNS PPP panel in the L2TP Session (View) form (LNS only)
- PPP Session button in the Subscriber Host form

See 28.94 “To view PPP sessions” (p. 995) for information about viewing PPP sessions.

28.14 PIM

28.14.1 Overview

PIM is a component of multicast routing that defines the one-to-many or many-to-many transmission of information. You can use the following variations for PIM configurations:

- sparse mode
- dense mode
- source-specific multicast
- bidirectional

Sparse mode is the most common PIM configuration. Sparse mode is used for data transmission to NEs in multiple Internet domains that contain a small ratio of NEs that subscribe to the multicast traffic. Dense mode is used when a large ratio of the potential NEs subscribe to the multicast traffic. In source-specific multicast, paths originate at a single, defined source. Bidirectional PIM is not source-specific.

28.14.2 Anycast RP

Anycast RP for PIM-SM enables fast convergence when a PIM RP router fails. The receivers and sources rendezvous at the closest RP after the router failure. Anycast RP allows an arbitrary number of RPs for each group in a single, shared-tree PIM-SM domain. Triple play configurations

that distribute multicast traffic using PIM-SM realize the benefits of fast RP convergence, which helps to avoid the loss of multicast data streams or IPTV delivery to the end user.

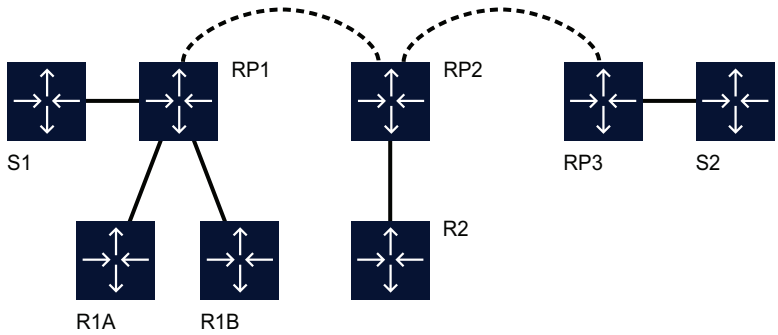
Anycast RP for PIM-SM environments is supported in the base routing PIM-SM instance of the service router, and in VPRN instances that are configured with PIM on supporting NEs.

Anycast RP for PIM requires the completion of the following configuration information:

- An IP address specified as the RP address. This address is statically configured, or distributed using a dynamic protocol, to all PIM routers in the domain.
- A set of routers in the domain designated as RPs for the RP address. These routers form an anycast RP.
- Each of these routers is configured with a loopback interface that uses the RP address. The RP address, or a prefix that includes the RP address, is injected into the unicast routing system inside the domain.
- Each router in the anycast RP also needs a separate IP address, to be used for communication between the RPs.
- Each router in the anycast RP is configured with the addresses of all other routers in the anycast RP. The addresses must be consistently configured in all RPs in the set.

The following figure shows a sample implementation of anycast RP for PIM-SM.

Figure 28-4 Sample implementation of anycast RP for PIM-SM



The following figure summarizes the sequence of events for the Anycast RP implementation shown in Figure 28-4, “Sample implementation of anycast RP for PIM-SM” (p. 902).

Table 28-1 Sequence of events for Anycast RP fast convergence

Sequence	Event description
1	S1 sends a multicast packet.

Table 28-1 Sequence of events for Anycast RP fast convergence (continued)

Sequence	Event description
2	The router connected to S1 forms a PIM registration message to send to the Anycast RP address. The Unicast routing system delivers the PIM registration message to the nearest RP, in this case RP1.
3	RP1 receives the PIM registration message, decapsulates the message, and sends the packet down the shared tree to the R1A and R1B receivers.
4	RP1 is configured with the IP address for RP2 and RP3. Since the registration message did not come from one of the RPs in the anycast RP set, RP1 assumes that the packet came from a designated router.
5	RP1 sends a copy of the registration message from the S1 designated router to RP2 and RP3. RP1 uses its IP address as the source address for the PIM registration message.
6	RP1 can join the source tree by sending a join message to S1. However, RP1 must create a source-specific state.
7	RP2 receives the registration message from RP1, decapsulates the message, and send the packet down the share tree to the R2 receiver.
8	RP2 sends a registration-stop message back to RP1. RP2 can wait to send the registration-stop message if it decides to join the source tree. RP2 should wait until it receives data from the source tree before it sends the registration-stop message. If RP2 does wait for the data, the registration-stop message is sent to RP1 when it receives the next registration message. If RP2 does not wait for the data, the registration-stop message is immediately sent to RP1.
9	RP2 can join the source tree by sending a join message to S1. However, RP2 must create a source-specific state.
10	RP3 receives the registration message from RP1 and decapsulates the message. No receivers joined for the group, so RP3 discards the packet.
11	RP3 sends a registration-stop message back to RP1.
12	RP3 creates a source-specific state, so when a receiver joins after S1 starts sending traffic, RP3 can quickly join the source tree for S1.
13	RP1 processes the registration-stop message from RP2 and RP3. RP1 can cache the receipt of registration-stop messages from the RPs in the anycast RP set. (The cache of messages is completed on a per-RP or per-source-specific basis.) The cache of messages increases the reliability of the delivery of registration messages to each RP. Subsequent registration messages received by RP1 are sent only to the RPs in the anycast RP set that have not previously sent registration-stop messages from the source-specific entry.
14	RP1 sends a registration-stop message to the DR under the following conditions: • after receiving a registration message from the DR • if all RPs in the anycast RP set have returned registration-stop messages for a specific source-specific route

28.14.3 SPT switchover thresholds

SPT switchover thresholds allow you to configure the switchover threshold, in Kbps, for the group prefixes. The threshold value determines when the router switches from the shared tree to the source-specific tree. The switchover is attempted only if the traffic rate on the shared tree for the group exceeds the configured threshold.

28.14.4 L3 Multicast Load Balancing for ECMP

The NFM-P distributes multicast traffic by balancing the load based on the total available multicast bandwidth on all ECMP paths. You can configure ECMP rebalancing on the VPRN and base PIM Routing Instance configuration forms.

NFM-P ECMP rebalancing has the following important characteristics:

- Multicast load balancing over ECMP links is enabled, by default.
- The rebalancing timer is set to 30 minutes, by default.
- Distribution of the multicast groups over the available links is processed based on the bandwidth configured for the specified group address. If the bandwidth is not configured for the multicast stream, then the configured default value is used.
- If a link failure occurs, the load on the failed channel is distributed to the remaining channels. The bandwidth required to accommodate the load from the failed link is evenly distributed over the remaining links.
- If an additional link becomes available for a specific multicast channel, it is then treated in an equivalent manner to the other links of the interface.
- A manual (operator-initiated) re-balance command is typically used to re-evaluate the current balance, with regard to bandwidth utilization. If necessary, multicast streams can subsequently be moved to different links to achieve a balance.
- In an automatic timed re-balance, the system re-balances multicast streams over the available links, based on the configured bandwidth and interval. If no links have been added or removed, or it is determined that no multicast streams will benefit from a re-balance, then it is not be implemented.
- When multicast load re-balancing is not enabled, any ECMP changes are not optimized. However, whenever a link is added, an attempt is made to balance the number of multicast streams on all the available ECMP links. This may however, not result in balanced bandwidth utilization of all the ECMP links.
- Only a single re-balance command can be executed at any specific time. If a re-balance is in progress and a manual re-balance command is entered, it is rejected and a message is displayed informing the user who a re-balance is already in progress.

28.14.5 VRRP-aware PIM

VRRP aware PIM enables PIM to track the state of a VRRP instance and know if the associated VRRP interface is the master. This feature is supported on base router, IES and VPRN interfaces.

PIM monitors the state of the VRRP interface using an operational group. The operational group is up when the VRRP interface is the master, and down for all other VRRP states. A VRRP instance can only be associated with one operational group, and an operational group can only have one associated VRRP instance.

If the monitored interface is the VRRP master, PIM becomes the DR by setting its priority to the configured Operational DR Priority value. Priorities must be configured so that the Operational DR Priority is the highest priority on the IP interface.

If a PIM router is the DR and then receives an indication from VRRP that the interface is no longer the VRRP master, PIM will relinquish the DR role by setting its priority back to the default or configured priority value.

If the VRRP instance or operational group is not configured, PIM will operate as normal with the default or configured priority value.

Two operational groups are supported per PIM interface, one for IPv4 and one for IPv6. A change in operational group status is address family independent; IPv4 and IPv6 priorities are configured independently of each other.

28.15 IGMP

28.15.1 Overview

IGMP is a multicast protocol which service providers can use to establish multicast group memberships on a LAN. Within the LAN, end users use IGMP to communicate with a local multicast router, which then uses PIM to distribute the IGMP messages to other local and remote multicast routers. Multicast routers send regular membership queries to IGMP hosts which respond with membership reports. Multicast routers can use these reports to determine which hosts are interested in receiving particular multicast messages.

Configuring a group interface query source IP address on the IGMP site allows a VPLS IGMP snooping instance to register the port facing an ESM port as a multicast router port.

In a multi-chassis implementation on an NE configured with active/active MC-LAG, multicast IGMP traffic from an access network is forwarded to both multicast redirection interfaces. This would cause the downstream device to receive duplicate IGMP messages. The Redundant Multicast option allows you to identify a single IGMP interface as the designated forwarder to the redirection interface, ensuring that the downstream device only receives the IGMP traffic once.

IGMP operates above the network layer on IPv4 networks.

28.16 MSDP

28.16.1 Overview

MSDP is a protocol that enables multiple PIM-SM domains to communicate with each other using their own RPs. MSDP also enables multiple RPs in a single PIM-SM domain to establish MSDP mesh-groups and to synchronize information between anycast RPs about the active sources being served by each anycast RP peer. The 7950 XRS, 7750 SR, and the 7450 ESS in mixed mode support MSDP.

Each PIM-SM domain has its own RPs and MSDP enables these RPs to inform each other about active sources. When an active source is detected, the RPs send PIM-SM explicit join messages to the active source. When RPs in remote domains know about active sources, they can pass on this information to their local receivers and multicast data can be forwarded between the domains.

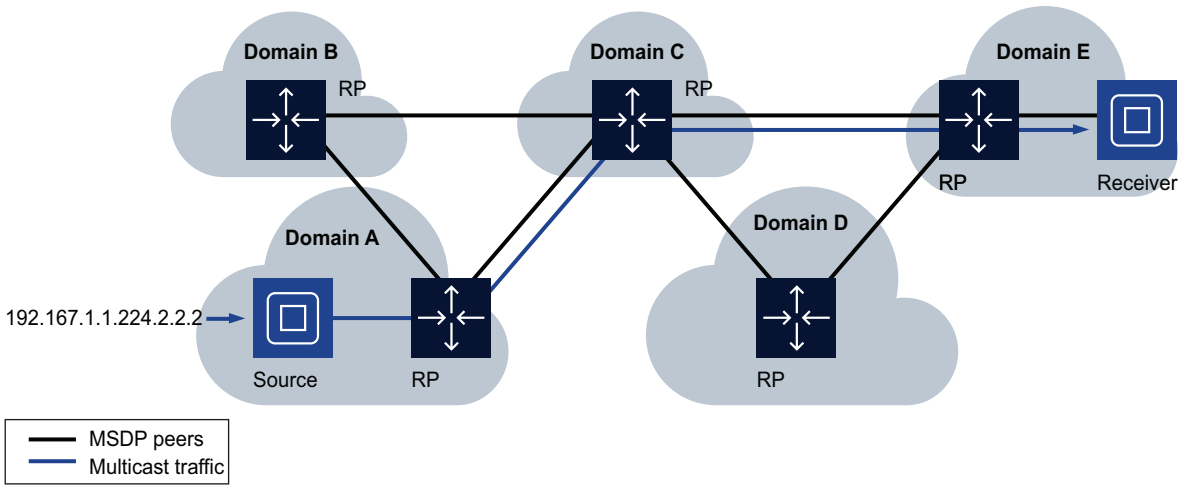
The RP learns about a new multicast source within its domain through the PIM register mechanism and encapsulates the first data packet in a source active message. After an RPF check, the MSDP source active message is flooded by each peer to its MSDP peers until it reaches every MSDP router in the interconnected networks. If the receiving MSDP peer is an RP, and the RP has a (*,G)

entry for the group in the source active message, the message is accepted. The RP creates an (S,G) state for the source and join to the shortest path tree for the state of the source.

The encapsulated data is forwarded down the RP shared tree. When the packet is received by a receiver's last hop router, the last-hop may also join the shortest path tree to the source.

The following figure shows a sample of how data flows from a source in Domain A to a receiver in Domain E in an MSDP implementation for PIM-SM.

Figure 28-5 Sample implementation of MSDP for PIM-SM



28.17 MLD

28.17.1 Overview

MLD is an asymmetric protocol used by IPv6 routers to discover the presence of multicast listeners, that is, NEs that wish to receive multicast packets. MLD specifies separate behaviors for multicast address listeners and multicast routers.

The purpose of MLD is to enable each multicast router to discover, for each of its directly attached links, which multicast addresses and which sources have interested listeners on that link. The information gathered by MLD is provided to whichever multicast routing protocol is used by the router, such as PIM, to ensure that multicast packets are delivered to all links where there are listeners interested in such packets.

An MLD group interface is configurable on a base routing instance, VPRN routing instance, and on an IES site. To allow the delivery of IPv6 multicast content to subscribers, group interfaces are configurable under MLD. MLD report/done/query messages use the link-local address as their source address. An MLD policy is applied to the subscriber profile to allow unique behavior per subscriber.

To support MCS for subscribers using MLD, MLD information is synced across chassis. During a failover scenario, standby MLD becomes active and PIM sends a join message to all necessary multicast sources.

MLD is supported on the 7950 XRS, in chassis mode C or D, and on the 7750 SR in chassis mode A or B with mixed mode enabled. MLD is supported on all variants of the 7705 SAR.

MLD under IES and VPRN is supported on the 7950 XRS, the 7750 SR in chassis mode D, and the 7450 ESS in chassis mode D with mixed mode enabled.

28.18 Bridging

28.18.1 Overview

Bridging is used between an OmniSwitch device and a 7450 ESS to create a fast ring. The fast ring bridges the end-user devices, such as BTV set-top boxes, and Layer 2 services, such as VPLS, that distribute multicast traffic. If required, you can configure the devices with MSTP or another STP.

STP is active by default on an OmniSwitch. The default mode of operation is 1x1 mode using RSTP. A loop-free network topology is automatically calculated based on default STP switch, bridge, and port parameter values.

Additional OmniSwitch configuration such as enabling and configuring OmniSwitch learned port security parameters for VLAN ports, DHCP relay, and DHCP snooping can be done while configuring other bridge parameters.

You can configure MVRP as part of the bridging configuration on the OmniSwitch. MVRP provides a mechanism to maintain the contents of dynamic VLAN registration entries for each VLAN, and to propagate that information to other bridges.

In the NFM-P, a bridge is represented in the network view below a device, similar to the routing instance of a device.

28.19 WPP

28.19.1 Overview

WPP (Web Portal Protocol) runs between a BNG and a Web portal server. It is used for Web portal authentication of WLAN users (DHCP hosts). WPP can be enabled on base routing instances or VPRN routing instances. WPP version 2.0 has an updated packet format and additional message types.

Subscriber creation triggered by WPP messages (log in via HTTP) supports a topology where the subscriber host IP address is provided via the CMTS NE. The ESM host is created after the client is authenticated through the Web portal.

In the case of WPP traffic on an SRRP dual homing configuration, the Web portal is not aware of SRRP mastership. A network interface on a base routing instance, or an L3 access interface on an IES or VPRN service can be configured with the Track SRRP Instance option, which specifies the master NE to which WPP traffic is directed.

28.20 BIER

28.20.1 Overview

Bit Indexed Explicit Replication (BIER) offers an architecture for forwarding multicast data packets without the need for multicast trees or for intermediate routers to maintain a per-multicast flow state. BIER information is distributed in the network using the underlay IGP.

A BIER domain is a connected set of bit forwarding routers, each with a unique ID. A BIER domain can be divided into sub-domains for scalability without a linear increase in size of the BIER header. For example, in IS-IS, a BIER sub-domain is an IS-IS multi topology, where ipv4-unicast is a single sub-domain and ipv4-multicast is another sub-domain.

BIER is supported on FP4 network interfaces. BIER is not supported on FP3 or earlier cards, or on access interfaces.

If a chassis has a mix of FP3 and FP4 network ports, BIER is signaled on all FP3 and FP4 interfaces which are part of the IS-IS.

28.20.2 BIER templates

BIER is configured by creating a BIER template. The BIER template contains the sub-domain to multi-topology mapping and other BIER configurations, such as the bit forwarding router ID and BIER prefix.

28.21 IPSec

28.21.1 Overview

IPSec tunnel parameters for VSR or 7705 SAR-Hm can be configured from a routing interface on the NE. See Chapter 34, “IPsec” for general information about IPSec.

Routing protocol configuration workflow and procedures

28.22 Routing protocol configuration workflow

28.22.1 Stages

1

Configure a base routing instance or VRF instance on a device; see 27.2 “To configure a routing instance or a VRF instance” (p. 826) .

2

Enable the routing protocols to be supported on the device or routing instance. The supported protocols are device dependent. The options are:

- IPv6; enabled during interface creation
- BGP and MP-BGP; see 28.29 “To enable BGP on a routing instance” (p. 916) and 28.31 “To configure global-level BGP” (p. 918) , 28.32 “To configure peer-group-level BGP” (p. 922) , and 28.33 “To configure peer-level BGP” (p. 926)
- RIP and RIPng; see 28.44 “To enable RIP or RIPng on a routing instance” (p. 937) , 28.45 “To configure global-level RIP or RIPng” (p. 937) , 28.46 “To configure group-level RIP or RIPng” (p. 938) , and 28.47 “To configure interface-level RIP or RIPng” (p. 939)
- LDP; see 28.50 “To enable LDP on a routing instance” (p. 940) and 28.51 “To configure global-level LDP” (p. 941)
- IS-IS; see 28.59 “To enable IS-IS on a routing instance” (p. 952) and 28.60 “To configure IS-IS on a routing instance” (p. 953)
- OSPFv2 and OSPFv3; see 28.66 “To enable OSPF on a routing instance” (p. 963)
- RSVP; see 28.85 “To configure RSVP on a routing instance” (p. 985)
- L2TP; see 28.89 “To configure L2TP on a routing instance” (p. 989)
- WPP; 28.134 “To create a web portal routing instance” (p. 1051)
- Bridging; see 28.128 “To configure bridging on an OmniSwitch” (p. 1043)
- MPLS; see 31.5 “To enable MPLS on a routing instance” (p. 1115)
- MPLS-TP; see 32.3 “To enable MPLS-TP on a routing instance” (p. 1168)
- Multicast
  - PIM; see 28.97 “To enable PIM on a routing instance” (p. 998)
  - IGMP; see 28.103 “To enable IGMP on a routing instance” (p. 1016)
  - MSDP; see 28.112 “To enable MSDP on a routing instance” (p. 1026)
  - MLD; see 28.121 “To enable MLD on a base routing instance” (p. 1034)

Note: L2TP is enabled by default on a base routing instance, but not on a VPRN routing instance.

3

Configure L3 network interfaces as required if you need to enable multicast routing protocols. See the 27.1.17 “Workflow to configure NE routing and forwarding” (p. 823) in Chapter 27, “NE routing and forwarding” .

4

Configure the appropriate routing policies as required; see Chapter 54, “Routing policies” .

5

Review the following protocol workflows as required to configure additional functionality:

a. BGP and MP-BGP; see 28.28 “Workflow to configure BGP and MP-BGP” (p. 915)

b. RIP; see 28.43 “RIP and RIPng configuration workflow” (p. 936)

c. LDP; see 28.49 “Workflow to configure LDP” (p. 940)

d. IS-IS; see 28.58 “Workflow to configure IS-IS” (p. 952)

e. OSPFv2 or OSPFv3; see 28.65 “Workflow to configure OSPFv2 and OSPFv3” (p. 962)

f. RSVP; see 28.84 “Workflow to configure RSVP” (p. 985)

g. L2TP; see 28.88 “Workflow to configure L2TP” (p. 988)

h. PIM; see 28.95 “Workflow to configure PIM” (p. 997)

i. IGMP; see 28.102 “Workflow to configure IGMP” (p. 1016)

j. MSDP; see 28.111 “Workflow to configure MSDP” (p. 1025)

k. MLD; see 28.120 “Workflow to configure MLD” (p. 1033)

l. bridging; see 28.127 “Workflow to configure bridging on an OmniSwitch” (p. 1043)

m. WPP; see 28.133 “Workflow to configure WPP” (p. 1051)

n. BIER; see 28.135 “Workflow to configure BIER” (p. 1053)

o. IPSec; see 28.137 “Workflow to configure IPSec ” (p. 1055)

6

Configure routing protocol monitoring as required; see 28.39 “Workflow to configure BMP” (p. 933).

7

Configure the protocol for the remote device as required.

BFD and SBFD configuration workflow and procedures

28.23 BFD and SBFD configuration overview

28.23.1 General information

BFD configuration consists of the following:

- creation of a BFD template policy

  A BFD template policy defines the fast forwarding path failure detection requirements for BFD packets/sessions such as the transmit/receive timer interval, the minimum echo receive interval, and the number of consecutive BFD messages that can be missed before the BFD session status changes to down.
- configuration of BFD or SBFD on a path or interface

Configuration of Seamless BFD requires configuration of an SBFD reflector and peer. The reflector is configured in the NE properties and peers are added to the routing instance.

28.24 Workflow to configure BFD

28.24.1 Stages

1

Configure a BFD template policy; see 28.25 “To configure a BFD template policy” (p. 911).

2

Configure BFD or SBFD on the path or interface as needed; see the configuration procedures for the path or interface type.

3

Configure SBFD; see 28.26 “To configure Seamless BFD ” (p. 912).

28.25 To configure a BFD template policy

28.25.1 Purpose

You can apply a BFD template policy to the following:

- LSP-path bindings; see 31.13 “To configure a Dynamic or segment routing TE LSP” (p. 1132) .
- Proactive OAM template on an enabled MPLS-TP routing instance; see 32.4 “To configure MPLS-TP on a routing instance” (p. 1169) .
- Bidirectional MPLS-TP LSP; see 32.7 “To create a bidirectional MPLS-TP LSP” (p. 1173) .
- PW Template Binding; see 77.110 “To configure a site for BGP AD or BGP VPLS” (p. 2408) .
- Spoke SDP binding

- For VLL sites; see 76.34 “To configure a spoke SDP binding on a VLL site” (p. 2161) , or 76.35 “To configure a spoke SDP binding with an L2TPv3 tunnel on a VLL Epipe site” (p. 2165).
- For a VPLS; see 77.101 “To configure BFD on a VPLS SDP binding” (p. 2400) .
- For an IES; see 78.12 “To configure BFD on an IES spoke SDP binding” (p. 2441) .
- For a VPRN; see 79.71 “To configure BFD on a VPRN spoke SDP binding” (p. 2642) .

28.25.2 Steps

1

Choose Policies→BFD Templates from the NFM-P main menu. The Manage BFD Templates form opens.

2

Click Create. The BFD Template, Global Policy (Create) form opens.

3

Configure the required parameters.

4

Click Apply. The BFD Template (Edit) form refreshes with additional tabs.

5

As required, click on the appropriate tabs and click Search to determine to which network objects the BFD template policy is applied.

6

Click OK to save the policy and close the form. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

END OF STEPS

28.26 To configure Seamless BFD

28.26.1 Purpose

Use this procedure to create a Seamless BFD reflector and peer. The reflector is configured in the NE properties and peers are added to the routing instance.

28.26.2 Steps

To configure a Seamless BFD reflector

1

In the navigation tree equipment view, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, then the BFD sub-tab.

3

Click Create. The Seamless BFD Reflector (Create) form opens.

4

Configure the parameters and click OK.

The reflector is added to the list in the NE properties and the routing instance.

To configure a Seamless BFD peer

5

In the navigation tree routing view, expand Network→*NE*→Routing Instance.

6

Click on the Seamless BFD tab, then the Peers sub-tab.

7

Click Create. The Seamless BFD Peer (Create) form opens.

8

Configure the parameters and click OK.

9

Save your changes and close the forms.

END OF STEPS

BGP configuration workflow and procedures

28.27 BGP configuration workflow and procedures

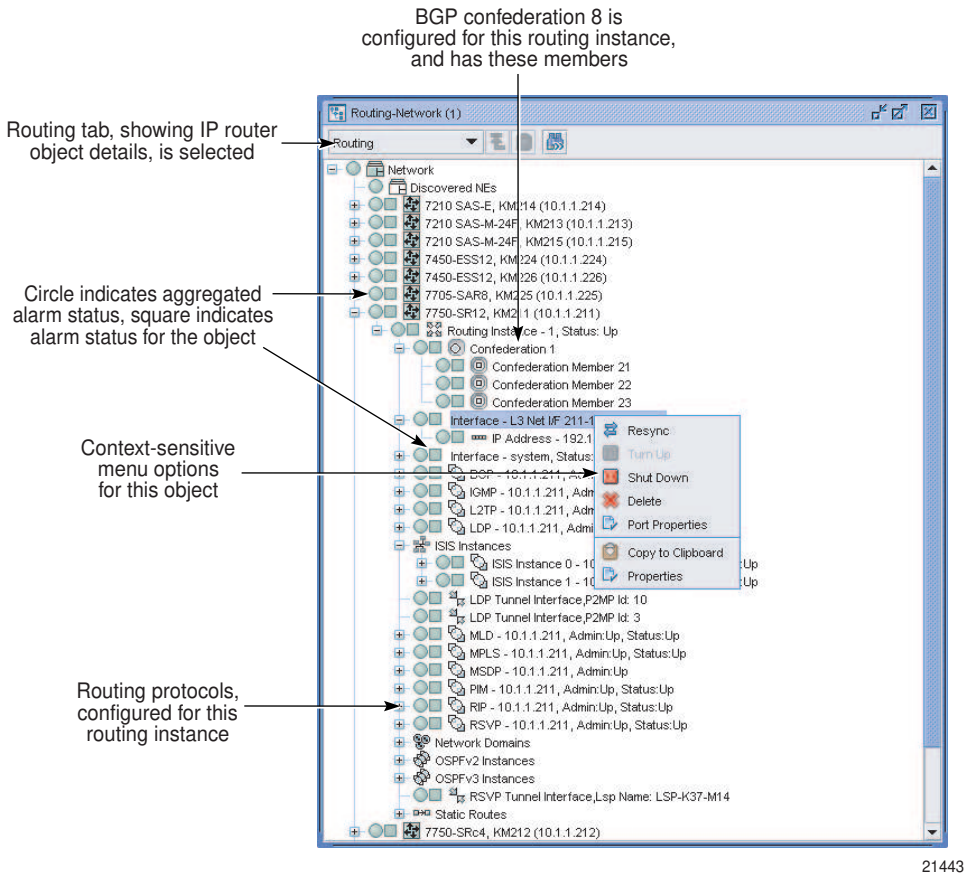
28.27.1 Overview

The BGP command hierarchy consists of three levels:

- global
- peer group
- peer (also known as neighbor)

The following figure shows the network view open to show Confederations and BGP settings.

Figure 28-6 BGP in the navigation tree network view



BGP parameters are initially applied at the global level. The parameters are inherited by the group and peer levels. Parameters can be modified and overridden on a level-specific basis.

Many of the hierarchical BGP commands can be modified at different levels. BGP group-level parameters take precedence over BGP global-level parameters. BGP peer-level parameters take precedence over group- and global-level parameters.

The following procedures describe how to configure BGP.

28.28 Workflow to configure BGP and MP-BGP

28.28.1 Stages

1

Enable BGP on a routing instance; see 28.29 “To enable BGP on a routing instance” (p. 916) .

2

If BGP mesh scaling is an issue due to the number of NEs in an AS, configure a BGP confederation; see 28.30 “To configure a BGP confederation” (p. 916) .

3

If you are configuring MP-BGP, enable multicast IPv4 on the base routing instance of each NE that is to participate in a VPRN; see 28.31 “To configure global-level BGP” (p. 918) and Chapter 79, “VPRN service management” .

4

Create at least one BGP peer group; see 28.32 “To configure peer-group-level BGP” (p. 922) .

5

Configure peer-level BGP as required; see 28.33 “To configure peer-level BGP” (p. 926) .

6

Configure BGP SIDR prefix origin validation as required; see 28.34 “To configure BGP SIDR prefix origin validation” (p. 930) .

7

Configure long-lived graceful restart as required; see 28.37 “To configure long-lived graceful restart on a BGP site” (p. 932).

8

Enable or disable BGP peering as required; see 28.35 “To enable or disable BGP peering” (p. 931) .

9

Configure a site for BGP AD or BGP VPLS as required, see 77.110 “To configure a site for BGP AD or BGP VPLS” (p. 2408) .

10

Verify BGP routes against a routing policy statement as required; see 54.23 “To verify BGP routes against a routing policy statement” (p. 1769)

11

Verify a BGP prefix list against a routing policy statement as required; see 54.24 “To verify a BGP prefix list against a routing policy statement” (p. 1770) .

28.29 To enable BGP on a routing instance

28.29.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance.

2

Right-click on a routing instance icon and choose Properties.

3

Click on the Protocols tab and configure the BGP Enabled parameter.

Note: You must configure an AS number before enabling BGP. Configure the Autonomous System parameter on the Routing tab of the Routing Instance (Edit) form.
If a confederation is required, configure the Confederation Autonomous System parameter on the Routing tab on the Routing Instance (Edit) form.

4

Save your changes and close the form.

END OF STEPS

28.30 To configure a BGP confederation

28.30.1 Purpose

For BGP confederations, the following rules apply:

- A device can only belong to one confederation.
- Multiple devices can belong to one BGP confederation.

You must configure BGP on the device and configure global-level BGP parameters before you configure BGP confederations, as described in 28.29 “To enable BGP on a routing instance” (p. 916) and 28.31 “To configure global-level BGP” (p. 918) .

28.30.2 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance.

2

Right-click on the Routing Instance icon and choose Properties.

3

Click on the Routing tab.

4

Enter the confederation number for the Confederation Autonomous System parameter and click Apply.

5

Click on the BGP Confederations tab.

6

Click Create to add a BGP confederation, or choose a BGP confederation and click Properties to configure an existing BGP confederation.

Note: You can only have one BGP confederation per device.

7

Add a new member to the confederation:

Perform the following steps:

1. Click on the Members tab.
2. Click Create.
3. Configure the Member AS parameter as the number of ASs for the confederation. The member AS number represents the BGP instance of the device.
4. Click OK.

   You can verify the confederation membership by opening the Confederation icon to view icons that represent the members of the confederation.

8

Close the form.

END OF STEPS

28.31 To configure global-level BGP

28.31.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→BGP.

2

Right-click on the BGP icon and choose Properties.

3

Click on the General tab and configure the required parameters.

4

Select a TCP key chain in the KeyChain panel, if required.

Note: You can assign a TCP key chain to a BGP site, group, or peer on a 7450 ESS in mixed mode, 7705 SAR, 7750 SR, or 7950 XRS.

5

Configure the required parameters in the Optimal Route Reflection Shortest Path First Timers panel.

6

Configure the required parameters in the Graceful Restart panel.

The graceful restart parameters are configurable when you enable the Graceful Restart parameter.

7

Configure the required parameters in the MED panel.

The parameters are used to find a way to leave the AS when there are multiple methods of leaving the AS.

8

Configure the required parameters in the MultiPath panel.

Set the MultiPath parameter to 1 to disable. When set from 2 to 16, multipath is enabled and BGP load shares traffic across the number of links specified. If the equal cost routes available are greater than the configured value, then routes with the lowest next hop IP address are chosen.

9

Configure the Backup Path parameter in the Backup Path panel.

10

Configure the required parameters in the Best Path Selection panel.

When you set the MED Compare parameter to off, the Strict parameter is set to true and is not configurable. When you set the MED Compare parameter to on, the Strict parameter is set to false and is not configurable.

To include routes from BGP peers for MVPN IPv4, MVPN IPv6, or both, in RR convergence, set the Ignore Router ID parameter to true and configure the Ignore Router ID Internal parameter.

11

Configure the required parameters in the OLC panel.

12

Click on the Behavior tab and configure the required parameters.

Note: You must set the Enable Add-Path Send parameter to True in order to configure the additional Add-Path parameters.
When you configure the Peer Tracking Policy, you can use the Select button to choose a single policy, or click on the Create Expression button to use a logical expression as described in 28.36 “To create a BGP policy expression” (p. 931).

13

Click on the AS Properties tab and configure the required parameters.

The Local AS parameters are used to configure a virtual AS. A virtual AS is used when a router (RTA) is moved from one AS (AS1) to another AS (AS2). However, the customer router (CR1) is configured to belong to the AS1. To avoid reconfiguring CR1 to belong to AS2, CR1 can continue to belong to AS1, but RTA has its local AS value set to AS1. RTA can advertise AS1 for routes advertised to CR1.

14

Click on the VPN tab and configure the required parameters.

Note the following:

- If you are configuring global-level BGP for BGP AD in VPLS or for BGP VPLS, you must enable the L2 VPN option for the Family parameter.
- You must set the AS Path Ignore parameter to True in order to configure the AS Path Ignore Family parameters.
- The Apply Import Route Policies and Apply Export Route Policies parameters are not configurable on a VPRN routing instance.
- The Apply Import Route Policies and Apply Export Route Policies parameters specify whether to apply the existing import and export route policies configured on the Import Policies and Export Policies tabs.
- Selecting an address family in the Rapid Update panel reduces the minimum route advertisement interval (MRAI) to zero. Families that are not selected will retain the default MRAI.

15

Configure next hop resolution:

1. Click on the Next-Hop Resolution tab.
2. Configure the Use BGP Routes, Resolve Label Routes, Allow Static Routes, and Weighted ECMP parameters as applicable.
3. To defer hardware fast-reroute protection to the SR tunnel, enable the Prefer Transport Frr parameter.
4. Select a routing policy statement.
5. Click Create Expression and configure the parameters to add a policy expression.
6. Configure the parameters in the Use Leaked Routes panel.
7. Choose a Shortcut Tunnel and click Properties.
8. Configure the required parameters for the Shortcut Tunnel, save the changes, and close the form.
9. In the Label Route Transport Tunnel panel, choose a family from the available entries and click Properties.
10. Configure the required parameters.

    You can choose segment routing as a tunnel option. Segment routing must be configured if you select the SR-ISIS or SR-OSPF parameters; see 28.11 “Segment routing” (p. 894).
11. Save your changes and close the form.

16

Configure ORF Extended Community:

1. Configure the Accept ORF parameter.
2. Configure the Send ORF parameter.

   If Send ORF is set to True, provide the RTL details:
   a. Click on the Create button.
   b. Enter site and route target details.
   c. Click OK.

17

Configure Optimal Route-Reflection:

1. Click on the Optimal Route-Reflection tab.
2. Click Create. The Optimal Route Reflection (Create) form opens.
3. Configure the parameters.
4. Click OK to create an optimal route-reflection location and close the form.

   You can create up to 16 locations.
5. Configure the Cluster ID and Optimal Route-Reflection location parameters on the General tab.

18

Click on the Segment Routing V6 tab and configure the required parameters.

19

Add a peer group.

Perform the following steps:

1. Click on the Groups tab and click Create.
2. Perform Step 3 to Step 22 of 28.32 “To configure peer-group-level BGP” (p. 922) .
3. Save the changes.

20

Add a peer.

Perform the following steps:

1. Click on the Peers tab.
2. Click Create.
3. Perform Step 3 to Step 18 of 28.33 “To configure peer-level BGP” (p. 926) .
4. Save the changes.

21

Configure dynamic peer prefixes as required:

1. Click on the Dynamic Peer Prefixes tab.
2. Click Create.
3. Configure the required parameters.
4. Save the changes.

22

Create a route target list as required:

1. Click on the Route Target List tab.
2. Click Create to create a route target.
3. Configure the required parameters.
4. Save the changes.

Routes with one or more of the route targets in the list are accepted or advertised to route-reflector clients. This is only applicable if the router is a route-reflector server.

23

Click on the Import Policies and Export Policies tabs and configure the required parameters.

Configure the import route policies to determine which routes are accepted from peers. The policies should match the policies you configure using the Routing Policy Manager, as described in Chapter 27, “NE routing and forwarding” . There is no validation performed by the router to ensure the policies match.

Configure the export route policies to determine which routes are advertised to peers. The policies should match the policies you configure using the Routing Policy Manager, as described in Chapter 27, “NE routing and forwarding” . A router performs no validation to ensure the policies match.

You can use the Select button to choose a single policy, or click on the Create Expression button to use a logical expression, as described in 28.36 “To create a BGP policy expression” (p. 931).

24

Click on the RIB Management tab to assign leak import and export policies:

1. On the IPv4 Leak Import Policies, IPv6 Leak Import Policies, Label IPv4 Leak Import Policies, and Label IPv6 Leak Import Policies tabs, assign up to 15 leak import policies to the BGP site as required.
2. Click on the IPv4 Leak Export Policies tab and assign up to 15 leak export policies to the BGP site.
3. Click on the Route Table Import tab and configure the required parameters.

25

Click on the Authentication tab and configure the required parameters.

26

Save your changes and close the forms.

END OF STEPS

28.32 To configure peer-group-level BGP

Note: For most parameters in this procedure, you can specify that the parameter value is inherited from the parent BGP configuration using the Inherit Value parameter.

If you disable value inheritance for a parameter, the available options are restricted, based on the parent parameter value and the protocol functionality. For example, if a parameter in the global-level BGP configuration is set to True, the only available option for the same parameter in the peer-group-level BGP configuration is False, unless a value of False violates a protocol rule, in which case the only available option is True.

The parameters that you configure for a BGP peer group take precedence over the parameters that are configured for global-level BGP.

28.32.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→BGP.

2

Right-click on the BGP icon and choose Create Group.

3

Configure the required parameters.

4

Select a TCP key chain in the KeyChain panel, if required.

Note: You can assign a TCP key chain to a BGP site, group, or peer on a 7450 ESS in mixed mode, 7705 SAR, 7750 SR, or 7950 XRS.

5

Configure the required parameters in the Graceful Restart panel.

The graceful restart parameters are configurable when the Graceful Restart parameter is enabled.

6

Configure the required parameters in the MED panel.

The parameters are used to find a way to leave the AS when there are multiple methods of leaving the AS.

7

Click Apply.

8

Configure the required parameters in the OLC panel.

9

Configure dynamic peer prefixes as required:

1. Click on the Dynamic Peer Prefixes tab.
2. Click Create.
3. Configure the required parameters.
4. Save the changes.

10

Click on the Behavior tab and configure the required parameters.

The Fault Tolerance parameter allows BGP routers to be more tolerant of certain UPDATE message errors, use less disruptive error recovery mechanisms, and provide better operational and diagnostics information.

The Idle Timeout parameter is configurable when the Never Timeout parameter is disabled.

11

Click on the AS Properties tab and configure the required parameters.

The Peer AS parameter specifies the peer AS for this specific group, and the behavior, internal or external. Multipath configurations are not supported at the BGP peer level.

12

Configure the required parameters in the Local AS panel.

The No Prepend Global AS is configurable only if you set the Local AS parameter to a value other than 0.

The Local AS parameters are used to configure a virtual AS. A virtual AS is used when a router (RTA) is moved from one AS (AS1) to another AS (AS2). However, the customer router (CR1) is configured to belong to the AS1. To avoid reconfiguring CR1 to belong to AS2, CR1 can continue to belong to AS1, but RTA has its local AS value set to AS1. RTA can advertise AS1 for routes advertised to CR1.

13

Configure the required parameters in the Remove Private AS panel.

14

Click on the VPN tab and configure the required parameters in the VPN panel.

Note the following:

- The Advertise Label, Apply Import Route Policies and Apply Export Route Policies parameters are not configurable on a VPRN routing instance.
- The Apply Import Route Policies and Apply Export Route Policies parameters specify whether to apply the existing import and export route policies configured on the Import Policies and Export Policies tabs.
- Selecting an address family in the Rapid Update panel reduces the minimum route advertisement interval (MRAI) to zero. Families that are not selected will retain the default MRAI.

15

Configure ORF Extended Community:

1. Configure the Accept ORF parameter.

2. Configure the Send ORF parameter.

   If Send ORF is set to True, provide the RTL details:

   a. Click on the Create button.

   b. Enter site and route target details.

   c. Click OK.

16

Click on the Add Path tab and configure the required parameters.

You must select the Enable Add-Path parameter in order to configure the additional Add-Path parameters.

IMPORTANT INFORMATION

For release 22.2 and later, the modification of parameters under Add Path will still work with pre 22.2 OSSI scripts. However, to enable or disable Add-Path parameter using pre 22.2 OSSI scripts, the following workaround is mandatory;

- To disable AddPath, specify **<sendAddPath>false</sendAddPath>** along with the **<paramsInheritanceMask>** tag with all AddPath bits removed.
- To enable AddPath, specify **<sendAddPath>true</sendAddPath>** along with the **<paramsInheritanceMask>** tag with AddPath bits specified.

Note: It is recommended to use either pre-22.2 and 22.2 OSSI script consistently for Add-Path Configuration and do not alternate.

Note: The inheritance from parent BGP configuration applies to all the parameters. The inheritance values are displayed as read-only fields for operational setup. For non-operational setup, inheritance values are not displayed.

17

Click on the Segment Routing V6 tab and configure the required parameters.

18

To add a peer, perform the following steps:

1. Click on the Peers tab.
2. Click Create.
3. Perform Step 3 to Step 18 of 28.33 “To configure peer-level BGP” (p. 926) .
4. Save your changes and close the form.

19

To configure prefix limits, perform the following steps:

1. Click on the Prefix Limit tab.

   Note:

For node releases earlier than 13.0R1, prefix limit parameters appear on the Behavior tab and the Prefix Limit tab is not available.

2. Click Create. The Prefix Limit (Create) form opens.
3. Configure the required parameters.
4. Save your changes and close the form.

20

Click on the Import Policies and Export Policies tabs and configure the required parameters.

Configure the import route policies to determine which routes are accepted from peers. The policies should match the policies you configure using the Routing Policy Manager, as described in Chapter 27, “NE routing and forwarding” . There is no validation performed by the router to ensure the policies match.

Configure the export route policies to determine which routes are advertised to peers. The policies should match the policies you configure using the Routing Policy Manager, as described in Chapter 27, “NE routing and forwarding” . A router performs no validation to ensure the policies match.

You can use the Select button to choose a single policy, or click on the Create Expression button to use a logical expression, as described in 28.36 “To create a BGP policy expression” (p. 931).

21

To configure interface instance, perform the following steps:

1. Click on the Dynamic Peer Interfaces tab.
2. Create or select an entry and click Properties. The Dynamic Peer Interface (Create/Edit) form opens.
3. Configure the required parameters in General tab.
4. Click on the AS Allowed Ranges tab and configure the Minimum and Maximum values.

   Note:

   Upto 32 AS Allowed Range can be configured.
5. Save the changes and close the form.

22

Click on the Authentication tab and configure the required parameters.

23

Save your changes and close the form.

END OF STEPS

28.33 To configure peer-level BGP

Note: For most parameters in this procedure, you can specify that the parameter value is inherited from the parent BGP configuration using the Inherit Value parameter.

If you disable value inheritance for a parameter, the available options are restricted, based on the parent parameter value and the protocol functionality. For example, if a parameter in the peer-group-level BGP configuration is set to True, the only available option for the same parameter in the peer-level BGP configuration is False, unless a value of False violates a protocol rule, in which case the only available option is True.

The parameters that you configure for a BGP peer take precedence over the parameters that are configured for group-level BGP.

28.33.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→BGP→Peer Group.

2

Right-click on the Peer Group icon and choose Create Peer.

3

Configure the general parameters.

4

Select a TCP key chain in the KeyChain panel, if required.

Note: You can assign a TCP key chain to a BGP site, group, or peer on a 7450 ESS in mixed mode, 7705 SAR, 7750 SR, or 7950 XRS.

5

Configure the required parameters in the Graceful Restart panel.

The graceful restart parameters are configurable when the Graceful Restart parameter is enabled.

6

Configure the required parameters in the MED panel.

The MED parameters are used to find a way to leave the AS when there are multiple methods of leaving the AS.

7

Click Apply.

8

Configure the required parameters in the OLC panel.

9

Click on the Behavior tab and configure the required parameters.

Note: The Fault Tolerance parameter allows BGP routers to be more tolerant of certain UPDATE message errors, use less disruptive error recovery mechanisms, and provide better operational and diagnostics information.

10

Click on the AS Properties tab and configure the required parameters.

The Peer AS parameter specifies the peer AS for the group to which the peer belongs, and the behavior, internal or external. Multipath configurations are not supported at the BGP peer level.

11

Configure the required parameters in the Local AS and Remove Private AS panels.

The No Prepend Global AS parameter is configurable when you set the Local AS parameter to a value other than 0.

12

Click on the VPN tab and configure the required parameters.

Note the following:

- To enable VPN IPv6, select VPN IPv6 and IPv6 for the Family parameter.
- To enable VPN IPv6, select IPv6 for the Advertise Label parameter.
- The Advertise LDP Prefix and Use Service Routes parameters are configurable when the Advertise Label parameter is enabled for IPv4 routes.
- The Apply Import Route Policies and Apply Export Route Policies parameters specify whether to apply the existing import and export route policies configured on the Import Policies and Export Policies tabs.
- Selecting an address family in the Rapid Update panel reduces the minimum route advertisement interval (MRAI) to zero. Families that are not selected will retain the default MRAI.

13

Click on the ORF Extended Community tab and perform the following:

1. Configure the Accept ORF parameter.
2. Configure the Send ORF parameter.

   If Send ORF is set to True, provide the RTL details:

   a. Click on the Create button.
   b. Enter site and route target details.

c. Click OK.

14

Click on the Add Path tab and configure the required parameters.

You must select the Enable Add-Path parameter in order to configure the additional Add-Path parameters.

IMPORTANT INFORMATION

For release 22.2 and later, the modification of parameters under Add Path will still work with pre 22.2 OSSI scripts. However, to enable or disable Add-Path parameter using pre 22.2 OSSI scripts, the following workaround is mandatory;

- To disable AddPath, specify **<sendAddPath>false</sendAddPath>** along with the **<paramsInheritanceMask>** tag with all AddPath bits removed.
- To enable AddPath, specify **<sendAddPath>true</sendAddPath>** along with the **<paramsInheritanceMask>** tag with AddPath bits specified.

Note: It is recommended to use either pre-22.2 and 22.2 OSSI script consistently for Add-Path Configuration and do not alternate.

Note: The inheritance from parent BGP configuration applies to all the parameters. The inheritance values are displayed as read-only fields for operational setup. For non-operational setup, inheritance values are not displayed.

15

To configure prefix limits, perform the following steps:

1. Click on the Prefix Limit tab.

   Note:

   For node releases earlier than 13.0R1, prefix limit parameters appear on the Behavior tab and the Prefix Limit tab is not available.
2. Click Create. The Prefix Limit (Create) form opens.
3. Configure the required parameters.
4. Save your changes and close the form.

16

Click on the Import Policies and Export Policies tabs and configure the required parameters.

Configure the import route policies to determine which routes are accepted from peers. The policies should match the policies you configure using the Routing Policy Manager, as described in Chapter 27, “NE routing and forwarding” . There is no validation performed by the router to ensure the policies match.

Configure the export route policies to determine which routes are advertised to peers. The policies should match the policies you configure using the Routing Policy Manager, as described in Chapter 27, “NE routing and forwarding” . A router performs no validation to ensure the policies match.

You can use the Select button to choose a single policy, or click on the Create Expression button to use a logical expression, as described in 28.36 “To create a BGP policy expression” (p. 931).

17

Click on the Segment Routing V6 tab and configure the required parameters.

18

Click on the Authentication tab and configure the required parameters.

19

Save the changes and close the form.

20

Configure the protocol for the far-end device, if applicable. Use CLI for devices that are managed outside the scope of the NFM-P.

END OF STEPS

28.34 To configure BGP SIDR prefix origin validation

28.34.1 Purpose

To help prevent BGP prefix spoofing, you can configure validation of the AS values that are received from EBGP peers. When a BGP speaker that supports the validation function receives a route AS value, the speaker can check the associated prefix for validity. If the origin AS is not correct for the advertised prefix, the route is considered invalid and treated according to the routing policy configuration.

28.34.2 Steps

1

Configure an RPKI session on a routing instance; see 27.2 “To configure a routing instance or a VRF instance” (p. 826) .

2

Configure origin validation on an EBGP peer session.

Perform the following steps:

1. Configure the Origin Validation parameter on the Behavior tab on the Peer Group (Edit) form; see 28.32 “To configure peer-group-level BGP” (p. 922) .
2. Configure the Origin Validation parameter on the Behavior tab on the Peer, Peer Group (Create) form; see 28.33 “To configure peer-level BGP” (p. 927) .

3

Create a policy statement entry to match IPv4 or IPv6 routes in the routing information database. Configure the Origin Validation State parameter on the Action, From Criteria, and Default Action tabs; see 54.5 “To configure a routing policy statement” (p. 1745) .

4

On a BGP site properties form, on the General tab in the Best Path Selection panel, set the Compare Origin Validation State and Origin Invalid Unusable parameters to control how the origin validation states associated with routing information database entries are used in the BGP decision process. See 28.31 “To configure global-level BGP” (p. 918) .

5

On a Community Routing Policy, configure the Community Member parameter with the new origin validation state. See 54.8 “To configure a community policy” (p. 1752) .

END OF STEPS

28.35 To enable or disable BGP peering

28.35.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→BGP→Peer Group.

2

Click on the Peer Group icon to display the peers in the peer group.

3

Right-click on a peer and choose one of the following menu items:

a. Turn Up to activate a peer

b. Shut Down to deactivate a peer

4

Click Yes.

END OF STEPS

28.36 To create a BGP policy expression

28.36.1 Overview

Use this procedure to create logical expressions when configuring policy selections on BGP configuration forms.

28.36.2 Steps

1

Click on the Create Expression button in a BGP site, peer, or peer group configuration form.

2

Click on the Select button and choose a policy. Click on the Add button to add the policy to the expression. You can add up to 15 policies to a single expression.

3

Use the Boolean operator buttons (AND, OR, and NOT) to form expressions, or click on the text box to manually enter an expression. You can use parentheses to create more complicated expressions.

4

Save your changes and close the form.

END OF STEPS

28.37 To configure long-lived graceful restart on a BGP site

28.37.1 Steps

1

Click on the Graceful Restart tab on a BGP site or BGP peer configuration form.

2

Configure the parameters in the Long-lived Graceful Restart panel.

3

Create stale route timer configurations for each applicable family.

1. In the Family panel, click Create. The Long-lived Graceful Restart (New Instance) form opens.
2. Configure the stale route timer parameters and click OK. A new entry appears in the Family panel. You can create one entry for each family type.

4

Click OK and confirm to close the form.

END OF STEPS

BMP configuration workflow and procedures

28.38 BMP configuration overview

28.38.1 General information

BMP configuration consists of the following:

- configuring a BMP client, including creation of monitoring stations
- enabling monitoring on BGP sites, groups, or peers

BMP monitoring status is not inherited from global BGP settings. Stations that have been configured globally can be selected from a local BGP entity.

28.39 Workflow to configure BMP

28.39.1 Stages

1

Configure BGP on the NE or VPRN routing instance; see 28.28 “Workflow to configure BGP and MP-BGP” (p. 915) or 79.23 “To configure BGP on a VPRN routing instance” (p. 2557).

2

Configure a BMP client; see 28.40 “To configure an NE as a BMP client” (p. 933)

3

Enable BMP; see 28.41 “To enable BMP” (p. 934).

28.40 To configure an NE as a BMP client

28.40.1 Steps

1

In the navigation tree Equipment or Routing view, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, then the BMP sub-tab.

3

Configure the Administrative State parameter.

4

Click on the Stations sub-tab.

5

From the Stations sub-tab, click Create. The Monitoring Station (Create) form opens.

6

Configure the parameters to create a monitoring station.

7

Repeat Step 5 to create additional monitoring stations as needed. Up to eight monitoring stations can be created.

8

Save your changes and close the forms.

END OF STEPS

28.41 To enable BMP

28.41.1 Steps

1

Perform one of the following:

a. Navigate to a BGP site, peer group, or peer on an NE.

In the navigation tree Routing view, expand to one of the following:

- Network→NE→Routing Instance→BGP
- Network→NE→Routing Instance→BGP→Peer Group.
- Network→NE→Routing Instance→BGP→Peer Group→Peer.

b. Navigate to a BGP site, peer group, or peer on a VPRN routing instance.

1. Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.
2. Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.
3. On the service navigation tree, expand to one of the following:
   - Sites→Routing Instance→Protocols→BGP
   - Sites→Routing Instance→Protocols→BGP→Peer Group.
   - Sites→Routing Instance→Protocols→BGP→Peer Group→Peer.

Right-click on the BGP entity and choose Properties. The *BGP entity* (Edit) form opens.

2

Click on the BMP tab.

3

Configure the Enable Monitoring parameter and click Apply. The Monitor and Stations panels appear.

4

Configure the All Stations parameter to enable all stations to monitor BGP, or select individual stations in the Stations panel.

5

Configure the parameters.

6

Save your changes and close the forms.

END OF STEPS

RIP and RIPng configuration workflow and procedures

28.42 RIP and RIPng configuration overview

28.42.1 Overview

The RIP command hierarchy consists of three levels:

- global
- group
- interface (also known as neighbor)

For RIP configuration, you must define at least one group and one interface. The parameters that are configured on the global level are inherited by the group and interface levels. Parameters can be modified and overridden on a level-specific basis.

Many of the hierarchical RIP commands can be modified on different levels. RIP group-level parameters take precedence over BGP global-level parameters. RIP interface-level parameters take precedence over peer-group and global-level parameters.

When configuring RIP on the 7705 SAR, 7750 SR, or 7705 SAR-Hm, a RIP routing site is created under the routing instance which can be seen in the routing network tree. Using this RIP routing site, RIP groups and RIP interfaces can be configured.

The following procedures describe how to configure RIP and RIPng.

28.43 RIP and RIPng configuration workflow

28.43.1 Stages

1

Enable RIP or RIPng on a routing instance; see 28.44 “To enable RIP or RIPng on a routing instance” (p. 937) .

2

Configure global-level RIP or RIPng as required; see 28.45 “To configure global-level RIP or RIPng” (p. 937) .

3

Configure group-level RIP or RIPng as required; see 28.46 “To configure group-level RIP or RIPng” (p. 938) .

4

Configure neighbor-level RIP or RIPng as required; see 28.47 “To configure interface-level RIP or RIPng” (p. 939) .

28.44 To enable RIP or RIPng on a routing instance

28.44.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance.

2

Right-click on a routing instance icon and choose Properties.

3

Click on the Protocols tab and select the RIP Enabled or RIPNG Enabled parameters.

4

Save your changes and close the form.

END OF STEPS

28.45 To configure global-level RIP or RIPng

28.45.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→RIP or RIPng.

2

Right-click on the RIP or RIPng icon and choose Properties.

3

Configure the required general parameters.

4

Click on the Behavior, Authentication, Import Policies and Export Policies tabs, and configure the required parameters.

5

Create one or more RIP or RIPng groups, as required.

Perform the following steps:

1. Click on the Group tab.
2. Click Create. The RIP Group (Create) form opens.

3. Configure the required parameters. See 28.46 “To configure group-level RIP or RIPng” (p. 937) .

6

Create one or more RIP or RIPng interfaces, as required.

Perform the following steps:

1. Click on the Interface tab.
2. Click Create.
3. Configure the required parameters. See 28.47 “To configure interface-level RIP or RIPng” (p. 939) .

7

Save and close the forms.

END OF STEPS

28.46 To configure group-level RIP or RIPng

Note: You can choose to inherit values from the global-level RIP configuration by selecting the Inherit Value parameter. If you choose not to inherit a parameter value from the global-level RIP configuration, only the parameter options that are not set in the parent configuration are available. For example, if the Check Zero parameter is set to false in the global-level RIP configuration, you can only set the parameter to true in the group-level RIP configuration.

The parameters that you configure for a RIP group take precedence over the parameters that are configured for the global-level RIP configuration.

28.46.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→RIP or RIPng.

2

Right-click on the RIP or RIPng icon and choose Create Group.

3

Configure the Name parameter.

4

Configure the required general parameters.

5

Click on the Behavior, Authentication, Import Policies and Export Policies tabs, and configure the required parameters.

6

Save your changes and close the form.

END OF STEPS

28.47 To configure interface-level RIP or RIPng

Note: You can choose to inherit values from the global-level RIP configuration by selecting the Inherit Value parameter. If you choose not to inherit a parameter value from the global-level RIP configuration, only the parameter options that are not set in the parent configuration are available. For example, if the Check Zero parameter is set to false in the global-level RIP configuration, you can only set the parameter to true in the interface-level RIP configuration.

The parameters that you configure for a RIP interface, also known as a RIP neighbor, take precedence over the parameters that are configured for the group- and global-level RIP configuration.

28.47.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→RIP or RIPng.

2

Right-click on the RIP or RIPng group icon and choose Create Interface.

3

Configure the required general parameters.

4

Select an RIP group.

5

Select an interface.

6

Click on the Behavior, Authentication, Import Policies and Export Policies tabs, and configure the required parameters.

7

Save your changes and close the form.

END OF STEPS

LDP configuration workflow and procedures

28.48 LDP configuration overview

28.48.1 Overview

An LDP instance in the NFM-P network navigation tree has the following child objects:

- Interfaces–The interfaces object contains the configured LDP interfaces for directly connected peers.
- Targeted Peers–The targeted peers object contains the indirectly connected peers.

28.49 Workflow to configure LDP

28.49.1 Stages

1

Enable LDP on a routing instance; see 28.50 “To enable LDP on a routing instance” (p. 940) .

2

Configure global-level LDP; see 28.51 “To configure global-level LDP” (p. 941) .

3

Configure one of the following options:

a. If two LDP peers are adjacent devices, create an LDP interface; see 28.52 “To configure an LDP interface” (p. 944) .

b. If two LDP peers are non-adjacent devices, create an LDP targeted peer; see 28.53 “To configure an LDP targeted peer” (p. 945) .

4

Create an LDP keychain; see 28.54 “To configure an LDP peer” (p. 946) .

5

Configure ECMP for LDP routing as required; see 28.55 “To configure ECMP for LDP routing” (p. 948) .

6

View LDP session information as required; see 28.56 “To view the LDP session information” (p. 949) .

28.50 To enable LDP on a routing instance

28.50.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance.

2

Right-click on a routing instance icon and choose Properties. The Routing Instance (Edit) form opens.

3

Click on the Protocols tab and enable the LDP enabled parameter.

4

Save the changes.

END OF STEPS

28.51 To configure global-level LDP

28.51.1 Steps

1

Enable LDP on a router, as described in 28.50 “To enable LDP on a routing instance” (p. 941) .

2

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→LDP.

3

Right-click on the LDP icon and choose Properties. The LDP, Routing Instance (Edit) form opens.

4

Configure the Administrative State parameter.

5

Click on the Common tab and configure the required parameters.

Configure the Targeted Sessions Allowed parameter to true to configure the router for T-LDP. Targeted sessions are LDP sessions that distribute labels between indirectly connected peers.

The Neighbor Liveness Time (seconds) and Maximum Recovery Time (seconds) parameters are configurable when the Enforce Graceful Restart parameter is enabled.

6

Click on the Interface Properties tab and configure the required parameters. By default, the parameter values are inherited by all LDP interfaces.

7

Click on the Targeted Peer Properties tab and configure the required parameters. By default, these parameter values are inherited by all LDP targeted peers.

Note: If the Enable Hello Reduction parameter is disabled while the targeted LDP session to the peer is operationally up, the change in the hold time will take effect only when the targeted LDP session is re-established.

8

Click on the Policies tab and configure the required parameters.

9

Click on the Import Tunnel Table and Export Tunnel Table sub-tabs and configure the required parameters.

The tunnel table policies are used to allow LDP-capable PE devices to offer services to PE routers in areas or domains where BGP-labeled routes are not supported. They are used to determine which routes are advertised to LDP. Only policy entries supporting the LDP protocol are considered; all other policies are ignored. See also 28.33 “To configure peer-level BGP” (p. 927) for information on enabling the advertisement of LDP prefixes to BGP peers.

10

Click on the OAM tab, then the Ecmp sub-tab. See 28.55 “To configure ECMP for LDP routing” (p. 948) for more information about configuring ECMP for LDP interfaces.

11

Click on the Interfaces tab. See 28.52 “To configure an LDP interface” (p. 944) for more information about configuring LDP interfaces.

12

Click on the Peers tab. See 28.54 “To configure an LDP peer” (p. 946) for more information about creating peers.

13

Click on the Targeted Peers tab. See 28.53 “To configure an LDP targeted peer” (p. 945) for more information about creating and configuring targeted peers.

14

Click on the Authentication tab, configure the Type and Key parameters. And, assign an authentication keychain to the LDP.

15

Click on the Import Policies tab and configure the required parameters.

16

Click on the Export Policies tab and configure the required parameters.

17

Click on the Static Prefix FECs tab.

Perform the following steps:

1. Click Create. In the StaticFec (Create) form, configure the required parameters.
2. Click OK.
3. Click Yes.

18

Click on the LSP BFD tab.

Perform the following steps:

1. Click Create. In the LSP BFD(Create) form, configure the required parameters.

   The Prefix List and BFD Template policies attached to the LSP BFD must already exist.
2. Click OK.

19

Click on the Aggregate Prefix Match tab and configure the required parameters.

When the Aggregate Prefix Match Enabled parameter is enabled, the LDP installs a prefix binding in the LDP FIB by performing a longest match against an aggregate prefix in the routing table, as opposed to requiring an exact match of the prefix. The LDP prefix binding continues to be advertised on a per individual /32 prefix basis.

The Administrative State parameter can only be configured if the Aggregate Prefix Match Enabled parameter is enabled.

20

Configure the required parameters in the Prefix Exclude Policies panel.

The Prefix Exclude Policies can only be configured if the Aggregate Prefix Match Enabled parameter is enabled.

When routing policy statements are specified in the Prefix Exclude Policies panel, any prefixes defined in the routing policies are excluded from the aggregate prefix matching procedure. In this case, when LDP receives an FEC-label binding for this prefix, it performs an exact match of a specific FEC element prefix, as opposed to a longest match of one or more LDP FEC element prefixes.

21

Click on the Accounting tab. Click Create. In the AccountingFecPrefix (Create) form, configure the FEC Prefix parameter.

22

In the Egress Accounting Statistics panel, click Select and choose the required accounting policy. Only accounting policies with the CombinedLdpLspEgressStats statistics type are available for selection. Click OK and configure the required parameters.

See the *NSP NFM-P Statistics Management Guide* for general information about configuring and collecting statistics.

23

Save your changes and close the form.

END OF STEPS

28.52 To configure an LDP interface

Note: You can choose to inherit values from the global-level LDP configuration by selecting the Inherit Value parameter.

28.52.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→LDP.

2

Right-click on the LDP icon and choose Create Interface.

3

Select an interface in the Interface panel.

4

Configure the required general parameters.

5

Click on the Protocol Properties tab and configure the required parameters on the available tabs.

By default, the parameter values are inherited by all LDP interfaces.

For the Address Type parameter:

- Choose System to have the system IP address set up LDP sessions.

- Choose Interface to have the IP interface address set up LDP sessions only if there are not multiple interfaces between the two neighbors.

6

If you set the Local LSR ID parameter to Interface, click Select in the Interface panel and select a routing interface.

For LDP interfaces on the 7210 SAS, the Interface panel does not appear when you set the Local LSR ID parameter to Interface. The address of the interface you are configuring is used by default.

7

Save your changes and close the form.

8

Configure the protocol for the far-end device, if applicable. Use CLI for devices that are managed outside the scope of the NFM-P.

END OF STEPS

28.53 To configure an LDP targeted peer

Note: You can choose to inherit values from the global-level LDP configuration by selecting the Inherit Value parameter.

The parameters that you configure for a targeted peer take precedence over the parameters that are configured for the global-level LDP configuration.

28.53.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→LDP.

2

Right-click on the LDP icon and choose Properties.

3

Configure a targeted LDP peer.

Perform the following steps:

1. Click on the Targeted Peers tab and click on Create or choose a targeted peer and click Properties. The Targeted Peer (Create|Edit) form opens.

   Alternatively, you can right-click on LDP and choose Create Targeted Peer. To configure an existing peer, you can expand LDP→Targeted Peers and right-click on a targeted peer and choose Properties.
2. Configure the required general targeted peer parameters.

4

Configure the protocol properties of the targeted peer.

Perform the following steps:

1. Click on the Protocol Properties tab and configure the required protocol parameters.
2. Choose a local LSR ID in the Local LSR ID panel.
3. Configure the required parameters in the Timer Control panel.

   By default, these parameter values are inherited from the global-level LDP instance.

   If the Enable Hello Reduction parameter is disabled while the targeted LDP session to the peer is operationally up, the change in the hold time will take effect only when the targeted LDP session is re-established.

   The parameters are not configurable if you are modifying an auto-created LDP targeted peer that was created using a CLI template. You can determine whether a targeted peer was automatically created on the NE using a template by verifying the Creator indicator.

5

Associate LSP with a targeted peer.

Click on the LSPs tab and click on Add. Choose an LSP.

Click on the Multicast LSPs tab and click on Add. Choose an LSP.

The Multicast LSPs tab is available on enabling the Multicast Tunneling Enabled parameter in the Protocol Properties tab.

Note: If you are associating a dynamic LSP with a targeted peer, the destination of the LSP and targeted peer must be the same.

See Chapter 31, “MPLS” for information on how to create and configure LSPs.

6

Save your changes and close the form.

7

Configure the protocol for the far-end device, if applicable. Use CLI for devices that are managed outside the scope of the NFM-P.

END OF STEPS

28.54 To configure an LDP peer

28.54.1 Purpose

LDP performs the label distribution only in MPLS environments. The LDP operation begins with a hello discovery process to find LDP peers in the network. LDP peers are two LSRs that use LDP to exchange label or FEC mapping information. An LDP session is created between LDP peers. A single LDP session allows each peer to learn the label mappings (LDP is bi-directional) of the other peer and to exchange label binding information.

28.54.2 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→LDP.

2

Right-click on the LDP icon and choose Properties.

3

Configure an LDP peer.

Perform the following steps:

1. Click on the Peers tab and click on Create or choose a peer and click Properties.
2. Configure the required general LDP peer parameters.

   To use LDP DoD, the DoD Label Distribution parameter must be enabled for both peers. If the DoD Label Distribution parameter is not enabled for a peer, LDP DU is used.
3. Configure the required parameters in the FEC panel to specify the number of LDP FECs that the LSR accepts from a given peer and adds into the LDP label database before the NFM-P raises an alarm.

   The LDP service must be up, and a session established between peers before the NFM-P raises an alarm. If the FEC value is above the Threshold parameter value, an implicitly cleared warning is raised. When the value falls below the threshold, the alarm is removed. If the FEC value goes above the FEC Limit parameter value, the NFM-P raises an implicitly cleared major alarm. When the value falls below the limit, but remains above the threshold, the MaxFECLimitReached alarm is cleared.

   You cannot configure the Log Only parameter if the FEC Limit parameter is set to 0.

   You cannot configure the Threshold parameter if the FEC Limit parameter is set to 0.

4

To assign an authentication keychain to the LDP peer, click on the KeyChain tab and select an LDP peer keychain.

5

Click on the Authentication tab and configure the Type and Key parameters.

6

Click on the Import Policies tab and choose up to 5 import policies.

The FEC prefix Import Policy provides a mean of controlling which FEC prefixes received from other LDP and T-LDP peers should be re-distributed to this LDP peer. If no policy name is specified, the NE imports all of the FEC prefixes it learns from other LDP and T-LDP peers to this LDP peer.

7

Click on the Export Policies tab and configure up to 5 export policies.

The FEC prefix Export Policy provides a mean of controlling which FEC prefixes from this peer should be re-distributed to all other LDP and T-LDP peers. If no policy name is specified, the NE will export all FEC prefixes it learns from this LDP peer to all other LDP and T-LDP peers.

8

Save your changes and close the forms.

END OF STEPS

28.55 To configure ECMP for LDP routing

28.55.1 Purpose

The NFM-P supports LDP ECMP when LDP routing is configured on supporting NEs.

For supporting 7210 SAS NEs, resources for LDP ECMP must be allocated using the system resource profile; see 12.50 “To configure the global system resource profile on a 7210 SAS or 7250 IXR” (p. 380) .

28.55.2 Steps

1

In the navigation tree Routing view, expand *NE*→Routing Instance→LDP.

2

Right-click on an LDP icon and choose Properties. The LDP Routing Instance (Edit) form opens.

3

Click on the OAM tab, then the ECMP sub-tab, and set the Tree Trace parameter to Configured.

4

Configure the required tree discovery configuration parameters.

5

Click on the Discovered FECs tab.

6

Choose an FEC and click Properties. An Autodiscovered FEC (Edit) form opens.

7

Perform one of the following:

a. Click Create LDP Tree Trace to configure and execute an LDP tree trace. See Chapter 90, “OAM diagnostic tests” for information about how to configure this test.

b. Click Create LSP Ping to configure and execute an LSP ping test. See Chapter 90, “OAM diagnostic tests” for information about how to configure this test.

c. Click Create LSP Trace to configure and execute an LSP trace test. See Chapter 90, “OAM diagnostic tests” for information about how to configure this test.

8

Click on the Discovered ECMP tab and choose an ECMP path.

9

Click Properties. An Autodiscovered Path (Edit) form opens.

10

Click Create LSP. See Chapter 90, “OAM diagnostic tests” for information about how to configure and execute an LSP trace test.

11

Click Create LSP Ping. See Chapter 90, “OAM diagnostic tests” for more information about how to configure and execute an LSP ping test.

12

Save your changes and close the form.

END OF STEPS

28.56 To view the LDP session information

28.56.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→LDP.

2

Right-click on the LDP icon and choose Properties. The LDP - Routing Instance (Edit) form opens.

3

Click on the Sessions tab.

4

To view the information for a specific session, choose the session entry and click Properties. The Session (View) form opens.

5

Click on the Session tab to view specific session and connection information.

6

View information about the addresses exchanged in LDP peer sessions.

Perform the following steps:

1. Click on the Addresses tab. A list of the addresses received from peers is displayed on the Received tab.
2. To view the information about a received address, choose the address entry and click Properties. The Received Addresses (View) form opens.
3. To view the information about the addresses sent to peers, click on the Sent tab.
4. To view the information about a sent address, choose the address entry and click Properties. The Sent Addresses (View) form opens.

7

Save your changes and close the form.

END OF STEPS

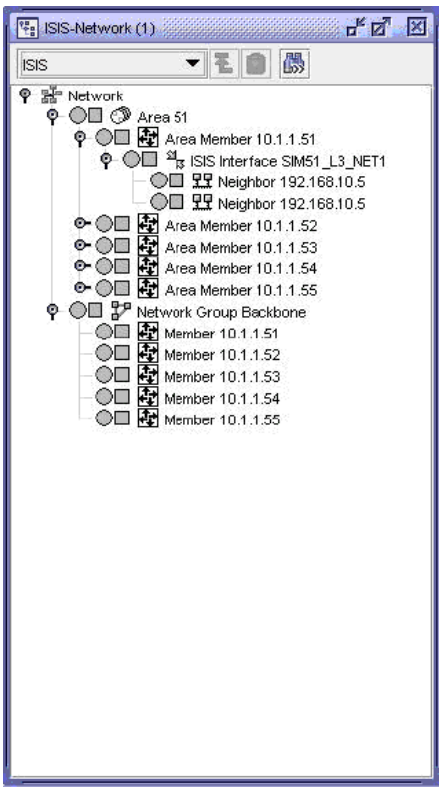
IS-IS configuration workflow and procedures

28.57 IS-IS configuration overview

28.57.1 Overview

Configuration planning is essential to organize devices in level 1, level 2 and level 1 and 2 areas. IS-IS provides defaults for basic protocol operability. Use the NFM-P to configure the IS-IS parameters. The following figure shows the IS-IS view in the navigation tree

Figure 28-7 IS-IS view



The IS-IS information that is displayed includes:

- backbone area and backbone-area devices
- a list of areas and the participating routers in each area
- a list of devices and associated interfaces that shows the IP address and the configured level (1, 2, or 1 and 2) of each interface
- the IS-IS adjacencies for each interface

The following procedures describe how to configure IS-IS.

28.58 Workflow to configure IS-IS

28.58.1 Stages

1

Enable IS-IS on a routing instance; see 28.59 “To enable IS-IS on a routing instance” (p. 952) .

2

Configure global-level IS-IS on a routing instance; see 28.60 “To configure IS-IS on a routing instance” (p. 953) .

3

Configure IS-IS segment routing as required; see 28.79 “To configure IS-IS segment routing” (p. 978) .

4

Configure an IS-IS link group on a routing instance as required; see 28.61 “To configure an IS-IS link group on a routing instance” (p. 956) .

5

Configure at least one IS-IS NET address; see 28.62 “To configure an IS-IS NET address” (p. 957) .

6

Configure at least one IS-IS interface; see 28.63 “To configure an IS-IS interface” (p. 958) .

7

If LDP over RSVP is enabled for IS-IS, configure an operational LSP between routers; see Chapter 31, “MPLS” .

28.59 To enable IS-IS on a routing instance

28.59.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance

2

Right-click on a routing instance icon and choose Properties. The Routing Instance (Edit) form opens.

3

Click on the Protocols tab and select the IS-IS Enabled parameter.

4

Click OK.

5

Click Yes. IS-IS is displayed in the list of enabled protocols.

6

Save your changes and close the form. The ISIS Instance object is displayed in the navigation tree.

END OF STEPS

28.60 To configure IS-IS on a routing instance

28.60.1 Purpose

Routing instance IS-IS parameter values can differ from the IS-IS interface parameter values that are configured in 28.63 “To configure an IS-IS interface” (p. 958) . Interface capabilities are compared to the router-wide capabilities to determine the type of level 1, level 2, and level 1 and 2 adjacencies that are set up between routers to exchange IS-IS routing information.

28.60.2 Steps

1

Enable the IS-IS protocol on a routing instance, as described in 28.59 “To enable IS-IS on a routing instance” (p. 952) .

2

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→ISIS Instances.

3

Right-click on the ISIS Instances object and choose Create ISIS Instance, or right-click on an ISIS Instance object and choose Properties. The ISIS Site, Routing Instance, ISIS Instance (Create|Edit) form opens.

4

Configure the required general IS-IS instance parameters.

A level 1 adjacency can be established when there is at least one area ID shared by this router and a neighboring router. A level 2 adjacency is established when another router is configured as a level 2 or a level 1 and 2 router with interfaces configured as level 2 or level 1 and 2. A level 1 and 2 adjacency is created when the neighboring router is also configured as a level 1 and 2 router and the routers have at least one area ID in common.

5

Click on the Behavior tab and configure the required parameters in the General panel.

Note the following:

- You can configure the IPv6 Unicast Multi-Topology parameter only when the Multi-Topology parameter is set to true.
- If you plan to enable IPv6 on the IS-IS instance (see Step 8), you must set the Multi-Topology and IPv6 Unicast Multi-Topology parameters to true.
- You can configure the IID TLV parameter only when the L1 MAC Address and L2 MAC Address parameters are modified from the default values.

6

Click on the LFA tab to configure the required Loop-free Alternates parameters.

Remote loop-free alternate uses segment routing by default. To configure segment routing, see 28.79 “To configure IS-IS segment routing” (p. 978).

7

Configure the required parameters on the Graceful Restart tab.

8

Configure the required parameters to specify the allowed IP versions for the IS-IS instance on the IP Versions tab.

9

Click Apply.

10

Configure the authentication behavior:

Perform the following steps:

1. Click on the Authentication tab and enable authentication.
2. Specify the type of authentication and a key.
3. Select an authentication key chain. See the *NSP System Administrator Guide* for information about how to create a key chain.

11

Configure route preferences and authentication for level 1 or level 2:

Perform the following steps:

1. Click on the Level 1 or Level 2 tab and configure the required parameters.
2. Click on the Authentication tab and configure the required parameters.

12

Select up to five routing policy statements on the Export Policies tab.

You can specify multiple routing policies, in order of preference, to determine the routes that are exported from the routing table to IS-IS. When multiple policies are specified, the policies are evaluated in numerical order.

13

Select up to five routing policy statements on the Import Policies tab.

You can specify multiple routing policies, in order of preference, to determine the routes that are imported to IS-IS. When multiple policies are specified, the policies are evaluated in numerical order.

14

Select up to five loop-free alternate policy statements on the LFA tab.

15

Configure participation in one or more flexible algorithms as needed:

1. Click on the Flexible Algorithms tab.
2. Click Search to populate a list of flexible algorithms.
3. Choose a flexible algorithm and click Properties, or click Create. The Flexible Algorithm (Create|Edit) form opens.
4. Configure the Algorithm ID and Participate parameters.
5. Select a local Flexible Algorithm Definition if needed.
6. Click OK.

Repeat this step to add additional flexible algorithms as needed.

16

Configure one or more IGP shortcuts as needed:

1. Click on the IGP Shortcut tab.
2. Choose a hop and click Properties. The IGP Shortcut Tunnel Next Hop (Edit) form opens.
3. Configure the parameters.
4. Click OK to close the form.

17

Configure a NET address:

Perform the following steps:

1. Click on the NET Addresses tab.
2. Click Create and configure the Area ID parameter on the Area ID, ISIS Instance (Create) form.

3. Save your changes and close the form.

18

Configure a route summarization. IS-IS route summaries allow users to create aggregate IPv4 or IPv6 addresses that include multiple groups of IPv4 or IPv6 addresses for a specific IS-IS summary level. This can help reduce the size of the link state database and the routing table.

Perform the following steps:

1. Click on the Route Summarizations tab and click Create. The Route Summarization (Create) form opens.
2. Configure the required parameters.
3. Save your changes and close the form.

19

To add an IS-IS interface:

Perform the following steps:

1. Click on the Interfaces tab and click Create. The ISIS Interface (Create) form opens.
2. Select an interface in the Interface panel.
3. Click OK and confirm.
4. Perform Step 5 to Step 11 of 28.63 “To configure an IS-IS interface” (p. 958) .

20

Save your changes and close the form.

END OF STEPS

28.61 To configure an IS-IS link group on a routing instance

28.61.1 Purpose

You can create an IS-IS link group to bundle multiple member interfaces that are treated as a single virtual link for ECMP. See 28.60 “To configure IS-IS on a routing instance” (p. 953) and 28.63 “To configure an IS-IS interface” (p. 958) for more information about how to create and configure IS-IS interfaces.

28.61.2 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→ISIS Instances→ISIS Instance.

2

Right-click on an ISIS Instance object and choose Properties. The ISIS Routing Instance, ISIS Instance (Edit) form opens.

3

Create a link group for an ISIS routing instance:

Perform the following steps:

1. Click on the Link Group tab and click Create. The Link Group Config (Create) form opens.
2. Configure the required parameters.

4

Configure Level 1 or Level 2 for the link group:

Perform the following steps:

1. Click on the Level 1 or Level 2 tab. The General sub-tab is displayed.
2. Configure the required parameters.

5

To add a member to the Level 1 or Level 2 link group:

Perform the following steps:

1. Click on the Members tab and click Add. The Select... form opens.
2. Choose an interface and click OK.

6

Save your changes and close the form.

END OF STEPS

28.62 To configure an IS-IS NET address

28.62.1 Steps

1

Enable the IS-IS protocol on a device, as described in 28.59 “To enable IS-IS on a routing instance” (p. 952) .

2

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→ISIS Instances→ISIS Instance.

3

Right-click on the ISIS Instance object and choose Add NET Address. The Area ID (Create) form opens.

4

Configure the Area ID parameter.

Note: The Area ID forms part of the NET address. NET addresses are built from some non-configurable elements, including the device system ID and the network selector ID.The NET address is exchanged in hello and link-state PDUs. Level 1 interfaces must have at least one area ID in common. Level 2 interfaces can have different area IDs. If all of the interfaces have different area IDs, they are considered level 2 interfaces only.

5

Save your changes and close the form.

END OF STEPS

28.63 To configure an IS-IS interface

28.63.1 Purpose

The IS-IS interface parameters can differ from the IS-IS routing instance parameters configured in 28.60 “To configure IS-IS on a routing instance” (p. 953) . Interface parameters specify the interface routing levels. Interface level capabilities are compared to the router-wide level capabilities to determine the type of level 1, level 2, and level 1 and 2 adjacencies that are created between devices.

28.63.2 Steps

1

Enable the IS-IS protocol on a routing instance, as described in 28.59 “To enable IS-IS on a routing instance” (p. 952) . If no IS-IS instance exists, you must create one by performing 28.60 “To configure IS-IS on a routing instance” (p. 953) .

2

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→ISIS Instances→ISIS Instance.

3

Right-click on the ISIS Instance object and choose Create Interface or right-click on an ISIS Interface object and choose Properties. The ISIS Interface (Create|Edit) form opens.

4

If you are creating an IS-IS interface, select an interface in the Interface panel.

5

Configure the required parameters on the General tab.

6

Click on the Behavior tab and configure the required parameters.

To create a mesh group, set the Mesh Group Status parameter to Enabled and specify the same mesh group value for all interfaces. The mesh group parameters specify the assigned mesh group for the interface. Mesh groups limit the amount of flooding that occurs when a new or changed LSP is advertised in an area.

The TE Metric parameter is a read-only field that displays the TE metric used for LSP path computation by CSPF.

The Default Instance parameter is configurable on interfaces on non-zero IS-IS instances.

7

Click on the Segment Routing tab and configure the required parameters.

You cannot configure the IPv4 or IPv6 SID Type or SID Value parameter on a network interface that is not loopback enabled or that is on a service interface. In the navigation tree Routing view, expand Network→NE→Routing Instance→Interface, right-click on the interface and choose Properties. Configure the Loopback Enabled parameter on the Network Interface (Edit) form.

The IPv4 or IPv6 SID Value range depends on the Prefix Start Label and Prefix Map Index configured in the IS-IS instance, see 28.79 “To configure IS-IS segment routing” (p. 978). The IPv6 SID value cannot be the same as the IPv4 SID.

8

Configure the required parameters on the Flexible Algorithms tab.

You cannot configure the IPv4 or IPv6 SID Type or SID Value parameter on a network interface that is not loopback enabled or that is on a service interface. In the navigation tree Routing view, expand Network→NE→Routing Instance→Interface, right-click on the interface and choose Properties. Configure the Loopback Enabled parameter on the Network Interface (Edit) form.

The IPv6 SID value cannot be the same as the IPv4 SID.

1. Click Search to populate a list of flexible algorithms.
2. Choose a flexible algorithm and click Properties, or click Create. The Interface Flexible Algorithm (Create|Edit) form opens.
3. Configure the Flexible Algorithm ID parameter.
4. Configure the IPv4 and IPv6 SID parameters as needed.
5. Click OK.

Repeat this step to add additional flexible algorithms as needed.

9

Configure the required parameters on the Authentication and Policies tabs.

10

Configure the route preferences and authentication for level 1 or level 2:

Perform the following steps:

1. Click on the Level 1 or Level 2 tab and configure the required parameters on the General sub-tab.
2. Click on the Authentication sub-tab and configure the required parameters.

11

Save your changes and close the form.

END OF STEPS

OSPF configuration workflow and procedures

28.64 OSPF configuration overview

28.64.1 Overview

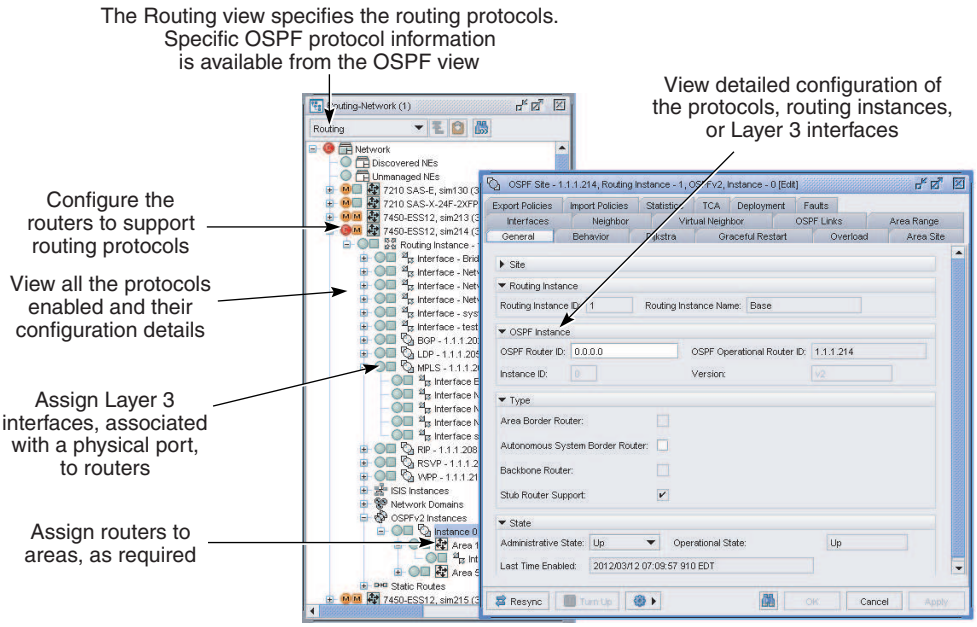
The NFM-P supports the configuration of OSPFv2 and OSPFv3 on supporting NEs.

Configuration planning is essential to organize OSPF areas, interfaces, and virtual links. OSPF provides defaults for basic protocol operability. OSPF configuration requires, as a minimum, that:

- you create a single OSPF backbone area that contains the area border routers.
- for larger networks, you create several areas that contain the other routers.
- for smaller networks, you place all routers in the OSPF backbone area.

Use the NFM-P navigation tree to configure the OSPF parameters. The following figure shows the OSPF view in the navigation tree.

Figure 28-8 OSPF view



22868

The OSPF parameters that are required for OSPF deployment are:

- Router ID — Each device that runs OSPF must be configured with a unique router ID. The router ID is used by the OSPF and BGP routing protocols in the routing table manager. When you configure a new router ID, protocols are not automatically restarted with the new router ID. You must shut down and restart the protocol to initialize the new router ID.

- An area — At least one OSPF area must be created. An interface must be assigned to each OSPF area. The types of OSPF areas include a backbone area, stub area, and NSSA.
- Layer 3 interfaces — A Layer 3 interface is the logical IP connection between a router and one of its attached networks. A physical interface is associated with the Layer 3 interface to provide the cabled connected to another device. A Layer 3 interface has state information from the underlying lower-level protocols and the routing protocol. A network interface has an associated IP address and mask that combine to create an IP prefix, unless the interface is in an unnumbered, point-to-point network.

The following procedures describe how to configure OSPF.

28.65 Workflow to configure OSPFv2 and OSPFv3

28.65.1 Stages

1

Enable OSPF on a routing instance; see 28.66 “To enable OSPF on a routing instance” (p. 963) .

2

Create at least one OSPFv2 or OSPFv3 area; see 28.67 “To create an OSPF area” (p. 963) .

3

Create an OSPF neighbor on an OmniSwitch as required; see 28.68 “To create an OSPF neighbor on an OmniSwitch” (p. 965) .

4

Assign Layer 3 interfaces to the routers in the OSPFv2 or OSPFv3 area; see 28.69 “To add a Layer 3 interface to an OSPF router” (p. 965) .

5

Create an OSPF area range as required; see 28.70 “To create an OSPF area range” (p. 967) .

6

Create a virtual link between the backbone OSPF area and a remote OSPF area that does not advertise the OSPF topology as required; see 28.71 “To create a virtual link between OSPF areas” (p. 968) .

7

Configure OSPF on a default routing instance or a VRF routing instance; see 28.72 “To configure OSPF on a default routing instance or a VRF routing instance” (p. 969) .

8

Configure OSPF segment routing as required; see 28.80 “To configure OSPF segment routing” (p. 980).

9

Assign routers to the OSPFv2 or OSPFv3 area; see 28.74 “To add a router to an OSPF area” (p. 972) .

28.66 To enable OSPF on a routing instance

28.66.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance.

2

Right-click on a routing instance icon and choose Properties. The Routing Instance (Edit) form opens.

3

Click on the Protocols tab.

4

Select the OSPFv2 Enabled parameter to enable OSPFv2, if required.

5

Select the OSPFv3 Enabled parameter to enable OSPFv3, if required.

6

Save your changes and close the form.

END OF STEPS

28.67 To create an OSPF area

28.67.1 Steps

1

In the navigation tree OSPF view, right-click on the Network icon and choose Create Area. The Area (Create) form opens.

2

Configure the required general parameters and click Apply. The form refreshes with additional tabs.

3

Click on the Area Site tab and click Create to add a routing instance to the area. The Area Site (Create) form opens.

4

Click Select to choose a routing instance.

5

Configure the required parameters and click Apply. Additional configurable tabs appear, and an icon for the new area appears in the navigation tree.

Configure the area as a blackhole range to avoid routing loops.

The Type parameter is not configurable for a backbone-area routing instance.

6

Depending on the Type parameter value, the Stub/NSSA tab is configurable. Configure stub or NSSA functionality, if required.

The Default Cost parameter is configurable only when the Type parameter value in Step 5 is Stub (No Type 5 External) or Totally Stub (No Summaries).

1. Click on the Stub/NSSA tab.
2. Configure the required parameters.

   The Redistribute External Routes, Originate Default Route, and Adjacency Check parameters are configurable only when the Type parameter value from Step 5 is NSSA (No Type 5 External) or NSSA (No Summaries).

   The Adjacency Check parameter is configurable only when the Originate Default Route is set to Originate Type 3 or Originate Type 7. Enable the Adjacency Check parameter to enforce an ABR to have an adjacency in area 0 before the default route or routes can be advertised into the NSSA.

7

Click on the Import Policies and Export Policies tabs and configure the required parameters. Routing policies determine the routes that are advertised to peers, and are created as routing policy statements. See 54.5 “To configure a routing policy statement” (p. 1745) .

8

If the area is a backbone area that requires links to remote areas that do not advertise OSPF topology, configure a virtual link.

Perform the following steps:

1. Click on the Virtual Link tab.
2. Perform Step 4 to Step 7 of 28.71 “To create a virtual link between OSPF areas” (p. 968) .
3. Save your changes. The new virtual link entry appears in the list.

9

Create an area range:

Perform the following steps:

1. Click on the Area Range tab and click Create. The Area Range (Create) form opens.
2. Perform Step 3 and Step 4 of 28.70 “To create an OSPF area range” (p. 967) .
3. Save your changes. The new area range entry appears in the list.

10

Save your changes and close the form.

END OF STEPS

28.68 To create an OSPF neighbor on an OmniSwitch

28.68.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→OSPFv2.

2

Right-click on the OSPFv2 icon and choose Create Neighbor. The OspfNeighbor (Create) form opens.

3

Configure the required parameters.

4

Save your changes and close the form.

END OF STEPS

28.69 To add a Layer 3 interface to an OSPF router

28.69.1 Purpose

Perform this procedure to allow an OSPF-enabled router to participate in area discovery and share routing information with other area members.

Note: This action assigns an existing Layer 3 interface to the router in the OSPF area rather than creating a new Layer 3 interface.

28.69.2 Steps

1

In the navigation tree OSPF view, expand Network→Instance.

2

Right-click on an Instance icon and choose Create Interface. The OSPF Interface (Create) form opens.

3

Configure the required general parameters.

4

Choose an interface in the Interface panel.

5

Click on the Protocol Properties tab and configure the required parameters.

6

Perform one of the following steps to configure authentication for the interface. Otherwise, go to Step 10 .

a. Click on the Authentication tab, and go to Step 7 .

b. For OSPFv3 interfaces, go to Step 8 .

7

Configure the Authentication Type parameter.

a. Choose MD5-based Authentication.

Perform the following steps:

1. Click Create to create an MD5 authentication key. The Md5Key (Create) form opens.
2. Configure the required parameters and save your changes.

b. Choose Simple Password.

Perform the following steps:

1. Click Change Password to enter a password. The Password (Create) form opens.
2. Configure the required parameters and save your changes.

8

Click on the IPsec Static SA tab and configure the required parameters.

9

Click on the Policies tab and configure the required parameters.

10

Click on the Segment Routing tab and configure the required parameters.

You cannot configure the IPv4 SID Type or SID Value parameter on a network interface that is not loopback enabled or that is on a service interface. In the navigation tree Routing view, expand Network→NE→Routing Instance→Interface, right-click on the interface and choose Properties. Configure the Loopback Enabled parameter on the Network Interface (Edit) form.

The IPv4 SID Value range depends on the Prefix Start Label and Prefix Map Index configured in the OSPF instance, see 28.80 “To configure OSPF segment routing” (p. 980) .

11

Save your changes and close the form.

END OF STEPS

28.70 To create an OSPF area range

28.70.1 Purpose

An area range summarizes a range of IP addresses in an LSA to minimize the number of flooded advertisements in the LSA.

28.70.2 Steps

1

In the navigation tree OSPF view, expand Network→Instance.

2

Right-click on an Instance icon and choose Create Area Range. The Area Range (Create) form opens.

3

Configure the required parameters.

4

Save your changes and close the form. An icon for the new area range appears in the navigation tree below the OSPF area.

END OF STEPS

28.71 To create a virtual link between OSPF areas

28.71.1 Purpose

Perform this procedure to create a virtual link between a backbone OSPF area and a remote OSPF area that does not advertise the OSPF topology. When you create a virtual link, a virtual neighbor is automatically created.

28.71.2 Steps

1

On the NFM-P navigation tree, choose OSPF from the view selector.

2

Click on the backbone area icon in the navigation tree to display the area routers. The backbone area ID is 0.0.0.0.

3

Right-click on a backbone-area router instance icon and choose Create Virtual Link. The Virtual Link (Create) form opens.

4

Configure the general parameters.

5

Click on the Protocol Properties tab and configure the required parameters.

6

Perform one of the following steps to configure authentication for the virtual link. Otherwise, go to Step 9 .

a. Click on the Authentication tab, and go to Step 7 .

b. For OSPFv3 interfaces, go to Step 8 .

7

Configure the Authentication Type parameter.

a. Choose MD5-based Authentication.

   Perform the following steps:

   1. Click Create to create an MD5 authentication key. The Md 5 Key (Create) form opens.
   2. Configure the required parameters.
   3. Save your changes and go to Step 9 .

b. Choose Simple Password.

   Perform the following steps:

   1. Click Change Password to enter a password. The Password (Create) form opens.
   2. Configure the required parameters.
   3. Save your changes and go to Step 9 .

8

Click on the IPsec Static SA tab and configure the required parameters.

9

Save your changes and close the form. The Virtual Link (Create) form closes, and the NFM-P displays two new icons: one for the virtual link and one for the virtual neighbor.

10

As required, review the properties of the virtual link or virtual neighbor, by clicking on the appropriate icon and selecting Properties.

Note: You can delete a virtual link by selecting the virtual link icon and clicking Delete. To delete a virtual neighbor, you must select the virtual link icon and click Delete.

END OF STEPS

28.72 To configure OSPF on a default routing instance or a VRF routing instance

28.72.1 Steps

1

In the navigation tree Routing view, perform one of the following:

a. For NEs that support multiple OSPF instances, expand Network→*NE*→Routing Instance→OSPFv*N* Instances, where *N* is the OSPF version number; for example, 2 or 3.

b. For all other supported devices, expand Network→*NE*→Routing Instance→OSPFv*N*, where *N* is the OSPF version number; for example, 2 or 3.

2

Perform one of the following:

a. For NEs that support multiple OSPF instances, right-click on the appropriate OSPFv*N* Instances icon and choose Create OSPFv*N* Instance. The OSPF Site (Create) form opens. Go to Step 3 .

b. For all other supported devices, right-click on the appropriate OSPFv*N* icon and choose Properties. The OSPF Site, Routing instance, OSPFv*N* instance (Edit) form opens. Go to Step 3 .

3

Configure the required general parameters.

4

Click on the Behavior tab and configure the required parameters.

Some parameters are configurable for OSPFv2 only.

Remote loop-free alternate uses segment routing by default. To configure segment routing, see 28.80 “To configure OSPF segment routing” (p. 980).

5

Click on the Dijkstra tab and configure the required parameters:

For SPF:

- SPF Max Wait (milliseconds)
- Redistribute Delay (milliseconds)
- Initial Wait (milliseconds)
- Second Wait (milliseconds)
- Incremental SPF Wait (milliseconds)

For LSA:

- LSA Generate Max Wait (milliseconds)
- LSA Arrival Wait (milliseconds)
- Initial Wait (milliseconds)
- Second Wait (milliseconds)
- LSA Accumulate (milliseconds)

6

Click on the Graceful Restart tab and configure the required parameters.

7

Depending on the OSPF version, the Overload tab is configurable. Click on the Overload tab and configure the required parameters.

The Overload Interval (seconds) parameter is configurable when the Overload Enabled parameter is selected.

The Boot Overload Interval (seconds) parameter is configurable when the Boot Overload Enabled parameter is enabled.

8

Click on the LFA tab and configure the required parameters.

Additional parameters are available when you select the Loop-free Alternate parameter.

9

Configure participation in one or more flexible algorithms as needed:

1. Click the Flexible Algorithms tab.
2. Click Search to populate a list of flexible algorithms.
3. Choose a flexible algorithm and click Properties, or click Create. The Flexible Algorithm (Create|Edit) form opens.
4. Configure the Algorithm ID and Participate parameters.
5. Select a local Flexible Algorithm Definition if needed.
6. Click OK.

Repeat this step to add additional flexible algorithms as needed.

10

If the OSPF version is OSPFv2, the OSPF Super-Backbone tab is configurable. Click on the OSPF Super-Backbone tab and configure the required parameters.

The following parameters apply only to VPRN instances of OSPF:

- VPN Domain Type
- VPN Domain ID (hex)
- VPN Tag
- Super-Backbone

11

Click on the Import Policies and Export Policies tabs and configure the required parameters. Routing policies determine the routes that are advertised to peers, and are created as routing policy statements. See 54.5 “To configure a routing policy statement” (p. 1745) .

12

Select up to five loop-free alternate policy statements on the LFA Policies tab.

13

To configure segment routing, see 28.80 “To configure OSPF segment routing” (p. 980)

14

Click on the following tabs to add optional OSPF configuration items. Click Search to list previously configured items or click Create to create the item, if supported.

- Area Sites; see 28.67 “To create an OSPF area” (p. 963)
- Interfaces (Layer 3 interfaces); see 28.69 “To add a Layer 3 interface to an OSPF router” (p. 966)
- Area Range; see 28.70 “To create an OSPF area range” (p. 967)

- Virtual Neighbor; see 28.71 “To create a virtual link between OSPF areas” (p. 968)
- OSPF Links (configurable only in a backbone area); see 28.71 “To create a virtual link between OSPF areas” (p. 968)
- IGP Shortcut; see 28.73 “To configure an IGP shortcut on an OSPF instance” (p. 971)

15

Save your changes and close the form.

END OF STEPS

28.73 To configure an IGP shortcut on an OSPF instance

28.73.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→OSPFv*N* Instances, where *N* is the OSPF version number; for example, 2 or 3.

2

Right-click on the appropriate OSPFv*N* Instance icon and choose Properties. The OSPF Site (Edit) form opens.

3

Click on the IGP Shortcut tab.

4

Choose a hop and click Properties. The IGP Shortcut Tunnel Next Hop (Edit) form opens.

5

Configure the parameters.

6

Save your changes and close the forms.

END OF STEPS

28.74 To add a router to an OSPF area

28.74.1 Steps

1

In the navigation tree OSPF view, expand Network→Routing→OSPF Area.

2

Right-click on the OSPF area icon and choose Add OSPF Instance. The Area Site (Create) form opens.

3

Configure the required parameters.

Configure the area as a blackhole range to avoid routing loops.

4

Select a Routing Instance in the Routing Instance panel.

5

Depending on the Type parameter value from Step 3 , the Stub/NSSA tab is configurable. Click on the Stub/NSSA tab and configure the required parameters.

The Default Cost parameter is configurable only when the Type parameter value from Step 3 is Stub (No Type 5 External) or Totally Stub (No Summaries).

The Redistribute External Routes, Originate Default Route, and Adjacency Check parameters are configurable only when the Type parameter value from Step 3 is NSSA (No Type 5 External) or NSSA (No Summaries).

The Adjacency Check parameter is configurable only when the Originate Default Route is set to Originate Type 3 or Originate Type 7. Enable the Adjacency Check parameter to enforce an ABR to have an adjacency in area 0 before the default route or routes can be advertised into the NSSA.

6

Save your changes and close the form. An icon for the router appears in the navigation tree under the OSPF Area icon.

END OF STEPS

28.75 To configure an OSPF interface

28.75.1 Purpose

The OSPF interface parameters can differ from the OSPF routing instance parameters configured in 28.72 “To configure OSPF on a default routing instance or a VRF routing instance” (p. 969) . Interface parameters specify the interface routing levels. Interface level capabilities are compared to the router-wide level capabilities to determine the type of level 1, level 2, and level 1 and 2 adjacencies that are created between devices.

28.75.2 Steps

1

Enable the OSPF protocol on a routing instance, as described in 28.66 “To enable OSPF on a routing instance” (p. 963) . If no OSPF instance exists, you must create one by performing 28.72 “To configure OSPF on a default routing instance or a VRF routing instance” (p. 969) .

2

In the navigation tree Routing view, perform one of the following:

a. For NEs that support multiple OSPF instances, expand Network→*NE*→Routing Instance→OSPFv*N* Instances, where *N* is the OSPF version number; for example, 2 or 3.

b. For all other supported devices, expand Network→*NE*→Routing Instance→OSPFv*N*, where *N* is the OSPF version number; for example, 2 or 3.

3

Perform one of the following:

a. For NEs that support multiple OSPF instances, right-click on the appropriate OSPFvN Instances icon and choose Create OSPFvN Interface. The OSPF Interface (Create) form opens. Go to Step 4.

b. For all other supported devices, right-click on the appropriate OSPFvN icon and choose Properties. The OSPF Interface, Routing instance, OSPFvN instance (Edit) form opens. Go to Step 4.

4

Configure the required parameters on the Segment Routing tab.

You cannot configure the SID Type or SID Value parameter on a network interface that is not loopback enabled or that is on a service interface. In the navigation tree Routing view, expand Network→*NE*→Routing Instance→Interface, right-click on the interface and choose Properties. Configure the Loopback Enabled parameter on the Network Interface (Edit) form.

5

Configure the required parameters on the Flexible Algorithms tab.

You cannot configure the SID Type or SID Value parameter on a network interface that is not loopback enabled or that is on a service interface. In the navigation tree Routing view, expand Network→*NE*→Routing Instance→Interface, right-click on the interface and choose Properties. Configure the Loopback Enabled parameter on the Network Interface (Edit) form.

1. Click Search to populate a list of flexible algorithms.
2. Choose a flexible algorithm and click Properties, or click Create. The Interface Flexible Algorithm (Create|Edit) form opens.
3. Configure the Flexible Algorithm ID parameter.
4. Click OK.

Repeat this step to add additional flexible algorithms as needed.

6

Configure the required parameters on the Authentication and Policies tabs.

7

Save your changes and close the form.

END OF STEPS

Segment routing configuration workflow and procedures

28.76 Workflow to configure segment routing

28.76.1 Stages

1

Configure a segment routing policy; see 28.77 “To create a segment routing policy” (p. 976)

2

Configure BGP sites to learn a segment routing policy as needed; see 28.78 “To enable SR policy support on a BGP site, peer, or peer group” (p. 977)

3

Configure segment routing for ISIS and OSPF instances as needed:

- 28.79 “To configure IS-IS segment routing” (p. 978)
- 28.80 “To configure OSPF segment routing” (p. 980)

4

Configure segment routing trees as needed; see 28.81 “To create a segment routing tree” (p. 981)

28.77 To create a segment routing policy

28.77.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance. Right-click on a routing instance and select Properties.

2

Click on the Segment Routing tab.

3

Select the SR policy entry in the SR Policy tab and click Properties. The Segment Routing Policy form opens.

4

Configure the required parameters in the General tab.

5

To enable ingress statistics collection, perform the following:

1. In the Statistics Configuration panel, click Create. The Segment Routing Policy Statistics Configuration form opens.
2. Set the Administrative State to Up, and configure all other required parameters.
3. Click OK and confirm to close the form. A statistics configuration entry appears in the table.

Note: Statistics are not collected unless there are at least two NEs using the policy.

6

Click on the Static Policies tab. Create segment routing static policies by performing the following:

1. Click Create. The Segment Routing Static Policy form opens.
2. Configure the parameters in the General tab.
3. If you will need to use Seamless BFD, click Select in the Maintenance Policy panel to add a maintenance policy; see 54.18 “To configure a maintenance policy” (p. 1764).
4. Click on the Segment List tab and click Create. The Segment List form opens.
5. Configure the parameters on the General tab.
6. Click on the Segment List Entries tab and click Create. The Segment List Entry form opens.
7. Configure the parameters then click OK and confirm to close the Segment List Entry form. A segment list entry appears in the table.
8. Click OK and confirm to close the Segment List form. A segment list appears in the table.
9. Click on the Segment Routing SRv6 tab, and then on the Binding SID sub-tab.
10. Click Create. The Binding SID form opens.
11. Configure the parameters on the General tab.
12. Click OK and confirm to close the Binding SID form.
13. Click OK and confirm to close the Segment Routing Static Policy form. A static policy appears in the table.

7

Click OK and confirm to close the Segment Routing Policy form.

END OF STEPS

28.78 To enable SR policy support on a BGP site, peer, or peer group

28.78.1 Steps

1

Click on the VPN tab on a BGP site, peer, or peer group configuration form.

2

Enable the SR Policy IPv4 parameter.

3

Click on the Next-Hop Resolution tab.

4

Enable SR policies on tunnel interfaces by performing the following:

1. Select an instance in the Shortcut Tunnel or Label Route Transport Tunnel and click Properties.
2. Enable the SR Policy parameter.
3. Repeat for each tunnel family on which you need to enable SR policies.

5

Click on the Behavior tab and enable the Import Segment Routing Policy parameter.

6

Click OK and confirm to close the form.

END OF STEPS

28.79 To configure IS-IS segment routing

28.79.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→ISIS Instances.

2

Right-click on an ISIS Instance object and choose Properties. The ISIS Site, Routing Instance, ISIS Instance (Edit) form opens.

3

Click on the Behavior tab.

4

In the General panel, set the Advertise Router Capability parameter to AS or to Area.

5

Click on the Segment Routing tab.

6

Configure the parameters on the SID Statistics panel.

7

Set the Administrative State parameter to Up and configure the required parameters.

The Prefix SID Start Label is configurable only when the Prefix SID Type parameter is set to Local.

The minimum value you can enter for the Prefix SID Start Label parameter depends on the value of the Start Segment Routing Label parameter on the MPLS instance. See 31.6 “To configure an MPLS instance” (p. 1116) .

8

To support dual adjacency SIDs, configure the parameters in the Adjacency SID panel.

9

Configure the parameters in the Multi-Topology panel.

10

To configure IS-IS/LDP segment routing interworking, perform the following:

1. Set the Export Tunnel Table Protocol attribute to LDP.
2. Click on the Mapping Prefix sub-tab.
3. Click on the Create button. The Mapping Server form opens.
4. Configure the required parameters.
5. Save your changes and close the form.

11

To configure an adjacency set and SID, perform the following:

1. In the Reserved Label Block panel, click on the Select button and choose a reserved label block. See 31.35 “To create a reserved label block” (p. 1163) for information about creating reserved label blocks.
2. In the Adjacency Set panel, click on the Create button. The Segment Routing Adjacency Set form opens.
3. Configure the required parameters.
4. Save your changes and close the form.

12

Save your changes and close the form.

END OF STEPS

28.80 To configure OSPF segment routing

28.80.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→OSPF Instances.

2

Right-click on an OSPF Instance object and choose Properties. The OSPF Site, Routing Instance, OSPF Instance (Edit) form opens.

3

Click on the Behavior tab.

4

In the General panel, set the Advertise Router Capability parameter to AS or to Area.

Note: For OSPFv3, the parameter must be set to Area.

5

Click on the Segment Routing tab.

6

Set the Administrative State parameter to Up and configure the required parameters.

The Prefix SID Start Label is configurable only when the Prefix SID Type parameter is set to Local.

The minimum value you can enter for the Prefix SID Start Label parameter depends on the value of the Start Segment Routing Label parameter on the MPLS instance. See 31.6 “To configure an MPLS instance” (p. 1116) .

7

To support dual adjacency SIDs, configure the parameters in the Adjacency SID panel.

8

To configure OSPF/LDP segment routing interworking, perform the following:

1. Set the Export Tunnel Table Protocol attribute to LDP.
2. Click on the Mapping Prefix sub-tab.
3. Click on the Create button. The Mapping Server form opens.
4. Configure the required parameters.
5. Save your changes and close the form.

9

To configure an adjacency set and SID, perform the following:

1. In the Reserved Label Block panel, click on the Select button and choose a reserved label block. See 31.35 “To create a reserved label block” (p. 1163) for information about creating reserved label blocks.
2. In the Adjacency Set panel, click on the Create button. The Segment Routing Adjacency Set form opens.
3. Configure the required parameters.
4. Save your changes and close the form.

10

Save your changes and close the form.

END OF STEPS

28.81 To create a segment routing tree

28.81.1 Purpose

Use this procedure to create a segment routing multicast tree for P2MP traffic engineering. The segment routing tree must be created on a routing instance of the NE that will serve as the root node.

A reserved label block is required; see 31.35 “To create a reserved label block” (p. 1163).

28.81.2 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance. Right-click on a routing instance and select Properties.

2

Click on the Segment Routing tab.

3

Click on the SR-Tree tab and click Create. The Segment Routing Tree form opens.

4

Configure the required parameters in the General tab.

5

Click on the SR-Tree Replication Policies tab. Create segment routing tree replication policies by performing the following:

1. Click Create. The Replication Segment Policy form opens.
2. Configure the parameters in the General tab.
3. Click on the Next Hop Entries tab and click Create. The Replication Segment Policy Next Hop form opens.
4. Configure the parameters.
5. Click OK to close the Replication Segment Policy Next Hop form. A next hop entry appears in the table.
6. Create additional hops as needed.
7. Click OK to close the Replication Segment Policy form. An SR-Tree Replication policy appears in the table.

6

Click on the SR-Tree Policies tab. Create segment routing tree policies by performing the following:

1. Click Create. The Segment Routing Tree Policy form opens.
2. Configure the parameters in the General tab.
3. Click on the Candidate Paths tab and click Create. The Candidate Path form opens.
4. Configure the parameters.

   The Active Instance parameter indicates the replication policy instance ID to be used.
5. Click OK to close the Candidate Path form. A candidate path appears in the table.
6. Create additional candidate paths as needed. The candidate path with the higher preference becomes the active candidate path.
7. Click OK to close the Segment Routing Tree Policy form. An SR-Tree policy appears in the table.

7

Click OK and confirm to close the Segment Routing Tree form.

END OF STEPS

28.82 To configure segment routing with IPv6

28.82.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance. Right-click on a routing instance and select Properties.

2

Click on the Segment Routing tab.

3

Create or select an entry in the SRv6 tab and click Properties. The Segment Routing V6 (Create/Edit) form opens.

4

Create or select an entry in the Locators tab and click Properties. The SRv6 Locator (Create/Edit) form opens.

5

Configure the required parameters in the General tab.

1. Associate FPE ID under FPE block. See 12.41 “To create an FPE” (p. 374) for more information on FPE.

   Note: The associated Termination FPE must have SRv6 Type set as Termination. Similarly, Origination FPE must be configured with SRv6 Type as Origination.
2. Under Prefix panel, specify the network address for the Prefix Address parameter.
3. Associate a label block under Static Function panel.

   Note: The configuration of FPE ID, Prefix Address, and parameters under Static Function panel are required to set the Administrative State parameter to Up.
4. Save your changes and close the form.

6

On the Segment Routing V6 (Create/Edit) form, configure the required parameters in the General tab.

7

Create or select an entry in the Base Routing Instance panel and click Properties. The SRv6 Function (Create/Edit) form opens.

8

Configure the required parameters in the General tab.

1. Associate a locator under Locator panel.
2. Configure parameters under End Function panel.

   Supported End Function types are Dynamic and Static.

9

Configure the End Function, the End-X Function, and the End -X Allocate Function in respective tabs.

Note: End (End DT4, End DT6, End DT46, End-X) Functions range configuration is dependent on the max entries configured in static function.

10

Save your changes and close the forms.

END OF STEPS

28.83 To configure IS-IS segment routing with IPv6

28.83.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→ISIS Instances.

2

Right-click on an ISIS Instance object and choose Properties. The ISIS Site, Routing Instance, ISIS Instance (Edit) form opens.

3

Click on the Behavior tab.

4

In the General panel, set the Advertise Router Capability parameter to Area.

5

Click on the Segment Routing V6 tab.

6

Create or select an entry in the Locator tab and click Properties. The Segment Routing V6 Locator (Create/Edit) form opens.

1. Associate a locator under Locator panel.
2. Save your changes and close the form.

7

Configure the required parameters in the General tab. Set the Administrative State parameter to Up.

8

Save your changes and close the forms.

END OF STEPS

RSVP configuration workflow and procedures

28.84 Workflow to configure RSVP

28.84.1 Stages

1

Configure MPLS, LSP, MPLS path, and LSP path parameters as required; see Chapter 31, “MPLS” .

2

Configure RSVP on a routing instance; see 28.85 “To configure RSVP on a routing instance” (p. 985) .

3

Configure an RSVP interface; see 28.86 “To configure an RSVP interface” (p. 986) .

28.85 To configure RSVP on a routing instance

28.85.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→RSVP.

2

Right-click on the RSVP icon and choose Properties. The RSVP form opens.

3

Configure the required parameters.

4

To configure Diff-Serv TE, MPLS must be shutdown. Otherwise, go to Step 5 .

Perform the following steps:

1. Configure the required parameters in the Diff-Serv TE panel.

   Note:

   Enabling a Diff Serv Model only takes effect if you have already enabled traffic engineering at one or both of the following routing protocol levels:

   - IS-IS, as described in 28.60 “To configure IS-IS on a routing instance” (p. 953)
   - OSPF, as described in 28.72 “To configure OSPF on a default routing instance or a VRF routing instance” (p. 969)

A dialog box appears if IS-IS and/or OSPF TE is not enabled, but you can save your configuration if IS-IS and/or OSPF TE is not enabled.

The Class Type BW Percent parameters are configured globally and the parameters are applied to all RSVP interfaces in the system. After the parameters are configured, the parameters can only be changed after you shut down the MPLS protocol. The total bandwidth specified for the eight classes should not exceed 100%.

2. Configure the parameters in the TE Update panel. The TE Update parameters are only configurable if the TE Threshold Update Enabled parameter is enabled in 1 .
3. Configure the Include Node in RRO parameter.
4. Configure the required parameters in the Merge Point Abort Timer and GR Helper Time panels.
5. Configure the Authentication Over Bypass Enabled parameter to support authentication per RSVP interface.
6. Click on the TE Classes tab, select one of the TE classes, and click Properties. The TE Class (Edit) form opens.

   Note:

   The TE Class Definition is used to map all TE Classes (up to a maximum of 8) to Class Type and LSP setup priority. There is no default TE Class after Diff-Serv is enabled. You must explicitly define each TE Class. If Diff-Serv is disabled, the default CT (CT0) and eight pre-emption priorities are used internally.
7. Configure the required parameters and click Apply.
8. Click on the ForwardingClassMaps tab and click Create. The Forwarding Class Map (Create) form opens.
9. Configure the required parameters and click Apply.
10. Click on the TE Thresholds tab and configure the required parameters.

    You can also click Reset TE Up/Down Thresholds to Default to set the Up or Down Thresholds to their default values, respectively.

5

Save your changes and close the form.

END OF STEPS

28.86 To configure an RSVP interface

28.86.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→RSVP→Interfaces→Interface.

2

Right-click on the Interface icon and choose Properties. The RSVP Interface (Edit) form opens.

3

Configure the required parameters.

4

Click on the Protocol Properties tab and configure the required parameters.

The Class Type BW Percent parameters can only be configured if the Inherit NFM-P Class Type BW parameter is disabled. If you enter values at the RSVP interface level, they override the global values configured in 28.85 “To configure RSVP on a routing instance” (p. 985) for the RSVP routing instance on the NE.

5

Click on the Authentication tab and configure the Key parameter.

6

Select an RSVP Keychain.

7

Click on the TE Thresholds tab and configure the required parameters.

You can only configure the Up Threshold (%) and Down Threshold (%) parameters if the Inherit TE Up Thresholds and Inherit TE Down Thresholds parameters are disabled, respectively.

8

Save your changes and close the form.

END OF STEPS

L2TP configuration workflow and procedures

28.87 L2TP configuration

28.87.1 Overview

The NFM-P supports the configuration and management of L2TP sites, tunnel group profiles, and tunnel profiles. L2TPv2 and L2TPv3 tunnels are available. Both can be configured at the same time.

A typical L2TPv2 configuration is applied to two NEs; one NE performs the LAC role and the other NE performs the LNS role. An NE can perform both LAC and LNS roles. At least one ISA-LNS group must be configured for the LNS NE. See 13.1.5 “Working with ISA-LNS groups” (p. 407) for information about ISA-LNS groups. See 13.12 “To configure an ISA-LNS group” (p. 426) for information about creating and configuring an ISA-LNS group member.

L2TPv3 tunnels pass Ethernet traffic. The tunnels are symmetric and do not have LAC and LNS ends.

Note: An NE must be in chassis mode B or higher to support L2TP.
You can also enable L2TP on a VPRN site. See Chapter 79, “VPRN service management” .

The following procedures describe how to configure L2TP.

28.88 Workflow to configure L2TP

28.88.1 Stages

1

Configure L2TP on a routing instance; see 28.89 “To configure L2TP on a routing instance” (p. 989) .

2

Update tunnel instance endpoints on an L2TP site as required; see 28.90 “To update tunnel instance endpoints on an L2TP site” (p. 992) .

3

Create and configure an LNS group and group member for an LNS site. If the site is an LAC, this configuration is not required; see 13.12 “To configure an ISA-LNS group” (p. 426) .

4

Configure the ESM profiles for LNS L2TP termination of the following as required:

a. VPRN; see 79.37 “To configure a group interface on a VPRN” (p. 2586)

b. IES; see 78.19 “To configure a group interface on an IES” (p. 2449)

5

Configure L2TP on each local user database PPPoE host to be forwarded to the LNS (applicable for the LAC and the LNS, where RADIUS is not used) as required; see 74.9 “To configure a local user database for subscriber host authentication” (p. 2025) .

6

View the following L2TP related objects, as required:

- L2TP tunnels and tunnel endpoints; see 28.91 “To view L2TP tunnels and tunnel endpoints” (p. 993) .
- L2TP tunnel instance endpoints associated with a subscriber host; see 28.92 “To view L2TP tunnel instance endpoints on a subscriber instance” (p. 994) .
- L2TP sessions; see 28.93 “To view L2TP sessions” (p. 994) .
- PPP sessions on an LAC or LNS; see 28.94 “To view PPP sessions” (p. 995) .

28.89 To configure L2TP on a routing instance

Note: For most parameters in this procedure, you can specify that the parameter value is inherited from the parent L2TP configuration using the Inherit Value parameter.

If you disable value inheritance for a parameter, the available options are restricted, based on the parent parameter value and the protocol functionality. For example, if a parameter in the global-level L2TP configuration is set to True, the only available option for the same parameter in the tunnel group profile-level L2TP configuration is False, unless a value of False violates a protocol rule, in which case the only available option is True.

The parameters that you configure for a L2TP tunnel group profile take precedence over the parameters that are configured for global-level L2TP.

28.89.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→L2TP.

2

Right-click on the L2TP icon and choose Properties. The L2TP Site (Edit) form opens.

3

Configure the required parameters.

4

Select an L2TP Accounting Policy next to the RADIUS Accounting Policy field. See 57.5 “To configure an L2TP RADIUS accounting policy” (p. 1796) for information on creating an L2TP RADIUS Accounting Policy.

5

On the Failover Information panel, configure the failover recovery parameters, as required.

All tunnel group profiles and tunnel profiles configured on the L2TP site can be configured to inherit the failover recovery information specified here, or they can be configured individually with local failover recovery information.

6

Click on the Tunnel Selection Blacklist tab and configure the required parameters.

7

Click on the L2TPv3 tab to configure L2TPv3 support on the L2TP site.

Configure the required parameters.

8

To create a tunnel group profile:

If you are modifying an existing tunnel group profile, you can manually update the Tunnel Instance Endpoints list for the L2TP site after saving your changes. See Step 11 .

1. Click on the Tunnel Group Profiles tab and click Create. The L2TP Tunnel Group Profile (Create) form opens.
2. Select the L2TP Protocol Version in the Identification panel. Different tabs and parameters are available based on the L2TP protocol version.
3. Configure the required L2TPv2 parameters.
   a. To generate operational L2TPv2 tunnels, a start operation must be performed on the L2TP tunnel on the LAC NE. You can also perform a start operation from a tunnel profile on the LNS.

      Failover recovery information can be configured locally or inherited from the parent L2TP site.
   b. Select an LNS group in the LNS Group ID panel.

      You must choose an LNS group for the tunnel group profile or tunnel profile of the site that acts as the LNS.
   c. Select a RADIUS accounting policy in the L2TP Radius Accounting Policy panel.
4. Configure the required parameters in the L2TPv3 tab if L2TPv3 is chosen.

   When a tunnel group is established, the L2TPv3 Ethernet Sessions tab will list a single item.

9

To configure PPP on an L2TPv2 tunnel group profile:

PPP is required only for LNS L2TP tunnel group profiles and L2TP tunnel profiles.

1. Click on the PPP tab and configure the required parameters.
2. Configure the CHAP challenge length parameters, as required.
3. Select an authentication policy in the Authentication Policy panel.

4. If you did not choose an authentication policy in 3 , select a user database in the User Database panel.
5. Select a default service ID in the Default Service ID panel.
6. Select a default group interface in the Default Group Interface panel.

10

To configure a tunnel profile on the L2TP tunnel group profile:

If you are modifying an existing tunnel profile, you can manually update the Tunnel Instance Endpoints list for the L2TP site after saving your changes. See Step 11 .

1. Click on the Tunnel Profiles tab and click Create. The L2TP Tunnel Profile (Create) form opens.

   Failover recovery information can be configured locally or inherited from the parent tunnel group profile.
2. Configure the v2 parameters as required:
   a. Select an LNS group in the LNS Group ID panel.

      You must choose an LNS group for the tunnel group profile or tunnel profile of the site that acts as the LNS.
   b. Click Select in the L2TP Radius Accounting Policy panel and choose a RADIUS accounting policy from the Select L2TP RADIUS Accounting Policy form.
   c. Click on the PPP tab and repeat Step 9 to configure PPP on the L2TP tunnel profile, as required.
   d. You only configure PPP for LNS L2TP tunnel group profiles and L2TP tunnel profiles.

      The values for the MTU, Keep-Alive Interval, Keep-Alive Multiplier, and CHAP Challenge Length Min and Max parameters can be inherited from the parent tunnel group profile.
   e. Click on the MLPPP tab and configure the required parameters.

      When Inherit from Tunnel Group Profile beside a parameter is enabled, the parameter value from the tunnel group profile is used. You must disable Inherit from Tunnel Group Profile beside a parameter before you can configure the parameter.
3. Save your changes and close the forms.

11

If the tunnel group profiles or tunnel profiles for the L2TP site have been modified, you can update the Tunnel Instance Endpoints list for the L2TP site.

Perform the following steps:

1. Click on the Tunnel Instance Endpoints tab.
2. Click Resync Tunnel Instance Endpoints. A warning message window opens.
3. Click Yes.

12

To configure an L2TP failover SRRP peer site:

Perform the following steps:

1. Click on the Failover SRRP Peers tab.
2. Click Create or select an existing L2TP peer and click Properties. The L2TP Failover SRRP Peer (Create|Edit) form opens.
3. Select a peer address.
4. Select a Track SRRP Instance.
5. Configure the Sync Tag parameter.
6. Save your changes and close the form.

13

Save your changes and close the form.

END OF STEPS

28.90 To update tunnel instance endpoints on an L2TP site

28.90.1 Purpose

If a tunnel group profile or tunnel profile is modified on an L2TP site, the list of tunnel instance endpoints for the site is not updated automatically. Perform this procedure to manually update the content of the Tunnel Instance Endpoints tab for the L2TP site.

28.90.2 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→L2TP.

2

Right-click on the L2TP icon and choose Properties. The L2TP Site (Edit) form opens.

3

Click on the Tunnel Instance Endpoints tab and click Resync Tunnel Instances Endpoints.

4

Save your changes and close the form.

END OF STEPS

28.91 To view L2TP tunnels and tunnel endpoints

28.91.1 Steps

1

Choose Manage→ISA Functions→ISA-L2TP from the NFM-P main menu. The Manage ISA-L2TP form opens.

2

Choose L2TP tunnel (L2TP).

3

Click Search. A list of L2TP tunnels is displayed.

4

Choose an entry in the list and click Properties. The L2TP Tunnel - Endpoint A - Endpoint B form opens.

5

View the information for Tunnel Endpoint A and Tunnel Endpoint B.

6

Click on the L2TP Tunnel Endpoints tab. The two L2TP tunnel endpoints are displayed.

7

Choose an entry in the list and click Properties. The L2TP Tunnel Endpoint (View) form opens.

8

View the information. You can also click Properties to view additional information for the following:

- Site ID
- Tunnel Instance Endpoint
- Tunnel Profile
- Tunnel Group Profile
- Peer

9

Close the forms.

END OF STEPS

28.92 To view L2TP tunnel instance endpoints on a subscriber instance

28.92.1 Steps

1

Choose Manage→Residential Subscribers from the NFM-P main menu. The Manage Residential Subscribers form opens.

2

Choose Residential Subscriber Instance (Residential Subscriber) from the Select Object Type drop-down menu.

3

Choose a subscriber instance and click Properties. The Residential Subscriber Instance (Edit) form opens.

4

Click on the L2TP Tunnel Instance Endpoints tab.

5

Choose an L2TP tunnel instance endpoint and click Properties. The L2TP Tunnel Instance Endpoint (View) form opens.

6

View the information, as required. You can also click on the Sessions tab to view session information.

7

Close the forms.

END OF STEPS

28.93 To view L2TP sessions

28.93.1 Steps

1

Choose Manage→Residential Subscribers from the NFM-P main menu. The Manage Residential Subscribers form opens.

2

Choose L2TP Session (L2TP) from the Select Object Type drop-down menu.

3

Select a site ID and a routing instance site.

4

Configure the Connection ID parameter.

5

Choose a session and click Properties. The L2TP Session (View) form opens.

6

View the information in the following tabs, as available:

Note: Different tabs and panels will be displayed based on whether the session is using L2TPv2 or L2TPv3.

- General tab:
  - Session
  - Tunnel
  - Operational Information
  - LNS PPP

    Note:

    The LNS PPP panel is applicable only for an LNS.
  - L2TPv3 Information
- L2TPv3 Ethernet Tunnel Stats tab

7

Close the forms.

END OF STEPS

28.94 To view PPP sessions

28.94.1 Steps

1

Choose Manage→Residential Subscribers from the NFM-P main menu. The Manage Residential Subscribers form opens.

2

Choose PPP Session (PPP Policy and Session) from the Select Object Type drop-down menu.

3

Select a site ID and a service site.

4

Choose a session in the list and click Properties. The PPP Session form opens.

5

View the information in the following panels:

- PPP General
- Residential Subscriber
- Business Subscriber
- DHCP

6

Click on the following tabs to view the information:

- Authentication Protocols
- DNS and NBNS IP Addresses
- QoS Overrides
- Deployment

7

Close the forms.

END OF STEPS

PIM configuration workflows and procedures

28.95 Workflow to configure PIM

28.95.1 Stages

1

Enable PIM on a routing instance; see 28.97 “To enable PIM on a routing instance” (p. 998) .

2

Configure PIM on a routing instance or a VPRN routing instance; see 28.98 “To configure PIM on a routing instance” (p. 998) and 28.99 “To create a PIM site on a VPRN routing instance” (p. 1003) .

3

Configure Anycast RP for PIM on a router as required; see 28.100 “To configure Anycast PIM on a router” (p. 1011) .

4

Configure a PIM interface; see 28.101 “To create a PIM interface on a base routing instance or VPRN routing instance” (p. 1013) .

28.96 Workflow to configure VRRP-aware PIM

28.96.1 Stages

1

Create an operational group. Do not enable BDF Interface monitoring. See 12.8 “To create an operational group” (p. 345).

2

Configure a VRRP instance on either a base router, IES interface, or VPRN interface. In the Operational Group panel, add the operational group created in Stage 1.

See one of the following:

- 78.54 “To create a VRRP instance on an IES L3 access interface for a virtual router” (p. 2500)
- 79.110 “To create a VRRP instance on a VPRN L3 access interface for a virtual router” (p. 2685)
- 37.4 “To create and configure a VRRP instance” (p. 1283)

3

Configure a PIM interface on the instance. Configure the Designated Router parameters in the Behavior tab to ensure that the Operational DR Priority is the highest priority on the interface if the monitored group is up. For example, if Delta Priority Action is set to Add, Operational DR Priority is equal to DR Priority plus Operational Group Delta Priority.

See one of the following:

- 28.101 “To create a PIM interface on a base routing instance or VPRN routing instance” (p. 1013)
- 78.9 “To add a PIM interface to an IES” (p. 2435)
- 79.45 “To add a PIM interface to a VPRN” (p. 2606)

28.97 To enable PIM on a routing instance

28.97.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance.

2

Right-click on a routing instance and choose Properties. The Routing Instance (Edit) form opens.

3

Enable PIM:

Perform the following steps:

1. Click on the Multicast tab.
2. Select the PIM Enabled parameter.

4

Save your changes and close the form. The PIM icon appears in the navigation tree below the routing instance.

END OF STEPS

28.98 To configure PIM on a routing instance

28.98.1 Purpose

Note: If you are creating a PIM site on a VPRN routing instance, perform 28.99 “To create a PIM site on a VPRN routing instance” (p. 1003) . See 79.22 “To configure ISIS, L2TP, MLD, OSPFv2, OSPFv3, PIM, RIP, or WPP on a VPRN routing instance” (p. 2555) for more information about configuring PIM on a VPRN routing instance.

The tabs and parameters that are configurable vary, depending on the NE on which the PIM site resides.

28.98.2 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→PIM.

2

Right-click on the PIM icon and choose Properties. The PIM Site (Edit) form opens.

3

Configure the Administrative State parameter in the States panel.

4

Configure the required parameters in the PIM General Configurations and ECMP Balancing panels.

5

In the Lag Usage panel, configure the Lag Usage Optimization parameter.

6

Click on the RP Behavior tab. The IPv4 tab is displayed.

7

If you are configuring for IPv4, click on the IPv4 tab and go to Step 8 . Otherwise click on the IPv6 tab and go to Step 12 .

8

Configure the IPv4 Administrative State parameter in the States panel.

9

Configure the required parameters in the PIM General Configurations panel.

10

Configure the required parameters in the Candidate Bootstrap Router and Candidate Rendezvous Point panels.

11

Go to Step 15 .

12

Configure the IPv6 Administrative State parameter in the States panel.

13

Configure the IPv6 RPF Lookup Sequence parameter in the PIM General Configurations panel.

14

Configure the required parameters in the Candidate Bootstrap Router, Candidate Rendezvous Point, and Embedded-RP panels.

15

Add one or more C-RP groups.

Perform the following steps:

1. Click on the Candidate-RP Groups tab.
2. Click Create to add a new entry. The C-RP Group Prefix (Create) form opens.
3. Configure the required parameters.
4. Save your changes.

16

Add one or more embedded RP groups.

The Embedded-RP Groups tab is only selectable if you enabled the Enable Embedded-RP parameter.

Perform the following steps:

1. Click on the Embedded-RP Groups tab.
2. Click Create to add a new entry. The E-RP Group Range (Create) form opens.
3. Configure the required parameters.
4. Save your changes.

17

Click on the Group To RP tab. The Static RP tab is displayed.

18

Click Create. The Static RP (Create) form opens.

19

Configure the required parameters.

20

Click on the Static Group-To-RP tab.

21

Click Create. The Static Group To RP (Create) form opens.

22

Configure the required parameters.

23

Click on the Import Policies tab, then on the BootStrap Import Policies tab.

24

Configure the required parameters to filter bootstrap messages and to control the flow of bootstrap messages to the routing instance.

25

Click on the Join/Prune Import Policies tab.

26

Configure the required parameters to filter join/prune messages.

27

Click on the Register Import Policies tab.

28

Configure the required parameters to filter PIM register messages.

29

Click on the Export Policies tab, then on the BootStrap Export Policies tab.

30

Configure the required parameters to filter PIM-related export messages.

31

Depending on the device release, the Anycast RP tab is configurable. Click on the Anycast RP tab to configure Anycast RP.

Note: You can use the PIM configuration form to add peers to an anycast RP. The complete configuration of anycast RP for PIM requires additional supporting components, such as the configuration of loopback interfaces and static RPs. Due to the complex configuration dependencies, Nokia recommends that you use the Virtual Anycast manager. The Virtual Anycast manager automatically configures many of the supporting requirements for the protocol, which reduces operator configuration errors and assists in troubleshooting activities. See 28.100 “To configure Anycast PIM on a router” (p. 1011) for more information about using the Virtual Anycast manager.

32

Click on the General tab.

33

Configure the RP IP Address parameter.

34

Click on the Anycast Peer tab.

35

Click Create. The Anycast Peer (Create) form opens.

36

Configure the Peer IP Address parameter.

37

Save your changes.

38

Click on the SSM Groups tab.

39

Click Create.

40

Configure the required parameters.

41

Save your changes.

42

Click on the Interfaces tab to create an interface.

43

Click Create; see 28.101 “To create a PIM interface on a base routing instance or VPRN routing instance” (p. 1013)

44

Click on the SPT Switch Threshold tab to configure SPT switchover, if required.

45

Click Create. The Spt Switch Over Threshold (Create) form opens.

46

Configure the required parameters.

47

Save your changes.

48

Click on the following tabs to view and edit information.

- Groups
- Neighbor
- Statistics
- Faults

The Statistics and Faults tabs are unavailable for PIM in VPRN.

49

Save your changes and close the form.

END OF STEPS

28.99 To create a PIM site on a VPRN routing instance

28.99.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Click Search, choose a VPRN service, and click Properties. The VPRN Service (Edit) form opens.

3

On the navigation tree, expand Sites →Routing Instance - NE System ID→Routing Instance.

4

Right-click on Protocols and choose Create PIM Site. The PIM Site (Create) form opens.

5

Configure the required parameters.

6

Click on the RP Behavior tab, then on the IPv4 and IPv6 sub-tabs and configure the required parameters.

7

Click on the MVPN tab.

8

Configure the required parameters.

Note: You must configure the Inclusive Tunnel Type parameter if you are creating an inclusive tunnel.

9

Configure redundant MVPN sources.

Perform the following steps:

1. Click on the Redundant Sources sub-tab and click Create. The Redundant Source (Create) form opens.
2. Configure the required parameters and click OK.

10

Configure primary and standby UMH addresses.

Perform the following steps:

1. Click on the UMH PE Backup sub-tab and click Create. The MVPN UMH PE Backup (Create) form opens.
2. Configure the required parameters and click OK.

11

Configure RPF select groups.

Perform the following steps:

1. Click on the RPF Select sub-tab and click Create. The RPF Select (Create) form opens.
2. Configure the required parameters and click OK.

12

Click on the MVPN Inclusive Tunnel tab. Configure UMH rate monitoring triggers for PMSI redundancy, if required.

Note: The MVPN Inclusive Tunnel tab appears only if you set the Inclusive Tunnel Type parameter to an option other than None in Step 8 .
The tab that appears on the MVPN Inclusive Tunnel tab depends on the Inclusive Tunnel Type parameter option that you configured in Step 8 .

13

Perform one of the following:

a. Create a PIM inclusive tunnel.

   Perform the following steps:

   1. Click on the PIM sub-tab.
   2. Configure the required parameters.
   3. Go to Step 14 .

b. Create an RSVP inclusive tunnel.

   Perform the following steps:

   1. Click on the RSVP tab.
   2. Configure the P2MP Administrative State parameter. You cannot set the P2MP Administrative State parameter to Up until you choose an MVPN LSP template. To create an MVPN LSP template, see 31.29 “To create an LSP template MVPN policy” (p. 1156) .
   3. Click Select. The Select MVPN Lsp Template - RSVP MVPN Provider Tunnel form opens.
   4. Choose an MVPN LSP template and click OK. The MVPN LSP template is displayed.
   5. Configure the required parameters.

c. Create an MLDP inclusive tunnel.

   Perform the following steps:

   1. Click on the MLDP tab.
   2. Configure the P2MP Administrative State parameter.
   3. Go to Step 14 .

d. Create a BIER inclusive tunnel.

   Perform the following steps:

   1. Click on the BIER tab.
   2. Configure the P2MP Administrative State parameter.
   3. Enter the BIER Subdomain number.
   4. Go to Step 14 .

e. Create a Segment Routing inclusive tunnel.

   Perform the following steps:

   1. Click on the Segment Routing tab.
   2. Configure the P2MP Administrative State parameter.
   3. Click Select and choose an SR-Tree policy.
   4. Go to Step 14 .

14

Click on the MVPN Selective Tunnel tab.

15

Configure the Delay Interval (seconds) parameter in the Data MDT panel.

16

Create UMH rate monitoring groups as required, by performing the following:

1. In the UMH Rate Monitoring panel, click Create. The UMH Rate Monitoring Group (Create) form is displayed.
2. Configure the required parameters, and click OK. The new rate monitoring group is added to the list.

Note: You can create multiple entries with the same group address and different source addresses.

17

Configure a data MVPN threshold entry by performing one of the following:

a. Choose an existing data MVPN threshold entry.

Perform the following steps:

1. Click Search in the Data MVPN Threshold tab. The Data MVPN Threshold (Create) form is displayed.
2. Choose a Data MVPN Threshold entry, and click Apply.
3. Go to Step 18 .

b. Create and choose a data MVPN threshold entry.

Perform the following steps:

1. Click Create in the Data MVPN Threshold tab. The Data MVPN Threshold (Create) form is displayed.
2. Configure the required parameters.
3. Click OK, choose the Data MVPN Threshold entry that you created, and click Apply.

18

Configure a data MT interface entry by performing one of the following:

Note: A data Multicast Tunnel (MT) is a connector between a set of PE routers forming a multicast domain. In the context of a VPN-specific PIM instance, a multicast tunnel is a single multi-access interface. The data MT Interface can be created or selected when the PIM address is configured with a value other than null (0.0.0.0).

a. Choose an existing data MT interface entry.

Perform the following steps:

1. Click Search in the Data MT Interface tab.
2. Choose a Data MT Interface entry.
3. Save your changes.
4. Go to Step 19 .

b. Create and choose a data MT interface.

Perform the following steps:

1. Click Add in the Data MT Interface tab. The Data MT Interface (Create) form is displayed.
2. Configure the required parameters.
3. Click OK, choose the data MT interface that you created, and click Apply.

19

Configure the required parameters on the PIM sub-tab.

20

Configure the required parameters on the RSVP sub-tab.

If the RSVP sub-tab is not available, go to Step 23.

21

Click Select in the RSVP panel to choose an MVPN Lsp Template. The Select MVPN Lsp Template form is displayed.

22

Perform one of the following:

a. Choose an existing LSP template for MVPN.

Perform the following steps:

1. Click Search. All of the available MVPN p2mp LSP templates for the local NE (the NE contains this VPRN/PIM) are displayed.
2. Choose the required template and click OK.
3. Go to Step 23 .

b. Create an LSP template for MVPN.

Perform the following steps:

1. Click Create and perform 31.29 “To create an LSP template MVPN policy” (p. 1156) .
2. Choose the newly-created template in the Select MVPN Lsp Template form and click OK.

23

Configure the required parameters on the MDLP sub-tab.

24

Configure the required parameters on the BIER sub-tab.

25

Configure the required parameters on the Segment Routing sub-tab.

26

Perform the following steps as needed to create a Selective PMSI:

1. Choose the MultiStream S-PMSI sub-tab.
2. Click Create. The MultiStream S-PMSI, Routing Instance (Create) form opens.
3. Click Select in the Routing Instance panel to choose an MVPN Lsp Template. The Select MVPN Lsp Template form is displayed.

27

Perform one of the following. Available options depend on the Selective Tunnel Type parameter.

a. Choose an existing LSP template for MVPN.

   Perform the following steps:

   1. Click Search. All of the available MVPN p2mp LSP templates for the local NE (the NE that contains this VPRN/PIM) are displayed.
   2. Choose the required template and click OK.
   3. Complete the configuration and close the forms.

b. Create an LSP template for MVPN.

   Perform the following steps:

   1. Click Create and perform 31.29 “To create an LSP template MVPN policy” (p. 1156) .
   2. Choose the newly-created template in the Select MVPN Lsp Template form and click OK.
   3. Complete the configuration and close the forms.

c. Select an SR-Tree policy.

   Perform the following steps:

   1. Click Search. All of the available SR-Tree policies for the local NE (the NE that contains this VPRN/PIM) are displayed.
   2. Choose the required policy and click OK.
   3. Complete the configuration and close the forms.

Go to Step 28.

28

Configure import policies.

Perform the following steps:

1. Click on the Import Policies tab.
2. Click on the BootStrap Import Policies, Join/Prune Import Policies, and Register Import Policies sub-tabs and configure the message filter parameters.

29

Configure export policies.

Perform the following steps:

1. Click on the Export Policies tab.
2. Click on the BootStrap Export Policies sub-tab and configure the required parameters to filter PIM-related export messages.

30

Create an interface. Click on the Interfaces tab, click Create, and perform 28.101 “To create a PIM interface on a base routing instance or VPRN routing instance” (p. 1013) .

31

Add one or more C-RP groups.

Perform the following steps:

1. Click on the Candidate-RP Groups tab.
2. Click Create to add a new entry. The C-RP Group Prefix (Create) form opens.
3. Configure the required parameters and click OK.

32

Add one or more static RPs.

Perform the following steps:

1. Click on the Group To RP tab.
2. Click Create. The Static RP (Create) form opens.
3. Configure the required parameters.
4. Click on the Static Group-To-RP tab.
5. Click Create. The Static Group To RP (Create) form opens.
6. Configure the required parameters.
7. Save your changes and close the form.

33

Create one or more SSM groups.

Perform the following steps:

1. Click on the SSM Groups tab and click Create.
2. Configure the required parameters and click OK.

34

Create one or more SPT switch thresholds.

Perform the following steps:

1. Click on the SPT Switch Threshold tab and click Create.
2. Configure the required parameters and click OK.

35

Configure GRT extranet group prefixes.

Perform the following steps:

1. Click on the GRT Extranet tab and configure the required parameters.
2. Click on the Group Prefix sub-tab and click Create.
3. Configure the required parameters and click OK.

36

Configure Anycast RP, as required.

Note: You can use the PIM configuration form to add peers to an anycast RP. The complete configuration of anycast RP for PIM requires additional supporting components, such as the configuration of loopback interfaces and static RPs. Due to the complex configuration dependencies, Nokia recommends that you use the Virtual Anycast manager.

The Virtual Anycast manager automatically configures many of the supporting requirements for the protocol, which reduces operator configuration errors and assists in troubleshooting activities. See 28.100 “To configure Anycast PIM on a router” (p. 1011) for more information about using the Virtual Anycast manager.

1. Click on the Anycast RP tab and click Create.
2. Configure the required parameters.
3. Click on the Anycast Peer tab and click Create.
4. Configure the required parameters and click OK.
5. Save your changes and close the form.

37

Click on the following tabs to view and edit information.

- Groups
- Neighbor
- Statistics
- Faults

The Statistics and Faults tabs are unavailable for PIM in VPRN.

38

Save your changes and close the form.

END OF STEPS

28.100 To configure Anycast PIM on a router

28.100.1 Purpose

This procedure describes how to use the Virtual Anycast Manager to configure anycast PIM on a router. The Virtual Anycast Manager automatically configures many of the supporting requirements for the protocol, which reduces operator configuration errors and assists in troubleshooting activities.

Note: The NFM-P does not automatically delete the supporting requirements for the protocol when you delete an anycast RP member.

You can also manually add peers to an anycast RP by navigating to the Anycast RP tab of the PIM configuration form. Ensure that PIM is enabled on the router. See 28.98 “To configure PIM on a routing instance” (p. 998) .

The NFM-P raises an alarm when VRFs from different VPRNs are added to a single anycast RP set. You can only mismatch VRFs using methods that are not associated with the Virtual Anycast Manager; for example, by using the CLI or the PIM configuration form.

28.100.2 Steps

1

Choose Manage→Networking→Virtual Anycast RP from the NFM-P main menu. The Manage Virtual Anycast RP form opens.

2

Click Create. The Virtual Anycast RP form opens.

3

Configure the required parameters.

4

If the Anycast RP Type parameter value is VPRN, choose a VPRN service for the anycast RP.

5

Click Apply. The Status panel appears. The Status panel is used in Step 9 of this procedure to identify configuration problems.

6

Click on the Components tab.

7

Add virtual Anycast RP members to the PIM configuration.

Perform the following steps:

1. Right-click on the Virtual Anycast RP Members icon and choose Add Anycast RP Member. The Enter Interface Name form opens.
2. Enter the interface name for the loopback interface. The Auto Created Interface Name parameter value appears, if configured.
3. Click OK. The Enter Interface Name form closes, and the Select Local Address form opens.
4. Configure the filter criteria.
5. Choose the local IP address that is used to communicate with the other RP members in the virtual anycast set and click OK. The new local address entry appears on the Components tab under the Virtual Anycast RP Members icon. The new local address entry also appears under the Static RP icon.

   Note:

   The local address is typically the system address.

   The NFM-P automatically performs the following virtual anycast RP configuration tasks.
   - creates a PIM-enabled loopback interface, if not present, with the RP address
   - adds a local address to the anycast RP peer set
   - updates the peer sets that participate in the anycast RP so that all peer sets contain the same members
   - enables PIM on the interface that contains the local IP address
   - creates a static RP that uses the anycast RP address. Groups must be manually created using the Components tab
6. Repeat Step 7 1 to 5 for each member in the virtual anycast RP.

8

Add a static group-to-RP mapping for the anycast configuration.

Perform the following steps:

1. Right-click on a member in the Static RP list and choose Create Static RP. The Static RP (Create) form opens.
2. Configure the required parameters.
3. Save your changes and close the form.
4. Repeat Step 8 1 to 3 for each static group-to-RP mapping that you want to add to the virtual anycast RP configuration. Each member needs a static RP and at least one static group-to-RP mapping. The mappings typically use the same configuration values for each member in the group.

9

Verify the status of the anycast RP for PIM configuration.

Perform the following steps:

1. Click on the General tab. The Status panel displays the status of the anycast RP configuration. The NFM-P updates the status when you add a member to or delete a member from the virtual anycast RP. You can also use the Update Status button to manually update the Status panel.

   The following table lists the status check boxes that identify potential configuration problems.

Check box	Description
Missing Group Range(s) Configurations	At least one anycast RP member does not have a group range for the anycast RP address.
Inconsistent Peer Sets	Peer sets of all the anycast RP members are not equal.
PIM not enabled on loopback interface(s)	PIM is not enabled on all loopback interfaces that are configured in the virtual anycast RP.
Only one peer configured	Only one peer is configured for anycast RP. The configuration requires two or more peers for correct functionality.
Loopback interface(s) not properly configured	At least one anycast RP member does not have a loopback interface configured with the anycast RP address.
Missing Static RP configuration(s)	A member of the virtual anycast RP does not have a static RP. Each member requires a static RP.

2. Save your changes and close the form.

END OF STEPS

28.101 To create a PIM interface on a base routing instance or VPRN routing instance

28.101.1 Steps

1

Perform one of the following:

a. Create a PIM interface on a base routing instance.

   Perform the following steps:

   1. In the navigation tree Routing view, expand Network→*NE*→Routing Instance→PIM.
   2. Right-click on the PIM icon and choose Create Interface. The PIM Interface (Create) form opens.

b. Create a PIM interface on a VPRN routing instance.

Perform the following steps:

1. Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.
2. Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.
3. Expand VPRN Service→Sites→Routing Instance - NE System ID→Routing Instance→Routing Instance: *VPRNinstance*→Protocols→PIM.
4. Right-click on the PIM instance and choose Create PIM Interface. The PIM Interface, Routing Instance (Create) form opens.

2

Click Select, choose a Layer 3 interface, and click OK. The Select Interface - PIM Interface form closes, and the interface name appears in the Interface panel.

3

Configure the required parameters.

Note: If you are configuring IPv6 BFD on a VPRN routing instance, you need to enable the IPv6 Allowed parameter on the associated L3 access interface and set the BFD IPv6 Admin State parameter to Up on the BFD tab. See 79.106 “To configure BFD for a VPRN L3 access interface” (p. 2680) .

4

Click on the Behavior tab, then on the General sub-tab.

5

Configure the required parameters.

Note: The Sticky DR Priority parameter is configurable when the Sticky DR parameter is enabled.

6

Click on the Neighbor tab to view and edit information. The Neighbor tab is configurable only when a neighbor PIM interface exists.

7

Click on the IPv4 or IPv6 sub-tab.

8

Configure the IPv4 Administrative State or IPv6 Administrative State parameter in the States panel.

9

Click on the Multicast CAC tab to add a multicast CAC policy.

Perform the following steps:

1. Select a multicast CAC policy.
2. Configure the required parameters.
3. Click on the Levels tab.
4. Click Create. The PIM Interface Multicast CAC level form opens.
5. Configure the required parameters.
6. Click on the LAG Port Down tab.
7. Click Create. The PIM Interface Multicast CAC LAG Port Down form opens.
8. Configure the required parameters.

10

Save your changes and close the form.

END OF STEPS

IGMP configuration workflow and procedures

28.102 Workflow to configure IGMP

28.102.1 Stages

1

Enable IGMP on a routing instance; see 28.103 “To enable IGMP on a routing instance” (p. 1016) .

2

Configure IGMP on a routing instance; see 28.104 “To configure an IGMP site on a router” (p. 1017) .

3

Configure IGMP on an OmniSwitch; see 28.105 “To configure IGMP on an OmniSwitch” (p. 1019) .

4

Configure an IGMP interface; see 28.106 “To configure an IGMP interface” (p. 1019) .

5

Turn up or shut down an IGMP interface as required; see 28.107 “To turn up or shut down an IGMP interface” (p. 1021) .

6

View IGMP multicast reporting statistics or IGMP source statistics as required; see 28.108 “To view IGMP multicast reporting statistics for an IGMP site” (p. 1022) or 28.109 “To view IGMP source statistics” (p. 1022) .

28.103 To enable IGMP on a routing instance

28.103.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance.

2

Right-click on a routing instance icon and choose Properties. The Routing Instance (Edit) configuration form opens.

3

Click on the Multicast tab.

4

Select the IGMP Enabled check box.

5

Save your changes and close the form.

END OF STEPS

28.104 To configure an IGMP site on a router

28.104.1 Purpose

Before you can configure an IGMP site on a router, you must enable IGMP on a routing instance. See 28.103 “To enable IGMP on a routing instance” (p. 1016) .

28.104.2 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→IGMP.

2

Right-click on the IGMP icon and choose Properties. The IGMP Site (Edit) form opens.

3

Configure the required parameters.

4

Click on the SSM Translation tab to configure SSM Translation.

Perform the following steps:

1. Click Create. The SSM Translation (Create) form opens.
2. Configure the required parameters.
3. Save your changes and close the form. The new SSM Translation entry appears on the form.

5

Click on the Interfaces tab to add an IGMP interface; see 28.106 “To configure an IGMP interface” (p. 1019) for information about configuring an IGMP interface.

6

Click on the Group Interfaces tab to view IES group interfaces added to IGMP.

7

Click on the LDP Tunnel Interfaces tab to configure an LDP tunnel interface entry.

Perform the following steps:

1. Click Create. The LDP IGMP Tunnel Interface (Create) form opens.
2. Select an LDP tunnel interface.
3. Click on the Static Group/Source tab to configure a static multicast entry.
4. Click Create. The StaticGrpSrc (Create) form opens.
5. Configure the required parameters.
6. Save your changes and close the forms.

8

Click on the RSVP Tunnel Interfaces tab to configure an RSVP tunnel interface.

Perform the following steps:

1. Click Create. The RSVP IGMP Tunnel Interface (Create) form opens.
2. Select an RSVP IGMP tunnel interface.
3. Click on the Static Group/Source tab to configure a static multicast entry.
4. Click Create. The StaticGrpSrc (Create) form opens.
5. Configure the required parameters.
6. Save your changes and close the forms.

9

Click on the Static Range Group tab to configure static ranges. Perform the following:

1. Click Create to add a static range group. The Static Grp Range Src form opens.
2. Configure the required parameters.
3. Save your changes and close the form.

10

Click on the following tabs to view and edit information.

- Multicast Group/Source
- Statistics
- Faults

11

Save your changes and close the forms.

END OF STEPS

28.105 To configure IGMP on an OmniSwitch

Note: IGMP parameters can be configured globally or for each VLAN site. The VLAN site IGMP configuration overrides the routing instance IGMP settings. You can only configure VLAN site IGMP parameters after you create the VLAN. See 75.16 “To configure IGMP on an OmniSwitch VLAN site” (p. 2086) for information about configuring IGMP on an OmniSwitch VLAN site.

28.105.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→IGMP.

2

Right-click on the IGMP icon and choose Properties. The IGMP (Edit) form opens.

3

Configure the required parameters.

Note: When the Administrative State parameter is set to Up, the IP multicast switching is enabled on the OmniSwitch.

4

Save your changes and close the form.

END OF STEPS

28.106 To configure an IGMP interface

28.106.1 Purpose

Before an IGMP interface can be configured, the following prerequisites must be met:

- The host routing instance must be configured for IGMP; see 28.103 “To enable IGMP on a routing instance” (p. 1016) .
- The host routing instance must be configured with an L3 interface; see 27.17 “To create an L3 network interface on a routing instance” (p. 856) .

Note: IGMP IPv6 interfaces are supported on the 7950 XRS, on the 7750 SR in chassis mode A or B with mixed mode enabled, and on the 7750 SR in chassis mode C or D.

The tabs and parameters that are configurable vary, depending on the NE on which the IGMP site resides.

28.106.2 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→IGMP.

2

Right-click on the IGMP icon and choose Create Interface, or right-click on an existing IGMP interface and choose Properties. The IGMP Interface (Create|Edit) form opens.

3

Select a Layer 3 interface in the Interface panel.

4

Configure the required parameters.

5

Click on the Behavior tab.

6

Select an import policy, and configure the required parameters.

7

To configure multicast CAC:

Perform the following steps:

1. Click on the Multicast CAC tab
2. Select a multicast CAC policy in the Multicast CAC Policy panel.
3. Configure the required parameters.
4. Click on the Levels tab.
5. Click Create or select an existing multicast CAC level entry and click Properties. The Multicast CAC Level (Create|Edit) form opens.
6. Configure the required parameters.
7. Save your changes and close the form.
8. Click on the LAG Port Down tab.
9. Click Create or select an existing LAG port down entry and click Properties. The LAG Port Down (Create|Edit) form opens.
10. Configure the required parameters.
11. Save your changes and close the form.

8

Click on the SSM Translation tab to configure SSM translation entries.

Perform the following steps:

1. Click Create or select an existing SSM translation entry and click Properties. The SSM Translation (Create|Edit) form appears.
2. Configure the required parameters.
3. Save your changes and close the form.

9

Click on the Static Group/Source tab to create a static multicast entry.

Perform the following steps:

1. Click Create or select an existing static multicast entry and click Properties. The Static Grp Src (Create|Edit) form appears.
2. Configure the required parameters.
3. Save your changes and close the form.

10

Save your changes and close the form.

END OF STEPS

28.107 To turn up or shut down an IGMP interface

28.107.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→IGMP.

2

Right-click on the IGMP icon and choose Properties. The IGMP Site (Edit) form opens.

3

Click on the Interfaces tab.

4

Turn up or shut down the IGMP interface:

a. Click Turn Up to activate the interface.

b. Click Shut Down to deactivate the interface.

5

Save your changes and close the forms.

END OF STEPS

28.108 To view IGMP multicast reporting statistics for an IGMP site

28.108.1 Purpose

Use the following procedure to view IGMP multicast reporting statistics for an IGMP site. See the *NSP NFM-P Statistics Management Guide* for general information about configuring and collecting statistics.

28.108.2 Steps

1

Choose Manage→Networking→Routing Instances from the NFM-P main menu. The Manage Routing Instances form opens.

2

Choose an IGMP Site (IGMP) from the Select Object Type menu.

3

Click Search, choose an IGMP site and click Properties. The IGMP Site form opens.

4

Click Show IGMP Multicast Reporting Statistics. The IGMP IGMP Stats Show IGMP Multicast Reporting Statistics form opens.

5

Configure the IP address.

6

Save your changes and close the form.

END OF STEPS

28.109 To view IGMP source statistics

28.109.1 Purpose

Use the following procedure to view IGMP source statistics. See the *NSP NFM-P Statistics Management Guide* for general information about configuring and collecting statistics.

28.109.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a service and click Properties. The Service (Edit) form opens.

3

Click on the Sites tab to view a list of sites.

4

Choose a site and click Properties. The Site (Edit) form opens.

5

Click on the Multicast tab.

6

Click on the Group Interfaces tab to display a list of group interfaces.

7

Choose a group interface and click Properties. The IGMP Group Interface (Edit) form opens.

8

Click on the Group Interface SAP tab.

9

Choose a group interface SAP and click Properties. The Group Interface SAP (Edit) form opens.

10

Click on the Group tab.

11

Choose a group and click Properties. The Group Interface SAP Group (View) form opens.

12

Click on the Source tab.

13

Click Search to display a list of sources.

14

Close the Group Interface SAP Group (View) form.

15

Click on the Statistics tab.

16

Click Collect to collect additional statistics.

17

Choose a statistics record and click Properties. The Statistics Record - Group Interface SAP Stats form opens.

18

Review the statistics and close the Statistics Record - Group Interface SAP Stats form.

19

Close the forms.

END OF STEPS

MSDP configuration workflow and procedures

28.110 MSDP configuration overview

28.110.1 Overview

The MSDP command hierarchy consists of three levels:

- global level
- peer level and group level
- group peer level

MSDP parameters are initially applied at the global level. The parameters are inherited by the group and peer levels. Parameters can be modified and overridden on a level-specific basis.

The following procedures describe how to configure MSDP.

28.111 Workflow to configure MSDP

28.111.1 Stages

1

Enable MSDP on a routing instance; see 28.112 “To enable MSDP on a routing instance” (p. 1026) .

2

Configure global MSDP on a routing instance; see 28.113 “To configure global-level MSDP” (p. 1026) .

3

Create at least one group-level MSDP peer or peer-level MSDP; see 28.114 “To configure group-level MSDP” (p. 1027) or 28.115 “To configure peer-level MSDP” (p. 1029) .

4

Configure group-peer-level MSDP as required; see 28.116 “To configure group-peer-level MSDP” (p. 1030) .

5

As required, configure an MSDP source; see 28.117 “To configure an MSDP source” (p. 1031) .

6

As required, enable or disable MSDP peering; see 28.118 “To enable or disable MSDP peering” (p. 1032) .

28.112 To enable MSDP on a routing instance

28.112.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance.

2

Right-click on a routing instance icon and choose Properties. The Routing Instance (Edit) form opens.

3

Enable MSDP.

Perform the following steps:

1. Click on the Multicast tab.
2. Select the MSDP Enabled parameter.

4

Save your changes and close the form.

END OF STEPS

28.113 To configure global-level MSDP

28.113.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→MSDP.

2

Right-click on the MSDP icon and choose Properties. The MSDP (Edit) form opens.

3

Configure the required parameters.

4

Click on the Group tab to add a group. See 28.114 “To configure group-level MSDP” (p. 1027) for more information about how to configure a group-level MSDP.

5

Click on the Peer tab to add a peer. See 28.115 “To configure peer-level MSDP” (p. 1029) for more information about how to configure a peer-level MSDP.

6

Click on the Source tab to add a source. See 28.117 “To configure an MSDP source” (p. 1031) for more information about how to configure an MSDP source.

7

Click on the Import Policies tab.

8

Configure the required parameters.

Configure the import route policy to determine which routes are accepted from peers. The policies should match the policies you set when configuring the Routing Policy Manager, as described in Chapter 27, “NE routing and forwarding” . There is no validation performed by the router to ensure the policies match.

9

Click on the Export Policies tab.

10

Configure the required parameters.

Configure the export route policy to determine which routes are advertised to peers. The policies should match the policies you set when configuring the Routing Policy Manager, as described in Chapter 27, “NE routing and forwarding” . A router performs no validation to ensure the policies match.

11

Click on the following tabs to view information:

- Data Source Active
- Data Source Active Rejected
- Statistics
- Faults

12

Save your changes and close the form.

END OF STEPS

28.114 To configure group-level MSDP

28.114.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→MSDP.

2

Right-click on the MSDP icon and choose Create Group. The MSDP Peer Group (Create) form opens.

3

Configure the required parameters.

4

Click on the Peer tab to add a peer.

5

Click Create. The MSDP Peer Group (Create) form opens.

6

Configure the required parameters.

7

Configure the import and export policies for the MSDP peer.

Perform the following steps:

1. Click on the Import Policies tab.
2. Configure the required parameters.

   Configure the import route policy to determine which routes are accepted from peers. The policies should match the policies you set when configuring the Routing Policy Manager, as described in Chapter 27, “NE routing and forwarding” . There is no validation performed by the router to ensure the policies match.
3. Click on the Export Policies tab.
4. Configure the required parameters.

   Configure the export route policy to determine which routes are advertised to peers. The policies should match the policies you set when configuring the Routing Policy Manager, as described in Chapter 27, “NE routing and forwarding” . There is no validation performed by the router to ensure the policies match.

8

Click on the Authentication tab.

9

Configure the required parameters.

10

Save your changes and close the form.

11

Configure the import and export policies for the MSDP group.

Perform the following steps:

1. Click on the Import Policies tab.
2. Configure the required parameters.

   Configure the import route policy to determine which routes are accepted from peers. The policies should match the policies you set when configuring the Routing Policy Manager, as described in Chapter 27, “NE routing and forwarding” . There is no validation performed by the router to ensure the policies match.
3. Click on the Export Policies tab.
4. Configure the required parameters.

   Configure the export route policy to determine which routes are advertised to peers. The policies should match the policies you set when configuring the Routing Policy Manager, as described in Chapter 27, “NE routing and forwarding” . There is no validation performed by the router to ensure the policies match.

12

Save your changes and close the form.

END OF STEPS

28.115 To configure peer-level MSDP

28.115.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→MSDP.

2

Right-click on the MSDP icon and choose Create Peer. The MSDP Peer (Create) form opens.

3

Configure the required parameters.

4

Configure the import and export policies.

Perform the following steps:

1. Click on the Import Policies tab.
2. Configure the required parameters.

   Configure the import route policy to determine which routes are accepted from peers. The policies should match the policies you set when configuring the Routing Policy Manager, as

described in Chapter 27, “NE routing and forwarding” . There is no validation performed by the router to ensure the policies match.

3. Click on the Export Policies tab.
4. Configure the required parameters.

   Configure the export route policy to determine which routes are advertised to peers. The policies should match the policies you set when configuring the Routing Policy Manager, as described in Chapter 27, “NE routing and forwarding” . There is no validation performed by the router to ensure the policies match.

5

Click on the Authentication tab.

6

Configure the required parameters.

7

Save your changes and close the form.

END OF STEPS

28.116 To configure group-peer-level MSDP

Note: The parameters that you configure for a MSDP peer take precedence over the parameters that are configured for the MSDP peer group.

28.116.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→MSDP.

2

Right-click on the MSDP icon and choose Create Group. The MSDP Group Peer, MSDP Peer Group (Create) form opens.

3

Configure the required parameters.

4

Configure the import and export policies.

Perform the following steps:

1. Click on the Import Policies tab.
2. Configure the required parameters.

Configure the import route policy to determine which routes are accepted from peers. The policies should match the policies you set when configuring the Routing Policy Manager, as described in Chapter 27, “NE routing and forwarding” . There is no validation performed by the router to ensure the policies match.

3. Click on the Export Policies tab.
4. Configure the required parameters.

   Configure the export route policy to determine which routes are advertised to peers. The policies should match the policies you set when configuring the Routing Policy Manager, as described in Chapter 27, “NE routing and forwarding” . There is no validation performed by the router to ensure the policies match.

5

Click on the Authentication tab.

6

Configure the required parameters.

7

Save your changes and close the form.

END OF STEPS

28.117 To configure an MSDP source

28.117.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→MSDP.

2

Right-click on the MSDP icon and choose Properties. The MSDP (Edit) form opens.

3

Click on the Source tab.

4

Click Create. The MSDP Source (Create) form opens.

5

Configure the required parameters.

6

Save your changes and close the forms.

END OF STEPS

28.118 To enable or disable MSDP peering

28.118.1 Steps

1

Perform one of the following:

a. Enable or disable MSDP peering in a peer group.

Perform the following steps:

1. In the navigation tree Routing view, expand Network→*NE*→Routing Instance→MSDP→MSDP Peer Group.
2. Right-click on an MSDP Peer Group icon.

b. Enable or disable MSDP peering in a group peer.

Perform the following steps:

1. In the navigation tree Routing view, expand Network→*NE*→Routing Instance→MSDP→MSDP Peer Group→MSDP Group Peer.
2. Right-click on an MSDP Group Peer icon.

2

Choose one of the following menu options:

a. Turn Up to activate

b. Shut Down to deactivate

3

Save your changes and close the form. The state information beside the appropriate MSDP icon changes accordingly.

END OF STEPS

MLD configuration workflow and procedures

28.119 MLD configuration overview

28.119.1 Overview

MLD is supported on the 7950 XRS, on a chassis mode C or D, and on the 7750 SR in chassis mode A or B with mixed mode enabled.

MLD is supported on a VPRN or IES routing instance on the 7950 XRS, the 7750 SR in chassis mode D, and the 7450 ESS in chassis mode D with mixed mode enabled.

The following procedures describe how to configure MLD.

28.120 Workflow to configure MLD

28.120.1 Stages

1

Enable MLD on a routing instance; see 28.121 “To enable MLD on a base routing instance” (p. 1034) .

2

Configure MLD on a routing instance or VPRN routing instance; see 28.122 “To configure MLD on a base routing instance or VPRN routing instance” (p. 1034) .

3

Create an MLD interface on a routing instance or VPRN routing instance; see 28.123 “To configure an MLD interface on a base routing instance or VPRN routing instance” (p. 1035) . Create an MLD interface on an IES L3 access interface; see 28.124 “To configure an MLD interface on an IES L3 access interface” (p. 1037) .

4

Configure an MLD policy; see 64.25 “To configure an MLD policy” (p. 1866) . Bind the MLD policy to a subscriber profile; see 64.4 “To configure a subscriber profile” (p. 1840) .

5

Configure an MLD group interface on a base routing instance or VPRN routing instance; see 28.125 “To configure an MLD group interface on a base routing instance or VPRN routing instance” (p. 1039) . Configure an MLD group interface on an IES site; see 28.126 “To configure an MLD group interface on an IES site” (p. 1041) .

6

Configure an MC peer group for MLD; see 40.4 “To configure an MC peer group” (p. 1330) .

28.121 To enable MLD on a base routing instance

28.121.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance.

2

Right-click on the Routing Instance icon and choose Properties. The Routing Instance (Edit) form opens.

3

Click on the Multicast tab and enable the MLD Enabled check box.

4

Save your changes and close the form. An MLD icon appears in the navigation tree below the routing instance.

END OF STEPS

28.122 To configure MLD on a base routing instance or VPRN routing instance

28.122.1 Purpose

Perform this procedure to configure MLD on a base routing instance or on a VPRN routing instance.

Note: You must first enable MLD on the base routing instance of the VPRN site. See 28.121 “To enable MLD on a base routing instance” (p. 1034) .

You must ensure that the VPRN routing instance has an associated L3 access interface, and that the IPv6 Allowed parameter on the interface is enabled. You must add an IPv6 address to the L3 access interface. See 79.83 “To configure an L3 access interface on a VPRN site” (p. 2656) and 79.102 “To assign an IP address to a VPRN L3 access interface” (p. 2677) .

MLD is supported on a VPRN routing instance on the 7950 XRS, the 7750 SR in chassis mode D, and the 7450 ESS in chassis mode D with mixed mode enabled.

28.122.2 Steps

1

Perform one of the following:

a. Configure MLD on a base routing instance.

Perform the following steps:

1. In the navigation tree Routing view, expand Network→*NE*→Routing Instance→MLD.

2. Right-click on the MLD icon and choose Properties. The MLD, Routing Instance (Edit) form opens.

b. Configure MLD on a VPRN routing instance.

Perform the following steps:

1. Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.
2. Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.
3. On the VPRN Service tree, click on the site to which you need to configure MLD.
4. Expand Routing Instance - NE System ID→Routing Instance→Routing Instance *name*→Protocols.
5. Right-click on the Protocols icon and choose Create MLD Site. The MLD Site (Create) form opens.

2

Configure the required parameters.

3

Click Apply to save the changes.

4

Click on the SSM Translation tab, and click Create. The SSM Translation, Routing Instance (Create) form opens.

5

Configure the required parameters.

6

Save your changes and close the forms.

END OF STEPS

28.123 To configure an MLD interface on a base routing instance or VPRN routing instance

28.123.1 Steps

1

Perform one of the following:

a. Create an MLD interface on a base routing instance.

Perform the following steps:

1. In the navigation tree Routing view, expand Network→*NE*→Routing Instance→MLD.

2. Right-click on the MLD icon and choose Create Interface. The MLD Interface, Routing Instance (Create) form opens.

b. Create an MLD interface on a VPRN routing instance.

Perform the following steps:

1. Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.
2. Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.
3. On the VPRN Service tree, click on the site to which you need to add the routing instance.
4. Expand Routing Instance - NE System ID→Routing Instance→Routing Instance *name*→Protocols.
5. Right-click on the MLD instance and choose Create MLD Interface. The MLD Interface, Routing Instance (Create) form opens.

2

Configure the required parameters on the General tab.

In the Interface panel, make sure you choose a network interface that has IPv6 enabled.

3

Click on the Behavior tab and configure the required parameters.

4

Click on the Import Policy tab and choose an import policy.

5

Click on the Multicast CAC tab to configure multicast CAC for the MLD interface.

Perform the following steps:

1. On the General tab, select a multicast CAC policy and configure the required parameters.

   The Unconstrained Bandwidth parameter value must be greater than or equal to the Mandatory Bandwidth parameter value.
2. Click on the Levels tab to configure multicast CAC levels.
3. Click Create or select an existing multicast CAC level item and click Properties. The Multicast CAC Level (Create|Edit) form opens.
4. Configure the Level ID and Bandwidth parameters.

   The Level ID parameter can only be configured upon multicast CAC level creation.

   The Lower Level Bandwidth parameter value must be greater than the Higher Level Bandwidth parameter value.
5. Save your changes and close the form.
6. Click on the Lag Port Down tab to configure LAG port down entries.

7. Click Create or select an existing LAG port down entry and click Properties. The LAG Port Down (Create|Edit) form opens.
8. Configure the Number Of Ports Down and Level parameters.

   The Number Of Ports Down parameter can only be set upon LAG port down object creation.
9. Save your changes and close the form.

6

Click on the Static/Group Source tab and create an MLD Interface Group Source Static.

7

Click on the Static Range Group tab and create a static group range, if required.

8

Click on the SSM Translation tab and create an MLD Interface Source Specific Multicast.

9

Save your changes and close the form.

END OF STEPS

28.124 To configure an MLD interface on an IES L3 access interface

28.124.1 Purpose

Perform this procedure to create an MLD interface on an IES L3 access interface. You must ensure that MLD is enabled on the site NE. MLD is supported on an IES routing instance on the 7950 XRS, the 7750 SR in chassis mode D, and the 7450 ESS in chassis mode D with mixed mode enabled. See 28.121 “To enable MLD on a base routing instance” (p. 1034) .

28.124.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES service and click Properties. The IES Service (Edit) form opens.

3

On the IES Service tree, expand Sites→Site *name*→L3 Access Interfaces.

4

Right-click on an L3 access interface icon and choose Properties. The IES L3 Access Interface (Edit) form opens.

5

Ensure that the IPv6 Allowed parameter is enabled.

6

Click on the Addresses tab and perform the following tasks:

Perform the following steps:

1. Click Create. The IP Address (Create) form opens.
2. Configure the Address ID parameter with a value greater than 1.
3. Enter an IPv6 address for the IP Address parameter.
4. Configure the Prefix Length parameter.
5. Configure the required parameters in the IPv6 panel.
6. Save your changes and close the form.

7

Click on the Multicast tab and perform the following tasks:

Perform the following steps:

1. Click Add. The Create Interface form opens.
2. Choose MLD and click OK. The Create Interface form closes and the MLD Interface (Create) form opens.
3. Configure the Description parameter.
4. Click Select in the Interface panel. The Select Interface - MLD Interface - Routing Instance form opens.
5. Choose a network interface that has IPv6 enabled and click OK. The Select Interface - MLD Interface - Routing Instance form closes.
6. Configure the required parameters in the States panel.

8

Click on the Behavior tab and configure the required parameters.

9

Click on the Import Policy tab and choose an import policy.

10

Click on the Static/Group Source tab and perform the following tasks:

Perform the following steps:

1. Click Create. The MLD Interface Group Source Static (Create) form opens.
2. Configure the required parameters.
3. Save your changes and close the form.

11

Click on the SSM Translation tab and perform the following tasks:

Perform the following steps:

1. Click Create. The MLD Interface Source Specific Multicast (Create) form opens.
2. Configure the required parameters.
3. Save your changes and close the form.

12

Save your changes and close the form.

END OF STEPS

28.125 To configure an MLD group interface on a base routing instance or VPRN routing instance

28.125.1 Steps

1

Perform one of the following:

a. Create an MLD group interface on a base routing instance.

Perform the following steps:

1. In the navigation tree Routing view, expand Network→*NE*→Routing Instance.
2. Right-click on a routing instance icon and choose Properties. The Routing Instance (Edit) form appears.
3. Click on the Multicast tab, select an MLD site and click Properties. The MLD Site (Edit) form appears.
4. Click on the Group Interfaces tab.
5. Click Create or select an existing group interface and click Properties. The MLD Group Interface (Create|Edit) form appears.

b. Create an MLD group interface on a VPRN routing instance.

Perform the following steps:

1. Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.
2. Choose a VPRN service and click Properties. The VPRN Service (Edit) form appears.
3. On the VPRN Service tree, click on the site to which you need to add the MLD group interface.
4. Expand Routing Instance - NE System ID→Routing Instance→Routing Instance *name*→Protocols.
5. Right-click on the MLD icon and choose Properties. The MLD Site form appears.
6. Click on the Group Interfaces tab.
7. Click Create or select an existing group interface and click Properties. The MLD Group Interface (Create|Edit) form appears.

2

Configure the required parameters.

3

Select a forwarding service.

4

Select an interface ID.

5

Click on the Behavior tab and configure the required parameters.

If any (or all) of the three query interval parameters are configured, the following validation rules apply:

1. The Query Interval parameter value must be greater than the Last Listener Query Interval and Response Query Interval parameter values.
2. Setting any (or all) of the three Query Interval parameter values to zero on the MLD group interface has the same effect as enabling the Inherit From Site check box for the parameter: the corresponding query interval value configured on the MLD site is used for the MLD group interface.
3. In cases where a mix of MLD site-configured and MLD group interface-configured query interval parameters are in use, validation rule 1 still applies.

   For example, if the Query Interval parameter is NOT configured on the MLD group interface but the Last Listener Query Interval and Response Query Interval parameters ARE configured on the MLD group interface, the MLD site-configured Query Interval parameter value must be greater than the MLD group interface-configured Last Listener Query Interval and Response Query Interval parameter values.

6

Click on the Multicast CAC tab to configure multicast CAC for the MLD group interface.

Perform the following steps:

1. Select a multicast CAC policy.
2. Configure the required parameters.

7

Save your changes and close the form.

END OF STEPS

28.126 To configure an MLD group interface on an IES site

28.126.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES service and click Properties. The IES Service (Edit) form appears.

3

On the navigation tree, expand the Sites icon and click on the site to which you want to add an MLD group interface. The IES Service form is updated with the IES site parameters.

4

Click on the Multicast tab.

5

Click on the Group Interfaces tab and click Create. The MLD Group Interface (Create) form appears.

6

Configure the required parameters.

7

Click Select next to the Interface ID field and choose an interface from the Select Group Interface form.

8

Click on the Behavior tab and configure the required parameters.

9

Save your changes and close the form.

END OF STEPS

Bridging configuration workflow and procedures

28.127 Workflow to configure bridging on an OmniSwitch

28.127.1 Stages

1

Configure bridging on an OmniSwitch; see 28.128 “To configure bridging on an OmniSwitch” (p. 1043) .

2

Release a violated OmniSwitch LSP port if required; see 28.129 “To release a violated OmniSwitch LPS port” (p. 1047) .

28.128 To configure bridging on an OmniSwitch

CAUTION

Service Disruption

Changing bridge parameter values may affect the spanning tree calculations and trigger a topology change in the network.

Note: Not all steps described in this procedure are supported by all OmniSwitches. If a step in this procedure does not apply, proceed to the next applicable step for your OmniSwitch type.

28.128.1 Steps

1

In the navigation tree Routing view, expand Network→*OmniSwitch NE*→Bridge Instance.

2

Right-click on the Bridge Instance Object icon and choose Properties. The Bridge Instance (Edit) form opens.

3

Configure the required parameters.

4

Perform the following to configure the OmniSwitch with a dynamically learned MAC address to restrict a port's ingress traffic, otherwise go to Step 7 .

Perform the following steps:

1. Click on the Learned Port Security tab and configure the required parameters.

   Note:

   The Status parameter does not appear until you enter a non-zero value for the Learning Time Window (minutes) parameter.

   Click Restart Timer to restart the MAC source learning timer if you need to restart dynamic MAC address learning on a port.
2. Click on the Ports tab and click Create to select ports on which you want to enable learned port security. The Select Port - Bridge form opens.
3. Choose one or more ports and click OK. If you need to apply the same LPS properties to multiple ports but do not need to configure static MAC addresses on the ports, go to Step 6 .

5

Optionally, configure static MAC addresses on the ports.

Note: Static MAC addresses can only be added to LPS-enabled ports individually.
A port must be LPS-enabled and belong to a VLAN before you can add static MAC addresses.
If traffic containing MAC addresses outside of the allowable MAC address range attempts to access an LPS port, the switch either restricts access to the port for that traffic or shuts the port down to all traffic. When this happens, the port is in an operationally violated state and an alarm is raised. See 28.129 “To release a violated OmniSwitch LPS port” (p. 1047) for information about how to release a violated LPS port.

Perform the following steps:

1. Choose a port and click Properties. The Learned Port Security (Edit) form opens. See 28.130 “To add MAC address range entries to an OmniSwitch LPS port” (p. 1048)for information about how to add static MAC range entries.
2. Click Properties. The Physical Port (Edit) form opens.
3. Configure the required parameters.
4. Click Select in the VLAN Site panel. The Select VLAN Site form opens.
5. Choose a VLAN site and click OK.
6. Save the changes and close the form. The Learned Port Security (Edit) form reappears.
7. Optionally choose a port and click Convert to Static to stop the aging out of dynamic MAC addresses on LPS ports.
8. Repeat Step 5 if you need to add another static MAC address to the port.

6

Optionally, apply the same LPS properties to multiple ports.

Perform the following steps:

1. Choose multiple ports and click Properties. The Learned Port Security (Edit) form opens.
2. Configure the required parameters.
3. Save your changes and close the forms. The Bridge Instance (Edit) form reappears.

7

Click on the Spanning Tree tab to configure the STP modes to the bridge. This prevents bridge loops and the broadcast radiation that results from them.

a. To apply a STP Flat Mode to the bridge; go to Step 8 .

b. To apply a STP 1x1 Mode to the bridge; go to Step 10 .

8

CAUTION

Service Disruption

Service Disruption

Changing the Protocol parameter to MSTP resets the flat bridge priority and path.

Click on the STP Flat Mode tab and choose a 1x1 instance and click Properties. The VLAN STP Instance (Edit) form opens.

1. Configure the required parameters.
2. Click on the Port tab and choose one or more ports.
3. Click Properties. The CIST Instance Ports (Edit) form opens.
4. Configure the required parameters.
5. Save your changes.

9

Optionally, click on the MSTI tab to configure a multiple spanning tree instance to represent represents a group of VLANs, otherwise go to Step 11 .

Note: In order to configure MSTI, the Protocol parameter must be set to MSTP.

Perform the following steps:

1. Click Create. The MST instance form opens.
2. Configure the required parameters.
3. Click on the VLAN tab and click Create to assign a VLAN to the MSTI. The Select VLAN Sites - MST Instance form opens.

4. Choose one or more VLANs and click OK.
5. Save your changes and close the forms. The Bridge Instance (Edit) form reappears.
6. Click on the MST Region tab and configure the required parameters. Go to Step 11 .

10

CAUTION

Service Disruption

Changing the STP 1x1 Mode configuration may affect the STP calculations for this instance of the VLAN and trigger a topology change in the network.

Click on the STP 1x1 Mode tab and choose a 1x1 instance and click Properties. The VLAN STP Instance (Edit) form opens.

1. Configure the required parameters.
2. Click on the Port tab and choose one or more ports from the list of ports that have been assigned to VLANs and click Properties. The VLAN STP Instance Ports (Edit) form opens.
3. Configure the required parameters.
4. Save your changes and close the form. The Bridge Instance (Edit) form reappears.

11

Click on the TLS tab and configure the TLS Mode parameter.

12

Click on the QoS tab and configure the required parameters.

Note: The applied values for the Default Bridged Disposition, Default Routed Disposition, and Default IGMP Disposition parameters should be the same as the configured values.

13

Click on the MVRP tab and configure the required parameters.

14

Click on the IGMP Port Group Limit tab and perform one the following:

a. Configure active (administratively Up) ports:

Perform the following steps:

1. Choose one or more ports and click Properties. The IGMP Port Group Limit (Edit) or IGMP Port Group Limit - (Multiple Instances) (Edit) form opens.

   Note:

   Only ports that are active (administratively Up) appear in the list. You can view the configuration of the inactive ports using the OmniSwitch CLI.

2. Configure the required parameters.
3. Save your changes and close the form. The Bridge Instance (Edit) form reappears.

b. Configure inactive (administratively Down) ports.

Perform the following steps:

1. Click Create. The Select Port - Bridge form opens.
2. Choose an inactive port and click Properties. The Physical Port (Edit) form opens.
3. Configure the required parameters.
4. Save your changes and close the form. The Bridge Instance (Edit) form reappears.

Note:

As required, click on the Multicast VLAN Port tab in the multicast VLAN IGMP site properties to view the Port Max Group and Port Action parameter information for a multicast VLAN port. You can also view the number of IGMP groups dynamically learned by the port.

15

Save your changes and close the form.

END OF STEPS

28.129 To release a violated OmniSwitch LPS port

28.129.1 Purpose

Perform the following procedure to release a violated LPS port.

Releasing a violated port restores the port to the same operational state it was in before the violation. When a violated port is released, all MAC addresses known to the port are flushed from the switch MAC address table.

28.129.2 Steps

1

In the navigation tree Routing view, expand Network→*OmniSwitch NE*→Bridge Instance.

2

Right-click on the Bridge Instance Object icon and choose Properties. The Bridge Instance (Edit) form opens.

3

Click on the Learned Port Security tab.

4

Click on the Port tab.

5

Select one or more violated LPS ports. Violated LPS ports are highlighted in orange.

6

Click Release Violated Port to release the selected ports.

7

Save your changes and close the form.

END OF STEPS

28.130 To add MAC address range entries to an OmniSwitch LPS port

28.130.1 Overview

Perform the following procedure to add a static MAC address to an OmniSwitch LPS port.

You can add up to eight MAC address range entries. The default entry with Low MAC Range value 00-00-00-00-00-00, and High MAC Range value FF-FF-FF-FF-FF-FF, is auto-created under LPS Learned MAC Ranges tab when a port is added as an LPS port. Overlapping of Low MAC range or High MAC range is not allowed.

28.130.2 Steps

1

In the navigation tree Routing view, expand Network→*OmniSwitch NE*→Bridge Instance.

2

Right-click on the Bridge Instance Object icon and choose Properties. The Bridge Instance (Edit) form opens.

3

Choose a port and click Properties. The Learned Port Security (Edit) form opens.

4

Click on the LPS Learned MAC Ranges tab. By default, an entry of Low MAC range and High MAC range is displayed.

5

Click Create. The MAC Range (Create) form opens.

6

Enter the Low MAC Range and High MAC Range values.

7

Click OK to save your changes.

8

Repeat steps Step 5 to Step 7 to add up to eight MAC address range entries.

9

Click Apply to save the changes and close the forms.

END OF STEPS

28.131 To modify MAC address range entries in an OmniSwitch LPS port

28.131.1 Steps

1

In the navigation tree Routing view, expand Network→*OmniSwitch NE*→Bridge Instance.

2

Right-click on the Bridge Instance Object icon and choose Properties. The Bridge Instance (Edit) form opens.

3

Choose a port and click Properties. The Learned Port Security (Edit) form opens.

4

Click on the LPS Learned MAC Ranges tab. A list of Low and High MAC address ranges added on the LPS port is displayed.

5

Select the MAC address range entry to modify. You may either click Properties button or double-click the MAC range entry.

6

You can edit the MAC address range entries to meet the following conditions:

- Overlapping Low or High MAC Ranges are not allowed.
- When the MAC address range entry must contain the Low MAC Range starting from 00-00-00-00-00-00, click on the default entry 00-00-00-00-00-00 to FF-FF-FF-FF-FF-FF to modify the High MAC Range
- To expand the LPS MAC range, keep the Low MAC Range the same and modify the High MAC Range to a higher value than the current High MAC Range value
- To shrink the LPS MAC range, keep the Low MAC Range the same and modify the High MAC Range to a lower value than the current High MAC Range value
- Overlapping low or high MAC range is not allowed.

7

Click OK to save your changes.

8

If required, repeat steps Step 5 to Step 7 to modify the MAC range entries.

9

If required, repeat steps Step 3 to Step 7 to modify the MAC range entries for other LPS ports.

10

Click Apply to save the changes and close the form.

END OF STEPS

28.132 To Delete MAC address range from an OmniSwitch LPS port

28.132.1 Steps

1

In the navigation tree Routing view, expand Network→*OmniSwitch NE*→Bridge Instance.

2

Right-click on the Bridge Instance Object icon and choose Properties. The Bridge Instance (Edit) form opens.

3

Choose a port and click Properties. The Learned Port Security (Edit) form opens.

4

Click on the LPS Learned MAC Ranges tab. A list of Low and High MAC address ranges added on the LPS port is displayed.

5

Select one or multiple MAC address range entries. Click Delete.

Note: You can delete a newly added MAC address range entry that is not in the NFM-P database.

6

Confirm your action. Click OK to save the change and close the form.

END OF STEPS

WPP configuration workflow and procedures

28.133 Workflow to configure WPP

28.133.1 Stages

1

Enable WPP on the following routing instances as required:

a. Base routing instance; see 27.2 “To configure a routing instance or a VRF instance” (p. 826) .

b. VPRN routing instance; see 79.21 “To enable routing protocols on a VPRN site” (p. 2554) .

2

Create a Web portal routing instances; see 28.134 “To create a web portal routing instance” (p. 1051) .

3

If required, configure a local user database for WPP-based host authentication. Bind the local user database to a WPP-enabled base routing instance or VPRN routing instance, and a Web portal; see 74.9 “To configure a local user database for subscriber host authentication” (p. 2025) .

4

Bind a web portal to a group interface as follows:

a. IES group interface; see 78.19 “To configure a group interface on an IES” (p. 2449) .

b. VPRN group interface; see 79.37 “To configure a group interface on a VPRN” (p. 2586) .

28.134 To create a web portal routing instance

28.134.1 Steps

1

Enable WPP on a routing instance as described in 27.2 “To configure a routing instance or a VRF instance” (p. 826) .

2

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→WPP.

3

Right-click on the WPP icon and choose Create Web Portal. The Web Portal - Routing Instance (Create) form appears.

4

Configure the required parameters.

5

Click on the WPP Hosts tab to view WPP hosts connected to the Web portal, and to manually clear hanging WPP hosts in the logout state.

Perform the following steps:

1. Select a host item in the list and click Clear Logging Out WPP Host.
2. To clear the entire list, click Clear All Logging Out WPP Hosts.

6

Save your changes and close the form.

END OF STEPS

BIER configuration workflow and procedures

28.135 Workflow to configure BIER

28.135.1 Stages

1

Configure a BIER template on a routing instance; see 28.136 “To configure a BIER template on a routing instance” (p. 1053)

2

Apply the BIER template as needed:

a. Bind the template to an IS-IS site in the Level 1 or Level 2 tab; see 28.63 “To configure an IS-IS interface” (p. 958) .

b. Bind the template to an OSPFv2 site on a routing instance; see 28.67 “To create an OSPF area” (p. 963) .

c. Select BIER as a tunnel type on a VPRN interface; see 28.99 “To create a PIM site on a VPRN routing instance” (p. 1003) .

28.136 To configure a BIER template on a routing instance

28.136.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance.

2

Right-click on the routing instance and choose Properties. The Routing Instance (Edit) form opens.

3

Configure the Fast Reroute and the BFD Enabled parameter.

4

From the BIER tab, click Create. The BIER (Create) form opens.

5

From the BIER form, perform the following to configure BIER:

1. Click Create to create a template
2. In the BIER Template (Create) form, enter a template name and click Create to create a subdomain.

3. Configure the parameters in the BIER Sub-Domain (Create) form and click OK.
4. Create and configure additional sub-domains if needed.

6

Click OK in each form to save your changes and close the form.

END OF STEPS

IPSec configuration workflow

28.137 Workflow to configure IPSec

28.137.1 Stages

1

Configure an IPSec security policy on the NE; see Step 35 in 27.2 “To configure a routing instance or a VRF instance” (p. 826).

2

Create an IPSec instance on a routing instance.

Perform the following steps:

1. In the navigation tree Routing view, expand Network→*NE*→Routing Instance.
2. Right-click on a routing instance icon and choose Properties. The Routing Instance (Edit) form opens.
3. Click on the IPSec tab and click Create. The Ipsec, (New Instance) (Create) form opens.
4. Configure the required parameters.

3

Configure IPsec Tunnels on the IPSec instance.

Perform Step 6 to Step 19 of 34.21 “To configure an IPsec tunnel on a VPRN tunnel interface” (p. 1253).

29 OpenFlow

OpenFlow overview

29.1 OpenFlow overview

29.1.1 Overview

OpenFlow is a communication protocol for managing multiple NE forwarding planes using an external controller. The direct external control enables traffic management that is superior to the use of local ACL filters and routing information alone.

As an OpenFlow controller, the NFM-P uses a flow table on each switch to manage flows of routing information. Each entry in a flow table is a set of match criteria, packet counters, and the action to perform on matching packets.

29.2 OpenFlow switches

29.2.1 Overview

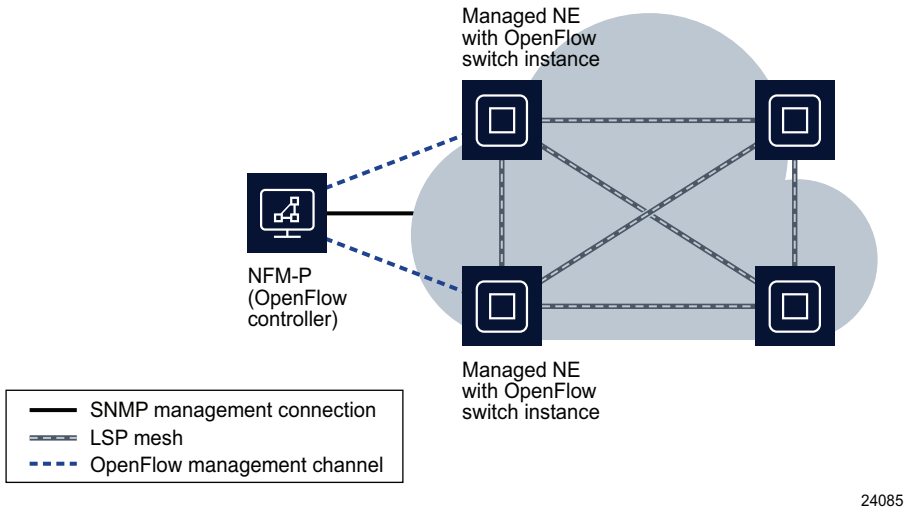
An NFM-P-managed OpenFlow switch includes the following:

- one flow table
- one communication channel for each OpenFlow controller of the switch
- the OpenFlow protocol

The NFM-P uses SNMP to create and enable an OpenFlow switch instance on an NE. After the initial configuration, the controller and switch communicate using the OpenFlow protocol over an in-band or out-of-band connection. One NE can have up to eight OpenFlow switch instances.

The following figure shows an NFM-P system that manages two OpenFlow switches on separate NEs.

Figure 29-1 Basic OpenFlow management topology



29.3 Configuration

29.3.1 Overview

You can use an NFM-P GUI or OSS client to configure an OpenFlow switch on a 7450 ESS, 7750 SR, or 7950 XRS that has an IOM3.

As part of the OpenFlow switch configuration, an NFM-P operator defines one or more controllers using the IPv4 address of the NFM-P OpenFlow communication interface. The operator also specifies the ports that the switch uses to forward traffic; each port connects to an MPLS-TP or RSVP-TE LSP. IPv4 or IPv6 ACL filters that the operator creates are embedded in the switch logic, and flow entries specify the action to perform on matching packets.

Note the following:

- An IPv6 OpenFlow switch is configurable only on an NE in chassis mode D that has mixed mode enabled.
- SR-TE LSP is not supported for OpenFlow.

29.4 Operation and management

29.4.1 Operation

The OpenFlow protocol uses unsecured TCP as the transport. Using OpenFlow, a controller adds, updates, and deletes flow entries in response to changing network conditions, and retrieves OpenFlow performance and forwarding statistics.

29.4.2 Management

The Manage OpenFlow form is the interface for all GUI management of OpenFlow. Using the form, you can display and manage the following:

- OpenFlow channel states
- flow tables and flow entries
- ACL filter bindings to switch instances
- LSPs associated with a switch
- SNMP statistics for OpenFlow ports
- OpenFlow operation and forwarding statistics

The properties form of an OpenFlow switch displays the following:

- controller communication parameters
- OpenFlow host device type and software release
- OpenFlow configuration information

Note: OpenFlow information is displayed only when there is an active OpenFlow session between the switch and controller.

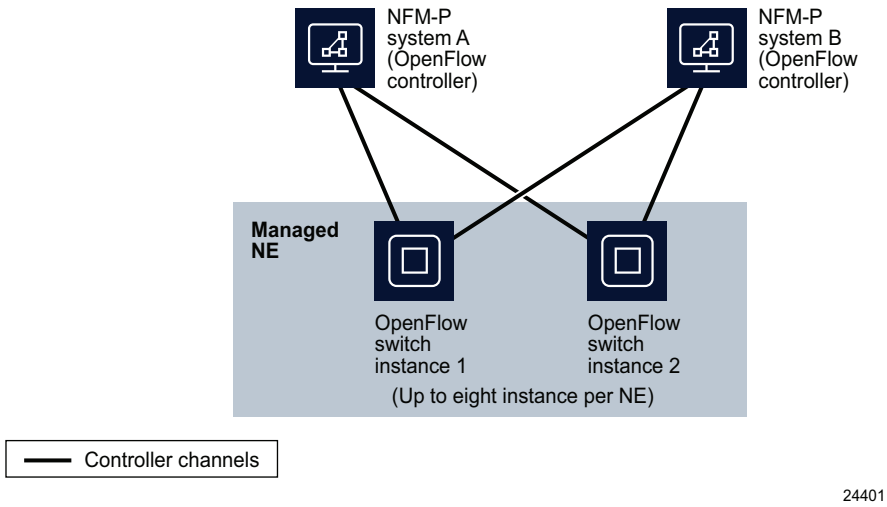
From an IPv4 or IPv6 ACL filter properties form, you can list and view the associated OpenFlow filter.

29.4.3 Multiple controllers

You can create up to two OpenFlow controller definitions for each switch instance. The controllers have no awareness of each other, but have access to all switch information, including the flow information associated with the other controller.

The following figure shows two NFM-P systems that act as independent OpenFlow controllers of multiple switch instances on one NE.

Figure 29-2 Dual OpenFlow controllers



29.4.4 OpenFlow statistics

The NFM-P collects the following statistics from each OpenFlow switch:

- port statistics collected using SNMP
- aggregated packet counts per flow table
- aggregated packet and byte counts per flow entry

OpenFlow configuration and management procedures

29.5 OpenFlow configuration and management workflow

29.5.1 Stages

1

Create the IPv4 and IPv6 ACL filters that are to be embedded in the switch logic. See Chapter 51, “Filter policies” for information about creating ACL filters.

2

Configure and enable OpenFlow switch instances on NEs, as required. See 29.6 “To configure an OpenFlow switch” (p. 1061) .

3

Configure additional flow table entries, as required. See 29.7 “To configure an OpenFlow flow table entry” (p. 1063) .

4

Monitor OpenFlow, as required.

a. View the controller channel status and SNMP statistics. See 29.8 “To display the OpenFlow controller channel status and SNMP statistics” (p. 1065) .

b. View the OpenFlow port status and SNMP statistics. See 29.9 “To display the ports and port SNMP statistics of an OpenFlow switch” (p. 1066) .

c. View the OpenFlow flow table statistics. See 29.10 “To display aggregate flow table statistics” (p. 1067) .

d. View the OpenFlow flow table entry statistics. See 29.11 “To display aggregate flow table entry statistics” (p. 1067) .

29.6 To configure an OpenFlow switch

29.6.1 Steps

1

Choose Manage→OpenFlow from the NFM-P main menu. The Manage OpenFlow form opens.

2

Perform one of the following.

a. Create an OpenFlow switch.

Perform the following steps.

1. Click Create→OpenFlow switch. The Select Network Element form opens.

2. Select an NE and click OK. The Select Network Element form closes, and the OpenFlow Switch (Create) form opens.
3. Configure the Displayed Name parameter.
4. Click Apply. The form displays additional tabs and status indicators, and the form name changes to OpenFlow Switch (Edit).

b. Configure an existing OpenFlow switch. Perform the following steps.

Perform the following steps.

1. Configure the filter criteria and click Search. A list of OpenFlow switches is displayed.
2. Select an OpenFlow switch and click Properties. The OpenFlow Switch (Edit) form opens.

3

Configure the required parameters.

4

Define an OpenFlow controller.

Perform the following steps.

1. Click on the Controller tab.
2. Click Create. The OpenFlow Controller (Create) form opens.
3. Configure the required parameters.
4. Click OK to save your changes and close the forms.

5

Repeat Step 4 to define an additional controller for the switch.

6

Configure a flow table.

Perform the following steps.

1. Click on the Flow Table tab.
2. Click Create, or select an existing flow table and click Properties. The Flow Table (Edit) form opens.
3. Configure the required parameters.
4. Click OK to save your changes and close the forms.
5. To add one or more entries to the flow table, perform Step 5 to Step 13 of 29.7 “To configure an OpenFlow flow table entry” (p. 1063) .

7

To configure an embedded IPv4 or IPv6 filter, perform the following steps.

Perform the following steps.

1. Click on the Embedded Filter tab.
2. Click Create, or select an existing filter and click Properties. The OpenFlow Embedded IP Filter (Create | Edit) form opens.
3. Configure the required parameters.
4. Choose an ACL IP or IPv6 filter.
5. Click OK to save your changes and close the form.

8

Close the open forms, as required.

END OF STEPS

29.7 To configure an OpenFlow flow table entry

29.7.1 Steps

1

Choose Manage→OpenFlow from the NFM-P main menu. The Manage OpenFlow form opens.

2

Click Search. A list of OpenFlow switches is displayed.

3

Select an OpenFlow switch and click Properties. The OpenFlow Switch (Edit) form opens.

4

Click on the Flow Table tab.

5

Select the flow table and click Properties. The Flow Table (Edit) form opens.

6

Perform one of the following.

a. Add a flow table entry. Perform the following steps.

Perform the following steps.

1. Click Create. The OpenFlow Flow Entry (Create) form opens.
2. Configure the Auto-Assign ID and Flow ID parameters.

3. Click Create to add an action. The OpenFlow Flow Action (Create) form opens.
4. Configure the Action Type parameter.
5. If you choose Output Action as the Action Type parameter value, click Select to choose a port.
6. If you choose Redirect to Next Hop as the Action Type parameter value, configure the Next Hop IP Address parameter.
7. Click OK to save the changes and close the OpenFlow Flow Action (Create) form.

b. Configure an existing flow table entry. Perform the following steps.

Perform the following steps:

1. Configure the filter criteria and click Search. A list of flow table entries is displayed.
2. Select an entry and click Properties. The OpenFlow Flow Entry (Edit) form opens.

7

Configure the required parameters:

8

Click on the Match Criteria tab.

Note: You must select the check box beside a parameter on the tab before you can configure the parameter.

9

Configure the Ethernet Type parameter.

Note: The parameter setting must match the IP address type configured in the actions associated with the flow entry.

10

Configure the following parameters:

- Ethernet Type
- IP Source Address
- IP Dest Address
- DSCP
- Protocol Type
- Prefix
- Prefix

11

If the Protocol Type parameter is set to TCP, configure the TCP Source Port and TCP Dest Port parameters:

12

If the Protocol Type parameter is set to ICMPv4 or ICMPv6, configure the ICMP Type and ICMP Code parameters:

13

Click OK to save the changes and close the forms, as required.

14

Close the Manage OpenFlow form.

END OF STEPS

29.8 To display the OpenFlow controller channel status and SNMP statistics

29.8.1 Steps

1

Choose Manage→OpenFlow from the NFM-P main menu. The Manage OpenFlow form opens.

2

Select an OpenFlow switch and click Properties. The OpenFlow Switch (Edit) form opens.

3

Click on the Controller tab.

4

Select the controller and click Properties. The OpenFlow Controller (Edit) form opens.

5

Click on the Channel tab.

6

Select a channel and click Properties. The OpenFlow Controller Channel Info form opens.

7

View the channel status information, as required.

8

Click on the Statistics tab.

9

Click Collect. A statistics record is listed.

10

Select the statistics record and click Properties. The statistics record form opens.

11

View the statistics, as required.

12

Close the open forms.

END OF STEPS

29.9 To display the ports and port SNMP statistics of an OpenFlow switch

29.9.1 Steps

1

Choose Manage→OpenFlow from the NFM-P main menu. The Manage OpenFlow form opens.

2

Select an OpenFlow switch and click Properties. The OpenFlow Switch (Edit) form opens.

3

Click on the Ports tab. A list of ports is displayed.

4

To view a port entry, select the entry and click Properties. The OpenFlow Ports (View) form opens.

5

To view the aggregate statistics of all ports in use by the switch.

Perform the following steps.

1. Click on the Statistics tab.
2. Click Collect to perform an on-demand statistics collection, or the Collect All to retrieve all collected statistics records.
3. Select a statistics record and click Properties. The Statistics Record form opens.
4. View the statistics counter data, as required.

6

Close the open forms.

END OF STEPS

29.10 To display aggregate flow table statistics

29.10.1 Steps

1

Choose Manage→OpenFlow from the NFM-P main menu. The Manage OpenFlow form opens.

2

Select an OpenFlow switch and click Properties. The OpenFlow Switch (Edit) form opens.

3

Click on the Flow Table tab.

4

Select the flow table and click Properties. The Flow Table (Edit) form opens.

5

Click on the Flow Table Counts tab.

6

View the statistics counter data, as required.

Note: OpenFlow statistics information is displayed only when there is an active OpenFlow session between the switch and controller.

7

Close the open forms.

END OF STEPS

29.11 To display aggregate flow table entry statistics

29.11.1 Steps

1

Choose Manage→OpenFlow from the NFM-P main menu. The Manage OpenFlow form opens.

2

Select an OpenFlow switch and click Properties. The OpenFlow Switch (Edit) form opens.

3

Click on the Flow Table tab.

4

Select the flow table and click Properties. The Flow Table (Edit) form opens.

5

Select a flow table entry and click Properties. The Flow Table Entry (Edit) form opens.

6

Click on the Statistics tab.

7

Click Collect to perform an on-demand statistics collection, or the Collect All to retrieve all collected statistics records.

8

Select a statistics record and click Properties. The Statistics Record form opens.

9

Click on the Flow Stats tab.

10

View the statistics counter data, as required.

11

Close the open forms.

12

View the statistics counter data, as required.

Note: OpenFlow statistics information is displayed only when there is an active OpenFlow session between the switch and controller.

13

Close the open forms.

END OF STEPS

29.12 To list the OpenFlow bindings of an IP filter

29.12.1 Steps

1

Choose Policies→Filter→ACL IP Filter or Policies→Filter→ACL IPv6 Filter from the NFM-P main menu. The ACL IP Filter Policies or ACL IPv6 Filter Policies form opens.

2

Click on the Embedded Filters tab.

3

Click on the OpenFlow Embedded tab. A list of embedded OpenFlow filters is displayed.

4

View the list entries, as required.

5

Close the ACL IP Filter Policies or ACL IPv6 Filter Policies form.

END OF STEPS

30 NAT

30.1 Network Address Translation

30.1.1 Overview

Network Address Translation (NAT) rewrites address information in IP packets that travel between private and public networks. NAT effectively extends the public IPv4 address space; multiple end users can share one IP address. NAT provides security by preventing an internal IP address, such as an end-user address, from entering a public network.

NAT translates internal, or private, host IP address and TCP port values to external, or public, values. When NAT receives a packet from an internal host, it replaces the source address information in the packet with public address information, and forwards the packet to the destination. NAT assigns private IP addresses and ports dynamically using values from an allocated pool, but can also use values that are statically assigned to internal hosts, depending on the type of NAT deployment.

The NFM-P NAT support includes:

- policy-based management
- subscriber-specific implementation
- configurable port usage limits per subscriber, address range, or policy
- reserved port ranges for specified forwarding classes that are exempt from port usage limits
- configurable protocol timeout periods for efficient resource management

The NAT configuration on a routing instance includes:

- one or more NAT address pools that are associated with local ISA-NAT groups
- a NAT policy that specifies port ranges and operational parameters, and optionally, an IPFIX export policy that specifies IP traffic flow export information
- host address match criteria
- one or more NAT destinations

An NFM-P operator assigns port ranges in an address pool configuration. Port ranges specify the number of ports that are allocated to a subscriber for mapping to host sessions. If all ports for a subscriber are in use, additional port assignments cannot occur and host sessions are rejected. This function helps to prevent the flooding of NAT by a virus attack or multiple peer-to-peer file transfers. You can override a port range limit by configuring a range of reserved ports that are assigned based on the traffic forwarding class.

Note: You cannot use ports 0 to 1023, which are called the well-known ports or privileged ports, in a NAT configuration.

To provide equitable and timely NAT resource allocation to hosts, you can specify timeout values in a NAT policy for protocols such as ICMP, TCP, and UDP. NAT ends a host session after the timeout period, for example, when a TCP handshake takes an excessive amount of time.

The NAT drain function is a mechanism that is used to gracefully remove the host sessions associated with an address range in a NAT address pool. When an address range is in the draining state, NAT drops new session requests for the address range. After an existing session associated with a draining address range closes, a new session for the same host is created using a different address range. The drain function removes an address range only when there are no sessions associated with the address range. See 30.13 “To start or stop a NAT address-pool drain operation” (p. 1094) for information about using the NAT drain function.

You can view general NAT statistics, for example, address pool allocation and session counts for different protocols on the Statistics tab of an ISA-NAT group member properties form.

Note: The NFM-P does not record detailed NAT session information such as session duration or packet counts. You can obtain this information from a request to a participating NE.

The NFM-P supports the following NAT deployment types:

- L2-aware—Hosts of the same subscriber can share a private address, and are assigned public addresses from a pool in a base routing instance.
- large-scale—Each host can have a unique static or dynamic private address, and is assigned a public address from a pool in a VPRN routing instance.

30.1.2 L2-aware NAT

In L2-aware NAT, a NAT policy is associated with a subscriber profile that is applied to an IES SAP or a VPRN routing instance. The policy specifies an address pool on the base routing instance. When DHCP assigns a private IP address that is in an L2-aware NAT address range, NAT assigns a public IP address to the host packets. See Chapter 78, “IES management” for information about configuring NAT in an IES. See Chapter 79, “VPRN service management” for information about configuring NAT on a VPRN.

Note: A NAT configuration on a base routing instance applies to each IES site or VPRN routing instance on the NE.

A NAT policy that is specified in a subscriber profile redirects the IPv4 traffic for the subscriber to NAT.

External address assignment

The External Assignment option on L2–aware NAT pools allows the assignment of outside IP addresses to a subscriber by an external system (for example, a RADIUS server). The External Assignment configuration ensures that all traffic to or from a particular L2-aware subscriber is received on the same ISA card when outside IP addresses are allocated by an external system.

30.1.3 Large-scale NAT

Large-scale NAT, or LSN, is required when each host in a customer VPRN service has a unique private IP address and requires a unique public IP address, for example, in mobile network deployments. Large-scale NAT is used between routing instances. A customer VPRN routing instance provides host access and forwards packets through NAT to a VPRN or through an IES to an NE routing instance, which provides public network access.

A VPRN routing instance requires an ACL IP filter or static route to transmit host traffic through the NAT function, and uses an address pool in the VPRN routing instance. You can configure large-scale NAT to statically and dynamically assign private addresses. See Chapter 79, “VPRN service management” for information about configuring NAT in a VPRN service. See 30.1.4 “Static port forwarding” (p. 1072) for information about configuring NAT to use static private addresses.

You can use the NFM-P Statistics Plotter to plot real-time LSN subscriber host statistics on a base or VPRN routing instance. See 30.16 “To plot LSN subscriber host statistics” (p. 1097) .

30.1.4 Static port forwarding

In a large-scale NAT deployment, you can configure NAT to assign static private addresses to subscriber hosts using static port forwarding. Static port forwarding ensures that an internal host uses the same private IP address and port each time they connect to the network. You can use the NFM-P to configure static port forwarding for TCP and UDP independently.

A standby routing instance can be specified to create static port forwards for pools in a redundant configuration. The NFM-P identifies the active pool from the two specified NEs and creates a static port forward on the active pool. In the event of a wildcard static port forward request, if there is a switch-over of the active pool, the NFM-P attempts to create the static port forward on the other pool. If there is a second pool switch-over, the static port forward is not created.

See Chapter 79, “VPRN service management” for information about configuring static port forwarding in a VPRN service. See Chapter 74, “Residential subscriber management” for information about configuring L2Aware static port forwarding on a residential subscriber instance.

30.1.5 Base router and VPRN static one-to-one NAT

With static one-to-one NAT, NAT is performed on packets traveling from an inside (private) interface to an outside (public) interface or from an outside interface to an inside interface. Static one-to-one NAT can be applied to a single IP address or a subnet of IP addresses and is performed on the IP header of a packet, not on the UDP/TCP port.

Mapping statements, or entries, can be configured to map an IP address range to a specific IP address. The direction of the NAT mapping entry dictates whether NAT is performed on a packet source IP address or subnet, or on a packet destination IP address or subnet. The 7705 SAR supports inside mapping entries that map an inside IP address range to an outside IP address range sequentially.

With an inside mapping entry, consider the following:

- Packets that originate from an inside interface and are destined for an inside interface are forwarded without any NAT being applied.
- Packets that originate from an outside interface and are destined for an outside interface are forwarded without any NAT being applied.
- If there is a matching one-to-one NAT mapping entry, packets that originate from an inside interface and are destined for an outside interface undergo static one-to-one NAT where NAT changes the source IP address of the packet IP header. The packet is forwarded whether or not a NAT mapping entry is found unless the Drop Packets without NAT parameter is enabled. When a mapping entry is not found and the Drop Packets without NAT parameter is enabled, the packet is not forwarded.
- If there is a matching one-to-one NAT mapping entry, packets that originate from an outside

interface and are destined for an inside interface undergo static one-to-one NAT where NAT changes the destination IP address of the packet IP header. The packet is forwarded whether or not a NAT mapping entry is found unless the Drop Packets without NAT parameter is enabled. When a mapping entry is not found and the Drop Packets without NAT parameter is enabled, the packet is not forwarded.

Static one-to-one NAT is performed on packets that transit the node and match the mapping entry. These packets include IPSec packets, GRE packets, and IP packets. NAT can be performed on packets from a single inside interface or multiple inside interfaces that are traveling to a single outside interface or multiple outside interfaces.

Static one-to-one NAT is not performed on packets that are destined for the node, on self-generated traffic, or on routing protocols. The 7705 SAR blocks static one-to-one NAT to a public prefix that has the same IP subnet as a local interface.

Static one-to-one NAT is supported on the GRT and on VPRNs.

The following table lists the types of outside and inside interfaces that are supported on the GRT for static one-to-one NAT.

Table 30-1 GRT interfaces supported for static one-to-one NAT

GRT interface type	Outside	Inside
Network interface	Yes	No
IES interface	Yes	Yes
IES R-VPLS interface	Yes	Yes
IES Layer 3 spoke SDP interface	Yes	Yes
IPSec public interface	n/a	n/a

VPRN static one-to-one NAT

For VPRNs, static one-to-one NAT can be configured between an inside interface and a outside MP-BGP MPLS transport tunnel interface. See the 7705 SAR NE documentation for more information about VPRNs and one-to-one NAT.

The following table lists the types of outside and inside interfaces that are supported on a VPRN for one-to-one NAT.

Table 30-2 VPRN interfaces supported for static one-to-one NAT

VPRN interface type	Outside	Inside
SAP interface	Yes	Yes
R-VPLS interface	Yes	Yes
Layer 3 spoke SDP interface	Yes	Yes
IPSec private interface	Yes	Yes

Table 30-2 VPRN interfaces supported for static one-to-one NAT (continued)

VPRN interface type	Outside	Inside
Auto-bind GRE/MPLS (MP-BGP), where MPLS includes segment routing, LDP, and RSVP	Yes	No

30.1.6 Dynamic block reservation

To prevent starvation of dynamic port blocks for subscribers that use static port forwarding, dynamic port blocks can be reserved for the lifetime of the static port forward. Dynamic port blocks are associated with the same inside IP addresses that are associated with the static port forward. A log entry is not generated until the dynamic port block is used.

At the time of static port forward creation:

- If the corresponding dynamic port block mapping (same inside IP address) does not exist, dynamic port block(s) are reserved and associated with the same inside IP addresses used in the static port forward. No log entries are generated for the reserved dynamic port blocks.
- If corresponding dynamic mappings (relative to the inside IP address) exist, the existing port block is reserved (or kept) after the last mapping within it has expired. The reserved dynamic port block(s) continue to be associated with the same inside IP address until the static port forward is deleted. A log entry is generated when the last mapping in the dynamic port block expires (even if the dynamic port block continues to be reserved).

30.1.7 NAT pools

A NAT pool is a range of public IP addresses that are translated to inside private IP addresses in a Large Scale or L2 Aware NAT configuration. A NAT pool is required in order to configure a NAT policy, as well as static port forwarding, DS Lite, and NAT 64.

In a dual-homing redundant NAT configuration, a group of NAT pools is configured for switch-over. The group is called a Pool Fate Sharing Group (PFSG), in which there is one lead pool, and a group of subordinate pools that follow the lead pool. The subordinate pools inherit the lead pool activity and state. The lead pool has its own export route which must match the monitoring route of all the pools in the corresponding PFSG on the peering node. All pools in a PFSG should belong to the same ISA-NAT group.

30.1.8 Application-agnostic NAT

If a NAT pool is created as application-agnostic, IP addresses are translated in 1:1 fashion, regardless of protocol. Ports are not translated for TCP or UDP traffic. Traffic through the NAT pool can be initiated from inside or outside. When a NAT pool is configured as application-agnostic, certain parameters in the pool are pre-configured and cannot be changed:

- Subscriber Limit: 1
- Deterministic NAT Port Reservation: 65536
- Pool Mode: One-to-One
- Port Reservation Type: Blocks

- Port Reservation Value: 1
- Port Forward Range End: 0

An application agnostic NAT pool is used to configure static 1:1 NAT, where the operator has control of mapping between the inside and outside IP addresses.

ALG for TCP/UDP are supported in a protocol-agnostic NAT pool.

30.1.9 NAT policies

A NAT policy defines general NAT properties and associates a NAT address pool with an ISA-NAT group on the same NE. A NAT policy is associated with a subscriber profile for L2-aware NAT in an IES or VPRN service, or for large-scale NAT in a VPRN service.

A NAT pool must be assigned to the local NAT policy before the NAT policy can be associated with the NAT configuration. A NAT policy is required in order to configure DS Lite, NAT 64, and NAT subscriber identification.

Individual NAT policies can be configured on various objects on an inside NAT configuration in order to create flexible mapping of inside traffic to outside pools, based on traffic criteria. Subscribers are mapped to different NAT pools, based on their source IP.

- A local NAT policy can be configured for each destination prefix. Destination prefixes point to the global NAT policy for a NAT configuration by default.
- A local NAT policy can be configured for each static port forward entry. Static port forwards point to the global NAT policy for a NAT configuration by default.
- ACL IP and IPv6 filter policies can be configured to divert traffic to NAT based on filter match criteria. Each filter entry can point to an individual NAT policy. For IPv6 filter entries, you can specify the NAT type (DS-LITE or NAT-64).
- A local NAT policy is configured on a NAT prefix list for L2-aware NAT configurations. The NAT policy must be configured with a NAT pool.

The subscriber retention timeout configuration specifies the time a NAT subscriber and its associated IP address is kept after all hosts and associated port blocks have expired. If a NAT subscriber host appears before the retention timeout has elapsed, it is assigned the same outside IP address.

30.1.10 NAT firewall policies

A firewall policy is associated with a subscriber profile for IPv6 firewall configurations. The policy is configured with an NE, on which downstream forwarding occurs. Incoming network traffic to the NE is disallowed if there is no matching traffic flow, or if port forwarding does not exist. IPv6 domains are provisioned, containing IPv6 prefixes. Each domain points to a NAT group and the IPv6 prefixes are micronetted over the NAT group members. The IPv6 address is assigned externally, using DHCPv6 relay.

Several components must be configured to function with the firewall policy:

- a local DHCPv6 server
- a firewall domain
- IPv6 prefixes

All of these components can be configured on both base and VPRN routing instances.

30.1.11 NAT prefix lists

A NAT prefix list is used to create a set of mappings between destination IP prefixes and a specific NAT policy for an L2-aware NAT configuration. The NAT prefix list is associated with a subscriber profile, and with a NAT policy.

30.1.12 NAT classifiers

The NAT classifier is referenced by the NAT policy in DNAT configurations. It determines the destination IP address and the type of traffic that is subject to DNAT.

30.1.13 IPFIX export policies

An IPFIX export policy defines how IP traffic flow information is formatted and transferred from an exporter to a collector to facilitate services such as measurement, accounting, and billing. You can specify the router instance type, IPFIX Collector address, MTU, and refresh timeouts. You can add an IPFIX export policy to a NAT policy.

30.1.14 ISA-NAT groups

An ISA-NAT group provides a redundant NAT function for routing instances using ISA Broadband Applications MDAs or ESA VMs.

See the NE documentation for more information about NAT deployment.

30.1.15 NAT Destinations

A NAT destination prefix applies NAT to all traffic that matches a given route. A NAT Destination cannot be configured in conjunction with a NAT policy that points to a NAT pool that resides in the same service. Such a configuration would result in a routing loop.

30.1.16 NAT 64

NAT 64 allows IPv6 hosts to connect to IPv4-only servers, mapping their inside IPv6 addresses to outside IPv4 addresses. NAT 64 configuration requires support for IPv6 (chassis mixed mode) on the NE. You must assign a NAT policy to the NAT configuration before enabling NAT 64. IP fragmentation can be configured to allow IPv6 packet fragmentation before transmission.

30.1.17 DS Lite

DS Lite is intended for network operators that have an IPv6-only access network, but IPv4-only CPEs. The inside IPv4 host information is encapsulated into a 4to6 tunnel that runs over the IPv6 network. At the other end, the IPv4 address is de-encapsulated and translated to an outside IPv4 address via CGN. You must assign a NAT policy to the NAT configuration before enabling DS Lite. IP fragmentation can be configured to allow IPv6 packet fragmentation before transmission if the packets are larger than the tunnel MTU for a given DS Lite address.

30.1.18 Deterministic NAT

Deterministic NAT is a mode of operation in which the inside IP address and source ports are deterministically mapped to the outside IP address and port range at the time of configuration. Each inside IP address is permanently mapped to an outside IP address and a dedicated port block. The dedicated port block is referred to as the deterministic port block. Deterministic mapping can be automatically extended by a dynamic port block in cases where a deterministic port range runs out of ports. Because a simple formula is used to determine the inside IP address based on the outside IP address and port, there is no need for NAT logging.

The NAT deterministic script generates an offline calculation of the deterministic NAT map entries. You can save the script results to a folder on a remote server by specifying a URL for the server in the local NE properties.

In the NFM-P, inside IP addresses are configured in the form of prefixes. Any inside prefix on any routing instance can be mapped to any deterministic pool on any routing instance, including the deterministic pool in which the inside prefix is defined. The mapping between the inside prefix and the deterministic pool is achieved through a NAT policy that is referenced for each individual prefix. IP addresses from the prefixes on the inside are distributed over the IP addresses defined in the outside pool referenced by the NAT policy.

A port block is a collection of ports that is assigned to a subscriber. A deterministic LSN subscriber can have only one deterministic port block that can be extended by multiple dynamic port blocks. All port blocks for an LSN subscriber must be allocated from a single outside IP address.

A port range is a collection of ports that can spawn multiple port blocks of the same type. For example, a deterministic port range includes all ports that are reserved for deterministic consumption. A dynamic port range is a total collection of ports that can be allocated in the form of dynamic port blocks.

30.1.19 Destination NAT

Destination NAT (DNAT) is used for traffic steering when the destination IP address is rewritten. A typical use of DNAT is the redirection of unauthenticated traffic to an authentication server. Once authenticated, DNAT would be removed by means of a RADIUS CoA request.

DNAT is used as part of large-scale NAT (deterministic and non-determistic) and L2–aware NAT configurations. DNAT-only configuration is applicable only to large-scale NAT. When a NAT policy is configured for use in DNAT-only configurations, it must not be configured with port limit or NAT pool parameters. When a NAT policy is configured for use in DNAT configurations, it must reference a NAT classifier, which determines the destination IP address and the type of traffic that is subject to DNAT.

30.2 Workflow to configure NAT

30.2.1 Stages

1

Configure an ISA RADIUS accounting policy that is used to configure an ISA-NAT group; see 57.12 “To configure an ISA RADIUS policy” (p. 1803).

2 Configure an ISA-NAT group; see 30.3 “To configure an ISA-NAT group” (p. 1080).

3 Configure an IPFIX export policy as required and add it to the NAT policy; see 30.4 “To configure an IPFIX export policy” (p. 1081).

4 Configure a NAT classifier, if required; see 30.8 “To configure a NAT classifier” (p. 1085).

5 Configure a NAT policy; see 30.5 “To configure a NAT policy” (p. 1082).

6 Configure a NAT prefix list, if required; see 30.7 “To configure a NAT prefix list” (p. 1084).

7 Associate a NAT policy with a subscriber profile; see 64.4 “To configure a subscriber profile” (p. 1840).

8 Configure NAT on a routing instance; see 30.9 “To configure NAT on a routing instance” (p. 1086).

9 Start or stop a NAT address-pool drain operations; see 30.13 “To start or stop a NAT address-pool drain operation” (p. 1094).

10 Configure a NAT deterministic script on a remote server; see 30.14 “To configure a NAT deterministic script on a remote server” (p. 1095).

11 Configure statistics on an ISA-NAT group; see 30.15 “To configure statistics on an ISA-NAT group” (p. 1096).

12 View LSN subscriber host statistics data in graphical form; see 30.16 “To plot LSN subscriber host statistics” (p. 1097).

13 View reserved IP address and reserved block information on ISA-NAT groups; see 30.17 “To view reserved IP address and reserved block information on an ISA-NAT group” (p. 1098).

14

View ISA-NAT object information such as Classic LSN Subscriber, ISA-NAT Group, or LSN block allocation; see 30.18 “To view ISA-NAT object information” (p. 1099).

30.3 To configure an ISA-NAT group

30.3.1 Purpose

Perform this procedure to configure an ISA-NAT group on supported 7750 SR devices. An ISA-NAT group provides a redundant NAT function for routing instances using ISA broadband applications MDAs or ESA VMs.

30.3.2 Steps

1

In the navigation tree Equipment view, expand Network→*NE*→Logical Group.

2

Right-click on the ISA-NAT Groups object and choose Create ISA-NAT Groups or select an existing ISA-NAT Group and click Properties. The ISA-NAT Group (Create|Edit) form opens.

3

Configure the parameters, as required.

The Redundancy and Failed MDA Limit parameters can be configured only when the Administrative State parameter is set to Down.

4

Select an ISA RADIUS policy. See 57.12 “To configure an ISA RADIUS policy” (p. 1803) for information about how to configure a ISA RADIUS policy.

5

Click Apply. The ISA-NAT Group form refreshes with additional tabs and parameters.

6

When the Hardware Type parameter is set to ISA, perform the following steps:

1. Click on the ISA-NAT MDA tab.
2. Click Create.The ISA-NAT Group MDA (Create) form opens.
3. Select an ISA Broadband Applications MDA. See 15.78 “To configure an MDA” (p. 536) for information about how to configure an MDA.

   NOTE: You can configure up to six ISA-NAT group members. Each group member must be an ISA Broadband Applications MDA
4. Click on the General tab and configure the Administrative State parameter.

NOTE: You can set the Administrative State parameter to Up only when the ISA-NAT group contains at least one MDA and when the Active MDA Limit parameter is set to a value greater than 0.

5. Click on the Dynamic MDA tab.
6. Click Create. The Dynamic MDA (Create) form opens.
7. Configure the required parameters.

7

When the Hardware Type parameter is set to ESA VM, perform the following steps:

1. Click on the NAT ESA VM tab.
2. Click Create. The NAT ESA VM (Create) form opens.
3. Select an ESA ID and an ESA VM ID.

8

Save your changes and close the forms.

END OF STEPS

30.4 To configure an IPFIX export policy

30.4.1 Steps

1

Choose Policies→IPFIX Export Policy from the NFM-P main menu. The IPFIX Export Policy form opens.

2

Click Create or select an existing IPFIX export policy and click Properties. The IPFIX Export Policy (Create|Edit) form opens.

3

Configure the required parameters.

4

Click on the IPFIX Collectors tab and click Create. The IpfixCollector form opens.

5

Configure the required parameters.

6

If you specified a Router Instance Type of VPRN, perform the following:

1. Click Select in the VPRN panel. The Select vprnPointer form opens.
2. Select a VPRN pointer and click OK.

7

Save your changes and close the forms. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

END OF STEPS

30.5 To configure a NAT policy

30.5.1 Purpose

Perform this procedure to configure a NAT policy for a large-scale or L2-aware NAT implementation.

30.5.2 Steps

1

Choose Policies→ISA Policies→NAT from the NFM-P main menu. The NAT Policies form opens.

2

Click Create or select an existing NAT policy and click Properties. The NAT Policy (Create|Edit) form opens.

3

Configure the parameters as required.

4

In the IPFIX Export Policy panel, select an IPFIX export policy, if required.

5

In the DNAT panel, select a NAT classifier, if required.

6

Click Apply. The NAT Policy (Create|Edit) form refreshes with additional tabs.

7

Assign a NAT pool to a local definition of the policy, as required.

Note: The policy must be distributed to the NE on which the NAT pool is configured before the local definition of the policy can be configured. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

Perform the following steps:

1. Click on the Local Definitions tab and click Search. A list of NEs to which the policy has been distributed appears.
2. Click on an item in the list and click Properties. The NAT Policy, Local Policy form appears.
3. Ensure that the Distribution Mode field of the local policy is set to Local Edit Only. Click Switch Mode to change the distribution mode if required.
4. Select a NAT pool.

8

If the policy is part of a DNAT-only configuration, associate a local definitions of the policy with a routing instance and an NAT-ISA group, as required.

Note: The policy must be distributed to an NE before the local definition of the policy can be configured. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

Perform the following steps:

1. Click on the Local Definitions tab and click Search. A list of NEs to which the policy has been distributed appears.
2. Click on an item in the list and click Properties. The NAT Policy, Local Policy form appears.
3. Ensure that the Distribution Mode field of the local policy is set to Local Edit Only. Click Switch Mode to change the distribution mode if required.
4. In the DNAT-only panel, select a routing instance and NAT-ISA group.

9

Save your changes and close the forms.

END OF STEPS

30.6 To configure a NAT firewall policy

30.6.1 Purpose

Perform this procedure to configure a NAT firewall policy for an IPv6 firewall configuration for vRGW hosts.

30.6.2 Steps

1

Choose Policies→ISA Policies→NAT from the NFM-P main menu. The NAT Policies form opens.

2

Select Firewall Policy (Network Address Translation) in the object drop-down.

3

Click Create or select an existing firewall policy and click Properties. The Firewall Policy (Create|Edit) form opens.

4

Configure the parameters as required.

5

Click on the Timeouts tab to configure timeout parameters as required.

For each timeout category, you must disable the Default check box before specifying non-default timeout values.

6

Click Apply. The Firewall Policy (Create|Edit) form refreshes with additional tabs.

7

Save your changes and close the forms.

End of steps

30.7 To configure a NAT prefix list

30.7.1 Purpose

Perform this procedure to configure a NAT prefix list for an L2-aware or dynamic NAT implementation.

30.7.2 Steps

1

Choose Policies→ISA Policies→NAT Prefix Lists from the NFM-P main menu. The NAT Prefix Lists form opens.

2

Click Create or select an existing NAT prefix list and click Properties. The NAT Prefix List (Create|Edit) form opens.

3

Configure the Displayed Name and Application parameters.

4

Click Apply. The NAT Prefix List form refreshes with additional tabs.

5

Click on the NAT Prefix tab to configure NAT prefixes. Up to 1024 prefixes can be configured on a prefix list.

1. Click Create or select an existing NAT prefix and click Properties. The NAT Prefix (Create|Edit) form opens.
2. Configure the Prefix Address and Prefix Length parameters.
3. Select a NAT policy if the NAT prefix list is part of an L2–aware NAT configuration.

6

Save your changes and close the forms. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

30.8 To configure a NAT classifier

30.8.1 Purpose

Perform this procedure to configure a NAT classifier for use in a destination NAT (DNAT) configuration.

30.8.2 Steps

1

Choose Policies→ISA Policies→NAT Classifiers from the NFM-P main menu. The NAT Classifiers form opens.

2

Click Create or select an existing NAT classifier and click Properties. The NAT Classifier (Create|Edit) form opens.

3

Configure the required parameters.

If the Default Action parameter is set to DNAT, you can configure the Default Action Address parameter, the Default DNAT Address parameter, or both.

4

Click on the Classifier Entries tab to configure NAT classifier entries. You can configure up to 32 classifier entries.

1. Click Create or select an existing classifier entry and click Properties. The NAT Classifier Entry (Create|Edit) form opens.
2. Configure the required parameters.

   If the Action parameter is set to DNAT, you must configure the DNAT Address parameter, unless the Default DNAT Address parameter was configured in Step 3.
3. Save your changes and close the form.

5

Save your changes and close the forms. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

30.9 To configure NAT on a routing instance

30.9.1 Purpose

Perform this procedure to configure NAT on a base or VPRN routing instance.

30.9.2 Steps

1

Do one of the following:

a. To configure NAT on a base routing instance, in the navigation tree Routing view, expand Network→*NE*→Routing Instance. Right-click on a routing instance icon that has a NAT configuration and choose Properties. The Routing Instance (Edit) form opens.

b. To configure NAT on a VPRN routing instance, choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens. Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens. On the service navigation tree, expand the Sites icon. Right-click on a routing instance icon that has a NAT configuration and choose Properties. The Routing Instance (Edit) form opens.

2

Click on the NAT tab.

3

Click Create or select an existing entry and click Properties. The NAT Configuration form (Create|Edit) opens.

4

Click on the Hints button at the bottom of the form to display information about the various NAT components and options available.

5

Configure the MTU parameter.

6

Click Select to assign any of the following types of ACL IP filter policy:

- Upstream IPv4 Filter
- Downstream IPv4 Filter
- Upstream IPv6 Filter
- Downstream IPv6 Filter

See 51.5 “To configure an ACL IP filter policy” (p. 1671) for information about configuring an ACL IP filter policy.

7

Configure one or more NAT pools.

Perform the following steps:

1. Click Create or select an existing entry and click Properties. The NAT Pool form (Create|Edit) appears.
2. Configure the required parameters.

   The Deterministic NAT Port Reservation and Port Forwarding Dynamic Block Reservation parameters are mutually exclusive. If one is configured, the other is disabled. The Port Forwarding Dynamic Block Reservation parameter applies only to large scale NAT pools.

   The Application Agnostic parameter can only be configured at NAT pool creation time. When a NAT pool is configured as application-agnostic, the Subscriber Limit, Deterministic NAT Port Reservation, Port Forwarding Dynamic Block Reservation, Pool Mode, Port Reservation (Type and Value), and Port Forward Range End parameters are pre-configured and cannot be changed.

   If the NAT Pool Type parameter is set to L2–aware, you can configure the External Assignment parameter, if required.
3. If the NAT pool belongs to a PFSG, click Select in the Redundancy panel to assign a lead NAT pool for the PFSG.
4. Select an ISA-NAT group for the NAT pool. See 30.3 “To configure an ISA-NAT group” (p. 1080) for information about configuring a ISA-NAT group.
5. Click on the NAT Pool Ranges tab.
6. Click Create or select an existing entry and click Properties. The Pool Range form (Create|Edit) opens.
7. Configure the required parameters.

8. Save your changes and close the forms. The NAT Configuration form reappears.

8

Click on the Inside tab.

Perform the following steps:

1. In the Deterministic NAT panel, select a NAT policy.

   Note:

   The NAT policy you choose must be distributed to the local NE, and the local definition of the NAT policy must be configured with a NAT pool.
2. Click Select to choose a NAT policy, as required. If you select a NAT policy, the NAT 64 Enabled parameter also becomes configurable, if required.
3. Click Select to choose a Downstream IPv4 filter, as required.
4. If a RADIUS Proxy Server is in use, click Select in the RADIUS Proxy Server panel and choose the following:
   - routing instance
   - RADIUS proxy server; see 27.9 “To configure a RADIUS proxy server on a routing instance” (p. 847). The selection of the RADIUS Proxy Server Name is dependent on the selected routing instance. You can only select servers enabled for accounting.
5. In the RADIUS Vendor Information panel select a RADIUS attribute type.
6. In the DNAT Only panel, select a DNAT source prefix list.

9

Click on the L2 Aware IP Addresses tab to configure IP addresses for L2-aware NAT forwarding.

Perform the following steps:

1. Click Create or choose an existing entry and click Properties. The L2 Aware IP Address, Routing Instance (Create|Edit) form opens.
2. Configure the required parameters.
3. Save your changes and close the form. The NAT Configuration form reappears.

10

Click on the DS Lite Address tab to configure DS Lite addresses.

In order to assign DS Lite Addresses, you must assigned a NAT policy in Step 8.

1. Click Create or choose an existing entry and click Properties. The Dual Stack Lite Address (Create|Edit) form opens.
2. Configure the required parameters.

   If address IP fragmentation is enabled, the Tunnel MTU parameter value must be equal to or greater than 1232 bytes.
3. Save your changes and close the form. The NAT Configuration form reappears.

11

Click on the NAT 64 tab to configure NAT 64.

In order to configure NAT 64, you must enable the NAT 64 Enabled parameter in Step 8.

1. Configure the Subscriber Prefix Length parameter.
2. If the Administrative State parameter is set to Out Of Service, you can configure the required parameters.

   Bits 64 to 71 of the NAT Destination Prefix parameter should be set to zero in order for the prefix value to be in compliance with RFC6052.

   If IP fragmentation is enabled, the IPv6 MTU parameter value must be equal to or greater than 1280 bytes.

12

Click on the Destination Prefixes tab to configure inside NAT destination addresses.

Perform the following steps:

1. Click Create or choose an existing entry and click Properties. The Destination Prefix (Create|Edit) form opens.
2. Configure the required parameters:
3. If you require a local NAT policy configuration for the destination prefix, click Select and choose a NAT policy. See 30.5 “To configure a NAT policy” (p. 1082).
4. Save your changes and close the form. The NAT Configuration form reappears.

13

Click on the Deterministic Prefixes tab to configure inside NAT deterministic prefixes.

In order to configure a NAT deterministic prefix, you must have configured one of the Deterministic NAT parameters in Step 8.

1. Click Create or choose an existing entry and click Properties. The Deterministic NAT Prefix (Create|Edit) form opens.
2. Configure the required parameters.
3. Select a NAT policy. See 30.5 “To configure a NAT policy” (p. 1082).
4. In the Deterministic Map panel, click Create or choose an existing entry and click Properties. The Deterministic NAT Map, Routing Instance (Create|Edit) form opens.
5. Configure the required parameters.
6. Save your changes and close the forms. The NAT Configuration form reappears.

14

Click on the NAT Port Forwarding tab to configure NAT port forwarding.

Perform the following steps:

1. Configure the Resync Static and Dynamic parameter, if required. If this parameter is enabled, both static and dynamic forwarders are retrieved from the NE.

   Static port forwards are persisted in the NFM-P database. Dynamic port forwards are retrieved from the NE, and are retained in the NFM-P GUI only for the duration of the current session.
2. Click on the Static tab.
3. Click Create or choose an existing entry and click Properties. The NAT Static Port Forwarding (Create|Edit) form opens.
4. Configure the required parameters.

   You cannot specify the same set of Inside Port and Protocol values in more than one static port mapping to an Inside IP Address.

   You can specify the same Outside Port value in multiple mappings to an Inside IP Address.

   The B4 Address and AFTR Address parameters apply only to DS Lite LSN configurations.
5. If you require a local NAT policy configuration for NAT port forwarding, click Select and choose a NAT policy. See 30.5 “To configure a NAT policy” (p. 1082).
6. If a redundant pool configuration is in use, click Select and choose the following for the standby pool.
   - routing instance
   - NAT policy; see 30.5 “To configure a NAT policy” (p. 1082)
7. Save your changes and close the forms. The NAT Configuration form reappears.

15

Click Resync NAT Port Forward and confirm the synchronization.

16

Save your changes and close the form.

END OF STEPS

30.10 To configure static one-to-one NAT on a 7705 SAR base routing instance or VPRN routing instance

30.10.1 Purpose

Perform this procedure to configure static one-to-one NAT on a 7705 SAR base or VPRN routing instance.

30.10.2 Steps

1

Perform one of the following:

a. To configure static one-to-one NAT on a base routing instance, in the navigation tree Routing view, expand Network→*NE*→Routing Instance. Right-click on a routing instance icon and choose Properties. The Routing Instance (Edit) form opens.

b. To configure static one-to-one NAT on a VPRN routing instance, choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens. Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens. On the service navigation tree, expand the Sites icon. Right-click on a routing instance icon and choose Properties. The Routing Instance (Edit) form opens.

2

Click on the Static NAT tab, and then on the General subtab.

3

Enable the Enable Static NAT parameter.

4

Configure the Drop Packets without NAT parameter, as required.

This parameter configures the router to drop packets that are traveling from either an inside network to an outside network or an outside network to an inside network that do not have a NAT mapping entry. By default, packets traveling from either an inside network to an outside network or an outside network to an inside network are forwarded whether or not there is a NAT mapping entry.

5

Click on the Inside Map subtab and click Create. The Static NAT Inside Map (Create) form opens.

6

Configure the required parameters.

The Inside Map maps a range of inside source IP addresses that will undergo NAT to a specified outside IP address range. The 7705 SAR will sequentially map each inside source IP address to its corresponding outside IP address.

7

Save your changes and close the form.

8

Perform one of the following:

a. Navigate to the IES L3 Access Interface Properties form, General tab, and enable the Enable

Static NAT Inside parameter.

b. Navigate to the VPRN L3 Access Interface Properties form, General tab and enable the Enable Static NAT Inside parameter.

c. Navigate to the VPRN Tunnel Interface Properties form, General tab and enable the Enable Static NAT Inside parameter.

9

Save your changes and close the form.

END OF STEPS

30.11 To configure an IPv6 firewall domain

30.11.1 Purpose

Perform this procedure to configure an IPv6 firewall domain on a NAT configuration on a base or VPRN routing instance.

30.11.2 Steps

1

Do one of the following:

a. To configure an IPv6 firewall domain on a base routing instance, in the navigation tree Routing view, expand Network→*NE*→Routing Instance. Right-click on a routing instance icon that has a NAT configuration and choose Properties. The Routing Instance (Edit) form opens.

b. To configure an IPv6 firewall domain on a VPRN routing instance, choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens. Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens. On the service navigation tree, expand the Sites icon. Right-click on a routing instance icon that has a NAT configuration and choose Properties. The Routing Instance (Edit) form opens.

2

Click on the NAT tab.

3

Click on the Firewall Domain tab.

4

Click Create or select an existing firewall domain in the list and click Properties. The Firewall Domain (Create|Edit) form opens.

5

Configure the parameters on the General tab and select an ISA group.

6

Click on the Prefixes tab to configure firewall prefixes.

1. Click Create or select an existing firewall prefix in the list and click Properties. The Firewall Prefix (Create|Edit) form opens.
2. Configure the parameters.

7

Save your changes and close the forms.

END OF STEPS

30.12 To configure a MAP-T domain

30.12.1 Purpose

Perform this procedure to configure an MAP-T domain on a NAT configuration on a base or VPRN routing instance.

30.12.2 Steps

1

Do one of the following:

a. To configure a MAP-T domain on a base routing instance, in the navigation tree Routing view, expand Network→*NE*→Routing Instance. Right-click on a routing instance icon that has a NAT configuration and choose Properties. The Routing Instance (Edit) form opens.

b. To configure a MAP-T domain on a VPRN routing instance, choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens. Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens. On the service navigation tree, expand the Sites icon. Right-click on a routing instance icon that has a NAT configuration and choose Properties. The Routing Instance (Edit) form opens.

2

Click on the NAT tab.

3

Click on the MAP-T Domain tab.

4

Click Create or select an existing MAP-T domain in the list and click Properties. The MAP-T Domain (Create|Edit) form opens.

5

Configure the required parameters.

6

Save your changes and close the forms.

END OF STEPS

30.13 To start or stop a NAT address-pool drain operation

30.13.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance.

2

Right-click on the routing instance icon that has one or more configured NAT pools and choose Properties. The Routing Instance (Edit) form opens.

3

Click on the NAT Configuration tab.

4

Click Search, select a NAT configuration in the list and click Properties.The NAT Configuration (Edit) form opens.

5

Click on the NAT Pools tab.

6

Click Search, select the required address pool and click Properties.The NAT Pool (Edit) form opens.

Note: You can also select multiple address pools and use the Drain or Stop Drain buttons to control the draining for the selected address pools, as described in subsequent procedure steps.

7

Click Drain to start a drain operation on the address pool. The number of host sessions that are associated with the address range decreases as sessions close.

8

Click Stop Drain to stop an active drain operation on the address pool. New host sessions can use the address range.

9

Close the forms.

END OF STEPS

30.14 To configure a NAT deterministic script on a remote server

30.14.1 Steps

1

In the navigation tree Equipment view, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab.

3

Click on the Subscriber Management tab.

4

Configure the Remote URL parameter using the following syntax:

[{ftp://|tftp://}<*login*>:<*password*>@<*remote_address*>/] [<*path_file*>]

where...

<*login*> is the login name of the remote server.

<*password*> is the login password of the remote server.

<*remote_address*> is the IP address of the remote server.

<*path_filename*> is the path to the folder on the remote server where the mappings are stored.

5

Click Apply and then click Save Script to save the current deterministic NAT mappings to a file on the specified remote server.

6

If required, click Resync to update the read-only information in the Save Needed, Last Saved Result, and Last Saved Time fields.

If a change occurs on the local NE that affects the deterministic NAT mappings, the Save Needed parameter changes to Yes, indicating that you must click Save Script to update the mappings.

7

Save your changes and close the form.

END OF STEPS

30.15 To configure statistics on an ISA-NAT group

30.15.1 Steps

1

In the navigation tree Equipment view, expand Network→*NE*→Logical Groups→ISA-NAT Groups→ISA-NAT Group *n*.

2

Right-click on the ISA-NAT Group *n* icon where you want to configure statistics and choose Properties. The ISA-NAT Group (Edit) form opens.

3

Click on the ISA-NAT MDA tab to configure ISA Member statistics, ISA Member Usage statistics, or Policy statistics,

Note: You can also collect ISA NAT Member statistics or ISA NAT Member Usage statistics (but not NAT Policy statistics) from the ISA-NAT Members tab. The procedure for collecting statistics is the same as is outlined below.

4

Click Search and select an ISA-NAT MDA and click Properties. The ISA-NAT Group MDA (Edit) form opens.

5

Click on the Statistics tab.

6

In the Select Object Type area, choose one of the following from the contextual menu:

- ISA NAT Member Usage Stats
- ISA NAT Resources Stats

- NAT Policy Stats

7

Click Collect, select a record on the ISA-NAT Group MDA (Edit) form and click Properties. The Statistics Record form opens.

8

View the read-only statistics parameter values for the ISA-NAT group MDA.

9

Close the forms.

END OF STEPS

30.16 To plot LSN subscriber host statistics

30.16.1 Purpose

Perform this procedure to view LSN subscriber host statistics data in graphical form.

Note: You can plot only real-time statistics data for a subscriber host. The NFM-P does not retain historical subscriber host information.

30.16.2 Steps

1

Perform one of the following.

a. Plot the statistics data from a base routing instance.

   Perform the following steps:

   1. In the navigation tree Routing view, expand Network→*NE*→Routing Instance.
   2. Right-click on the Routing Instance icon and choose Properties. The Routing Instance (Edit) form opens.

b. Plot the statistics data from a VPRN routing instance.

   Perform the following steps:

   1. Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.
   2. Click Search, select a VPRN service in the list and click Properties.The VPRN Service (Edit) form opens.
   3. In the service navigation tree, expand Sites→Routing Instance.
   4. Select a routing instance in the service navigation tree and choose Properties. The Site (Edit) form opens.

2

Click on the NAT tab and perform one of the following.

a. To plot host statistics for a DS Lite subscriber, click on the NAT DS Lite Subscribers tab.

b. To plot host statistics for a NAT 64 subscriber, click on the NAT64 Subscribers tab.

c. To plot statistics for classic LSN subscribers, click on the Classic LSN Subscribers tab.

3

Click Search, select a subscriber host in the list and click Properties. The subscriber host properties form opens.

4

Choose Plotter→New Plot. The Statistics Plotter window opens.

See “Graphing statistics” in the *NSP NFM-P Statistics Management Guide* for information about using the NFM-P Statistics Plotter.

5

View the plotted statistics data as required.

Save the tabular data or plot graph, as required.

6

Close the forms.

END OF STEPS

30.17 To view reserved IP address and reserved block information on an ISA-NAT group

30.17.1 Steps

1

In the navigation tree Equipment view, expand Network→*NE*→Logical Groups→ISA-NAT Groups→ISA-NAT Group *n*.

2

Right-click on an ISA-NAT Group *n* icon and choose Properties. The ISA-NAT Group (Edit) form opens.

3

Click on the ISA-NAT Members tab and select an ISA-NAT member and click Properties. The ISA-NAT Member form opens.

4

In the Metrics panel, review the information provided in the Reserved IP address and Reserved block read-only parameters.

Note: Click Resync to update the IP Address Reserved and Blocks Reserved values to the most recent information available on the MDA.

5

Close the forms.

END OF STEPS

30.18 To view ISA-NAT object information

30.18.1 Purpose

Use this procedure to perform an on-demand retrieval of large-scale NAT entries, based on a routing instance ID. Search results can be further constrained by specifying an inside address (for a classic LSN host, DS Lite subscriber, or NAT64 subscriber) or an outside address and start port number (for a LSN block allocation).

30.18.2 Steps

1

Click Manage→ISA Functions→ISA-NAT from the NFM-P main menu. The Manage ISA-NAT form appears.

2

Select the appropriate ISA-NAT object type, for example, Classic LSN Subscriber, ISA-NAT Group, or LSN block allocation. The Manage ISA-NAT form refreshes displaying the search parameters used to locate the ISA-NAT object.

3

Configure the parameters as required to locate the ISA-NAT object.

4

Click Search, select an entry in the list and click Properties. A read-only object properties form appears.

5

Review the information as required.

6

Close the forms.

END OF STEPS

31 MPLS

MPLS overview

31.1 MPLS overview

31.1.1 Overview

The NFM-P supports the configuration and provisioning of MPLS paths and LSPs.

MPLS is a data-carrying mechanism that emulates some properties of a circuit-switched network over a packet-switched network. MPLS prepends a packet with an MPLS header that is comprised of labels in a stack. As an NE forwards a packet through an MPLS network, it examines the top label for routing instructions and pops it off the stack; the contents below the label stack are not examined. The label stack is not removed until it reaches the egress NE.

MPLS uses one or more IGPs, such as IS-IS, OSPF, or RIP, to forward packets. Regardless of the IGP chosen, the MPLS configuration is the same. An advantage of MPLS is that if more than one IGP is enabled, it continues to work when another protocol fails. See Chapter 28, “Routing protocol configuration” for more information on IS-IS, OSPF, and RIP.

MPLS can be used as the underlying transport mechanism for service tunnels. For MPLS to be used as such, an MPLS mesh and an LSP mesh must be created before the tunnel is created. Since LSPs and service tunnels are unidirectional, they must be created in both directions. See Chapter 33, “Service tunnels” for more information about service tunnels.

When MPLS is enabled on an NFM-P-managed NE routing instance, the NFM-P displays an MPLS instance below the routing instance in the network view of the navigation tree. Using this view, you can perform various functions on the MPLS instance, for example, assign an L3 interface to an MPLS instance.

If a link, NE, or path fails, MPLS can determine a redundant path by using fast reroute. Fast reroute uses an alternative NE to complete the failed LSP. Fast reroute provides the following types of route protection.

- Many-to-one—one backup route is maintained for multiple protected LSPs on an NE.
- One-to-one—a separate backup route is maintained for each protected LSP on an NE algorithm.

You can list and view MPLS objects such as MPLS and RSVP instances and interfaces, static and dynamic LSPs, cross connections, and MPLS paths using the NFM-P Manage MPLS Objects form.

31.1.2 MPLS forwarding policies

The data model of a forwarding policy represents each pair of next hops (primary and backup) as a group and models the ECMP set as the set of next-hop groups. Flows of prefixes can be switched on a per next-hop group basis from the primary next-hop, when it fails, to the backup next-hop without disturbing the flows forwarded over the other next-hop groups of the policy. The same can be performed when reverting from a backup next-hop to the restored primary next-hop of the same next-hop group.

An endpoint MPLS forwarding policy allows the user to forward unlabeled packets over a set of user-defined direct (with option to push a label stack), indirect, or LSP next-hops. Routes are bound to an endpoint policy when their next-hop matches the endpoint address of the policy.

A label-binding MPLS forwarding policy provides the same capability for labeled packets. In this case, labeled packets matching the ILM of the policy binding label are forwarded over the set of next-hops of the policy.

31.2 LSPs

31.2.1 Overview

An LSP is a path through an MPLS network that is set up based on criteria in a forwarding equivalency class (FEC). An FEC is a set of characteristics that define how NEs in an MPLS network forward packets that are bound to an MPLS label. An FEC includes specifications such as the destination IP address and QoS parameters. An FEC is associated with a specific LSP, but an LSP may be used for multiple FECs.

An LSP begins at a PE device called an LER, which is the ingress NE that prepends a label to a packet based on an FEC and sends the packets to the next transit NE in the path. The transit NE swaps the packet label for a new one, and sends the packet to the next NE. The LER that acts as the egress PE NE removes the label and forwards the packet according to the header of the next layer, for example, IP.

LSPs are unidirectional; they enable the label switching of a packet through an MPLS network from one endpoint to another. Bidirectional communication through an MPLS network requires the configuration of an LSP in the opposite direction.

The NFM-P supports the following types of LSPs:

- Static LSPs specify a static path through an MPLS network. All transit NEs require manual configuration with LSP labels and require no signaling protocol, such as LDP or RSVP.
- Bypass-only LSPs are LSPs with manually configured bypass tunnels on Point-of-Local-Repair (PLR) NEs. Such LSPs are used exclusively for the purpose of bypass protection.
- Dynamic, or signaled LSPs, use a protocol such as LDP or RSVP. The signaling protocol allows an ingress NE to dynamically assign labels to an egress NE. You must configure the ingress NE, but not the transit NEs in an LSP. LDP LSPs are not explicitly defined. The downstream unsolicited (DU) method configures them automatically through the network.
- Segment Routing TE LSPs (SR-TE LSPs) are established with traffic engineering and protection requirements based on different parameters, such as hop limit, IGP shortcut, BGP shortcut and maximum segment routing labels.
- Point-to-Multipoint LSPs allow the source of multicast traffic to forward packets to one or many multicast receivers over a network without requiring a multicast protocol, such as PIM, to be configured in the network.

You can apply a metric value to a Dynamic LSP or a Point-to-Multipoint LSP that determines which LSP the NFM-P uses when multiple LSPs lead to the same destination. The metric value for a static route is set to 1 and cannot be configured.

You can list and view detailed information on LSPs, templates, cross connections, service tunnels, and detour and bypass information on the LSP (Edit) forms.

31.2.2 Dynamic LSPs

A Dynamic LSP uses a signaling protocol such as LDP or RSVP-TE and an MPLS path between two NEs. You can then create an LSP between the two NEs and bind it to an MPLS path. An LSP-MPLS path binding is called an LSP path. You can configure the LSP path after the MPLS path and the LSP are bound.

Dynamic LSPs are categorized as follows:

- Explicit-path LSPs resemble static LSPs when all hops are strict; each hop in the LSP requires explicit configuration. MPLS uses RSVP-TE to set up an explicit-path LSP. Transit NE hops can be strict, and use a direct path between NEs, or loose, and include other NEs in the path between NEs.
- Constrained-path LSPs have dynamically assigned intermediate NE hops that rely on CSPF to find a path that satisfies the LSP constraints. CSPF is a routing algorithm that takes different LSP constraints, such as the available bandwidth and MPLS administrative groups, into account to balance the network load. When the CSPF path is found, RSVP uses the path to request the LSP setup. If Fast Reroute is enabled, the ingress NE signals the downstream NEs to set up a detour configuration for the LSP.

When an LSP is established, the reserved bandwidth is controlled by the bandwidth parameter at the primary path level, regardless of whether the LSP has auto-bandwidth enabled. When auto-bandwidth is enabled and a trigger occurs, the NE attempts to change the bandwidth of the LSP to a value between the minimum and maximum bandwidth, which are configurable at the LSP level. Automatic bandwidth allocation is supported on RSVP LSPs that have both CSPF and MBB enabled. If an RSVP LSP is configured for auto-bandwidth, the ingress LER determines, at every adjust interval, whether to attempt an auto-bandwidth adjustment. You can change the minimum bandwidth, maximum bandwidth, or threshold parameters on an operational LSP, however, the changes do not take effect until the next auto-bandwidth trigger, for example, an adjust interval expiry. If the bandwidth adjustment fails, for example, the CSPF cannot find a path, the existing LSP is maintained with its existing bandwidth reservation. See 31.11 “To create a Dynamic LSP” (p. 1126) for more information.

The NFM-P provides OAM tools for troubleshooting service and network transport issues. You can run an OAM validation test for the Dynamic LSP by clicking on the One Time Validation button. If a check mark appears beside the OAM Validation Failed state cause indicator, the test has failed. The One Time Validation Result tab on the Tests tab displays detailed information about the OAM test result. See 90.55 “To run a one-time validation test on a service” (p. 3084) for information on how to use the One Time Validation function.

You can manually switch away or switch back to the primary path for a RSVP-TE using the Manual Switch Path button on the Tunnels tab of the Dynamic LSP form. Selecting the Switch Away option will degrade the primary path, switching to a standby path, and selecting the Switch Back option will restore the primary path.

31.2.3 Static LSPs

A static LSP uses an IGP instead of a signaling protocol, such as LDP or RSVP-TE. The NFM-P attempts to derive the hop configurations based on the hop labels in the path. You must use an ingress label that is unique within an NE when you create a new static hop; otherwise, the NFM-P rejects the new hop.

You can assign static label mappings for LSP cross-connections on an MPLS interface during interface creation or modification. A static label map is used only for intervening unmanaged NEs. The NFM-P attempts to derive the interface and label values from the swap egress label of the previous hop. The Static Label Maps form lists the static label maps for an interface whether they are created using the NFM-P client GUI, an OSS client, or CLI.

The NFM-P does not raise an alarm against an unmanaged NE.

The NFM-P raises an alarm against a static LSP under the following conditions when the LSP destination is managed by the NFM-P:

- No hops are configured for the static LSP.
- The last hop does not match the LSP destination.
- The label action specified for the last hop is not a pop action.

31.2.4 SR-TE LSPs

You can configure a Segment Routing Traffic Engineered (SR-TE) LSP using the Manage→MPLS→Segment Routing LSPs option. You can associate an empty path or a path with strict or loose explicit hops with the primary path of the SR-TE LSP.

The SR-TE LSP has the following characteristics:

- Static route tunnel binding configuration allows the forwarding of packets of a static route to an indirect next-hop over an SR-TE LSP.
- BGP shortcut tunnel binding configuration allows the forwarding of packets of BGP prefixes over an SR-TE LSP.
- The BGP transport tunnel can be enabled so that the SR-TE LSP can resolve the next-hop of a BGP IPv4 or IPv6 (6PE) label route.
- An SDP sub-type of the MPLS encapsulation type allows service binding to a SR-TE LSP.
- The support of SR-TE LSP in the data path requires that the ingress LER pushes a label stack where each label represents a hop, a TE link, or an NE, in the ERO for the LSP path computed by the PCE.

An SR-TE LSP is configured on the NE, but its path can be computed by the NE or by an external Traffic Engineering controller referred to as a Path Computation Element (PCE). This feature works with the Nokia stateful PCE, which is part of the NSP. Three modes of operations can be configured for an SR-TE LSP:

- When the path of the SR-TE LSP is computed by the NE acting as a PCC, the LSP is referred to PCC-initiated and PCE-controlled.
- When the path of the SR-TE LSP is computed by the PCE at the request of the PCC, it is referred to as PCC-initiated and PCE-computed.
- When the path of the SR-TE LSP is computed and updated by the PCE following a delegation from the PCC, it is referred to as PCC-initiated and PCE-controlled.

You can manually switch away or switch back to the primary path for a SR-TE using the Manual Switch Path button on the Tunnels tab of the Segment Routing LSP form. Selecting the Switch Away option will degrade the primary path, switching to a standby path, and selecting the Switch Back option will restore the primary path.

31.2.5 Point-to-Multipoint LSPs

A Point-to-Multipoint (P2MP) MPLS LSP allows the source of multicast traffic to forward packets to one or many multicast receivers over a network without requiring a multicast protocol, such as PIM, to be configured in the network. A P2MP LSP tree is established in the control plane for which the path consists of a head-end NE, one or many branch NEs, and multiple leaf NEs. Packets that are injected by the head-end NE are replicated in the data plane at the branching NEs before they are delivered to the leaf NEs.

The P2MP LSP has a source IP address but does not a have a destination address. Instead, you must create S2L leaf NEs for each destination in the P2MP LSP tree. The P2MP LSPs are not supported in SDP bindings.

Each P2MP LSP object has one P2MP LSP instance object. This is the primary instance, and can contain multiple child S2L path objects. Just as the P2MP LSP can appear as a tree, each S2L path object represents a root-to-leaf (S2L) sub-LSP path for the primary instance. The S2L paths can be empty paths or can specify a list of explicit hops. The same path can be used by more than one S2L of the instance. However the destination IP address must have a unique argument per S2L, because it corresponds to the address of the egress LER NE.

PIM tunnel interfaces are associated with a P2MP LSP. The tunnel interfaces are needed at both the ingress LER and the egress LER NEs. You must also associate static multicast groups with the tunnel interfaces that are associated with the P2MP LSPs.

On the ingress side, you can create one or more tunnel interfaces in PIM and associate each with a different RSVP P2MP LSP. The tunnel interface is associated with the P2MP LSP name. You can then assign static multicast group joins to each tunnel interface using an IGMP configuration. A specific <*,G> or <S,G> can only be associated with a single tunnel interface. A multicast packet which is received on an interface and matches the <*,G> or <S,G> specified in the IGMP join for the tunnel interface is replicated and forwarded to all branches of the P2MP LSP.

On the egress side, the PIM tunnel interface is associated with both the P2MP LSP name and the system address of the ingress LER. You must define a multicast info policy to associate specific multicast groups, or a specific <S,G>, to the primary tunnel interface on each egress LER leaf NE. The multicast info policy must then be applied to the router. A multicast packet synced from a tunnel interface associated with a P2MP LSP on the egress leaf NE can then be forwarded over a PIM or IGMP interface, which can be an access interface or a network interface, including a spoke SDP-based IES interface. You may create multiple tunnel interfaces per NE, where each interface is associated with a different P2MP LSP. The P2MP LSP association to a multicast group can be applied at the bundle, channel, and/or source channel level in the policy.

You can create a P2MP, one-hop P2P, or mesh P2P LSP using the LSP template for MVPN from the Policies→MPLS→LSP Template MVPN menu option. You can configure the scope as either local or global. The global template can be modified and multiple local versions can exist on the NEs. You must assign a default MPLS path to the template on the local definition before the template is turned up. If you modify the template, you must shut down the local policy first. When you turn up the local policy, all previously created P2MP LSP parameters are synchronized with the new template. See 31.29 “To create an LSP template MVPN policy” (p. 1156) for more information.

31.2.6 Bypass LSPs and manual bypass tunnels

You can create manual bypass tunnels and dynamic (or automatic) bypass tunnels on the SR/ESS, 7705 SAR, and 7210 SAS. You can manually configure an LSP to be bypass-only on a PLR NE. The LSP is then used exclusively for the purpose of bypass protection.

You can use manual bypass alone or with dynamic bypass. When used with the dynamic bypass, the manual bypass has precedence over the dynamic bypass for the path selection.

Dynamic bypass tunnels can be disabled on a per-NE basis. They are enabled by default. If dynamic bypass is disabled on a network element while dynamic bypass tunnels are active, traffic loss occurs. Furthermore, if no suitable manual bypass LSPs are found, the protected LSP remains without protection.

A bypass-only LSP does not have all the configurable attributes of a regular dynamic LSP. The main differences include:

- Manual bypass LSPs only support primary path. Secondary or standby paths cannot be created.
- Manual bypass LSPs do not support bandwidth or fast-reroute.
- Path monitoring is not available for manual bypass LSPs.
- Manual bypass LSPs cannot be assigned to a service tunnel, or be added to an LDP targeted peer as the LDP tunneling LSP.
- There is no rule-based topology support available for manual bypass LSPs.
- There is no network-wide LSP view (the physical map LSP view) support available for manual bypass LSPs,
- You cannot create a static LSP using a tunnel template.

The following additional characteristics also apply to a manual bypass:

- The default protection level for a bypass tunnel is “node-protect”.
- CSPF is supported for the manual bypass tunnel. When CSPF is enabled, loose path and hop-less path are allowed on a manual bypass tunnel. The CSPF calculation is performed when the manual bypass tunnel is first set up.

31.2.7 Administrative groups with facility bypass backup LSPs

Administrative group constraints configured on an LSP primary path are used for signaling of bypass LSPs. The NFM-P supports P2P LSP and P2MP S2L path bypass LSPs. Administrative groups with one-to-one detour LSPs are not supported.

You can enable the use of administrative group constraints in the association of a manual or dynamic bypass LSP with the primary LSP path on the MPLS instance of the NE. When constraints are enabled, each PLR NE reads the constraints in the FAST_REROUTE object in the path message of the primary path LSP. If the FAST_REROUTE object is not included in the path message, the PLR NE reads the constraints from the session attribute object in the path message. The PLR NE uses the administrative group constraints and other constraints, such as the hop limit and SRLG, to choose a manual or dynamic bypass LSP from the LSPs that are in use.

You can enable the use of the administrative group constraints on FRR backup LSP on the P2P and the P2MP LSP configuration forms, and in the LSP template MVPN policy. The constraints apply only to new attempts to find a valid bypass.

31.2.8 Automatic ABR selection and dynamic ABR bypass protection

The ABR selection for the inter-area RSVP P2P LSP path computation by CSPF is automatic at the ingress LER. You do not need to include the ABR as a loose-hop in the LSP path definition. On the LSP path binding configuration form, you can view whether:

- the operational path is inter-area or intra-area
- the current CSPF hop is an ABR (on the CSPF Path tab)

31.2.9 Dynamic bypass LSP for ABR NE protection

The NFM-P provides dynamic bypass computation, signaling, and association with the primary path of an inter-area P2P LSP to provide ABR NE protection. For a PLR NE within the local area of the ingress LER to provide ABR NE protection, the NE must dynamically signal a bypass LSP and associate it with the primary path of the inter-area LSP. You can view the address of the NE that must be bypassed along the path in the RSVP session tab on the Dynamic LSP properties form.

31.2.10 FRR protection

Fast reroute protection is a MPLS and IP resiliency technology that provides fast traffic recovery upon link or router failures for mission critical services. FRR allows a user to provide local protection for an LDP FEC by pre-computing and downloading to the IOM both primary and backup next hops for the FEC.

FRR provides for the use of the Loop-free Alternate (LFA) backup next-hop for forwarding in-transit and CPM generated IP packets when the primary next-hop is not available. IP FRR is supported on IPv4 and IPv6 prefixes forwarded in the base router instance over a network IP interface, or an IES SAP or spoke interface. It is also supported for VPRN VPN-IPv4 prefixes and VPN-IPv6 prefixes forwarded to a VPRN SAP or spoke interface.

FRR requires SPF computation of an LFA next-hop (in addition to the primary next-hop) for all prefixes used by LDP to resolve FECs. The LFA next-hop is populated into the routing table along with the primary next-hop for each prefix.

LFA is configured on IS-IS routing instances, enabling LFA computation by SPF under the IS-IS routing protocol. The LFA next hop can be excluded individually on the IS-IS Level 1 and IS-IS Level 2 objects, as well as on IS-IS interface objects.

LFA is configured on OSPF routing instances, enabling LFA computation by SPF under the OSPF routing protocol. The LFA next hop can be excluded individually on the OSPF area objects, as well as on OSPF interface objects.

31.2.11 Tunnel Templates

Tunnel templates allow users to configure Dynamic LSP, LSP path, and SDP templates to define common characteristics for a tunnel or templatable tunnel object.

To simplify creating tunnel templates, the NFM-P provides examples of common tunnel templates that can be copied and customized. You can also create a tunnel template from an existing templatable object.

After a template is configured, Dynamic LSPs, SR-TE LSPs, LSP paths and SDPs can be configured by choosing a create from template button during configuration. Users can configure

multiple LSP paths for a Dynamic or SR-TE LSP. For example, you can configure one primary, one standby, and many secondary LSP paths.

When the NFM-P auto-tunnel creation is used to create LSP paths, the LSP paths must use a hopless path. If the paths belong to the same LSP, they must use different MPLS paths, even when the MPLS paths are hopless. For a RSVP LSP policy, one LSP template can be specified. When an LSP template with multiple LSP paths is specified, many LSP paths are created.

31.2.12 LSP Path Optimization

The NFM-P allows you to resignal LSP Paths to take advantage of new paths that are less congested, fewer hops, have a lower metric and meet least-fill criteria. NEs periodically check the network to determine whether a more efficient path is available and notify the NFM-P when another path is eligible for re-signaling. The NFM-P maintains a list of LSP Paths that are eligible for re-signaling. When an LSP Path is eligible for optimization, the LSP Path can be routed to a different path. When a LSP Path is not eligible for optimization, the LSP Path cannot use newly available network resources. See 31.24 “To configure an LSP Path optimization policy” (p. 1148) for information about configuring an LSP Path optimization policy.

31.2.13 LDP-over-RSVP tunnels

In networks that contain dozens of NEs spanning multiple routing areas, many RSVP service tunnels may be required. To reduce the number of RSVP tunnels required for service deployment in large networks, you can use the NFM-P to create LSPs using LDP-over-RSVP, sometimes called tunnel-in-tunnel encapsulation. An SDP can ride on multiple LDP-over-RSVP tunnels.

The NFM-P supports automatic, rule-based service-tunnel creation using NEs that are grouped according to their role in the NFM-P-managed network. This functionality greatly reduces the time and effort required to provision a mesh of service tunnels. See Chapter 33, “Service tunnels” for more information about rule-based automatic service-tunnel creation.

The NFM-P can use tunnel rules and groups to create new RSVP LSP bindings between a PE device that is added to the network and the existing ABRs. It can also create a new LDP-over-RSVP tunnel between a new NE and an existing PE NE. See Chapter 33, “Service tunnels” for more information about tunnel creation using rules and groups.

Service traffic that is transported by an LDP-over-RSVP tunnel requires a VC label, an LDP label, and an RSVP label. Unlike T-LDP sessions that use IGP SPF algorithms, RSVP LSPs are not advertised to an IGP instance. When the same FEC applies to the destination of an LDP-over-RSVP LSP tunnel and an IGP-based LDP tunnel, the NFM-P uses the LDP tunnel by default to minimize network overhead.

Using tunnel-in-tunnel encapsulation, a pair of LSP tunnels and a T-LDP session between two NEs are equivalent to two adjacent LDP NEs with a non-tunneled LDP session between them. In other words, the LDP tunnel uses the RSVP LSP as one hop between LSRs in the network.

During the configuration of LDP-over-RSVP, you can specify an explicit list of dynamic and static LSPs, or use the NFM-P to find eligible LSPs. After an LSP is explicitly configured for LDP tunneling, the NFM-P associates the LDP targeted peer with the LSP.

You can configure LDP-over-RSVP to enable an OSPF area router to be a stitching point. You can specify which NEs to use as the stitching points in each area. When there are many NEs in an area, this function helps to reduce the number of LSPs required, because a full mesh is not required.

For an LSP to be eligible for LDP-over-RSVP, the following conditions apply:

- The LSP must be an RSVP-owned LSP (strict or loose)
- The LSP must start and terminate either on:
  - The router ID (system IP address)
  - The router ID (loopback address when used in multi-instance OSPF
- The OSPF system/loopback address must be advertised
- A T-LDP session must exist between the originating and terminating routers using the addresses cited above
- LDP-over-RSVP availability must be enabled in the LSP configuration. This indicates that the LSP is eligible for LDP-over-RSVP, and RSVP signals to the IGP that the LSP should be included in the SPF run.

31.2.14 Shared Risk Link Groups

Shared Risk Link Groups (SRLGs) are constructs which allow you to perform two operations that enhance overall system reliability. Firstly, you can establish a FRR LSP path. In addition, you can also use SRLGs to establish a secondary LSP path which is disjointed from the primary LSP path.

Configured SRLGs are associated with MPLS interfaces. The SRLGs are used by the CSPF when computing a FRR detour/bypass path, or a secondary LSP path. Links which are members of the same SRLG represent resources which are assumed to share the same risk. These links are therefore avoided when computing and setting up an alternate LSP path.

- FRR backup

  The SRLG constraint can be enabled system-wide on a PLR NE, in the computation of a FRR detour or bypass to be associated with a primary LSP path. CSPF includes the SRLG constraint in the computation of a FRR detour or bypass. CSPF then prunes all links with interfaces which belong to the same SRLGs as the egress interface being protected (or the immediate downstream NE, depending on the protection level). If a path is found, the bypass or detour is set up. If not, and you included the Enable SRLG for FRR - Strict option, then the bypass or detour is not set up. If the Enable SRLG for FRR - Strict option is not specified, and a path exists that meets other TE constraints (other than the SRLG constraint), then the bypass or detour is still set up.

- Secondary LSP backup

  The SRLG constraint can also be enabled per LSP path on a head-end LER in the computation of an LSP secondary path that includes the standby path. The SRLG constraint is additional to the admin group constraint on the same secondary LSP path. CSPF includes the SRLG constraint in the computation of the secondary LSP path, which requires that the primary LSP path is configured and active. CSPF prunes links with interfaces that belong to the same SRLGs as the interfaces included in the primary path. If a path is found, the secondary LSP path is set up. Otherwise, CSPF keeps trying to set up the secondary LSP path.

You can enable only the SRLG constraint for the FRR backup operation. However, you can enable both the SRLG constraint and the admin-group include/exclude constraint for the secondary LSP backup path operation. In either case, you can still apply the admin-group constraint for the primary path.

The following conditions also apply to SRLGs:

- An SRLG is modeled as a policy object. It therefore follows the normal policy behavior for creation, listing, updating, deletion, distribution and resynchronization
- SRLGs are defined node-wide
- Configured SRLGs are associated with MPLS interfaces. A specific MPLS interface can belong to multiple SRLGs. Up to 64 SRLGs can be associated with a specific MLPLS interface

31.2.15 Bandwidth-based equal cost RSVP LSP path selection

When multiple equal-cost paths satisfy the constraints of a specific RSVP LSP path, CSPF in the 7x50 head-end NE uses a random number generator to choose a path and return it to MPLS. While this method actually balances the number of LSP paths over the links in the network, it does not necessarily balance the bandwidth utilization across those links.

In order to achieve load balancing of the bandwidth amongst the available LSP paths, CSPF must include the link utilization as a criterion in the path selection. One algorithm that considers this is referred to as the “least-fill” path selection. This algorithm identifies the single link in each of the equal-cost paths that has the least available bandwidth in proportion to its maximum reservable bandwidth. CSPF then selects the path containing the link with the largest such available bandwidth to maximum reservable bandwidth percentage. The net effect of using this algorithm is that over time, LSP paths become spread over the network links in such a way that the percentage of link utilization is balanced.

When comparing the percentages of least available link bandwidth across the sorted paths, if two percentages differ by less than a value you configure as a minimum threshold, CSPF considers them equal. It then applies a random number generator to choose amongst these paths. You can also specify a reoptimization threshold, which allows you include a path cost consideration into the decision of when to alter the paths used by the LSP.

31.2.16 LSP on-demand resynchronization

LSP on-demand resynchronization is supported on the 7750 SR and 7950 XRS. On-demand resynchronization does not affect the existing manual full NE resynchronization functionality. However, when LSP on-demand resynchronization is enabled, any scheduled resynchronization is blocked for the following LSP objects:

- RSVP session
- cross-connect
- in-segment
- out-segment
- actual hop
- CSPF hop

Therefore, these LSP objects are not resynchronized as a result of a relevant trap. The exception is that for CPAM path monitored LSPs, the actual hop trap (a generic trap) is still processed.

By default, the LSP on-demand resynchronization functionality is disabled. See the procedure to enable LSP on-demand resynchronization in the *NSP System Administrator Guide* for more information. After you enable LSP on-demand resynchronization, click on the Resync button on the LSP configure form to start the manual LSP on-demand resynchronization. The following objects are resynchronized, depending on the type of LSP:

- for a Dynamic LSP: the LSP, LSP path, CSPF and actual paths, bypass or detour path, cross-connects, in-segments, out-segments, and RSVP sessions
- for a Manual Bypass LSP: the LSP, LSP path, CSPF and actual paths, cross-connects, in-segments, out-segments, and RSVP sessions
- for a Static LSP: the head-end LSP, the static hops, static label maps, cross-connects, in-segments, and out-segments. You must manually resynchronize all of the planned hop sites in a Static LSP before creating a Static LSP.

31.2.17 Administrative tagging

An administrative tag is an identifier you can apply to a dynamic LSP, a segment routing LSP, or an LSP template. You can use an administrative tag policy to include or exclude tags from automatic tunnel binding, giving you explicit control over which LSPs are used by a given BGP site or VPRN service.

Workflow for configuring administrative LSP tagging

The following workflow describes the steps to tag an LSP and enable administrative tagging filtering on a BGP site or VPRN service.

1. Create administrative LSP tags. See 31.33 “To create an administrative LSP tag” (p. 1162).
2. Create administrative LSP tag policies. See 31.34 “To create an administrative tag policy” (p. 1162).
3. Distribute the created tags and tag policies to NEs where you need to perform administrative tagging filtering. See 49.6 “To release and distribute a policy” (p. 1476).
4. Associate administrative LSP tags with dynamic LSPs, segment routing LSPs, or LSP templates using the Admin Tags tab on the configuration form for each object. See 31.11 “To create a Dynamic LSP” (p. 1126), 31.13 “To configure a Dynamic or segment routing TE LSP” (p. 1132), 31.14 “To create a Dynamic or segment routing LSP from a tunnel template” (p. 1134), and 31.12 “To create a segment routing TE LSP ” (p. 1130) for general information about configuring these LSPs.
5. Enable the Enforce Strict Tunnel Tagging parameter on BGP sites and VPRN services where you need to use administrative LSP tagging.

31.2.18 Forwarding policies

An MPLS forwarding policy allows you to direct traffic flows to certain endpoints or endpoint groups. There are two types of MPLS forwarding policy, endpoint policies and label-binding policies:

- An **endpoint policy** forwards unlabeled packets over a set of direct, indirect, or LSP next-hops. Routes are bound to an endpoint policy when their next-hop matches the endpoint address of the policy.
- A **label-binding policy** forwards labeled packets matching the ILM of the policy label over the next-hops defined in the policy.

The NFM-P supports configuring endpoint policies on MPLS instances. See 31.35 “To create a reserved label block” (p. 1163) for information about creating reserved label blocks for use with forwarding policies. See 31.6 “To configure an MPLS instance” (p. 1116) for information about configuring MPLS, including configuring forwarding policies.

MPLS workflow and procedures

31.3 Workflow to configure MPLS

31.3.1 Stages

1

Enable and configure one or more IGPs such as IS-IS, RIP, and OSPF to include the system interface on all NEs that are to participate in the MPLS network. See the appropriate device documentation for more information.

2

Enable MPLS on the routing instances of all NEs that are to participate in the MPLS network. See 31.5 “To enable MPLS on a routing instance” (p. 1115) .

3

Create or configure an MPLS instance. Assign Layer 3 interfaces, including the system management interface, to the MPLS instance. See 31.6 “To configure an MPLS instance” (p. 1116) or 31.7 “To create an MPLS interface” (p. 1120) .

4

Create a mesh of MPLS paths. See 31.8 “To create an MPLS path” (p. 1122) .

5

As required, create a mesh of LSPs.

a. Create a static LSP. See 31.10 “To create a static LSP” (p. 1124) .

b. Create a Dynamic LSP. See 31.11 “To create a Dynamic LSP” (p. 1126) . See 31.14 “To create a Dynamic or segment routing LSP from a tunnel template” (p. 1134) for more information about how to create a Dynamic LSP from a tunnel template.

c. Create a Segment Routing TE LSP. See 31.12 “To create a segment routing TE LSP ” (p. 1130).

d. Create a Point-to-Multipoint LSP. See 31.18 “To create a Point-to-Multipoint LSP” (p. 1137) .

e. View MVPN Point-to-Multipoint LSP objects as required. See 31.19 “To view an MVPN Point-to-Multipoint LSP object” (p. 1140) .

f. Create or configure a Manual Bypass LSP. See 31.20 “To create a Manual Bypass LSP” (p. 1141) or 31.21 “To configure a Manual Bypass LSP” (p. 1143) .

6

If your mesh includes Dynamic LSPs or Bypass-only LSPs, configure an LSP path. See 31.22 “To configure an LSP path” (p. 1144) or 31.23 “To create an LSP path using a tunnel template” (p. 1147) .

7

Create an LSP Path optimization policy, if required. See 31.24 “To configure an LSP Path optimization policy” (p. 1148) .

8

Create and apply administrative LSP tags, if required. See 31.2.17 “Administrative tagging” (p. 1111).

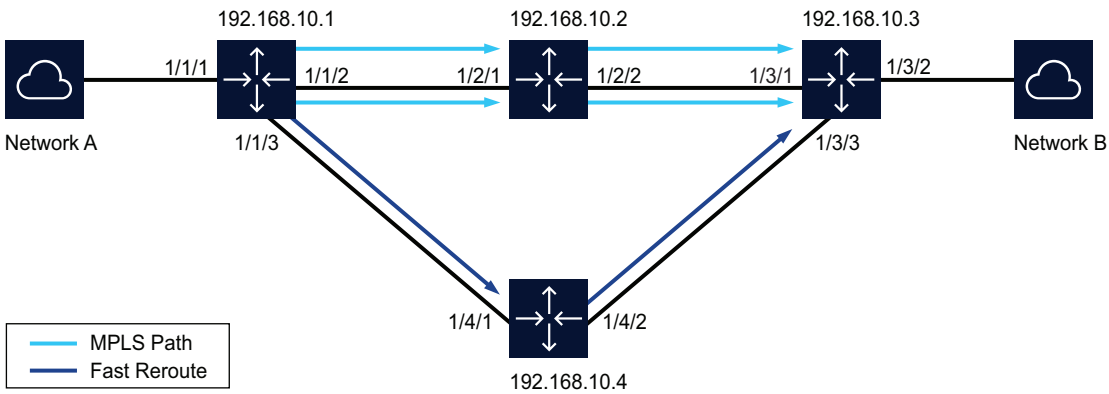
Note: Only Static LSPs and Static FRR LSPs are supported on the OS 9700E and OS 9800E NEs.
RSVP is not supported on the OS 9700E and OS 9800E NEs.
Label actions cannot be modified on NEs after the labels are created by the NFM-P.

31.4 Sample MPLS configuration

31.4.1 Overview

The following figure shows an example of an MPLS service configuration. The actual configuration depends on the specific network requirements.

Figure 31-1 Sample MPLS configuration



31.4.2 Stages

This process describes the high-level tasks that are required to configure the MPLS service example shown in the figure.

Preconfiguration

1

Before you begin, verify that the following preconfigurations have been made.

- An IGP is enabled on all participating NEs and includes the system interface in the IS-IS or OSPF area.
- Any additional Layer 3 interfaces that you wish to use are configured.

Configuration

2

Create an MPLS path.

Use the following steps:

1. Specify 192.168.10.1 as the source network element.
2. Specify 192.168.10.2 and 192.168.10.4 as hops.
3. Specify interface 1/3/2 on 192.168.10.3 as the destination site. This is the final hop in the MPLS path.

3

Create a Dynamic LSP.

Use the following steps:

1. Specify interface 1/1/1 on 192.168.10.1 as the source IP address.
2. Specify 192.168.10.3 as the destination IP address.

4

Bind the Dynamic LSP created in Stage 3 to the MPLS path created Stage 2 .

31.5 To enable MPLS on a routing instance

31.5.1 Steps

1

Choose Routing from the NFM-P navigation tree view selector.

2

Navigate to Routing→NE→Routing Instance.

3

Right-click on the routing instance and choose Properties. The Routing Instance (Edit) form opens.

4

Click on the Protocols tab.

5

Enable the MPLS Enabled parameter. RSVP is enabled by default and cannot be disabled using the NFM-P.

6

Save the changes and close the forms.

END OF STEPS

31.6 To configure an MPLS instance

31.6.1 Steps

1

Enable MPLS on an NE, as described in 31.5 “To enable MPLS on a routing instance” (p. 1115)
.

2

Choose Routing from the NFM-P navigation tree view selector.

3

Navigate to Routing→NE→Routing Instance→MPLS.

4

Right-click on the MPLS object in the navigation tree and choose Properties. The MPLS (Edit) form opens.

5

Configure the Administrative State parameter in the States panel.

6

Configure the required parameters in the Configuration panel.

The Static Label Range parameter affects the range of the Ingress Label parameter on MPLS static hops, MPLS static label maps, and VPLS, IES, and VLL spoke and mesh bindings.

The minimum value you can enter for the Start Segment Routing Label parameter is the value of the Static Label Range parameter, plus 32.

The PCE Report parameter specifies the PCE report types for the MPLS instance and the router-level configuration of reporting of LSPs to the PCE.

Enable the Logger Event Bundling parameter to generate the vRtrMplsXCBundleChange trap.

7

Configure the required parameters in the LSP Resignal panel.

8

Configure the required parameters in the P2MP LSP Resignal panel.

9

Configure the required parameters in the LSP Bypass Resignal panel.

10

Configure the required parameters in the SR-TE LSP Resignal panel.

11

Configure the Hold Timer (seconds) parameter in the Hold Timer panel.

12

Configure the required parameters in the Shared Risk Link Group panel.

13

Configure the required parameters in the Least-Fill panel.

14

Configure the required parameters in the TTL Propagate panel.

15

Configure the required parameters in the Auto Bandwidth Multipliers panel.

16

Configure the CSPF On Loose Hop parameter in the Inter Area/Level Traffic Engineering panel.

17

Configure LSP Self Ping as needed in the LSP Self Ping panel.

18

Configure the required parameters in the RSVP-TE LSP Resignal panel.

19

Configure the RSVP-TE and SR-TE tunnel types values in the Tunnel Table Preference panel.

20

Configure the reserved label block name as needed in the LSP BSID Block panel.

21

Configure LSP History as needed in the LSP History panel.

22

To configure OAM diagnostics for the MPLS instance, click on the Tests tab. See Chapter 90, “OAM diagnostic tests” for more information about how to configure OAM diagnostics.

23

To configure MPLS interfaces on the MPLS instance, click on the Interfaces tab. See 31.7 “To create an MPLS interface” (p. 1120) for more information about how to configure MPLS interfaces.

24

To configure the collection of ingress accounting statistics for the MPLS instance, click on the Accounting tab.

25

To configure the collection of ingress statistics for LSPs, perform the following.

Use the following steps:

1. Click on the LSP tab.
2. Click Create. The IngStatsPolicy, Routing Instance (Create) form opens.
3. Configure the parameters in the LSP Information panel.
4. Select an accounting policy in the Ingress Accounting Statistics panel. Only accounting policies with the CombinedMplsLspIngressStats statistics type are available for selection.
5. Configure the required parameters in the Ingress Accounting Statistics panel.

   Note:

   The collection of egress accounting statistics is configured in 31.11 “To create a Dynamic LSP” (p. 1126) for Dynamic LSPs and 31.18 “To create a Point-to-Multipoint LSP” (p. 1137) for P2MP LSPs.

26

To configure the collection of ingress statistics for LSP templates:

Use the following steps:

1. Click on the LSP Template tab.
2. Click Create. The LSP Template Ingress Stats, Routing Instance (Create) form opens.
3. Configure the required parameters in the LSP Information panel.
4. Select an accounting policy in the Ingress Accounting Statistics panel. Only accounting policies with the CombinedMplsLspIngressStats statistics type are available for selection.
5. Configure the required parameters in the Ingress Accounting Statistics panel.

   Note:

   The collection of egress accounting statistics is configured in 31.29 “To create an LSP template MVPN policy” (p. 1156) .

27

To configure policies for class-based forwarding:

1. Click on the Class Forwarding Policies tab.
2. Click Create. The Class Forwarding Policy (Create) form opens.
3. Configure the required parameters in the General tab.
4. Click OK. The Class Forwarding policy is created.

28

To configure MPLS forwarding policies:

1. Click on the Forwarding Policies tab.
2. Click Create. The Forwarding Policies form opens.
3. Configure the parameters in the General tab as required.
4. Click on the Forwarding Policy tab and click Create. The Forwarding Policies - Forwarding Policy form opens.
5. Configure the parameters in the General tab as required.
6. Click on the Next Hop Group tab and click Create. The Next Hop Group form opens.
7. Configure the parameters in the General tab as required.
8. Click on the Next Hop tab and click Create to configure a primary next hop and, as required, a backup next hop.
9. Click OK and close the Next Hop Group, Forwarding Policy, and Forwarding Policies forms.

29

To view information about the MPLS instance, click on the following tabs:

- In Segments to view the MPLS ingress segment information, such as label assignments
- Cross Connects to view the LSP cross-connection information
- Out Segments to view the MPLS egress segment information, such as label assignments
- Static Label Maps to view static hop mapping information
- Statistics to view MPLS site and interface statistics
- Faults to view alarm information for the MPLS instance

30

Click View RSVP Site to view the associated RSVP instance on the NE.

31

Save the changes and close the forms.

END OF STEPS

31.7 To create an MPLS interface

31.7.1 Purpose

Create an MPLS interface by assigning a network interface to an MPLS instance.

This procedure requires the existence of a numbered or unnumbered L3 network interface on the NE that hosts the MPLS instance. See 27.1 “NE routing and forwarding” (p. 817) for more information about how to configure network interfaces.

31.7.2 Steps

1

Choose Routing from the NFM-P navigation tree view selector.

2

Navigate to Routing→NE→Routing Instance→MPLS.

3

Right-click on the MPLS object and choose Create Interface. The MPLS Interface (Create) form opens.

4

Assign a numbered or unnumbered L3 network interface as the MPLS interface by selecting an interface in the Interface panel.

5

Configure the required general parameters.

6

Configure the required parameters in the TE Metric panel.

7

To create a TP MEP interface:

Use the following steps:

1. Click Create in the TP MEP panel. The TP MEP Interface (Create) form opens.
2. Configure the required parameters.
3. Save the changes and close the form.

8

Click Apply. The form displays additional tabs, and the NFM-P creates the MPLS interface and displays it below the MPLS and RSVP instances in the navigation tree.

9

To configure a Shared Risk Link Group:

Use the following steps:

1. Click on the Shared Risk Link Groups tab.
2. Click Create. The SharedRiskLinkGroup (Path/Routing Management: MPLS) Select form opens.
3. Search and select the required SRLGs and click OK. Up to 64 SRLGs can be associated with a specific MPLS interface. The SharedRiskLinkGroup (Path/Routing Management: MPLS) Select form closes and the selected SRLG is displayed.

10

A static label map is required when there are intervening unmanaged NEs between the managed NEs in an MPLS path. To configure a static label map:

Use the following steps:

1. Click on the Static Label Maps tab.

   Note:

   Nokia recommends that you use a static label mapping only to specify unmanaged NEs.
2. Click Create. The Static Label Map (Create) form opens. Alternatively, you can choose a Static Label Map and click Properties to edit the Static Label Map properties.
3. Configure the Label Action parameter. When you change the Label Action parameter from unspecified to Pop or Swap, the Static Label Map (Create) form changes to include other parameters. Configure the required parameters.

   The Egress Label, Next Hop and Enable Implicit Null Label parameters are only configurable when the Label Action parameter value is set to Swap.

   The Egress Label and Next Hop parameters are configurable only when the Label Action parameter value is set to Swap/Protect-Swap.

   The range of the Ingress Label parameter depends on the parameter value set for the Static Label Range on the MPLS instance. See 31.6 “To configure an MPLS instance” (p. 1116) .

   The NFM-P sets the Label Action parameter value to Pop when the hop destination matches the destination LSP.
4. Save the changes and close the form.

11

To assign MPLS administrative groups to the interface, click on the Administrative Groups tab. After you assign administrative groups to an MPLS interface, the total value of the groups is displayed in a bit mask format by the Groups Included (bitmask) indicator on the General tab.

12

Save the changes and close the forms.

END OF STEPS

31.8 To create an MPLS path

31.8.1 Steps

1

Choose Manage→MPLS→MPLS Paths from the NFM-P main menu. The Manage MPLS Paths form opens.

2

Click Create. The Create MPLS Path form opens with the Name the MPLS Path step displayed.

3

Configure the parameters:

- Name
- Description

4

Click Next. The Define Source Site step is displayed.

5

Perform one of the following to specify an NFM-P-managed NE for the Starting Network Element parameter value.

a. Choose an NE from a list.

Use the following steps:

1. Click Select. The Select a Network Element - Select Source Site form opens.
2. Choose an NE and click OK. The management IP address of the NE is displayed as the source site of the MPLS path.

b. Enter the management IP address of the port.

6

Click Next. The Define the provisioned Path step is displayed.

7

Click Insert Hop to insert an MPLS path hop. The Hop for New MPLS Path (Create) form opens.

8

Configure the Specify Site parameter. Perform one of the following actions.

a. Specify the IP address of an unmanaged NE.

Use the following steps:

1. Choose Manually.
2. Configure the IP Address parameter.

b. Choose a managed NE.

Use the following steps:

1. Choose By Selection.
2. Click Select. The Select a Network Element - New MPLS Path form opens.
3. Choose an NE and click OK. The management IP address of the NE is displayed as the IP Address value.
4. Specify an alternative or loopback (only for Dynamic P2P RSVP LSPs) interface on the NE to be used as the hop point, if required. Otherwise, go to Step 9 .
5. Click IP Address parameter Select. The Select a Virtual Router Interface form opens with a list of the available interfaces.
6. Choose an interface and click OK. The Select a Virtual Router Interface form closes and the Hop for New MPLS Path (Create) form displays the IP Address of the selected loopback interface.

c. Specify the SID of an NE.

Use the following steps:

1. Choose SID Label.
2. Configure the Value parameter.

9

Configure the Hop Type parameter.

10

Click Apply.

11

Insert an additional hop, if required, by repeating Step 8 to Step 10 .

12

Click OK. The Create MPLS Path form reappears.

13

To change the hop sequence, choose a hop and click Move Up or Move Down. The first hop in the list is the first hop, and the last hop becomes the destination site when the form changes are saved.

14

Click Next. The Set Initial State step is displayed.

15

Configure the Administrative parameter.

16

Click Finish to save the configuration. You are prompted to view the MPLS path.

17

Enable the View the newly created MPLS path parameter to view the MPLS path configuration after closing the form, if required.

18

Close the forms.

END OF STEPS

31.9 To view an MPLS path

31.9.1 Steps

1

Choose Manage→MPLS→MPLS Paths from the NFM-P main menu. The Manage MPLS Paths form opens.

2

View the MPLS path information as required.

END OF STEPS

31.10 To create a static LSP

Note: When LSP on-demand resynchronization is enabled, manually resynchronize all of the planned hops in the static LSP before you create a static LSP. This is to ensure that validations on the static LSP can be run properly. See the procedure to enable LSP on-demand resynchronization in the *NSP System Administrator Guide* for more information.

31.10.1 Steps

1

Choose Manage→MPLS→Static LSPs from the NFM-P main menu. The Manage Static LSPs form opens.

2

Click Create. The Static LSP (Create) form opens.

3

Configure the parameters in the Identity panel.

Note: If a range policy is applied to a service tunnel, a grey text box appears beside the Service ID parameter to indicate that a range policy is in effect.
If a format policy is applied to a service tunnel, a drop-down menu appears beside the object field during object creation, to indicate that a format policy is enforced. When there is only one matching policy, the drop-down menu is dimmed. When there are multiple matching policies, the drop-down menu is used to choose a policy. The items in the drop-down menu are ordered by the policy's Priority parameter.

4

Configure the parameters in the Source panel.

The Administrative parameter applies to the source NE only, not to the entire static LSP

5

Select a destination site in the Destination panel.

The Administrative parameter applies to the source NE only, not to the entire static LSP

6

Click Apply.

7

To configure one or more static hops:

Use the following steps:

1. Click on the Static Hops tab.
2. Click Create. The Static Hop (Create) form opens.
3. Configure the Hop Index parameter.
4. Select a site in the Site panel.
5. Select an interface in the Interface panel.
6. Configure the parameters:

   The Egress Label, Enable Implicit Null Label and Next Hop parameters are configurable when the Label Action parameter value is set to Swap.

   The Egress Label and Next Hop parameters are configurable only when the Label Action parameter value is set to Swap/Protect-Swap.

   The range of the Ingress Label parameter depends on the parameter value set for the Static Label Range on the MPLS instance. See 31.6 "To configure an MPLS instance" (p. 1116) .

Note: Static hop configuration performed in CLI is not synced to the NFM-P.

8

Save the changes and close the forms.

END OF STEPS

31.11 To create a Dynamic LSP

31.11.1 Steps

1

Choose Manage→MPLS→Dynamic LSPs from the NFM-P main menu. The Manage Dynamic LSPs form opens.

2

Click Create. The Create Dynamic LSP step form opens with the Identification step displayed.

3

Configure the required parameters.

Note: When a range policy is applied to a Dynamic LSP, a dimmed text field appears beside the Service ID parameter to indicate that a range policy is in effect.
If a format policy is applied to a Dynamic LSP, a drop-down menu appears beside the object field during object creation, to indicate that a format policy is in effect. When there is only one matching policy, the drop-down menu is dimmed. When there are multiple matching policies, the drop-down menu is used to choose a policy. The sequence of the options in the drop-down menu are specified by the policy Priority parameter.

4

Click Next. The Define Source and Destination Sites step is displayed.

5

Specify the source and destination sites for the Dynamic LSP.

Note: You can also manually specify an IP address for each parameter in the step.

Use the following steps:

1. Click on the Source Site ID parameter Select. The Select a Network Element - Create Dynamic LSP form opens with a list of the available sites.
2. Choose a site and click OK. The Select a Network Element - Create Dynamic LSP form closes and the Create Dynamic LSP form displays the source site information, which

includes the system Source IP Address parameter value. The parameter is automatically populated with the system IP address of the site.

Use the following steps:

1. If you are creating a P2P RSVP LSP, you can alternatively configure a loopback interface other than the system interface. Otherwise, go to 4 .
2. Click on the Source IP Address parameter Select. The Select a Virtual Router Interface form opens with a list of the available interfaces.
3. Choose an interface and click OK. The Select a Virtual Router Interface form closes and the Create Dynamic LSP form displays the Source IP Address and Source Interface Name information of the selected loopback interface.
4. Click on the Destination Site ID parameter Select. The Select a Network Element - Create Dynamic LSP form opens with a list of the available sites.
5. Choose a site and click OK. The Select a Network Element - Create Dynamic LSP form closes and the Create Dynamic LSP form displays the destination site information. The default displayed destination interface is the system interface.
6. If you are creating a P2P RSVP LSP, you can alternatively configure a loopback interface other than the system interface as the destination. Otherwise, go to Step 6 .
7. Click on the Destination IP Address parameter Select. The Select a Virtual Router Interface form opens with a list of the available interfaces.
8. Choose an interface and click OK. The Select a Virtual Router Interface form closes and the Create Dynamic LSP form displays the Destination IP Address and Destination Interface Name information of the selected loopback interface.

6

Click Next. The Auto Select Hop-Less MPLS Path step form opens. Configure the required parameters.

The Reserved Bandwidth (Mbps) parameter is configurable when the Auto Select Hop-less Path parameter is enabled.

7

If the Auto Select Hop-less Path parameter is enabled, go to Step 11 .

8

Click Next. The Add MPLS Paths form opens. This step binds the LSP to the MPLS path to create an MPLS path.

Use the following steps:

1. Configure the Path Destination Matching parameter.
2. Click Create. The LSP-Path Binding step form opens with the Choose Path Type step displayed. Configure the Type parameter.

Use the following steps:

1. Click Next. The Choose MPLS Path step is displayed. Choose an MPLS path to associate

with the LSP. You can also create an MPLS path by clicking Create MPLS Path. See 31.8 “To create an MPLS path” (p. 1122) for more information.

2. Click Next. The Set Traffic Options form opens. Configure the required parameters.

   The Path Preference is only configurable on Standby LSP paths (Type parameter set to standby).

3. Click Next. The Set Initial States form opens. Configure the required parameters.
4. Click Finish. The LSP-Path Binding form closes and a dialog box appears.
5. Click OK. The Create Dynamic LSP step form reappears.

9

Click Next. The Properties - Configuration step is displayed. Configure the required parameters.

10

Click Next. The Properties - PCE step is displayed. Configure the required parameters.

11

Click Next. The Properties - Traffic Engineering and Protection step is displayed. Configure the required parameters.

12

Click Next. The Properties - IGP Shortcut step is displayed. Configure the required parameters.

13

Click Next. The Properties - Fast Reroute step is displayed. Configure the required parameters.

14

Click Next. The Properties - Signalling step is displayed. Configure the required parameters.

15

Click Next. The Properties - Administrative Groups step is displayed.

16

Assign one or more MPLS administrative groups to the Dynamic LSP.

Use the following steps:

1. Select the required MPLS administrative groups in the Unassigned list.
2. Click on the right arrow button. The groups are assigned to the Dynamic LSP and moved to the Assigned list.

   After you assign administrative groups to an MPLS interface, the total value of the groups is displayed in a bit mask format by the Groups Included (bitmask) indicator on the General tab.

17

Click Next. The Properties - Class Forwarding step is displayed. Configure the parameters.

18

Click Next. The Properties - BFD step is displayed. Configure the parameters.

19

Click Next. The Properties - Entropy Label Capability step is displayed. Configure the Entropy Label parameter.

20

Click Next. The Add Path Profiles step is displayed. Specify a path profile ID for the LSP. If no path profiles are available for selection, then create a path profile.

21

Click Next. The Set Initial State step is displayed. Configure the Administrative parameter.

22

Click Finish. The NFM-P prompts you to view the Dynamic LSP.

23

Enable the View the newly created Dynamic LSP parameter to view the Dynamic LSP configuration after closing the form, if required.

Note: If you enable the View the newly created Dynamic Lsp parameter you can configure the collection of egress accounting statistics using the Dynamic LSP configuration form.

24

Click Close. The Create Dynamic LSP form closes.

25

If the View the newly created Dynamic LSP parameter is enabled in Step 23 , the Dynamic LSP (Edit) form opens with the newly created Dynamic LSP configuration displayed.

Use the following steps:

1. View the configuration, if required.
2. If you need to enable the collection of egress accounting statistics, go to 3 . Otherwise go to 5 .
3. Click on the Accounting tab.
4. Configure the parameters in the Egress Accounting Statistics panel.
   - Click Select. The Select Accounting Policy - Dynamic LSP form opens. Choose the required accounting policy and click on the OK button. Only accounting policies with the CombinedMplsLspEgressStats statistics type are available for selection.

- Collect Accounting Statistics
- Administrative State
- Statistics Mode. RSVP-TE supports Aggregate mode and Per Flow Control mode, SR and SR-TE supports only Aggregate mode.

Note:

The Ingress Accounting Statistics panel displays a read-only view. If an ingress accounting statistics record exists, you can click Properties to view the record.

The collection of ingress accounting statistics is configured in 31.6 “To configure an MPLS instance” (p. 1116) .

5. Click on OK to close the Dynamic LSP (Edit) form.

26

Click OK to close the Manage Dynamic LSPs form.

END OF STEPS

31.12 To create a segment routing TE LSP

31.12.1 Purpose

This procedure describes how to create and configure a segment routing TE LSP. The steps are provided in linear sequence. However, each step gives you the option to click Back to return to previous steps and review or change your configuration, as required.

31.12.2 Steps

1

Choose Manage→MPLS→Segment Routing LSPs from the NFM-P main menu. The Manage Segment Routing LSPs form opens.

2

Click Create. The Create Segment Routing LSP Wizard opens. Configure the required parameters in the Identification step.

3

Click Next. The Define Source and Destination Sites step is displayed. Configure the required parameters.

4

Click Next. The Auto Select Hop-less MPLS Path step is displayed. Perform one of the following:

a. If you want the NFM-P to automatically create a hopless MPLS path for the LSP, configure the required parameters and then go to step Step 8.

b. If you want to create or choose the MPLS path manually, then do not to select the Auto

Select Hop-less Path option and proceed to the next step.

5

Click Next. The Add MPLS Paths step is displayed. Create an MPLS path to bind to the LSP:

1. Click Create. The LSP-Path Binding Wizard opens.

   The Choose Path Type step does not require configuration. The Primary path type is selected by default and cannot be modified.
2. Click Next. The Choose MPLS Path step opens.
3. Choose an MPLS path for the LSP. If no eligible MPLS path is available, then click Create MPLS Path. See 31.8 “To create an MPLS path” (p. 1122). for details about creating an MPLS path.
4. Click Next. The Set Traffic Options step is displayed. Configure the required parameters.
5. Click Next. The Set Initial State is displayed. Set the Administrative state to Up.
6. Click Finish. You are returned to the Create Segment Routing LSP Wizard.

6

Click Next. The Properties – Configuration step is displayed. Configure the required parameters.

7

Click Next. The Properties – PCE step is displayed. Configure the required parameters.

8

Click Next. The Properties – Traffic Engineering And Protection step is displayed. Configure the required parameters.

9

Click Next. The Properties – IGP Shortcut step is displayed. Configure the required parameters.

10

Click Next. The Properties – Signalling step is displayed. Configure the required parameters.

11

Click Next. The Properties – Administrative Groups step is displayed. Configure the required parameters.

12

Click Next. The Properties – BFD step is displayed. Configure the required parameters. A BFD Template must be specified if BFD is enabled.

13

Click Next. The Add Path Profiles step is displayed. Specify a path profile ID for the LSP. If no path profiles are available for selection, then create a path profile.

14

Click Next. The Pce Associations step is displayed. Create an association for the LSP by providing an Association Type and selecting the configured Diversity or Policy.

15

Click Next. The Set Initial State step opens.

16

Click Finish. The Summary step is displayed, informing you that the segment routing TE LSP has been created and giving you the opportunity to view the configuration of the segment routing TE LSP that you created.

The LSP is created with the Administrative State parameter set to Down. See Step 5 in 31.13 “To configure a Dynamic or segment routing TE LSP” (p. 1131) to change the administrative state.

END OF STEPS

31.13 To configure a Dynamic or segment routing TE LSP

31.13.1 Steps

1

Choose Manage→MPLS→(Dynamic|Segment Routing) LSPs from the NFM-P main menu. The Manage (Dynamic|Segment Routing) LSPs form opens.

2

Click Search. A list of the selected type of LSPs is displayed.

3

Choose an LSP and click Properties. The (Dynamic|Segment Routing) LSP (Edit) form opens.

4

Configure the Description parameter.

5

Configure the Administrative parameter in the States panel.

6

Click on the Accounting tab and select an accounting policy.

7

Configure the parameters on the Properties tab.

8

Click on the OAM tab to view or configure OAM tests.

9

Click on the Statistics tab to view or configure statistics collection.

10

Click on the Tunnels tab. A list of LSP path bindings is displayed. Perform one of the following:

a. Create an LSP path binding.

   Use the following steps:

   1. Click Create. The LSP-Path Binding step form opens and the Choose Path Type step is displayed. The Type parameter is set to secondary if a primary path exists.
   2. Click Next. The Choose MPLS Path step is displayed. Choose an MPLS path to associate with the LSP. You can also create an MPLS path by clicking Create MPLS Path. See 31.8 “To create an MPLS path” (p. 1122) for more information.
   3. Click Next. The Set Traffic Options step is displayed. Configure the required parameters.
   4. Click Next. The Set Initial States step is displayed. Configure the Administrative State parameter.
   5. Click Finish to save your changes and close the form.

b. Configure an existing LSP path binding.

   Use the following steps:

   1. Choose an LSP path binding and click Properties. The LSP-Path Binding (Edit) form opens.
   2. Configure the required parameters.
   3. Select a BFD template in the BFD panel and configure the required parameters.

      The BFD template can be assigned to either the LSP-path or the LSP, but not both.

      When the LSP path is up and operational, the BFD on LSP Sessions tab contains an entry for the head and tail, respectively. When a BFD session is removed or the path is deleted, the BFD sessions are removed. The BFD session shows information about the current BFD session. BFD session information is automatically updated when a change occurs on the NE.
   4. Configure the required parameters on the Administrative Groups tab.

11

Click on the PCE-Associations tab. A list of LSP PCE associations is displayed. Perform one of the following:

a. Create an LSP PCE Association.

   Use the following steps:

   1. Click Create. The MPLS LSP PCE-Association form is displayed.
   2. Select the Association type (Diversity or Policy).
   3. Select the pre-configured Associations from the list.
   4. Save your changes and close the form.

b. Configure an existing LSP PCE Association.

   Use the following steps:

   1. Choose an LSP PCE Association and click Properties. The MPLS LSP PCE-Association (Edit) form opens.
   2. Configure the required parameters.
   3. Save your changes and close the form.

12

Save your changes and close the form.

END OF STEPS

31.14 To create a Dynamic or segment routing LSP from a tunnel template

31.14.1 Purpose

Before you can create an LSP from a tunnel template, you must create the tunnel template. You can use an existing LSP to create a tunnel template.

31.14.2 Steps

1

Choose Manage→MPLS→(Dynamic|Segment Routing) LSPs from the NFM-P main menu. The Manage (Dynamic|Segment Routing) LSPs form opens.

2

Click Create from Template. A Create (Dynamic|Segment Routing) LSP from Template form opens with a list of tunnel templates.

3

Choose a template and click OK. A Create (Dynamic|Segment Routing) LSP from Template form opens.

4

Configure the required parameters.

5

Specify the source sites for the LSP.

1. Select a Source Site ID and click OK.
2. Select a Source IP Address and click OK.

6

Configure the Destination Site ID and the Destination IP Address parameters.

7

Click on the Accounting tab and select an accounting policy.

8

Click OK.

9

Configure the Collect Accounting Statistics and the Administrative State parameters.

10

Click on the Properties tab and configure the required parameters.

Note: The number of parameters that can be configured depends on how the template was created. All of the parameters are configurable when the template is based on an object. A subset of the parameters can be configured when the template is based on an object class.

11

Click OK. The Create (Dynamic|Segment Routing) LSP from Template form closes.

12

When the Show Created Object parameter is enabled on the template, the (Dynamic|Segment Routing) LSP (Edit) form opens. Close the (Dynamic|Segment Routing) LSP (Edit) form.

13

Close the Manage (Dynamic|Segment Routing) LSPs form.

END OF STEPS

31.15 To list Dynamic or segment routing LSPs

31.15.1 Steps

1

Choose Manage→MPLS→(Dynamic|Segment Routing) LSPs from the NFM-P main menu. The Manage Dynamic LSPs form opens.

2

Choose an LSP and click Properties. The (Dynamic|Segment Routing) LSP (Edit) form opens.

3

To view LSP path information:

Use the following steps:

1. Click on the Tunnels tab.
2. Double-click on an LSP path.
3. Review the state information.

   The LSP path information includes whether the bypass tunnel for the LSP is active, or whether the LSP is in a fast reroute state.

END OF STEPS

31.16 To view ping results on a BFD LSP session for a Dynamic LSP

31.16.1 Steps

The ping results are available only if the LSP BFD session has been established.

1

Choose Manage→MPLS→Dynamic LSPs from the NFM-P main menu. The Manage Dynamic LSPs form opens.

2

Choose an LSP and click Properties. The Dynamic LSP (Edit) form opens.

3

Click on the BFD On LSP Sessions tab, select a session with a Link Type of LSP Head and click Properties. The BFD On LSP Session - LSP (View) form opens.

Note: The session ping results are available only for LSP Head BFD sessions.

4

Review the information on the General tab, as required, and click on the Ping Result tab.

5

Click Resync on the Ping Result tab to display the latest ping results.

END OF STEPS

31.17 To run an OAM validation test for a Dynamic or segment routing LSP

31.17.1 Steps

1

Choose Manage→MPLS→(Dynamic|Segment Routing) LSPs from the NFM-P main menu. The Manage (Dynamic|Segment Routing) LSPs form opens.

2

Choose an LSP and click Properties. The (Dynamic|Segment Routing) LSP (Edit) form opens.

3

Click One Time Validation.

4

See 90.55 “To run a one-time validation test on a service” (p. 3084) for more information on using the One Time Validation function and reviewing the test results.

END OF STEPS

31.18 To create a Point-to-Multipoint LSP

31.18.1 Steps

1

Choose Manage→MPLS→Point-to-Multipoint LSPs from the NFM-P main menu. The Manage Point-to-Multipoint LSPs form opens.

2

Click Create. The P2MP LSP (Create) form opens.

3

Configure the required parameters.

When you configure the System ID (Loopback IP Address) parameter, the Management IP Address and Site Name parameters are automatically populated with the values associated with that NE. The IP Address parameter is also automatically populated, however, you can specify a new value for the parameter, if required.

4

Click on the Properties tab.

5

Configure the parameters in the Traffic Engineering and Protection panel.

6

Configure the parameters in the Fast Reroute panel.

The Node Protect parameter is only configurable when the Reserved Bandwidth (Mbps) parameter is set to a value greater than 0.

7

Configure the Make before Break parameter.

8

Configure the parameters in the CSPF panel.

9

Configure the parameters in the Signalling panel.

10

To configure a P2MP primary instance:

Use the following steps:

1. Click on the P2MP Primary Instance tab and click Create. The P2MP Instance (Create) form opens.
2. Configure the required parameters.
3. Click on the Properties tab.
4. Configure the parameters in the Traffic Engineering Properties panel.

   When you enable the Inherit Value parameter, the Hop Limit parameter for the P2MP Instance is set to the same value as you configured for the parent P2MP LSP.
5. Configure the parameters in the Make Before Break panel.

   When you enable the Inherit Value parameter, the Make before Break parameter for the P2MP instance is set to the same value as you configured for the parent P2MP LSP.
6. Configure the parameters in the Administrative Groups panel.

   When you enable the Inherit Value parameters, the Included and/or Excluded Groups for the P2MP instance are set to the same values you configure for the parent P2MP LSP. If you do not enable the Inherit Value parameters, you can configure the Included Groups and Excluded Groups for the P2MP Instance independently from the parent P2MP LSP. See 8 .
7. To create one or more S2L paths click on the S2L Paths tab and click Create. The S2L Path (Create) form opens. Configure the required parameters and save and close the form.

Each S2L path object represents a root-to-leaf (S2L) sub-LSP path for the primary instance of the P2MP LSP.

8. To assign one or more MPLS administrative groups to the P2MP Instance, click on the Administrative Groups tab.
9. Choose the required Included Groups in the Unassigned list and click on the right arrow button. The groups are assigned to the Point-to-Multipoint LSP and moved to the Assigned list.
10. Select the required Excluded Groups in the Unassigned list and click on the right arrow button. The groups are assigned to the Point-to-Multipoint LSP and moved to the Assigned list.

    After you assign the Included and Excluded Groups, the total value of the groups is displayed in a bit mask format by the Groups Included and Groups Excluded indicators on the P2MP Instance Properties tab.
11. Save your changes and close the form.

11

To assign one or more MPLS administrative groups to the P2MP LSP:

Use the following steps:

1. Select the required Included Groups in the Unassigned list and click on the right arrow button. The groups are assigned to the Point-to-Multipoint LSP and move to the Assigned list.
2. Select the required Excluded Groups in the Unassigned list and click on the right arrow button. The groups are assigned to the Point-to-Multipoint LSP and move to the Assigned list.

   After you assign the Included and Excluded Groups, the total value of the groups is displayed in a bit mask format by the Groups Included (bitmap) and Groups Excluded (bitmap) indicators on the P2MP LSP Properties tab.

12

Save your changes and close the forms.

13

To complete the configuration of the Point-to-Multipoint LSP, you must:

a. Configure the required PIM tunnel interfaces. See 27.2 “To configure a routing instance or a VRF instance” (p. 826) .

b. Configure tunnel interfaces on the required IGMP routing instance. See 28.104 “To configure an IGMP site on a router” (p. 1017) .

c. Configure tunnel interfaces on the required multicast info policy. See 52.13 “To configure an ingress multicast information policy” (p. 1720) .

14

After you complete the configuration of the Point-to-Multipoint LSP, you can reopen the P2MP LSP form to create, configure and run OAM diagnostics, or configure accounting statistics collection, if required. To configure OAM diagnostics, go to Step 15 . To configure accounting statistics collection, go to Step 16 .

15

Perform the following to configure OAM diagnostics.

Use the following steps:

1. Click on the Tests tab. The Test Suite, P2MP Ping, and P2MP Trace tabs are displayed.
2. Create or search for the test suite or particular type of test you want to run from the tab pages. Click on either the Create or Search buttons as required.
3. Click Execute to run a selected test.

   See Chapter 89, “Service Test Manager” and Chapter 90, “OAM diagnostic tests” for more information about how to configure OAM diagnostics.

16

Perform the following to configure accounting statistics.

Use the following steps:

1. Click on the Accounting tab.
2. Select an accounting policy.
3. Configure the required parameters.

END OF STEPS

31.19 To view an MVPN Point-to-Multipoint LSP object

31.19.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service, and click Properties. The VPRN Service (Edit) form opens.

3

Expand VPRN Service→Sites→Routing Instance - NE System ID→Routing Instance→Routing Instance: *VPRNinstance*→Protocols→PIM. The PIM Site (Edit) form opens.

4

Click on the MVPN Inclusive Tunnel tab, then on the RSVP tab.

5

Choose an interface from the Inclusive Provider Tunnel PMSIs panel and click Properties. The Inclusive RSVP PMSI Interface (Edit) form opens.

6

Click Properties next to the P2MP LSP ID parameter. The P2MP LSP (View) form opens.

7

Click on the tabs to view information about the MVPN P2MP LSP object.

8

Close the forms.

END OF STEPS

31.20 To create a Manual Bypass LSP

31.20.1 Steps

1

Choose Manage→MPLS→Manual Bypass LSPs from the NFM-P main menu. The Manage Manual Bypass LSPs form appears.

2

Click Create. The Create Bypass-only LSP form opens with the Identification step displayed.

3

Configure the required parameters.

4

Click Next. The Define Source and Destination Sites step is displayed.

5

Specify the source and destination sites for the manual bypass LSP.

Note: You can also manually specify an IP address for the source and destination sites in this step.

Use the following steps:

1. Click on the Source Site ID parameter Select button.

2. Choose a site and click OK. The Create Bypass-only LSP form displays the source site information, which includes the Source IP Address parameter value.

Use the following steps:

1. Click on the Destination Site ID parameter Select button.
2. Choose a site and click OK. The Create Bypass-only LSP form displays the destination site information. The displayed destination interface is the system interface because an LSP can only terminate on a system interface.

6

Click Next. The Auto Select Hop-Less MPLS Path form opens.

7

Configure the Auto Select Hop-Less Path parameter.

8

If the Auto Select Hop-less Path parameter in Step 7 is enabled, go to Step 10 .

9

Click Next. The LSP-Path Binding opens, with the Choose MPLS Path step displayed.

Use the following steps:

1. Choose an MPLS path to associate with the LSP or create one by clicking on the Create MPLS Path button. See 31.8 “To create an MPLS path” (p. 1122) .
2. Click Next. The Set Traffic Options step is displayed.
3. Configure the required parameters.
4. Click Next. The Set Initial States step is displayed.
5. Configure the Administrative parameter.
6. Click Finish. The LSP-Path Binding form closes and a dialog box appears.
7. Click OK. The Create Bypass-only LSP form reappears.

10

Click Next. The Properties step is displayed.

11

Configure required parameters.

12

Click Next. The Admin Groups step is displayed.

13

Assign one or more included and excluded MPLS administrative groups to the bypass-only LSP.

Use the following steps:

1. Choose the required MPLS administrative groups in the Included Groups - Unassigned and Excluded Groups - Unassigned lists.
2. Click on the right arrow button. The groups are assigned to the bypass-only LSP and move to the Assigned list.

   Note:

   When you assign included and excluded administrative groups to an MPLS interface, the assigned groups are displayed in bit mask form by the Groups Included/Excluded (bitmap) indicator.

14

Click Next. The Set Initial State step is displayed.

15

Configure the Administrative parameter.

16

Click on the Finish button. The NFM-P prompts you to view the bypass-only LSP.

17

Enable the View the newly created Bypass Only Lsp parameter, if required.

18

Close the form(s).

END OF STEPS

31.21 To configure a Manual Bypass LSP

31.21.1 Steps

1

Choose Manage→MPLS→Manual Bypass LSPs from the NFM-P main menu. The Manage Manual Bypass LSPs form opens.

2

Choose a Bypass-only LSP and click Properties. The Bypass-only LSP (Edit) form opens.

3

Configure the required parameters.

4

Click on the Properties tab.

5

Configure the required parameters.

6

Save your changes and close the forms.

END OF STEPS

31.22 To configure an LSP path

31.22.1 Purpose

Use this procedure to configure an LSP path. This procedure applies to Dynamic LSPs, SR-TE LSPs, and Manual Bypass LSPs, unless otherwise noted. Dynamic LSPs are used to demonstrate the steps.

31.22.2 Steps

1

Choose Manage→MPLS→Dynamic LSPs from the NFM-P main menu. The Manage Dynamic LSPs form opens.

2

Choose a Dynamic LSP from the list and click Properties. The Dynamic LSP (Edit) form opens.

3

Click on the Tunnels tab. A list of LSP paths is displayed.

4

If you are accessing this form to update the MPLS path for a Dynamic LSP, then go to Step 8 . Otherwise, go to Step 5.

5

Choose an LSP-Path Binding and click Properties. The LSP-Path Binding (Edit) form opens.

6

Configure the required parameters.

7

Replace the existing MPLS path for a primary or secondary LSP with another MPLS path, if required, by proceeding as follows:

Note: You can update the existing MPLS path only for a primary or secondary LSP path that has the Make before Break parameter enabled. The MPLS path you want to use must already exist on the NE, and must not be used by any other LSP paths under the parent LSP.

Use the following steps:

1. Click on the Update MPLS Path button. The Choose MPLS Path form opens and displays the eligible MPLS paths.
2. Choose the required MPLS path and click OK.

   The Choose MPLS Path form closes and the LSP-Path Binding (Edit) form is refreshed with the parameters related to the updated MPLS path selection.
3. Click OK. The LSP-Path Binding (Edit) form closes and the LSP-Path Binding list is refreshed with the updated MPLS path you selected.
4. Go to Step 9 .

8

Choose the MPLS path that you want to use to replace the existing path.

Note: You can update the existing MPLS path only for a primary or secondary LSP path that has the Make before Break parameter enabled. The MPLS path you want to use must already exist on the NE, and must not be used by any other LSP paths under the parent LSP.

Use the following steps:

1. Click on the Update MPLS Path button. The Choose MPLS Path form opens and displays the eligible MPLS paths.
2. Choose the required MPLS path and click OK.

   The Choose MPLS Path form closes and the LSP-Path Binding (Edit) form is refreshed with the parameters related to the updated MPLS path selection.

9

Click the Set as Secondary or Set as Standby button for a selected LSP-Path Binding to change its Type to one of these choices, if required.

10

Click the Switch Standby to Standby button for a selected LSP-Path Binding if you need to switch from the current active standby LSP path to another standby LSP path. This applies only to Dynamic LSPs.

The button choices include:

- Switch: This option allows you to switch manually from an active standby path to another inactive standby path. You can do this as often as required, without having to select Clear first.
- Force Switch: This option is essentially the same as the Switch option, but you cannot switch back unless you first press Clear to remove the Force Switch flag.
- Clear: This option is used to clear the Force Switch flag.

11

Click on the Administrative Groups tab.

12

Assign an MPLS administrative group to the Dynamic LSP.

Use the following steps:

1. Choose an MPLS administrative group in the Unassigned list.
2. Click on the right arrow button. The group is assigned to the Dynamic LSP and moves to the Assigned list.

   After you assign administrative groups to an MPLS interface, the total value of the assigned groups is displayed in a bit mask format by the Groups Included indicator on the General tab.

13

Click on the General Tab and in the Shared Risk Link Group panel, configure the Enable SRLG for FRR or Enable SRLG parameter, if available and required.

14

Click on the Tests tab to configure OAM diagnostics for the LSP path, if required. The supported test type tabs appear. See Chapter 90, “OAM diagnostic tests” for more information about how to configure OAM diagnostics.

15

View path hops information on the following tabs, as available and required:

- Provisioned Path
- Actual Path
- CSPF Path

16

Save your changes and close the forms.

END OF STEPS

31.23 To create an LSP path using a tunnel template

31.23.1 Purpose

Before you can create an LSP path from a tunnel template, you must create the tunnel template. You can use an existing LSP path to create a tunnel template.

31.23.2 Steps

1

Choose Manage→MPLS→Dynamic LSPs from the NFM-P main menu. The Manage Dynamic LSPs form opens.

2

Click on the Create from Template button. The Create Dynamic LSP from Template list form opens displaying previously created templates.

3

Choose an LSP template. The template must be one where you associated a child LSP Path template to the parent LSP template.

4

Click OK. The Create Dynamic LSP from Template form opens. See 31.14 “To create a Dynamic or segment routing LSP from a tunnel template” (p. 1134) for information about creating a Dynamic LSP from a template.

5

Click OK and perform one of the following:

a. If the Show Created Object parameter is enabled on the template, the Dynamic LSP (Edit) form opens. Go to Step 6 .

b. Open the Dynamic LSPs (Edit) form.

Use the following steps:

1. Choose Manage→MPLS→Dynamic LSPs from the NFM-P main menu. The Manage Dynamic LSPs form opens.
2. Select the Dynamic LSP that you created in Step 4 and click Properties. The Dynamic LSP (Edit) form opens.

6

Click on the LSP-Path Bindings tab.

7

Click on the Create from Template button. A pop-up menu appears with a selection of LSP path templates.

8

Click on the template you require for the LSP path.

9

Configure the required parameters.

10

Click on the Inheritance tab.

11

Configure the Overridden Properties parameter.

12

Save your changes and close the forms.

END OF STEPS

31.24 To configure an LSP Path optimization policy

31.24.1 Purpose

An LSP Path optimization policy allows you to filter LSP Path candidates and set the execution rules to determine the candidacy and priority of an LSP Path for re-signaling. You can define LSP Paths that are eligible for re-signaling and if a path is selected, the LSP Path is added to a candidate list. Execution rules determine the sequence in which the LSP Paths can re-signal and the number of seconds between re-signaling. Execution rules apply to the entire candidate list. Each time that optimization starts, the candidate list is filtered according to the candidate definition values and then resequenced according to the sequencing target and order values.

To ensure that NEs are not overloaded by LSP re-signaling, an LSP Path optimization schedule can be created to identify when re-signaling can be evaluated and executed. You can also manually execute LSP Path optimization schedules. To avoid network congestion and maintain QoS standards, only one policy should be executed at a time. Repetitive re-signaling requests are ignored, including manual or scheduled re-signaling requests. However, a re-signaling request that

is initiated from the LSP Path binding properties form executes regardless of whether another LSP optimization policy is in progress.

The NEs notify the NFM-P about the current state and outcome of LSP Path re-signaling. You can access the LSP Path property form to view information about the state of LSP Path optimization. The following parameters are displayed:

- The Resignal Eligible parameter indicates whether an LSP Path is eligible for optimization. When the parameter value is true, the LSP Path can be optimized. When the parameter value is false, the LSP Path is not eligible for optimization.
- The Last Performed Type parameter indicates how re-signaling was performed. Typically the value is Manual Resignal. However, if a schedule was set, the value is Timer Based Resignal.
- The Last Performed parameter indicates the last time the LSP Path was chosen to be re-signaled.
- The Last Performed State parameter indicates the re-signal state of a specific LSP Path.

31.24.2 Steps

1

Choose Manage→MPLS→LSP Path Optimization from the NFM-P main menu. The Manage LSP Path Optimization form opens.

2

Choose LSP Path Optimization Policy (Path/Routing Management: MPLS).

3

Click Create and choose Optimization Policy.

The LSP Path Optimization Policy (Create) form opens with the General tab displayed.

4

Configure the required parameters.

5

Click on the Candidate Definition tab to apply filters to define eligible LSP Paths for optimization. If no filters are applied, then all eligible LSP Paths will be listed in the Execution Candidates form. Perform one of the following for LSP Path Filters and/or Dynamic LSP Filters.

a. Select an existing filter:

Use the following steps:

1. Click on Select beside the Filter Name parameter. A list of filters is displayed.
2. Choose a filter and click OK. The list closes and the Filter Name field is populated with your selection.

b. Create a new filter:

Use the following steps:

1. Click on Select beside the Filter Name parameter. A list of filters is displayed.
2. Click Create. The Create LSP Path/Dynamic LSP Filter forms opens.
3. Choose an Attribute and assign an associated Function and Value to it.
4. Click Add. The Attribute and its Function and Value appear in the Filter field. This is the first portion of the string that will be used to filter the execution candidates.
5. Add to the filter string by selecting an operator from the Operators drop-down menu, and then define a subsequent Attribute and its associated Function and Value.
6. Click Add. The Operator and subsequent Attribute (and its associated Function and Value) are added to the filter string in the Filter field.
7. Continue to build the filter string by repeating 5 and 6 , as required.
8. Click Save. The Save Filter dialog box appears.
9. Configure the parameters and click Save.
10. Close the Create Filter form. The newly-created filter appears in the filter selection list.
11. Select the newly-created filter and click OK. The list closes and the Filter Name field is populated with your selection.

6

To further limit the number LSP Paths that will be listed in the Execution Candidate form, define a Rule-Based Group to add only those NEs that contain the LSP Paths that you need include. Perform one of the following:

a. Select an existing group.

Use the following steps:

1. Click on Select beside the Group Name parameter. The Select Rule-Based Group form is displayed.
2. Choose a rule-based group and click OK. The list closes and the Group Name field is populated with your selection.
3. Go to Step 7 .

b. Create a new group.

Use the following steps:

1. Click on Select beside the Group Name parameter. The Select Rule-Based Group form is displayed.
2. Click Create. The Rule-Based NE Group (Create) forms opens with the General tab displayed.
3. Configure the parameters and click Apply.
4. Click the Group Members tab and click Create. The Select Network Elements list is displayed.
5. Choose the required NEs and click OK. The list closes and the selected NEs are listed in the Group Members tab.

Note:

If you configured the Order parameter on the General tab in 3 as Ordered Group, then you can only select one NE at a time. When you click OK, the selected NE will appear in the list. To add the next NE in the order, click Create again, choose another NE, then click OK. Repeat as required.

6. Click OK to save your configuration and close the Rule-Based NE Group (Create) form. The newly-created group appears in the Select Rule-Based Group form.
7. Select the new group and click OK. The list closes and the Group Name field is populated with your selection.

7

Click on the Execution Rules tab.

8

Configure the parameters and click on the Apply button. The form displays with schedule information.

Note: The Schedule Optimization button does not appear during LSP path optimization policy creation. The LSP path optimization policy must be created first before a schedule can be applied. You must click on the Apply button.
After a schedule is applied to a LSP Optimization Policy, you cannot make changes to the schedule from the Optimization Scheduled Task form.

9

Click on the Schedule Optimization button. An Optimization Scheduled Task (Create) form opens.

10

Configure the parameters.

11

Click on the Select button beside the ID parameter. A Select Schedule - Optimization Scheduled Task form opens.

12

Perform one of the following:

a. Choose an existing schedule.

b. Click Create to create a schedule. The NFM-P Schedule (Create) form opens. See 5.6 “To configure an NFM-P-based schedule” (p. 193) for information on creating a schedule.

13

Click on the OK button. The Optimization Scheduled Task form displays schedule and optimization information.

14

Click on the OK button. The Select Schedule - Optimization Scheduled Task form closes and the LSP Path Optimization Policy form reappears.

15

Click on the Execution Candidates tab.

16

Click on the Search button to display only the eligible LSP Paths that were filtered in Step 5 and Step 6 . If a filter was not applied, all eligible LSP Paths are listed.

17

Click on the Optimize button. To view the results of optimization, see 31.26 “To view LSP Path optimization policy results” (p. 1153) .

18

Close the form.

END OF STEPS

31.25 To terminate an LSP Path optimization policy that is in progress

31.25.1 Steps

1

Choose Manage→MPLS→LSP Path Optimization from the NFM-P main menu. The Manage LSP Path Optimization form opens.

2

Choose LSP Path Optimization Policy (Path/Routing Management: MPLS).

3

Create a filter to search for optimization policies that are in progress.

Use the following steps:

1. Click the Filter icon. The Manage LSP Path Optimization - Filter form opens.
2. Select General→Optimization from the Attributes drop-down menu.
3. Set the Function to EQUALS and the Value to In Progress, then click the Add button.
4. Click Apply and then Close. The Manage LSP Path Optimization - Filter form closes and the filter is applied to the Search list.

4

Choose the required LSP Path optimization policy and click Properties. The LSP Path Optimization Policy (Edit) form opens.

5

Click on the Stop Current Optimization button. The Optimization parameter value changes from In Progress to Not In Progress.

6

Close the form.

END OF STEPS

31.26 To view LSP Path optimization policy results

31.26.1 Purpose

Use the following procedure to view the re-signaling information as a result of the LSP Path optimization policy execution. See 31.24 “To configure an LSP Path optimization policy” (p. 1148) for information on configuring an LSP Path optimization policy.

31.26.2 Steps

1

Choose Manage→MLPS→LSP Path Optimization from the NFM-P main menu. The Manage LSP Path Optimization form opens.

2

Select LSP Path (Path/Routing Management MPLS) and click Search. A list of LSP Paths appears.

3

Choose the LSP Path on which you executed an LSP optimization policy and click Properties. The LSP-Path Binding (Edit) form opens.

4

View the following parameters, as described in 31.24 “To configure an LSP Path optimization policy” (p. 1148) :

- Resignal Eligible
- Last Performed Type
- Last Performed
- Last Performed State

5

Close the forms.

END OF STEPS

31.27 To view detour and bypass path information

31.27.1 Purpose

Perform this procedure to view information regarding detour and bypass tunnel paths and their protected LSPs. Detour and bypass paths are typically configured for fast-reroute-enabled LSPs on NEs for service protection against NE or link failure. The RSVP protocol is used to detect an NE or link loss.

Note: This procedure only applies to Dynamic LSPs.

Detours are employed in One-to-One backup configurations. A separate backup LSP is established for each LSP that is backed up.

Bypass Tunnels are employed in Many-to-One backup configurations in which a single backup LSP is used to back up multiple original LSPs.

Whether a path is a detour or bypass path is determined by the Backup Type parameter value specified during LSP creation. The Backup Type parameter can be set only when the Fast Reroute parameter for the LSP is set to true.

31.27.2 Steps

1

Choose Manage→MPLS→Dynamic LSPs. The Manage Dynamic LSPs form opens.

2

Select the required Dynamic LSP and click Properties. The Dynamic LSP (Edit) form opens.

3

Click on the RSVP Sessions tab. The detour or bypass originating, transiting, and terminating RSVP sessions associated with the LSP are listed. Type, site, next and previous hop, and other related information is available.

Note: The SRLG Disjoint FRR Properties and SRLG Not Strict FRR Properties indicators apply to primary LSP sessions only, and not to bypass LSP sessions.

4

Select the desired RSVP session of type detour or bypass and click Properties. The Session (View) form opens.

5

To view the Protected LSPs for the specific bypass or detour.

Use the following steps:

1. Click on the Protected LSP Paths tab. All the protected LSPs for a specific bypass or detour tunnel are listed.
2. Use the scroll bar at the bottom of the list frame to view the available information on the Protected LSPs.

6

To view the Detour or Bypass Tunnel Paths for the detour or bypass tunnel.

Use the following steps:

1. Click on the Detour/Bypass Tunnel Path tab. Information regarding the detour or bypass paths is displayed. Sufficient information is provided to permit tracing a path from its originating site, through its transit hops, and to its termination site.
2. Use the scroll bar at the bottom of the list frame to view the available information on the paths.

7

To view additional specific Detour or Bypass information, perform the following steps, as appropriate:

a. For a selected detour session, click on the Detour tab. The Detour Session ID, Detour PLR ID, and Avoided Downstream Site ID are listed.

b. For a selected bypass session, click on the Bypass Tunnel tab. The Bypass Tunnel's current State is displayed.

Note: For the NFM-P to accurately gather the information about the detour and bypass tunnel path (and the LSPs protected by a detour or a bypass tunnel), the NFM-P must be managing all routers participating in the LSP fast reroute. This is required by NFM-P for all SR and 7705 SAR network elements along the primary path of a fast reroute-enabled LSP.

8

Close the forms.

END OF STEPS

31.28 To view exclude route object information

31.28.1 Purpose

Perform this procedure to view the address of the NE to be avoided as signaled in the EXCLUDE_ ROUTE object.

Note: This procedure only applies to Dynamic LSPs.

31.28.2 Steps

1

Choose Manage→MPLS→Dynamic LSPs from the NFM-P main menu. The Manage Dynamic LSPs form opens.

2

Select the required Dynamic LSP and click Properties. The Dynamic LSP (Edit) form opens.

3

Click on the RSVP Sessions tab.

4

Select the desired RSVP session and click Properties. The Session (View) form opens.

5

View the Exclude Node IP Address property. If no EXCLUDE_ROUTE object is signaled, the address is 0.0.0.0.

6

Close the forms.

END OF STEPS

31.29 To create an LSP template MVPN policy

31.29.1 Purpose

This procedure defines the template used to create LSPs across a multicast VPN. The LSP template MVPN policy can be configured locally on a specific NE or globally across the network.

The following can be created:

- P2MP
- one-hop P2P
- mesh P2P
- one-hop P2P SR TE
- mesh P2P SR TE
- OnDemand P2P SR TE

If you need to use entropy labels, the type must be One-Hop P2P LSP or Mesh P2P LSP.

31.29.2 Steps

1

Choose Policies→MPLS→LSP Template MVPN from the NFM-P main menu. The LSP Template MVPN Policies form opens.

2

Perform one of the following:

a. Configure the Policy scope parameter to Global.

b. Configure the Policy scope parameter to Local and click on the Select button to choose a device.

3

Click Create. The LSP Template MVPN Policy (Create) form opens.

4

Configure the parameters.

5

Click on the Properties tab.

Note: The panels and parameters that appear in the Properties tab can vary based on configuration.

6

Configure the required parameters.

7

Click on the PCE-Associations tab. A list of LSP Template PCE associations is displayed. Perform one of the following:

a. Create an LSP Template PCE Association.

Use the following steps:

1. Click Create. The MPLS LSP Template PCE-Association form is displayed.
2. Select the Association type (Diversity or Policy).
3. Select the pre-configured Associations from the list.
4. Save your changes and close the form.

b. Configure an existing LSP Template PCE Association.

Use the following steps:

1. Choose an LSP Template PCE Association and click Properties. The MPLS LSP Template PCE-Association (Edit) form opens.

2. Configure the required parameters.
3. Save your changes and close the form.

8

Click on the Accounting tab.

9

Configure the parameters.

10

Click on the Administrative Groups tab.

11

Assign one or more MPLS administrative groups to the LSP template MVPN policy.

Use the following steps:

1. Choose the required Included Groups in the Unassigned list.
2. Click on the right arrow button. The groups are assigned to the LSP and moved to the Assigned list for inclusion.
3. Choose the required Excluded Groups in the Unassigned list.
4. Click on the right arrow button. The groups are assigned to the LSP and moved to the Assigned list for exclusion.

   After you assign the Included and Excluded Groups, the total value of the groups is displayed in a bit mask format by the Groups Included and Groups Excluded indicators on the LSP Template MVPN Policy Properties tab.

12

Click OK to apply the changes. The LSP Template MVPN Policy, Global Policy (Create) form closes and the LSP Template MVPN Policies form reappears with the LSP MVPN template displayed.

13

Re-select the LSP MVPN template and click Properties. The LSP Template MVPN Policy - Global Policy (Edit) form opens.

14

Click on the Switch Mode button to distribute the policy locally to devices. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

Note: The MVPN LSP template cannot be used until you choose a default MPLS path and configure the Administrative parameter in a local policy definition after the global policy is distributed. After the changes are applied to the local policy, the policy can be switched back to Sync With Global mode and the local changes are saved.

15

Click on the Local Definitions tab.

16

Select an LSP MVPN template and click Properties. The LSP Template MVPN Policy, Local Policy (Edit) form opens.

17

Click on the Switch Mode button to change the configuration mode to Local Edit Only.

18

Click on the Properties tab.

19

Click on the Select button to choose a default MPLS path. The Select Default MPLS Path - Lsp MVPN Template, Local Policy form opens with a list of default MPLS paths displayed.

20

Choose an MPLS path and click OK. The default MPLS path is displayed.

21

Click on the General tab.

22

Configure the Administrative parameter.

23

Save your changes and close the form.

END OF STEPS

31.30 To view LSP templates for MVPN created using CLI

31.30.1 Purpose

Perform this procedure to view read-only LSP templates created using CLI.

Note: You cannot modify the local or global definitions of these template types using the NFM-P.

You cannot distribute these template types to other NEs using the NFM-P.

See the specific device documentation for information on how to create a One-hop P2P LSP, Mesh P2P LSP, or SR TE template.

31.30.2 Steps

1

Choose Policies→MPLS→LSP Template MVPN from the NFM-P main menu. The LSP Template MVPN Policies form opens.

2

Perform one of the following:

a. Configure the Policy scope parameter to Global.

b. Configure the Policy scope parameter to Local and click on the Select button to choose a device.

3

Choose one of the following from the Type column drop-down menu:

- One-Hop P2P LSP
- Mesh P2P LSP
- Segment Routing

4

Click on the Search button. A list of Lsp MVPN Templates is displayed.

5

Select the LSP MVPN template and click Properties. The LSP Template MVPN Policy (Edit) form opens.

6

Click on the various tabs to view information about the LSP template.

7

Close the forms.

END OF STEPS

31.31 To view LSPs created by One-hop P2P and Mesh P2P templates

31.31.1 Purpose

Dynamic LSPs are automatically created when you use CLI to create and distribute a One-hop P2P, Mesh P2P, or SR TE LSP template, and then associate the LSP template with an auto-LSP. Perform the following procedure to view the LSPs that are automatically created by the templates.

Note: The dynamically-created LSPs cannot be associated with SDPs, and are not listed when you are creating an SDP.

31.31.2 Steps

1

Choose Manage→MPLS→Dynamic LSPs from the NFM-P main menu. The Manage Dynamic LSPs form opens.

2

Choose one of the following from the Type column drop-down menu.

- One-Hop Point-To-Point
- Mesh Point-To-Point
- Segment Routing

3

Click on Search to display a list of Dynamic LSPs.

4

Select an LSP and click Properties. The properties form for the object appears.

5

View the information on the various tabs, as required.

6

Close the forms.

END OF STEPS

31.32 To list and view MPLS objects

31.32.1 Steps

1

Choose Manage→MPLS→MPLS Objects from the NFM-P main menu. The Manage MPLS Objects form opens.

2

Select an MPLS Object Type and click on Search. A list of those MPLS objects is displayed.

3

Select an object and click Properties. The properties form for the object appears.

4

View the information on the various tabs, as required.

5

Close the forms.

End of steps

31.33 To create an administrative LSP tag

31.33.1 Steps

1

Choose Policies→Routing→Admin Tags from the NFM-P main menu. The Routing Policy - Admin Tags management form opens.

2

Click Create. The Admin Tag (Create) form opens.

3

Configure the tag name.

4

Click OK and confirm to save the form. The new administrative tag appears in the list. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

End of steps

31.34 To create an administrative tag policy

31.34.1 Steps

1

Choose Policies→Routing→Admin Tag Policy from the NFM-P main menu. The Routing Policy - Admin Tag Policy management form opens.

2

Click Create. The Admin Tag Policy (Create) form opens.

3

Configure the general parameters.

4

In the Included Admin Tags panel, click on the Create button and select one or more administrative tags from the list that appears, then click OK. LSPs with the selected tags will be used for auto-binding at sites using this policy.

5

In the Excluded Admin Tags panel, click on the Create button and select one or more administrative tags from the list that appears, then click OK. LSPs with the selected tags will be rejected for auto-binding at sites using this policy.

6

Click OK and confirm to save the form. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

END OF STEPS

31.35 To create a reserved label block

31.35.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→MPLS. Right-click on a routing instance or MPLS object in the navigation tree and choose Properties. The MPLS (Edit) form opens.

2

Click on the Reserved Label Block tab.

3

Click Create. The Reserved Label Block form opens.

4

In the General tab, configure a name for the label block and the reserved label range.

5

Click OK and confirm to close the forms.

END OF STEPS

31.36 Workflow to collect segment routing TE LSP rate PM statistics

31.36.1 Stages

1

Create an accounting policy for the rate statistics. See *NSP NFM-P Statistics Management Guide* for more information.

Note: Configure the Type parameter of the policy to Combined MPLS SRTE Egress and set the Log To File Type to "No File".

2

Configure a segment routing LSP. See 31.13 “To configure a Dynamic or segment routing TE LSP” (p. 1132) for more information.

- Associate the accounting policy created in Stage 1 under Accounting tab.
- In Statistics tab, select MPLS LSP Egress Stats (Path/Routing Management MPLS) as the Object Type.

Note: The rate statistics are available as MIB-based accounting statistics.

To maintain accuracy and to avoid duplicate records, it is recommended to have the collection interval and the polling interval synchronised.

32 MPLS-TP

MPLS-TP overview

32.1 MPLS-TP overview

32.1.1 Overview

MPLS-TP is a set of MPLS protocol functions that enables the use of MPLS in transport networks and applications. MPLS-TP provides in-band proactive OAM and protection mechanisms that do not rely on a control plane, such as RSVP-TE, to operate. MPLS-TP enables MPLS to be deployed in a statically configured transport network without the need for a dynamic control plane.

Supporting NEs have two primary roles in an MPLS-TP network:

- as a gateway PE between IP/MPLS and MPLS-TP domains
- as an LSR or LER for MPLS-TP LSPs

The NFM-P can configure LSR NEs even when LERs are not configured, or when the LERs or LSRs are not supporting NEs. See the specific NE documentation for more information about MPLS-TP.

The NFM-P provides simple provisioning for MPLS-TP management in a transport network. MPLS-TP relies on static configuration, rather than a control plane, to ensure end-to-end path configuration and consistency. The NFM-P support of MPLS-TP includes:

- bidirectional co-routed MPLS-TP LSPs and PWs
- MPLS-TP identifiers for NEs, LSPs, and PWs
- linear protection for MPLS-TP LSPs with working and protection paths for each LSP
- OAM and protection with both IP and non-IP encapsulation
- proactive CC/V for MPLS-TP LSPs using BFD
- on-demand CV for MPLS-TP LSPs and PWs using LSP ping and trace and VCCV ping and trace diagnostics
- static PW status signaling, with support for PW redundancy, MC-LAG, MC-APS, BGP multi-homing and active and standby dual-homing into IES, VPRN, or VPLS
- stitching of static MPLS-TP PWs to T-LDP dynamically signaled PWs (LDP, RSVP, and BGP) on Epipe, Apipe, and Cpipe VLL switching sites

32.1.2 Proactive OAM templates

A proactive continuity check detects a loss of continuity defect between two MEPs in a MEG. Proactive connectivity verification detects an unexpected connectivity defect between two MEPs, and unexpected connectivity within the MEG with an unexpected MEP. The NFM-P implements both tests with a proactive OAM template.

Proactive OAM templates are based on BFD. BFD packets are sent using configurable timers. Continuity check packets contain a BFD control packet, while connectivity verification packets also

include an identifier for the source MEP. The destination MEP can detect a connectivity defect if it is receiving packets from an incorrect peer MEP. When a defect is detected, the NFM-P generates an alarm.

32.1.3 MPLS-TP LSP provisioning

The NFM-P significantly simplifies the provisioning process of bidirectional MPLS-TP LSPs, where using CLI can be cumbersome and prone to error. Using the NFM-P, all of the components of an end-to-end bidirectional MPLS-TP LSP are automatically configured. Using CLI, all of the components of a bidirectional MPLS-TP LSP, including interfaces and labels, must be configured. The NFM-P automatically creates opposite interfaces based on the physical links between NEs, and assigns in and out labels across all of the interfaces. However, if a physical link does not exist between NEs, the NFM-P cannot auto-create the interfaces. The NFM-P prompts you to manually create the interfaces.

Consider the following when you create a bidirectional MPLS-TP LSP using NFM-P simplified provisioning:

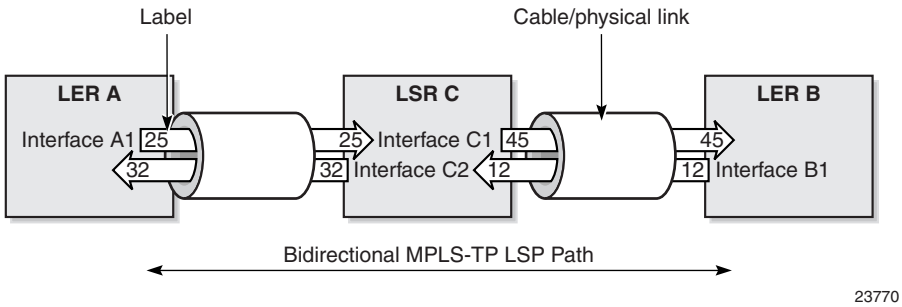
- the NEs must be NFM-P-managed
- MPLS-TP tunnels that are created on the NEs using CLI are discovered by the NFM-P

  Note:

  The NFM-P does not create the bidirectional MPLS-TP LSP when all of the MPLS-TP LSP endpoints (LERs) are not managed by the NFM-P. However, cross-connections (on LSRs) appear in the NFM-P database if the LSRs are managed.

In the example in the following figure, you configure the LER A and LER B using the NFM-P. For the bidirectional MPLS-TP LSP path, you identify the hops by specifying the interfaces. In this example, the interfaces are A1 on LER A and C1 on LSR C. Since MPLS-TP is co-routed, the other interfaces (B1 and C2) are determined by the NFM-P based on the link between the two NEs. The NFM-P automatically chooses all of the labels, in both directions, based on the available labels on the two adjacent NEs. The NFM-P also creates the LSR C object. You must configure proactive OAM on LER NEs.

Figure 32-1 Sample bidirectional MPLS-TP LSP



MPLS-TP workflow and procedures

32.2 Workflow to configure MPLS-TP

32.2.1 Stages

1

Enable MPLS-TP on the routing instances of all NEs that are to participate in the MPLS-TP network; see 32.3 “To enable MPLS-TP on a routing instance” (p. 1168) .

2

Create a BFD template policy; see 28.25 “To configure a BFD template policy” (p. 911) .

3

Configure MPLS-TP on the routing instance; see 32.4 “To configure MPLS-TP on a routing instance” (p. 1169) .

4

Perform one of the following, as required:

a. Create a mesh of MPLS-TP LSPs or an MPLS-TP LSR cross-connect path; see 32.5 “To create an MPLS-TP LSP” (p. 1170) or 32.6 “To create an MPLS-TP LSR cross-connect path” (p. 1171) .

b. Create a bidirectional MPLS-TP LSP using simplified provisioning; see 32.7 “To create a bidirectional MPLS-TP LSP” (p. 1173) .

5

Create a IP/MPLS service tunnel, if required, and enable MPLS-TP; see 33.9 “To create an IP/MPLS service tunnel” (p. 1190) .

6

Create a spoke SDP binding using an MPLS-TP service tunnel on the following, if required:

- VLL service; see 76.34 “To configure a spoke SDP binding on a VLL site” (p. 2161) and 76.35 “To configure a spoke SDP binding with an L2TPv3 tunnel on a VLL Epipe site” (p. 2165)
- VPLS or MVPLS service; see 77.92 “To create a VPLS or MVPLS spoke SDP binding” (p. 2386)
- IES; see 78.10 “To create an L2 SDP spoke termination on an IES service” (p. 2437)
- VPRN service; see 79.69 “To create an L2 SDP spoke termination on a VPRN service” (p. 2638)
- mirror service; see 93.6 “To create a source site on a mirror service” (p. 3169)

7

Configure static MPLS-TP pseudowires on the following, if required:

- VLL service; see 76.15 “To configure an MPLS-TP static pseudowire on a VLL spoke SDP binding” (p. 2136)
- VPLS service; see 77.93 “To configure an MPLS-TP static pseudowire on a VPLS spoke SDP binding” (p. 2392)
- IES; see 78.11 “To configure an MPLS-TP static pseudowire on an IES spoke SDP binding” (p. 2440)
- VPRN service; see 79.70 “To configure an MPLS-TP static pseudowire on a VPRN spoke SDP binding” (p. 2641)
- mirror service; see 93.8 “To configure an MPLS-TP static pseudowire on a mirror SDP binding” (p. 3172)

8

Perform the following OAM diagnostic tests on MPLS-TP objects, if required:

- VCCV ping OAM diagnostic test; see 90.8 “To create and run a VCCV ping OAM diagnostic test from the STM” (p. 3008)
- VCCV trace OAM diagnostic test; see 90.10 “To create and run a VCCV trace OAM diagnostic from a static PW to a dynamic PW segment from the STM” (p. 3010)
- MPLS-TP LSP ping OAM diagnostic test; see 90.25 “To create and run a MPLS LSP ping OAM diagnostic test from the STM” (p. 3030)
- MPLS-TP LSP trace OAM diagnostic test; see 90.26 “To create and run a MPLS LSP trace OAM diagnostic test from the STM” (p. 3031)

32.3 To enable MPLS-TP on a routing instance

32.3.1 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance.

2

Right-click on a routing instance icon and choose Properties.

3

Click on the Protocols tab and enable the MPLS Enabled and MPLS-TP Enabled parameters.

4

Save your changes and close the form. The MPLS-TP icon appears in the navigation tree below the routing instance.

END OF STEPS

32.4 To configure MPLS-TP on a routing instance

32.4.1 Purpose

Use the following procedure to configure MPLS-TP on a routing instance. Ensure that you enable MPLS-TP on all NEs that are participating in the MPLS-TP network, as described in 32.3 “To enable MPLS-TP on a routing instance” (p. 1168) .

32.4.2 Steps

1

In the navigation tree Routing view, expand Network→*NE*→Routing Instance→MPLS-TP.

2

Right-click on a MPLS-TP icon and choose Properties. The MPLS-TP, Routing Instance (Edit) form opens.

3

Configure the required parameters

The Global ID and Node ID parameters are identifiers of an MPLS-TP site on the NE. The TP-LSP ID Minimum and TP-LSP ID Maximum parameters reserve a range of IDs that you use for MPLS-TP LSPs.

4

Configure the Administrative State parameter in the States panel.

Configure a proactive OAM template

5

Right-click on a MPLS-TP icon and choose Properties. The MPLS-TP, Routing Instance (Edit) form opens.

Perform the following steps:

1. Configure the required parameters.
2. Click Select in the BFD Template panel and click Search. A list of configured BFD template policies appears. See 28.25 “To configure a BFD template policy” (p. 911) for information about how to create a BFD template policy.
3. Choose a BFD template policy and click OK. The Proactive OAM Template (Create) form refreshes with the BFD template information.
4. Save your changes and close the form. The MPLS-TP, Routing Instance (Edit) form reappears.

Configure a protection template

6

Click on the Protection Template tab and click Create.The Protection Template, Routing Instance (Create) form opens.

Perform the following steps:

1. Configure the required parameters.
2. Save your changes and close the form. The MPLS-TP, Routing Instance (Edit) form reappears.

7

Save your changes and close the form.

END OF STEPS

32.5 To create an MPLS-TP LSP

32.5.1 Purpose

Use the procedure to create an MPLS-TP LSP. This procedure requires the existence of a numbered or unnumbered L3 network interface on the NE that hosts the MPLS-TP instance. See 27.1 “NE routing and forwarding” (p. 817) for more information about how to configure network interfaces.

32.5.2 Steps

1

Choose Manage→MPLS→MPLS-TP LSPs from the NFM-P main menu. The Manage MPLS-TP LSPs form opens.

2

Click Create and choose Create LER TP-LSP. The LER TP-LSP (Create) form opens.

3

Configure the required parameters in the Identity and Destination panels.

The TP-LSP ID must be in the range of the TP-LSP ID Minimum and TP-LSP ID Maximum parameters that you specified in Step 3 of 32.4 “To configure MPLS-TP on a routing instance” (p. 1169) .

4

Click Select in the Source Site panel and choose a source site and click OK.

5

Click on the TP-LSP Path tab and click Create. The MPLS-TP LSP Path (Create) form opens.

Note: You can create one working path and one protecting path per LSP. As required, repeat Step 5 to Step 12 to create the alternate path type.

6

Configure the required parameters.

7

Click Select in the Out-Link panel and choose an interface and click OK. See 31.7 “To create an MPLS interface” (p. 1120) for information about how to configure MPLS interfaces.

8

Click on the Path MEP tab and click Create. The Path MEP (Create) form opens with the General tab displayed.

9

Configure the required parameters.

10

As required, click Select in the Proactive OAM Template panel and choose a template and click OK. See 32.4 “To configure MPLS-TP on a routing instance” (p. 1169) for information about how to create a Proactive OAM Template.

11

As required, click Select in the Protection Template panel and choose a template and click OK. See 32.4 “To configure MPLS-TP on a routing instance” (p. 1169) for information about how to create a Protection Template.

12

Save your changes and close the forms.

END OF STEPS

32.6 To create an MPLS-TP LSR cross-connect path

32.6.1 Purpose

Use this procedure to create an MPLS-TP LSR cross-connect path. This procedure requires the existence of a numbered or unnumbered L3 network interface on the NE that hosts the MPLS-TP instance. See 27.1 “NE routing and forwarding” (p. 817) for more information about how to configure network interfaces.

32.6.2 Steps

1

Choose Manage→MPLS→MPLS-TP LSPs from the NFM-P main menu. The Manage MPLS-TP LSPs form opens.

2

Click Create and choose Create LSR Path. The LSR Path (Create) form opens.

3

Configure the required parameters in the Identity and States panel. By default, the Forward Path Enabled and Reverse Path Enable parameters are configured to enabled.

4

Click Select in the Site panel and choose a site to be used as the cross-connect and click OK.

5

Configure maintenance intermediate points, if required. The Maintenance Intermediate Points panel displays when you configure a cross-connect site in Step 4 .

Perform the following steps:

1. In the Maintenance Intermediate Points panel, click Create. The Maintenance Intermediate Point (Create) form opens.
2. Configure the required parameters.
3. Click OK to close the form.

6

Perform the following if you enabled the Forward Path Enabled parameter, otherwise, go to Step 8 .

1. Configure the required parameters in the Forward panel.
2. Click Select in the Forward Out-Link panel and choose an interface and click OK. See 31.7 “To create an MPLS interface” (p. 1120) for information about how to configure MPLS interfaces.
3. If you choose a numbered outlink interface, configure the Forward Next Hop parameter.

7

Perform the following if you enabled the Reverse Path Enabled parameter, otherwise, go to Step 8 .

1. Configure the parameters in the Reverse panel.
2. Click Select in the Reverse Out-Link panel and choose an interface and click OK. See 31.7 “To create an MPLS interface” (p. 1120) for information about how to configure MPLS interfaces.
3. If you choose a numbered outlink interface, configure the Reverse Next Hop parameter.

8

Click on the LSP Path Binding tab and click Create to associate the LSR cross-connect path with LER LSPs.The LSR Path Binding (Create) form opens.

9

Configure the required parameter and click OK.

10

Save your changes and close the form.

END OF STEPS

32.7 To create a bidirectional MPLS-TP LSP

32.7.1 Purpose

A bidirectional LSP consists of MPLS-TP LSPs or LER LSPs that are created on the edge NEs, and the LSR cross-connect—or transit path—that is created on the transit NEs. The NFM-P guides you through the creation of the bidirectional MPLS-TP LSP. When the Apply or OK button is disabled, verify that all necessary parameters are configured. When all possible parameters are configured, the NFM-P displays a Hint button to provide instructions on the necessary actions.

This procedure requires the existence of a numbered or unnumbered L3 network interface on the NE that hosts the MPLS-TP instance. See 27.1 “NE routing and forwarding” (p. 817) for more information about how to configure network interfaces.

Note: NFM-P guided provisioning is available only for the creation of bidirectional MPLS-TP LSPs. The Hint button does not appear if you are configuring an existing bidirectional MPLS-TP LSP.

32.7.2 Steps

1

Choose Manage→MPLS→MPLS-TP LSPs from the NFM-P main menu. The Manage MPLS-TP LSPs form opens.

2

Click Create and choose Create Bidirectional TP-LSP. The Bidirectional TP-LSP (Create) form opens.

3

Configure the required parameters.

The TP-LSP ID must be in the range of the TP-LSP ID Minimum and TP-LSP ID Maximum parameters that you specified in Step 3 of 32.4 “To configure MPLS-TP on a routing instance” (p. 1169) .

4

Click Select in the LER A panel and choose a source site and click OK.

5

Click Select in the LER B panel and choose a source site and click OK.

6

Click on the LSP Path tab and click Create. The Bidirectional TP-LSP Path (Create) form opens.

7

Configure the required parameters

Note: You can create one working path and one protecting path per LSP. As required, repeat Step 6 to Step 17 to create the alternate path type.

The LSP Path Number parameter is a global LSP path number that configures the LSP path number on the LER A working and protecting paths, the LER B working and protecting paths, and on the LSR static hop.The LSP Path Number parameter must be the same on all of the hops.

8

Click on the LER A tab and click Select. The Select Out-Link - Bidirectional TP-LSP Path list form opens.

9

Choose a site and click OK.

10

Click on the Hint button. A window appears displaying an instructional message.

11

Perform one of the following:

a. If the message “You have configured the LER-A Out-Link Interface. As a result, NFM-P has created the next LSR Path Hop, and has auto-filled the data between the LER-A and the newly created LSR Path Hop” appears, perform the following steps:
   1. Click on the LSR Path Hops tab and choose the LSR path hop with a configuration state of Incomplete and click Properties. The LSR Hop (Edit) form opens.
   2. Configure the required parameters and click OK. Go to Step 14 .

b. If the message “You have configured the LER-A Out-Link Interface. NFM-P is unable to determine the next hop (this could be due to an unconnected cable). As a result, NFM-P has enabled the LSR Path Hop creation, and the LER-B Out-Link Interface selection.” appears, perform the following:
   - If the next hop in the path is not the LER B, go to Step 12 to create an LSR path hop.

- If the next hop is the LER B, go to Step 14 .

c. If the message “You have configured the LER-A Out-Link Interface. As a result, NFM-P has auto-completed the data between LER-A and LER-B.” appears, click OK to complete the path configuration.

12

Create an LSR path hop:

Perform the following steps:

1. Click on the LSR Path Hops tab and click Create. The LSR Hop (Create) form opens.
2. Configure the Display Name parameter.
3. Click Select in the Forward Out-Link panel and choose an interface and click OK. See 31.7 “To create an MPLS interface” (p. 1120) for information about how to configure MPLS interfaces.
4. Click on the Hint button. The message “You have configured the Forward Out-Link Interface. As a result, NFM-P has auto-completed the data between this LSR Path Hop and the previous hop on the forward path.” appears.
5. Click Select in the Reverse Out-Link panel and choose an interface and click OK. See 31.7 “To create an MPLS interface” (p. 1120) for information about how to configure MPLS interfaces.
6. Click OK to close the form.

13

Click on the Hint button. Perform one of the following based on the message returned:

a. If the message “You have configured the LSR Path Hop Reverse Out-Link Interface. NFM-P is unable to determine the next hop (this could be due to an unconnected cable). As a result, NFM-P has enabled the LSR Path Hop creation, and the LER-B Out-Link Interface selection.”, perform the following.

- If the next hop in the path is not the LER B, return to Step 12 to create an LSR path hop.
- If the next hop is the LER B, go to Step 14

b. If the message “You have configured the Reverse Out-Link Interface. As a result, NFM-P has created the next LSR Path Hop, and auto-completed the data between this LSR Path Hop and the newly created LSR Path Hop.” appears, perform the following steps:

1. Click on the LSR Path Hops tab.
2. Choose the LSR path hop with a configuration state of Incomplete and click Properties. The LSR Hop (Edit) form opens.
3. Configure the required parameters and click OK. Go to Step 14 .

c. If the message “You have configured the Reverse Out-Link Interface. As a result, NFM-P has auto-filled the data between this LSR Path Hop and LER-B.” appears, go to Step 17 .

14

Click on the LER B tab.

15

Click Select in the Out-Link panel and choose an interface and click OK. See 31.7 “To create an MPLS interface” (p. 1120) for information about how to configure MPLS interfaces.

16

Click on the Hint button. The message “You have configured the LER-B Out-Link Interface. As a result, NFM-P has auto-completed the data between LER-B and its next hop on the forward path. The path configuration is now complete.” appears, click OK to complete the path configuration.

17

Save your change and close the forms.

18

Create a BFD template on the LER A and LER B. See 28.25 “To configure a BFD template policy” (p. 911) .

19

Create a proactive OAM template on the LER A and LER B. See 32.4 “To configure MPLS-TP on a routing instance” (p. 1169) .

END OF STEPS

33 Service tunnels

Service tunnel overview

33.1 Service tunnel overview

33.1.1 Overview

A service tunnel is an entity used to uni-directionally direct traffic from one device to another device. The service tunnel is provisioned to use a specific encapsulation method, such as GRE or MPLS, and the services are then mapped to the service tunnel. For instance, multi-NE VLL and VPLS traffic is transmitted using uni-directional service tunnels in this way.

The most common type of tunnel used in NFM-P is a Service Distribution Point binding. Service tunnels originate on an SDP on a source NE and terminate at a destination NE. The destination NE directs packets from the service tunnel to the correct service egress interfaces (SAPs) on that device. Services that originate and terminate on the same NE do not require service tunnels, because the same NE is both the source and the destination.

However, because the concept of a tunnel is a logical construct within the NFM-P, a number of different configurable objects can actually be used as service tunnels, including:

- SDP binding:
  Because SDP bindings can be associated to a service of any type, the service tunnel discovery includes services that are associated to SDP bindings of a given service.
- Service to Tunnel Association:
  Discovery adds tunnels that are associated to a given service.
- G.8031 Ethernet tunnel:
  Discovery adds the global Ethernet Tunnel that the Tunnel Endpoint (SAP's terminating port) is a member of.
- G.8032 Ethernet ring:
  Discovery adds the Ethernet Ring that the Ethernet Element is a member of.
- G.8032 Ethernet radio ring:
  Discovery adds the Ethernet radio ring that the Ethernet Element is a member of. See the *NSP Wavence Device Support Guide* for more information.
- PBB:
  Discovery adds the VPLS or MVPLS services which contain the PBB tunnel (B-Sites) of the given Epipe or VPLS.
- P2MP RSVP LSP:
  Discovery adds the P2MP LSPs retrieved from the MVPN LSP Template associated to PIM sites.
- Optical Transport Service:
  Discovery adds optical services that are traversing network interfaces which are being used by an L2/L3 VPN through any static, dynamic or SR-TE LSPs that are bound to SDPs on the service if the following are true:
  − LSPs are bound to service tunnels (SDPs) on the service

  - One or more of the corresponding hops on the LSP active path share the same port with the optical service termination

- Mobile backhaul (applicable to Wavence SM and 7705 SAR on MPLS-based services running over VLAN):

  Discovery adds Wavence VLL services that are associated to an SDP tunnel or are traversing through network interfaces which are being used by an L2/L3 VPN through any static, dynamic or SR-TE LSPs that are bound to SDPs on the service.

The Service Tunnels tab exists on the applicable service configuration forms. This tab lists the objects considered as service tunnels (such as SDPs, Ethernet rings, Ethernet tunnels, other services) that are currently used by the service you are querying. The associated Discover Service Tunnels button removes any previously discovered service tunnels on the service and initiates a manual rediscovery of the tunnels, based on direct usage and current service configurations.

For composite services, the service tunnel discovery action initiates the discovery of service tunnels on the participating services. The listing includes the service tunnels that are currently used by member services.

The Flow-through Services tab is on the configuration forms of the objects that can be used as a service tunnel. The tab lists the other services that are currently using the object you are querying as a service tunnel. The associated Discover Flow-through Services button removes any previously discovered flow-through services and initiates a manual rediscovery of the tunnels, based on direct usage and current service configurations.

For composite services, the concept of using a service as a service tunnel is not supported. The Flow-through Services tab does not appear on the composite service configuration forms.

For alarm management, an association type of alarm relationship exists between a service and the service tunnels that the service uses. This allows the service tunnel alarms to propagate up to the service level. These association alarms are displayed on the Alarms on Related Objects tab, under the Faults tab of the service. Because this is a one-way association, service alarms are not propagated to the service tunnels that the service is using.

33.2 Tunnel selection profiles

33.2.1 Overview

The NFM-P uses a tunnel selection profile to assign transport tunnels for a service when the service is configured for automatic SDP binding creation. Tunnel selection profiles can also be used for services when the SDP binding creation is performed manually. The NFM-P chooses tunnels and return tunnels when the automatic selection of transport tunnels is enabled and a tunnel selection profile is specified.

A tunnel selection profile contains tunnel administrative groups. When the profile is used within a service to create SDP bindings, any tunnels that include the tunnel administrative group in that profile become eligible for consideration in the tunnel selection process. See Chapter 88, “Tunnel administrative groups” for more information about tunnel administrative groups.

33.2.2 Default tunnel selection profiles

When you enable automatic SDP binding creation on a service, the NFM-P uses the Generated Default TSP for tunnel selection unless you specify a different tunnel selection profile. The

Generated Default TSP is configured to use any transport type, and cannot be modified.

33.3 IP/MPLS service tunnels

33.3.1 Overview

Distributed service traffic is transported between PE NEs by circuits aggregated in unidirectional service tunnels.

The operational theory of a service tunnel is that the encapsulation of the data between the two managed edge NEs appears as a Layer 2 path to the service data although it is really traversing an IP or IP/MPLS core.

Tunnel policies from older releases can be converted to the newer template-based policies by using a “Convert” button located on the rule configuration form. You cannot configure CoS forwarding, LDP-over-RSVP, or multiple LSP bindings on SDP features.

A service tunnel uses GRE or MPLS encapsulation. For MPLS, a mesh of MPLS paths and LSPs must be present in the network core. You associate service tunnels with LSPs during service tunnel configuration. The NFM-P supports LSP creation using a basic LDP variant such as T-LDP, or using LDP over RSVP for tunnel-in-tunnel functionality based on traffic classification.

An NFM-P operator binds a service site to a service tunnel during service configuration. A service tunnel has a unique ID on an NE and cannot be deleted when it is currently associated with a service.

ACL IP and ACL MAC policy filters for service tunnels contain options for forwarding packets on a specific service tunnel based on matching criteria, as described in Chapter 51, “Filter policies” .

33.3.2 IP/MPLS service tunnels design considerations

Consider the following before you configure IP/MPLS service tunnels:

- Service tunnels are unidirectional, so they are required in both directions between the source NE and the destination NE.
- The tunnel is not specific to one service or one type of service. After a tunnel exists, multiple SDPs can be aggregated over the tunnel. The SDPs can belong to different services and different customers.
- When a tunnel already exists, the NFM-P does not automatically create a new tunnel, even if the only available tunnel is down. This prevents the creation of multiple inoperable tunnels.
- All services that are mapped to a tunnel use the same transport encapsulation type defined for the tunnel.
- Operations on the tunnel affect all the services that are associated with the tunnel. For example, the operational and administrative states of a tunnel control the state of service circuits that are carried on the tunnel. In the case of LSP-based tunnels, an LSP can be replaced in the tunnel without reconfiguring each service bound to the tunnel.
- A service tunnel is locally unique to an NE. The same tunnel ID can appear on other NEs.
- A service tunnel uses the system IP address to identify the far-end edge NE.
- When a newly created service tunnel terminates on a local loopback network interface of the

base routing instance, the topology map shows the tunnel terminating on a managed NE. If the service tunnel destination address is provisioned with an IP address from an IES or VPRN interface, the tunnel is shown as terminating on unmanaged NE.

- A service tunnel can be configured using a tunnel template. A user who is assigned the create tunnel template scope of command role can create a tunnel template. The template manager can also apply the tunnel template to a service tunnel.
- An SDP tunnel template can be applied to an auto tunnel policy.

See the appropriate device documentation for more detailed information about service tunnels.

33.3.3 Class-based forwarding

Packets of the same CoS and service are forwarded over a specific RSVP LSP (or a static LSP), which is part of an SDP that the service (instance) is bound to. The forwarding decision is based on the forwarding class of the packet, as assigned by the ingress QoS policy defined for the SAP.

When implementing class-based forwarding, consider the following:

- Class-based forwarding is typically implemented using the service tunnel configuration forms, as detailed in 33.9 “To create an IP/MPLS service tunnel” (p. 1190) . Class-based forwarding configurations can also be altered after their initial creation by editing the service tunnel configuration form as detailed in 33.24 “To view and manage service tunnels and tunnel elements” (p. 1224) .
- An LSP can carry packets of a forwarding class for one service and at the same time, carry packets of a different forwarding class for another service. In other words, the same LSP can be used by more than one SDP, even where the forwarding class assignments are different.
- Within an SDP, only one LSP can support a specific CoS.
- A service instance (or service site) can be bound to SDPs of differing CoS configurations, as well as regular SDPs.
- One LSP in the SDP must be designated as the default LSP. The default LSP is used by the SDP if there is no available LSP that matches the packet's forwarding class. When the default LSP is down, the SDP is also brought down.
- Class-based forwarding can be applied to all services supported by the SRs. For VPLS, you can specify an LSP to forward all multicast/broadcast packets (by default, the default LSP is used). For VLL, shared queuing must be enabled on the ingress SAP to support the class-based forwarding.
- Class-based forwarding is configurable on the 7750 SR, 7450 ESS, and 7950 XRS.

33.4 Ethernet G.8031 tunnels

33.4.1 Overview

The IEEE 802.1ah Provider Backbone Bridging specification employs Provider MSTP to ensure loop avoidance in a resilient native Ethernet core. With P-MSTP, failover times depend largely on the size of the network and the connectivity model used in the network. MPLS tunnels provide core scaling and fast failover times using MPLS FRR. A service based on native Ethernet backbone achieves the same fast failover times as MPLS FRR.

Core Ethernet tunnels compliant with the ITU-T G.8031 specification achieve 50 ms resiliency for backbone failures. A configured Ethernet tunnel can be selected when configuring an L2 access interface on a B-VPLS.

The NFM-P uses two different approaches to configure Ethernet tunnels in the network.

- Approach 1 (recommended):
  The NFM-P provisions an end-to-end Ethernet G.8031 tunnel which reduces configuration errors and aids the diagnosis of any problem in the tunnel. The NFM-P automatically configures the Ethernet tunnel endpoint and path endpoint on each of the participating NEs. See 33.15 “To configure an Ethernet tunnel” (p. 1204) for more information.

  The Ethernet tunnel and path are network wide objects that provide the following benefits:
  - the Ethernet tunnel provides the aggregated State of the Tunnel and reports any inconsistency in the configuration of the endpoints or paths
  - faster and easier provisioning that allows you to configure common properties such as holdTime and revertTime at the network level and then apply them to each tunnel endpoint
  - The NFM-P accelerates the creation of global and local MAs, and MEPs by using a continuity check
- Approach 2:
  The NFM-P provides the ability to provision Ethernet tunnel endpoints and path endpoints separately on each NE. See 33.14 “To configure an Ethernet tunnel endpoint” (p. 1203) for more information on creating Ethernet endpoints. If Ethernet tunnel endpoints are created this way (or discovered from the NE) you can associate them to a network-wide Ethernet tunnel and path, but this must be done manually.

Note: Network-wide Ethernet tunnels and paths are not automatically discovered from the NE.

33.4.2 Transit services

You can use the NFM-P to configure and manage transit services on supporting 7210 SAS and 7705 SAR NEs.

Transit services use default QinQ SAPs (which are also called transit SAPs) to forward traffic for data services. Transit SAPs (notation *.*) receive and forward frames with any encapsulation value, and eliminate the need for customer VLAN-specific SAPs on virtual switching instances for service sites with transit SAPs. Data services use transit services for transparent forwarding, which can reduce configuration time and move traffic more efficiently.

Although transit services function as service tunnels, they are managed in the same way as other VPLS and VLL services in the NFM-P: they have service IDs, appear as services in navigation trees, contain sites and interfaces, and appear on service topology maps. Properties forms for transit services share the same tab structure and functionality as forms for other services in the NFM-P. You can use the Transported Services tab to view and access the data services that use the transit service (you must first discover the services). You can also view and access a transit service that is associated with a VLAN Uplink, using the Transit Services tab on the VLAN Uplink form. You can access VLAN Uplink forms from the service topology map. See 4.1.5 “Service topology maps” (p. 171) in 4.1 “Topology map types” (p. 169) for more information.

Any alarms that are generated on a transit service are propagated to the data service that uses the transit service, and appear as alarms on related objects on the Faults tab of the data service properties form.

You can create transit services automatically for VPLS G.8032 Ethernet rings using the Create Transit Services function. See 33.20 “To configure a transit service on an Ethernet ring” (p. 1220) for more information. Transit services created by this method are new services, and contain only transit SAPs. The NFM-P creates linked transit SAPs on all sites on the ring.

For non-G.8032 VPLS and VLL services, manually-configured transit SAPs on the services are used as a transit service by the NFM-P when the transit SAPs are connected by a physical link.

When you use the Connect to Ethernet Ring function to connect a data service to an Ethernet ring configured with a transit service, the NFM-P creates VLAN-specific SAPs for the data service only on the ring site for which Connect to Ethernet Ring is selected. The transit SAPs on the ring transparently forward traffic through other sites on the service.

You can combine transit services using the composite service functionality in the NFM-P. Composite services are created automatically when Auto Discover Composite Services is enabled in System Preferences, or manually using the Rediscover Composite Services function. See Chapter 85, “Composite service management” for more information about composite services.

For more information about transit services and transit SAPs (default QinQ SAPs), including restrictions, see the appropriate NE documentation.

Ethernet G.8032 rings

33.5 Ethernet G.8032 rings

33.5.1 Overview

Ethernet Ring Protection (ERP) as specified in ITU-T G.8032, is a protection mechanism for Ethernet ring topologies that provides a resilient Ethernet network. ERP provides sub-50ms protection and recovery switching for Ethernet traffic in a ring topology, and, at the same time, ensures that loops are not formed at the Ethernet layer. G.8032v1 supports a single ring topology; G.8032v2 supports multiple rings/ladder topology. For more information about Ethernet G.8032 rings, see the ITU website at http://itu.int.

33.5.2 ERP topology

An ERP topology is a collection of Ethernet ring nodes that forms a closed physical loop. Between two and sixteen Ethernet ring nodes are supported per ERP topology. One ERP topology is supported per NE. Up to two ERP instances are supported per ERP topology. Ethernet ring links connect two adjacent Ethernet ring nodes participating in the same ERP topology.

Loop avoidance in the ring is achieved by guaranteeing that at anytime, traffic may flow on all but one of the ring links. This link is called the ring protection link (RPL). One designated node, the RPL Owner (also referred to as the master node), is responsible to block traffic over the RPL.

33.5.3 Supported ERP service types

You can configure the following service types in an ERP G.8032 topology using the NFM-P on NEs that support ERP:

- VLAN service
  - Wavence SM; see the *NSP Wavence Device Support Guide* for more information
- VLL service (Cpipe and Epipe services only)
- VPLS that support ERP SAPs can connect to other rings and Ethernet services using VPLS SAPs. A VPLS can use a single ring (main or sub-ring) or multiple rings.

33.5.4 Ethernet ring discovery

The NFM-P automatically unites discovered Ethernet ring elements in the network into Ethernet rings, and creates path objects to link endpoints within the ring. In order for the NFM-P to create an Ethernet ring, the following must exist:

- at least two Ethernet ring elements with path endpoints
- a physical link between the endpoints

The NFM-P detects the ring elements and the physical link, then creates an Ethernet ring to contain the ring elements, and path objects to link them. If one of the ring elements is already part of an Ethernet ring, then the other element is added to the existing ring. If both elements are part of existing rings, then the rings are merged (see 33.5.7 “Merging Ethernet rings” (p. 1184) below).

See 33.8 “Workflow to configure Ethernet G.8032 rings” (p. 1189) for information about using the NFM-P to automatically create Ethernet rings.

You can manually create Ethernet G.8032 rings using the NFM-P GUI or using the OSS service provisioning client. See 33.18 “To create an Ethernet G.8032 ring” (p. 1212) to create Ethernet G.8032 rings using the NFM-P GUI. See “MPLS, LSP, and service tunnel configuration” in the *NSP NFM-P XML API Developer Guide* for information about configuring Ethernet G.8032 rings using the OSS client application.

33.5.5 Triggering automatic ring creation

Automatic Ethernet ring creation is triggered by the following events:

- creation or detection of a path endpoint on an Ethernet ring element
- creation or detection of a physical link between two path endpoints on Ethernet ring objects
- performance of a global Ethernet ring audit (see 33.5.11 “Auditing Ethernet rings” (p. 1185))

Path endpoints and physical links can be detected through LLDP or when a node is discovered, or created through NFM-P or CLI. In each case, the NFM-P attempts to create an appropriate Ethernet ring for the discovered object.

33.5.6 Ethernet sub-rings

The NFM-P also detects and creates Ethernet sub-rings, and creates interconnects between upper rings and sub-rings when appropriate. You can view the sub-rings associated with a ring in the Sub-Rings tab of the Ethernet ring configuration form, and the parent upper rings on the Upper Rings tab.

33.5.7 Merging Ethernet rings

When the NFM-P detects a physical link between two Ethernet ring element path endpoints on separate Ethernet rings, the rings are automatically merged together. One of the Ethernet rings is deleted, and the elements and paths from that ring are added to the other ring. The following criteria are used to determine which ring is deleted:

- If one of the rings was created manually using the NFM-P, then the other ring is merged into the manually-created ring.
- If both rings were created manually, then the smaller ring is merged into the larger ring, based on the number of Ethernet ring elements.
- If both rings were created automatically, then the smaller ring is merged into the larger ring, based on the number of Ethernet ring elements.
- If the rings have the same number of elements, and were both created the in the same manner, then the ring with the higher Manager ID is merged into the other ring.

33.5.8 Naming of discovered Ethernet rings

Global Ethernet rings inherit the Description parameter of the first element added to the ring. The Name parameter for automatically created rings is always “N/A”.

33.5.9 Deleting Ethernet rings

Automatically created Ethernet rings are deleted when the underlying physical links are removed. When a physical link is deleted - for example, manually, or by disabling LLDP on the related node - the associated path is also deleted, and the existing Ethernet ring is modified or deleted appropriately.

33.5.10 Adding or removing elements in an Ethernet ring

You can cut-in or cut-out an NE in an existing Ethernet ring as part of a network adjustment. The NFM-P alters the existing Ethernet rings and updates the associated endpoints and services to reflect the new configuration.

To add (cut-in) an NE to an Ethernet ring, perform the following:

1. Shut down ports on NEs that will be connected to the cut-in NE.
2. Configure Ethernet ring endpoints on the cut-in NE. See 4.10 “To create a physical link” (p. 183).
3. Update OAM parameters for NEs to be connected to the cut-in NE. See Chapter 77, “VPLS management ”.
4. Re-cable the network to include the cut-in NE in the Ethernet ring.
5. Enable all related ports.
6. (In-band network only) Configure the cut-in NE as an Ethernet ring element (including control SAPs). See 33.16 “To configure an Ethernet Ring Element” (p. 1208).
7. Discover the cut-in node in the NFM-P. See “Discovering devices using the NFM-P” (p. 277).
8. The NFM-P creates paths and merges them appropriately into the Ethernet rings. (Out-of-band network only) Control SAPs for the cut-in NE are created on the associated control VPLS automatically.
9. You can perform an Ethernet ring audit to verify that the rings have been created properly. See 33.27 “To perform an Ethernet G.8032 ring audit” (p. 1226).
10. Trigger an Update Data Service function to create data SAPs on the cut-in NE and to the associated data VPLS. See 33.21 “To manually update data services on an Ethernet ring” (p. 1221).

To remove (cut-out) an NE from an Ethernet ring, perform the following:

1. Shut down ports that are connected to the cut-out NE.
2. Update OAM parameters for NEs connected to the cut-out NE. See Chapter 77, “VPLS management ”.
3. Re-cable the network to exclude the cut-out NE from the Ethernet ring.
4. Enable all related ports.
5. Unmanage the cut-out NE in the NFM-P. See 9.27 “To manage, suspend, or unmanage a device” (p. 316).

33.5.11 Auditing Ethernet rings

You can use the NFM-P to perform a global or local audit of an Ethernet ring. An audit can find missing elements, paths, and interconnects, and potentially merge rings if a link is found. When an audit discovers a problem that cannot be resolved, an alarm is raised against the Ethernet ring, and the problems encountered by the audit are displayed in the alarm details. Performing another audit clears the alarm, if the problems have been resolved.

33.27 “To perform an Ethernet G.8032 ring audit” (p. 1226) describes how to audit Ethernet rings. Performing a global Ethernet ring audit both creates and merges Ethernet rings, even if automatic Ethernet ring creation is disabled.

33.5.12 Service provisioning on Ethernet G.8032 rings

The NFM-P accelerates the provisioning of VPLS instances on Ethernet G.8032 rings by automatically creating the control services and data services on the rings. Services are configured on Ethernet G.8032 rings in the same method as service tunnels.

You can automatically configure transit services on VPLS G.8032 Ethernet rings. See 33.4.2 “Transit services” (p. 1181) in 33.4 “Ethernet G.8031 tunnels” (p. 1180) and 33.20 “To configure a transit service on an Ethernet ring” (p. 1220) for more information.

You can create Ethernet G.8032 rings using the NFM-P GUI or using the OSS service provisioning client. See 33.18 “To create an Ethernet G.8032 ring” (p. 1212) to create Ethernet G.8032 rings using the NFM-P GUI. See “MPLS, LSP, and service tunnel configuration” in the *NSP NFM-P XML API Developer Guide* for information about configuring Ethernet G.8032 rings using the OSS client application.

33.6 L2TPv3 service tunnels

33.6.1 Overview

L2TPv3 transport tunnels enable the encapsulation of L2 Ethernet frames into IPv6 packets transported by L2TPv3. L2TPv3 tunnels provide services similar to Ethernet pseudowire services but without the use of MPLS encapsulation and labels for network and service offerings that are IPv6-only, with no MPLS or IPv4 services.

L2TPv3-encapsulated traffic is transported over the IPv6 address family, without using any session or label identifier or signaling control plane.

Consider the following when you create an L2TPv3 tunnel:

- you must enable the IPv6 Allowed and Loopback Enabled parameters on the network interface of the NE
- you can configure multiple IPv6 addresses on the loopback interface
- you can add the loopback interfaces as ISIS and OSPFv3 routing instances so that the IGP is used to route the traffic between loopback interfaces
- you can configure an address aggregation policy to distribute the loopback interface IP addresses

Only Epipe spoke and mirror SDP bindings can use L2TPv3 tunnels. See 76.35 “To configure a spoke SDP binding with an L2TPv3 tunnel on a VLL Epipe site” (p. 2165) for more information

about how to create an Epipe SDP binding with an L2TPv3 tunnel. See 93.5 “To create a destination site on a mirror service” (p. 3167) for more information about how to add a remote source mirror SDP binding on a mirror destination site with an L2TPv3 tunnel. See 93.6 “To create a source site on a mirror service” (p. 3169) for more information about how to create a mirror SDP binding on a mirror source site with an L2TPv3 tunnel.

Configuring service tunnel workflows and procedures

33.7 Workflow to configure service tunnels

33.7.1 Stages

1

Before you can create an MPLS service tunnel, you must create a static LSP, dynamic LSP or segment routing TE LSP. See the following procedures:

- 31.10 “To create a static LSP” (p. 1124)
- 31.11 “To create a Dynamic LSP” (p. 1126)
- 31.12 “To create a segment routing TE LSP ” (p. 1130)

2

Create an IP/MPLS service tunnel and assign it to an NE as follows:

a. Create an IP/MPLS service tunnel; see 33.9 “To create an IP/MPLS service tunnel” (p. 1190) .

b. Create an IP/MPLS service tunnel using a tunnel template. See 33.12 “To create an SDP using a tunnel template” (p. 1200) .
Note: Service tunnels are unidirectional, so they are required in both directions between the source NE and the destination NE.

c. Create a tunnel administrative group and a tunnel selection profile and assign the tunnel selection profile to an SDP binding. See 88.3 “To create a tunnel administrative group” (p. 2897) and 33.9 “To create an IP/MPLS service tunnel” (p. 1190) and 33.13 “To create a tunnel selection profile” (p. 1201) for more information.

3

Create an L2TPv3 tunnel and assign it to an NE as follows:

a. Create an L2TPv3 tunnel; see 33.11 “To configure an L2TPv3 service tunnel” (p. 1199) .

b. Create an L2TPv3 service tunnel using a tunnel template. See 33.12 “To create an SDP using a tunnel template” (p. 1200) .

Note: Service tunnels are unidirectional, so they are required in both directions between the source NE and the destination NE.

4

Perform one of the following to create an Ethernet service tunnel:

a. Create an Ethernet service tunnel endpoint. See 33.14 “To configure an Ethernet tunnel endpoint” (p. 1203) .

b. Create an Ethernet service tunnel and assign endpoints to the tunnel. See 33.15 “To configure an Ethernet tunnel” (p. 1204) .

5

Create transit services on Ethernet rings as required. See 33.20 “To configure a transit service on an Ethernet ring” (p. 1220) .

6

As required, discover and list service tunnel information. See 33.22 “To discover service tunnels” (p. 1222) and 33.23 “To discover flow-through services” (p. 1223) .

7

Perform one of the following to view service tunnel information:

a. View and manage service tunnels and tunnel elements. See 33.24 “To view and manage service tunnels and tunnel elements” (p. 1224) .

b. View the service tunnel topology. See 33.25 “To view the service tunnel topology” (p. 1224) .

8

As required, run an OAM validation test on a service tunnel. See 33.26 “To run an OAM validation test on a service tunnel” (p. 1225) .

33.8 Workflow to configure Ethernet G.8032 rings

33.8.1 Stages

1

Perform one of the following to create Ethernet ring elements:

a. Create an Ethernet ring element for all supported devices except for OmniSwitch and Wavence devices. See 33.16 “To configure an Ethernet Ring Element” (p. 1208) for more information.

b. Create an Ethernet ring element for an OmniSwitch. See 33.17 “To configure an OmniSwitch Ethernet Ring Element” (p. 1209) .

c. Create an Ethernet radio ring element for a Wavence SM. See the *NSP Wavence Device Support Guide* for more information.

2

Perform one of the following to create physical links:

a. Configure LLDP to automatically discover and create physical links. See 12.21 “To enable LLDP on an NE” (p. 358) .

b. Manually create a physical link. See 4.10 “To create a physical link” (p. 183) .

3

If required, perform a global Ethernet ring audit to trigger Ethernet ring creation and mergers. See 33.27 “To perform an Ethernet G.8032 ring audit” (p. 1226) .

33.9 To create an IP/MPLS service tunnel

33.9.1 Purpose

Use this procedure to create an IP/MPLS service tunnel. Before you can create an MPLS service tunnel, you must create a static LSP, dynamic LSP or segment routing TE LSP. See the following procedures:

- 31.10 “To create a static LSP” (p. 1124)
- 31.11 “To create a Dynamic LSP” (p. 1126)
- 31.12 “To create a segment routing TE LSP ” (p. 1130)

The steps that display in the wizard will vary based on parameter selection and source NE and release.

33.9.2 Steps

1

Choose Manage→Service Tunnels from the NFM-P main menu. The Manage Service Tunnels form opens.

2

Click Create→IP/MPLS Service Tunnel (SDP). The IP/MPLS Service Tunnel (SDP) wizard opens.

3

Configure the required parameters.

If a range policy is applied to a service tunnel, a gray text box appears beside the ID parameter to indicate that a range policy is in effect.

If a format policy is applied to a service tunnel, a drop-down menu appears beside the object field during object creation to indicate that a format policy is in effect. When there is only one matching policy, the drop-down menu is dimmed. When there are multiple matching policies, use the drop-down menu to choose a policy. The sequence of the options in the drop-down menu are ordered by the policy Priority parameter.

4

Click Next. The Pick Source Node step is displayed.

5

Select a source site or enter its IP address.

6

Click Next. The Pick Destination Node step is displayed.

7

To create an SDP tunnel using MPLS-TP:

Use the following steps:

1. Enable the MPLS-TP Far-End parameter.
2. Select an NE on which MPLS-TP is enabled.

8

To create an SDP tunnel without MPLS-TP, enter the IP address of the destination site or select an NE.

9

Click Next. The Specify Transport step is displayed.

10

Perform one of the following:

a. For GRE service tunnels:

   Use the following steps:

   1. Specify GRE for the Underlying Transport parameter.
   2. Configure the Signaling parameter.
   3. Enable SR-ISIS or SR-OSPF as needed.

b. For MPLS service tunnels:

   Use the following steps:

   1. Specify MPLS for the Underlying Transport parameter.

      Specify MPLS for the Underlying Transport parameter. The following considerations apply:

      - When you implement class-based forwarding or specify a transport destination address, you must choose MPLS as the Underlying Transport parameter.
      - When you plan to bind an SR-TE LSP to the service tunnel, you must choose MPLS as the Underlying Transport parameter and not configure any other parameters in the Specify Transport step.
      - When you specify a transport destination address, you cannot implement class-based forwarding.
      - When you configure a service tunnel with a source site that is a 7705 SAR, you can choose IPv4 as the Underlying Transport parameter if the destination site is also a 7705 SAR, a GNE, or an unmanaged IP address.

   2. Configure the required parameters.

The Revert Time (seconds) parameter appears when the Mixed LSP Mode parameter is set to true.

When you implement class-based forwarding, you must use one of the following parameter configurations:

- Set Mixed LSP Mode to true.
- Set Mixed LSP Mode, Enable LDP, and Enable BGP-Tunnel parameters to false.

When you specify a transport destination address, you must use the following parameter configurations:

- Set Enable LDP to true.
- Set Mixed LSP Mode and Enable BGP-Tunnel to false.

You cannot set Enable BGP-Tunnel to true when Enable LDP or Mixed LSP Mode is set to true.

You cannot create a BGP or an LDP tunnel when an LSP exists between the source and destination NEs that you specified in Step 5 and Step 8 respectively.

3. If you set the Enable LDP parameter to true, go to Step 18 .
4. If you set the Enable BGP-Tunnel parameter to true, go to Step 20 .

11

Click Next. The Specify Class Forwarding step is displayed.

12

Configure the parameters.

When the Class Forwarding Capability parameter is set to Off, the existing class-forwarding configurations are removed.

The Administrative State and Enforce Diff-Serv Lsp-Fc Map parameters are configurable when the Class Forwarding Capability parameter is set to On.

13

Click Next. The Associate LSPs step is displayed.

14

Click Add to bind an LSP to the service tunnel. The Bind LSPs to Service Tunnel form opens with the Bind LSP to Service Tunnel Stage step displayed.

If no eligible LSP is available for binding to the service tunnel, the form provides actions buttons to:

- Create Dynamic LSP—for details, see 31.11 “To create a Dynamic LSP” (p. 1126)
- Create Static LSP—for details, see 31.10 “To create a static LSP” (p. 1124)
- Create SR-TE LSP—for details, see 31.12 “To create a segment routing TE LSP ” (p. 1130)

15

Choose an LSP and click Finish.

16

Click Close. The Bind LSPs to Service Tunnel form closes and the LSP is listed on the Create Service Tunnel (SDP) form.

17

If you are enabling class-based forwarding on the LSP:

Use the following steps:

1. Choose an LSP and click Set As Default LSP. This is mandatory. The Default LSP Name appears in the associated field.
2. For a VPLS, specify an LSP to forward all multicast/broadcast packets. Otherwise, the default LSP is used. If the LSP is specified, the Multicast LSP Name appears in the associated field.
3. For any LSPs used for class-based forwarding (including the default), choose the LSP and click Choose a Forwarding Class. Choose the required forwarding class from the contextual menu, which then appears in the Forwarding Class to LSP Mappings table.

18

Click Next. The Specify Transport Destination Address step is displayed.

Note: This step appears if you set the Underlying Transport parameter to MPLS in Step 10 and set the Enable LDP parameter to true.

19

Configure the Transport Destination Address parameter.

Note: You cannot assign tunnel administrative groups to the SDP if you configure the Transport Destination Address parameter with an IPv6 address.

20

Click Next. The Specify Local End IP Address step is displayed, if applicable.

21

Select a virtual router or enter its IP address.

22

Click Next. The Specify Hello Parameters step is displayed.

23

Configure the required parameters.

24

Click Next. The Specify MTU Values step is displayed.

25

Configure the required parameters.

26

Click Next. The Specify Metric step is displayed, if applicable.

27

Configure the Metric parameter, if applicable.

28

Click Next. The VC Type Related Parameters step is displayed, if applicable.

29

Configure the VLAN VC Ethertype parameters.

30

Click Next. The Specify Initial State step is displayed.

31

Configure the Administrative parameter.

32

Click Next. The Booking Factor step is displayed, if applicable.

Note: This step appears if you set the Underlying Transport parameter to MPLS in Step 10 and set the Ldp Enabled parameter to false.

33

Configure the SDP Bandwidth Booking Factor (%) parameter, if required.

34

Click Next. The Associate Service step is displayed.

35

Select a service.

36

Click Next. The Tunnel Admin Groups step is displayed.

37

Select the tunnel administrative groups in the Unassigned list that you want to assign to the tunnel and click the right arrow to move them into the Assigned list.

Note: You cannot assign tunnel administrative groups to the SDP if you configured the Transport Destination Address parameter with an IPv6 address in Step 19 .

38

Click Next. The Network Domain step is displayed.

39

Select a network domain.

Note: All SDPs are associated with a network domain. This association is done during the creation or when editing an SDP in the Tunnel (Edit) form. You can also modify the network domain in the Tunnel (Edit) form. See Step 58 . The Egress Interfaces Consistency State status specifies if all the interface associations to SDP belong to a particular domain.

40

Perform one of the following:

a. If you specified MPLS for the Underlying Transport parameter and TLDP or None for the Signaling parameter in Step 10 , click Next and go to Step 41 .

b. If you specified MPLS for the Underlying Transport parameter, and BGP for the Signaling parameter in Step 10 , go to Step 43 .

c. If you specified GRE for the Underlying Transport parameter in Step 10 , click Next and go to Step 54 .

41

The Port Binding step is displayed.

42

Select an Ethernet or HSMDA port, or a LAG.

Only ports in hybrid mode or a LAG that contains hybrid ports can be selected.

43

Click Next. The Configure Source B-MAC LSB step is displayed.

44

Configure the required parameters.

45

Click Next. The Weighted ECMP step is displayed, if applicable.

46

Configure the parameter if required.

47

Click Next. The Configure PW Ports step form is displayed, if applicable.

48

Click Create. The PW Port Binding (Create) form opens.

49

Perform one of the following:

a. Select an existing PW port in the PW Port ID panel.

b. Create a PW port:

Use the following steps:

1. Click Select in the PW Port ID panel and click Create. The PW Port (Create) form opens.
2. Configure the parameters.
3. Click on Node Redundancy to configure node redundancy for the PW port. The Manage Node Redundancy form appears, preconfigured for MC peer groups.

   The Node Redundancy button allows you to access the MC sync group configuration within the MC peer group in order to add PW port sync tags.
4. Search for an existing MC peer group or click Create and configure a new MC peer group, as described in 40.4 “To configure an MC peer group” (p. 1330) .
5. Save the changes and close the form.
6. Choose the created PW port and click OK. The Select PW Port ID - PW Port Binding form closes.

50

Configure the required general parameters.

51

Configure the required parameters in the Encapsulation panel.

52

Select an egress shaper virtual port in the QoS panel.

53

Save the changes and close the form.

The PW port can be used in the Service Access Points of the following service types:

- VPRN (see 34.20 “To configure a tunnel interface on an IES or VPRN” (p. 1249))
- IES (see 34.20 “To configure a tunnel interface on an IES or VPRN” (p. 1249))
- VPLS Capture (see 74.26 “To configure a capture SAP” (p. 2049))

See the specific service chapter and forms when creating the required service access points. Specify the PW port as the Terminating Port when you create these service access points.

The PW port can be specified as the terminating port for L3 access interfaces of the following service types:

- VPRN (see 79.83 “To configure an L3 access interface on a VPRN site” (p. 2656))
- IES (see 78.28 “To configure an L3 access interface on an IES site” (p. 2472))

The PW port can be specified as the terminating port for L2 access interfaces of the VLL Epipe services. See 76.40 “To create a VLL L2 access interface on a terminating site” (p. 2174) .

The service access point and L2 or L3 access interfaces you create appears in the lists on the Service Access Points and L2 Access Interfaces or L3 Access Interfaces tabs of the PW Port (Edit) form.

54

Configure the Allow Fragmentation parameter if required.

55

Click Finish to save the configuration.

56

To view the service tunnel configuration after closing the form, enable the View the newly created tunnel parameter.

57

Close the form.

58

If the View the newly created tunnel parameter in Step 56 is enabled, the Tunnel (Edit) form opens with the newly-created service tunnel configuration displayed.

Use the following steps:

1. View or modify the configuration, if required.
2. Click on the Create a template button, if required.
3. Close the Tunnel (Edit) form.

59

Close the Manage Service Tunnels form.

END OF STEPS

33.10 To configure a service tunnel

33.10.1 Steps

1

Choose Manage→Service Tunnels from the NFM-P main menu. The Manage Service Tunnels form opens.

2

Select a service tunnel and click Properties. The Tunnel (Edit) form opens.

Note: The parameters and tabs that appear depend on the underlying transport of the service tunnel and the NEs on which the service tunnel is configured.

3

Configure the required parameters.

You can only configure the Allow Fragmentation parameter on a GRE tunnel.

4

Review the parameters in the Segment Routing panel. The values of the parameters in the Segment Routing panel cannot be modified. Only one check box (SR-ISIS, SR-OSPF or SR-TE-LSP) can be selected, indicating the type of LSP with which the service tunnel is associated.

5

Click on the Maintenance tab and configure the required parameters.

6

To configure an accounting policy, click on the Accounting tab and select an accounting policy.

7

To configure an associated service, click on the Associated Service tab and select an associated service.

8

To configure a port binding, click on the Port Binding tab.

1. Select a port in the Port panel.
2. Click Create in the PW Port Bindings panel. The PW Port Binding (Create) form opens.
3. Select an existing PW port in the PW Port ID panel or click Create. The PW Port (Create|Edit) form opens. Configure the required parameters and save your changes.

   See Step 49 of 33.9 “To create an IP/MPLS service tunnel” (p. 1190) for more information about how to create a PW port and to configure node redundancy for the PW port.

4. Configure the required parameters.
5. To configure an operational group to be monitored on the PW port binding of the service tunnel, select a monitored group in the Operational Group panel.

   Note:

   The operational state of the PW port binding follows the operational state of the operational group. You can view the Operational Group Down state cause indicator on the PW Port Binding (Edit) form.
6. To configure an HS override on the interface, select a secondary shaper in the PW SAP Secondary Shaper panel.
7. Save your changes and close the form.

9

To configure LSPs for an MPLS service tunnel, click on the LSPs tab.

1. Click Create. The Bind LSPs to Service Tunnel (SDP) step form opens.
2. Select an existing LSP.

   If no eligible LSP is available for binding to the service tunnel, the form provides actions buttons to:
   - Create Dynamic LSP—for details, see 31.11 “To create a Dynamic LSP” (p. 1126)
   - Create Static LSP—for details, see 31.10 “To create a static LSP” (p. 1124)
   - Create SR-TE LSP—for details, see 31.12 “To create a segment routing TE LSP ” (p. 1130)
3. Click Finish.

10

Save your changes and close the forms.

END OF STEPS

33.11 To configure an L2TPv3 service tunnel

33.11.1 Steps

1

Choose Manage→Service Tunnels from the NFM-P main menu. The Manage Service Tunnels form opens.

2

Click Create→L2TPv3 Tunnel (SDP) or select an existing L2TPv3 tunnel entry and click Properties. The L2TPv3 Tunnel (SDP) (Create) form opens.

3

Configure the parameters in the Identity panel.

If a range policy is applied to a service tunnel, a gray text box appears beside the ID parameter to indicate that a range policy is in effect.

If a format policy is applied to a service tunnel, a drop-down menu appears beside the object field during object creation to indicate that a format policy is in effect. When there is only one matching policy, the drop-down menu is dimmed. When there are multiple matching policies, use the drop-down menu to choose a policy. The sequence of the options in the drop-down menu are ordered by the policy Priority parameter.

4

Configure the parameters in the Source panel.

Use the following steps:

1. Select a source site.
2. Select a local end IP address.

   The local end IP address must be configured under a loopback network interface on the NE. The IPv6 Allowed and Loopback Enabled parameters must be enabled on the network interface of the NE.

5

Configure the parameters in the Destination panel.

Use the following steps:

1. Select a destination site.
2. Select a far end IP address.

   The destination end IP address must be configured under a loopback network interface on the NE. The IPv6 Allowed and Loopback Enabled parameters must be enabled on the network interface of the NE.

6

Configure the remaining parameters, as required.

7

Save your changes and close the form.

END OF STEPS

33.12 To create an SDP using a tunnel template

33.12.1 Purpose

Use this procedure to create an SDP using a tunnel template. Before you can create an SDP from a tunnel template, you must create the SDP tunnel template.

33.12.2 Steps

1

Choose Manage→Service Tunnels from the NFM-P main menu. The Manage Service Tunnels search form opens.

2

Click Create from Template. The Create Service Tunnel From Template form opens.

3

Select a tunnel template and click OK. The Create Tunnel from Template form opens.

4

Configure the required parameters.

5

Click on the SDP Bandwidth tab and configure the SDP Bandwidth Booking Factor parameter.

6

Click on the Maintenance tab and configure the required parameters.

7

Click on the Accounting tab and select an accounting policy for the service tunnel.

8

Save your changes and close the forms.

END OF STEPS

33.13 To create a tunnel selection profile

33.13.1 Steps

1

Choose Manage→Service Tunnels from the NFM-P main menu. The Manage Service Tunnels form opens.

2

Click Create→Tunnel Selection Profile or select an existing tunnel selection profile and click Properties. The Tunnel Selection Profile (Create | Edit) form opens.

3

Configure the required parameters.

As part of the configuration of a tunnel selection profile, you need to select a transport preference. The Transport Preference panel lists all the transport types in static priority order, followed by the PBB Only transport preference option. When configuring your transport preferences, take into account the following considerations:

- You can select either transport types or the PBB Only option. If you select a transport type, the PBB Only option is disabled. If you select the PBB Only option, the transport type options are disabled.
- You need to select one transport preference to be able to create a tunnel selection profile.
- The Allow Auto Tunnel Creation option becomes active only if you selected at least one transport type that supports the automatic tunnel creation. The automatic tunnel creation depends on the support of the selected transport type by both NEs.

Note: On selection of Mixed LSP mode transport type, if multiple tunnels with mixed-mode are operationally up and available, and if Auto SDP Binding is enabled in the service, then the SDP binding association takes following precedence: RSVP, LDP, BGP. This is irrespective of LSP type selected in Tunnel Selection Profile.

When determining what tunnel to use for binding, apply the following guidelines:

- If tunnels that meet the constraints are operationally up and available, then select them in static priority order.
- If no tunnels that meet the constraints are operationally up, then select available tunnels that are operationally down.
- If there are no tunnels, then create tunnels following the static priority order.

4

Select an SDP binding template for the profile, if required.

Note: An SDP binding template allows the NFM-P to use the configuration information contained in the template for the automatic creation of SDP bindings.

5

Click on the Tunnel Admin Groups tab to assign included and excluded admin groups to the profile.

6

In either of Included- or Excluded-Unassigned panels, click on the admin group that you want to include in the profile, and click on the Right arrow to move the selected admin group to the Assigned panel.

You can select multiple groups by holding down the Ctrl key and clicking on the groups.

If required, you can move an assigned admin group to the unassigned portion of the form by selecting the group and clicking on the Left arrow.

7

Save your changes and close the forms.

END OF STEPS

33.14 To configure an Ethernet tunnel endpoint

33.14.1 Steps

1

Choose Manage→Service Tunnels from the NFM-P main menu. The Manage Service Tunnels form opens.

2

Perform one of the following:

a. Click Create→Ethernet Tunnel Endpoint. The Select Network Elements form opens.

   Select a site on which to create an Ethernet tunnel endpoint and click OK. The Ethernet Tunnel Endpoint (Create) form opens.

b. Select an existing tunnel endpoint and click Properties. The Ethernet Tunnel Endpoint (Edit) form opens.

3

Configure the required parameters.

The Tunnel Endpoint ID and Site ID parameters are only configurable when you are creating a new Ethernet Tunnel Endpoint.

The Access Adapt QoS, Enable Per Forwarding Path Ingress Queue, and Operational Path Endpoint Threshold parameters are only displayed when the Protection Type parameter is set to Load Sharing.

4

Click on the Path Endpoints tab to configure path endpoints.

Use the following steps:

1. Click Create or select an existing path endpoint and click Properties. The Ethernet Tunnel Path Endpoint (Create|Edit) form opens.
2. Configure the required parameters.

   The Path ID parameter is only configurable when you are creating a new Ethernet tunnel path endpoint.

   The APS Command parameter is only displayed and configurable when you are configuring an existing Ethernet tunnel path endpoint and when the Protection Type parameter you configured in Step 3 is set to G8031 1:1. The associated Perform APS Command button is used to perform the selected command on the path endpoint.

3. Click on the Properties button in the Ethernet Path panel if you need to view or alter parameters on the Ethernet Path or configure a CFM Test. The Ethernet Path - Properties button is only displayed and selectable when you are configuring an existing Ethernet Tunnel Path Endpoint.
4. Click on the Port tab to configure a terminating port for a new Ethernet tunnel path endpoint.
5. Select a terminating port.
6. Configure the Control Tag (Outer Encapsulation Value) and Control Tag (Inner Encapsulation Value) parameters.
7. Save your changes and close the form.

5

Click on the MEPs tab to configure a MEP for a new Ethernet tunnel path endpoint.

Use the following steps:

1. Click Create. The MEP (Create) form opens.
2. Configure the required parameters.

   The Control MEP parameter is only displayed if the Interface Type parameter is set to Ethernet Tunnel Path Endpoint.

   The CCM Padding Packet Size (Bytes) parameter cannot be configured when the CCM interval parameter is set to 10 ms or 100 ms.

   When configuring a Down MEP on a Subscriber Group Interface SAP, the Direction parameter cannot be configured.
3. If the Maintenance Domain for this MEP has a Name Type of none and its Maintenance Association has a Name Format of icc-based, then the Y.1731 TEST and the AIS tabs will also be displayed. See 74.25 “To configure a MEP on a SAP” (p. 2047) for more information.
4. Save your changes and close the form.

6

Save your changes and close the form.

END OF STEPS

33.15 To configure an Ethernet tunnel

33.15.1 Purpose

Use this procedure to configure an Ethernet tunnel. Before you can create an Ethernet tunnel, you must configure an Ethernet tunnel endpoint. See 33.14 “To configure an Ethernet tunnel endpoint” (p. 1203) .

33.15.2 Steps

1

Choose Manage→Service Tunnels from the NFM-P main menu. The Manage Service Tunnels form opens.

2

Click Create→Ethernet Tunnel or select an existing Ethernet tunnel and click Properties. The Ethernet Tunnel (Create|Edit) form opens.

3

Configure the required parameters.

The Access Adapt QoS, Enable Per Forwarding Path Ingress Queue, and Operational Path Endpoint Threshold parameters are only displayed when the Protection Type parameter is set to Load Sharing.

4

Automatically configure a CFM MEG on an Ethernet tunnel path and MEPs for each Ethernet tunnel path endpoint.

Perform the following steps:

1. Configure the parameters in the Path CFM Defaults panel.
2. Select a maintenance domain.

   Note:

   The configuration performed here when creating an Ethernet tunnel object cascades to each Ethernet tunnel path that is subsequently configured.

5

Click on the Apply button. The Ethernet Tunnel form refreshes with additional tabs displayed.

6

Click on the Components tab.

7

Right-click on the Tunnel Endpoints object and choose one of the following:

a. Create Ethernet Tunnel Endpoint.

   Perform the following steps:

   1. See 33.14 “To configure an Ethernet tunnel endpoint” (p. 1203) to create an Ethernet Tunnel Endpoint. The endpoint will be listed as Endpoint A on the Ethernet Tunnel form in the Tunnel Endpoints Section.

      Note:

The parameter values specified in Step 3 are automatically applied in the Ethernet Endpoint form when creating an endpoint.

2. Repeat 1 to create Endpoint B.

b. Add Existing Endpoint. The Select Endpoints form opens.

Perform the following steps:

1. Select an endpoint and close the form.

   The endpoint is listed as Endpoint A on the Ethernet Tunnel form in the Tunnel Endpoints Section.

2. Repeat 1 to select Endpoint B.

   Note:

   The parameter values specified in Step 3 are not automatically applied to the selected Ethernet endpoint.

8

Right click on the Paths object and choose Create Ethernet Path. The Ethernet Path (Create) form opens.

9

Configure the required parameters.

10

Click on the Endpoints tab. Perform one of the following:

a. Manually configure the required parameters for endpoints A and B.

A path endpoint cannot be administratively enabled if one of the following is true:

- An operationally up same-fate SAP on the Ethernet tunnel endpoint does not have a tag configured for the path endpoint.
- The Control Tag (Outer Encapsulation Value), Control Tag (Inner Encapsulation Value), and Member Port parameters are not configured.

b. Select existing path endpoints for endpoints A and B. The endpoint parameters are automatically populated.

11

Click on the Intermediate Services tab to view and specify the intermediate services for the Ethernet path. The services that you add to the list (or that already appear there) are in the order of proceeding from Endpoint A to Endpoint B. Perform the following to add an intermediate service:

Perform the following steps:

1. Click Create. The Select Service form opens.
2. Click on the Search button to display a list of intermediate services available to include in this path. Only VLL services can be included.

3. Select the required service and click OK.

   The NFM-P does not perform a validation to confirm whether the selected service is actually along the path between the two path endpoints.

   If you have an intermediate service highlighted in the list and want to add another service immediately above it, click on the Insert Component button rather than the Create button. The Create button places an additional service at the bottom of the list, whereas the Insert Component button places it directly above a highlighted service.

   You can change the ordering of intermediate services in the list by selecting a particular service and using the Move Up or Move Down buttons.

12

Click on the CFM Continuity Check tab to configure a CFM Continuity Check test for each path.

You must complete the following steps before selecting a test:

- Create a maintenance domain with the Name Type parameter set to None. See Chapter 91, “Ethernet CFM” for more information.
- Create a CFM continuity check test. See 91.20 “To create and run a Continuity Check OAM diagnostic test from the STM” (p. 3122) for information.

13

In the CFM Test panel, select a CFM test.

14

Perform one of the following:

a. Perform one of the MEP auto creation functions:
   - Click Run Continuity Check Protocol to create maintenance associations and local and remote MEPs. Any existing remote MEPs that do not match the local MEPs are deleted. MEPs are turned up and CCM messages are enabled, and the control MEP property is set on the MEPs.
   - Click Create MEPs to create local MEPs. Any existing remote MEPs that do not match the local MEPs are deleted.

b. Continue to Step 15 . Perform the Run Continuity Check Protocol or Create MEPs function at a later date.

15

If required, click on the MEP tab to display the MEP form and select the check box to configure the Control MEP parameter.

16

Save your changes and close the form.

17

If the Protection Type parameter was set to G8031 1:1 in Step 3 , repeat Step 8 to Step 16 for the other path.

If the Protection Type parameter was set to Load Sharing in Step 3 , repeat Step 8 to Step 16 for all paths.

18

Click Apply. The Path Id, Operational State, and CC Protocol State parameters are updated and the path endpoints with this specific configuration are sent to the NEs.

The CC protocol state appears under the global path (in the navigation tree and on the CFM Continuity Check form). The CC protocol state displays the state of the continuity check protocol running between the MEPs of the two endpoints of the path.

19

Save your changes and close the form.

END OF STEPS

33.16 To configure an Ethernet Ring Element

33.16.1 Steps

1

Choose Manage→Service Tunnels from the NFM-P main menu. The Manage Service Tunnels form opens.

2

Perform one of the following:

a. Click Create→Ethernet Ring Element. The Select Network Elements form opens.

   Select a site for the Ethernet ring element and click OK. The Ethernet Ring Element (Create) form opens.

   You can create multiple ring elements by selecting multiple sites.

b. Select an existing ring element and click Properties. The Ethernet Ring Element (Edit) form opens.

3

Configure the required parameters.

The ID and Site ID parameters are only configurable when you are creating a new Ethernet ring element.

4

Configure the parameters for a sub-ring, if required.

5

Click on the Path Endpoints tab to configure the path endpoints for the Ethernet ring element.

6

Click Create or select an existing path endpoint and click Properties. The Ethernet Ring Path Endpoint (Create|Edit) form opens.

7

Configure the required parameters.

The Path ID parameter is only configurable when you are creating a new Ethernet Ring Path Endpoint.

8

Click on the Port tab.

Perform the following steps:

1. Select a terminating port for the ring path endpoint.
2. Configure the R-APS Tag (Outer Encapsulation Value) and R-APS Tag (Inner Encapsulation Value) parameters.

9

Save your changes and close the forms.

END OF STEPS

33.17 To configure an OmniSwitch Ethernet Ring Element

33.17.1 Important information

Configuration requirements for OmniSwitch Ethernet ring elements vary depending on the chassis type and release, and whether the service is a stacked VLAN or standard VLAN. See the NE documentation for information about the configuration requirements for a specific chassis type and release.

For ERP created for stacked VLAN services, only NNIs (network ports) can be added as ERP path endpoints. You must use a port or LAG in network mode as the endpoint. To configure a port or LAG in network mode, see 16.29 “To change the port mode” (p. 611).

For stacked VLAN services on some chassis types and releases, the network port must be configured as an ERP binding port, with the Bind Type parameter set to ERP, before configuration as an ERP ring element. However, for some chassis types and releases, a network port or LAG does not have to be configured as an ERP binding port before it is added to the ring.

33.17.2 Steps

1

Perform this step if the chassis type you are configuring requires preliminary configuration of an ERP binding on the network port.

Configure the required network ports with an ERP binding. For each port:

1. Open the port properties form; see 16.24 “To configure Ethernet ports” (p. 599).
2. Click on the Network Interfaces tab, then on the L2 Network Interfaces subtab.
3. Select the required interface in the list and click Properties. The L2 Network Interface (Edit) form opens.
4. Click on the VLAN tab.
5. If the VLAN association is the same as the one in which the ERP binding is required, delete it.
6. Click Create. The VLAN Bindings (Create|Edit) form opens.
7. Select a VLAN, and set the Bind Type parameter to ERP.
8. Save your changes and close the forms.

2

Choose Manage→Service Tunnels from the NFM-P main menu. The Manage Service Tunnels form opens.

3

Perform one of the following:

a. Click Create→Ethernet Ring Element. The Select Network Elements form opens.

   Select an OmniSwitch site for the Ethernet ring element and click OK. The Ethernet Ring Element (Create) form opens.

   You can create multiple ring elements by selecting multiple sites.

b. Select an existing ring element on an OmniSwitch site and click Properties. The Ethernet Ring Element (Edit) form opens.

4

Configure the required parameters.

The ID and Site ID parameters are only configurable when you are creating a new Ethernet ring element.

5

Click on the Path Endpoints tab to configure the path endpoints for the Ethernet ring element.

6

Click Create or select an existing path endpoint and click Properties. The Ethernet Ring Path Endpoint (Create|Edit) form opens.

7

Configure the required parameters.

The Path ID parameter is only configurable when you are creating a new Ethernet ring path endpoint.

8

Click on the Port tab.

9

Select a terminating port for the Ethernet ring path endpoint.

If you are configuring a standard VLAN:

- For some chassis types and releases, the port must be added as a tagged access interface to the corresponding VLAN before being selected as a member port for the ERP.
- For some chassis types and releases, when a port is added in a ring, it is automatically added to the corresponding VLAN as a tagged port.

See the NE documentation for information about the configuration requirements for a particular chassis type and release.

You must select a ring element for each site that will be part of the Ethernet ring.

The Ethernet ring can only have one element configured as an RPL owner or None. This is configured using the Ring Protection Link Type parameter for the element.

The Ethernet ring path can be a LAG or port.

10

Configure the Path ID parameter.

11

Save your changes and close the form.

12

Repeat Step 6 to Step 11 to create another Ethernet ring path endpoint, if required.

If only one Ethernet ring path endpoint is created, the Ethernet ring element is created as a sub-ring.

13

Save your changes in the Ethernet Ring Element form.

14

Perform one of the following:

a. If you are configuring an Ethernet Ring Element on an OmniSwitch NE that supports G.8032v1, continue to Step 15 .

b. If you are configuring an Ethernet Ring Element on an OmniSwitch NE that supports G.8032v2, go to Step 16 .

15

Click on the Protected Services tab to view and specify the services for the Ethernet path. The services that you add to the list (or that already appear there) are in the order of proceeding from Endpoint A to Endpoint B. Perform the following to add a standard or stacked VLAN service:

1. Click Add. The Select Service form opens.
2. Select the required service and click OK.

   The NFM-P does not perform a validation to confirm whether the selected service is actually along the path between the two path endpoints.

   If ERP is created with standard VLAN service, then standard VLAN services for Release 6.4.4/6.6.2 NEs and IPM Enterprise VLAN services for Release 6.6.2 NEs can be added as Protected services.

   If ERP is created with stacked VLAN service, then stacked/IPM stacked VLAN services for 6.4.4/6.6.2 NEs can be added as Protected Services.

16

To edit or view protected services, click on the Properties button of a selected standard VLAN service. The Ethernet Ring Element (Edit) form opens.

17

Click on the Protected Services tab. Select a service and click Properties. The Protected Services (Edit) form opens. Click on the Properties tab to edit or view the protected service.

18

Save your changes and close the form.

END OF STEPS

33.18 To create an Ethernet G.8032 ring

33.18.1 Steps

1

Choose Manage→Service Tunnels from the NFM-P main menu. The Manage Service Tunnels search form opens.

2

Click Create→Ethernet Ring. The Ethernet Ring (Create) form opens.

3

Configure the required parameters.

If you enable the Auto Create Global MEG parameter, the ETH-CFM tab displays all associated Global MEGs created for this Ethernet ring.

If path discovery generates Ethernet ring paths, then the Auto Create Global MEG, Maintenance Domain ID, CCM Interval, and Run CCM on Create parameters are not propagated to the per-path CFM Continuity Check tab configuration. Auto-generation of a MEG and/or MEPs can be configured on a per-path basis.

Alternatively, if path discovery is not operational (that is, no Ethernet ring paths are populated into the Ethernet ring), then Path CFM Defaults parameters on the General tab are propagated and a MEG and/or MEPs are generated upon manual creation of the Ethernet ring paths.

4

Click Apply. The Ethernet Ring (Edit) form opens.

5

Click on the Components tab.

6

Right-click on Ring Elements and choose one of the following:

a. Create Ethernet Ring Element.

   Perform the following steps:

   1. Create an Ethernet ring element as described in 33.16 “To configure an Ethernet Ring Element” (p. 1208) . The element displays on the Components tab on the Ethernet Ring form.

      You must create a ring element for each site that will be part of the Ethernet ring.

      The Ethernet ring can only have one element configured as an RPL owner and one element configured as an RPL neighbor. This is configured using the element’s Ring Protection Link Type parameter.

      The parameter values specified in Step 3 are initially populated in the Ethernet Ring Element form when creating a ring element from the Components tab. However, you can change these as required.

   2. Repeat 1 to create the other required ring elements.

      You can create all the ring elements required for the ring in one step; see 33.16 “To configure an Ethernet Ring Element” (p. 1208) .

   3. Go to Step 7 .

b. Add Existing Element.

   Perform the following steps:

   1. The Select Element form opens.
   2. Click Search, select an element, and click OK.

      The element displays on the Components tab on the Ethernet Ring form.

You must select a ring element for each site that will be part of the Ethernet ring.

The Ethernet ring can only have one element configured as an RPL owner and one element configured as an RPL neighbor. This is configured using the element's Ring Protection Link Type parameter.

When you add an existing Ethernet endpoint, the parameter values specified in Step 3 are not populated into the properties of that endpoint.

3. Repeat 1 to 2 to select the other required ring elements.

7

Create an Ethernet path.

Perform the following steps:

1. Right-click on Paths and choose Create Ethernet Ring Path. The Ethernet Path (Create) form opens.

   You must create a path for each element in the ring. Each element (site) in the ring will therefore have two endpoints from two different paths associated with it.
2. Configure the required parameters.
3. Click on the Endpoints tab to configure the endpoints for the path.

   One and only one endpoint within the entire Ethernet ring must have its Ring Protection Link Type parameter configured as Ring Protection Link End. All other endpoints in the Ethernet ring must have this parameter set to a value of Normal.
4. Configure the required parameters for endpoints A and B.

   Path endpoints cannot be administratively enabled if:
   - the R-APS Tag or Member Port parameters are not configured
   - a MEP is not configured on the path endpoint
5. Select an available path endpoint on endpoints A and B.

8

Click on the CFM Continuity Check tab to configure a CFM Test for the path.

9

Modify the parameters in the Global MEG Auto Creation panel, if required.

If path discovery generates Ethernet ring paths, then these parameters are not propagated to individual paths. Auto-generation of a MEG and/or MEPs may be configured on a per-path basis.

10

Click Select. The Select CFM Test form opens. Perform one of the following:

a. Select the required CFM test.

b. Click Create. The Global Maintenance Entity Group (Create) form opens.

The Initial CCM Interval for the CFM test you select or create must be set to 10 ms or 100 ms, otherwise the subsequent MEP creation will fail.

See 91.20 “To create and run a Continuity Check OAM diagnostic test from the STM” (p. 3122) for information about creating the test.

11

Click on the Intermediate Services tab to view and specify the intermediate services for the Ethernet path. The services in the list are in an order proceeding from endpoint A to endpoint B.

To add an intermediate service:

1. Click Create. The Select Service form opens.
2. Click Search, select the required service, and click OK.

   The Select Service form closes and the service is displayed in the list on the Intermediate Services tab.

   The NFM-P does not perform a validation to confirm whether the selected service is along the path between the two path endpoints.
3. Repeat 1 to 2 to add another intermediate service, if required.

   If you have an intermediate service highlighted in the list and want to add another service immediately above it, click Insert Component rather than Create. Clicking Create places an additional service to the bottom of the list, whereas clicking Insert Component places it directly above a highlighted service.

   You can change the ordering of intermediate services in the list by selecting a particular service and using the Move Up or Move Down buttons.

12

Perform this step if you need to create interconnects for sub-rings. The interconnects connect a sub-ring to the main ring.

Perform the following steps:

1. Right-click on Interconnects and choose Create Ethernet Ring Interconnect. The Ethernet Ring Interconnect (Create) form opens.
2. Configure the required parameters.
3. Configure the Element A end node for the interconnect.

   In the Element A panel, select a site, and configure the required parameters.
4. Configure the Element B end node for the interconnect.

   In the Element B panel, select a site, and configure the required parameters.

13

To automatically create a control service for the Ethernet G.8032 ring, go to Step 14 . To manually create the control service, go to Step 15 .

14

To automatically create a control service for the Ethernet G.8032 ring:

Perform the following steps:

1. Click Create Control Service. The Create Control Service form opens.
2. Select a customer.
3. Configure the required parameters if your Ethernet ring is an Ethernet Virtual link sub-rings.
4. Select a template.

   Only use the Control Service Template if you need to customize the parameters associated with the sites or SAPs such as the description or name.

   If you need to create a Control Service Template, choose Manage→Templates from the NFM-P main menu. Click Browse Example and select the Ethernet ring example.

   If a template is not specified, all created objects use their default property values.
5. Save your changes and close the form.

15

Manually create a control service for the Ethernet ring if you did not auto-create one in Step 14 .

Perform the following steps:

1. Perform 77.5 “To create a VPLS” (p. 2249) to create a control service on a VPLS.
2. Perform 77.67 “To create a VPLS or MVPLS L2 access interface” (p. 2332) to create an L2 access interface for each path endpoint in the Ethernet ring. Each site in the control VPLS must have two control L2 access interfaces.

   When creating the L2 access interfaces, ensure the following requirements:
   - The Terminating Port and Encap Type parameters must have the same values used to create the particular path endpoint as in Step 7 .
   - The Outer Encapsulation Value and Inner Encapsulation Value parameters for the port in each L2 access interface must be set to the same value as the R-APS Tag (Outer Encapsulation Value) and R-APS Tag (Inner Encapsulation Value) parameters, respectively, that you used for the particular path endpoint in Step 7 . This defines the interface as a control SAP for the Ethernet ring.

16

Perform 77.5 “To create a VPLS” (p. 2249) to create data services on the VPLS required for the Ethernet ring. The data service must be a regular VPLS, I-VPLS, or B-VPLS type.

17

To automatically connect the data services to the Ethernet ring, go to Step 18 . To manually connect the data service, go to Step 19 .

18

Automatically connect the data service to the Ethernet ring.

Perform the following steps:

1. Select one or more Site icon(s) associated with the data service and choose Connect to Ethernet Ring from the contextual menu. The Connect to Ethernet Ring form opens.

   When you use the Connect to Ethernet Ring function to connect a data service to an Ethernet ring configured with a transit service, the NFM-P creates VLAN-specific SAPs for the data service only on the ring site for which Connect to Ethernet Ring is selected. The transit SAPs on the ring transparently forward traffic through other sites on the service.
2. Select an Ethernet ring.
3. Configure the required parameters.
4. Select a data site template.

   Only use the data site template if you need to create an I-VPLS or B-VPLS type data service.

   If you need to create a data site template, choose Manage→Templates from the NFM-P main menu. Click Browse Example and select the Ethernet ring example.

   If a template is not specified, all created objects use their default property values.
5. Save your changes close the form.

19

To manually connect the data service to the Ethernet ring, perform 77.67 “To create a VPLS or MVPLS L2 access interface” (p. 2332) to create an L2 access interface for each path endpoint in the Ethernet ring. Each site in the data service must have at least two L2 access interfaces.

When creating the L2 access interfaces, the Terminating Port and Encap Type parameters must have the same values that were used to create the particular path endpoint in Step 7 .

END OF STEPS

33.19 To create an Ethernet G.8032v2 ring on an OmniSwitch

33.19.1 Steps

1

Choose Manage→Service Tunnels from the NFM-P main menu. The Manage Service Tunnels search form opens.

2

Click Create→Ethernet Ring. The Ethernet Ring (Create) form opens.

3

Configure the required parameters.

If you set the Service Composition parameter to VPLS or VPLS and VLAN, configure the following parameters:

- Hold Time Down (centiseconds)
- Hold Time Up (deciseconds)
- Revert Time (seconds)
- Guard Time (deciseconds)
- Compatible Version

4

If the Service Composition parameter was set to VLAN or VPLS and VLAN, perform the following steps to configure control service defaults:

Perform the following steps:

1. Configure the VLAN Application Type parameter.
2. Select a VLAN control service.

5

Click Apply. The Ethernet Ring (Edit) form opens.

6

Click on the Components tab.

7

Right-click on Ring Elements and choose one of the following items:

You must create a ring element for each site in the Ethernet ring, and a path for for each of these ring elements. Each element will therefore have two endpoints from two different paths associated with it.

The Ethernet ring can only have one element configured as an RPL owner and one element configured as an RPL neighbor. This is configured using the element's Ring Protection Link Type parameter.

The parameter values specified in Step 3 are initially populated in the Ethernet Ring Element form when creating a ring element from the Components tab, however, you can change these as required.

Only one endpoint within the entire Ethernet ring must have its Ring Protection Link Type parameter configured as Ring Protection Link End. All other endpoints in the Ethernet ring must have this parameter set to Normal.

a. Create Ethernet Ring Element with path endpoints.

   Perform the following steps:

   1. See 33.17 "To configure an OmniSwitch Ethernet Ring Element" (p. 1209) for information

about creating an Ethernet ring element with path endpoints on OmniSwitch NEs. The element is displayed on the Components tab in Ethernet Ring (Edit) form.

2. Repeat 1 to create more required ring elements with path endpoints.

b. Add an existing Ethernet Ring Element.

Perform the following steps:

1. The Select Element form opens.
2. Click Search and select an element.
3. Repeat 2 to select the other required ring elements.

8

Right-click on Paths and choose Properties. The Ethernet Ring Paths (Edit) form opens.

9

Click on the CFM Continuity Check tab to configure a CFM test for the path.

10

Configure the Auto Create Global MEG parameter.

11

Select a maintenance domain.

12

Configure the CCM Interval and Run CCM On Create parameters.

13

Click Select in the CFM Test panel. The Select CFM Test form opens. Perform one of the following:

a. Select the required CFM test.

b. Click Create. The Global Maintenance Entity Group (Create) form opens.

See 91.20 “To create and run a Continuity Check OAM diagnostic test from the STM” (p. 3122) for information about creating the test.

The Initial CCM Interval for the CFM test that you select or create must be set to 10 ms or 100 ms, otherwise the subsequent MEP creation fails.

14

Save your changes and close the forms.

END OF STEPS

33.20 To configure a transit service on an Ethernet ring

33.20.1 Purpose

Perform this procedure to create a transit service on a VPLS G.8032 Ethernet ring. The Ethernet ring must already exist; see 33.4.2 “Transit services” (p. 1181) in 33.4 “Ethernet G.8031 tunnels” (p. 1180) .

Transit SAPs apply only on QinQ ports.

33.20.2 Steps

1

Choose Manage→Service Tunnels from the NFM-P main menu. The Manage Service Tunnels form opens.

2

Choose Ethernet Ring (Ethernet Ring) and click Search. A list of Ethernet ring services is displayed.

3

Choose an Ethernet ring and click Properties. The Ethernet Ring (Edit) form opens.

4

Click Create Transit Service.

5

Select a customer from the Select Customer form.

6

Configure the required parameters.

The default value for these parameters is *, or 4095. When you create a transit service, you must leave the parameters at the default value.

7

Select a transit service template.

Only use the transit service template if you need to customize the parameters associated with the sites or SAPs, such as the description or name.

If you need to create a transit service template, choose Manage→Templates from the NFM-P main menu. Click Browse Example→Ethernet Ring.

If a template is not specified, all created objects use their default property values.

8

Click OK. A dialog box appears.

9

Perform one of the following:

a. Click Yes to view the properties of the service. The properties form for the transit service opens. View the properties, and close the form. The Ethernet Ring (Edit) form is displayed.

b. Click No. The Create Transit Service form closes and the Ethernet Ring (Edit) form is displayed.

10

Discover the transit service.

Perform the following steps:

1. Click on the Flow-through Services tab. A list of services is displayed.
2. Click Discover Services. The transit service is added to the list.

11

Save your changes and close the form.

You can combine transit services using the composite service functionality in the NFM-P. Composite services are created automatically when Auto Discover Composite Services is enabled in System Preferences, or manually using the Rediscover Composite Services function. See Chapter 85, “Composite service management” for more information about composite services.

END OF STEPS

33.21 To manually update data services on an Ethernet ring

33.21.1 Purpose

Use this procedure update the data VPLS for an Ethernet ring configuration after adding NEs in the Ethernet ring.

33.21.2 Steps

1

Choose Manage→Service Tunnels from the NFM-P main menu. The Manage Service Tunnels form opens.

2

Choose Ethernet Ring (Ethernet Ring) and click Search. A list of Ethernet ring services is displayed.

3

Choose an Ethernet ring and click Properties. The Ethernet Ring (Edit) form opens.

4

Click on the Transported Services tab.

5

Click Update Data Services.

An information window opens, indicating the number of VPLSs being checked. Click Ok.

6

Close the form.

END OF STEPS

33.22 To discover service tunnels

33.22.1 Purpose

Use this procedure to list all service tunnels objects (SDPs, Ethernet rings, Ethernet tunnels, other services, and so forth) that are currently used by the service you are querying.

33.22.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Click Search, choose a service, and click Properties. The Service (Edit) form opens.

3

Click on the Service Tunnels tab.

4

Click Discover Service Tunnels to re-populate the list.

Any previously-discovered service tunnels on the service are removed and an on-demand re-discovery of these tunnels is triggered.

A confirmation dialog appears when the discovery is complete.

5

Click OK.

6

Click on an item in the list and click Properties to view the object information.

7

Close the form.

END OF STEPS

33.23 To discover flow-through services

33.23.1 Purpose

Use this procedure to list all other services that are currently using the object you are querying as a service tunnel. These are collectively referred to as flow-through services. See the "Service tunnel overview" (p. 1177) section for a list of applicable service tunnel objects.

33.23.2 Steps

1

Open the configuration form of the object that you want to examine.

2

Click on the Flow-through Services tab.

3

Click Discover Flow-through Services to re-populate the list.

Any previously discovered flow-through services are removed and a manual re-discovery of these services is triggered.

A confirmation dialog appears when the discovery is complete.

4

Click OK.

5

Click on a service in the list and click Properties to view the service information.

6

Close the form.

END OF STEPS

33.24 To view and manage service tunnels and tunnel elements

33.24.1 Steps

1

Choose Manage→Service Tunnels from the NFM-P main menu. The Manage Service Tunnels form opens.

2

Click Search, choose a service tunnel, and click Properties. The Tunnel (Edit) form opens.

If you searched on Service (or on a specific service type) used as a service tunnel, be aware that the generated list contents are subject to change, depending on current usage and on when the last on-demand (manual) discovery was conducted. There is no auto-discovery for this listing.

In other words, only those services will be listed that were known to be used as service tunnels when the last discovery was conducted. Because the discovery is only updated on user demand, the list of services generated here may not be up to date.

33.22 “To discover service tunnels” (p. 1222) details the on-demand discovery of service tunnels (including a service used by another service as a tunnel).

3

View or configure the parameters, as required.

View the States and State Cause indicators, if applicable, for troubleshooting information, such as a failed OAM diagnostic.

4

Select a tunnel and click Rediscover Destination Site as needed to rediscover the service tunnel destination. If the tunnel selected has its Terminating Site ID set with an interface IP address and a managed node is found that owns that IP address, the rediscovery will update the Terminating Site ID with the node ID.

5

Save the changes and close the forms.

END OF STEPS

33.25 To view the service tunnel topology

33.25.1 Steps

1

Choose Application→Service Tunnel Topology from the NFM-P main menu. The Service Tunnel Topology map opens.

2

View the topology map as required. See Chapter 4, “Topology map management” for information about using topology maps.

3

Close the topology map.

END OF STEPS

33.26 To run an OAM validation test on a service tunnel

33.26.1 Purpose

Use this procedure to run an OAM validation test on a service tunnel. An OAM validator test suite must be created for the tested entity; see Chapter 89, “Service Test Manager” .

Note: Alternatively, you can also run an OAM validation test on the service tunnel by performing a one-time validation; see 90.55 “To run a one-time validation test on a service” (p. 3084) .

33.26.2 Steps

1

Choose Manage→Service Tunnels from the NFM-P main menu. The Manage Service Tunnels form opens

2

Click Search, choose a service tunnel, and click Properties. The Tunnel (Edit) form opens.

3

Click Validate.

If an OAM validator test suite is not associated with the service tunnel, a dialog box appears. Click OK, choose an OAM validator test suite, and click OK.

4

View the State Cause indicators. When the validation test fails, a check mark appears beside the OAM Validation Failure indicator.

5

Click on the Tests tab, then on the Tested Entity Result tab.

6

Choose an entry and click Properties. The Tested Entity Result (Edit) form opens.

7

Click on the Results tab to display the validation test results.

8

If you need to compare two test results from the same type of test, choose the two test results and click Compare. The Difference form opens. Otherwise, go to Step 10 .

9

Compare the test results.

10

Close the forms.

END OF STEPS

33.27 To perform an Ethernet G.8032 ring audit

33.27.1 Steps

1

Choose Manage→Service Tunnels from the NFM-P main menu. The Manage Service Tunnels form opens.

2

Click Search and choose one of the following:

a. To perform a global Ethernet ring audit, go to Step 3 ,

b. To perform a local Ethernet ring audit, go to Step 6 .

3

Click Global Ring Audit. The Global Ring Audit dialog box appears.

4

Click Yes. The dialog box closes, and the Ring Audit progress window appears. When the audit completes, a notification box appears.

5

Click Yes. Go to Step 8 .

6

Select an Ethernet ring and click Properties. The Ethernet Ring (edit) form opens.

7

Click Ring Audit. When the audit completes, a warning or information window appears displaying the results of the audit.

8

If the audit encountered any problems that could not be resolved, an alarm is raised against the Ethernet ring listing the problems. To clear the alarm, resolve the problems and then repeat the audit.

END OF STEPS

34 IPsec

34.1 Overview

34.1.1 IPsec overview

You can use the NFM-P to configure IPsec sessions and the Security Associations (SAs) that are required in a bidirectional IPsec tunnel. You can configure multiple IPsec tunnels for a VPRN.

NFM-P IPsec session configuration supports the following:

- encryption methods such as DES, 3DES, AES-128, AES-192, and AES-256
- authentication and hashing methods such as HMAC-MD5, HMAC-SHA1, and HMAC-SHA2
- key distribution methods such as IKE shared secret with PFS, and manual exchange
- key generation algorithms such as Diffie-Hellman
- IPsec modes
- shared secret authentication
- NAT traversal for IKEv1 and IKEv2
- DPD for the IPsec tunnel

An IPsec VPN service includes IPsec tunnels that terminate on IES or VPRN IPsec gateways. These gateways support L3 forwarding through an interface that connects to an IPsec tunnel. You can use the NFM-P to configure VPRN services to which individual hosts can connect over the Internet to an IES or VPRN IPsec gateway. You can configure one or more tunnel interfaces in a VPRN service, and can configure multiple tunnel security profiles for each tunnel interface.

IKE policies are used to negotiate IPsec SAs between IPsec peers. An SA is a relationship between two or more IPsec peers that defines how the peers communicate securely. IKE policies are exchanged between IPsec peers to negotiate a secure communication channel; the policies specify how traffic is encrypted between source and destination sites in an IPsec VPN by establishing a shared security policy using authentication keys.

IPsec transform policies specify the protocol for the IPsec authentication header and the encryption protocol for the Encapsulating Security Payload (ESP) and define the attributes that are used to secure the data.

IPsec client databases provide a mechanism to create secure LAN-to-LAN tunnels between an IPsec gateway and multiple VPN clients. The system checks the client database during tunnel authentication and the database returns client credentials, a private VRF ID, private interface name, and other IPsec parameters.

See Chapter 49, “Policies overview” for general information about policies.

After an IPsec peer initiates an IPsec session, there are two main phases:

- authentication and protection of IPsec peer identities and negotiation of matching IKE SA policies between peers to establish a secure channel for negotiating IPsec SAs in the next phase
- IPsec SA parameter negotiation and establishment of matching peer SAs

After the second phase, the IPsec peers exchange data over the IPsec tunnel according to the IPsec parameters in the IKE and IPsec transform policies.

You can create a tunnel template to configure shared IPsec transforms and IKE policies. Each IPsec peer configuration can include the following:

- one or more configured IPsec transforms
- one IKE policy
- one unique IPsec tunnel
- one tunnel filter defined in the IPsec tunnel configuration

Each IPsec tunnel between IKE peers is identified by a unique remote peer IP address or a unique local IP address.

You can use the IPsec Application Function Manager to create and manage end-to-end IPsec components to form a secure VPN.

The NFM-P XML API supports IPsec VPN configuration.

34.1.2 IPv6 IPsec

OSPFv3 authentication requires IPv6. IPv6 IPsec requires the following:

- IPsec transport mode — required because the NE acts as an OSPFv3 authentication host
- IPsec static security association — defines the SPI values, algorithms, protocol, and keys to be used, and requires the same configuration at each end of the tunnel
- AH and ESP
- MD5, SHA1, and SHA2

34.1.3 BFD

You can use BFD for static LAN-to-LAN IPsec tunnels on supporting NEs.

Consider the following when implementing BFD over static LAN-to-LAN IPsec tunnels:

- You can have only one BFD session between a source/destination address pair.
- Each tunnel can be associated with only one BFD session. However, one or more tunnels, to a maximum of 500, can be associated with the same BFD session.
- If one BFD session is associated with multiple tunnels, the tunnel that carries the BFD traffic must be operationally up before any of the other tunnels can be operationally up.
- When the NFM-P does not receive BFD packets from a peer before the detection time expires or a signal down notification is sent from a remote peer, the BFD session is considered down.

  When the NFM-P sets the associated IPsec tunnels in a down state, the NFM-P performs the following:
  - sends a Delete Payload message to each remote peer from each associated tunnel and SA
  - removes the state and table entries from each associated tunnel and SA

34.1.4 Temporary MTU

You can configure an IPSec tunnel to propagate ICMP messages for use in temporary MTU learning by configuring the parameters in the IP Fragmentation, ICMP Message Generation, and ICMPv6 Generation panels of an IPSec Tunnel, IP/GRE Tunnel, or IPSec Tunnel template.

34.2 IPsec VPNs

34.2.1 Overview

You can create and manage the association between IPsec components, and public and private services, to form a secure VPN. See 34.2.3 “Typical applications for IPsec corporate services” (p. 1232) for the typical applications of an IPsec VPN.

You use the IPsec VPN step forms to perform the following:

- Configure the corporate service type.
- Enable the link between the corporate and secure service.
- Choose an NE service site.
- Configure the secure VPRN service.
- Configure the delivery service.
- Choose the tunnel group.
- Create the policy.
- Deploy the IPsec VPN.

34.2.2 Tunnel types

The following table lists the tunnel types for an IPSec VPN in different products.

Table 34-1 Tunnel types for an IPsec VPN

Tunnel type	7705 SAR	7750 SR	7450 ESS in mixed mode	7210 SAS
Dynamic (site-to-site)		✓	✓	
Dynamic (soft client)		✓	✓	
Static	✓	✓	✓	✓

The NFM-P creates the following after the successful creation of an IPsec VPN, regardless of the tunnel type:

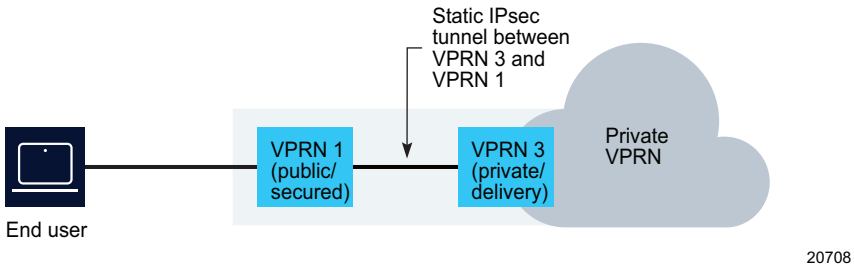
- a secure VPRN service and NE sites
- the IES or VPRN delivery service and NE sites
- if you specify that the secure and corporate services are to be linked, a composite service that contains the corporate and secure services

The NFM-P performs specific configuration actions after the successful creation of an IPsec VPN, depending on the tunnel type; see 34.26 “To assign policies and configurations for a dynamic site-to-site IPsec VPN” (p. 1264) to 34.28 “To assign policies and configurations for a static IPsec VPN” (p. 1266) for information.

34.2.3 Typical applications for IPsec corporate services

The following figure shows a public VPRN service that is associated with a private VPRN service. The private service belongs to a larger private VPRN. The public service can be a VPRN or IES service. The private service can only be a VPRN service.

Figure 34-1 Static IPsec tunnel



The following figure shows two public L3 VPRNs, VPRN 1 and VPRN 2, which are connected to the private, secure service VPRN 3 through an IPsec gateway. The public services can be VPRN or IES services. The private service can only be a VPRN service.

Figure 34-2 IPsec tunnels for a site

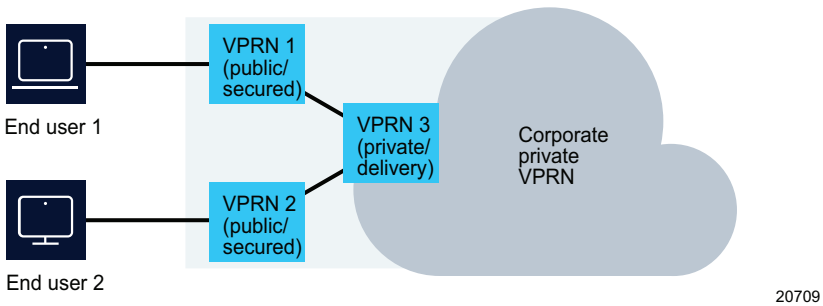


Figure 34-3, “IPsec tunnels for multiple sites” (p. 1233) is the same as Figure 34-1, “Static IPsec tunnel” (p. 1232), but Figure 34-3, “IPsec tunnels for multiple sites” (p. 1233) shows IPsec tunnels across multiple sites. Site A, Site B, and Site C are part of the private service VPRN 4. For the site, there is a secure IPsec tunnel between a public service and a private service. The public services can be L3 VPRN or L3 IES services. The private service can only be a VPRN service.

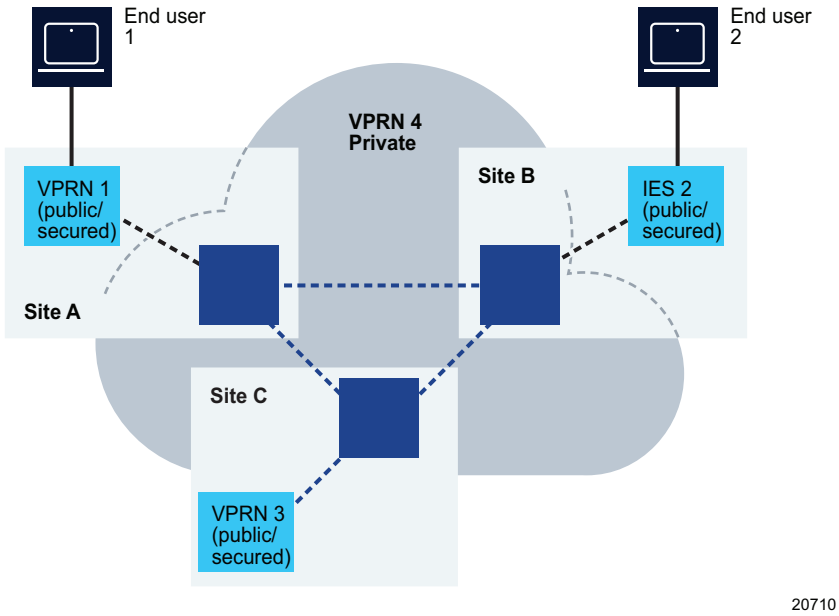
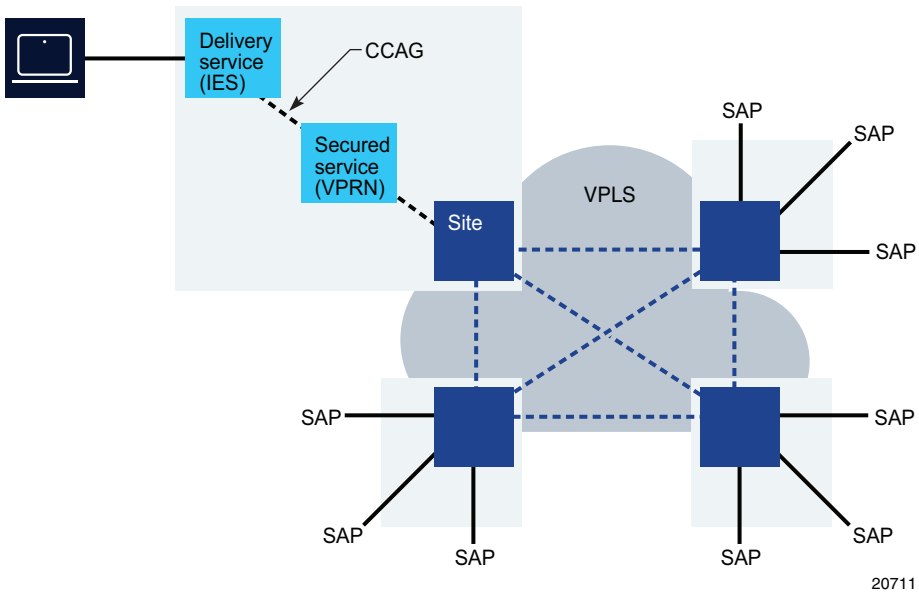
Figure 34-3 IPsec tunnels for multiple sites



The following figure shows a private VPRN that is connected to a corporate VPLS. The public IES and private VPRN service connect to the VPLS through a CCAG or SCP. A CCAG connects the private VPRN to the VPLS.

Figure 34-4 IPsec VPN in a corporate network



34.3 Multichassis IPsec

34.3.1 Overview

Multichassis (MC) IPsec provides a stateful failover mechanism for IPsec tunnels between two 7750 SRs or 7450 ESSs in mixed mode—an active NE and a standby NE. Stateful failover enables IPsec traffic to continue being forwarded without interruption in the event of a failure. MC IPsec provides protection for NE failure or MS-ISA failure. When an active NE fails, the IPsec tunnels failover to the standby peer without having to re-establish the session. The failover mechanism can occur at the tunnel group level. A tunnel group can failover to the standby NE, independently of other tunnel groups on the active NE; see Chapter 41, “MC IPsec” for more information.

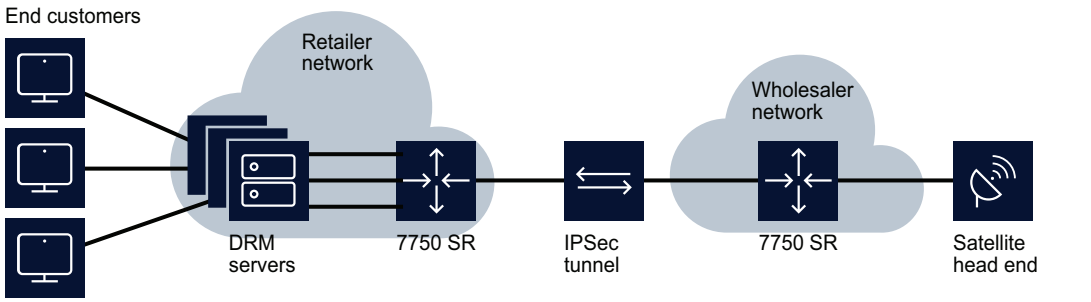
34.4 Sample video wholesale IPsec configuration

34.4.1 Overview

Larger providers or a cooperative of smaller providers often unite to provide a video head end to avoid the costs of investing in satellite head end locations on their own ground station, to provide triple-play features. Each retail subscriber can purchase content from this single station and receive it over IP. However, encryption is required so that the signal cannot be understood if intercepted.

The following figure shows a sample video wholesale configuration with a high-speed encrypted tunnel.

Figure 34-5 Sample video wholesale configuration



34.5 Workflow to configure IPsec

34.5.1 Stages

1

Provision an ISA tunnel MDA on each participating NE; see Chapter 11, “Working with network objects” and Chapter 13, “Logical group object configuration” for information about IPsec equipment configuration.

Use the following steps:

1. Create or configure ISA-tunnel groups.
2. Assign the active and backup tunnel group members to the ISA-tunnel groups.

2

Configure an IKE policy; see 34.8 “To configure an IPsec IKE policy” (p. 1238).

3

Configure an IPsec transform policy; see 34.10 “To configure an IPsec transform policy” (p. 1240).

4

If your network includes shared IPsec transform and IKE policies, configure an IPsec tunnel template; see 34.12 “To configure an IPsec tunnel template” (p. 1241).

5

Configure an IPsec security policy; see 34.13 “To configure an IPsec security policy” (p. 1242).

6

Configure a RADIUS authentication policy to apply to an IES or VPRN IPsec gateway; see 34.14 “To configure a RADIUS authentication policy” (p. 1243).

7

Configure a RADIUS accounting policy to apply to an IES or VPRN IPsec gateway; see 34.15 “To configure a RADIUS accounting policy” (p. 1244).

8

Configure a trust anchor profile; see 34.17 “To configure a trust anchor profile” (p. 1246).

9

Configure a certificate profile; see 34.18 “To configure a certificate profile” (p. 1247) .

10

If you are configuring IPsec on a VPRN, create the private-facing tunnel interface; see 34.20 “To configure a tunnel interface on an IES or VPRN” (p. 1249).

Use the following steps:

1. Create a private IPsec SAP.
2. Configure ingress and egress policies.

11

Create the public-facing tunnel interface; see 34.22 “To configure an IES or VPRN IPsec gateway” (p. 1256).

Use the following steps:

1. Create an L3 access interface on an IES or VPRN; see Chapter 78, “IES management” and Chapter 79, “VPRN service management” for information about creating L3 access interfaces.
2. Define the IPsec public SAP for the L3 access interface.
3. Specify the IPsec gateway, if required, on the NE.

12

If you are configuring IPsec on a VPRN, create IPsec tunnels on the VPRN tunnel interface; see 34.21 “To configure an IPsec tunnel on a VPRN tunnel interface” (p. 1253).

13

Configure the static route; see 27.13 “To configure a static route on a routing instance” (p. 852).

34.6 Workflow to configure IPsec VPNs

34.6.1 Stages

1

Create a corporate service; see the appropriate service chapter.

2

Create an IPsec VPN; see 34.25 “To configure an IPsec VPN” (p. 1262).

3

Select the NE service sites for the IPsec VPN; see 34.25 “To configure an IPsec VPN” (p. 1262).

4

Create or select the secure VPRN service for the IPsec VPN; see 34.25 “To configure an IPsec VPN” (p. 1262).

5

Create or select the delivery service for the IPsec VPN; see 34.25 “To configure an IPsec VPN” (p. 1262).

6

Select the tunnel group for the IPsec VPN; see 34.25 “To configure an IPsec VPN” (p. 1262).

7

Assign policies and configurations to the IPsec VPN.

a. If you chose Dynamic (Site-to-Site) for the Tunnel Type parameter in 34.25 “To configure an IPsec VPN” (p. 1262), see 34.26 “To assign policies and configurations for a dynamic site-to-site IPsec VPN” (p. 1264).

b. If you chose Dynamic (Soft Client) for the Tunnel Type parameter in 34.25 “To configure an IPsec VPN” (p. 1262), see 34.27 “To assign policies and configurations for a dynamic soft client IPsec VPN” (p. 1265).

c. If you chose Static for the Tunnel Type parameter in 34.25 “To configure an IPsec VPN” (p. 1262), see 34.28 “To assign policies and configurations for a static IPsec VPN” (p. 1266).

8

Deploy the IPsec VPN.

34.7 Workflow to enable BFD over a static LAN-to-LAN IPsec tunnel

34.7.1 Stages

1

Create a tunnel interface on a VPRN, as described in 34.20 “To configure a tunnel interface on an IES or VPRN” (p. 1249).

2

Create an IPsec tunnel on the VPRN tunnel interface, as described in 34.21 “To configure an IPsec tunnel on a VPRN tunnel interface” (p. 1253).

3

Enable BFD for the static LAN-to-LAN IPsec tunnel, as described in 34.24 “To enable BFD for a static LAN-to-LAN IPsec tunnel” (p. 1261).

4

Assign a BFD service and interface that can be used for the BFD session on the IPsec tunnel.

34.8 To configure an IPsec IKE policy

34.8.1 Purpose

Use this procedure to set up IPsec IKE policies.

34.8.2 Steps

1

Choose Policies→ISA Policies→IPsec Policies from the NFM-P main menu. The IPsec Policies form opens.

2

Click Create→IKE Policy, or choose a policy and click Properties. The IPsec IKE Policy (Create|Edit) form opens.

3

Configure the required parameters on the General tab.

4

Click on the NAT Traversal tab and configure the required parameters.

5

Click on the DPD tab and configure the required parameters.

The Interval and Max Retries parameters can only be configured when the Dead Peer Detection (DPD) parameter is set to Enable.

6

Click on the Lockout tab and configure the required parameters.

If you select the Enable Lockout check box, you can configure a set of parameters that define the lockout condition.

7

If applicable, click on the IKE Transforms tab and associate IKE Transform policies to the IKE policy. Depending on the NE software release, up to four IKE Transform policies may be applicable.

Perform the following steps:

1. Choose an entry and click Properties. The IPSec IKE Transform Associations form opens.
2. Click Select in the IKE Transform panel and choose or create an IKE transform policy to associate. See 34.9 “To configure an IKE transform policy” (p. 1239).
3. Click OK to close the form.

8

If the IKE version is v2, the Fragment tab becomes available.

If you select the Fragment check box, you can configure a set of parameters that define the fragmentation.

9

Click Apply.

10

Distribute the policy to NEs.

11

Close the IPsec IKE Policy (Create|Edit) form.

12

Close the IPsec Policies form.

END OF STEPS

34.9 To configure an IKE transform policy

34.9.1 Steps

1

Choose Policies→ISA Policies→IPsec Policies from the NFM-P main menu. The IPsec Policies form opens.

2

Click Create→IKE Transform, or choose a policy and click Properties. The IPsec IKE Transform (Create|Edit) form opens.

3

Configure the required parameters.

4

Click Apply.

5

Close the IPsec IKE Transform (Create|Edit) form.

6

Close the IPsec Policies form.

END OF STEPS

34.10 To configure an IPsec transform policy

34.10.1 Steps

1

Choose Policies→ISA Policies→IPsec Policies from the NFM-P main menu. The IPsec Policies form opens.

2

Click Create→Transform Policy, or choose a policy and click Properties. The IPsec Transform (Create|Edit) form opens.

3

Configure the required parameters.

4

Click Apply.

5

Distribute the policy to NEs.

6

Close the IPsec Transform (Create|Edit) form.

7

Close the IPsec Policies form.

END OF STEPS

34.11 To configure an IPsec static security association

34.11.1 Steps

1

Choose Policies→ISA Policies→IPsec Policies from the NFM-P main menu. The IPsec Policies form opens.

2

Click Create→Static Security Association Policy, or choose a policy and click Properties. The IPsec Static Security Association (Create|Edit) form opens.

3

Configure the required parameters.

4

Click Apply.

5

Distribute the policy to NEs.

6

Close the IPsec Static Security Association (Create|Edit) form.

7

Close the IPsec Policies form.

END OF STEPS

34.12 To configure an IPsec tunnel template

34.12.1 Steps

1

Choose Policies→ISA Policies→IPsec Policies from the NFM-P main menu. The IPsec Policies form opens.

2

Click Create→Tunnel Template Policy. The IPsec Tunnel Template (Create|Edit) form opens.

3

Configure the required parameters.

4

Click on the IPsec Transforms tab.

5

Click Select in the Transform ID 1 to Transform ID 4 panels to choose one or more IPsec transforms.

6

Click Apply.

7

Distribute the policy to NEs.

8

Close the IPsec Tunnel Template (Create|Edit) form.

9

Close the IPsec Policies form.

END OF STEPS

34.13 To configure an IPsec security policy

34.13.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

Click on the Sites tab.

4

Choose a site and click Properties. The VPRN Site (Edit) form opens.

5

Click on the IPsec Security Policies tab.

6

Click Create. The IPsec Security Policy (Create) form opens.

7

Configure the required parameters.

8

Click on the IPsec Security Policy Entries tab.

9

Add one or more security policy entries.

Use the following steps:

1. Click Create. The Security Policy Entry (Create) form opens.
2. Configure the Entry ID parameter.
3. Configure the parameters in the Local IP Address panel.
4. Configure the parameters in the Local IPv6 Address panel.
5. Configure the parameters in the Remote IP Address panel.
6. Configure the parameters in the Remote IPv6 Address panel.
7. Save your changes and close the form.

10

Save your changes and close the forms.

END OF STEPS

34.14 To configure a RADIUS authentication policy

34.14.1 Steps

1

Choose Policies→ISA Policies→IPsec Policies from the NFM-P main menu. The IPsec Policies form opens.

2

Click Create→Radius Authentication Policy, or choose a policy and click Properties. The IPsec Radius Authentication Policy (Create|Edit) form opens.

3

Configure the required parameters.

4

Select a RADIUS server policy.

5

Click Apply.

6

Distribute the policy to NEs.

7

Close the IPsec Radius Authentication Policy (Create|Edit) form.

8

Close the IPsec Policies form.

END OF STEPS

34.15 To configure a RADIUS accounting policy

34.15.1 Steps

1

Choose Policies→ISA Policies→IPsec Policies from the NFM-P main menu. The IPsec Policies form opens.

2

Click Create→Radius Accounting Policy, or choose a policy and click Properties. The IPsec Radius Accounting Policy (Create|Edit) form opens.

3

Configure the required parameters.

4

Select a RADIUS server policy.

5

Click Apply.

6

Distribute the policy to NEs.

7

Close the forms.

END OF STEPS

34.16 To configure an IPsec traffic selector list

34.16.1 Steps

1

Choose Policies→ISA Policies→IPsec Policies from the NFM-P main menu. The IPsec Policies form opens.

2

Click Create→Traffic Selector List, or choose a list and click Properties. The IPsec Traffic Selector List (Create|Edit) form opens.

3

Configure the List Name parameter.

4

Click on the Local Entries tab.

5

Click Create. The IPsec TS Local List Entry (Create) form opens.

6

On the General tab, perform one of the following:

a. Set the Address Format parameter to None.

b. Set the Address Format parameter to Range Address and configure the From IP Address and To IP Address parameters.

c. Set the Address Format parameter to Prefix and configure the IP Prefix and Prefix Length parameters:

7

On the Protocol tab, perform one of the following.

a. Choose Any.

b. Choose a specific protocol option and a port option. If you choose the Manual port option, you need to configure the minimum and maximum port parameters.

c. Choose Manual and configure a Protocol ID.

8

Save your changes and close the IPsec TS Local List Entry (Create) form.

9

Distribute the policy to NEs.

10

Close the IPsec Traffic Selector List (Create|Edit) form.

11

Close the IPsec Policies form.

END OF STEPS

34.17 To configure a trust anchor profile

34.17.1 Steps

1

Choose Policies→ISA Policies→IPsec Policies from the NFM-P main menu. The IPsec Policies form opens.

2

Click Create→Trust Anchor Profile, or choose a profile and click Properties. The IPsec Trust Anchor Profile (Create|Edit) form opens.

3

Configure the general parameters.

4

Associate one or more certificate authority profiles with the trust anchor profile.

Use the following steps:

1. Click on the Trust Anchor CA Profile tab.
2. Click Create. The Trust Anchor Entry (Create) form opens.
3. Select a certificate authority profile.
4. Save and close the form.

5

Click Apply.

6

Distribute the policy to NEs.

7

Close the IPsec Trust Anchor Profile (Create|Edit) form.

8

Close the IPsec Policies form.

END OF STEPS

34.18 To configure a certificate profile

34.18.1 Steps

1

Choose Policies→ISA Policies→IPsec Policies from the NFM-P main menu. The IPsec Policies form opens.

2

Click Create→Certificate Profile, or choose a profile and click Properties. The IPsec Certificate Profile (Create|Edit) form opens.

3

Configure the required parameters.

4

Click on the Certificate Profile Entries tab.

5

Click Create. The Certificate Profile Entry (Create) form opens.

6

Configure the required parameters.

7

Associate one or more certificate chain CA profiles with the certificate profile entry.

Use the following steps:

1. Click on the Certificate Chain CA Profile tab.
2. Click Create. The Certificate Chain CA Profile (Create) form opens.
3. Select a certificate authority profile.
4. Save your changes and close the form.

8

Click Apply.

9

Distribute the policy to NEs.

10

Close the IPsec Certificate Profile (Create|Edit) form.

11

Close the IPsec Policies form.

END OF STEPS

34.19 To configure an IPsec client database

34.19.1 Steps

1

Choose Policies→ISA Policies→IPsec Policies from the NFM-P main menu. The IPsec Policies form opens.

2

Click Create→IPsec Client DB, or choose a profile and click Properties. The IPsec Client DataBase (Create|Edit) form opens.

3

Configure the required parameters.

Note: The Private Service ID and Private Interface Name parameters can only be configured on local policies.

4

Click on the Client Entries tab.

5

Click Create to create a client entry. Configure the required parameters and close the form.

Up to 8000 entries can be created per database.

6

Save your changes and close the IPsec Client DataBase (Create|Edit) form.

7

To configure the local-only parameters:

1. Choose a global policy and click Properties.

2. Change the distribution mode to Local Edit Only; see 49.9 “To change the distribution mode of a policy” (p. 1482).
3. Configure the Private Service ID and Private Interface Name parameters.
4. Save your changes and close the form.

8

Add the IPsec client database to the IPsec gateway; see 34.22 “To configure an IES or VPRN IPsec gateway” (p. 1256).

The gateway association appears in the IPsec Gateways tab of the global policy.

END OF STEPS

34.20 To configure a tunnel interface on an IES or VPRN

Note: The tabs and parameters that are configurable vary depending on the NE.
The 7705 SAR only supports the configuration of a tunnel interface on a VPRN service.

34.20.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES or VPRN service and click Properties. The service properties form opens.

3

Click on the Interfaces tab. The TMS Interfaces tab is displayed.

4

Click on the Tunnel Interfaces tab.

5

Click Create. The Tunnel Interface (Create) form opens.

6

Configure the required parameters.

7

Configure Cflowd sampling, if applicable.

Use the following steps:

1. Click Create in the Cflowd Sampling panel. The Cflowd Sampling (Create) form opens.

2. Configure the parameters.
3. Save your changes and close the form.

8

Configure a port for the interface.

Use the following steps:

1. Click on the Port tab.
2. Select a port.

   Additional tabs may become available based on the type of port selected.
3. Configure the required parameters.

   Note:

   You can configure the NFM-P to automatically assign the lowest unused outer encapsulation value by enabling the Auto-Assign ID parameter.

   You can set the Auto-Assign ID parameter to be the default parameter for dot1q encapsulation by enabling the Access Interface Encap Value (Dot1q only) parameter in the User Preferences form. Choose Application→ User Preferences from the main menu.

   Private and public tunnel connection points support only dot1q encapsulation.

9

To configure multichassis redundancy, if applicable, see 41.4 “To configure MC IPsec on an MC peer group” (p. 1343).

10

Assign ingress and egress QoS policies to the interface.

Use the following steps:

1. Click on the QoS tab.
2. Configure the required parameters.
3. Click Select in the Ingress Policy and Egress Policy panels to choose ingress and egress QoS policies.

11

Assign an accounting policy to the interface, if applicable.

Use the following steps:

1. Click on the Accounting tab.
2. Select an accounting policy.
3. Configure the Collect Accounting Statistics parameter.

12

Configure scheduling.

Use the following steps:

1. Click on the Schedulers tab.
2. Configure the Aggregate Rate Limit (kbps) parameter.

   Note:

   The Aggregate Rate Limit (kbps) parameter is configurable when the Assign Aggregate Rate Limit check box is enabled and there is no scheduler specified in the Egress Scheduler panel.

   You cannot specify an egress scheduler when the Aggregate Rate Limit (kbps) parameter is set to a value greater than zero.
3. Select ingress and egress schedulers in the Ingress Scheduler and Egress Scheduler panels.
4. Select ingress and egress policer control policies in the Ingress Policer Control Policy and Egress Policer Control Policy panels.

13

Assign ingress and egress ACL filters to the interface.

Use the following steps:

1. Click on the ACL tab.
2. Select ingress and egress ACL filters in the IP Filter and IPv6 Filter panels.

14

Configure BFD.

Use the following steps:

1. Click on the BFD tab.
2. Set the Administration Status parameter to Up. Additional parameters are displayed.
3. Configure the required parameters.
4. To view local and remote session peers, click on the BFD Session tab. The NFM-P retrieves information from the local and remote NEs and lists the current BFD sessions.
5. Select a session and click Properties. The session properties form opens.

   View the following:
   - BFD status
   - protocol used
   - local address
   - remote address
   - operational status and statistics

   The BFD Status field indicates one of the following:
   - no service, when BFD is disabled

- in service, when BFD is running
- out of service, when BFD has failed

6. Close the session properties form.

   Note:

   You cannot enable BFD on an interface if BFD is not configured on the interface, and cannot administratively disable the interface if a routing protocol that uses the interface has BFD enabled.

   See Chapter 28, “Routing protocol configuration” for information about enabling and disabling BFD for routing protocols.

15

Assign a security zone policy to the VPRN tunnel interface, if applicable.

Use the following steps:

1. Click on the Zone tab.
2. Select a security zone policy.
3. Configure the ByPass Zone Config parameter.
4. Save your changes and close the form.

16

Assign an IP address to the interface.

Use the following steps:

1. Click on the Addresses tab and click Create. The IP Address (Create) form opens.
2. Configure the required parameters.
3. Save your changes and close the form.

17

Configure ICMPv6 if IPv6 is enabled.

Use the following steps:

1. Click on the ICMPv6 tab.
2. Configure the parameters, as required.
3. Save and close the form.

18

Configure an IP-IP tunnel or GRE tunnel on the interface.

Note: Step 8 must be performed before this step.

Use the following steps:

1. Click on the IP/GRE Tunnels tab and click Create. The IP/GRE Tunnel - IP-GRE|IP-IP Tunnel (Create) form opens.
2. Configure the required parameters.
3. If you are configuring a GRE tunnel, enable the Include GRE Header parameter and configure the GRE tunnel parameters.
4. Select a delivery service in the Delivery Service panel.
5. Click on the States tab and configure the Administrative State parameter.
6. Save and close the form.

19

To specify queue overrides, click on the Override Policy Items tab.

Note: The Override Policy Items tab contains a number of sub-tabs. However, the sub-tabs that are displayed depend on the port type that you have chosen for this interface.

- If the port is not an HSMDA port, the Access Ingress Queues, Access Egress Queues, Ingress Policer, and Egress Policer sub-tabs are active.
- If the port is an HSMDA port, the Access Ingress Queues, Access Egress HSMDA Queues, and Ingress Policer sub-tabs are active.

20

Save your changes and close the forms.

END OF STEPS

34.21 To configure an IPsec tunnel on a VPRN tunnel interface

Note: Availability of some parameters varies depending on the NE and release; see the NE documentation for more information.

34.21.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

Click on the Interfaces tab. The TMS Interfaces tab is displayed.

4

Click on the Tunnel Interfaces tab.

5

Choose a tunnel interface and click Properties. The Tunnel Interface (Edit) form opens.

6

Click on the IPsec Tunnels tab.

Note: The IPsec Tunnels tab is displayed only when a port is assigned to the tunnel interface.

7

Click Create. The IPsec Tunnel (Create) form opens.

8

Configure the required parameters.

9

Select a security policy in the Security Policy ID panel.

To ensure that no multiple tunnels are created with same security policy, enable the Strict Match parameter.

Note: Strict Match parameter must be set at the same time Security Policy ID is set.

10

Configure the required parameters in the Tunnel Endpoints panel.

11

Configure the required parameters in the IP Fragmentation panel.

12

Configure the required parameters in the ICMPv6 Generation panel.

13

If you set the Keying parameter to Dynamic in Step 8, configure dynamic keying.

Use the following steps:

1. Click on the Dynamic Keying tab.
2. Select an IPsec transform in the Transform ID 1 to Transform ID 4 panels.
3. Select an IKE policy in the IKE Policy panel.
4. Configure the Pre-shared Key and Auto-Establish parameters.

5. Configure the parameters in the Local ID panel.

   Note:

   The parameters in the Local ID panel, and the Certificate File and Key File parameters, are configurable when IKEv2 is specified in the IKE policy associated with the tunnel, and the Authorization Method is set to Certificate Authentication.

6. To specify a single certificate trust anchor, certificate file, and key file where available:
   a. Configure the Certificate File and Key File parameters.
   b. Click Select beside the Certificate Trust Anchor parameter to select a CA profile.

   Note:

   If there is a problem with the Certificate File or the Key File after the tunnel becomes administratively up, the Invalid Certificate File or Invalid Key File operational indicators are enabled on the States tab, and the NFM-P raises an alarm.

7. To specify multiple certificate trust anchors, certificate files, and key files, click Select beside the Trust Anchor Profile and Certificate Profile parameters to select the appropriate profiles.

   Note:

   If there is a problem with a Certificate File or Key File after the tunnel becomes administratively up, the Invalid Certificate File or Invalid Key File operational indicators are enabled on the States tab, and the NFM-P raises an alarm.

14

If you set the Keying parameter to Manual in Step 8, configure manual keying.

Use the following steps:

1. Click on the Manual Keying tab.
2. Click Create. The IPsec Security Association (Create) form opens.
3. Select a security policy entry in the Security Policy Entry panel.
4. Configure the required parameters.
5. Select a transform policy in the Transform panel.
6. Save your changes and close the form.

15

Configure BFD.

Use the following steps:

1. Click on the BFD tab.
2. Configure the required parameters.
3. Select a BFD service in the BFD Service panel.
4. Select an interface in the Interface panel.
5. Configure the Destination Address parameter.

16

Click on the States tab.

17

Configure the Administrative State parameter.

18

Configure static tunnel destination IP addresses.

Use the following steps:

1. Click on the Dest-IP Addresses tab and click Create. The IPsec Tunnel Dest-IP Address (Create) form opens.
2. Configure the required parameters.
3. Save your changes and close the form.

19

Save your changes and close the forms.

END OF STEPS

34.22 To configure an IES or VPRN IPsec gateway

Note: Availability of some parameters varies depending on the NE and release; see the NE documentation for more information.

The parameters in the Local ID panel and the Certificate File and Key File parameters, if applicable, are configurable when IKEv2 is specified in the associated gateway IKE policy and the Authorization Method is set to Certificate Authentication.

34.22.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES or VPRN service and click Properties. The service properties form opens.

3

Click on the Interfaces tab, then on the L3 Access Interfaces tab.

4

Choose the L3 access interface on which you want to create the IPsec gateway and click Properties. The L3 Access Interface (Edit) form opens.

Note: The port configured on the L3 access interface must be a Tunnel Group SAP, which is the public-facing interface for an IPsec tunnel.

5

Click on the IPsec Gateway tab.

6

Click Create. The IPsec Gateway (Create) form opens.

7

Configure the required parameters.

8

To associate an IKE policy with the IPsec gateway, select an IKE policy in the IKE Policy panel.

Note: For the IPSec Gateway administrative status to be set to “Up”, the associated IKE Policy must have a IKE Transform policy configured on it.

9

To associate an IPsec tunnel template with the IPsec gateway, select an IPsec tunnel template in the IPsec Tunnel Template panel.

10

To associate an IPsec client database with the IPsec gateway, select an IPsec client database in the IPsec Client DataBase panel.

11

Select the far-end VPRN service site of the tunnel in the Secure Service Id panel.

12

Select the tunnel interface of the far-end site in the Tunnel Interface Name panel.

13

Configure the Local Gateway Address parameter.

14

Configure the parameters in the Local ID panel.

15

Configure the parameters in the Certificate panel as needed.

1. To specify a single CA to use as a trust anchor, click Select beside the Certificate Trust Anchor parameter and select a certificate trust anchor.

2. To specify multiple certificates and CAs, click Select beside the Trust Anchor Profile and Certificate Profile parameters, and select the appropriate profiles.

Note: If there is a problem with a Certificate File or Key File after the tunnel becomes administratively up, the Invalid Certificate File or Invalid Key File operational indicators are enabled on the States tab, and the NFM-P raises an alarm.

16

Select a RADIUS authentication policy in the Radius Authentication Policy panel.

17

Select a RADIUS accounting policy in the Radius Accounting Policy panel.

18

Click on the States tab and configure the Administrative State parameter.

19

Associate a traffic selector list with the IPsec gateway.

Use the following steps:

1. Click on the Traffic Selector Negotiation tab.
2. Click Create. The Traffic Selector Negotiation (Create) form opens.
3. Select a traffic selector policy in the Traffic Selector Policy panel.
4. Save your changes and close the form.

20

On IES and VPRN L3 access interface IPsec gateways, you can lease a local IP address from a pool in a local DHCPv4 or DHCPv6 server defined in the VPRN routing instance or NE base routing instance. To lease an IP address from an external DHCP server, see Step 21.

To configure the local address assignment for the IKEv2 remote access tunnel on an IES or VPRN L3 access interface IPsec gateway:

1. Click on the Local Address Assignment tab.
2. Configure the Administrative State parameter.
3. Select the DHCP server name in the IPv4 and IPv6 panels.

   Note:

   After the tunnel is established and the address is leased, you can view the lease on the Leases tab on the Local DHCP Server (Edit) form. On the VPRN Site (Edit) form, click on the RADIUS/DHCP/Diameter tab and select the required DHCPv4 server to open the Local DHCP Server (Edit) form. You can filter the leases by choosing IPsec from the Client Type column header.

   On the NE base routing instance, navigate to Routing→*NE*→Routing Instance, right click and choose Properties. Click on the Local DHCP Servers tab.

See 79.33 “To configure a local DHCPv4 server on a VPRN site” (p. 2579) and 79.34 “To configure a local DHCPv6 server on a VPRN site” (p. 2581) for information about configuring a local DHCPv4 or DHCPv6 server on a VPRN site. See 27.5 “To configure a local DHCPv4 server on a routing instance” (p. 839) and 27.6 “To configure a local DHCPv6 server on a routing instance” (p. 842) for information about configuring a local DHCPv4 or DHCPv6 server on a base routing instance.

21

Lease an IP address for the IPsec gateway from an external DHCPv4 server.

Use the following steps:

1. Click on the DHCP Address Assignment tab and click Create. The Internal DHCPv4 Address Assignment form opens.
2. Configure the Gi Address and either the Router or Service ID parameters.
3. Specify up to eight DHCPv4 servers in the DHCP Servers panel.
4. Save and close the form.

22

Lease an IP address for the IPsec gateway from an external DHCPv6 server.

Use the following steps:

1. Click on the DHCPv6 Address Assignment tab and click Create. The Internal DHCPv6 Address Assignment form opens.
2. Configure the Link Address and either the Router or Service ID parameters.
3. Specify up to eight DHCPv6 servers in the DHCP Servers panel.
4. Save and close the form.

23

Close the forms.

END OF STEPS

34.23 To view current remote users connected to an IPsec gateway and remote user security associations

34.23.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES or VPRN service and click Properties. The service properties form opens.

3

Expand the Sites object in the service navigation tree.

4

Expand the Routing Instance object in the service navigation tree.

5

Expand the L3 Access Interfaces object in the service navigation tree, click on the appropriate L3 access interface, and click Properties. The L3 Access Interface (Edit) form opens.

6

Click on the IPsec Gateway tab.

7

Choose the IPsec gateway for which you want to view the current remote users and click Properties. The IPsec Gateway (Edit) form opens.

8

Click on the Statistics tab to view and collect statistics as required.

Note: If a remote user has been removed, the previously collected statistics for the remote user will remain visible on the Statistics tab of the IPsec gateway.

9

Click on the Remote Users tab. The current remote users are listed.

10

Select a user and click Properties. The IPsec Remote User (Edit) form opens.

11

Click on the Remote User Security Associations tab. The security associations of the remote user are listed.

12

Select a security association and click Properties. The IPsec Remote User Security Association (Edit) form opens.

13

View general information and parameters that were negotiated with IPsec gateway.

These include but are not limited to:

- Internet IP address
- Private IP address and Second Private IP address

- SA lifetime
- DH group
- Replay window

14

Click on the Algorithms tab to view authentication and encryption algorithm information.

15

Click on the Traffic Selector tab to view the list of IPsec remote user dynamic security association traffic selector entries.

16

Close the forms.

END OF STEPS

IPsec remote user statistics

Starting with Release 20.6, the NFM-P collects and displays IPsec remote user statistics under the Statistics tab of the IPSec gateway instead of the IPsec Remote User. This means that IPsec remote user statistics are retained in the event of a failover.

34.24 To enable BFD for a static LAN-to-LAN IPsec tunnel

34.24.1 Steps

1

On the private side, use the device CLI to specify a tunnel and to enable BFD on the tunnel.

Note: See the device documentation for information about the CLI commands required to perform the action.

2

On the public side, use the device CLI to configure the transmit interval.

Note: See the device documentation for information about the CLI commands required to perform the action.

3

Create a tunnel interface in a VPRN service, as described in 34.20 “To configure a tunnel interface on an IES or VPRN” (p. 1249).

4

Create an IPsec tunnel on the tunnel interface, as described in 34.21 “To configure an IPsec tunnel on a VPRN tunnel interface” (p. 1253).

5

Close all open forms.

END OF STEPS

34.25 To configure an IPsec VPN

Note: The NFM-P does not support IPsec VPN creation when language localization is enabled.

See 1.2.5 “Localized language support” (p. 79) in Chapter 1, “NFM-P GUI” for information.

34.25.1 Steps

1

Choose Manage→Service→IPsec from the NFM-P main menu. The Manage IPsec VPNs form opens.

2

Click Create. The IPsec VPN (Create) step form opens with the Create IPsec VPN step displayed.

3

Configure the parameters in the IPsec VPN panel.

4

Specify a corporate service.

Use the following steps:

1. Configure the Service Type parameter.
2. Select a corporate service in the Corporate Service panel.

5

Configure the Link Corporate and Secured Service parameter in the Composite Service panel.

6

Click Next. The Select Service Sites step form is displayed.

7

Click Create to select the IPsec VPN service sites.

8

Click Next. The Create/Select Secure VPRN Service step form is displayed.

9

Perform one of the following.

a. Click Select Service to select a service, and configure the parameters on the Service Site tab.

b. Click Create Service to create a service, and configure the parameters on the Service and Service Site tabs.

c. Click Create Service from Template and select a service.

Note: The template must be configured for one site. The template cannot be used if the template is configured for multiple sites.

10

Click Next. The Create/Select Delivery Service(s) step form is displayed.

11

CAUTION

Service Disruption

Service Disruption

When you remove a service, the service is removed without confirmation and cannot be restored.

Perform one of the following.

a. To select a delivery service, click Select Service, select a service, and configure the parameters on the Service Site tab.

b. To create a delivery service, click Create Service, choose IES or VPRN, and configure the parameters on the Service and Service Site tabs.

c. To create a service from a template, click Create Service from Template, choose VPRN Templates or IES Templates, and select a template.

Note: The template must be configured for one site. The template cannot be used if the template is configured for multiple sites.

d. To remove a service, click Remove Service, select a service, and click Remove Service.

12

Click Next. The Tunnel Group Selection step form is displayed.

13

Configure each parameter that has a field with a yellow background by clicking in the field and entering a value or choosing an option.

Note: The parameters are not included in the XML model. However, using the OSS interface, you can create the ServiceSiteStructs and can create the IPsec VPN objects in the ServiceSiteStructs.

14

Click Next. The Create Policy step form opens.

15

Perform one of the following, depending on the Tunnel Type parameter setting in Step 13.

a. If the parameter is set to Dynamic (Site-to-Site), perform 34.26 “To assign policies and configurations for a dynamic site-to-site IPsec VPN” (p. 1263).

b. If the parameter is set to Dynamic (Soft Client), perform 34.27 “To assign policies and configurations for a dynamic soft client IPsec VPN” (p. 1265).

c. If the parameter is set to Static, perform 34.28 “To assign policies and configurations for a static IPsec VPN” (p. 1266).

END OF STEPS

34.26 To assign policies and configurations for a dynamic site-to-site IPsec VPN

34.26.1 Purpose

Perform this procedure if the Tunnel Type parameter in Step 13 of 34.25 “To configure an IPsec VPN” (p. 1262) is set to Dynamic (Site-to-Site).

34.26.2 Steps

1

Select an IPsec tunnel template.

2

Configure the Pre-shared key parameter.

3

Click Finish.

The NFM-P performs the following:

- creates a secure VPRN service and sites
  - creates an access interface
  - creates a tunnel interface
  - configures the service name
- creates the IES or VPRN delivery service and sites

- creates an access interface
- configures the IP address of the SAP
- assigns a tunnel group with an auto-generated outer encapsulation as a public SAP
- creates an IPsec gateway
- assigns the secure service
- assigns the tunnel interface of the secure service
- assigns the tunnel template
- assigns the IKE policy
- configures the local gateway address
- configures the pre-shared key
- configures the service name

- if the Link Corporate and Secure Service parameter is enabled, creates a composite service that contains the corporate and secure services

4

To view the IPsec VPN, click View the newly created IPsec Secured VPN. The IPsec VPN (Create) step form closes, and the IPsec VPN form opens.

5

Close the forms.

END OF STEPS

34.27 To assign policies and configurations for a dynamic soft client IPsec VPN

34.27.1 Purpose

Perform this procedure if the Tunnel Type parameter in Step 13 of 34.25 “To configure an IPsec VPN” (p. 1262) is set to Dynamic (Soft Client).

34.27.2 Steps

1

Select an IPsec tunnel template.

2

Click Select beside the Displayed Name parameter to select a subscriber authentication policy.

3

Click Finish.

The NFM-P performs the following:

- creates a secure VPRN service and sites

  - creates an access interface
  - creates a tunnel interface
  - configures the IP address of the SAP
  - configures the service name
- creates the IES or VPRN delivery service and sites
  - creates an access interface
  - configures the IP address of the SAP
  - assigns the RADIUS authentication policy
  - assigns a tunnel group with an auto-generated outer encapsulation as a public SAP
  - creates an IPsec gateway
  - assigns the tunnel template
  - assigns the IKE policy
  - configures the local gateway address
  - configures the pre-shared key
  - configures the service name
- if the Link Corporate and Secure Service parameter is enabled, creates a composite service that contains the corporate and secure services

4

To view the IPsec VPN, click View the newly created IPsec Secured VPN. The IPsec VPN (Create) step form closes, and the IPsec VPN form opens.

5

Close the forms.

END OF STEPS

34.28 To assign policies and configurations for a static IPsec VPN

34.28.1 Purpose

Perform this procedure if the Tunnel Type parameter in Step 13 of 34.25 “To configure an IPsec VPN” (p. 1262) is set to Static.

34.28.2 Steps

1

Select an IPsec tunnel template.

2

Configure the required parameters.

3

If you set the Keying parameter to Manual, configure the parameters in the Manual Keying - Inbound and Manual Keying - Outbound panels.

4

Select an IPsec transform policy.

5

Configure the Auto-Establish parameter.

Note: The Auto-Establish parameter is configurable only if dynamic keying is enabled.

6

Click Finish.

The NFM-P performs the following:

- creates a secure VPRN service and sites
  - creates the IPsec security policy
  - creates a tunnel interface
  - assigns a tunnel group with an auto-generated outer encapsulation as a private SAP
  - creates the IPsec tunnel
  - assigns the security policy to the tunnel
  - configures the local and remote gateway addresses
  - configures the delivery service
  - configures the replay window
  - configures the keying
  - if set, enables auto-establish
  - configures the static route
  - configures the service name
- creates the IES or VPRN delivery service and sites
  - creates an access interface
  - assigns a tunnel group with an auto-generated outer encapsulation as a public SAP
  - configures the IP address of the SAP
  - configures the service name
- if the Link Corporate and Secure Service parameter is enabled, creates a composite service that contains the corporate and secure services

7

To view the IPsec VPN, click View the newly created IPsec Secured VPN. The IPsec VPN (Create) step form closes, and the IPsec VPN form opens.

8

Close the forms.

END OF STEPS

34.29 To configure an IPsec tunnel on a IES or VPRN service

34.29.1 Before you begin

For VPRN service IPsec tunnel, IPsec security policy and entry should belong to same VPRN.

34.29.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES or VPRN service and click Properties. The service properties form opens.

3

Choose the L3 access interface on which you want to configure an IPsec tunnel and click Properties. The L3 Access Interface (Edit) form opens.

4

Click the IPSec tab.

5

Click Create. The IPSec (Create) form opens. Configure the required parameters.

6

Click IPSec Tunnel tab.

7

Click Create. The IPSec Tunnel (Create) form opens.

8

Configure the parameters on the General tab.

9

Configure the Copy Traffic Class Upon Decapsulation and Keying parameters.

Note: Based on the value selected for the Keying parameter, additional tabs will be displayed.

10

If Dynamic value is selected for the Keying parameter, the Dynamic Keying tab is displayed. Click Dynamic Keying tab.

11

Configure the IPsec transform sets, IKE policies and the Pre-shared key parameter.

12

Save your changes and close the forms.

END OF STEPS

35 ISA-Video

ISA-Video overview

35.1 ISA_Video overview

35.1.1 Overview

The NFM-P supports, on a 7450 ESS or 7750 SR, the equipment and service configuration of the following enhancements to multicast video services based on the ISA-Video MDA:

- Reliable Delivery/Retransmission (RT) Proxy
- Fast Channel Change (FCC)

You can use the NFM-P to configure the required ISA-Video groups and members, as well as the associated multicast info policies. VPRN and IES services can then be configured for the customer video delivery.

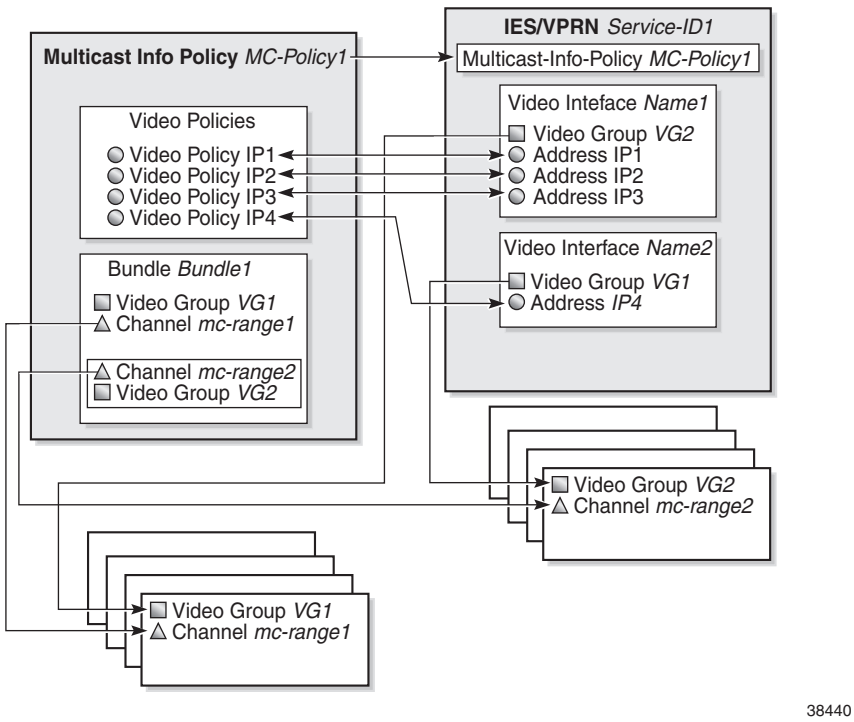
These enhancements are provisioned in NFM-P in the following three areas:

- a video group configuration to manage the ISA resources and service grouping.
- multicast information policy configuration parameters and objects to handle the RT and FCC capabilities.

  These include the following:
  - a video policy configuration under the multicast information policy
  - video parameters added to multicast bundles, channels and channel override configurations
- video interface configurations added under VPRN/IES services sites.

The following figure shows the relationship of these elements and how they are associated through configuration.

Figure 35-1 ISA-Video configuration elements



A video interface within a service site can have up to eight IP addresses. The IP addresses assigned to a video interface determine which multicast info policy is applied. The video group you assign to the video interface determines which bundle/channel configuration inside the multicast info policy is applied to the interface. You also configure the ingress and egress QOS policies for the video interface using the video group.

If a request is received on a video interface for a channel not serviced by the video group associated with that specific video interface, then the request is considered invalid and is dropped. For example, in Figure 35-1, “ISA-Video configuration elements” (p. 1272) , a request for mc-range2 received on IP1, IP2, or IP3 is invalid. A request for mc-range2 is only valid on IP4.

A video group manages the ISA-Video MDA resource and the configurations of the enhanced video functionality. You can assign a video group (for example, VG1 in Figure 35-1, “ISA-Video configuration elements” (p. 1272)) for each bundle, and this is the default video group for all of the channels in that bundle. You can then apply specific configuration overrides for each channel within a video group assignment.

Up to four video groups (ID 1-4) can be configured on a single NE. Each video group in turn, can have multiple primary video ISAs assigned to provide load balancing and redundancy protection.

However, any specific video ISA can only be bound to one video group. The binding of a video ISA to the video group is referred as a video group member.

Additional considerations for the Ad Insertion functionality:

- Ingress Ad Insertion channels are configured on the video interface configuration form.
- If Ad Insertion functionality is enabled on a video group, then the group can only have one video group member.
- You can configure zone channels for egress Ad Insertion on each Ad Insertion channel configuration.

Workflow to configure and manage an ISA-Video configuration

35.2 Workflow to configure and manage an ISA-Video configuration

35.2.1 Stages

1

Provision the ISA-Video MDA. See Chapter 11, “Working with network objects” and Chapter 12, “Device object configuration” for more information about ISA-Video MDA equipment configuration.

2

Create or configure ISA-Video groups and add members under the video groups. See 13.13 “To configure an ISA-Video group” (p. 427) for more information.

3

Configure and distribute a global Multicast Information policy. Configure the channel bundle, channel range, channel overrides, and video interface for the NE. See 52.13 “To configure an ingress multicast information policy” (p. 1720) for more information.

4

Create and enable a video interface for the IES or VPRN service. See 35.3 “To add a video interface to an IES or VPRN site” (p. 1275) for more information.

ISA-Video procedures

35.3 To add a video interface to an IES or VPRN site

35.3.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose the required IES or VPRN service and click Properties. The IES or VPRN (Edit) form opens with the General tab displayed.

3

On the navigation tree, click on the site to which you want to add the video interface and expand the entries for that site.

4

Right-click on Video Interfaces and choose Create Video Interface. The Video Interface (Create) form opens with the General tab displayed.

5

Configure the required parameters.

After you select a Group Number, the following selectable fields are displayed:

- Ingress QoS Policy
- Egress QoS Policy
- Ingress IP Filter
- Egress IP Filter

6

Select the required policies and filters. You can search or choose the entry that appears for each of these items.

7

Click on the Security tab and select an NE DoS Protection policy.

8

Click on the Addresses tab and click Create. The IP Address (Create) form opens.

9

Configure the required parameters.

10

To configure ad insertion, click on the ADI Channels tab and click Create. The Video ADI Channel (Create) form opens with the General tab displayed.

11

Configure the required parameters.

12

Click on the Zone Channels tab and click Create. The Video ADI Zone Channel (Create) form opens.

13

Configure the required parameters and save your changes.

14

Save your changes and close the form.

END OF STEPS

36 Alarm management

Alarm management overview

36.1 Alarm management overview

36.1.1 Overview

The NFM-P converts SNMP traps from NEs and NFM-P events to alarms that are associated with the managed equipment, configured services and policies. The NSP alarm management system provides the following:

- conversion of SNMP traps from NEs to alarms using the X.733 standard
- correlation of alarms with equipment- and service-affecting faults
- updates to the managed-object operational status in near-real-time
- the ability to log the actions performed to resolve a related fault by adding notes to the alarm
- alarm history for performing trend analysis

Viewing and managing alarms is performed using the NSP alarm management. Using the NSP alarm management, you can display and filter alarms, explore root causes, and manage, dismiss, or escalate alarms, among other functions. For more information about using the NSP alarm management, see the *NSP Network and Service Assurance Guide*.

36.2 Correlated alarms

36.2.1 Overview

The NFM-P generates a correlated alarm when a fault condition on one object causes an alarm condition on another object. For example, if a port goes down, an alarm is generated for the port, which is the affected object. Each service that uses the port generates an alarm. The alarm information for the affected object includes the correlated alarms.

The NFM-P automatically promotes the severity of correlating alarms to match the severity of correlated alarms. For example, if a major correlating port alarm has one or more critical correlated service alarms, the NFM-P changes the severity of the correlated port alarm to critical. The correlating alarm cannot have a severity that is lower than the severity of the correlated alarms. However, the severity that is defined by a specific alarm policy takes precedence over the correlated severity. The NFM-P does not lower the severity of correlating alarms when correlated alarms are cleared.

Note: Alarm correlation does not affect the severity of alarms that originate from an external EM system.

When the event that initiates an affected object alarm is resolved and the alarm clears, the correlated alarms also clear. If a correlated alarm does not clear after the affected object alarm clears, the source of the correlated alarm is an event other than the initiating event. In this case, the alarm correlation is removed and the alarm is displayed in the dynamic alarm list.

36.2.2 Service and transport alarm correlation

The NFM-P provides limited service and transport alarm correlation. When an LSP goes out of service, the NFM-P generates an alarm for the LSP and a correlated alarm for each LSP path that is a child object of the LSP. The LSP alarm is listed as an aggregated alarm for each SDP that uses the LSP. An NFM-P operator can use the aggregated LSP alarm for SDP troubleshooting.

There may not be a direct relationship between an LSP and the SDPs that use the LSP. For example, when LDP over RSVP is the transport mechanism, the NFM-P does not correlate SDP alarms with LSP alarms.

37 VRRP

37.1 VRRP

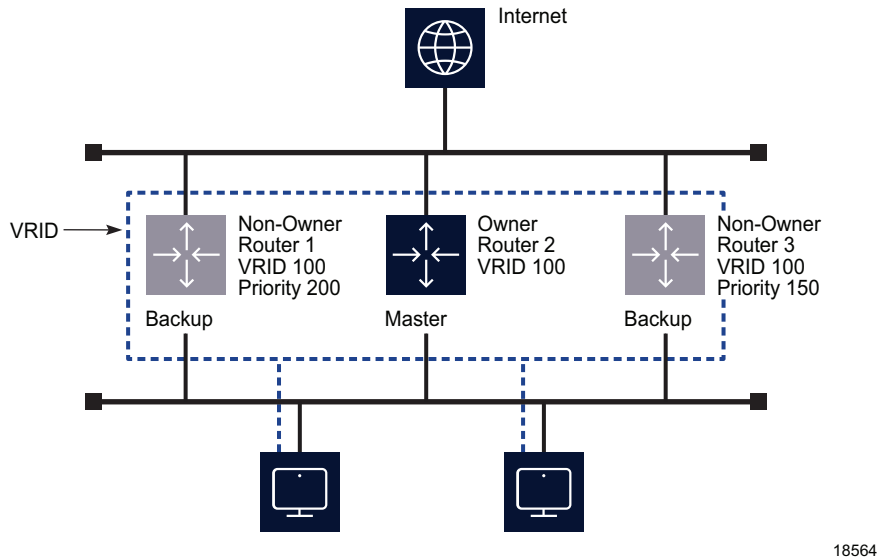
37.1.1 Overview

The NFM-P supports VRRP management. VRRP creates a redundant routing system that takes over packet transmission on a common LAN segment when a router fails. VRRP designates alternative routing paths in the form of virtual routers, or VRs, without changing the IP or MAC address of a protected router.

A VRRP protected router owns the IP address of the VR. The VRRP owner forwards packets using the default gateway. When the owner router fails, packet-forwarding responsibilities are transferred to a designated backup router. This router becomes the master and forwards packets using the VR IP address.

The following figure shows a basic VR that acts in parallel with the real network. Router 2 is the owner with the address from which packets are forwarded. If Router 2 fails, Router 3, which has been configured to route using the master address in a backup role, begins to forward packets using this IP address. Router 1 is also a backup router, but because its priority number is higher, it ranks below Router 3.

Figure 37-1 VR concepts



The NFM-P supports the configuration of VRs for network interfaces and for L3 access interfaces.

VRRP in an IES involves interfaces from separate IESs. VRRP in a VPRN requires interfaces that are in the same VPRN service. The NFM-P supports on-demand, but not scheduled, statistics

collection for VRRP in a VPRN. Certain VRRP SNMP traps do not apply to VPRN; see the appropriate NE documentation for information.

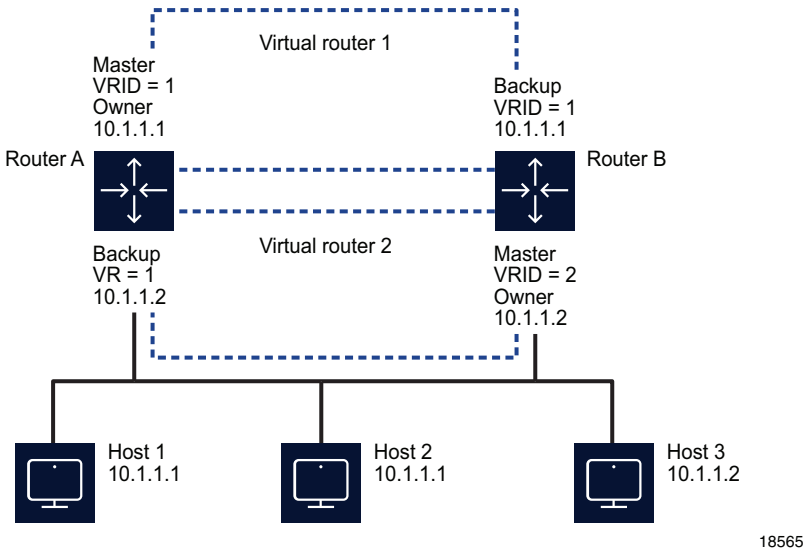
You can configure the VR through another set of tabbed forms and a navigation tree, which allows you to add VRRP instances IP owner and non-owner router interfaces, as shown in the following figure.

37.1.2 VR

A VR is a logical entity, managed by VRRP, that acts as a default router for hosts on a shared LAN. The VR consists of a VRID and a subnet (that is, ip_address/mask). A VRRP router can back up one or more VRs. The purpose of supporting multiple IP addresses in a single VR is for multi-netting. This common mechanism allows multiple local subnet attachments on a single routing interface. Up to four VRs are allowed on a single IP interface. The VRs must be in the same subnet.

The following figure shows a common VR setup in which associated routers provide mutual backup using VRRP. Router A forwards packets on IP address 10.1.1.1 to Hosts 1 and 2 on its default gateway. Router B forwards packets on IP address 10.1.1.2 to Host 3 on its default gateway. If Router A fails, VRID 1 uses IP address 10.1.1.1 to forward packets from Router B to Hosts 1 and 2. At the same time, the Router B interface is still configured to deliver packets on IP address 10.1.1.2 to Host 3. If Router B fails, VRID 2 forwards these packets through backup Router A.

Figure 37-2 Sample VRs



37.1.3 Master router

The VRRP master router, in either a normal or a failover situation, routes all IP packets into the LAN using the physical MAC address for the IP interface as the Layer 2 source MAC address. ARP packets also use the parent IP interface MAC address as the Layer 2 source MAC address.

37.1.4 Owner and non-owner VRRP instances

A VRRP instance is configured in either an owner or non-owner mode.

The owner instance controls the IP address of the VR and is responsible for forwarding packets sent to this IP address. The IP address of the owner VRRP instance is the same as the real interface IP address of the router. The owner assumes the role of the master VR when it is functioning normally in the network. Only one VRRP instance in the domain is configured as the owner. All other instances participating in the domain are non-owners and must have the same VRID.

A backup router becomes the master router after a failover and continues to use the IP address of the original master. As a result, the new master router is the IP address non-owner.

The most important parameter to define for a non-owner VRRP instance is the priority. The priority defines for a VR the selection order. The priority value and the preempt mode combine to determine which VR has the highest priority and becomes the master.

The base priority is used to derive the in-use priority of the VRRP instance as modified by an optional VRRP priority-control policy. VRRP priority-control policies are used to either override or adjust the base priority value depending on events or conditions in the NE. See Chapter 55, “VRRP policies” for more information.

37.1.5 Passive VRRP instances

A VRRP instance can be configured in passive mode. A passive VRRP instance does not transmit or receive keep-alive messages.

The following cannot be configured on a VRRP instance in passive mode:

- Authentication
- BFD Interface
- Init Delay
- Master Inherit Interval
- VRRP Policy association
- Preempt Mode
- Base Priority
- Standby Forwarding

37.1.6 VRRP types

When you create a VR, you specify the VRRP type, for example, network or L3 service, and the VR instance is restricted to the specified VRRP type. Configuring a VR using a mix of network and service interfaces through CLI raises a configuration mismatch alarm.

37.1.7 Primary addresses

A primary IP address is an address that is selected from the set of real interface addresses on the VR. VRRP advertisements between master and backup VRRP instances are sent using the primary IP address as the source of the IP packet.

An IP interface must always have an assigned primary IP address for VRRP to operate on the interface. The primary IP address of the VR and the primary address on the IP interface are always the same.

37.1.8 Backup addresses

A maximum of 16 IP addresses (for either IPv4 or IPv6) in different subnets can be configured for a VRRP instance. One backup address is permitted for a subnet. The number of backup addresses is limited to the number of primary and secondary addresses configured on the IP interface.

The backup IP addresses for the owner VRRP instance must match the primary address or one of the secondary addresses on the IP interface. If the VRRP instance is not the owner, the backup addresses must be in the subnets of the primary and secondary addresses of the IP interface.

The NFM-P includes only eligible IP addresses in the search list.

37.1.9 VRRP message authentication

The type of authentication used by the VR in VRRP advertisement is specified during VRRP instance creation. The current master router uses the configured authentication type when sending VRRP advertisements to backup routers, which authenticate the messages.

37.2 Workflow to configure VRRP

37.2.1 Stages

1

Before you create a VR, ensure that a primary IP address is configured for the network or L3 service interface. Each interface must have a primary IP address. See 27.18 “To configure L3 network interfaces” (p. 863) for more information.

2

Configure an SNMP community for VPRN sites that will contain a VRRP instance. See 79.17 “To configure an SNMP community on a VPRN site” (p. 2551) for more information.

3

Configure the VRRP priority-control policy for a non-owner VRRP instance. See Chapter 55, “VRRP policies” for more information about VRRP priority-control policy events.

4

Create the VR. See 37.3 “To create a VR” (p. 1283) for more information.

5

As required, create VRRP instances in the VR. See 37.4 “To create and configure a VRRP instance” (p. 1283) for more information.

37.3 To create a VR

37.3.1 Steps

1

Choose Manage→Networking→VRRP Virtual Routers from the NFM-P main menu. The Manage VRRP Virtual Routers form opens.

2

Click Create. The Virtual Router (Create) form opens.

3

Configure the required parameters.

Note: If you are creating an IPv6 VR, then you need to specify an IPv6 address as the Backup Address parameter value.

4

Save your changes and close the form.

END OF STEPS

37.4 To create and configure a VRRP instance

37.4.1 Purpose

Before you create a VRRP instance on an interface, ensure that the L3 service or network interface is configured with a primary IP address. The backup IP address that is configured in 37.3 “To create a VR” (p. 1283) must belong to the same subnet as the primary IP address of the owner VRRP instance created in this procedure. The NFM-P automatically configures a backup address using the IP address of the VR. A search of interface IDs in Step 5 of this procedure displays the interface IDs that are eligible for the creation of a VRRP instance for the VR.

Interfaces on VPRN sites must be associated with an SNMP community. See 79.17 “To configure an SNMP community on a VPRN site” (p. 2551) for more information about configuring an SNMP community for a VPRN site.

You can configure up to a total of four VRRP instances (IPv4 plus IPv6) on one IP interface. The maximum number of mixed IPv4 and IPv6 VRRP instances on an NE is 1024.

Note: The 7705 SAR does not support the configuration of a passive VRRP instance or the configuration of VRRP on a network interface.

37.4.2 Steps

1

Choose Manage→Networking→VRRP Virtual Routers from the NFM-P main menu. The Manage VRRP Virtual Routers form opens.

2

Choose a VR and click Properties. The Virtual Router (Edit) form opens.

3

Click on the Components tab.

4

Right-click on VR Instances and choose Create VRRP Instance. The VRRP Instance (Create) form opens.

If the Backup Address parameter value that you specified in Step 3 of 37.3 “To create a VR” (p. 1283) is an IPv6 address, then the contextual menu item is Create VRRP IPv6 Instance, and the VRRP IPv6 Instance (Create) form opens.

5

Assign an interface to the instance.

Perform the following steps:

1. Click Select in the Interface panel. The Select Interface - VRRP Instance or Select Interface - VRRP IPv6 Instance form opens, depending on whether you are creating an IPv4 or IPv6 VRRP instance respectively.
2. Choose an interface, and click OK. The Select Interface - VRRP Instance (or Select Interface - VRRP IPv6 Instance) form closes and the VRRP Instance (Create) or VRRP IPv6 Instance (Create) form reappears with the interface information displayed.

6

Configure the required parameters in the VRRP Instance Information panel.

If your set the Owner parameter to true, then you cannot configure the Administrative State and Base Priority parameters, and cannot associate a policy with this VRRP instance. Go to Step 8 .

7

Assign a VRRP policy to the instance, if required.

The same VRRP policy can be applied to both IPv4 VRRP instances and IPv6 VRRP instances.

1. Click Select in the Policy panel. The Select VRRP Policy form opens.
2. Choose a VRRP policy and click OK. The Select VRRP Policy form closes and the VRRP Instance (Create) form reappears with the VRRP policy information displayed.

8

Click on the Behavior tab and configure the required parameters.

9

If you require bidirectional forwarding detection for the VRRP instance.

Then, perform the following tasks:

1. Select the Enable BFD Interface check box. The BFD Interface tab appears.
2. Click on the BFD Interface tab.
3. Click Select beside the Service Name parameter, and choose a service from the Select Service - BFD Interface form.
4. Click Select beside the Interface Name parameter, and choose an interface from the Select Interface - BFD Interface form.
5. Configure the Destination Address parameter.

10

Click on the Authentication tab, and configure the required parameters.

11

Click on the Backup Addresses tab.

12

Click Create. The Backup Address (Create) form opens.

13

Perform one of the following to configure backup addresses:

a. Enter an IPv4 address (for an IPv4 VR) or IPv6 address (for an IPv6 VR) manually in the IP Address field in the Backup Address section.

b. Select the IP address from a list.

Perform the following steps:

1. Click Choose IP Address adjacent to the IP Address field. The Select IP Address form opens.
2. Choose an IP address and click OK.

   The Select IP Address form closes and the IP Address parameter is populated with your selection.
3. Click Add Link Local Address. The Admin Link Local Address defined for the network L3 access interface appears in the IP Address field.

   If you need to add the Link Local Address as a backup address, then the Admin Link Local Address must be configured and the Admin Link Local Address Preferred parameter must be enabled for the network L3 access interface that you are using. See 27.17 “To create an L3 network interface on a routing instance” (p. 856) for more information.

14

Save your changes and close the form.

15

Click OK. The Virtual Router (Edit) form reappears with the VRRP instances displayed in the VR instances tree.

END OF STEPS

37.5 To add a VRRP instance

37.5.1 Purpose

Use the following procedure to add a VRRP instance. A VRRP instance that you add to the VR must have an IP address with the same VRID and subnet as those of the VR.

37.5.2 Steps

1

Choose Manage→Networking→VRRP Virtual Routers from the NFM-P main menu. The Manage VRRP Virtual Routers form opens.

2

Choose a VR and click Properties. The Virtual Router (Edit) form opens.

3

Click on the Components tab.

4

Right-click on VR Instances and choose Add VRRP Instance.

Note: If you chose an IPv6 VR in Step 2 , the contextual menu item is Add VRRP IPv6 Instance, and the Select VRRP IPv6 Instance form opens.

The Select VRRP Instance form opens.

5

Choose a VRRP instance and click OK. The Select VRRP Instance (or Select VRRP IPv6 Instance) form closes and the Virtual Router (Edit) form reappears with the interface information displayed.

END OF STEPS

37.6 To modify a VR or VRRP instance

37.6.1 Steps

1

Choose Manage→Networking→VRRP Virtual Routers from the NFM-P main menu. The Manage VRRP Virtual Routers form opens.

2

Choose a VR and click Properties. The Virtual Router (Edit) form opens.

3

Configure the VR parameters.

To configure parameters for a VRRP instance, click on the Components tab, select and right-click on the VRRP instance, and choose Properties.

You can also choose another configuration option to configure the NE associated with the VRRP instance or to configure the interface associated with the VRRP instance.

4

Click Properties in the Instance panel. The VRRP Instance (Edit) form opens.

5

The following tabs list the VRRP instance properties that you can select and configure:

- General—associations between the VRRP instance and NEs, network interfaces, and policies (non-owner VRRP instances only).
- Behavior—a virtual MAC address that must be the same for all participating VRRP instances
- Authentication—enables authentication of VRRP advertisements among participating VRRP instances in the VR. For more information, see 37.1.9 “VRRP message authentication” (p. 1282) in 37.1 “VRRP” (p. 1279) .
- Backup Addresses—lists backup addresses, whose configuration options you can access by selecting a site and clicking Properties. For more information, see 37.1.8 “Backup addresses” (p. 1282) in 37.1 “VRRP” (p. 1279) .
- VR Instances—lists VRs, whose configuration options you can access by selecting a VR and clicking Properties. For more information, see 37.1.4 “Owner and non-owner VRRP instances” (p. 1281) in 37.1 “VRRP” (p. 1279) .

6

Modify the parameters for the VRRP instance as required.

7

Save your changes. The VRRP Instance (Edit) form closes and the VR Instance (Edit) form reappears.

8

Close the VR Instance (Edit) form.

END OF STEPS

37.7 To view the status of a VR

37.7.1 Purpose

The status of a VR informs you of potential problems, such as problems involving VR preconditions and operational states. You can view the following virtual status information:

- Aggregated Operational State—indicates the collective operational states of the VRRP instances in the VR, such as whether all instances are up, all instances are down, or one or more is down
- Number Of VRRP Instances—the number of owner and non-owner VRRP instances in the current VR
- Multiple Owners configured—one owner for each VR
- VR Instance(s) Down—one or more VRs are not working
- Backup Address Mismatch—the backup address for a VRRP instance does not match the primary IP address of the owner, and so does not match the VR IP address
- Only one instance configured—only one VR instance exists, either a master or backup; both are required
- Subnet Mismatch—the IP addresses of the owner and non-owner routers do not belong to the same subnet
- No Owner configured—an IP address owner is not assigned to the current VR

37.7.2 Steps

1

Choose Manage→Networking→VRRP Virtual Routers from the NFM-P main menu. The Manage VRRP Virtual Routers form opens.

2

Configure the filter criteria. A list of VRs is displayed at the bottom of the Manage VRRP Virtual Routers form.

3

Choose a VR and click Properties. The Virtual Router (Edit) form opens. Status information is in the Status panel.

4

Close the Virtual Router (Edit) form.

END OF STEPS

37.8 To delete a VRRP instance

37.8.1 Steps

1

Choose Manage→Networking→VRRP Virtual Routers from the NFM-P main menu. The Manage VRRP Virtual Routers form opens.

2

Configure the filter criteria. A list of VRs is displayed at the bottom of the Manage VRRP Virtual Routers form.

3

Choose a VR and click Properties. The Virtual Router (Edit) form opens.

4

Click on the Components tab.

5

Right-click on a VR instance and choose Delete. A dialog box appears.

6

Click Yes to confirm your action. The VR is deleted and removed from the VR instances tree.

7

Close the Virtual Router (Edit) form.

END OF STEPS

37.9 To delete a VR

37.9.1 Steps

1

Choose Manage→Networking→VRRP Virtual Routers from the NFM-P main menu. The Manage VRRP Virtual Routers form opens.

2

Configure the filter criteria. A list of VRs is displayed at the bottom of the Manage VRRP Virtual Routers form.

3

Choose a VR and click Delete. A dialog box appears.

4

Confirm your action. The VR is removed from the list.

5

Close the Manage VRRP Virtual Routers form.

END OF STEPS

38 APS

38.1 Overview

38.1.1 Purpose

APS protects SONET/SDH lines from linear bidirectional failures. The NEs in a SONET/SDH network constantly monitor the health of the network. When a failure is detected, the network proceeds to transfer, or switch over, live traffic from the active, or working line, to the standby, or protection line. The transfer occurs quickly to minimize traffic loss. The traffic remains on the protection line until the fault on the working line clears, at which time the traffic can optionally revert to the working line.

In a 1+1 APS architecture, the active OC-*n* signal is transmitted to both the working and protection ports, so the same payloads are transmitted identically to the working and protection ports in the egress direction. The working and protection signals are selected independently in the ingress direction.

38.1.2 Contents

APS overview

38.2 APS overview

38.2.1 Overview

CAUTION

Service Disruption

An NE transmits data only on the working line.

For a single failure, this configuration can cause a delay of up to 100 ms during an APS switch.

On the NFM-P, the main APS elements are the following:

- APS groups

  An APS group is an aggregation of one or two SONET/SDH ports and the associated logical ports, known as APS channels. The first port is known as the working channel and must be configured in the APS group. The second port is the protection channel, which is optionally configurable. In a 1+1 optimized APS group, the protection channel is replaced with a second working channel.

- APS channels

  APS channels are logical and model the physical ports. The set of associated data for an APS channel includes the corresponding physical port identifier, the role, which is working or protection, and the name of the APS group to which the port belongs. If a protection channel is configured, it carries the traffic of the failed working channel. If the protection channel fails, the working channel carries the traffic.

- APS bundles

  APS bundles protect multilink PPP and IMA bundles on channelized ASAP MDAs. All the members of a working or protection APS bundle must belong to the same working or protection line of the APS group.

- APS common port configurations

  All SONET/SDH port parameters on the working and protection channels in an APS group must be identical except for the following:
  - Clock Source
  - Loopback
  - Report Alarms
  - BER Signal Degradation Threshold
  - BER Signal Failure Threshold
  - SONET Section Trace Mode

- APS commands

  Each APS channel has one APS operational command associated with it. The APS operational command is determined by the last command that is issued to both APS channels and the signal condition of the working and protection ports. APS commands affect the APS operational states but do not affect the configuration. The operational state does not persist through an NE restart.

Table 38-1, “Events affecting 1+1 protection” (p. 1293) The following table describes the events that affect 1+1 protection and their relative priority.

Table 38-1 Events affecting 1+1 protection

Priority	Event	Event type
1	Lockout of protection	User initiated
2	Signal failure on protection line	Automatically initiated
3	Forced switch	User initiated
4	Signal failure on working line	Automatically initiated
5	Signal degradation	Automatically initiated
6	Manual switch	User initiated
7	WTR time (revertive switching only)	User initiated (state request)
8	No reversion (non-revertive switching only)	User initiated (state request)

Consider the following when configuring APS:

- A port can belong to only one APS group.
- Two ports that belong to the same APS group must be of the same port type and have the same traffic speed.
- An APS group has one set of APS channels. The set can contain one or two APS channels.
- An APS channel can belong to only one APS group.
- A SONET/SDH port can either belong to only one APS channel.

38.2.2 Bidirectional mode

In 1+1 system bidirectional mode, a signal failure in either direction causes both the near-end and far-end NEs to switch to the protection channels. The highest-priority local request is compared with a remote request; the request that has the greater priority is selected. See Table 38-1, “Events affecting 1+1 protection” (p. 1294) for the list of events that affect 1+1 protection.

38.2.3 Unidirectional mode

In a 1+1 system unidirectional mode, the working interface switches to the protection interface only for the direction in which a signal failure occurs. For example, if there is a signal failure in the transmit direction, the working interface switches to the protection interface for transmission but not for the receipt of data.

38.3 Switching modes

38.3.1 Overview

The following 1+1 system switching modes are available:

- non-revertive (default)

- revertive

In non-revertive switching, a switch to the protection channel is maintained even after the working line has recovered from a failure or a manual switch is cleared.

In revertive switching, the traffic is switched back to the working channel after the working line has recovered from a failure or a manual switch is cleared.

For revertive switching, you can define a period of time that the system must wait before it can restore traffic from the protection line to the working line. This delay, or WTR time, prevents frequent automatic switches from occurring as a result of intermittent failures.

In case of failure on both the working and protection lines, the line that has the less severe error remains active. If there is a signal degradation on both lines, the active line that failed last remains active. If there is a signal failure on both lines, the working line always remains active because a signal failure on the protection line is a higher priority than a signal failure on the working line.

38.4 MLPPP

38.4.1 Overview

MLPPP provides a way to distribute data across multiple links within an MLPPP APS bundle to achieve high bandwidth. MLPPP allows for a single frame to be fragmented and transmitted across multiple links. This reduces latency and allows for a higher maximum received recovery unit, or MRU.

MLPPP is supported in MC APS groups. See 38.7 “MC APS” (p. 1298) for more information about MC APS.

38.4.2 Multiclass MLPPP

Multiclass MLPPP is an extension of the MLPPP standard which allows multiple classes of service to be transmitted over an MLPPP bundle.

Multiclass MLPPP changes the MLPPP header to include either two or four class bits to allow for up to either four or 16 classes of service. This allows multiple classes of services over a single MLPPP connection. The highest priority traffic is transmitted over the MLPPP bundle with minimal delay, regardless of the order in which packets are received.

Multiclass MLPPP is useful in mobile network deployments where multiple types of traffic, each with its own priority level, travel across a single MLPPP link bundle between the base station router and the aggregation router in the point of presence (POP) mobile operator.

Note: Multiclass MLPPP allows for several classes of services to be transmitted over an MLPPP bundle. Link fragmentation and interleaving, however, allows for only two classes of service to be transmitted. Multiclass MLPPP and link fragmentation and interleaving are mutually exclusive.

38.5 APS port configurations

38.5.1 Overview

A 7750 SR network or access port can be connected to another 7750 SR with both the working and protection channels on different IOMs in a single NE, or with the working channel on one NE and the protection channel on another.

A 7705 SAR access port can be connected to another 7705 SAR with both the working and protection channels on different MDAs on a single NE, or with the working channel on one NE and the protection channel on another.

For the 7705 SAR, for clear channels sts3 and sts12, only network mode for APS groups is supported.

Note: Mirroring parameters configured on a specific port or service are maintained during an APS failover.

All SONET/SDH MDAs support APS functionality. Table 38-2, “APS port configurations” (p. 1295)The following table lists the possible port pairings to provide APS protection. Both ports must be of the same type and have the same traffic speed.

Table 38-2 APS port configurations

MDA type—Working channel	MDA type—Protection channel
16 × OC12/OC3 SFP	8 × OC12/OC3 SFP or 16 × OC12/OC3 SFP
8 × OC12/OC3 SFP	8 × OC12/OC3 SFP or 16 × OC12/OC3 SFP
16 × OC3 SFP	8 × OC3 SFP or 16 × OC3 SFP
8 × OC3 SFP	8 × OC3 SFP or 16 × OC3 SFP
4 × OC48 SFP	2 × OC48 SFP or 4 × OC48 SFP
2 × OC48 SFP	2 × OC48 SFP or 4 × OC48 SFP
1 × OC192	1 × OC192
16 × ATM OC3 SFP	16 × ATM OC3 SFP
4 × ATM OC12/OC3 SFP	4 × ATM OC12/OC3 SFP
4 × Channelized OC3 ASAP	4 × Channelized OC3 ASAP
4 × Channelized OC3/OC12 ASAP SFP	4 × Channelized OC3/OC12 ASAP SFP
1 × Channelized OC12 ASAP	1 × Channelized OC12 ASAP
1 × Channelized OC3 CES	4 × Channelized OC3 CES
4 × Channelized OC3 CES	1 × Channelized OC3 CES
1 × Channelized OC12 CES	1 × Channelized OC12 CES

Note: The working and protection channels for the following MDA port pairs are set to the same traffic speed based on the APS group speed configuration:

- 16 × OC12/OC3 SFP and 16 × OC12/OC3 SFP

- 16 × OC12/OC3 SFP and 8 × OC12/OC3 SFP
- 8 × OC12/OC3 SFP and 16 × OC12/OC3 SFP
- 8 × OC12/OC3 SFP and 8 × OC12/OC3 SFP
- 4 × ATM OC12/OC3 SFP and 4 × ATM OC12/OC3 SFP

38.6 SC APS

38.6.1 Overview

1+1 APS can be implemented on a port-by-port basis. If all ports on an MDA or IOM need to be protected, the ports must be individually configured.

The working and protection lines are capable of being connected to:

- two ports on the same MDA (not applicable to the 7705 SAR)
- two ports on different MDAs, and the MDAs are on the same IOM
- two ports on different MDAs on different IOMs

If the working channel and protection channel are on the same MDA, protection is limited to the physical port and the media that connect the two NEs. If different IOMs are used, protection extends to failure of each IOM.

Note: The working and protection channels should be configured on different MDAs but on the same IOM card for the 7705 SAR-8 and 7705 SAR-18.

Working and protection lines can be connected to a 7705 SAR-8, 7705 SAR-8v2, 7705 SAR-18, 7450 ESS, or 7750 SR, and serve as an access port that provides one or more services to the NE. The access port can be a single channel or multiple channels; each channel must support PPP. In the case of the ATM MDA, each channel must support ATM.

The end NE transmits a valid data signal to both the working and protection lines. The signal on the protection line is ignored until the working channel fails or degrades to the degree that requires a switchover to the protection channel. When the switchover occurs, all services, including all service QoS and filter policies, are activated on the protection channel.

The working channel on a 7705 SAR-8, 7705 SAR-8v2, 7705 SAR-18, 7750 SR, or 7450 ESS must connect to the working channel on a peer NE, and the protection channel on a 7705 SAR-8, 7705 SAR-8v2, 7705 SAR-18, 7750 SR, or7450 ESS must connect to the protection channel on a peer NE.

38.6.2 1+1 optimized

You can configure an SC APS group with a 1+1 optimized configuration. A 1+1 optimized APS group is optimized for networks which rely primarily on 1+1 bidirectional switching. A 1+1 optimized APS group is configured with two working channels, as opposed to one working channel and one protection channel. In a 1+1 optimized configuration, one working channel acts as the primary channel, through which the traffic will always default. A 1+1 optimized APS group always operates in bidirectional and nonrevertive modes.

38.7 MC APS

38.7.1 Overview

You can use APS to protect against NE failure by configuring the working channel of an APS group on one 7705 SAR-8, 7705 SAR-8v2, 7705 SAR-18, or 7750 SR, and configuring the protection channel of the same APS group on a different 7705 SAR-8, 7705 SAR-8v2, 7705 SAR-18, or 7750 SR. The two NEs connect using an IP link that is used to establish a signaling path between them.

The working channel on the near-end NE must connect to the working channel on a peer NE, and the protection channel on the far-end NE must connect to the protection channel on a peer NE.

When an MC APS group is configured, the NFM-P automatically creates a container which aggregates the MC APS group configurations of each NE.

Multi-chassis APS configuration is supported for ATM clear channel interfaces.

38.8 APS on channelized ASAP MDAs

38.8.1 Overview

You can protect a channelized SONET/SDH port on a channelized ASAP MDA with a protection port of the same speed on a different channelized ASAP MDA in the same NE. The APS configuration on a channelized ASAP MDA provides protection against a port, MDA, or IOM failure. All SONET/SDH paths and TDM channels in a SONET/SDH port are protected.

Consider the following when you configure APS protection on a deep channel on a channelized ASAP MDA:

- Both SONET and SDH channels are supported.
- Up to three common configuration SONET channels can be created in an APS configuration.

38.9 APS on channelized CES MDAs

38.9.1 Overview

You can protect a channelized SONET/SDH port on a channelized CES MDA with a protection port of the same speed on a different channelized CES MDA in the same NE. The APS configuration on a channelized CES MDA provides protection against a port, MDA, or IOM failure. All SONET/SDH paths and TDM channels in a SONET/SDH port are protected.

Consider the following when you configure APS protection on a deep channel on a channelized CES MDA:

- Both SONET and SDH channels are supported.
- Up to three common configuration SONET channels can be created in an APS configuration.

38.10 APS on multilink bundles

38.10.1 Overview

APS on multilink bundles consists of a working and protection bundle which provide bidirectional APS protection to each other. The members of a working or protection multilink bundle must belong to the same working or protection line of the APS group. User traffic is not sent on the protection line.

The NFM-P supports APS on MLPPP and IMA bundles. In IMA bundles, IMA cells are sent on the protection line as a keep-alive signal during an APS switchover.

APS 1+1 configuration on the channelized MDA provides protection to all the channels on the protected SONET/SDH port and to all of the multilink bundles with member that links reside on the protected SONET/ SDH port.

38.10.2 APS bundles on multiple NEs

You can configure APS bundles to provide bidirectional APS protection across multiple NEs. MC APS bundles are supported on the 7705 SAR and 7750 SR.

You can use APS to protect against failure by configuring the working bundle on one NE, and configuring the protection bundle of the same APS bundle group on a different NE. The two NEs connect to each other with an IP link that is used to establish a signaling path between them.

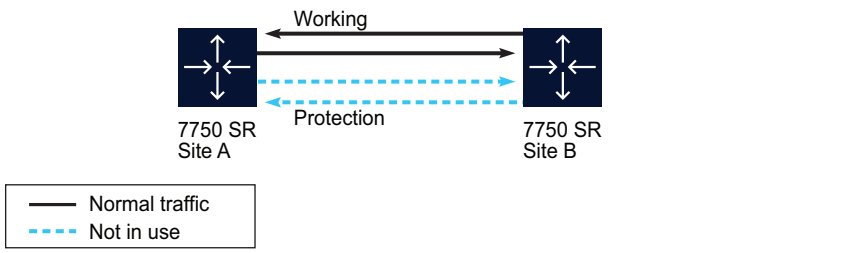
38.11 1+1 APS configuration example

38.11.1 Overview

Figure 38-1, “Normal operations between two 7750 SRs” (p. 1299)and Figure 38-4, “Normal operations resume on the protection line” (p. 1301) show an example of 1+1 APS for two 7750 SRs that are configured for 1+1 APS in bidirectional and non-revertive modes.

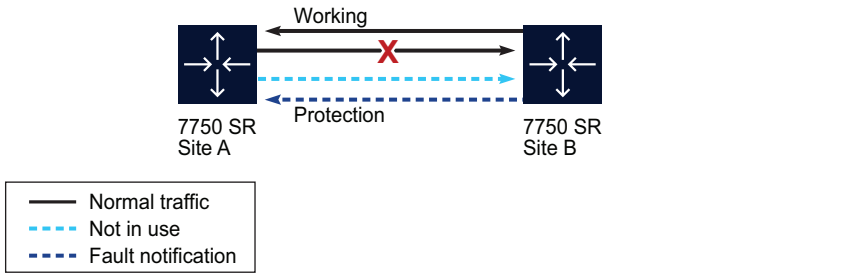
Figure 38-1, “Normal operations between two 7750 SRs” (p. 1299) shows normal operations between two 7750 SRs. There are no faults on the working line, and the protection line is not in use.

Figure 38-1 Normal operations between two 7750 SRs



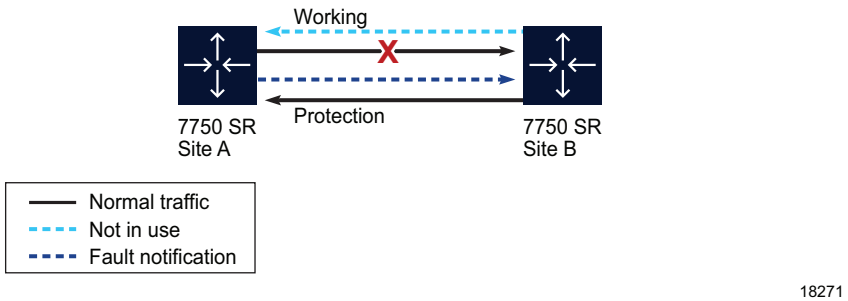
The working line degrades in the direction from site A to site B. Site B detects the fault and notifies site A of the fault using the protection line. The following figure shows the fault on the working line and site B notifying site A of the fault.

Figure 38-2 Site B detects the fault and notifies site A



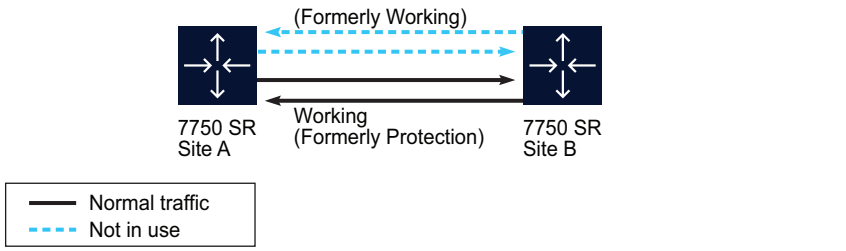
Site B automatically switches to the protection line. Site A receives the fault notification from site B and detects the fault on the working line. Site A acknowledges the fault and notifies site B that it is switching to the protection line. The following figure shows site B switching to the protection line and site A acknowledging the fault.

Figure 38-3 Site B switches to the protection line and site A acknowledges the fault



Site B receives the notification from site A and site A automatically switches to the protection line. The following figure shows normal operations resuming on the protection line between site A and site B. The protection line becomes and remains the working line since 1+1 APS is configured for non-revertive switching in this example.

Figure 38-4 Normal operations resume on the protection line



38.12 Configuring SAPs on APS-protected ports

38.12.1 Overview

You can use APS-protected ports to create SAPs for services. The SAP list of a service creation form displays the APS-group SONET channels with all other SONET channels, but uses a different port ID format. An example of an APS group port ID is Channel aps-1.sts3-1. To create a SAP that uses an APS group, you must first configure the SONET channels in the APS group.

APS management procedures

38.13 Workflow to manage APS

38.13.1 Stages

1

As required, create an SC APS group or MC APS group and configure the various channel types supported by APS groups. Configure the operational state for each APS channel. See 38.14 “To create an SC APS group” (p. 1302) and 38.15 “To create an MC APS group” (p. 1305) for more information.

2

As required, create an SC APS IMA or MLPPP bundle or MC APS MLPPP bundle. See 38.16 “To create an SC APS IMA or MLPPP bundle” (p. 1307) and 38.17 “To create an MC APS MLPPP bundle” (p. 1311) for more information.

3

As required, change the operational state of an APS channel; see 38.18 “To change the operational state of an SC APS channel” (p. 1313) .

4

As required, delete the APS group or bundle.

See the following procedures:

- See 38.19 “To delete an SC APS group” (p. 1314) to delete a SC APS group
- See 38.20 “To delete an SC APS bundle” (p. 1314) to delete a SC APS bundle
- See 38.21 “To delete an MC APS group or bundle” (p. 1315) to delete an MC APS group or bundle

38.14 To create an SC APS group

38.14.1 Purpose

Perform this procedure to create an SC APS group and configure the various channel types supported by APS groups including:

- APS working channels
- APS protection channels
- APS SONET channels
- SONET clear channels
- The maximum number of channels on ports that support multiple sub-channels

Note: When a multiservice site is configured on an IOM, the working and protection ports

must be configured on the same IOM.

38.14.2 Steps

1

On the equipment tree, navigate to the Network Element and expand the Shelf icon.

2

Right-click on the APS Groups object and choose Create APS Group. The SC APS Group (Create) form opens with the General tab displayed.

3

Configure the Description parameter.

4

Click on the APS Group tab and configure the required parameters.

5

Click on the States tab and configure the Administrative State parameter.

Note: When a working channel or protection channel is added to an APS group, the channel inherits the current administrative state of the APS group. After the channel is added to the APS group, the administrative state of the physical port can be changed independently.

6

Click Apply. An SC APS Group icon appears under the APS Groups object in the navigation tree.

7

Click on the APS Group tab and configure the required parameters.

8

To configure the working and protection channels for the APS group:

Note: Prior to completing this step, your NE device must be configured with a card that supports APS ports. See Table 38-2, “APS port configurations” (p. 1296) for a list of cards that support APS ports.
To create an APS working channel or APS protection channel, you can also right click on the SC APS Group icon under the APS Groups object in the navigation tree and choose

Create APS Working Channel or Create APS Protection Channel from the contextual menu. The Create APS Protection Channel option is available only when an APS Working Channel already exists.

The working and protection channels should be configured on different MDAs but on the same IOM card for the 7705 SAR-8 and 7705 SAR-18.

1. Click on the APS Channels tab and click Create. The APS Channel (Create) form opens.
2. Configure the Channel Role parameter, if applicable.

   Note:

   If you are creating a 1+1 SC APS group, you must create the working channel before you create the protection channel.
3. Select a port and click OK. The channel is listed on the SC APS Group (Edit) form.
4. Repeat 2 and 3 to add the protection channel or second working channel.
5. Click Apply.

9

To configure the operational state of the working and protection channels:

Use the following steps:

1. Choose a channel and click Properties. The APS Channel - *Type* (Edit) form opens with the APS Channel tab displayed.
2. Configure the Command Switch parameter and click OK.

10

To configure the APS SONET channels for the APS group:

Use the following steps:

1. Right-click on the SC APS Group icon in the navigation tree and choose Create APS SONET Channel. The Sts*n* SONET Channel (Create) form opens with the General tab displayed.
2. Configure the channels as described in 16.64 “To create VT15 (TU11) or VT2 (TU12) sub-channels” (p. 660) .

11

Perform one of the following for the APS group:

a. To create individual SONET clear channels:

   Use the following steps:

   1. Right-click on the APS Common Config SONET channel icon and choose Create Channel. The DSO Channel Group, (Create) form opens.
   2. Configure the channel as described in 16.60 “To configure SONET clear channels” (p. 653) .

b. To create the maximum number of channels on ports that support multiple sub-channels:

Use the following steps:

1. Right-click on the APS Common Config SONET channel icon and choose Create Maximum # of Channels. The Create Maximum # of Channels form opens.
2. Configure the channels as described in 16.61 “To perform a bulk channel creation on ports that support multiple sub-channels” (p. 654) .

12

Save your changes and close the form.

END OF STEPS

38.15 To create an MC APS group

38.15.1 Purpose

Perform this procedure to create an MC APS group and configure the various channel types supported by APS groups including:

- APS working channels
- APS protection channels
- APS SONET channels
- SONET clear channels
- The maximum number of channels on ports that support multiple sub-channels

38.15.2 Steps

1

Choose Manage→Redundancy→Node Redundancy from the NFM-P main menu. The Manage Node Redundancy form opens.

2

Choose MC APS Group (APS) from the object drop-down menu and click Create. The MC APS Group (Create) form opens.

3

Configure the Group Number parameter.

4

Select a Site Id and Network Interface Address in the First Element and Second Element panels.

Note: Only numbered IPv4 interfaces are listed.
The default interface is the NE system interface.

5

Click Apply. An MC APS Group Member icon appears under the APS Groups object in the navigation tree of the selected First Element and Second Element NEs.

6

Click on the Members tab to configure each MC APS group member.

7

Select a group member in the list and click Properties. The MC APS Group Member (Edit) form opens with the General tab displayed.

8

Configure the Description parameter.

9

Click on the APS Group tab and configure the required parameters.

Note: The Wait To Restore (seconds) parameter is configurable when the Revert Mode parameter is set to revertive.

10

Click on the States tab and configure the Administrative State parameter.

Note: When a working channel or protection channel is added to the APS group, the channel inherits the current administrative state of the APS group. After the channel is added to the APS group, the administrative state of the physical port can be changed independently.

11

Click on the Multi Chassis tab and configure the required parameters.

12

To configure the working and protection channels for the APS group:

Note: Prior to completing this step, your NE device must be configured with a card that supports APS ports. See Table 38-2, “APS port configurations” (p. 1296) for a list of cards that support APS ports.

Use the following steps:

1. Click on the APS Channels tab and click Create. The APS Channel (Create) form opens.
2. Configure the Channel Role parameter.
3. Select a port and click OK. The channel is listed on the MC APS Group (Edit) form.
4. Repeat 2 and 3 to add the protection channel or second working channel.
5. Click Apply.

13

To configure the operational state of the working and protection channels:

Use the following steps:

1. Choose a channel from the list and click Properties. The APS Channel - *Type* (Edit) form opens with the APS Channel tab displayed.
2. Configure the Command Switch parameter and click OK. The APS Channel - *Type* (Edit) form closes.

14

To configure the APS SONET channels for the APS group:

Use the following steps:

1. Right-click on the MC APS Group icon in the navigation tree and choose Create APS SONET Channel. The Channel Type Selection form opens.
2. Choose a channel type and click OK. The Sts*n* SONET channel (Create) form opens.
3. Configure the channels as described in 16.64 “To create VT15 (TU11) or VT2 (TU12) sub-channels” (p. 660) .

15

Perform one of the following for the APS group:

a. To create individual SONET clear channels:

   Use the following steps:

   1. Right-click on the APS Common Config SONET channel icon and choose Create Channel. The DSO Channel Group, (Create) form opens.
   2. Configure the channel as described in 16.60 “To configure SONET clear channels” (p. 653) .

b. To create the maximum number of channels on ports that support multiple sub-channels:

   Use the following steps:

   1. Right-click on the APS Common Config SONET channel icon and choose Create Maximum # of Channels. The Create Maximum # of Channels form opens.
   2. Configure the channels as described in 16.61 “To perform a bulk channel creation on ports that support multiple sub-channels” (p. 654) .

16

Save your changes and close the form.

END OF STEPS

38.16 To create an SC APS IMA or MLPPP bundle

38.16.1 Purpose

Perform this procedure to create an APS bundle using IMA or MLPPP links on one NE. Consider the following when you add a DS0 channel that is a member of an APS group to an APS bundle:

- An APS channel can be a member of an APS bundle only, not of an IMA or multilink PPP bundle.
- All members of a working bundle must belong to a working channel of the same APS group.
- All members of a protection bundle must belong to a protection channel of the same APS group.
- You must create the working bundle before you can add an APS member to the APS bundle. If the member has a protection port, you must create the protection bundle before you can add the member to the APS bundle.
- You cannot delete the working port member of an APS bundle until you remove the member from the APS bundle.

The rules for adding a member to a bundle that is part of an APS bundle also apply to adding a member to a non-APS protected multilink bundle. See 15.90 “To create an MLPPP bundle” (p. 551) and 15.88 “To create an IMA group bundle” (p. 550) for more information.

The following restrictions apply when adding a DS0 channel to an IMA bundle:

- The Clock Source parameter must be set to Node Timed.
- The encapsulation type of the DS0 channel must be ATM.

The following restrictions apply when adding a DS0 channel to a PPP bundle:

- All time slots on the DS0 channel must be selected.
- The encapsulation type of the DS0 channel must be IPCP.

38.16.2 Steps

1

On the equipment tree, right-click on the device where you want to configure an APS bundle and select Properties. The Network Element (Edit) form opens with the General tab displayed.

2

On the Network Element (Edit) form navigation tree, expand the Shelf icon.

3

Right-click on the APS Bundles object and choose Create Bundle. The APS Bundle Display form opens.

4

Configure the Bundle ID and Description parameters and click Next.

5

Set the Bundle Type parameter to IMA Group or PPP and configure the applicable parameters.

6

Click Finish and then click Close. The APS Bundle Display form closes.

7

If the Bundle Type parameter is set to PPP in Step 5 , configure the MLPPP bundle for multiclass service transmission.

Note: Consider the following when you configure MC MLPPP.

- MC MLPPP is supported only on channelized ASAP MDAs on a 7705 SAR or 7750 SR.
- You must configure MC MLPPP before you add bundle members.
- MC MLPPP is configured on the main APS bundle and the parameters are propagated to the working and protection bundles.
- You can only apply QoS profiles to an MC MLPPP bundle when the Class Count parameter is set to 4.

Use the following steps:

1. Right-click on the SC APS Bundle object in the navigation tree and choose Properties. The APS Bundles (Edit) form opens.
2. Click on the MLPPP tab and configure the required parameters.
3. Select a QoS profile in the MLPPP Ingress QoS Profile or MLPPP Egress QoS Profile panel, if required.

8

Click on the States tab and configure the Administrative State parameter.

Note: You must configure the End Point ID parameter on the APS PPP group before you set the Administrative State parameter to Up on the working and protection bundles.

9

Save your changes.

10

Configure the APS working and protection bundles:

Note: You must create the working bundle before you create the protection bundle.

Use the following steps:

1. Right-click on the SC APS Bundle icon in the navigation tree and choose Create APS Working Bundle. The Create APS Working/Protecting Bundle form opens.

2. Configure the required parameters and click Next to view the configured bundle parameters.
3. Click Finish and then click Close. The Create APS Working/Protecting Bundle form closes.
4. Right-click on the SC APS Bundle icon in the navigation tree and choose Create APS Protection Bundle. The Create Working/Protecting Bundle form opens.
5. Repeat 2 and 3 to create the APS protection bundle.

11

To configure the administrative state of the APS working and protection bundles:

Note: You must configure the End Point ID parameter on the APS PPP group before you change the working or protection bundle state.

Use the following steps:

1. Right-click on the working bundle object below the SC APS Bundle object in the navigation tree and choose Properties. The Multilink Bundle (Edit) form opens.
2. Click on the States tab and configure the Administrative State parameter.
3. Click OK.
4. Right-click on the protection bundle object below the SC APS Bundle object in the navigation tree and choose Properties. The Multilink Bundle (Edit) form opens.
5. Repeat 2 and 3 to configure the administrative state of the protection bundle.

12

Add members to the APS bundle.

Use the following steps:

1. Right-click on the SC APS Bundle icon in the navigation tree and choose Create Bundle Members. The Add Bundle Member form opens.
2. Click Next to add DS0 channel groups to the bundle. The Select Channels form opens.
3. Select a compatible channel from the list.

   Note:

   When initially adding bundle members, you must first add one channel group and then repeat the procedure to select up to seven additional channel groups.

   Only compatible channels are listed. If you want to configure and use a channel that is currently incompatible, you can click on the Back button, deselect the Show Only Compatible Channels parameter, click on the Next button, select the channel, click on the Properties button.

   The channel group with the lowest Port ID is the primary member for the bundle. The Encap Type of the primary member is used for all other members. When adding members to a bundle at a later time, the Encap Type must be the same as the primary member Encap Type for the member to be compatible.
4. Click Finish. The Add Bundle Member form closes.

5. Click Apply and then click Add. The Add Bundle Member form opens.
6. Configure the Show Only Compatible Channels parameter and click Next. The Select Channels form opens.
7. Select up to seven additional channels from the list.
8. Click Finish.

13

Save your changes and close the form.

END OF STEPS

38.17 To create an MC APS MLPPP bundle

38.17.1 Steps

1

Choose Manage→Redundancy→Node Redundancy from the NFM-P main menu. The Manage Node Redundancy form opens.

2

Choose MC APS Bundles (Bundle) and click Create. The MC APS Bundles (Create) form opens.

3

Configure the Bundle Number parameter.

4

Select a First Network Element and Second Network Element and click OK. The MC APS Bundle object appears in the navigation tree under the APS Bundles object for each specified NE.

5

Close the Manage Node Redundancy form.

6

To configure the MLPPP bundle for multiclass service transmission:

Note: Consider the following when you configure MC MLPPP.

- You must configure MC MLPPP before you add bundle members.

- MC MLPPP is configured on the main APS bundle and the parameters are propagated to the working and protection bundles.

Use the following steps:

1. Right-click on the new MC APS Bundle object in the navigation tree and choose Properties. The APS Bundles (Edit) form opens.
2. Click on the MLPPP tab and configure the required parameters.
3. Save your changes.

7

Click on the States tab and configure the Administrative State parameter.

Note: You must configure the End Point ID parameter on the APS PPP group before you set the Administrative State parameter to Up on the working and protection bundles.

8

Save your changes and close the form.

9

Configure the MC APS working and protection bundles.

Use the following steps:

1. Right-click on the MC APS Bundle object in the navigation tree and choose Properties. The APS Bundles (Edit) form opens.
2. Click on the Protection and Working Bundles tab and click Create. The Create APS Working/Protecting Bundle form opens.
3. Configure the required parameters.
4. Select a daughter card and click Next.
5. Configure the required parameters.

   Note:

   The working bundle must be on the same NE as the APS working channel and the protection bundle must be on the same NE as the APS protection channel.
6. Click Finish and then click Close. The Create APS Working/Protecting Bundle form closes.
7. Close the APS Bundles (Edit) form.
8. Repeat 1 to 7 to configure the MC APS protection bundle.

10

Configure the administrative state of the MC APS working and protection bundles.

Use the following steps:

1. Right-click on the working bundle object in the navigation tree and choose Properties. The Multilink Bundle (Edit) form opens.

2. Click on the States tab and configure the Administrative State parameter.
3. Save your changes.
4. Right-click on the protection bundle object in the navigation tree and choose Properties. The Multilink Bundle (Edit) form opens.
5. Repeat 2 and 3 .

11

Add multilink bundle members.

Use the following steps:

1. Right-click on the MC APS Bundle object on either NE in the navigation tree and choose Properties. The APS Bundles (Edit) form opens.
2. Click on the Bundle Members tab and click Add. The Add Bundle Member form opens.
3. Configure the Show Only Compatible Channels parameter and click Next. The Select Channels form opens.
4. Select a channel in the list.

   Note:

   When initially adding bundle members, you must first add one channel group and then repeat the procedure to select up to seven additional channel groups.

   Only compatible channels are listed. If you want to configure and use a channel that is currently incompatible, you can click Back, deselect the Show Only Compatible Channels parameter, click Next, select the channel, and click Properties.

   The channel group with the lowest Port ID is the primary member for the bundle. The Encap Type of the primary member is used for all other members. When adding members to a bundle at a later time, the Encap Type must be the same as the primary member Encap Type for the member to be compatible.
5. Click Finish.
6. Click Apply and then click Add. The Add Bundle Member form opens.
7. Configure the Show Only Compatible Channels parameter and click Next. The Select Channels form opens.
8. Select up to seven additional channels from the list and click Finish.

12

Save your changes and close the form.

END OF STEPS

38.18 To change the operational state of an SC APS channel

38.18.1 Steps

1

On the equipment tree, right-click on the device where you want to modify the APS channel and select Properties. The Network Element (Edit) form opens with the General tab displayed.

2

On the Network Element (Edit) form navigation tree, expand the Shelf icon.

3

Right-click on the APS Channel object. The APS Channel (Edit) form opens.

4

Configure the Command Switch parameter.

5

Save your changes and close the form.

END OF STEPS

38.19 To delete an SC APS group

38.19.1 Steps

1

On the equipment tree, right-click on the device where you want to delete an APS group and select Properties. The Network Element (Edit) form opens with the General tab displayed.

2

On the Network Element (Edit) form navigation tree, expand the Shelf icon.

3

CAUTION

Service Disruption

Removing an APS group removes the working and protection channels and associated ports from the APS group, and deletes the APS group ID.

Ensure that you select the correct APS group.

Right-click on the APS Group object and choose Delete.

4

Save your changes.

END OF STEPS

38.20 To delete an SC APS bundle

38.20.1 Steps

1

On the equipment tree, right-click on the device where you want to delete an APS bundle and select Properties. The Network Element (Edit) form opens with the General tab displayed.

2

On the Network Element (Edit) form navigation tree, expand the Shelf icon.

3

Right-click on the APS Bundle object and choose Delete.

4

Save your changes.

END OF STEPS

38.21 To delete an MC APS group or bundle

38.21.1 Steps

1

Choose Manage→Redundancy→Node Redundancy from the NFM-P main menu. The Manage Node Redundancy form opens.

2

Perform one of the following.

a. Choose MC APS Group (APS) from the object drop-down menu.

b. Choose MC APS Bundles (APS) from the object drop-down menu.

3

Select an entry in the list and click Delete.

4

Save your changes. The NFM-P deletes the MC APS group or bundle and the corresponding configuration on each member site.

END OF STEPS

39 lightRadio Wi-Fi

39.1 lightRadio Wi-Fi

39.1.1 Overview

To provide additional capacity and extended coverage to a network, the NFM-P supports the offloading of traffic to WLANs, also known as Wi-Fi Offload. Users within range of a WLAN access point can establish a secure connection using RADIUS authentication. WPA2 keys are provided by a RADIUS server. Data is then transmitted through a single GRE tunnel to the WLAN Gateway (GW), where a subscriber DHCP session is created. The WLAN GW supports a RADIUS proxy server, which stores all available information from the RADIUS access-accept message.

In cases where the RADIUS server instructs the WLAN GW to forward traffic to a GGSN, a mobile gateway (MG) peer is created on the NE. Read-only information relating to the MG peers can be viewed on a base routing instance configuration form, under the WLAN GW tab.

Wi-Fi access can be offered from:

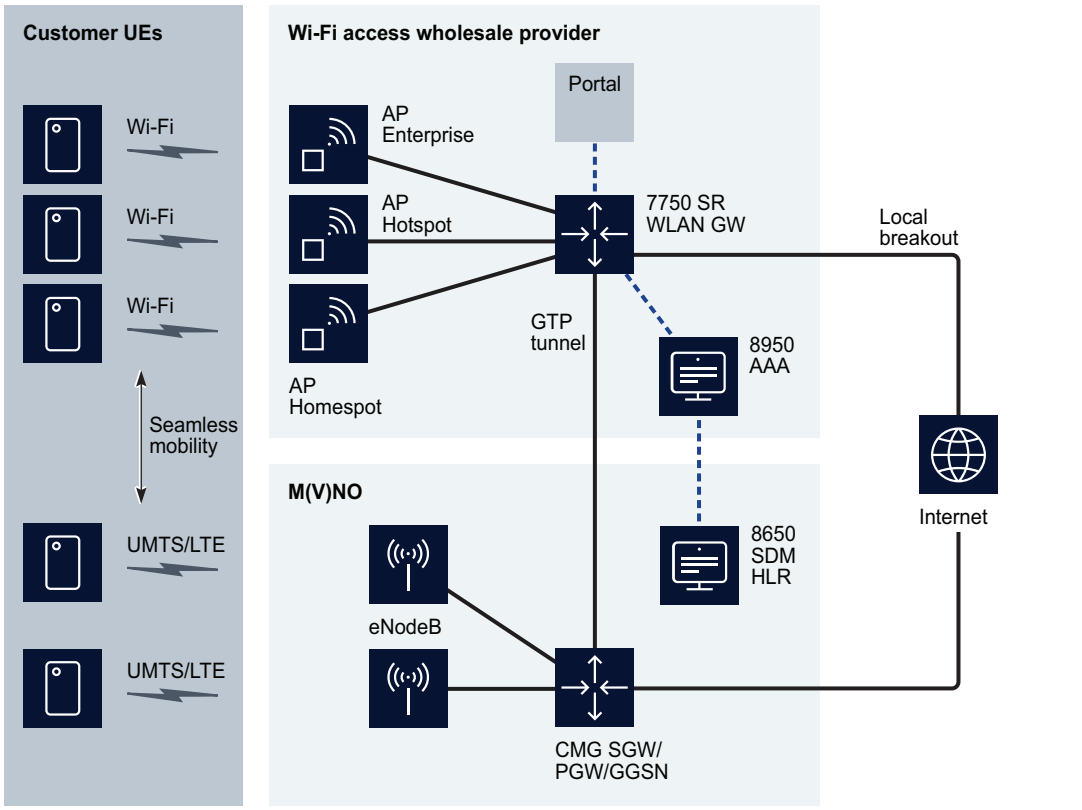
- hotspots - access points in public places.
- enterprise hotspots - access points in workplaces.
- homespots - access points on wireline CPEs from residential subscribers.

Wi-Fi access can be offered using the following SSID types:

- Private SSID - used by a residential subscriber to access wireline Internet service.
- Community SSID - used by visiting subscribers to access a Wi-Fi community broadband service after IEEE 802.1X authentication.
- Public SSID - used by visiting subscribers to access a free Internet service, or to access a Wi-Fi community broadband service after portal-based authentication.

The following figure shows a typical Wi-Fi Offload scenario. The UE attempts to switch over to Wi-Fi upon detection of a network SSID. Transparent IEEE 802.1X/EAP authentication takes place between the AP and UE. An optional GTP session can be established from the WLAN GW to the GGSN/PGW. This session is established dynamically so that UE traffic can be transferred back to an MMO.

Figure 39-1 Wi-Fi Offload



39.1.2 Migrant user handling

The NFM-P supports migrant user handling in a Wi-Fi offload application. Migrant users may have no intention of using the service, or may be invalid users who have failed authentication on the service. Both of these types of subscriber consume IP addresses and ESM resources on a WLAN GW. In a dormant subscriber handling model, the ESM subscriber is created on the IOM only when the following conditions are met:

- The subscriber is authenticated, either by RADIUS authentication or by MAC-based pre-authentication (where the RADIUS server remembers a previously authenticated UE).

- The subscriber is determined to be active by transmitting data beyond the initial DHCP request (data-triggered host creation).

Migrant user support works in conjunction with L2-aware NAT, where each UE is allocated the same inside IP address, and is assigned an outside address based on its subscriber ID (MAC address). In the case of L2-aware NAT and soft GRE, the address is assigned via DHCP, and each user is assigned the same lease. Migrant user handling is configured on an IES or VPRN soft GRE group interface, and includes the following functions:

- Data-triggered authentication and ESM host creation for ISA users.
- ESM host creation based on RADIUS COA request for portal-authenticated users.
- Migrant user DHCP performance.

  IP addresses are assigned on the ISA for L2-aware NAT (without ESM host). CPM-based DHCP is employed on a soft-GRE group interface without L2-aware NAT.

  An HTTP-redirect function is configured on the ISA.

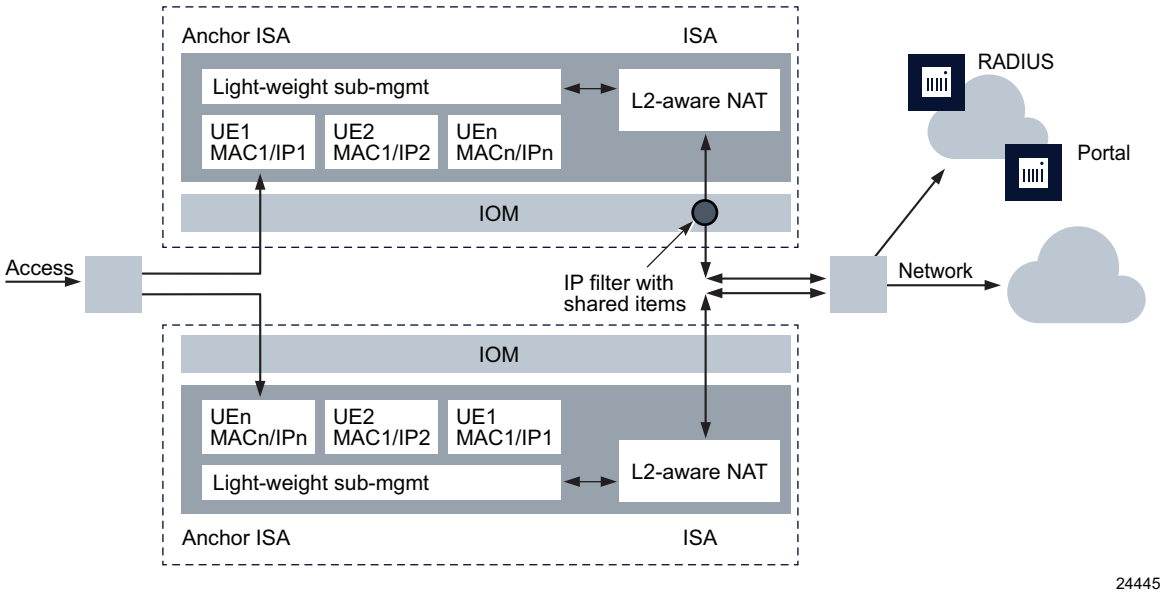
39.1.3 Distributed subscriber management

In a distributed subscriber management (DSM) scenario, the subscriber is instantiated as a distributed subscriber on the ISA, based on a RADIUS VSA during initial authentication. DSM works in conjunction with an L2-aware NAT configuration, under which the same inside IP address is allocated to all subscribers on the same group interface (WLAN GW tunnel endpoint), or on the same VLAN tag (corresponding to SSID). Upstream and downstream forwarding is implemented without the need for an ESM host.

The L2-aware NAT is configured on the anchor ISA, and packets do not require an extra pass through the switch fabric. The NAT configuration must include RADIUS accounting.

In a DSM configuration, traffic forwarding is performed without an IOM-based ESM host. Upstream traffic (AP to network) reaches the anchor ISA as usual via B-VPLS. On the anchor ISA, the subscriber state (and L2-aware NAT state) exist prior to DHCP. Downstream traffic (network to AP) passes through L2-aware NAT on the anchor ISA, resulting in an ISA-based subscriber lookup on the anchor ISA, based on the subscriber MAC address. Traffic does not require an additional switch fabric hop to perform the NAT function. Figure 39-2, “Distributed subscriber management” (p. 1320) The following figure shows a DSM configuration.

Figure 39-2 Distributed subscriber management



39.1.4 IPv6 pool manager

In order to support IPv6 migrant users and DSM users, an IPv6 pool manager can be configured on an IES or VPRN subscriber interface. The IPv6 pool manager uses an internal DHCPv6 client to delegate IA_NA or SLAAC prefixes to ISAs. Subnets are added to the FIB with respective ISAs as the next hop, allowing downstream forwarding without an ESM host. Up to eight DHCPv6 servers can be specified on the IPv6 pool manager.

The IPv6 pool manager keeps track of the context in which it allocates subnets in order to correctly acquire subnets after a fail-over or reboot. To support fail-over redundancy of this information, an identical virtual chassis identifier string can be configured on a redundant pair of NEs hosting IPv6 pool managers.

39.1.5 Local breakout using NAT

Typically, Wi-Fi traffic on a WLAN GW is considered GTP-tunneled or local breakout. Traffic is treated as local breakout by default. Local breakout traffic is controlled and routed to the Internet/ VPN from the WLAN GW directly.

For certain traffic from a Wi-Fi subscriber, it may be preferable to perform local breakout. This can be performed using the GTP Local Breakout action in the IP filter entries. When this action is applied to traffic marked for GTP-tunneling to the GGSN/PGW, the traffic is routed as local breakout. In this GTP local breakout case, the UE receives its IP address using GTP from the GGSN/PGW, but the matching traffic is routed as local breakout from the WLAN GW directly into the network. This traffic is passed through NAT. NAT is required to ensure the selected traffic is routed back to an IP address on the WLAN GW and not through the GGSN/PGW network. An L2-aware NAT host is created when the address is returned through GTP from the PGW/GGSN. The

returned address is the inside IP address. Internally, a GTP tunnel directs traffic to and from L2-aware NAT. Local and remote tunnel endpoint identifiers are create for the local breakout traffic and associated with the ESM host state. For packets that are not sent in the context of a GTP tunnel, this traffic is forwarded.

39.1.6 Hybrid access

In a hybrid access deployment model, the CPE sets up both an LTE and fixed access uplink to the Internet. Both uplinks share the same IP address and classifiers on the CPE, and the PDN gateway determines which link is to be used for traffic. The double uplinks can be used for both redundancy and bandwidth management. AMBR uplink and downlink bit rates are configurable on the mobile gateway/peer profile, along with radio access type. The PDN gateway is configurable for IPv4, IPv6, or Ipv4v6 address requests on the WLAN GW on a base or VPRN routing instance.

See 39.7 “Workflow to configure hybrid network access” (p. 1326).

39.1.7 VLAN access to anchor ISA

In cases where customers want to employ VLAN access from APs to the WLAN-GW over an L2 network, you can configure L2 APs as part of the WLAN GW configuration on IES and VPRN group interfaces. The NFM-P creates an internal epipe per access SAP or spoke SDP to the WLAN GW tunnel ISA, thereby preserving features requiring soft GRE functionality (for example, migrant user handling and distributed subscriber management). L2 frame processing on WLAN GW ISAs is functionally the same as with a WLAN GW tunnel.

An L2 AP configuration on a WLAN GW specifies an access port, encapsulation information, and an epipe SAP template policy. The epipe SAP template policy allows ingress and egress qos policy configuration and traffic filtering for access SAPs, allowing users to shape traffic based on the Wi-Fi radio technology of the AP.

39.1.8 L2 wholesale

In an L2 wholesale deployment model, subscribers are handled by a wholesale partner (MSO/telco) on behalf of the service provider (retailer), through an L2 network. In this model, the AP is configured with one or more SSIDs per service provider. The wholesaler does not host the subscriber for the service provider. L3 terminations (including address assignment, authentication, and subscriber management information) are performed by individual service providers on their own gateway.

The AP broadcasts an SSID per provider, and is configured with a unique .1q tag per SSID before bridging the L2 frames from the subscriber to the WLAN GW tunnel. VPLS L2 retail service instances are configured statically on the WLAN-GW. Static mappings of .1q tag(s) to L2 retail service instances are configured on the WLAN GW group interface. For each L2 service referenced under a VLAN tag range under the WLAN GW group interface, an internal SAP between the tunnel anchor ISA and IOM is created in that L2 service, on each of the WLAN GW IOMs in the WLAN GW group.

39.2 Workflow to configure lightRadio Wi-Fi

39.2.1 Stages

1

Configure a port policy to be bound to the ISA-WLAN GW group. See 50.65 “To configure a port policy” (p. 1609).

2

Configure a NAT RADIUS server policy to be bound to the ISA-WLAN GW group. See 57.4 “To configure a NAT RADIUS accounting policy” (p. 1795).

3

Configure an ISA-WLAN GW group. See 13.14 “To configure a WLAN GW group” (p. 428).

4

Configure RADIUS proxy functionality:

1. Configure RADIUS servers on a routing instance. See 27.8 “To configure a RADIUS server on a routing instance” (p. 846).
2. Configure RADIUS proxy servers on a routing instance. See 27.9 “To configure a RADIUS proxy server on a routing instance” (p. 847).
3. Configure RADIUS server policies. See 57.6 “To configure a RADIUS server policy” (p. 1797).
4. Configure RADIUS proxy caches. See 74.9 “To configure a local user database for subscriber host authentication” (p. 2025).

5

Configure a WLAN GW for an IES or VPRN group interface. See 78.23 “To configure a WLAN GW on an IES group interface” (p. 2462)or 79.66 “To configure a WLAN GW for a VPRN group interface” (p. 2631).

6

Configure a mobile gateway/peer profile. See 64.20 “To configure a mobile gateway/peer profile” (p. 1862).

7

Configure a WLAN GW for a routing instance or VPRN routing instance. See 27.2 “To configure a routing instance or a VRF instance” (p. 826)or 79.65 “To configure WLAN GW functionality on a VPRN site” (p. 2630).

8

Configure DNS addresses on a VPRN routing instance. See 79.12 “To configure DNS for a VPRN site” (p. 2546).

9

Configure serving network information on an NE. See 12.32 “To configure serving network information on an NE” (p. 367).

39.3 Workflow to configure Wi-Fi local breakout using L2–aware NAT

39.3.1 Stages

1

Configure an ACL IP filter policy. Configure the filter entries on the policy with the required match criteria and a filter action of GTP Local Breakout. See 51.5 “To configure an ACL IP filter policy” (p. 1671).

2

Bind the ACL IP filter policy configured in Stage 1 to the subscriber SLA profile. See 64.5 “To configure an SLA profile” (p. 1845).

3

Under the appropriate routing Instance, configure outside NAT pools with address ranges. See 30.9 “To configure NAT on a routing instance” (p. 1086).

4

Configure a NAT policy and bind it to the outside NAT pool configured in Stage 3 . See 30.5 “To configure a NAT policy” (p. 1082).

5

Bind the NAT policy configured in Stage 4 to the subscriber profile for the subscriber. See 64.4 “To configure a subscriber profile” (p. 1840).

39.4 Workflow to configure distributed subscriber management

39.4.1 Stages

1

Configure distributed subscriber management traffic policers. See 64.27 “To configure a distributed subscriber management traffic policer” (p. 1869).

2

Configure distributed subscriber management IPv4 and IPv6 filter policies. See 64.28 “To configure a distributed subscriber management IP filter policy” (p. 1869).

3

On an L2-aware NAT configuration, specify upstream and downstream IPv4 and IPv6 filter policies. See 30.9 “To configure NAT on a routing instance” (p. 1086).

4

On an IES soft GRE group interface, configure a VLAN tag range with the following (see 78.23 “To configure a WLAN GW on an IES group interface” (p. 2462)):

- Authenticate on DHCP parameter
- distributed subscriber management
- distributed subscriber management traffic policer
- distributed subscriber management IP filter policy
- Idle timeout action, SLAAC host lifetime, and DHCPv6 host lifetime

5

On a VPRN soft GRE group interface, configure a VLAN tag range with the following (see 79.66 “To configure a WLAN GW for a VPRN group interface” (p. 2631)):

- Authenticate on DHCP parameter
- distributed subscriber management
- distributed subscriber management traffic policer
- distributed subscriber management IP filter policy
- Idle timeout action, SLAAC host lifetime, and DHCPv6 host lifetime

6

To accommodate IPv6 hosts, configure the TCP Maximum Segment Size Adjustment parameter for the WLAN GW configuration on the VPRN site. See 79.65 “To configure WLAN GW functionality on a VPRN site” (p. 2630).

7

To accommodate IPv6 hosts, configure an IPv6 pool manager on IES or VPRN subscriber interfaces. See 78.16 “To configure a subscriber interface on an IES” (p. 2444) and 79.47 “To configure a subscriber interface on a VPRN” (p. 2610).

If required, configure WLAN GW redundancy on sites configured with IPv6 pool managers. See 12.34 “To configure WLAN GW redundancy on an NE” (p. 368).

8

Configure an ISA RADIUS policy with NAS IP Address, NAS Port, and Class accounting attributes, and with NAS IP Address and NAS Port authentication attributes. See 57.12 “To configure an ISA RADIUS policy” (p. 1803).

To accommodate IPv6 hosts, configure the ISA RADIUS poilcy with the IPv6 Address, Framed IPv6 Prefix, Framed Interface ID, and DHCPv6 Options accounting attributes, and the IPv6 Address and DHCPv6 Options authentication RADIUS attributes.

9

Configure an ISA-WLAN GW group with an ISA-AA group. See 13.14 “To configure a WLAN GW group” (p. 428).

10

Configure an HTTP redirect policy with the Prefix Length parameter. See 64.24 “To configure an HTTP redirect policy” (p. 1865).

11

Configure a RADIUS proxy server with RADIUS proxy users, default RADIUS policies, and a WLAN GW group. See 27.9 “To configure a RADIUS proxy server on a routing instance” (p. 847).

12

Configure an LI source WLAN distributed subscriber as a mirror source on a mirror service, if required. See 94.29 “To specify an LI WLAN distributed subscriber as an LI source” (p. 3224).

39.5 Workflow to configure VLAN to anchor ISA functionality

39.5.1 Stages

1

Configure an epipe SAP template policy. See 84.2 “To configure an epipe SAP template policy” (p. 2749).

2

Configure L2 access points on a WLAN GW on an IES or VPRN group interface. See 78.23 “To configure a WLAN GW on an IES group interface” (p. 2462) or 79.66 “To configure a WLAN GW for a VPRN group interface” (p. 2631). Associate the L2 access points with the SAP template policy configured in Stage 1 .

39.6 Workflow to configure L2 wholesale

39.6.1 Stages

1

Configure a VPLS SAP template policy. See 84.3 “To configure a VPLS SAP template policy” (p. 2750).

2

Configure the VPLS SAP template policy from Stage 1 on a VPLS service site. See 77.55 “To configure WLAN GW L2 wholesale forwarding on a VPLS site” (p. 2315).

3

Configure the VPLS service from Stage 2 on a WLAN GW on an IES or VPRN group interface. See 78.23 “To configure a WLAN GW on an IES group interface” (p. 2462) or 79.66 “To configure a WLAN GW for a VPRN group interface” (p. 2631).

39.7 Workflow to configure hybrid network access

39.7.1 Stages

1

Configure a mobile gateway/peer profile with Radio Access Type on the General tab, and AMBR downlink and uplink limits on the PGW and GGSN tabs. See 64.20 “To configure a mobile gateway/peer profile” (p. 1862).

2

Configure the PDN gateway address request type for the WLAN GW configuration on a base routing instance or VPRN routing instance on which hybrid access is implemented. Apply the mobile gateway/peer profile configured in Stage 1 to the WLAN GW. See 27.2 “To configure a routing instance or a VRF instance” (p. 826) or 79.65 “To configure WLAN GW functionality on a VPRN site” (p. 2630).

40 MC peer groups

40.1 Overview

40.1.1 Purpose

This chapter describes how to configure and manage MC peer groups.

40.1.2 Contents

MC peer groups overview

40.2 MC peer groups overview

40.2.1 Overview

An MC peer group is an NFM-P object that defines the relationship between two peer NEs to provide system redundancy in an Ethernet network. An MC peer group configuration includes a list of protocols and objects with state information that is to be synchronized between the peers.

On supporting NEs, you can create up to 20 MC peer groups using Ethernet ports in access mode. An MC peer group can contain one or more of the following child group objects:

- MC IPsec group—see Chapter 41, “MC IPsec”
- MC endpoint group—see Chapter 42, “MC endpoint groups”
- MC LAG group—see Chapter 43, “MC LAG groups”
- MC synchronization group—see Chapter 44, “MC synchronization groups”
- MC ring group—see Chapter 45, “MC ring groups”

Note: You can create MC endpoints only on a 7450 ESS, 7750 SR, or 7950 XRS.
You can create MC IPsec tunnel groups only on a 7450 ESS-4, 7450 ESS-6, 7450 ESS-6v, 7450 ESS-7, 7450 ESS-12 in mixed mode and in chassis mode D, or on a 7750 SR-7, 7750 SR-12, or 7750 SR-12E in chassis mode D.

When you create a child group object, the NFM-P automatically creates the child group members using the peer objects in the MC peer group.

The NFM-P automatically discovers MC peers that are configured on managed NEs and creates an MC peer group if the source address of each peer matches the peer address of the other. If an MC peer address on an NE is changed after discovery, for example, using a CLI, the NFM-Pdeletes the MC peer group but does not delete the peer configuration on either NE. When the mismatch is corrected, the NFM-P recreates the MC peer group.

When the MC peer addresses match but the NFM-P detects another MC peer group configuration mismatch, the NFM-P raises an alarm and displays a check mark beside the Asymmetrical Configuration Detected indicator on the General tab of the MC Peer Group properties form. The alarm information includes the type of configuration mismatch. When the mismatch is corrected, the alarm and check mark clear.

You can configure NE redundancy using the Manage Node Redundancy form or an NE properties form. When the NFM-P manages both NEs in an MC peer group, you can configure the MC peer and peer group parameters using the Manage Node Redundancy form. When the NFM-P manages only one NE in the MC peer group, you can configure the only the managed peer parameters, and only by using the NE properties form.

You can configure MC IPsec as a failover mechanism for IPsec tunnels between two 7750 SRs. MC IPsec provides protection for NE or MS-ISA failure. When the active peer fails, the IPsec tunnels failover to the standby peer without re-establishing the session. See Chapter 41, “MC IPsec” for more information.

40.2.2 OMCR on MC peer groups

You can configure the warm standby option on MC peer groups to provide oversubscribed multi-chassis redundancy, or OMCR, throughout the peer group.

In the OMCR model, a central standby NE backs up multiple subscriber hosts on multiple NEs; the subscribers are synchronized among the chassis CPMs. By avoiding subscriber host instantiation in the forwarding plane during normal operation, resources are used only as required.

MC peer group management procedures

40.3 MC peer group management workflow and procedures

40.3.1 Stages

1

Create an MC peer group; see 40.4 “To configure an MC peer group” (p. 1330) .

2

As required, configure an MC peer in an MC peer group to correct a configuration mismatch; see 40.5 “To configure an MC peer” (p. 1332) .

3

As required, perform an on-demand protocol synchronization between MC peer group members; see 40.6 “To perform an on-demand protocol synchronization between MC peer group members” (p. 1334) .

40.4 To configure an MC peer group

40.4.1 Steps

1

Choose Manage→Redundancy→Node Redundancy from the NFM-P main menu. The Manage Node Redundancy form opens.

2

Choose MC Peer Group (Multi-Chassis) from the drop-down menu.

3

Click Create or select a peer group and click Properties. The MC Peer Group (Create|Edit) form opens.

Use the following steps:

1. Choose a site for the peer group in the First Element panel.

   At least one MC peer must be an NFM-P-managed NE.

   The NFM-P raises an alarm when an MC peer group contains an unmanaged NE.
2. To specify an interface other than the NE system interface for MC peer communication, configure the Source Address parameter by typing a valid interface IP address, or by clicking Select and choosing an interface; only numbered, non-multicast IPv4 interfaces are listed.
3. Choose a site for the peer group in the Second Element panel.

4. To specify an interface other than the NE system interface for MC peer communication, configure the Source Address parameter by typing a valid interface IP address, or by clicking Select and choosing an interface; only numbered, non-multicast IPv4 interfaces are listed.
5. If you plan to configure an MC IPsec Group, configure the Authentication Key parameters and select the Enable MC IPsec parameter.
6. Click Apply.

4

Configure the required parameters in the First Element and Second Element panels.

You must configure the Warm Standby parameter only in the First Element or Second Element panel, and not in both panels.

If you do not configure the Peer Name parameter, the parameter is automatically configured using the peer IP address.

5

Click on the Associated Groups tab.

6

Configure an MC LAG group.

Use the following steps:

1. Right-click on the MC LAG Group object and choose Create MC LAG Group, or expand the object, right-click on a group and choose Properties. The MC LAG Group (Create | Edit) form opens.
2. Perform Step 6 to Step 10 of 43.5 “To create an MC LAG group” (p. 1365) .

7

Configure an MC synchronization group.

Use the following steps:

1. Right-click on the MC Sync Group object and choose Create MC Sync Group, or expand the object, right-click on a group and choose Properties. The MC Sync Group (Create | Edit) form opens.
2. Perform Step 6 to Step 11 of 44.4 “To create an MC synchronization group” (p. 1376) .

8

Configure an MC ring group.

Use the following steps:

1. Right-click on the MC Ring Group object and choose Create MC Ring Group, or expand the object, right-click on a group and choose Properties. The MC Ring Group (Create | Edit) form opens.

2. Configure the Name parameter.
3. Click Select to configure the Synchronization Tag parameter by choosing an MC synchronization group.
4. Click OK to save your changes and close the form.

9

Configure an MC endpoint group.

Use the following steps:

1. Right-click on the MC Endpoint Group object and choose Create MC Endpoint Group, or expand the object, right-click on a group and choose Properties. The MC Endpoint Group (Create | Edit) form opens.
2. Perform Step 7 to Step 10 of 42.4 “To configure an MC endpoint group” (p. 1357) .

10

Configure an MC IPsec group.

Use the following steps:

1. Right-click on the MC IPsec Group object and choose Create MC IPsec Group, or expand the object, right-click on a group and choose Properties. The MC IPsec Group (Create | Edit) form opens.
2. Perform Step 7 to Step 10 of 42.4 “To configure an MC endpoint group” (p. 1357) .

11

Click on the Peer Synchronization tab.

Use the following steps:

1. Configure the Sync Administrative State parameter and select peer group synchronization options, as required.

   NE synchronization status is displayed in the bottom half of the form.
2. Click Re-Synchronize to manually update the NE synchronization status.

12

Save your changes and close the forms.

END OF STEPS

40.5 To configure an MC peer

40.5.1 Purpose

Perform this procedure to correct a configuration mismatch between the peers in an MC peer group by modifying an MC peer configuration.

Note: The MC peer parameters are configurable only when there is a configuration mismatch, which is indicated when the Neighbor Match check box on the MC Peer (Edit) form is disabled.

40.5.2 Steps

1

Choose Manage→Redundancy→Node Redundancy from the NFM-P main menu. The Manage Node Redundancy form opens.

2

Choose MC Peer Group (Multi-Chassis) from the drop-down menu and click Search.

3

Click Create or select an MC peer group and click Properties. The MC Peer Group (Create|Edit) form opens.

4

Click on the Members tab.

5

Select a peer and click Properties. The MC Peer (Edit) form opens.

6

Configure the required parameters.

7

Click on the MC LAG tab and configure the parameters, as required.

8

Click on the Synchronization Protocol tab to configure MC synchronization group parameters.

Use the following steps:

1. Click Create or select an entry and click Properties. The MC Sync (Create|Edit) form opens.
2. Configure the required parameters on the General tab.
3. Click on the States tab to configure the Administrative State parameter for the synchronization protocol.
4. Click on the Track SRRP tab to configure a track SRRP instance for the synchronization protocol.
5. Click Create or select an existing track SRRP instance and click Properties. The Track SRRP (Create|Edit) form opens.
6. Configure the required parameters.

   The MCS State Disabled check box must be un-checked in order to configure the L2TP

Tunnel ID Range Start and End parameters.

7. Save your changes and close the form.

9

Save your changes and close the remaining forms.

END OF STEPS

40.6 To perform an on-demand protocol synchronization between MC peer group members

40.6.1 Purpose

Perform this procedure to distribute the most recent protocol synchronization configuration to each member of an MC peer group. This is required when the configurations do not match, for example, after the configuration is changed locally on only one MC peer using a CLI. When the peer configurations do not match, the NFM-P raises an alarm and displays a check mark beside the Asymmetrical Configuration Detected indicator on the General tab of the MC Peer Group properties form.

40.6.2 Steps

1

Choose Manage→Redundancy→Node Redundancy from the NFM-P main menu. The Manage Node Redundancy form opens.

2

Choose MC Peer Group (Multi-Chassis) from the drop-down menu and click Search. A list of MC peer groups is displayed.

3

Select an entry and click Properties. The MC Peer Group (Edit) form opens.

4

Click on the Peer Synchronization tab.

5

Click Resync. The NFM-P resynchronizes the information.

6

Close the MC Peer Group (Edit) form.

7

Close the Manage Node Redundancy form.

END OF STEPS

40.7 To view the unmanaged MC peer of an NE

40.7.1 Purpose

Perform this procedure to view an MC peer when the NFM-P manages only one NE in an MC peer group.

40.7.2 Steps

1

In the navigation tree equipment view, right-click on the NE where you need to view an MC peer and select Properties. The Network Element (Edit) form opens.

2

Click on the Redundancy tab.

3

Click on the MC Peer tab.

4

Click Search. A list of MC peers is displayed.

5

Select a peer and click Properties. The MC Peer (Edit) form opens.

6

View the information, as required.

7

Close the MC Peer (Edit) form.

8

Close the Network Element (Edit) form.

END OF STEPS

40.8 To delete an MC peer group

CAUTION

Service Disruption

Service disruption

Deleting an MC peer group removes all of the MC configurations that are associated with the MC peer group, such as the following:

- MC LAG groups
- MC synchronization groups
- MC ring groups

Ensure that you specify the correct MC peer group for deletion in this procedure.

40.8.1 Steps

1

Choose Manage→Redundancy→Node Redundancy from the NFM-P main menu. The Manage Node Redundancy form opens.

2

Choose MC Peer Group (Multi-Chassis) from the object drop-down menu.

3

Click Search. A list of MC peer groups is displayed.

4

Select one or more MC peer groups in the list and click Delete.

5

Click View Dependencies. A Warning form opens.

6

View the dependency information.

7

Select the I understand the implications of this action check box.

8

Click Yes. The NFM-P deletes the MC peer group and the corresponding configuration on each member NE.

9

Close the Manage Node Redundancy form.

END OF STEPS

41 MC IPsec

41.1 Overview

41.1.1 Purpose

This chapter describes MC IPsec and how to configure and manage it.

41.1.2 Contents

MC IPsec overview

41.2 MC IPsec overview

41.2.1 Overview

MC IPsec provides a stateful failover mechanism for IPsec tunnels between NEs in an active and standby configuration. Stateful failover allows IPsec traffic to continue to be forwarded without interruption if a failure occurs. MC IPsec provides protection for NE or MS-ISA failure. If an active NE fails, the IPsec tunnels failover to the standby peer without needing to re-establish the session. The failover mechanism can occur at the tunnel group level. A tunnel group can failover to the standby NE, independently of other tunnel groups on the active NE.

A mastership protocol is used to elect the active NE peer. The NFM-P synchronizes IPsec configuration states between the active and standby peers so that existing tunnels do not need to be re-established when a switchover occurs. The IPsec traffic is sent to the active NE peer using an IPsec route policy that exports IPsec routes to the routing protocol. The route metric is then changed according to the changes in active and standby roles.

You can view the role of a peer in an MC IPsec tunnel group by verifying the Master State indicator on the MC IPsec Group configuration form. The states are:

- Not Eligible—no election and not eligible for mastership
- Eligible—no election but eligible for mastership
- Discovery—no election during initial peer discovery interval
- Master—communicating with MC peer, elected active
- Standby—communicating with MC peer, elected standby

You can view the details of the last switchover on the MC IPsec Tunnel Group (Edit) form for a peer that is part of the group. Review the values of the following parameters provided on the States panel:

- Mastership Election State—indicates the result of the mastership election between the tunnel group entity and its peer
- Old Master State parameter—indicates the older mastership election state of the tunnel group after the last state change
- State Change Reason parameter—indicates the reason for the last mastership election state change of the tunnel group

MC IPsec only supports IKEv2 static LAN-to-LAN tunnel. MC IPsec is supported only on the 7450 ESS-4, 7450 ESS-6, 7450 ESS-6v, 7450 ESS-7, and 7450 ESS-12 in mixed mode and in chassis mode D, and on the 7750 SR-7, 7750 SR-12, 7750 SR-c12 and 7750 SR-12E in chassis mode D.

Note: The MC IPsec peers must be of the same device type. For example, the NEs in an MC peer group must each be 7750 SR or 7450 ESS.

You can use the NFM-P to create MC IPsec non-forwarding events on VRRP policies to track the MEP state of MC IPsec-based static routes. See 55.2 “To configure a VRRP priority-control policy” (p. 1774) for more information.

IPsec VPN does not support redundancy.

MC IPsec management procedures

41.3 Workflow to configure and manage MC IPsec

41.3.1 Stages

1

Configure an ISA tunnel MDA and ISA tunnel group on each MC IPsec peer NE; see 13.10 “To configure an ISA-tunnel group” (p. 424) .

You must do the following:

- Enable the Multiple Active ISA Support parameter.
- Enable the IPsec Responder Only parameter to configure the NE to act as an IKE responder when an MC IPsec switchover occurs, and not initiate a new SA policy or rekey an existing SA.

Ensure that the ISA tunnel groups have the same configuration on each MC IPsec peer NE; alternatively, you can create ISA tunnel groups when you configure the MC IPsec group in Stage 3

2

Enable MC IPsec on the MC peer group. See 41.4 “To configure MC IPsec on an MC peer group” (p. 1343) .

3

Create an MC IPsec tunnel group between the MC peer NEs. See 41.5 “To create an MC IPsec group” (p. 1344) .

4

Configure MC IPsec parameters.

The parameters must be configured on the following interfaces:

- VPRN tunnel interfaces; see 41.7 “To configure MC IPsec on a VPRN tunnel interface” (p. 1347) .
- IES or VPRN L3 access interfaces; see 41.8 “To configure MC IPsec on an IES or VPRN L3 access interface” (p. 1348) .

5

Note: The IPsec tunnels must have the same tunnel name, properties, and associated IKE, transform, and security policies.

Tunnels that have a configuration mismatch between peers are lost when a switchover occurs.

Configure two identical static IPsec tunnels using the redundant tunnel group on the two MC peer NEs; see 34.21 “To configure an IPsec tunnel on a VPRN tunnel interface” (p. 1253) .

6

Configure IPsec protocol and state parameters in the From Criteria of a routing policy statement entry; see 54.5 “To configure a routing policy statement” (p. 1745) .

You must do the following:

- Set the Protocol parameter to IPsec.
- Set the State parameter to one of the following:
  - IPsec Master with Peer—The corresponding tunnel group is the master with a reachable peer.
  - IPsec Master No Peer—The corresponding tunnel group is the master with an unreachable peer.
  - IPsec Non Master—The corresponding tunnel group is not the master.

7

If required, perform a manual switchover from the MC IPsec tunnel group and from all of the associated IPsec tunnels that are configured above the MC IPsec tunnel group. See 41.9 “To perform an MC IPsec switchover” (p. 1349) .

41.4 To configure MC IPsec on an MC peer group

41.4.1 Steps

1

Choose Manage→Redundancy→Node Redundancy from the NFM-P main menu. The Manage Node Redundancy form opens.

2

Choose MC Peer Group (Multi-Chassis) from the drop-down menu.

3

Click Search. A list of MC peer groups is displayed.

4

Choose an MC peer group and click Properties. The MC Peer Group (Edit) form opens.

5

Select the Enable MC IPsec parameter.

6

Click Apply.

7

Configure the parameters for the peer site.

8

Click on the Peer Synchronization tab.

9

Select the MC IPsec parameter.

10

Click Re-Synchronize.

11

Close the MC Peer Group (Edit) form.

12

Close the Manage Node Redundancy form.

END OF STEPS

41.5 To create an MC IPsec group

41.5.1 Purpose

Perform this procedure to create an MC IPsec group of ISA tunnels. You can create up to 16 MC IPsec groups on each MC peer site.

Note: You must first assign an ISA tunnel group to each MC peer site. You must enable the Multiple Active ISA Support parameter on each ISA tunnel group for MC IPsec. You can create ISA tunnel groups when you configure the MC IPsec peer groups.

Alternatively, you can create ISA tunnel groups on the peer NEs before you perform this procedure. See 13.10 “To configure an ISA-tunnel group” (p. 424) .

You must first ensure that MC IPsec is enabled on the MC peer group and ensure that the peers are configured for MC IPsec. See 41.4 “To configure MC IPsec on an MC peer group” (p. 1343) for more information.

An MC IPsec group can exist only when there is a member pair of MC IPsec tunnel groups between MC peer NEs. If one member of a tunnel group is deleted or changed from one peer NE, the NFM-P global MC IPsec group is also deleted or changed.

41.5.2 Steps

1

Choose Manage→Redundancy→Node Redundancy from the NFM-P main menu. The Manage Node Redundancy form opens.

2

Choose MC Peer Group (Multi-Chassis) from the drop-down menu and click Search. A list of MC Peer Groups is displayed.

3

Choose an MC peer group and click Properties. The MC Peer Group (Edit) form opens.

4

Click on the Associated Groups tab.

5

Right-click on the MC IPsec Group object in the components tree and choose Create MC IPsec Group. The MC IPsec Group (Create) form opens.

6

Configure the Synchronization Tag parameter.

7

Configure an MC IPsec tunnel group.

You must configure the tunnel group in each of the following panels:

- MC IPsec Tunnel Group on First Site
- MC IPsec Tunnel Group on Second Site

Perform the following:

1. Click Select. A list form opens.
2. To use an existing tunnel group, go to 8 .
3. Click Create. The ISA-Tunnel Group (Create) form opens.
4. Enable the Multiple Active ISA Support and IPsec Responder Only parameters.
5. Configure the remaining parameters.
6. Click OK. The MC IPsec Group (Create) form closes.
7. Click Search.
8. Select the tunnel group and click OK.
9. Configure the remaining parameters.

8

Click OK. The MC IPsec Group (Create) form closes.

9

Close the MC Peer Group (Edit) form.

10

Close the Manage Node Redundancy form.

END OF STEPS

41.6 To force the synchronization tag deployment to MC IPsec peers

41.6.1 Purpose

Each member of an MC IPsec group must have the same Synchronization Tag value in order for the group to be operationally up. If the value on a member NE is modified, for example, using a CLI, a mismatch exists and the NFM-P raises an alarm against each member NE.

Perform this procedure when the member NEs of an MC IPsec group have different Synchronization Tag values.

41.6.2 Steps

1

Choose Manage→Redundancy→Node Redundancy from the NFM-P main menu. The Manage Node Redundancy form opens.

2

Choose MC IPsec Group (Multi-Chassis) from the drop-down menu and click Search. A list of MC IPsec groups is displayed.

3

Choose an MC IPsec group and click Properties. The MC IPsec Group (Edit) form opens.

4

Click Force Sync.

Note: If you modify the global Synchronization Tag parameter, you cannot force the synchronization using this procedure. You must click Apply or OK to deploy the value to the NEs.

5

Click Yes. The NFM-P deploys the Synchronization Tag to the member NEs of the MC IPsec group.

6

Close the MC IPsec Group (Edit) form.

7

Close the Manage Node Redundancy form.

END OF STEPS

41.7 To configure MC IPsec on a VPRN tunnel interface

41.7.1 Purpose

Perform this procedure to configure MC IPsec to move traffic to the master NE in the event that the standby NE receives traffic.

Note: The port configured on the tunnel must be created using a tunnel SAP. For example, tunnel-x.private/public:y. See 34.20 “To configure a tunnel interface on an IES or VPRN” (p. 1249) for more information.

41.7.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Click Search. A list of services is displayed.

3

Select a VPRN service and click Properties. The VPRN Service (Edit) form opens.

4

Click on the Tunnel Interfaces tab.

5

Choose a tunnel interface and click Properties. The Tunnel Interface (Edit) form opens.

6

Configure the Redundant Next-Hop IP Address for Static ISA Tunnels and Redundant Next-Hop IP Address for Dynamic ISA Tunnels parameters.

Note: The next hop address that you specify is used by the standby NE to shunt traffic to the master NE in the event that the standby receives traffic. The next hop address is resolved in the routing table of the corresponding service.

7

Click OK. The Tunnel Interface (Edit) form closes.

8

Close the VPRN Service (Edit) form.

9

Close the Manage Services form.

END OF STEPS

41.8 To configure MC IPsec on an IES or VPRN L3 access interface

41.8.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Click Search, select an IES or VPRN service, and click Properties. The IES Service (Edit) or VPRN Service (Edit) form opens.

3

In the service navigation tree, expand the Sites icon, and then the icon of the Site or Routing Instance that hosts the L3 access interface.

4

Expand the L3 Access Interfaces icon and select the required L3 access interface.

5

Configure the Redundant Next-Hop IP Address for Static ISA Tunnels and Redundant Next-Hop IP Address for Dynamic ISA Tunnels parameters.

Note: The parameters are configurable only when the port on the interface is created with a tunnel SAP. For example, tunnel-x.private/public:y.
The next hop address that you specify is used by the standby NE to shunt traffic to the master NE if the standby receives traffic. The next hop address is resolved in the routing table of the corresponding service.

6

Click OK. The IES Service (Edit) or VPRN Service (Edit) form closes.

7

Close the Manage Services form.

END OF STEPS

41.9 To perform an MC IPsec switchover

41.9.1 Purpose

Perform this procedure to perform a manual switchover from an MC IPsec tunnel group and from all of the associated IPsec tunnels that are configured above the MC IPsec tunnel group.

41.9.2 Steps

1

Choose Manage→Redundancy→Node Redundancy from the NFM-P main menu. The Manage Node Redundancy form opens.

2

Choose MC IPSec Group (Multi-Chassis) from the drop-down menu and click Search. A list of MC IPSec groups is displayed.

3

Select an MC IPsec group and click Properties. The MC IPSec Group (Edit) form opens.

4

Click on the Components tab.

5

Right-click on a site object below the MC IPsec Group object and choose Properties. The MC IPsec Tunnel Group (Edit) form opens.

6

Perform one of the following:

a. If the Last Tunnel Group Switch Status indicator in the Protection Status panel reads Nominal, click Protection Switch.

b. When the Last Tunnel Group Switch Status in the Protection Status panel for the group is Not Ready, you cannot perform the switchover.

   This is due to one of the following:

   - there is no elected standby peer
   - the synchronization of pending IPsec states must occur
   - IKE states are pending download to ISAs

7

Close the MC IPSec Tunnel Group (Edit) form.

8

Close the MC IPSec Group (Edit) form.

9

Close the Manage Node Redundancy form.

END OF STEPS

41.10 To view the unmanaged MC IPsec peer of an NE

41.10.1 Purpose

Perform this procedure to view an MC IPsec peer when only one NE in the MC IPsec peer group is managed by the NFM-P.

41.10.2 Steps

1

In the navigation tree equipment view, right-click on the NE where you want to view an MC IPsec peer and choose Properties. The Network Element (Edit) form opens.

2

Click on the Redundancy tab, and then on the MC Peer sub-tab. The MC peers are listed.

3

Select an MC peer and click Properties. The MC Peer (Edit) form opens.

4

Click on the MC IPsec tab. The MC IPsec peers are listed.

5

Select an MC IPsec peer and click Properties. The MC IPsec (Edit) form opens.

6

View the information, as required.

7

Close the MC IPsec (Edit) form.

8

Close the MC Peer (Edit) form.

9

Close the Network Element (Edit) form.

END OF STEPS

41.11 To configure an MC IPsec peer

41.11.1 Steps

1

Choose Manage→Redundancy→Node Redundancy from the NFM-P main menu. The Manage Node Redundancy form opens.

2

Choose MC Peer Group (Multi-Chassis) from the drop-down menu and click Search. A list of MC peer groups is displayed.

3

Select an MC peer group and click Properties. The MC Peer Group (Edit) form opens.

4

Before you can configure an MC IPsec peer, you must administratively disable the tunnel groups associated with the peer site.

As required, administratively disable the associated tunnel groups.

1. Click Properties beside the First Peer Site ID or Second Peer Site ID parameter in the MC IPsec panel. The MC IPsec (Edit) form opens.
2. Click on the Tunnel Groups tab.
3. Select a tunnel group and click Properties. The MC IPsec Tunnel Group (Edit) form opens.
4. Set the Administrative State parameter to Down.
5. Click OK. The MC IPsec Tunnel Group (Edit) form closes.

5

Click on the General tab and configure the parameters.

6

Click OK. The MC IPsec (Edit) form closes.

7

Administratively enable the disabled tunnel groups.

Perform the following:

1. Click Properties beside the First Peer Site ID or Second Peer Site ID parameter in the MC

IPsec panel. The MC IPsec (Edit) form opens.

2. Click on the Tunnel Groups tab.
3. Select a tunnel group and click Properties. The MC IPsec Tunnel Group (Edit) form opens.
4. Set the Administrative State parameter to Up.
5. Click OK. The MC IPsec Tunnel Group (Edit) form closes.

8

Close the MC Peer Group (Edit) form.

9

Close the Manage Node Redundancy form.

END OF STEPS

41.12 To configure an MC IPSec domain

41.12.1 Steps

1

In the navigation tree equipment view, right-click on the *NE* and choose Properties. The Network Element (Edit) form opens.

2

Click on the Redundancy tab, and then on the MC IPSec Domain sub-tab.

3

Click Create or select an entry and click Properties. The MC IPSec Domain (Create|Edit) form opens.

4

Click on the General tab and configure the parameters.

5

Click on the Statistics tab to view and collect statistics, as required.

6

Save your changes and close the forms.

END OF STEPS

41.13 To configure an MC Peer IPSec domain

41.13.1 Steps

1

Choose Manage→Redundancy→Node Redundancy from the NFM-P main menu. The Manage Node Redundancy form opens.

2

Choose MC Peer Group (Multi-Chassis) from the drop-down menu and click Search.

3

Select an MC peer group and click Properties. The MC Peer Group (Edit) form opens.

4

Click on the Members tab.

5

Select a peer and click Properties. The MC Peer (Edit) form opens.

6

Click on the MC IPSec tab.

7

Select an MC IPsec peer and click Properties. The MC IPsec (Edit) form opens.

8

Click on the IPSec Domains tab.

9

Click Create or select an entry and click Properties. The MC Peer IPSec Domain (Create|Edit) form opens.

10

Configure the required parameters.

11

Associate a MC IPSec domain in the Peer panel; see 41.12 “To configure an MC IPSec domain” (p. 1352) .

12

Save your changes and close the forms.

END OF STEPS

42 MC endpoint groups

42.1 Overview

42.1.1 Purpose

This chapter describes MC endpoint groups and how to manage them.

42.1.2 Contents

MC endpoint groups overview

42.2 MC endpoint groups and MC peer groups

42.2.1 MC endpoint groups and MC endpoint peer groups

An MC endpoint group consists of two MC endpoint peers that are configured as peers in a pair of sites. Multiple VPLS endpoints can use the MC endpoint peer. The endpoints must be on a supporting NE, and must support PW redundancy. Each endpoint can be associated with different destinations, with a maximum of two spoke SDPs for each endpoint. The endpoints communicate with each other to get the associated status of the spoke SDPs, which ensures that only one spoke SDP is active at any time; the other spoke SDPs have a standby status. The grouping of multiple spoke SDPs that are associated with the two MC endpoint peers eliminates traffic loops in a VPLS or B-VPLS.

An MC endpoint group includes:

- two MC endpoint peers that can be used by a spoke SDP
- an MC protocol that is used for:
  - determination of which MC endpoint peers are active or standby
  - synchronization of the PW information between the peers
  - fault detection using centralized BFD; the MC endpoint protocol includes a keep-alive mechanism because BFD cannot detect the state of an MC endpoint peer
- T-LDP signaling, which is used to communicate whether a PW is active or standby to other gateway pairs. The other gateway pairs may not have an MC endpoint.

An MC peer group that is managed by the NFM-P contains two MC peers. Each MC peer is configured as the peer of the other MC peer. An MC peer group must be created before you create an MC endpoint group. When only one peer in an MC peer group is managed by the NFM-P, you can configure node redundancy parameters only for the managed peer and only from the NE properties form. See Chapter 40, “MC peer groups” for information about MC peer groups.

42.2.2 BFD

The MC endpoint protocol uses keep-alive mechanisms. The MC endpoint protocol also supports BFD to eliminate traffic loops. See 42.4 “To configure an MC endpoint group” (p. 1357) for information about how to configure an MC endpoint group for BFD.

MC endpoint group management procedures

42.3 Workflow to manage MC endpoint groups

42.3.1 Stages

1

Create an MC peer group; see 40.4 “To configure an MC peer group” (p. 1330) .

2

Create an MC endpoint group; see 42.4 “To configure an MC endpoint group” (p. 1357) .

3

Create an endpoint on a VPLS site; see 77.43 “To create an endpoint for redundancy (dual homing) on a VPLS site” (p. 2303) .

4

Perform one of the following; see 77.92 “To create a VPLS or MVPLS spoke SDP binding” (p. 2386) .

a. Create a redundant spoke SDP binding under an endpoint.

b. Create a spoke SDP binding for the site.

42.4 To configure an MC endpoint group

42.4.1 Steps

1

Choose Manage→Redundancy→Node Redundancy from the NFM-P main menu. The Manage Node Redundancy form opens.

2

Choose MC Peer Group (Multi-Chassis) from the drop-down menu.

3

Click Search. A list of MC peer groups is displayed.

4

Select an MC peer group and click Properties. The MC Peer Group (Edit) form opens.

5

Click on the Associated Groups tab.

6

Right-click on MC Endpoint Group and choose Create MC Endpoint Group. The MC Endpoint Group (Create) form opens.

7

Configure the Description parameter.

8

Configure the parameters in the MC Endpoint on First Site panel.

9

Configure the parameters in the MC Endpoint on Second Site panel.

10

Click OK to save your changes and close the form.

11

Close the MC Peer Group (Edit) form.

12

Close the Manage Node Redundancy form.

END OF STEPS

42.5 To view an MC endpoint peer on one NE

42.5.1 Steps

1

In the navigation tree equipment view, right-click on the NE where you need to view an MC endpoint peer and select Properties. The Network Element (Edit) form opens.

2

Click on the Redundancy tab.

3

Click on the MC Peer tab.

4

Click Search. A list of MC peers is displayed.

5

Select an MC peer in the list and click Properties. The MC Peer (Edit) form opens.

6

Click on the MC Endpoint tab.

7

Click Search. A list of MC endpoint peers is displayed.

8

Select a peer and click Properties. The MC Endpoint (Edit) form opens.

9

View the information, as required.

10

Close the MC Endpoint (Edit) form.

11

Close the MC Peer (Edit) form.

12

Close the Network Element (Edit) form.

END OF STEPS

42.6 To delete an MC endpoint group

CAUTION

Service Disruption

When you perform this procedure, the MC endpoint group is deleted from the NFM-P and member NE configurations.

In addition, deleting an MC endpoint group removes all of the MC configurations that are associated with the MC peer group.

Note: If one or more MC endpoints use the MC endpoint group, you cannot delete the MC endpoint group until you remove the MC endpoints from the group.

42.6.1 Steps

1

Choose Manage→Redundancy→Node Redundancy from the NFM-P main menu. The Manage Node Redundancy form opens.

2

Choose MC Endpoint Group (Multi-Chassis) from the drop-down menu.

3

Click Search. A list of MC endpoint groups is displayed.

4

Select one or more MC endpoint groups in the list and click Delete. A dialog box appears.

5

Click View Dependencies. A Warning form opens.

6

View the dependency information.

7

Select the I understand the implications of this action check box.

8

Click Yes. The NFM-P deletes the MC endpoint group and the corresponding configuration on each member NE.

9

Close the Manage Node Redundancy form.

END OF STEPS

43 MC LAG groups

43.1 Overview

43.1.1 Purpose

This chapter describes MC LAG groups and how to manage them.

43.1.2 Contents

MC LAG groups overview

43.2 MC LAG groups overview

43.2.1 Overview

A link aggregation group, or LAG, is a group of physical ports that form one logical link between two NEs to increase bandwidth, allow load balancing, and provide seamless redundancy. LAG support over multiple devices provides NE-level redundancy in addition to link-layer redundancy using a switchover function. An MC LAG configuration provides redundant L2 access connectivity that extends beyond link-layer protection by allowing two devices to share a common LAG endpoint.

An MC LAG configuration includes one active member NE and one standby member NE. The active and standby NEs synchronize the link state information to facilitate link-layer messaging between an access node and each NE. The active and standby NE coupling provides a synchronized forwarding plane to and from the access node. LACP is used to manage the active and standby states of the available LAG links; only the links of one member NE are active at one time.

The following NEs support the creation of MC LAG groups using Ethernet ports in Access mode.

- 7210 SAS
- 7250 IXR
- 7450 ESS
- 7705 SAR
- 7750 SR
- 7950 XRS

Support for MC LAGs on the 7210 SAS and 7705 SAR varies depending on the chassis type and release; see the NE documentation for support information.

The 7705 SAR-8, 7705 SAR-18, and 7705 SAR-M support the creation of MC LAG groups to provide NE-level redundancy. The operator has the option of creating an alternative path for deploying a service on the redundant NEs. The 7705 SAR NEs support inter-chassis backup, or ICB, on MC LAG to provide redundant Epipe service paths.

Some OmniSwitch NEs also support NE redundancy using MC LAGs; see 43.2.3 “MC AOS groups” (p. 1363) in this section.

When you use the NFM-P to change the MC LAG configuration on an NE, the NFM-P automatically updates the MC LAG configuration on the other NE. When you change the MC LAG configuration on an NE using, for example, a CLI, the NFM-P detects the configuration mismatch between the NEs and raises an alarm. The alarm information includes the type of configuration mismatch.

You can create an MC LAG group only from within an existing MC peer group. When only one peer in an MC peer group is managed by the NFM-P, you can configure NE redundancy parameters only for the managed peer, and only from the NE properties form. See Chapter 40, “MC peer groups” for information about MC peer groups.

43.2.2 MC synchronization

When subscriber management is enabled on an NE in an MC LAG configuration, the NE maintains dynamic state information for each subscriber host. The active and standby NEs synchronize the information to ensure uninterrupted service delivery in the case of an MC LAG switchover. See Chapter 44, “MC synchronization groups” for information about MC synchronization.

43.2.3 MC AOS groups

CAUTION

Service Disruption

You must not run an Ethernet OAM or SAA test on an OmniSwitch that has an MC LAG configuration.

MC AOS groups enable MC LAG creation on OS 9700E and OS 9800E NEs at Release 6.4.5 or later that are equipped with XNI-U12E cards, and on Release 7.3.1 and later OS 6900 and OS 10K NEs.

MC LAG group management workflows and procedures

43.3 Workflow to manage MC LAG groups

43.3.1 Stages

1

Create one or more LAGs using Ethernet access ports, as required; see Chapter 13, “Logical group object configuration” .

2

Create an MC peer group; see Chapter 40, “MC peer groups” .

3

Create an MC LAG group; see 43.5 “To create an MC LAG group” (p. 1365) .

4

As required, configure MC LAG group members; see 43.6 “To configure an MC LAG group member” (p. 1366) .

5

As required, configure MC LAG peer on one NE; see 43.7 “To configure an MC LAG peer on one NE” (p. 1367) .

43.4 Workflow to manage MC AOS groups

43.4.1 Stages

1

Create one or more LAGs using OmniSwitch ports, as required; see Chapter 13, “Logical group object configuration” .

2

Create an MC AOS Group; see 43.8 “To create an MC AOS group” (p. 1368) .

3

Create an MC AOS VFLink group; see 43.9 “To create an MC AOS VFLink Group” (p. 1369) .

4

Create an MC AOS LAG Group; see 43.10 “To create an MC AOS LAG Group” (p. 1370) .

5

As required, configure MC AOS Group members; see 43.11 “To configure an MC AOS group member” (p. 1371) .

43.5 To create an MC LAG group

43.5.1 Purpose

Perform this procedure to create an MC LAG group. Consider the following before you create an MC LAG group:

- You can create an MC LAG member only on an Ethernet MDA.
- MC LAG member ports must be in Access mode.
- The NFM-P assigns the same LACP key, system ID, and system priority to each MC LAG member.
- MC LAGs are not supported when MAC subnetting is enabled.

43.5.2 Steps

1

Choose Manage→Redundancy→Node Redundancy from the NFM-P main menu. The Manage Node Redundancy form opens.

2

Choose MC Peer Group (Multi-Chassis) and click Search.

3

Select an MC peer group and click Properties. The MC Peer Group (Edit) form opens.

4

Click on the Associated Groups tab.

5

Right-click on the MC Lag object in the navigation tree and choose Create MC LAG Group. The MC LAG Group (Create) form opens.

6

Configure the required parameters.

The LACP Key, System ID, and System Priority parameters must be left at the default when the Standby Signalling parameter is set to Power Off.

7

Configure the Use LACP Key and MAC LSB (hex) parameters.

Note: The parameters are configurable only on the 7750 SR, 7750 SR-c12, 7750 SR-12E, 7450 ESS, and 7950 XRS. The NE must also be configured with an IOM 3 MDA or an XMA.
The parameters are displayed and configurable only when both MC LAG members are PBB-capable.

8

Choose the LAG for the first MC LAG member in the First Site panel.

Note: If you are configuring access dual homing with local switching over PBB tunnels, the L2 access interfaces must be on LAGs that participate in the MC LAG.

9

Choose the LAG for the second MC LAG member in the Second Site panel.

10

Save your changes and close the forms.

END OF STEPS

43.6 To configure an MC LAG group member

43.6.1 Steps

1

Choose Manage→Redundancy→Node Redundancy from the NFM-P main menu. The Manage Node Redundancy form opens.

2

Choose MC LAG Group (Multi-Chassis) and click Search.

3

Select an MC LAG and click Properties. The MC LAG Group (Edit) form opens.

4

Configure the required parameters.

Note: The LACP Key, System ID, and System Priority parameters must be left at the default when the Standby Signalling parameter is set to Power Off.

5

Click on the States tab.

6

Configure the members in the First Site and Second Site panels.

Use the following steps:

1. Click Properties. The MC Peer (Edit) form opens.
2. Click on the MC LAG tab and configure the required parameters.

   Note:

   If you change the default values of the Keep-Alive Interval (deciseconds) and Lost Connection Wait Interval parameters, the MC LAG group configuration of the member sites is not removed when the MC LAG group is deleted. You can view the MC LAG member information under the LAG icon in the network view of the navigation tree.

7

Save your changes and close the forms.

END OF STEPS

43.7 To configure an MC LAG peer on one NE

43.7.1 Steps

1

In the navigation tree equipment view, right-click on an NE and select Properties. The Network Element (Edit) form opens.

2

Click on the Redundancy tab, and then on the MC Peer tab.

3

Choose an MC peer and click Properties. The MC Peer (Edit) form opens.

4

Click on the MC LAG tab and configure the required parameters.

5

Click on the Members tab.

6

Choose a member and click Properties. The MC LAG (Edit) form opens.

7

View the information, as required.

8

Save your changes and close the forms.

END OF STEPS

43.8 To create an MC AOS group

43.8.1 Steps

1

Choose Manage→Redundancy→Node Redundancy from the NFM-P main menu. The Manage Node Redundancy form opens.

2

Choose MC AOS Group (Aos Redundancy) and click Create. The MC AOS Group (Create) form opens.

3

Configure the required parameters.

4

Perform one of the following.

a. Configure the parameters in the First MultiChassis (Chassis Id 1) panel.

b. Select an OmniSwitch in the First MultiChassis (Chassis Id 1) panel and click OK.

5

Perform one of the following.

a. Configure the parameters in the Second MultiChassis (Chassis Id 2) panel.

b. Select an OmniSwitch in the Second MultiChassis (Chassis Id 2) panel and click OK.

6

Perform one of the following.

a. Configure the IPC VLAN Site ID parameter.

b. Enable the Default parameter.

7

Configure the remaining parameters.

Note: The Primary Minimum Lag Id and Primary Maximum Lag Id parameters are configurable only when the Configure Primary Lag Range parameter is enabled.

The Secondary Minimum Lag Id and Secondary Maximum Lag Id parameters are configurable only when the Configure Secondary Lag Range parameter is enabled. The Minimum MCLag Id and Maximum MCLag Id parameters are configurable only when the Configure MultiChassis Lag Range parameter is enabled.

8

Right-click on MC AOS LAG Group and choose Create MC AOS LAG Group. The MC AOS LAG Group (Create) form opens.

9

Configure the Lag ID parameter.

10

Save your changes and close the forms.

END OF STEPS

43.9 To create an MC AOS VFLink Group

43.9.1 Steps

1

Choose Manage→Redundancy→Node Redundancy from the NFM-P main menu. The Manage Node Redundancy form opens.

2

Choose MC AOS Group (Aos Redundancy) and click Search.

3

Choose an MC AOS group and click Properties. The MC AOS Group (Edit) form opens.

4

Click on the Associated Groups tab.

5

Right-click on MC AOS VFLink Group and choose Create MC AOS VFLink Group. The AOS VFLink Group (Create) form opens.

6

Select a Default Vlan for VFLink and click OK.

7

Click Apply.

8

Click Properties in the First MultiChassis VFLinkEnd (Chassis Id 1) panel. The AOS VF Link End form opens.

9

Click on the VF Link End Member Port tab and click Create. The Select Port - AOS VF Link End form opens.

Note: Up to eight member ports can be added for each OmniSwitch; the ports must be access ports with a speed of 10Gb or higher.

10

Select one or more ports and click OK. The Select Port - AOS VF Link End form closes.

11

Click Properties in the Second MultiChassis VFLinkEnd (Chassis Id 2) panel. The AOS VF Link End form opens.

12

Click on the VF Link End Member Port tab and click Create. The Select Port - AOS VF Link End form opens.

Note: Up to eight member ports can be added for each OmniSwitch; the ports must be access ports with a speed of 10Gb or higher.

13

Choose one or more ports and click OK. The Select Port - AOS VF Link End form closes.

Note: This member port cannot be used as a learned port security, VLAN access interface, or LAG member. Attempting to use the member port in such a way causes a deployment failure.

14

Save your changes and close the forms.

END OF STEPS

43.10 To create an MC AOS LAG Group

43.10.1 Steps

1

Choose Manage→Redundancy→Node Redundancy from the NFM-P main menu. The Manage Node Redundancy form opens.

2

Choose MC AOS Group (Aos Redundancy) and click Search.

3

Choose an MC AOS Group and click Properties. The MC AOS Group (Edit) form opens.

4

Click on the Associated Groups tab.

5

Right-click on MC AOS LAG Group and choose Create MC AOS LAG Group. The MC AOS LAG Group (Create) form opens.

6

Configure the Lag ID parameter.

Note: Configuring the Lag ID parameter with a range of Peer or MultiChassis results in a deployment failure.

7

Save your changes and close the forms.

END OF STEPS

43.11 To configure an MC AOS group member

43.11.1 Steps

1

In the navigation tree equipment view, right-click on an OmniSwitch NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the MultiChassis tab and configure the required parameters.

3

Click on the Lag Ranges tab and configure the required parameters.

Note: The Local Minimum Lag ID and Local Maximum Lag ID parameters are configurable only when the Configure Local Lag Range parameter is selected.
The Peer Minimum Lag ID and Peer Maximum Lag ID parameters are only configurable when the Configure Peer Lag Range parameter is selected.
The Minimum MCLag ID and Maximum MCLag ID parameters are only configurable when the Configure Local Lag Range parameter is selected.

4

Click on the Loopback Detection tab.

5

Configure the Admin Status and Transmit Interval (seconds) parameters.

6

Save your changes and close the form.

END OF STEPS

44 MC synchronization groups

44.1 Overview

44.1.1 Purpose

This chapter describes MC synchronization groups and how to manage them.

44.1.2 Contents

MC synchronization groups overview

44.2 MC synchronization groups overview

44.2.1 Overview

When subscriber management is enabled on an NE, the NE maintains dynamic subscriber host state information. The state information must be synchronized between the active and standby NEs in a redundant configuration to ensure that service delivery is uninterrupted if a switchover occurs.

The 7210 SAS, 7450 ESS, 7750 SR, and 7950 XRS support the creation of MC synchronization groups using Ethernet ports in Access mode.

Support for MC synchronization groups on the 7210 SAS varies depending on the chassis type and release; see the NE documentation for support information.

Note: You can create an MC synchronization group only in an existing MC peer group. See Chapter 40, “MC peer groups” for information about MC peer groups.

MC synchronization can be used to ensure that the following dynamic state information is synchronized:

- basic and enhanced subscriber management
- IGMP snooping in VPLS
- PIM snooping in VPLS
- IGMP on IES or VPRN group interfaces
- SRRP in VPRN

You create an MC synchronization group inside an MC peer group using a unique synchronization tag to define the pair of NEs and the two ports or LAGs on which the dynamic state information is synchronized. The synchronization is applied to all SAPs on the port or LAG that have the same synchronization tag. When only one peer in an MC peer group is managed by the NFM-P, you can configure node redundancy parameters only for the managed peer, and only from the NE properties form. See Chapter 40, “MC peer groups” for information about MC peer groups.

A synchronization tag can be applied to a specified VLAN range on a port or LAG. All of the SAPs in the VLAN range are assigned the synchronization tag. The SAPs that are not in the VLAN range are not synchronized.

Note: Only ports and LAGs that use dot1q or QinQ encapsulation support MC synchronization.

MC synchronization group VLAN ranges are configurable only after MC synchronization group creation.
