Assign the Redundant Interface to the Group Interface for the current site.

1. On the service navigation tree under the Subscriber Interface, right-click on the Group Interface and choose Properties. The VPRN Group Interface (Edit) form opens.
2. Select a redundant interface you created in Step 3 in the Redundant Interface panel.
3. Save the changes and close the form.

6

Create an SRRP Instance for the current site.

1. On the service navigation tree under Group Interfaces, right-click on the SRRP Instances item for the current site, and choose Create SRRP Instance. The SRRP Instance (Create) form opens.
2. Configure the required parameters.

   The SRRP ID value must be the same for the current and remote sites.
3. Click on the Behavior tab and configure the general parameters.

4. Select the SAP you need to use for the in-band messaging between the sites in the Port field.
5. Configure the Policy Pointers for the SRRP Instance.
6. Save the changes and close the form.

7

Click Turn Up to activate the SRRP instance.

8

Repeat Step 3 to Step 7 for the remote site.

Note: When you repeat Step 3 to Step 7 for the remote site, that site becomes the current site and the previously configured site is the remote site.
After the two sites have been properly set up, you can examine the SRRP peer associations at any time by right-clicking an SRRP Instance in the service navigation tree. This opens the SRRP Instance - Edit form, which contains a read-only field called SRRP Peer. The Site ID, Service ID, and Operational State of the associated peer appear in this field.
You can also examine the state of an SRRP Instance by checking the Operational Flags field. The flags indicate specific problems that might occur with the SRRP Instance, as follows:

- Duplicate Subscriber IF Address: one of the local subscriber IP addresses is the same as a subscriber IP address on the remote node.
- Redundant Interface Mismatch: the local SRRP instance and remote SRRP instance have mismatched redundant interfaces.
- SAP Mismatch: the local SRRP instance is backing a different set of SAPs than the peer.
- Subnet Mismatch: one of the subnets that SRRP is backing up does not have a match with the peer.
- Dual Master: both SRRP instances are master at the same time.
- SAP Tag Mismatch: the local SRRP instance is backing a set of SAPs with different remote and local tags.
- SRRP ID Mismatch: the peer has a different SRRP instance ID backing the same subnet.

9

Save the changes and close the forms.

END OF STEPS

79.47 To configure a subscriber interface on a VPRN

79.47.1 Prerequisites

The 7450 ESS in mixed mode, 7750 SR supports the configuration of a subscriber interface in a VPRN.

79.47.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Sites→Routing Instance, right-click on Subscriber Interfaces and choose Create VPRN Subscriber Interface, or expand Subscriber Interfaces, right-click on a subscriber interface and choose Properties. The VPRN Subscriber Interface (Create|Edit) form opens.

4

Configure the required general parameters.

The Tunnel Fault Notification parameter is configurable on interfaces where the device has ports configured in access or hybrid mode with QinQ encapsulation.

If you are configuring a tunnel facility MEP, Tunnel Fault Notification must be set to Accept, in order to receive the fault notification from the tunnel facility MEP.

The Name value for a subscriber interface must be unique in the context on the VPRN Service Site. That is, there cannot be another L3 access interface, subscriber interface, or group interface with the same name on the same VPRN site.

You must configure the Default Primary DNS Server Address parameter before you can configure the Default Secondary DNS Server Address parameter.

The WAN Mode parameter is configurable only on subscriber interface creation. The parameter is read-only on existing interfaces. The WAN Mode parameter is validated on retail/wholesale subscriber interfaces, in which case the parameter value should be equal across interfaces.

5

Configure the required parameters in the Interface Class panel.

If you selected a value of Unnumbered for the Class parameter, configure the Unnumbered Type parameter, and configure the Interface Name parameter or the IP Address parameter.

6

Configure the required parameters in the DHCP Server Synchronization panel.

7

In the WLAN GW panel, set the Redundancy/Pool Manager parameter to Enabled if you need to configure WLAN GW redundancy or an IPv6 pool manager. The WLAN GW Redundancy and WLAN GW IPv6 Pool Manager tabs appear.

8

Click on the WLAN GW Redundancy tab to configure WLAN GW redundancy.

9

Click on the WLAN GW IPv6 Pool Manager tab to configure DHCPv6 functionality for the subscriber interface.

In order to support WLAN GW IPv6 address pools, the subscriber interface must have the IPv6 and WLAN Redundancy/Pool Manager parameters enabled on the General configuration tab, and must be configured with a soft GRE group interface.

1. Select a WLAN GW group.
2. Configure the required parameters.

   The DHCPv6 Lease Query parameter must be enabled before the DHCPv6 Lease Query Max Retry parameter can be configured.

   The SLAAC and IA-NA Administrative State parameters must be set to Out Of Service before their related parameters can be configured.

10

To configure IPv6 forwarding on the subscriber interface:

1. Enable the IPv6 Allowed parameter.
2. Configure the IPv6 parameters.

   You must remove the check mark from the Default check box to access the Default Primary IPv6 DNS Server Address and Default Secondary IPv6 DNS Server Address parameters.
3. Click on the IPv6 Subscriber Prefixes tab.
4. Choose a subscriber prefix and click Properties, or click Create to create a new subscriber prefix. The Subscriber Prefix (Edit|Create) form opens.
5. Configure the parameters.
6. Save the changes and close the form.

11

To create a subscriber interface for a wholesale and retail VPRN:

Note: When you configure the routing instance for the VPRN, you can set the Type parameter to Subscriber Split Horizon to enable the forwarding service and forwarding subscriber information. The subscriber split horizon VPRN controls the flow of traffic for

wholesale subscriber applications. See 79.5 “To create a VPRN service” (p. 2534) for more information on how to configure this parameter.

You cannot create a group interface under a forwarding subscriber interface.

1. Select a forwarding service to assign to the subscriber interface in the Forwarding Service panel.
2. Configure the Private Retail Subnets parameter.
3. Select a forwarding subscriber interface in the Forwarding Subscriber Interface panel.
4. Configure the Export Host Routes parameter, if required.

   The Export Host Routes parameter is only available on retail subscriber interfaces when the Allow Unmatched Subnets parameter is enabled, or when the Interface Class parameter is set to Unnumbered.

12

To create one or more IP addresses for the subscriber interface that are inherited by the SAPs in the group interfaces that are child objects of the subscriber interface:

1. Click on the Addresses tab.
2. Click Create. The IP Address (Create) form opens.
3. Configure the required parameters.
4. Save the changes and close the form.

13

To configure IPv4 DHCP for the interface:

1. Click on the DHCP tab.
2. If you specified a forwarding service in Step 11 , the General tab is configurable. Configure the parameters that define the forwarding service information. Otherwise go to 4 .
3. If you specified a forwarding service in Step 11 and depending on the type and release of the device that you are configuring, the Subscriber Authentication Policy panel is present. Select a Subscriber Authentication policy. Otherwise, go to 4 .
4. Configure the required parameters.
5. Click on the Server tab and configure the required parameters.

   The Number of Days, Number of Hours, Number of Minutes, Number of Seconds, and Lease Time Override parameters are configurable only when the Lease Time parameter is set to Specified Time Period.
6. Click on the Client Applications tab and configure the Client Applications parameter. You can enable either or both of the PPPoE or DHCP choices.

14

To configure PPPoE for the interface:

Note: PPPoE is only configurable on a VPRN subscriber interface if the interface is a retailer interface.

1. Click on the PPPoE tab.
2. Configure the required parameters.

15

If the subscriber interface is part of a wholesale/retail configuration, click on the IPoE Linking tab and configure the required parameters.

The IPoE Linking tab is only configurable if a forwarding service is specified for the subscriber interface (see Step 11).

16

To configure the ARP host for the interface:

Note: The ARP host is only configurable on a VPRN subscriber interface when the interface is a retailer interface.

1. Click on the ARP Host Configuration tab.
2. Configure the required parameters.

17

Save the changes and close the forms.

END OF STEPS

79.48 To force a WLAN GW switchover to standby management on a VPRN subscriber interface

79.48.1 Purpose

Perform this procedure to force a WLAN gateway service to switch to a standby system for the UE associated with a subscriber interface.

Note: The Force Switchover command is only available on an active subscriber interface.

79.48.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN and click Properties. The VPRN Service form opens.

3

On the service navigation tree, expand Sites→Routing Instance→Subscriber Interfaces, right-click on the subscriber interface object on which you want to perform a WLAN GW switchover and choose Properties. The VPRN Subscriber Interface (Edit) form opens.

4

Click on the WLAN GW Redundancy tab.

5

Click Force Switchover.

6

Close the forms.

END OF STEPS

79.49 To add a TMS interface to a VPRN

79.49.1 Prerequisites

The 7750 SR-7 and 7750 SR-12 devices support the configuration of a TMS interface in a VPRN.

The following conditions must be met before you can configure a TMS interface.

- You must have one VPRN configured. The TMS interface is configured on this on-ramp VPRN.
- Optionally, you can have two addition VPRNs configured, one for the management VPRN and one for the off-ramp VPRN.
- Each VPRN must be associated within the same site on the same NE.
- An XP-IOM-3 is required.
- The ISA-TMS daughter card must be installed.

79.49.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN and click Properties. The VPRN Service Subscriber (Edit) form opens.

3

On the service navigation tree, expand Sites→Routing Instance, right-click on TMS Interfaces and choose Create TMS Interface. The TMS Interface (Create) form opens.

4

Configure the required parameters.

The Name value for a TMS interface must be unique in the context of the VPRN Service Site. That is, there cannot be another L3 access interface, subscriber interface, group interface or TMS interface with the same name on the same VPRN site.

5

To assign an off-ramp VPRN to the TMS interface, select a VPRN in the Off-Ramp VPRN panel.

6

Set the off-ramp ingress routing context. Configure the Routing Instance parameter.

7

To assign a management VPRN to the TMS interface, select a VPRN in the Management VPRN panel.

8

To associate an ISA-TMS daughter card with the TMS interface, select an ISA-TMS in the TMS Info panel and configure the ISA-TMS Authentication parameter.

Note: An ISA-TMS card can only be assigned to one TMS interface.

9

To assign an IP address to the TMS interface:

1. Click on the Addresses tab.
2. Click Create. The IP Address (Create) form opens.
3. Configure the required parameters.
4. Save the changes and close the form.

10

Save the changes and close the forms.

END OF STEPS

79.50 To configure VRF import and export policies on a VPRN site

79.50.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand the Sites icon, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

Configure the VRF import and export policies.

1. Click on the VRF Import Policies tab or on the VRF Export Policies tab.
2. Select the required VRF import or export policies 1 through 15.

   Note:

   Any RT values that are reserved in the RT reservation table for this service are automatically populated in the VRF import or export policy. See 79.63 “To reserve route targets for specific VPRN services” (p. 2628) for more information about how to reserve an RT for a specific VPRN service.

   If you enabled the Enable RT/RD Auto Assignment parameter when you created the VPRN service, the NFM-P automatically creates and assigns a VRF import or export policy to the VPRN site. Note 2 does not apply if the condition in Note 1 is met. See 79.51 “To configure a policy to reserve an RT and RD range for VPRN services” (p. 2616) for information about how to create a VPRN RT/RD Auto Assignment range policy.

5

Save the changes and close the forms.

End of steps

79.51 To configure a policy to reserve an RT and RD range for VPRN services

79.51.1 Purpose

Configure a range policy to reserve route targets and route distinguishers.

When you create the associated VPRN service, you must enable the Enable RT/RD Auto Assignment parameter on the General tab. You can only configure this parameter during VPRN service creation. See 79.5 “To create a VPRN service” (p. 2534) .

When you create the associated hub, spoke, or mesh VPRN site or sites, the NFM-P automatically generates the RT and RD based on the range policy. The NFM-P creates the routing policies and community for the sites, and automatically releases and distributes the policies and community to the NEs. The NFM-P assigns the VRF import and export policies to the VPRN site or sites, with the RT values that you are configuring in this range policy, and assigns the auto-generated RD to the VPRN site.

79.51.2 Steps

1

Choose Tools→Network Resources→VPRN RT/RD Auto Assignment from the NFM-P main menu. The VPRN RT/RD Auto Assignment (Edit) form opens.

2

Configure the Route Distinguisher Type parameter in the Route Distinguisher Range panel and configure the required parameters.

3

Configure the Route Target Format and Extended Community Type parameters in the Route Target Range panel and configure the required parameters.

4

Close the forms.

END OF STEPS

79.52 To automatically assign RT policies and RD configuration to VPRN sites

79.52.1 Purpose

The NFM-P can automatically assign route target policies and route distinguisher configuration to the VPRN sites from a pre-configured range policy. See 79.51 “To configure a policy to reserve an RT and RD range for VPRN services” (p. 2616) for more information about how to create a policy for RT and RD ranges.

79.52.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

Enable the Enable RT/RD Auto Assignment parameter in the VPRN Reservation panel.

4

Save and close the forms.

END OF STEPS

79.53 To configure a network ingress filter policy on a VPRN site

79.53.1 Purpose

Perform this procedure to assign an ingress IP and/or IPv6 template filter policy that will be applied to unicast traffic arriving on all network interfaces for the VPRN service site. The filter policy is applicable to both automatically created and explicitly defined spokes, and is supported for inter-AS and intra-AS network ports and for any label type. Network chassis mode D is required.

79.53.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Sites, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

In the Network Ingress Filters panel:

1. Select the required ACL IP Filter policy.
2. Select the required ACL IPv6 Filter policy.

   You can specify both an IP and an IPv6 policy here, if required.

5

Save the changes and close the forms.

END OF STEPS

79.54 To configure ingress QoS policies on a VPRN site

79.54.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Sites, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

In the Network Ingress QoS panel:

1. Select the required Network policy.
2. Select the required Queue Group policy.
3. Configure the Forwarding Plane Queue Group Instance ID parameter.

   Note:

   If the selected Network policy contains a policer, that same policer must also exist in the selected Ingress Queue Group template policy.

   The Network policy, Ingress Queue Group policy, and Instance ID must all be configured concurrently.

   All VPRN sites that employ the selected Network policy are listed in the VPRN Sites tab of the policy's properties form.

5

Save the changes and close the forms.

END OF STEPS

79.55 To configure a system-wide alternate source IP address for GRE encapsulation

79.55.1 Purpose

Use this procedure to configure an alternate source IPv4 address for the GRE tunnels in VPRN services. When an alternate address is configured, the system address is no longer used in VPRN services that auto-bind to the GRE tunnel.

79.55.2 Steps

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, then on the Service tab.

3

In the GRE Encapsulation panel, click Select and select an interface in the Select Interface form.

4

Click OK and close the forms.

END OF STEPS

79.56 To bind a VPRN site to service tunnels

79.56.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand the Sites icon, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

To configure an auto-bind tunnel, click on the SDP Binding tab, and then on the Auto-Bind Tunnel tab, and configure the required parameters.

When the Transport parameter is set to MPLS:LDP, you can choose segment routing as a tunnel option by selecting the SR-ISIS or SR-OSPF parameters. The following prerequisites apply:

- Segment routing must be configured; see 28.11 “Segment routing” (p. 894)
- You must configure segment routing on the ISIS or OSPF interfaces; see 28.63 “To configure an IS-IS interface” (p. 958) and 28.69 “To add a Layer 3 interface to an OSPF router” (p. 966)

5

Configure the Transport parameter:

a. To explicitly specify service tunnels and circuits for the service, set the Transport parameter to None.

b. To automatically bind the service to MPLS service tunnels utilizing MPLS, set the Transport parameter to LDP.

Note: To use MPLS as the transport type, you must bind LSPs to service tunnels during service tunnel configuration; see 33.9 “To create an IP/MPLS service tunnel” (p. 1190)

c. To automatically bind the service to MPLS service tunnels using RSVP-LSP, set the Transport parameter to RSVP-LSP.

Note: The RSVP-LSP option is available only on the 7450 ESS in mixed mode, the 7705 SAR, 7750 SR, and 7950 XRS.

d. To automatically bind the service to MPLS service tunnels using RSVP or LDP, set the Transport parameter to RSVP or LDP.

This choice provides the ability to simultaneously support both tunnel options, in networks that have a mixture of LDP and RSVP-TE in place. NFM-P always tries to resolve the VPN route by using RSVP-LSP tunnels first (lowest metric). If no RSVP-LSP service tunnels are available, then tunnels configured for LDP are used. If RSVP-LSP tunnels subsequently become available again, then the route resolution automatically returns to RSVP-LSP.

Note: The RSVP or LDP option is available only on the a 7450 ESS in mixed mode, the 7705 SAR, 7750 SR, or 7950 XRS.

e. To automatically bind the service to GRE service tunnels set the Transport parameter to GRE.

6

Save the changes and close the forms.

END OF STEPS

79.57 To configure static routes on a VPRN site

79.57.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand the Sites icon, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

Click on the Routing tab, then on the Static Routes tab.

5

Define a static route that the PE VRF is to exchange with the CE:

1. Click Create. The Static Route (Create) form opens.
2. Configure the required general parameters.
3. Configure the parameters in the Destination panel.

   The IP Address parameter is configurable when the Type parameter is set to an option other than Black Hole.
4. Select an interface for the static route in the Destination panel.
5. Select an IPsec tunnel for the static route in the Destination panel.
6. Configure the parameters in the Other panel.
7. Configure the parameters in the CPE Check panel.

   The Target IP Address, Interval (seconds), Drop Count, Log, and Packet Size parameters are configurable only when the Enable CPE Check parameter is enabled.
8. Select a prefix list name in the Prefix List panel and configure the Prefix List Flag parameter. The Prefix List Flag parameter is configurable only when you choose a prefix list.

   Note:

   You cannot specify a Prefix List if BFD Enabled or Enable CPE Check parameters are enabled for the static route.
9. Configure the parameters in the Source/Destination Class Index panel.
10. Save the changes and close the form.

6

Save the changes and close the forms.

END OF STEPS

79.58 To configure route aggregates on a VPRN site

79.58.1 Purpose

Route aggregation allows you to group a number of routes with common IP prefixes into a single entry in the routing table. This reduces the number of routes that need to be advertised by the hosting router and reduces the number of routes in the routing tables of downstream routers.

79.58.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand the Sites icon, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

Click on the Routing tab, then the Route Aggregation tab and click Create. The Aggregation (Create) form opens.

5

Configure the required parameters.

The IP Address Prefix you enter must be an IPv4 address in the form x.x.x.0, where the last integer is the host bits and must have a value of 0.

The Aggregator AS and Aggregator IP Address parameters are configurable when the Aggregator parameter value is set to True. The Indirect Address parameter is configurable when the Next Hop Type parameter is set to Indirect.

6

Save the changes and close the forms.

END OF STEPS

79.59 To enable a tunnel facility MEP on the VPRN site

79.59.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an VPRN and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand the Sites icon, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

Click the OAM tab, then the ETH-CFM tab.

5

Set the Tunnel Fault Notification parameter to Accept.

The Tunnel Fault Notification parameter is configurable on interfaces where the device has ports configured in access or hybrid mode with QinQ encapsulation.

6

Save the changes and close the forms.

END OF STEPS

79.60 To enable the automatic selection of a route distinguisher on a VPRN site

79.60.1 Purpose

Since a route distinguisher (RD) must be unique on each PE in the network, you can allocate either a RD that you manually select or an NE-selected route distinguisher for each service. When you configure an auto-RD on a VPRN site, a Type-1 RD is automatically allocated by the NE based on the community range that you configure.

79.60.2 Steps

1

Before you configure a site for auto-RD selection, you must:

1. Enable BGP on the routing instance of the NE; see Procedure ; 28.29 “To enable BGP on a routing instance” (p. 916)
2. Enable the automatic selection of an RD on the NE and specify the community range. See 12.11 “To enable the automatic selection of an RD on an NE” (p. 349) .

2

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

3

Choose a VPRN and click Properties. The VPRN Service (Edit) form opens.

4

On the navigation tree, right-click on VPRN Service and choose Create VPRN Site, or right-click on a site and choose Properties. The VPRN Site (Create|Edit) form opens.

5

Click on the Routing tab, then on the General tab.

6

Set the Route Distinguisher Type parameter to Type 1.

7

In the Type 1 panel, set the Auto Route Distinguisher parameter to true.

The Operational RD is displayed after you apply the changes to the site and to the service.

8

Save the changes and close the forms.

END OF STEPS

79.61 To add a Global Route Table to a VPRN site

79.61.1 Purpose

Packets within a VRF are able to perform a parallel lookup against a Global Route Table (GRT), as well as within the local VRF. A successful routing table match found in the local VRF is typically preferred over any match found in the GRT. However, a static route can be used to allow for specific prefixes covered by the static route to fail the lookup in the local VRF table, thus resulting in the guaranteed use of a route from the GRT.

The GRT is populated by defining export policies for each participating VPRN service, and the maximum number of routes that are exported from a specific VRF can be limited.

Note: The addition of a GRT to a VPRN service is supported on the 7450 ESS in mixed mode, 7705 SAR and 7750 SR.

79.61.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose the required VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Sites→Routing Instance, right-click on a site and choose Properties. The VPRN Site (Edit) form opens.

4

Click on the Routing tab and configure the Enable GRT Lookup parameter.

Enable the Allow Local Management parameter to enable SNMP/Telnet/SSH/FTP traffic to flow to the base dystem IP interface via the VPRN service.

5

Click on the GRT Export Policies tab and configure the required parameters.

6

Select up to five export policies.

7

Save the changes and close the forms.

END OF STEPS

79.62 To create an OSPF sham link between two VPRN sites

79.62.1 Purpose

Perform this procedure to create an intra-area OSPF sham link between two VPRN sites. See 79.1.10 “OSPF sham link support” (p. 2519) in “VPRN service management” (p. 2513) for more information.

79.62.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, choose the first site to participate in the sham link. If you need to create the site, perform 79.11 “To configure a VPRN site” (p. 2545) .

4

Choose an L3 access interface for the site. If you need to create the L3 access interface, see 79.83 “To configure an L3 access interface on a VPRN site” (p. 2656) .

5

Configure OSPFv2 for the site. Perform 79.22 “To configure ISIS, L2TP, MLD, OSPFv2, OSPFv3, PIM, RIP, or WPP on a VPRN routing instance” (p. 2555) . Ensure that you select sub79.22 c in Step 4 .

6

Right-click on OSPFv2 under the Protocols icon in the service navigation tree and choose Create Sham Link. The ShamLink (Create) form opens.

7

Select the Remote Neighbor IP Address. This is the IP Address of the other site participating in the sham link.

8

Select and interface in the Interface panel.

9

Select the area ID in the Area panel.

10

Configure the Administrative State parameter.

11

Click on the Protocol Properties tab and configure the required parameters.

12

The Authentication tab is configurable, depending on the OSPF version. To configure authentication for the sham link, click on the Authentication tab and either:

a. Create an MD5-based authentication key, by setting the Authentication Type parameter to MD5-based and clicking Create. The Md5Key (Create) form opens. Configure the required parameters and save and close the form.

b. Create a simple password, setting the Authentication Type parameter to Simple Password and clicking Change Password to enter a password. The Password (Create) form opens. Configure the parameters and close the form.

13

To view OSPF configuration information on neighbor sites, click on the Virtual Neighbor tab.

14

Save the changes and close the form.

15

Repeat for the second site participating in the sham link.

16

Save the changes and close the forms.

END OF STEPS

79.63 To reserve route targets for specific VPRN services

79.63.1 Purpose

Reserve route targets for a specific VPRN so that no other VPRN services can use the import/export RT.

When you create the associated VPRN service with the customer name that you specify for the RT reservation in Step 3 of this procedure, and the name of the VPRN service matches the Service Name parameter that you specify for the RT reservation in Step 3 , the Route Target Reservation (Edit) form updates with the service ID and the SVC Mgr Service ID of the VPRN.

When you create the associated hub, spoke, or mesh VPRN site or sites, the NFM-P creates the routing policies and community for the sites, and automatically releases and distributes the policies and community to the NEs. The NFM-P assigns the VRF import and export policies to the VPRN site or sites, with the RT values that you are configuring in this RT reservation. The Reserved Route Targets (Edit) form, in Step 4 , updates with the automatically created VRF export and import policies for each hub, spoke, and mesh site.

See 79.50 “To configure VRF import and export policies on a VPRN site” (p. 2615) for more information about how to configure VRF import and export policies. See 27.1.12 “NE routing policies” (p. 821) in Chapter 27, “NE routing and forwarding” for more information about routing policies.

79.63.2 Steps

1

Choose Tools→Network Resources→VPRN RT Reservation from the NFM-P main menu. The VPRN RT Reservation form opens.

2

Click Create or choose a route reservation entry and click Properties. The Route Target Reservation (Create) form opens.

3

Configure the Customer Name and Service Name parameters. The NFM-P automatically creates the customer if it does not already exist. You must manually create the VPRN service and associated routing policies.

4

Add a route target reservation instance.

1. Click Create in the Route Targets panel. The Reserved Route Targets (Create) form opens.

2. Configure the Route Target 1 and Route Target 2 parameters.

5

Close the forms.

END OF STEPS

79.64 To configure a VXLAN termination on a VPRN

79.64.1 Purpose

Use this procedure to configure VXLAN tunnel termination on a VPRN site. The address terminating the VXLAN tunnels can be an IPv4 or IPv6 address. An FPE must be created and configured to terminate on the VPRN, with an SPD ID range configured and VXLAN termination enabled. See 12.41 “To create an FPE” (p. 374).

79.64.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand the Sites icon, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

Create a VXLAN tunnel termination:

1. Click on the Routing tab, then the VXLAN Tunnel Termination sub-tab.
2. Enter the tunnel termination IP address.
3. In the FPE panel, click Select and choose the FPE ID.
4. Click Apply and close the form.

5

Close the forms.

END OF STEPS

79.65 To configure WLAN GW functionality on a VPRN site

79.65.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand the Sites icon, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

Enable the Enable WLAN GW parameter.

5

Click on the WLAN GW tab and configure the APN Network Identifier parameter.

6

Configure the parameters in the Mobile Triggered Accounting panel.

7

Click on the Mobile GW Address Map tab to configure a mobile GW address map.

1. Click Create. The Mobile Gateway Address Map (Create) form opens.
2. Configure the Mobile Gateway Address Prefix and Prefix Length parameters.
3. Select a mobile gateway/peer profile policy.
4. Save your changes and close the form.

8

Click on the Distributed Subscriber Management tab and configure the TCP Maximum Segment Size Adjustment parameter.

9

Click on the Distributed Subscriber Management tab and configure the TCP Maximum Segment Size Adjustment parameter.

10

If the WLAN GW is intended for a home LAN extension configuration, click on the Cross Connect tab.

Configure the required parameters and select a WLAN GW group.

11

Save the changes and close the forms.

END OF STEPS

79.66 To configure a WLAN GW for a VPRN group interface

79.66.1 Prerequisites

Before you can configure a WLAN GW for a VPRN group interface, you must configure a VPRN group interface with the Specific Type parameter set to Soft GRE. See 79.37 “To configure a group interface on a VPRN” (p. 2586) .

79.66.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Sites→*routing_instance*→Subscriber Interfaces→*subscriber_interface*.

4

Right-click on a WLAN GW group interface. The VPRN Group Interface (Edit) form opens.

5

Click on the WLAN GW tab and configure the required parameters.

The Interim Update parameter must be enabled if the Include Counters and Hold Down Time parameters are to be configured.

6

Select a WLAN GW group in the WLAN GW Group panel.

7

Select a tunnel router instance in the Tunnel Router Instance panel.

8

Select a default retail VPRN service in the Default Retail Service panel.

9

Configure egress QoS, if required.

1. In the Egress QoS panel, configure the required parameters.

   Do not configure the Aggregate Rate Limit parameter with a positive value if you specify a scheduler policy in 3 .
2. Select a QoS policy.
3. Select a Scheduler Policy.

10

If the WLAN GW is part of the home LAN extension configuration, configure the Maximum Number of Bridged Domains parameter on the LAN Extension panel.

This parameter can only be configured when the administrative state of the WLAN GW is Out of Service.

11

Select an authentication policy.

12

To configure an authentication hold time:

1. Enable the check box in the Authentication Hold Time panel.
2. Specify an authentication hold time in the Hours, Minutes, and Seconds fields.

13

Click on the SAP Parameters tab to configure SAP parameters, as required.

1. Configure the required parameters.

   If the Default ID Type parameter is set to Use String, configure the Default ID String parameter.

   If the WLAN GW is supporting managed routes, set the Anti-Spoofing parameter to Next Hop IP and MAC Address. To enhance security for MAC-only anti-spoofing, configure unicast RPF on the group interface; see 79.37 “To configure a group interface on a VPRN” (p. 2586) .
2. Select a subscriber profile.
3. Select an SLA profile.
4. Select an application profile.
5. Select a subscriber identification policy.

14

Click on the Gateway Addresses tab to configure gateway addresses for the WLAN GW.

1. Click Create or choose a gateway address entry and click Properties. The Gateway Address (Create|Edit) form opens.
2. Type a gateway IP address in the field and click OK.

   You can configure up to 10 gateway addresses (six IPv6 and four IPv4).

   One IPv6 address can be configured with the XConnect option.

15

Click on the VLAN Tag Ranges tab to configure VLAN tag ranges, as required.

1. Click Create or choose a VLAN tag range entry and click Properties. The VLAN Tag Range (Create|Edit) form opens.
2. Configure the required parameters.
3. Select a retail service.
4. Select a NAT policy.
5. Select an HTTP redirect policy.
6. Select an authentication policy.
7. Select a RADIUS proxy cache server.
8. If the VLAN tag range is part of an L2 wholesale-retail configuration, select a VPLS site in the L2 Retail panel, and configure the Administrative State and Description parameters as required.
9. Click on the DHCP tab and configure DHCP parameters, as required.
10. Click on the Distributed Subscriber Management tab to configure distributed subscriber management.
11. Configure the required parameters.
12. Select an accounting policy.
13. Select an ingress policer policy.
14. Select an egress policer policy.
15. Select an IP filter policy.
16. Select an application profile string, if required.
17. Click on the SLAAC tab to configure lifetimes for SLAAC-configured IPv6 hosts.

    The Administrative State parameter must be Up to configure parameters on the SLAAC tab.
18. Disable the Default check box and configure the lifetime parameters (in hours, minutes, and seconds) for any of the following categories:
    - Preferred Lifetime (Initial State)
    - Preferred Lifetime (Active State)
    - Valid Lifetime (Initial State)
    - Valid Lifetime (Active State)

19. Click on the DHCP6 tab to configure lifetimes for DHCPv6-configured IPv6 hosts.

    The Administrative State parameter must be Up to configure parameters on the DHCP6 tab.

20. Disable the Default check box and configure the lifetime parameters (in hours, minutes, and seconds) for any of the following categories:
    - Preferred Lifetime (Initial State)
    - Preferred Lifetime (Active State)
    - Valid Lifetime (Initial State)
    - Valid Lifetime (Active State)

21. Click on the BRG Configuration tab to configure BRG for the VLAN tag range.
    - Configure the Administrative State parameter.
    - Select a default BRG profile.
    - Enable the Authenticate BRG Only parameter, if only authenticated BRGs are permitted.

22. If the VLAN tag range is part of a LAN extension configuration, click on the Cross Connect tab.

    Configure the required parameters and select an ISA RADIUS policy.

    You must enable Authentication on DHCP on the VLAN Tag Range - General tab in order to set the Cross Connect configuration admin state to In Service

23. If the VLAN tag range is part of a home LAN extension configuration, click on the Home LAN Extension tab.

    Configure the required parameters.

    You must enable Authentication on DHCP on the VLAN Tag Range - General tab, and enable the Administrative State of the BRG on the VLAN Tag Range - BRG Configuration tab in order to enable the home LAN extension configuration.

24. Save the changes and close the form.

16

Click on the L2 AP tab to configure an L2 access point.

1. Click Create or select an existing L2 AP entry and click Properties. The WLAN GW L2 Access Point (Create|Edit) form opens.
2. Select a port.
3. Configure the required parameters.

17

Save the changes and close the forms.

END OF STEPS

79.67 To resync WLAN GW tunnels on a VPRN site

79.67.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Sites, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

Click on the WLAN GW Tunnels tab and click Resync WLAN GW Tunnels.

5

Close the forms.

END OF STEPS

79.68 To configure a VPRN spoke SDP binding

79.68.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand the Sites icon, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

Right-click on Spoke SDP Bindings and choose Create Spoke SDP Binding or expand Spoke SDP Bindings, right-click on an spoke SDP binding and choose Properties. The Spoke SDP Binding (Create|Edit) form opens.

5

Select a source interface for the SDP binding in the Source Interface panel.

6

Configure the required parameters.

These parameters appear only when a source interface is assigned to the spoke SDP binding.

7

Configure the parameters in the Hash Label panel.

The Enable Hash Label and Enable Signal Capability parameters can only be configured for spoke-SDP bindings that are access interface terminated.

8

To specify a destination node for the spoke SDP binding:

a. If the destination NE is a managed NE, select an NE from a list of managed NEs.

b. If the destination NE is an unmanaged NE, specify the system ID for the Tunnel Termination Site parameter.

9

Configure the required parameters.

10

To specify a transport tunnel for the spoke SDP binding:

a. For the NFM-P to configure the transport tunnel automatically, enable the Auto-Select Transport Tunnel parameter and configure the Profile Name or the Tunnel Auto-Selection Transport Preference parameter.

b. To configure the transport tunnel manually, select a tunnel in the Tunnel Panel.

c. To configure an MPLS-TP transport tunnel manually, select an MPLS-TP tunnel in the Tunnel Panel.

11

Select an application profile for the spoke SDP binding.

12

To choose an AA transit policy types:

Note: You can only associate one AA transit policy type with a service object.
You can bind a transit policy to only one L3 access interface or spoke SDP binding per node.
The transit policy and the application profile must belong to the same application assurance group or partition.

a. Select an AA transit IP policy in the Transit IP Policy panel.

b. Select an AA transit prefix policy in the Transit Prefix Policy panel.

13

To configure custom object attributes for AA reporting:

1. Click on the NSP Analytics Parameters tab, then on the Reporting tab.
2. Click Create. The AA Reporting (Create) form opens.
3. Configure the required parameters.
4. Save the changes and close the form.
5. Click on the General tab.

14

To specify a transport tunnel for the Return SDP binding:

Note: You can create a return tunnel only between sites that are within the same service. If the sites are not in the same service, the Return tab does not appear.

a. Let the NFM-P configure the transport tunnel automatically.
   1. Click on the Return tab.
   2. Enable the Auto Select Return Transport Tunnel parameter.
   3. Configure the Profile Name or the Return Tunnel Auto-Selection Transport Preference parameter.

b. Configure the transport tunnel manually.
   1. Click on the Return tab.
   2. Select a service tunnel in the Return Tunnel panel.

15

To configure CPU protection:

1. Click on the Security tab.
2. Configure the IP Src Monitoring parameter.

16

To associate a MEP to the spoke SDP binding:

1. Click on the OAM tab, then the ETH-CFM tab.
2. Click Create in the MEPs panel. The MEP (Create) form opens.
3. Select a MEG.
4. Configure the required parameters.

   The CCM Padding Packet Size (Bytes) parameter cannot be configured when the CCM interval parameter is set to 10 ms or 100 ms.

17

If the MD for the MEP has a Name Type of none and the associated MEG has a Name Format of icc-based, the Y.1731 Tests and AIS tabs are configurable; click on the Y.1731 Tests tab and configure the required parameters.

The Eth Test Pattern parameter is configurable when the Eth Test Enabled parameter is enabled.

18

Click on the AIS tab and configure the required parameters.

The AIS Meg Level parameter is configurable when the AIS Enabled parameter is enabled.

19

Save the changes and close the forms.

END OF STEPS

79.69 To create an L2 SDP spoke termination on a VPRN service

79.69.1 Prerequisites

Ensure that a service and site have been created in the VPRN. To terminate an L2 service on a VPRN SDP spoke, you must identify the VC and an interface belonging to the VC. The interface must not have an associated port.

79.69.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand the Sites→Routing Instance→Spoke SDP Bindings, right-click on Spoke SDP Bindings and choose Create Spoke SDP Binding or expand Spoke SDP Bindings, right-click on an spoke SDP binding and choose Properties. The Spoke SDP Binding (Create|Edit) form opens.

4

Select a source interface for the SDP binding in the Source Interface panel.

If you are creating this spoke SDP binding for use with an IP mirror interface, select the required IP mirror interface as the source interface.

5

To specify a destination node for the spoke SDP binding:

a. If the destination NE is a managed NE, select an NE from a list of managed NEs.

b. If the destination NE is an unmanaged NE, specify the system ID for the Tunnel Termination Site parameter.

6

Configure the required parameters.

These parameters appear only when a source interface is assigned to the spoke SDP binding.

7

Configure the parameters in the Hash Label panel.

The Enable Hash Label and Enable Signal Capability parameters can only be configured for spoke-SDP bindings that are access interface terminated.

8

To specify a transport tunnel for the spoke SDP binding:

a. For the NFM-P to configure the transport tunnel automatically, enable the Auto-Select Transport Tunnel parameter and configure the Profile Name or the Tunnel Auto-Selection Transport Preference parameter.

b. To configure the transport tunnel manually, select a tunnel in the Tunnel Panel.

c. To configure an MPLS-TP transport tunnel manually, select an MPLS-TP tunnel in the Tunnel Panel.

9

Select an application profile for the spoke SDP binding.

10

To choose an AA transit policy types:

Note: You can only associate one AA transit policy type with a service object.
You can bind a transit policy to only one L3 access interface or spoke SDP binding per node.
The transit policy and the application profile must belong to the same application assurance group or partition.

a. Select an AA transit IP policy in the Transit IP Policy panel.

b. Select an AA transit prefix policy in the Transit Prefix Policy panel.

11

To configure custom object attributes for AA reporting:

1. Click on the NSP Analytics Parameters tab, then on the Reporting tab.
2. Click Create. The AA Reporting (Create) form opens.
3. Configure the required parameters.
4. Save the changes and close the form.
5. Click on the General tab.

12

Click on the QoS tab.

13

Configure the required parameters in the Forwarding Plane Redirect panel.

1. Select a network policy.
2. Select and Ingress Queue Group Template Policy.
3. Configure the Instance ID parameter.

14

Configure the required parameters in the Port Redirect panel.

1. Select a network policy.
2. Select and Egress Queue Group Template Policy.
3. Configure the Instance ID parameter.

15

Click on the States tab and configure the Administrative State parameter.

16

To assign ingress and egress ACL filters to the spoke SDP binding:

1. Click on the ACL tab.
2. Select an ingress ACL filter in the Ingress Filter panel.

   If you are configuring IP mirroring, you can optionally select an ingress IP filter. This is a packet mirroring option which specifies that packets matching the IP filter are mirrored to the mirror destination.
3. Select an egress ACL filter in the Egress Filter panel.

17

If you are configuring IP mirroring, save the changes and close the forms.

18

To assign an accounting policy to the spoke SDP binding:

1. Click on the Accounting tab.
2. Configure the Collect Accounting Statistics parameter.
3. Select an accounting policy.

19

Save the changes and close the forms.

END OF STEPS

79.70 To configure an MPLS-TP static pseudowire on a VPRN spoke SDP binding

79.70.1 Purpose

Perform this procedure to create an MPLS-TP static pseudowire on the spoke SDP binding. An MPLS-TP service tunnel must be used in the SDP binding, and the Control Word parameter for pseudowire OAM must be set to Preferred. See 79.69 “To create an L2 SDP spoke termination on a VPRN service” (p. 2638) .

79.70.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select a VPRN and click Properties. The VPRN Service (Edit) form opens.

3

On the service tree, expand Sites→Routing Instance→Spoke SDP Bindings, right-click on the spoke SDP binding you need to configure and choose Properties. The Spoke SDP Binding (Edit) form opens.

4

Click on the Control Channel tab.

5

Configure the required parameters.

6

Configure the static PW:

1. Click on the Static PW tab.
2. Click Create. The PW Path ID (Create) form opens.
3. Configure the Path AGI parameter.
4. Configure the parameters in the Source Attachment Individual Identifier panel.
5. Configure the parameters in the Target Attachment Individual Identifier panel.
6. Click OK. The PW Path ID (Create) form closes.

7

Save the changes and close the forms.

END OF STEPS

79.71 To configure BFD on a VPRN spoke SDP binding

79.71.1 Purpose

BFD is used over the VCCV control channel for PW fault detection. BFD carried over a PW associated channel enables the monitoring of the PW between the terminating PEs, regardless of whether the service spans multiple hops. This allows faults that are local to individual PWs to be detected.

79.71.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Sites→Spoke SDP Bindings and click on the spoke SDP binding on which you want to configure BFD.

4

Click on the BFD tab and configure BFD on the spoke SDP binding:

1. On the General tab, enable the Enable BFD parameter.
2. Choose a BFD template. To create a BFD template, see 28.25 “To configure a BFD template policy” (p. 911) .

Note:

You must assign a BFD template to the spoke SDP binding if you enable BFD.

3. In the Failure Action dropdown, select the action to be performed on BFD failure.
4. Configure the Up-Timer parameter.

   Note:

   The Up-Timer parameter is applicable only when the value of Failure Action is set to down.

5

Save and close the forms.

End of steps

79.72 To clear BFD sessions and statistics on a VPRN spoke SDP binding

79.72.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Sites→Spoke SDP Bindings and click on the spoke SDP binding on which you want to view the BFD session information.

4

Clear BFD sessions or statistics on the spoke SDP binding:

1. Click on the BFD tab, then on the BFD Session tab.
2. Click Clear All to clear all BFD sessions.
3. Click Clear All Statistics to clear all BFD statistics.

5

Close the forms.

End of steps

79.73 To view the BFD session status on a VPRN SDP spoke binding

79.73.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Sites→Spoke SDP Bindings and click on the spoke SDP binding on which you want to configure BFD.

4

Click on the BFD tab and view the status of the BFD session on the spoke SDP binding:

1. Click on the BFD Session tab.
2. Choose a BFD session and click Properties. The BFD Session (View) form opens.

5

Close the forms.

END OF STEPS

79.74 To run an OAM validation test for a VPRN service

79.74.1 Prerequisites

An OAM validator test suite must be created for the tested entity. See Chapter 90, “OAM diagnostic tests” for more information about how to create an OAM validator test suite.

Note: As an alternative, you can also run an OAM validation test on the service by performing a One Time Validation. This is a mostly automated procedure and is described in 90.55 “To run a one-time validation test on a service” (p. 3084) .

79.74.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a service and click Properties. The VPRN Service (Edit) form opens.

3

Click Validate. If the Validate button is not visible, click on the More Actions button and choose Validate. If an OAM validator test suite is not associated to the service, a dialog box appears. Perform the following:

1. Click OK to associate the service with an existing OAM validator test suite. The Choose Validator Test Suite form opens.
2. Select an OAM validator test suite.

4

View the State Cause indicators. When the validation test fails, a check mark appears beside the OAM Validation Failure indicator.

5

Click on the Tests tab, then on the Tested Entity Result tab.

6

Choose an entry and click Properties. The Tested Entity Result (Edit) form opens.

7

Click on the Results tab to display the validation test results.

8

If you need to compare two test results from the same type of test, choose the two test results and click Compare; the Difference form opens.

9

Compare the test results.

10

Close the forms.

END OF STEPS

79.75 To configure OAM components on a VPRN site

79.75.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand the Sites icon, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

Click on the OAM tab, then on the ETH-CFM tab.

5

Configure the Tunnel Fault Notification parameter in the Facility MEPs panel.

This parameter must be set to Accept, in order to receive the fault notification from a tunnel facility MEP. Tunnel Fault Notification is configurable on sites where the device has ports configured in access or hybrid mode with QinQ encapsulation.

6

Click the OAM tab, then the Configuration tab.

7

Configure the required Test Generation Options parameters.

8

Click the OAM tab, then the TWAMP tab.

9

To add a TWAMP reflector to this site, perform 79.76 “To create a TWAMP Light reflector on a VPRN site” (p. 2647) .

10

Save the changes and close the forms.

END OF STEPS

79.76 To create a TWAMP Light reflector on a VPRN site

79.76.1 Prerequisites

A TWAMP Light reflector is required to conduct a TWAMP Light Test Session. See Chapter 92, “Performance Monitoring tests” for more information.

79.76.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

In the service navigation tree, expand Sites and right-click on the routing instance icon in the service navigation tree on which you need to configure a TWAMP Light reflector. The Site (Edit) form opens.

4

Click the OAM tab, then the TWAMP tab.

5

Configure the required parameters.

6

Click Create in the Reflector Prefixes panel. The Prefix TWAMP Light Reflector (Create) form opens.

7

Configure the required parameters.

Prefixes are added to the reflector to determine which PM Sessions can target the reflector. You should specify the prefix address and length if you require masking. Only those TWAMP Light test sessions with a Source IP matching a prefix will be valid. A maximum of 50 prefixes can be added to a reflector. TWAMP Light sessions without a matching prefix will cause an alarm to be generated.

8

Click the TWAMP Light Sessions tab.

9

Click Add to create a TWAMP Light Test Session. See 92.12 “To configure a TWAMP Light session OAM diagnostic test from the STM” (p. 3154) for more information.

10

Click the PM Sessions tab.

11

Click Add to create a PM Session. See 92.6 “To configure a PM session OAM diagnostic test from the STM” (p. 3146) for more information.

12

Save the changes and close the forms.

13

From the equipment view, right-click on the managed NE for which you want to configure a TWAMP Light Reflector and choose Properties. The Network Element (Edit) form opens.

14

Click on the Globals tab, then on the OAM tab.

15

Configure the TWAMP Light Reflector Inactivity Timer (seconds) parameter in the TWAMP-Light Reflector panel.

16

Save the changes and close the forms.

END OF STEPS

79.77 To view the last cleared BFD statistics and sessions on a VPRN site

79.77.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, click on the site on which you want to view the last cleared BFD statistics and sessions.

4

Click on the Clear Status tab and view the five last cleared BFD statistics and the five last cleared BFD sessions.

5

Close the forms.

END OF STEPS

79.78 To view VPRN services that use an auto-assigned RT and RD or reservation table

79.78.1 Steps

1

Choose Tools→Network Resources→Network Resources from the NFM-P main menu. The Network Resources form opens.

2

Click on the Route Distinguishers and Route Targets tab.

3

Click Search to view the services and sites that use an auto-assigned RT and RD or RT from a reservation table.

4

Close the forms.

END OF STEPS

79.79 To view DHCPv6 leases

79.79.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, click on the site where you need to view DHCPv6 leases; expand the entries for that site.

4

Choose routing instance from the navigation tree. The Site (Edit) form opens.

5

Click on the RADIUS/DHCP/Diameter tab. The Local DHCP Servers tab is displayed.

6

Click on the DHCP V6 tab. The list of associated DHCPv6 servers is displayed.

7

Choose a DHCPv6 server and click Properties. The Local DHCPv6 Server (Edit) form opens.

8

Click Show Leases. If the Show Leases button is not visible, click on the More Actions button and choose Show Leases. The DHCPv6 Server Show Leases form opens.

9

Perform one of the following:

a. To view the entire list of leases that are active on the DHCPv6 server, click OK.

b. To view the lease information for a specific prefix, enter the IP address in the Prefix parameter for the particular DHCPv6 server and click OK.

Note: If the prefix does not exist in the list of leases, a message displays.

c. To view the detailed lease information for a specific prefix, enter the IP address in the Prefix parameter for the particular DHCPv6 server, select the Detail check box, and click OK. The form displays the CLI details for the specific prefix.

10

Close the forms.

END OF STEPS

79.80 To view DHCPv6 log events

79.80.1 Purpose

This procedure describes how to view lease not owner and pool unknown log events for local DHCPv6 servers.

79.80.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, click on the site where you need to view DHCPv6 log events; expand the entries for that site.

4

Choose routing instance from the service navigation tree. The Site (Edit) form opens.

5

Click on the RADIUS/DHCP/Diameter tab. The Local DHCP Servers tab is displayed.

6

Click on the DHCP V6 tab. The list of associated DHCPv6 servers is displayed.

7

Choose a DHCPv6 server and click Properties. The Local DHCPv6 Server (Edit) form opens.

8

Click on the Logs tab. The Lease Not Owner Log and Pool Unknown Log tabs display.

9

Click on the tab for the type of log that you wish to display. Configure the filter criteria and click Search. A list of NE SHCV event logs appears.

10

Select an event logs and click Properties. The Log form opens.

11

View the log entry.

12

Close the forms.

END OF STEPS

79.81 To view the service topology map associated with a VPRN service

79.81.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Topology View. A Topology View dialog box appears.

3

Click Yes to proceed. The Service Topology - map opens.

See Chapter 4, “Topology map management” for more information about service topology views.

END OF STEPS

VPRN L3 access interfaces procedures

79.82 Workflow to configure VPRN L3 access interfaces

79.82.1 Overview

The following workflow lists the high-level steps required to configure L3 access interfaces on a VPRN site.

79.82.2 Stages

1

Configure an L3 access interface on a VPRN site; see 79.83 “To configure an L3 access interface on a VPRN site” (p. 2656) .

2

Configure an override source VPRN L3 access interface; see 79.84 “To configure an override source VPRN L3 access interface on a VPRN site” (p. 2658) .

3

Bind an application profile to a VPRN L3 access interface; see 79.85 “To bind an application profile to a VPRN L3 access interface” (p. 2659) .

4

Configure LAG per-link hashing on a VPRN L3 access interface; see 79.86 “To configure LAG per-link hashing on a VPRN L3 access interface” (p. 2660) .

5

Configure load balancing on a VPRN L3 access interface; see 79.87 “To configure load balancing on a VPRN L3 access interface” (p. 2661) .

6

Configure custom object attributes for AA reporting on a VPRN L3 access interface; see 79.88 “To configure custom object attributes for AA reporting on a VPRN L3 access interface” (p. 2661) .

7

Assign ingress and egress QoS policies to a VPRN L3 access interface; see 79.89 “To assign ingress and egress QoS policies to a VPRN L3 access interface” (p. 2662) or 79.90 “To assign ingress and egress QoS policies to a VPRN L3 access interface on a 7210 SAS site” (p. 2665).

8

Configure scheduling on a VPRN L3 access interface; see 79.91 “To configure scheduling on a VPRN L3 access interface” (p. 2666) .

9

Assign ingress and egress ACL filters to a VPRN L3 access interface; see 79.92 “To assign ingress and egress ACL filters to a VPRN L3 access interface” (p. 2668) .

10

Assign a virtual port to a VPRN L3 access interface; see 79.93 “To assign a virtual port to a VPRN L3 access interface” (p. 2669).

11

Assign an accounting policy to a VPRN L3 access interface; see 79.94 “To assign an accounting policy to a VPRN L3 access interface” (p. 2670) .

12

Assign an accounting template policy to a VPRN L3 access interface, tunnel interface, or subscriber group interface; see 79.95 “To assign an accounting template policy to a VPRN interface” (p. 2670) .

13

Associate a security zone policy with a VPRN L3 access interface on a 7705 SAR; see 79.96 “To associate a security zone policy with a VPRN L3 access interface on a 7705 SAR” (p. 2672) .

14

Assign a time of day suite to a VPRN L3 access interface; see 79.97 “To assign a time of day suite to a VPRN L3 access interface” (p. 2672) .

15

Bind a VPRN L3 access interface to a VPLS site or VPLS I-site; see 79.98 “To bind a VPRN L3 access interface to a VPLS site or VPLS I-site” (p. 2673) .

16

Associate a local DHCPv4 or DHCPv6 server with a VPRN L3 access interface; see 79.99 “To associate a local DHCPv4 or DHCPv6 server with a VPRN L3 access interface” (p. 2674) .

17

Assign an NE DoS protection policy or NE DDoS protection policy to a VPRN L3 access interface; see 79.100 “To assign an NE DoS or DDoS protection policy to a VPRN L3 access interface” (p. 2675) .

18

Configure residential subscriber management for a VPRN L3 access interface; see 79.101 “To configure residential subscriber management for a VPRN L3 access interface” (p. 2676) .

19

Assign an IP address to a VPRN L3 access interface; see 79.102 “To assign an IP address to a VPRN L3 access interface” (p. 2677) .

20

Configure IPv4 ICMP for a VPRN L3 access interface; see 79.103 “To configure IPv4 ICMP for a VPRN L3 access interface” (p. 2678) .

21

Configure IPv6 ICMP on a VPRN L3 access interface; see 79.104 “To configure IPv6 ICMP on a VPRN L3 access interface” (p. 2678) .

22

Configure BFD for a VPRN L3 access interface; see 79.106 “To configure BFD for a VPRN L3 access interface” (p. 2680) .

23

Configure ARP for a VPRN L3 access interface; see 79.107 “To configure ARP for a VPRN L3 access interface” (p. 2682) .

24

Configure neighbor discovery on a VPRN L3 access interface; see 79.108 “To configure neighbor discovery on a VPRN L3 access interface” (p. 2682) .

25

Configure IPv4 DHCP for a VPRN L3 access interface; see 79.109 “To configure IPv4 DHCP for a VPRN L3 access interface” (p. 2683) .

26

Create a VRRP instance on a VPRN L3 access interface for a virtual router; see 79.110 “To create a VRRP instance on a VPRN L3 access interface for a virtual router” (p. 2685) .

27

Configure anti-spoofing filters for a VPRN L3 access interface; see 79.111 “To configure anti-spoofing filters for a VPRN L3 access interface” (p. 2686) .

28

Configure router advertisement on a VPRN L3 access interface; see 79.112 “To configure router advertisement on a VPRN L3 access interface” (p. 2687) .

29

Assign an ANCP policy to a VPRN L3 access interface; see 79.113 “To assign an ANCP policy to a VPRN L3 access interface” (p. 2688) .

30

Specify queue or meter overrides on a VPRN L3 access interface; see 79.114 “To specify QoS policy overrides on a VPRN L3 access interface” (p. 2689) .

31

Configure IPv6 DHCP on a VPRN L3 access interface; see 79.115 “To configure DHCPv6 on a VPRN L3 access interface” (p. 2690) .

32

Associate a Multi-Chassis shunting profile to a VPRN L3 access interface; see 79.116 “To associate a Multi-Chassis shunting profile to a VPRN L3 access interface” (p. 2691) .

79.83 To configure an L3 access interface on a VPRN site

79.83.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand the Sites icon, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

Right-click on L3 Access Interfaces and choose Create VPRN L3 Access Interface or expand L3 Access Interfaces, right-click on an access interface and choose Properties. The VPRN L3 Access Interface (Create|Edit) form opens.

5

Configure the required parameters.

If you enable the Loopback Enabled parameter, you cannot associate a port with the L3 access interface.

The Admin Link Local Address parameters are only configurable when the IPv6 Allowed parameter is enabled.

The Unnumbered Type parameter is configurable when the Class parameter is set to Unnumbered.

The Unnumbered IP Address parameter is configurable when the Unnumbered Type parameter is set to IP Address.

The Unnumbered Interface Name parameter is configurable when the Unnumbered Type parameter is set to Name.

IPv6–specific parameters are only configurable when the IPv6 Allowed parameter is enabled.

The Tunnel Fault Notification parameter is configurable on interfaces where the device has ports configured in access or hybrid mode with QinQ encapsulation.

If you are configuring a tunnel facility MEP, Tunnel Fault Notification must be set to Accept, in order to receive the fault notification from the tunnel facility MEP.

6

Configure the required parameters in the Frame Size Constraints panel.

7

Configure the required parameters in the Unicast RPF panel.

8

Select a host lockout policy in the Host Lockout panel.

9

Configure the required parameters in the PTP HW panel.

You can only enable the PTP HW Assist parameter after the port is associated to the interface, and an IP address is configured on the interface.

10

To configure Cflowd sampling:

1. Click Create in the Cflowd Sampling panel. The Cflowd Sampling (Create) form opens.
2. Configure the required parameters and click Apply. The Cflowd sampling object appears in the Cflowd Sampling panel.
3. Save your changes.

11

Configure the required parameters in the Redundant Next Hop Addresses panel.

12

Select a monitored group in the Operational Group panel.

13

Associate a port with the L3 access interface:

1. Click on the Port tab.

   Note:

If the Loopback Enabled parameter in Step 6 is enabled, you cannot associate a port with the L3 access interface. Go to Step 14 .

2. Select a port in the Terminating Port panel.

   Note:

   Only ports in access or hybrid mode, or PW ports are listed. To choose a port that is not listed, you must set the Mode parameter for the port to Access or Hybrid. The port is listed when you click Search.

   The form only lists PW ports that are bound to a service tunnel. See 33.9 “To create an IP/MPLS service tunnel” (p. 1190) for information about how to create a service tunnel with a PW port binding.

   You can select a bundle in the Terminating Port panel.

3. Configure the required parameters.

   The Auto-Assign ID parameter is configurable if the port uses dot1q encapsulation. When the parameter is enabled, the NFM-P automatically configures the Outer Encapsulation Value parameter using the lowest unassigned value.

   You can set the Auto-Assign ID parameter to be the default parameter for dot1q encapsulation by enabling the Access Interface Encap Value (Dot1q only) parameter on the User Preferences form. Choose Application→ User Preferences from the main menu.

   The Inner Encapsulation Value is configurable only when the port is an Ethernet or frame relay port with QinQ encapsulation.

   The Outer Encapsulation Value (VPI) and Inner Encapsulation Value (VCI) parameters are configurable only for ATM ports.

4. Configure the required parameters in the Properties panel.
5. Select an NE DoS protection policy or an NE DDoS protection policy in the Security panel and configure the required parameters.

14

Save the changes and close the forms.

End of steps

79.84 To configure an override source VPRN L3 access interface on a VPRN site

79.84.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand the Sites icon, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

Click on the Source Addresses tab and click Create. The Source Address (Create) form opens.

5

Configure the Source IP Application parameter.

6

Set the Source Address Termination parameter to Interface Index.

7

Select a source address VPRN interface.

8

Save the changes and close the forms.

END OF STEPS

79.85 To bind an application profile to a VPRN L3 access interface

79.85.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Sites→Routing Instance→L3 Access Interfaces, right-click on an L3 access interface and choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

Click on the Application Assurance tab.

5

Select an application profile string.

Only local profiles that already exist on the NE can be selected.

6

To choose one of the following AA transit policy types:

Note: You can only associate one AA transit policy type with a service object.
To bind a transit policy to an L3 access interface, a port must already exist on the interface.
You can bind a transit policy to only one L3 access interface or spoke SDP binding per NE.
The transit policy and the application profile must belong to the same application assurance group or partition.

a. Select an AA transit IP policy in the Transit IP Policy panel.

b. Select an AA transit prefix policy in the Transit Prefix Policy panel.

7

Select an AA redundant protocol in the AA Redundant Protocol panel.

8

Save the changes and close the forms.

END OF STEPS

79.86 To configure LAG per-link hashing on a VPRN L3 access interface

79.86.1 Prerequisites

You can configure weighted per-link hashing on a VPRN L3 access interface if the terminating port has LAG per-link hashing enabled. The interface must be a LAG member.

79.86.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an VPRN and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Sites→Routing Instance→L3 Access Interfaces, right-click on the L3 access interface and choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

Click on the LAG Per Link Hash tab.

5

Configure the Class and Weight parameters.

6

Save the changes and close the forms.

END OF STEPS

79.87 To configure load balancing on a VPRN L3 access interface

79.87.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an VPRN and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Site→L3 Access Interfaces, right-click on an L3 access interface choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

Configure the L4 Load Balance, TEID Load Balancing, Egress IP Load Balancing, IPv6 Flow Label Load Balancing, and SPI Load Balancing parameters, as required.

5

Save the changes and close the forms.

END OF STEPS

79.88 To configure custom object attributes for AA reporting on a VPRN L3 access interface

79.88.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Site→L3 Access Interfaces, right-click on an L3 access interface choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

On the General tab, choose an Application Profile for the application Group and Partition.

5

Click on the Application Assurance tab, then the NSP Analytics Parameters sub-tab.

6

Click on the Reporting tab and click Create. The AA Reporting (Create) form opens.

7

Configure the required parameters.

8

Save the changes and close the forms.

END OF STEPS

79.89 To assign ingress and egress QoS policies to a VPRN L3 access interface

79.89.1 Before you begin

The available panels and parameters vary depending on the NE, chassis type, and release.

If you are assigning QoS policies to an access interface on a 7210 SAS NE, see 79.90 “To assign ingress and egress QoS policies to a VPRN L3 access interface on a 7210 SAS site” (p. 2665).

79.89.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Site→L3 Access Interfaces, right-click on an L3 access interface choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

Click on the QoS tab and configure the Ingress Match QinQ Dot1P parameter.

The QoS tab is configurable only if a port is assigned to the interface.

The Ingress Match QinQ Dot1P parameter is configurable only when the encapsulation type of the port is BCP dot1q, dot1q, or QinQ.

5

Select an ingress QoS policy in the Ingress Policy panel.

Note: If you select an ingress policy which has a forwarding class mapped to an ingress queue group, you must ensure that the port you selected in 79.83 “To configure an L3 access interface on a VPRN site” (p. 2656) has the access ingress queue group with the same name created on it.
See 16.24 “To configure Ethernet ports” (p. 599) for more information about how to configure Ethernet ports. See Chapter 49, “Policies overview” for more information about queue group template policies.

6

Select an ingress queue group template policy in the Forwarding Plane Redirect panel.

7

Configure the Instance ID and the Egress Mark QinQ Top Bits Only parameters.

The Egress Mark QinQ Top Bits Only parameter is configurable only when the encapsulation type of the port is BCP dot1q, dot1q, or QinQ.

8

Configure the required parameters in the Aggregate Rate Limit panel.

9

Select an egress policy in the Egress Policy panel.

Note: If you select an egress policy which has a forwarding class mapped to an egress queue group, you must ensure that the port you selected in 79.83 “To configure an L3 access interface on a VPRN site” (p. 2656) has the access egress queue group with the same name created on it.
See 16.24 “To configure Ethernet ports” (p. 599) for more information about how to configure Ethernet ports. See Chapter 49, “Policies overview” for more information about queue group template policies.
Queue Group Template policies are not applicable to L3 interfaces associated with HSMDA ports.

10

Select an Egress Queue Group Template Policy in the Port Redirect panel.

Note: Selecting an Egress Queue Group Template Policy here permits the redirection of Ethernet traffic packets to a queue ID specified in the egress port queue group of the SAP. The following properties and restrictions apply:

- If an Egress Queue Group Template Policy is specified here, the policy must have port redirection enabled.
- You cannot use policy-based redirection with the queue group when the SAP has SAP-based redirection enabled.
- Port access egress redirection is only supported on Ethernet/LAG ports. It is not supported on SAPs bound on non-Ethernet, Eth-tunnel, or CCAG ports.
- Supported ports include access, hybrid, and HSMDA.
- Queue groups can be applied to SAPs that incorporate LAGs. The LAGs can include port members from just a single card or from multiple cards.
- If you edit a LAG incorporated by the SAP, you cannot remove the last LAG member if a queue group reference exists to the containing SAP.
- You cannot add a secondary LAG member that has a queue group mismatch with primary LAG member.

11

If you are configuring an L3 access interface for a 7705 SAR, or if the port you selected in 79.83 “To configure an L3 access interface on a VPRN site” (p. 2656) is not an HSMDA port, then save the changes and close the forms.

Otherwise, configure the Packet Byte Offset (bytes) parameter. You must enable the associated Override parameter.

12

Select a WRR policy in the Egress HSMDA Override panel.

13

Select an HSMDA egress secondary shaper policy in the Egress HSMDA Override panel.

14

In the Shaper Group panel, select a Shaper Group for the access ingress port or access egress port.

15

In the IXR Specific panel, select an Egress Remark policy, Egress VLAN QoS policy, and a Shared Policer policy, as required. See 50.82 “To configure a 7250 SROS Remarking policy” (p. 1634), 50.54 “To configure a 7250 SROS VLAN QoS policy” (p. 1594), and 50.101 “To configure a shared policer policy” (p. 1661).

16

Select an HS secondary shaper in the HS Overrides panel, if required.

17

Save the changes and close the forms.

END OF STEPS

79.90 To assign ingress and egress QoS policies to a VPRN L3 access interface on a 7210 SAS site

Note: The available parameters and policies vary depending on the device type and chassis variant. The configurations that are supported on the site NE are shown on the form.

79.90.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Site→L3 Access Interfaces, right-click on an L3 access interface choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

Click on the QoS tab and expand the 7210/7250 Specific panel.

5

Select a SAP Access Ingress policy in the Ingress Policy panel.

When you assign an ingress policy, the Color Mode parameter setting for the meters in the policy must coincide with the Enable DEI parameter setting on the physical port. When Enable DEI is selected, the Color Mode for meters must be set to Color Aware. When Enable DEI is not selected, the Color Mode for meters must be set to Color Blind. See 16.24 “To configure Ethernet ports” (p. 599) and 50.29 “To configure a 7210, 7250, and 1830 SAP Access Ingress policy” (p. 1544) .

To support H-metering, you must choose an ingress policy with all meter rate modes set to trTCM (RFC 4115).

For 7250 IXR sites, the selected SAP Access Ingress policy must contain an assigned 7250 Ingress CoS policy.

6

Select a SAS egress policy.

7

To enable table-based color-aware ingress classification, select the Enable Table Classification parameter. See 50.23.2 “Table-based ingress classification on the 7210 SAS” (p. 1529).

8

Select an Egress Remarking policy in the Egress Remark Policy panel.

9

Configure the required parameters in the Aggregate Rate Limit panel.

You can configure the Ingress Meter parameter only during SAP creation. The parameter must be set to true to support H-metering.

You can configure the Ingress Meter Rate (kbps) and Ingress Meter Burst parameters only after SAP creation.

You can configure the Egress Meter Rate and Egress Meter Burst parameters only when resources are allocated to the SAP Egress Aggregate Meter parameter in the system resource profile; see 12.50 “To configure the global system resource profile on a 7210 SAS or 7250 IXR” (p. 380). To allocate resources on the 7210 SAS-R, configure the Egress SAP Aggregate Meter parameter in the system resource profile policy assigned to the device; see 12.51 “To configure a system resource profile policy for the 7210 SAS-R/T/Mxp, 7210 SAS-S/Sx, or 7210 SAS-S/Sx VC” (p. 382).

You must also enable port-based scheduling on 7210 SAS-Mxp and 7210 SAS-R NEs; see 12.53 “To configure port-based scheduling on the 7210 SAS” (p. 384).

The Enable Egress Meter Stats parameter is available when a value is configured for the Egress Meter Rate parameter.

10

Configure the required parameters in the IXR Specific panel. Select an Egress Remark policy, Egress VLAN QoS policy, and a Shared Policer policy, as required.

11

Save the changes and close the forms.

END OF STEPS

79.91 To configure scheduling on a VPRN L3 access interface

79.91.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Site→L3 Access Interfaces, right-click on an L3 access interface choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

Click on the Schedulers tab and configure the required parameters.

Note: The Schedulers tab is configurable only if a port is assigned to the SAP in 79.83 “To configure an L3 access interface on a VPRN site” (p. 2656) .

5

To configure scheduling on a 7210 SAS site, enable and configure the required parameters in the Egress Aggregate Rate Limit panel and go to Step 9 .

6

To configure scheduling on a 7705 SAR site:

Note: For the 7705 SAR, scheduler behavior is determined by the scheduler mode, which is 4-Priority by default. You can only configure the Egress and Ingress Aggregate Rate Limit parameters when the Scheduler Mode parameter is set to 16-Priority. You can set the Scheduler Mode to 16-Priority only when the port is on an MDA that supports 16-Priority. See the 7705 SAR documentation for more information.

If you change the Scheduler Mode parameter from 16-Priority to 4-Priority, the NFM-P automatically restores the default settings for the Egress Aggregate Rate Limit and Ingress Aggregate Rate Limit panels when you click on the Apply or OK button.

1. In the Egress Scheduler panel, configure the Scheduler Mode parameter.
2. In the Ingress Scheduler panel, configure the Scheduler Mode parameter.
3. If you set the Scheduler Mode parameter to 16-Priority in the Egress Scheduler panel or Ingress Scheduler panel, configure the parameters in the Egress Aggregate Rate Limit panel and Ingress Aggregate Rate Limit panel.

7

To specify that an aggregation scheduler policy is not applied to the interface:

1. Set the Aggregation parameter to Off.

   Note:

   The Aggregation parameter is not configurable if the port you selected in 79.83 “To configure an L3 access interface on a VPRN site” (p. 2656) is an HSMDA port.
2. Configure the required parameters.

The Aggregate Rate Limit (kbps), Frame-Based Accounting, and Limit Unused Bandwidth parameters are configurable only when there is no scheduler specified in the Egress Scheduler panel.

The Frame-Based Accounting parameter is not configurable if the port you selected in 79.83 “To configure an L3 access interface on a VPRN site” (p. 2656) is an HSMDA port.

You cannot specify an egress scheduler when the Aggregate Rate Limit (kbps) parameter is set to a value greater than zero.

3. Select an ingress scheduler in the Ingress Scheduler panel.
4. Select an ingress policer control policy in the Ingress Policer Control Policy panel.
5. If the port you selected in 79.83 “To configure an L3 access interface on a VPRN site” (p. 2656) is an HSMDA port, go to Step 8 .
6. Select an egress scheduler in the Egress Scheduler panel.
7. Select an egress policer control policy in the Egress Policer Control Policy panel.
8. Go to Step 9 .

8

To specify that an aggregation scheduler policy is applied to the interface:

Note: You cannot specify an access scheduler policy if the port you selected in 79.83 “To configure an L3 access interface on a VPRN site” (p. 2656) is an HSMDA port. Go to Step 9 .

1. Set the Aggregation parameter to On.
2. Select an aggregation scheduler in the Aggregation Scheduler panel.

9

Save the changes and close the forms.

END OF STEPS

79.92 To assign ingress and egress ACL filters to a VPRN L3 access interface

79.92.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Site→L3 Access Interfaces, right-click on an L3 access interface choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

Click on the ACL tab.

Note: When you configure ACL filters on a 7210 SAS NE, you must configure the system resource profile appropriately. See 6.5.13 “System resource profile” (p. 220) in 6.5 “7210 SAS” (p. 216) for more information.

5

Select the required ACL filter policies.

Note: Select the Ingress IP Filter Pair option to configure IP and IPv6 filters simultaneously to filter IP and IPv6 traffic respectively. Once the filters are paired, they can not be used separately or paired with another filter. This option is supported only for VPRN services on 7250 IXR NE, 22.2 R1 or later.

6

Save the changes and close the forms.

END OF STEPS

79.93 To assign a virtual port to a VPRN L3 access interface

79.93.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Site→L3 Access Interfaces, right-click on an L3 access interface choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

Click on the Virtual Port Name tab.

5

Configure the required parameters.

6

Save the changes and close the forms.

END OF STEPS

79.94 To assign an accounting policy to a VPRN L3 access interface

79.94.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Site→L3 Access Interfaces, right-click on an L3 access interface choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

Click on the Accounting tab.

5

Select an accounting policy.

6

Configure the required parameters.

Collect Egress Queue Statistics parameter can be configured only during VPRN L3 access interface creation. See 79.83 “To configure an L3 access interface on a VPRN site” (p. 2656).

7

Save the changes and close the forms.

END OF STEPS

79.95 To assign an accounting template policy to a VPRN interface

79.95.1 Purpose

This procedure applies to VPRN L3 access interfaces, tunnel interfaces, or subscriber group interfaces.

For information about creating an accounting template policy, see 54.12 “To configure an accounting template policy” (p. 1757) .

79.95.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Configure the filter criteria. A list of services appears.

3

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

4

Expand the Sites icon in the service navigation tree.

5

Expand the Routing Instance icon in the service navigation tree on which you need to configure the accounting template policy.

6

Right-click on the L3 access interface, tunnel interface, or subscriber group interface you need to configure and choose Properties.

7

Click on the Policies tab.

8

Select a accounting template in the accounting template panel.

9

Save and close the form.

END OF STEPS

79.96 To associate a security zone policy with a VPRN L3 access interface on a 7705 SAR

79.96.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Site→L3 Access Interfaces, right-click on an L3 access interface choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

Click on the Zone tab.

5

Select a security zone policy.

You can create a security zone policy by clicking Create.

6

Configure the ByPass Zone Config parameter.

7

Save the changes and close the forms.

END OF STEPS

79.97 To assign a time of day suite to a VPRN L3 access interface

79.97.1 Prerequisites

You can assign a ToD suite to a L3 access interface only if accounting statistics collection is disabled on the interface. You must disable the Collect Accounting Statistics parameter in Step 4 of 79.94 “To assign an accounting policy to a VPRN L3 access interface” (p. 2670) .

79.97.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Site→L3 Access Interfaces, right-click on an L3 access interface choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

Click on the TOD Suite tab.

5

Select a time of day suite.

Note: SapEgrQosPlcyStats and SapIngQosPlcyStats statistics are collected only if a Time Of Day Suite is applied on the SAP.

6

Save the changes and close the forms.

END OF STEPS

79.98 To bind a VPRN L3 access interface to a VPLS site or VPLS I-site

79.98.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Site→L3 Access Interfaces, right-click on an L3 access interface choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

Click on the Routed VPLS tab.

Note: The operational state of the IP interface binding will not be turned up until the Enable IP Interface Binding parameter is set to true.
You can create and manage a routed VPLS connector from the navigation tree on the Composite Service (Edit) form.

5

Enter a VPLS site name or select a VPLS site.

6

Configure EVPN Tunnel parameters as needed.

7

Expand the Ingress or Egress panel as needed.

8

To configure the filter policies:

1. Select an IPv4 filter in the IPv4 Filter panel.
2. Select an IPv6 filter in the IPv6 Filter panel.

9

To enable table-based color-aware ingress classification, select the Enable Table Classification For VPLS parameter, then select a 7210/7250 DSCP classification policy as the Routed Override QoS policy. See 50.23.2 “Table-based ingress classification on the 7210 SAS” (p. 1529).

10

To configure the egress QoS policies by selecting an QoS policy in the Egress QoS Policy panel.

11

Save the changes and close the forms.

END OF STEPS

79.99 To associate a local DHCPv4 or DHCPv6 server with a VPRN L3 access interface

79.99.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Site→L3 Access Interfaces, right-click on an L3 access interface choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

Click on the Local DHCP tab:

a. For local DHCPv4 servers, select a local DHCP server in the Local DHCP Server panel.

Note: You cannot associate a local DHCPv4 server to the L3 group Interface if the Administrative State parameter in the Local Proxy Service panel is up.

b. For local DHCPv6 servers, select a local DHCPv6 server in the Local DHCPv6 Server panel.

Note: To associate local DHCPv6 servers the IPv6 Allowed parameter must be enabled on the General tab.

5

Save the changes and close the forms.

END OF STEPS

79.100 To assign an NE DoS or DDoS protection policy to a VPRN L3 access interface

Note: See the procedure to configure an NE DoS protection policy in the *NSP System Administrator Guide* for more information about configuring and applying NE DoS protection policies.

79.100.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Site→L3 Access Interfaces, right-click on an L3 access interface choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

Click on the Port tab.

5

Select a DoS protection policy in the NE DoS Protection Policy panel.

6

Select a DDoS protection policy.

7

Save the changes and close the forms.

END OF STEPS

79.101 To configure residential subscriber management for a VPRN L3 access interface

79.101.1 Prerequisites

Residential subscriber management is supported on the 7450 ESS in mixed mode and 7750 SR.

79.101.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Site→L3 Access Interfaces, right-click on an L3 access interface choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

Click on the Subscriber Management tab.

5

Enable the SHCV Enabled parameter.

6

Configure the required parameters on the Subscriber Host Connectivity Verification panel.

7

Select an SHCV IPv4 policy.

8

Save the changes and close the forms.

END OF STEPS

79.102 To assign an IP address to a VPRN L3 access interface

79.102.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Site→L3 Access Interfaces, right-click on an L3 access interface choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

Click on the Addresses tab and click Create. The IP Address (Create) form opens.

5

Configure the required parameters.

The Broadcast Address Format parameter only appears if the IP Address parameter is set to an IPv4 address.

The parameters in the IPv6 panel only appear if the IP Address parameter is set to an IPv6 address.

6

Select a Track SRRP Instance, if required.

7

Save the changes and close the forms.

END OF STEPS

79.103 To configure IPv4 ICMP for a VPRN L3 access interface

79.103.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Site→L3 Access Interfaces, right-click on an L3 access interface choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

Click on the ICMP tab and configure the required parameters.

5

Configure the required parameters in the Redirects panel.

6

Configure the required parameters in the Unreachables panel.

7

Configure the required parameters in the TTL Expired panel.

8

Save the changes and close the forms.

END OF STEPS

79.104 To configure IPv6 ICMP on a VPRN L3 access interface

79.104.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Site→L3 Access Interfaces, right-click on an L3 access interface choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

Ensure that the IPv6 Allowed parameter is enabled.

5

Click on the IPv6 ICMP tab and configure the required parameters.

6

Configure the required parameters in the Redirects panel.

7

Configure the required parameters in the Unreachables panel.

8

Configure the required parameters in the Packet Too Big panel.

9

Configure the required parameters in the Param panel.

10

Configure the required parameters in the Time Exceeded panel.

11

Save the changes and close the forms.

END OF STEPS

79.105 To assign an ICMP ping template to a VPRN L3 access interface

79.105.1 Before you begin

ICMP ping templates are used to populate values for ICMP ping tests when the tests are used on L3 interfaces to control the operational state. ICMP ping templates are supported for IPv4 only. See 90.51 “To configure an ICMP Ping template” (p. 3079) for information about configuring ICMP ping templates.

Note: Nokia recommends that you assign an NE DoS protection policy, configured with a protocol of ICMP-Ping-Check, to the affected interfaces; see 79.100 “To assign an NE DoS or DDoS protection policy to a VPRN L3 access interface” (p. 2675).

79.105.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service tree, expand Site→L3 Access Interfaces, right-click on the L3 access interface you need to modify, and choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

Click on the ICMP Ping Template tab.

5

Click Create, or choose the template in the list and click Properties. The Virtual Interface ICMP Template Config form opens.

6

Click Select to choose a template pointer for the template. The Select Template Pointer form opens.

7

Choose an ICMP Ping template from the list and click OK to close the Select Template Pointer form.

8

On the Virtual Interface ICMP Template Config form, configure the Admin State and Destination Address parameters for the ICMP Ping test.

9

Save the changes and close the forms.

END OF STEPS

79.106 To configure BFD for a VPRN L3 access interface

Note: If the IPv6 Allowed parameter on the General tab is enabled, you can configure BFD parameters for IPv6.

79.106.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Site→L3 Access Interfaces, right-click on an L3 access interface choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

Click on the BFD tab.

5

In the IPv4 BFD Configuration panel, set the Admin Status parameter to Up and configure the required parameters.

6

In the IPv6 BFD Configuration panel, set the Admin Status parameter to Up and configure the required parameters.

7

To view local and remote session peers that are managed by the NFM-P, click on the BFD Session tab. A list of BFD current sessions on a router interface or an L3 interface appears.

8

Click on a session. The properties form for the session opens. View the following:

- BFD status
- protocol used
- local address
- remote address
- operational status and statistics

9

Save the changes and close the forms.

END OF STEPS

79.107 To configure ARP for a VPRN L3 access interface

79.107.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Site→L3 Access Interfaces, right-click on an L3 access interface choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

Click on the ARP tab and configure the required parameters.

5

To configure static ARP:

1. Click Create. The Static ARP (Create) form opens.
2. Configure the required parameters.
3. Save the changes and close the form.

6

Click on the Proxy ARP tab and configure the required parameters.

7

Save the changes and close the forms.

END OF STEPS

79.108 To configure neighbor discovery on a VPRN L3 access interface

79.108.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Site→L3 Access Interfaces, right-click on an L3 access interface choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

Set the IPv6 Allowed parameter to enabled.

5

Click on the Neighbor Discovery tab and click Create. The Neighbor Discovery (Create) form opens.

6

Configure the required parameters.

For the neighbor address to be communicated to the NE, you must configure an SNMP community on the site. See 79.17 “To configure an SNMP community on a VPRN site” (p. 2551) .

7

Save the changes and close the form.

8

Click on the Proxy ND tab and configure the required parameters.

Note: Do not leave an empty policy parameter between two configured policy parameters. For example, do not configure the Policy 1 and Policy 3 parameters and leave the Policy 2 parameter unconfigured, or the NFM-P reorders the policies and moves the policy specified for the Policy 3 parameter to the Policy 2 parameter.

9

Click on the Secure ND tab and configure the required parameters.

10

Save the changes and close the forms.

END OF STEPS

79.109 To configure IPv4 DHCP for a VPRN L3 access interface

79.109.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Site→L3 Access Interfaces, right-click on an L3 access interface choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

Click on the DHCP tab and configure the required parameters.

The Lease Populate parameter is configurable when the Enable parameter is enabled.

5

Select a subscriber authentication policy in the Subscriber Authentication Policy panel.

6

Configure the required parameters in the Option 82 panel.

The Remote ID String parameter is configurable when the Remote ID is set to Remote ID String.

When the Relay Unicast Message parameter is set to Renew or Release Update Source IP, the GI address parameter can be configured as any local configured address in the same routing instance as the GI address for the DHCP relayed messages. If the Relay Unicast Message parameter is set to None, the GI address is restricted to the IP address configured on the subscriber interface.

7

Configure the parameters in the Vendor Specific Option panel.

8

Configure the parameters in the GI-Address panel.

9

Select a Python policy, if required.

10

Click on the Server tab and configure the required parameters in the DHCP Servers and Local Proxy Server panels.

The Number of Days, Number of Hours, Number of Minutes, Number of Seconds, and Lease Time Override parameters are configurable only when the Lease Time parameter is set to Specified Time Period.

11

Save the changes and close the forms.

END OF STEPS

79.110 To create a VRRP instance on a VPRN L3 access interface for a virtual router

79.110.1 Prerequisites

You must know the VRID for an existing virtual router and ensure that the interface is a member of the same subnet as the virtual router.

See Chapter 37, “VRRP” for configuration information about VRRP instances and virtual routers.

The following configurations are required for the operation of the IPv6 VRRP instance:

- Two tabs are available under the VRRP tab, one for IPv4 instances and the other for IPv6 instances. You can only create an IPv6 VRRP Instance if you enable the IPv6 Allowed parameter on the General tab of the VPRN L3 Access Interface (Edit) form.
- The Link Local Address on the parent interface must be set to preferred or to disable DAD, depending on your node release, and configured as one of the backup addresses (or same subnet) for the IPv6 VRRP instance. The Admin Link Local Address and related parameters on the General tab of the VPRN L3 Access Interface (Edit) form must be set accordingly.
- The IPv6 address on the parent interface must be set to disable DAD to be used as a backup address (on same subnet) for the IPv6 VRRP instance. The IP Address and Disable DAD parameters in Step 5 of 79.102 “To assign an IP address to a VPRN L3 access interface” (p. 2677) must be set accordingly.
- The Send Advertisement and Use Virtual MAC Address parameters must be enabled in Step 6 of 79.112 “To configure router advertisement on a VPRN L3 access interface” (p. 2687) for the router advertisement on the parent interface.

79.110.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Site→L3 Access Interfaces, right-click on an L3 access interface choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

Click on the VRRP tab and click Create. The VRRP Instance (Create) form opens.

5

Configure the Virtual Router ID parameter.

6

Perform Step 3 to Step 15 of 37.4 “To create and configure a VRRP instance” (p. 1283) .

You can use the VR Instances tab to create, modify, and view VR instances.

7

Save the changes and close the forms.

END OF STEPS

79.111 To configure anti-spoofing filters for a VPRN L3 access interface

79.111.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Site→L3 Access Interfaces, right-click on an L3 access interface choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

Click on the Anti-Spoofing tab and configure the required parameters.

5

Configure the required general parameters.

The ARP Populate parameter is configurable when all of the IP addresses of the defined static hosts on the interface are in one of the subnets configured for the interface.

6

To configure static subscriber host entries, if subscriber entries are not available through DHCP lease management:

1. Click on the Static Hosts tab.

2. Click Create. The Access Interface Anti-Spoofing Static Host Display (Create) form opens.
3. Configure the required parameters.

   Specify at least one IP address or MAC address for each static host. The values specified for the Anti-Spoofing and ARP Populate parameters determine the type of address entry that is required for the static host. For example, when you set the Anti-Spoofing parameter to Source Ip Addr, you must specify at least the IP address for the static host.

   Note:

   You can configure a static host on a SAP only when no static ARP entries exist on the IP interface.

   When the ARP Populate parameter is enabled, the IP address of the new static host must be in one of the subnets that is configured for the interface in Procedure 79.102 “To assign an IP address to a VPRN L3 access interface” (p. 2677) .

7

Save the changes and close the forms.

END OF STEPS

79.112 To configure router advertisement on a VPRN L3 access interface

79.112.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Site→L3 Access Interfaces, right-click on an L3 access interface choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

Click on the Advertisement tab.

5

Click Create to add a router advertisement entry. The Router Advertisement (Create) form opens.

6

Configure the required parameters.

If you are configuring the L3 interface for an IPv6 VRRP instance, then the Send Advertisement and Use Virtual MAC Address parameters must both be enabled.

7

To configure RDNSS advertisement options:

1. Click on the DNS Options tab and click Create. The DNS Options form opens.
2. Configure the required parameters.
3. Save the changes and close the form.

8

To configure router advertisement prefixes:

1. Click on the Prefix tab and click Create. The Router Advertisement Prefix form opens.
2. Configure the required parameters.
3. Save the changes and close the form.

9

Save the changes and close the forms.

END OF STEPS

79.113 To assign an ANCP policy to a VPRN L3 access interface

79.113.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Site→L3 Access Interfaces, right-click on an L3 access interface choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

Click on the ANCP Static Map tab.

5

Click Create. The ANCP Static Map (Create) form opens.

6

Configure the ANCP String parameter.

7

Select an ANCP policy in the ANCP Policy panel.

8

Save the changes and close the forms.

END OF STEPS

79.114 To specify QoS policy overrides on a VPRN L3 access interface

79.114.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Site→L3 Access Interfaces, right-click on an L3 access interface choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

Click on the Override Policy Items tab.

Note: The Override Policy Items tab contains a number of tabs. However, the tabs that are displayed depend on the port type that you have chosen for this interface.

- If you configured a non-HSMDA port, then the Access Ingress Queues, Access Egress Queues, Ingress Policer, and Egress Policer tabs are active.
- If you configured an HSMDA port, then the Access Ingress Queues, Access Egress HSMDA Queues and Ingress Policer tabs are active.

Configure the policy overrides, as described in 50.97 “To configure QoS policy overrides on an L2 or L3 access interface” (p. 1654) .

To configure meter overrides on a 7210 SAS, see 50.98 “To configure QoS policy overrides on access ingress meters for the 7210 SAS” (p. 1657) .

To configure queue overrides on a 7210 SAS, see 50.99 “To configure QoS policy overrides on access ingress queues for a 7210 SAS-X” (p. 1659) .

5

Save the changes and close the forms.

END OF STEPS

79.115 To configure DHCPv6 on a VPRN L3 access interface

79.115.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Site→L3 Access Interfaces, right-click on an L3 access interface and choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

Set the IPv6 Allowed parameter to enabled.

5

Click on the DHCPv6 tab and configure the required parameters on the DHCPv6 Relay — General tab.

6

Click on the Server tab and configure Server 1 through Server 8 parameters.

7

To configure the interface name for each DHCPv6 server that you configured, select a configured interface in the Zone Index panel.

8

Click on the DHCPv6-Prefix tab and click Create. The DhcpRelayV6PrefixDelegation (Create) form opens.

9

Configure the required parameters.

10

Save the changes and close the forms.

END OF STEPS

79.116 To associate a Multi-Chassis shunting profile to a VPRN L3 access interface

79.116.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Site→L3 Access Interfaces, right-click on an L3 access interface and choose Properties. The VPRN L3 Access Interface (Edit) form opens.

4

Select a profile in the Multi-Chassis Shunting Profile panel; see 27.31 “To configure a Multi-Chassis shunting profile on a base routing instance or VPRN routing instance” (p. 876) .

Note: Only the shunting profile created on a VPRN routing instance can be selected.

5

Save the changes and close the forms.

END OF STEPS

79.117 To start or stop the ignore SAP port state tool on a VPRN interface

79.117.1 Purpose

Use the ignore SAP port state tool to bypass the checking of the physical port operational state if it is down during operational checks on the NE. The tool is available for 7x50 NEs on L3 and subscriber interfaces of IES and VPRN services. The interface can be IPV4/IPV6 or dual stack. An SAP must be attached.

If this procedure is performed when the IP interface is operationally up the command will be accepted but will enter a pending state. It will not become active unless the port state becomes non-operational.

79.117.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a service and click Properties. The VPRN Service (Edit) form opens.

3

Perform one of the following:

On the service navigation tree, expand Site→Subscriber Interfaces→Group Interface and right-click on a group interface.

a. On the service navigation tree, expand Site→L3 Access Interfaces and right-click on an L3 access interface.

b. On the service navigation tree, expand Site→Subscriber Interfaces→Group Interface and right-click on a group interface.

4

Choose Start Ignore SAP Port State or Stop Ignore SAP Port State.

END OF STEPS

80 SPB service management

80.1 Overview

80.1.1 Purpose

Shortest Path Bridging (SPB) is supported on OS 6900 and OS 10K NEs, Release 7.3.2 and later. SPB uses the Provider Backbone Bridge (PBB) network model to encapsulate (using IEEE 802.1ah headers) and tunnel customer traffic through the network backbone. The shortest path trees upon which the PBB network infrastructure operates are determined using a version of the Intermediate System-to-Intermediate System (IS-IS) link state protocol that supports TLV extensions for SPB (ISISSPB).

80.1.2 Contents

SPB service management procedures

80.2 Workflow to create SPB services (OmniSwitch)

80.2.1 Overview

The following workflow describes the sequence of high-level tasks required to create an SPB service on OmniSwitch devices.

80.2.2 Stages

1

Create an OmniSwitch Backbone VLAN service. See 80.3 “To create an OmniSwitch Backbone VLAN service” (p. 2695) for more information.

2

Configure an SPB control instance protocol. See 80.4 “To configure an SPB control instance protocol” (p. 2696) for more information.

3

Configure an SPB network interface. See 80.5 “To configure an SPB network interface” (p. 2696) for more information.

4

Configure an OmniSwitch Ethernet service L2 profile. See 80.6 “To configure an OmniSwitch Ethernet service L2 profile” (p. 2697) for more information.

5

Configure an SPB access interface. See 80.7 “To configure an SPB access interface” (p. 2698) for more information.

6

Create an SPB service. See 80.8 “To create an SPB service” (p. 2699) for more information.

7

Associate an access interface with an SPB service. See 80.9 “To associate an access interface with an SPB service” (p. 2700) for more information.

80.3 To create an OmniSwitch Backbone VLAN service

80.3.1 Steps

1

Choose Create→Service→VLAN from the NFM-P main menu. The VLAN Service (Create) form opens.

2

Choose a customer to associate with the VLAN.

3

Configure the required parameters.

The Service ID parameter is configurable when the Auto-Assign ID parameter is disabled.

The SVC Mgr Service ID parameter is configurable when the Auto-Assign ID parameter is disabled.

4

Click on the VLAN tab and set the Application parameter to Backbone VLAN.

5

Select a group to associate with the VLAN in the Group panel.

Note: All network elements within a backbone infrastructure must belong to the same VLAN group.

6

On the service tree, right-click on VLAN Service and choose Create VLAN Site. The Select Network Elements - VLAN Service form opens.

7

Choose one or more sites and click OK. The form closes.

8

Save your changes and close the form.

END OF STEPS

80.4 To configure an SPB control instance protocol

80.4.1 Steps

1

On the equipment tree, right-click on a Backbone VLAN site and choose Properties. The Network Element (Edit) form opens.

2

Click on the Backbone VLAN Parameters tab.

3

Configure the ECT Algorithm and Tandem Multicast Mode parameters.

Note: The ECT Algorithm parameter must be configured with the same value for all Backbone VLAN sites.

4

Click on the Globals tab.

5

Click on the Service tab and select an SPB control instance.

6

Click OK. The SPB Control Instance (Edit) form opens.

7

Select the required Backbone VLAN service in the Service panel.

8

Save your changes and close the forms.

END OF STEPS

80.5 To configure an SPB network interface

80.5.1 Steps

1

On the equipment tree, right-click on a Backbone VLAN site and choose Properties. The Network Element (Edit) form opens.

2

Click on the Network Interfaces tab.

3

Click Create. The Network Interface (Create) form opens.

4

Select a port in the Interface panel.

5

Close the form.

6

Click on the General tab and set the Administrative State parameter to Up.

7

Save your changes and close the form.

END OF STEPS

80.6 To configure an OmniSwitch Ethernet service L2 profile

80.6.1 Steps

1

Choose Policies→Ethernet→AOS Ethernet Service from the NFM-P main menu. The Manage Ethernet Service Policies form opens.

2

Click Create and choose Create L2 Profile. The Layer-2 Profile, Global Policy (Create) form opens.

3

Configure the required parameters.

4

Click OK. The form closes.

5

To create more L2 profiles repeat Step 2 to Step 4 .

6

Close the form.

End of steps

80.7 To configure an SPB access interface

80.7.1 Steps

1

Perform one of the following:

a. To configure an OmniSwitch LAG as an SPB access interface, continue to Step 2 .

b. To configure an OmniSwitch port as an SPB access interface, go to Step 6 .

2

Create an OmniSwitch LAG as described in 13.19 “To configure an OmniSwitch LAG” (p. 440) .

3

On the equipment tree, expand Device→LAG.

4

Right-click on the LAG object and choose Properties. The LAG (Edit) form opens.

5

Go to Step 9 .

6

On the equipment tree, right-click on an OmniSwitch object and choose Properties. The Network Element (Edit) form opens.

7

On the equipment tree, expand Shelf→Port.

8

Click on the required port. The Physical Port (Edit) form opens.

9

Set the Mode parameter to Access and click Apply to confirm.

10

Set the SPB Service Mode parameter to Enabled.

11

Configure the Description and Vlan Xlation Mode parameters in the Service Access Info panel.

12

Click Apply to confirm.

13

Click on the Policies tab and select a UNI profile in the UNI Profile panel.

Note: If no UNI profiles exist, perform 61.2 “To configure an OmniSwitch Ethernet service UNI profile” (p. 1815) to create one.

14

Select an L2 profile in the L2 Profile panel.

Note: If no L2 profiles exist, perform 80.6 “To configure an OmniSwitch Ethernet service L2 profile” (p. 2697) to create one.

15

Close the form.

End of steps

80.8 To create an SPB service

80.8.1 Steps

1

Choose Create→Service→SPB from the NFM-P main menu. The SPB Service (Create) form opens.

2

Select a customer to associate with the SPB.

3

Configure the required parameters.

The Service ID parameter is configurable when the Auto-Assign ID parameter is disabled.

The SVC Mgr Service ID parameter is configurable when the Auto-Assign ID parameter is disabled.

4

Select a Backbone VLAN service to associate with the SPB in the SPB panel.

5

Configure the ISID parameter.

6

On the equipment tree, right-click on Sites and choose Create SPB Site. The Select Network Elements - SPB Service form opens.

7

Choose one or more sites and click OK. The form closes.

8

Save your changes and close the form.

END OF STEPS

80.9 To associate an access interface with an SPB service

80.9.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose the SPB service to be associated with an interface and click Properties. The SPB - *Service Name* (Edit) form opens.

3

On the equipment tree, click on the site to which you want to associate the new access interface; expand the entries for that site.

4

Right-click on L2 Access Interfaces and choose Create SPB L2 Access Interface. The SPB L2 Access Interface (Create) form opens.

5

Configure the required parameters.

6

Click on the Port tab and select an SPB L2 access interface.

Note: The form lists only ports and LAGs that have been configured as an SPB access interface. See 80.7 “To configure an SPB access interface” (p. 2698) for more information.

7

Configure the required parameters.

8

Save your changes and close the forms.

END OF STEPS

81 PW routing and dynamic MS-PW service management

PW routing and dynamic MS-PW service management

81.1 Overview

81.1.1 General information

Service providers require a solution for interconnecting customer sites that span different domains, such as MAN-WAN or Inter-AS (in the same Service Provider or Inter-Provider). The NFM-P supports two methods for interconnecting customers sites:

- PW routing
- MS-PW routing

81.1.2 PW routing

The NFM-P supports inter-domain services for VLL through the use of VLL spoke switching, which allows creation of a VLL service by cross-connecting two spoke SDPs. However, this requires statically configuring the PW switching points at the gateway S-PEs between domains. See 76.2.2 “VLL spoke switching” (p. 2104) in Chapter 76, “VLL service management” for more information.

Static PW routing is supported on the 7210 SAS, 7450 ESS, 7750 SR, and 7950 XRS. Support for 7210 SAS NEs varies depending on the chassis type and release; see the NE documentation for information.

81.1.3 MS-PW routing

Multi-segment pseudowire routing provides solutions for inter-domain services by using dynamic MS-PW routing and signaling, in which the switching points are automatically instantiated in the Switching-Provider Edge (S-PE) NEs. The path of the MS-PW is dynamically signaled end-to-end by T-LDP, using PW routing information stored in the S-PEs by MP-BGP. Per-PW configuration is only required at the endpoints of the MS-PW in the Termination-Provider Edge (T-PE) NEs.

Dynamic MS-PWs are characterized by the following:

- They are supported for VLL Epipe services
- Dynamic and static routes, as well as explicit paths for MS-PWs are supported
- Dynamic MS-PWs may be established across LDP or RFC 3107 labeled BGP SDPs
- Dynamic MS-PWs may be used as a part of a set of PWs for PW redundancy, including MC-LAG. Diverse routes for the active and standby MS-PWs can be configured by using explicit paths, or dynamically by using a BGP route distinguisher.

- Diverse routes for the active and standby MS-PWs can be achieved by using explicit paths or dynamically using a BGP route distinguisher.

Dynamic MS-PWs are supported on the following NEs:

- 7210 SAS
- 7450 ESS and 7750 SR chassis types that support Epipe service creation
- 7950 XRS

Support for 7210 SAS NEs varies depending on the chassis type and release; see the NE documentation for information.

81.1.4 Dynamic MS-PW services

Spoke SDP FEC configuration will bind a service to an existing Service Distribution Point (SDP), using a dynamic MS-PW. When using dynamic MS-PWs, the particular SDP to bind to is automatically selected based on the Target Attachment Individual Identifier (TAII) and the path to use, specified under the Spoke SDP FEC. The selected SDP will terminate on the first hop S-PE of the MS-PW. Therefore, an SDP should be defined that can reach the first hop of the MS-PW. The NE creates a spoke SDP binding to associate an SDP with a service. If the required SDP does not exist, the NE creates one based on the parameters specified in the spoke SDP FEC, for example, the SAII/TAII, Path, or PW template. The Creation Mode attribute for such an SDP indicates Multi-Segment PW.

This differs from the regular spoke SDP binding creation in that it creates a spoke SDP binding using a PW with the FEC128. However, the Spoke SDP FEC enables PWs with other FEC types to be used.

Spoke SDP FEC configuration is currently only applicable to an Epipe site. It can be configured under the Epipe service or at a service endpoint of an Epipe site, with or without ICB. The creation under an Epipe service is demonstrated in 81.4 “To configure a dynamic MS-PW service using PW routing” (p. 2710) .

81.2 Workflow to configure PW routing and dynamic MS-PW services

81.2.1 Purpose

The following workflow lists the high-level steps required to configure PW routing and dynamic MS-PW services. Enabling MS-PW support requires configuration in the following areas:

- network commissioning
- SR NE pre-provisioning
- dynamic MS-PW service
- optional PW routing and MS-Service tasks

81.2.2 Stages

Network commissioning

1

To use PW routing to establish dynamic pseudo-wires from source to destination, without using static routes and a specified path:

a. Enable BGP on the routing instance of the required node. See 28.29 “To enable BGP on a routing instance” (p. 916) for more information.

b. Configure the BGP Family parameter to include the options MS-PW and IPv4. This must be done on the BGP site, associated BGP groups, and BGP peers.

See the following procedures:

- BGP Site configuration: See 28.31 “To configure global-level BGP” (p. 918)
- BGP Peer Group configuration: See 28.32 “To configure peer-group-level BGP” (p. 922)
- BGP Peers configuration: See 28.33 “To configure peer-level BGP” (p. 927)

2

If more than one equal cost route is required for the PW routing, configure the following:

a. In the routing instance for the required NE, set the Maximum Number of Equal Cost Routes parameter to a value greater than 1. See 27.2 “To configure a routing instance or a VRF instance” (p. 826) .

b. For the required BGP Site, set the Multi Path parameter to a value greater than 1. See 28.31 “To configure global-level BGP” (p. 918) .

3

Configure a routing policy statement with the Family parameter having the MS-PW option enabled. This will then be exported under the BGP site. See 54.5 “To configure a routing policy statement” (p. 1745) .

4

If path diversity is required for primary/standby MS-PWs, perform the following:

a. Configure a routing policy statement having multiple statement entries, each associated with a different community, from a different neighbour, with family including MS-PW and a local preference. The communities configured here are used further on in the procedure when configuring a MS-PW local prefix. See 54.5 “To configure a routing policy statement” (p. 1745) for more information.

b. Import the above policy under the BGP site. See 28.31 “To configure global-level BGP” (p. 918) .

5

If there are ASBRs, set Next Hop Self to True under each peer group. For example, set one for the inner-AS and one for the external-AS. Without this setting, the SDPs created by MS-PW routing only reach to the BGP interface's IP address, but not the system ID. See 28.32 “To configure peer-group-level BGP” (p. 922) . Refer also to Chapter 79, “VPRN service management” for information on ASBRs.

6

If all T-PEs and S-PEs are within the same AS, then the S-PEs must be configured as route reflectors (RR). Perform the following:

a. Set the Cluster ID parameter on the BGP site or BGP peer group that includes the T-PEs as BGP peers on the S-PE. See Step 3 in 28.31 “To configure global-level BGP” (p. 918) . Two T-PEs can not be configured as BGP peers to each other. They must be configured as BGP peers of the RR.

b. Configure a routing policy statement with Advertise Next Hop Self set to true and Action set to Accept, and then export this policy under the BGP site. See 54.5 “To configure a routing policy statement” (p. 1745) .

This completes the summary of essential network commissioning requirements.

SR NE pre-provisioning

7

Configure PW routing. See 81.3 “To configure PW routing on an NE” (p. 2708).

Configure a dynamic MS-PW service

8

Configure a dynamic MS-PW service using PW routing. See 81.4 “To configure a dynamic MS-PW service using PW routing” (p. 2710) .

Optional PW routing and MS-Service tasks

9

As required, perform one or more of the following:

a. On-demand resync of the MS-PW routing table for a specified NE is supported and can be accessed from a number of places in the NFM-P. See 81.5 “To display MS-PW routing tables” (p. 2712) for information on displaying MS-PW routing tables.

b. Conduct various spoke SDP FEC operations from the endpoint of an Epipe site. See 81.6 “To perform spoke SDP FEC operations from an Epipe site endpoint” (p. 2712) .

c. Discover and manage MS-PW switching sites. See 81.7 “To discover and manage MS-PW switching sites” (p. 2713) .

d. Run an OAM VCCV Ping or Trace validation test for the MS-PW service. See 81.8 “To

conduct MS-PW routing OAM tests” (p. 2713) .

PW routing and dynamic MS-PW service management procedures

81.3 To configure PW routing on an NE

81.3.1 Steps

1

Right-click on an NE in the navigation tree and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, then on the Service tab.

3

Click on the PW Routing tab.

4

Configure the general parameters.

The SPE Address must be unique in the network. This parameter must be configured on all T-PEs and S-PEs that are involved in this PW routing.

The Number of BGP Routes, Number of Static Routes, Number of Local Routes, and Number of Host Routes attributes are for information only and can be resync-ed from the NE.

5

To create one or more local prefixes:

1. Click on the Local Prefixes tab.
2. Click Create. The PW Routing NE Local Prefix (Create) form opens.
3. Configure the Local Prefix parameter.

   You must configure this parameter to enable the MS-PW routing configuration on a T-PE node. This Local Prefix is also used in other portions of the MS-PW configuration, such as setting static routes on the remote T-PE or intermediate S-PEs, and setting Source Attachment Individual Identifier (SAII) and Target Attachment Individual Identifier (TAII) addresses on a spoke SDP FEC on the T-PE.
4. Click Create in the BGP RD panel. The PW Routing NE BGP RD (Create) form opens.

   A route distinguisher must be configured to enable this local prefix to be advertised by MP-BGP to the network.
5. Configure the Route Distinguisher parameter.
6. Configure the BGP Community parameter.

The BGP Community can only be selected from the list. Members were created as part of the routing policy configuration in 54.5 “To configure a routing policy statement” (p. 1745) and importing the routing policy under the BGP site in 28.31 “To configure global-level BGP” (p. 918) .

7. Save the changes and close the forms.

   You can create up to four route distinguishers per local prefix. You can create up to 16 local prefixes per NE. The local prefixes you create must be unique in the network.

   At this point the NE can start to advertise the defined local prefix to its BGP peers.

6

To configure one or more static routes:

1. Click on the Static Routes tab.
2. Click Create. The PW Routing NE Static Route Configuration (Create) form opens.

   A static route can be configured on both the T-PE and S-PE, based on your requirements.
3. Configure the Target T-PE’s PW Address parameter to specify the local prefix defined in the remote T-PE. It can be selected from a managed T-PE or S-PE, or directly entered.
4. Configure the Next Hop parameter to specify the system IP address of the next-hop S-PE or T-PE. It can be selected from a managed T-PE or directly entered.
5. Save the changes and close the form.

   At this point the NE can start to advertise the defined static route to its BGP peers.

7

To configure an explicit path:

1. Click on the Configured Paths tab. All configured paths are listed.

   The path should be configured on the T-PEs, which is then used in the spoke SDP FEC to establish a pseudo-wire through the specified path.
2. Click Create. The PW Routing NE Path Configuration (Create) form opens.
3. Specify a Path Name.
4. Click Create in the Hops panel. The PW Routing Hop (Create) form opens.
5. Configure the Hop ID parameter.
6. Configure the Hop Address parameter.

   This specifies the system IP address of the next-hop S-PE or T-PE (where the T-LDP session to a given S-PE terminates). It can be entered directly or chosen from the managed S-PE or T-PE by clicking the Select button.
7. Save the changes and close the forms.

8

Save the changes and close the forms.

END OF STEPS

81.4 To configure a dynamic MS-PW service using PW routing

81.4.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Configure the filter criteria for Service→VLL (VLL)→Epipe Service→(Epipe). A list of services appears at the bottom of the Manage Services form.

3

Choose the required VLL Epipe service that contains the T-PE site and click Properties. The Epipe Service (Edit) form opens.

4

Click on the Spoke SDP FECs tab.

5

Click Create. The Spoke SDP FEC (Create) form opens.

Only one spoke can be configured on the terminating site, including both regular spoke SDP bindings and spoke SDP FECs.

6

Configure the required parameters.

The Auto Config parameter enables automatic endpoint configuration. This allows the configuration of a spoke SDP endpoint without specifying the TAII associated with that spoke SDP. In this mode, the far end T-PE actively initiates MS-PW signaling and will send the initial label mapping message using T-LDP, while the T-PE for which Auto Config is specified will act as the passive T-PE. The Auto Config parameter cannot be enabled if the Signaling Type is set to Master or if the TAII Address is specified.

If you are going to use SAII and TAII addresses instead of Auto Config, then you must decide which method will be used for the PW routing.

- For dynamic PW routing, the local prefix associated with the SAII/TAII address should be configured with a route distinguisher, with an optional community (see 81.3 “To configure PW routing on an NE” (p. 2708)). The SAII and TAII addresses must be unique in the network.
- For static routing, the local prefix should be associated with static routes configured under PW routing (see Step 5 and Step 6 in 81.3 “To configure PW routing on an NE” (p. 2708)). A spoke SDP FEC cannot be turned up if no local prefix is configured under PW routing.
- When using a specified path, the Path parameter must be configured. The associated Select button allows you to select a path that will be used for this spoke SDP and which is

configured under PW Routing. If no path is configured, then each next hop of the MS-PW used by the spoke SDP will be chosen locally at each S-PE and T-PE, using dynamic PW routing.

7

If redundancy is required, select an Endpoint.

8

Configure the required parameters.

9

To configure a return spoke SDP FEC:

1. Click on the Return Spoke SDP FEC tab.

   This tab is displayed only when the TAII Address configured in Step 6 was set by selection for the current spoke SDP FEC.

2. Configure the PW ID parameter for the return spoke SDP FEC and click Apply.

   When a valid PW ID for the return spoke SDP FEC is entered, additional parameters are displayed. If the PW ID is not valid, then the return spoke SDP FEC is not created.

3. Configure the required parameters.

4. Select an Endpoint.

   When the return spoke SDP FEC is created, it will have corresponding attributes such as the SAII and TAII Address values and AC ID cross-matching with the current spoke SDP FEC.

10

Save the changes and close the forms.

When a spoke SDP FEC is successfully created, it will be listed under the Spoke SDP FECs tab for this Epipe site.

The Spoke SDP Associated tab lists the spoke SDP bindings created by using this Spoke SDP FEC for MS-PW routing. All such spoke SDP bindings have their Creation Mode attribute set as Multi-Segment PW. The related SDP FEC Auto-bind tab shows the associated SAII or TAII defined in the Spoke SDP FEC.

The Faults tab displays any mis-configuration alarms associated with this spoke SDP FEC.

When the configuration for both T-PEs is complete, the NEs can start negotiating and establishing the spoke SDP bindings from T-PE to S-PE and from S-PE to T-PE.

END OF STEPS

81.5 To display MS-PW routing tables

81.5.1 Steps

1

Right-click on an applicable NE from one of the following locations and choose Show MS-PW Routes→BGP|Service:

- Navigation tree
- Physical Topology map
- Service Tunnel map

The Service Routing rtr BGP or Service Routing rtr Service form opens. The requested routing table information is presented, along with a detailed status/error report.

2

Close the Service Routing rtr report form.

END OF STEPS

81.6 To perform spoke SDP FEC operations from an Epipe site endpoint

81.6.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose the required VLL Epipe service that contains the primary and backup spoke SDP FECs and click Properties. The Epipe Service (Edit) form opens.

3

In the service navigation tree, expand Site→Spoke SDP FECs, right-click on the required spoke SDP FEC and choose:

- Force Switchover
- Clear Forced Switchover
- Turn Up
- Shut Down
- Delete
- Resync
- Properties

The Forced Switchover and Clear Forced Switchover options are only applicable where the Epipe site has been configured for redundancy, as detailed in 81.4 “To configure a dynamic

MS-PW service using PW routing” (p. 2710) . The switchover applies to the primary and backup spoke SDP FECs configured on the Epipe site.

4

Close the forms.

END OF STEPS

81.7 To discover and manage MS-PW switching sites

81.7.1 Purpose

With PW routing configured on T-PEs and S-PEs, and spoke SDP FECs configured on the T-PEs, the NE will establish the pseudo-wires between T-PEs. This includes creating switching sites between two T-PEs. A switching site for MS-PW is a read-only site (nothing can be modified) and it cannot be deleted. It is controlled by the NE.

Use the following method to discover such sites.

Note: The switching sites and spoke SDP bindings created by MS-PW routing are tagged with their Creation Mode attribute indicating Multi-Segment PW (as opposed to Manual for non-MS-PW entities).

When a switching site is discovered, the associated spoke SDP bindings under it are also discovered and re-synced. The NFM-P will create a composite service and connector(s) if there are matching spoke SDP bindings found in other Epipe services (based on cross-matching of the spoke SDP ingress/egress labels). The related service is added to the newly-created composite service.

81.7.2 Steps

1

Conduct an RCA Audit to discover switching sites. This is done within the Epipe service that contains the T-PEs having MS-PW configured. The audit will find all MS-PW switching sites associated with T-PEs in this service and provide management solutions.

See 95.7 “To configure an RCA audit policy” (p. 3238) for details on configuring an RCA audit.

2

Perform 95.8 “To perform an RCA audit of a service or multiple services” (p. 3240) .

END OF STEPS

81.8 To conduct MS-PW routing OAM tests

81.8.1 Purpose

Perform this procedure to test the MS-PW routing configuration using OAM VCCV Ping and Trace tests.

81.8.2 Steps

1

To conduct a VCCV Ping test, see 90.8 “To create and run a VCCV ping OAM diagnostic test from the STM” (p. 3008) .

The test can be created either from the Service Test Manager or from a configured Epipe service, Epipe site, or a Spoke SDP FEC.

If you choose a spoke SDP binding created by MS-PW routing, the VCCV ping is specifically for MS-PW, and the SAII and TAII parameters will be auto-filled. This allows you to conduct a MS-PW VCCV Ping on an S-PE.

If the test is created from a configured Spoke SDP FEC, the test object will be auto-filled with the configured spoke SDP FEC.

Alternatively, if the test is created from the Service Test Manager, an Epipe service, or an Epipe site (both the termination site and the switching site), then you must select a spoke SDP FEC (only for T-PE) or a spoke SDP binding of type FEC 129 created by the MS-PW routing.

2

To conduct a VCCV Trace test, see 90.9 “To create and run VCCV trace OAM diagnostic test from the STM” (p. 3009) or 90.10 “To create and run a VCCV trace OAM diagnostic from a static PW to a dynamic PW segment from the STM” (p. 3010) .

The test can be created either from the Service Test Manager or from a configured Epipe service, Epipe site, or a Spoke SDP FEC.

If the test is created from a configured Spoke SDP FEC, the test object will be auto-filled with the configured spoke SDP FEC.

Alternatively, if the test is created from the Service Test Manager, an Epipe service, or an Epipe site (both the termination site and the switching site), then you must select a spoke SDP FEC (only for T-PE) or a spoke SDP binding of type FEC 129 created by the MS-PW routing.

Note: When configuring either a VCCV Ping or VCCV Trace test for dynamic MS-PW from an S-PE, the Reply Type must be set to IP.
If the selected spoke SDP binding is created by MS-PW routing, you can only conduct a VCCV ping for MS-PW FEC129, not for FEC128.
If a PW template is used in the Spoke SDP FEC configuration, it must have its Enable Control Word parameter enabled, since both VCCV Ping and Trace require Control Word support.

3

To create a Test Suite, see 89.12 “To create an STM test suite” (p. 2951) .

A Test suite can be generated based on the selected policy for a specified VLL Epipe service.

If the selected policy has its Entity Type set to VLL Service, then the VCCV Ping and VCCV Trace tests that are generated will adhere to the following:

- No tests are generated for spoke SDP bindings created by MS-PW routing.

- Both VCCV Ping and VCCV Trace tests for MS-PW will be generated if there are spoke SDP FECs in the specified Epipe service.

If the selected policy has its Entity Type set to Service Connector, then there is also no test generated for the spoke SDP bindings created by MS-PW.

END OF STEPS

82 Network Group Encryption

82.1 Network Group Encryption overview

82.1.1

Network Group Encryption (NGE) is a mechanism for the end-to-end encryption of MPLS- or GRE-based traffic at the service level that does not require meshes of IPsec tunnels at the network layer. NGE is supported on 7705 SAR, 7705 SAR-Hm, VSR, and 7750 SR devices. With 7750 SR devices, only WLAN GW interface encryption is supported.

See the device documentation for information about the chassis variants that support NGE, and for detailed information about NGE operation on an NE.

NGE provides the following main levels of encryption to secure an IP/MPLS network:

- SDP encryption: GRE or MPLS
- VPRN encryption — MP-BGP-based VPRN-level encryption
- WLAN gateway interface encryption
- Router interface and Ethernet port encryption— Layer 3 and Layer 2 user plane and control plane encryption

  L2 encryption is supported for 7705 SAR NEs only
- PW template encryption for L2 service PW templates:
  - the template must be using auto-GRE
  - the template cannot be in use by more than 100 services
  - all sites in use by the template must support NGE

L3 routing interface encryption and L2 Ethernet port encryption are supported in an NGE domain; see 82.4 “NGE domains” (p. 2721).

NFM-P NGE management minimizes network downtime in the event of a catastrophic failure such as a natural disaster, and maintains network security functions and critical network traffic transmission during events such as unexpected NE reboots and link disruptions.

The NFM-P generates the keys for the participating NGE NEs. An NFM-P operator assigns encryption and authentication keys to a key group. The operator then associates NGE supported objects for inbound and outbound traffic with the key group, as required, and the NFM-P distributes the key group to each NE that hosts an associated NGE supported object. The keys in a key group are randomly generated by the NFM-P using the FIPS 140-2 standard.

NGE version support

The current NSP release only supports NGE version 2. To use NGE, all 7705 SAR NEs must be running Release 8.0 R4 or later, and all VSR and 7705 SAR-Hm NEs must be running Release 15.0 R4 or later.

82.1.2 NFM-P management of NGE

The NFM-P has a comprehensive suite of NGE functions that include the following:

- network-wide encryption configuration and management
- selective key distribution only to service sites associated with a key group
- automatic NGE configuration of sites added to an encrypted service
- key synchronization among participating NEs
- coordinated key updates without service degradation
- fault tolerance using NFM-P and NE redundancy functions
- alarm management
- statistics collection

The NFM-P uses SNMP to deploy general NGE attributes to NEs, and SSH2 sessions to configure the key values. You can use an existing SSH2 user account on each NE, or, to facilitate the tracking of key value configuration activity, you can use the UserNGE account. The NFM-P creates the account on each participating NGE NE and uses the account only for creating and updating key values. The NFM-P user activity log records all NGE configuration activity.

In a key group, an NFM-P operator specifies the service objects that are to be encrypted using the key group, then initiates the encryption. The NFM-P then deploys the key group to each NE associated with the service objects; for example, the two NEs associated with an SDP, or the sites in an MP-BGP VPRN service.

The NFM-P subsequently configures the key group for outbound traffic, then the key group for inbound traffic, on each NE. The NGE key group associations are displayed on the properties form of each associated service object.

The NFM-P ensures that the keys on all NEs in a key group are synchronized.

If a service object associated with a key group is deleted by the NFM-P or through a CLI, the NFM-P removes the object association from the key group.

A connectivity loss between the NFM-P and participating NEs does not affect the existing encrypted services.

82.1.3 Prerequisites for NGE management

To use NGE, all nodes must be configured to provide reachability to the NFM-P.

All NGE nodes must be managed by the same NFM-P.

Some potential scenarios to allow for a node to be reachable include:

- Out of band management – The node uses an out of band network to allow for NFM-P traffic. When the node comes back up, the NFM-P is reached using the out-band network and downloads the key group keys using this network.
- In-band using GRT (RI encryption disabled) – The node can establish routing and control plane functions when it comes back online. Based on established routing, the NFM-P re-discovers the node, and sends SNMP and SSH messages to the node to update the required key groups.
- In-band using GRT (RI encryption enabled) – IP exception ACLs are preconfigured in the

network to allow SNMP traffic through RI encryption enabled interfaces. Note that when the node that was off-line comes back up, it will not be able to send or receive any control plane packets as the RI interface NGE keys are old. The node will need static routes for the SNMP/SSH traffic to and from the NFM-P to allow these packets to be routed. If the network is over a L2/L3 service provider, then the IP exception ACLs are required on the off-line node itself and the gateway node. If the node is part of a private IP/MPLS network the IP exception ACLs are required on the expected bordering nodes to the node that goes off-line.

The default ACLs allow reachability to the NFM-P to then update key groups with new keys to bring up RI encryption and other services that were using old keys. The default ACLs do not need to be used for normal NFM-P management traffic after the NFM-P updates key groups.

- In-band using management VPRN service (preferred for 7705 SAR-Hm scenarios) – A default manually configured GRE-SDP with reachability to a gateway node and a default in-band management VPRN are configured, using the default GRE-SDP to reach the NFM-P. This VPRN could also be NGE encrypted using a key group that remains static (does not get rekeyed) for double encrypting the NFM-P traffic. When the node comes back on-line, this default VPRN service is available for the NFM-P to reach the node and update key groups.

82.2 Migration of CLI managed NGE to NFM-P managed NGE

82.2.1 Migration overview

If you have been using CLI for NGE management before setting up the NFM-P, you can migrate the NGE to the NFM-P after the NFM-P is installed and operational.

When the NFM-P is performing NGE migration from CLI to NFM-P managed NGE, the NFM-P tracks the key groups and encryption keys from the CLI NGE configurations and auto downloads key groups and encryption keys as necessary for all the services requiring encryption. In the end, the cleanup scheduled task removes un-used key groups and keys from CLI.

After the migration, do not make any NGE changes via CLI, including for troubleshooting purposes. If this occurs, the NFM-P generates a mismatch alarm and, if there is service impact, the NFM-P reverts the changes from CLI.

82.2.2 Migration scenarios

Migration from CLI NGE to NFM-P NGE is available in several scenarios. The process the user must perform in the NFM-P after node discovery differs slightly depending on the scenario.

See 82.11 “Workflow for migration of NGE management from CLI to NFM-P” (p. 2728) for details and prerequisites.

The following table shows the available scenarios and how the process differs in each.

Scenario	Configuration process in NFM-P after the node is discovered
Key group is the same on CLI and NFM-P VPRN and PW Template are configured on CLI but not in the NFM-P	Add the VPRN and the PW Template in the NFM-P, and encrypt
Key group and services are configured in CLI but not in the NFM-P	Create the key group, add the services, and encrypt

Scenario	Configuration process in NFM-P after the node is discovered
Key group and services are configured the same in both CLI and NFM-P	No further action is needed: the node will be discovered directly into the key group and services.
Key group and services are configured in CLI and NFM-P CLI key group is different from the key group in NFM-P, for example, the CLI key group is number 77 and the NFM-P key group is 60.	No further action is needed: the NFM-P will create key group 60 on the CLI and move the services to key group 60 on the NFM-P. If the migration leaves key group 77 unused on the CLI, the NGE cleanup task will remove it.

82.2.3 NSP alarms

If there is a difference between CLI and NFM-P NGE configuration, alarms will be generated as follows:

- The NSP raises a ConfigurationUnknown alarm if configuration is present on the CLI that is not present on the NFM-P

  ConfigurationUnknown alarms for global encryption label, key group, VPRN, and PW templates will be suppressed for first time node discovery. However, these alarms will be raised when there is subsequent addition of the key group or service association from CLI after the node has been discovered. Or if node resync is done after the node is already discovered by NFM-P and before the migration from CLI to NGE is completed.

  ConfigurationUnknown alarms for SDP, WLAN GW, L2 and L3 interfaces configured via CLI will still be present upon node discovery.
- The NSP raises a ConfigurationMismatch alarm if the NGE configuration on an NE is modified using CLI.

During migration from CLI, the alarms are suppressed.

82.3 Configuration

82.3.1 Configuration overview

You can configure NGE using an NFM-P GUI or OSS client.

82.3.2 Global encryption label

NFM-P NGE management requires a global encryption label that is used as a common NGE identifier by all participating NEs in the managed network. A global encryption label must be configured before any services are encrypted. A global encryption label is intended to be set once, for permanent use, and cannot be modified. The global encryption label can be deleted only if no key groups exist in the NFM-P and no local key groups exist on NEs.

If the deployment of a global encryption label fails, the NFM-P and NE labels do not match, or a global encryption label is detected during device discovery, an alarm is raised.

Note: An attempt to create a static MPLS ingress label is blocked if the label has the same value as the NGE group encryption label.

An attempt to create the group encryption label is blocked if the label has the same value as a static MPLS ingress label in the network.

If the NFM-P discovers an NE that supports NGE, and the NE has a static MPLS ingress label that matches the group encryption label, an alarm is raised.

82.3.3 Key groups

NGE deployment to one or more NEs requires a key group that contains the NGE keys. A key group defines the algorithms that the NFM-P uses to generate the encryption and authorization keys. A key group also contains a list of the current Security Associations (SAs) between the key group and the service objects that use the key group.

After you create a key group, you cannot modify the encryption and authentication algorithms; if such changes are required, you must create a new key group and delete the previous key group.

After the initial key group deployment, you can use a scheduled task for the regular and automatic replacement of the keys in the key group; see 82.8 “Key updates” (p. 2724) .

Keys are always encrypted when stored in the database; transfer of keys to the network elements is over a secure and encrypted connection.

Note: You cannot delete a key group if any SDPs, service objects, NGE domains, L3 router interfaces, or L2 Ethernet ports are associated with the key group.

82.3.4 NGE cleanup scheduled task

The NGE cleanup task is auto-created during NFM-P system initialization. The NGE cleanup task removes unused SPIs and key groups from the NE.

Key groups that are only present on CLI, but not on NFM-P, will be removed by the NGE cleanup schedule if there is no service association in the CLI.

When encryption is disabled on the last service using the key group of a site, the cleanup task will remove the key group from the site.

The NGE cleanup task runs every night at midnight by default. The task must not be deleted, however, it can be executed manually at any time.

Choose Manage→Network Group Encryption from the NFM-P main menu and choose Cleanup Scheduled Task from the drop-down menu to open the NGE Cleanup Scheduled Task.

82.4 NGE domains

82.4.1 NGE domain overview

An NGE domain is a group of L3 router interfaces, L2 Ethernet ports, or both, enabled for NGE. The domain is configured on a key group.

An NGE domain has the following components:

- general: the key group used by the NGE domain
- the list of gateway sites and gateway interfaces
  A gateway interface is required in order to add an unmanaged NE to a domain; see “NGE discovery” (p. 2722).
- the list of sites in the domain

A domain site is an NE that contains interfaces or ports that are participating in the domain. An NE can have interfaces or ports in more than one domain.

- the list of L3 router interfaces in the domain
- the list of L2 Ethernet ports in the domain
- the NGE encryption type (L3, L2, or both)

When NGE is configured, an interface can receive unencrypted packets or NGE encrypted packets from any configured key group on the NE, but no other type of IPsec formatted packet is allowed. If an IPsec packet is received on an NGE-enabled interface, it will not pass NGE authentication and will be dropped. Therefore, IPsec packets are prohibited from existing within the NGE domain without first being converted to an NGE packet. This delineates the boundary of the NGE domain and other IPsec services.

The maximum number of domains per network is 64. The domains can be in the same key group or distributed across multiple key groups.

82.4.2 NGE domain sites

When two or more sites are added to the domain, the NFM-P performs an auto-population: L3 router interfaces are added if their addresses are in the same subnet as interfaces already in the domain, and L2 Ethernet ports are added based on the router interfaces. If the L2 Ethernet port associated to the L3 router interface has a LAG, all member ports will be added to the domain.

Cellular interfaces on 7705 SAR-Hm NEs are populated when the site is added to the domain, regardless of subnet.

Ports and interfaces can also be added, encrypted, and deleted manually.

A port or interface cannot be added to more than one domain.

The following domain site encryption statuses are supported:

- partial: encryption enabled on some of the interfaces or ports of the same site
- Layer 3 encrypted: encryption enabled on all interfaces of the same site, but not on L2 ports
- Layer 2 and Layer 3 encrypted: encryption enabled on all interfaces and ports of the same site

NGE discovery

The NFM-P can add undiscovered NEs directly into an NGE domain. ACL IP exception filter policies are created automatically by the NFM-P and applied to a gateway interface to allow for NE discovery. A device discovery rule must be available; see 9.10 “Workflow for device discovery” (p. 288).

The NGE discovery process creates inbound and outbound ACL IP exception filters on the gateway NE. If the NSP server is restarted or switched to a secondary server during the NGE discovery process, the exception filters will become invalid and NGE discovery will fail. The NGE discovery process must be initiated again after the switchover or restart is completed. The NGE discovery process will be recovered from the failure state and the process will continue.

It is possible to delete a gateway interface during the NGE discovery process. The NGE discovery will continue but the ACL IP exception filter entries will not be removed automatically by the NFM-P after encryption has been enabled. You must manually delete the exception filter entries to resume

traffic between the NFM-P and the encrypted NEs. The exception filter to be deleted will have the IP address of the site most recently managed using NGE discovery as its Destination IP or Source IP. See 51.7 “To configure an ACL IP exception filter policy” (p. 1683).

82.4.3 L3 router interface encryption

Encryption for L3 interfaces in the NGE domain are configured with an inbound and an outbound key group: outbound packets are encrypted using the interface key group; inbound packets must be encrypted using the interface key group keys.

A security zone and NGE cannot be applied to the same interface.

L3 encryption exemption

It may be necessary for L3 packets to enter the NGE domain in clear text. To allow this, the NFM-P applies an ACL IP exception filter. See 51.1 “Filter policies” (p. 1663) for more information about filter policies.

82.4.4 L2 Ethernet port encryption

L2 encryption is configured on the Ethernet port. When L2 encryption is configured, all configured IS-IS and LLDP packets are encrypted using NGE.

L2 NGE encryption is enabled by configuring an outbound and inbound key group on the Ethernet port, similar to assigning key groups for router interface encryption, as described in 82.4.3 “L3 router interface encryption ” (p. 2723).

L2 Ethernet port encryption is not supported for VSR or 7705 SAR-Hm NEs.

82.5 PW template encryption

82.5.1 PW template encryption overview

PW templates allow you to automatically create SDP bindings. If the PW template is configured to use GRE delivery, there is no SDP configuration required, therefore no option to configure NGE on the services that make use of the SDP.

With PW template encryption, you can configure encryption on the PW template, providing encryption for the L2 services that will use the SDP. With PW template encryption, the NFM-P adds the NGE inbound and outbound encryption key-groups to a PW template.

This type of encryption can be useful for 7705 SAR-Hm networks that use the auto-bind function of the PW template for GRE-MPLS transport over the cellular interface.

82.6 Encryption for offline nodes

82.6.1 Encryption for offline nodes overview

A node is in offline mode if the NFM-P has lost connectivity to the node at the time of specific NGE action (rekey, encrypt, or disable encryption). A node is not in offline node if it responds to SSH and SNMP requests. Nodes in offline mode are skipped when enabling or disabling encryption.

The Administrative Status parameter of an SDP, service, or interface reflects the last encryption action on the node, and the Deployment Status parameter shows the current status of encryption.

For example, if encryption is enabled when the node is offline, the Administrative Status parameter will be updated to Encryption Enabled; however, since the encryption operation skipped the node, the Deployment Status remains Not Deployed. If encryption is disabled when the node is offline, the Administrative Status is updated to Encryption Disabled, but the Deployment Status remains Encrypting.

When the node is back online, the NFM-P will automatically apply the action based on the Administrative Status.

82.7 WLAN GW encryption

82.7.1 WLAN GW encryption overview

WLAN GW encryption allows the WLAN GW to terminate and originate WLAN AP traffic to and from a 7705 SAR-Hm or 7750 SR NE that is NGE encrypted. This provides a simple encryption approach using a single NGE key group on the WLAN GW interface to provide security to many WLAN APs.

The WLAN GW group interface is configured with the same key group for inbound and outbound.

When a WLAN group interface is added to or removed from a key group, all associated GRE-SDPs will be added or removed from the SDP tab of the WLAN GW automatically. When a new GRE-SDP with a far-end address the same as the WLAN GW address is added to the network, this GRE-SDP will be added to the SDP list under the WLAN GW in the key group automatically, with the same encryption status as the WLAN GW.

82.8 Key updates

82.8.1 Key updates overview

For increased security, Nokia recommends frequent replacement of the keys in a key group, which is called a rekeying operation. For each key group, you can configure a rekeying scheduled task that defines how often the NFM-P generates and deploys a new key set to each NE associated with the key group. The rekeying mechanism ensures that there is no service degradation during rekeying.

The rekeying scheduled task associated with the key group must be deleted before the key group can be deleted.

A rekeying scheduled task cannot use a schedule in which a delay is configured. However, an inter-nodal wait time can be configured as part of the rekey schedule. If an inter-nodal wait time is configured, the NFM-P will wait a specified amount of time after rekeying each NE.

Note: The execution of a rekeying scheduled task is skipped if a manual encryption operation using the same key group is in progress.

You can modify the wait time of a scheduled task. If a change to another parameter of a scheduled task is required, you must create a new scheduled task and delete the current scheduled task.

A rekeying operation has the following phases:

- Phase 1: deploy new key
- Phase 2: set new key as active outbound
- Phase 3: delete old key

If a rekeying operation fails, the NFM-P runs a cleanup operation the next time a rekey is triggered. The NFM-P checks and compares where the process failed, implements correction and inactive key cleanup, and continues with the rekey process.

After a rekeying operation, the NFM-P verifies that each key is correctly set by comparing the CRC checksums of the local and NFM-P key values. If the verification is delayed or unable to complete, an alarm is raised.

If a rekeying operation is unable to complete before the next rekeying operation is to begin, for example, when a large number of NEs are rekeyed using a schedule of high frequency, the NFM-P attempts the rekeying during the next scheduled task run.

You can view the results of rekeying scheduled task runs, which include the old and new CRC checksum values, from the properties form of the task; see 82.19 “To view rekeying results and statistics” (p. 2739).

The NFM-P also raises alarms for the following rekeying faults:

- failure to create an SA in a key group
- failure to delete an existing SA in a key group

82.8.2 Key updates with offline nodes

A node is in offline mode if the NFM-P has lost connectivity to the node at the time of specific NGE action (rekey, encrypt, or disable encryption). A node is not in offline mode if it responds to SSH and SNMP requests.

In some networks, it might be desirable to allow key groups to be rekeyed even though some of nodes in the key group are offline. For example, in a 7705 SAR-Hm network with vehicle-mounted deployments, it may not be possible to rekey the entire key group at once since some nodes (vehicles) will be periodically offline.

By default, the rekey procedure is halted if any node in the key group is offline.

Forced rekey

The Force Re-key option allows for the online nodes to be rekeyed when some nodes are offline. The offline nodes are skipped and online nodes are rekeyed. If rekey sites in a key group contain any site that belongs to a cellular domain, Force Re-key is skipped with a warning message in the server log.

When a node that has been skipped during a rekey operation comes back online, the node is rekeyed to apply the new key.

To allow nodes to learn new keys that were applied while the node was offline, the nodes require configurations that provide reachability to the NFM-P. The configuration cannot rely on any key groups that may be rekeyed while the node is offline. When the node comes back up, the node reaches the NFM-P, the NFM-P downloads the correct NGE keys for the key group to the node, and any services that were using the keys come back up.

Progressive rekey

A progressive rekey operation provides an alternative to forced rekeying if some nodes in the key group are offline. When offline nodes are encountered during the rekey operation, the NFM-P will wait for them to come back online, then proceed with the rekey operation. The use of progressive rekey prevents the need for the in-band configurations that provide reachability to the NFM-P for offline nodes if Force Re-key is in use.

The NFM-P provides the following information during the progressive rekey process:

- Current phase (Key Deployment, Key Activation, or Cleanup)
- Number of nodes remaining for key deployment
- Number of offline nodes pending rekey

If a progressive rekey operation is hung due to a node that remains offline, you can perform a force rekey operation for both the Key Deployment and Key Activation phases. While waiting in Key Deployment phase, you can also stop and fail the rekey process. When nodes come back online that did not receive the key-group keys, the NFM-P detects key groups that are not in sync and automatically updates the key group as needed.

You can add or remove sites from a key group during a progressive rekey operation. If a site is added, the new site is included in the rekey operation. If a site is deleted, the site information is deleted from the node.

82.9 NGE statistics

82.9.1 NGE statistics overview

You can collect NGE statistics for a key group on demand, and schedule NGE statistics collection using a MIB entry policy. The statistics are displayed on the Statistics tab of the Site properties form in a key group. See Chapter 9, “Device discovery” for information about configuring MIB entry policies.

NGE statistics can also be viewed and collected from the Statistics tab of the following object properties forms:

- card slot
- daughter card slot
- VPRN spoke-SDP binding
- network router interface
- Ethernet port

82.9.2 Rekeying operation statistics

The NFM-P monitors rekeying operations, and records statistics about the duration of rekeying operations for troubleshooting and assurance purposes. The statistics describe the duration of key replacement activities.

If the statistics reveal that rekeying activity is taking an increasing or excessively long time, investigation may be required to identify the cause of the latency. See 82.19 “To view rekeying results and statistics” (p. 2739) for information about viewing the rekeying operation statistics.

82.10 Workflow for NGE management using NFM-P

82.10.1 Stages

The following is the sequence of high-level actions required to manage NGE.

1

Enable SSH2 for the secure key transfers.

1. Ensure that SSH2 is enabled on each NE that is to participate in NGE; see 9.15 “To verify that SSH2 is enabled on a device” (p. 300).
2. Enable SSH2 host key persistence on devices that support host key persistence; see 9.16 “To enable SSH host key persistence on a device” (p. 301).
3. Create a mediation policy that specifies SSH2 as the CLI protocol; see 9.17 “To configure device mediation” (p. 301).

   If you specify SNMPv3 in the mediation policy, ensure that the associated SNMPv3 user has console access enabled.
4. Apply the SSH2 mediation policy as the Security Mediation Policy in each discovery rule associated with an NE that is to participate in NGE; see 9.23 “To configure a discovery rule” (p. 310).

2

Configure the global encryption label; see 82.12 “To create the NGE global encryption label” (p. 2730).

3

Create a key group to specify the security algorithms, encrypt objects, and create a rekeying scheduled task; see 82.13 “To create an NGE key group” (p. 2730).

4

As required, add objects to a key group, and encrypt the objects; see 82.14 “To add an object to a key group” (p. 2732).

5

As required, add NGE domains to a key group; see 82.15 “To create an NGE domain on a key group” (p. 2733).

6

As required, add managed sites to NGE domains, and apply encryption; see 82.16 “To configure an NGE domain” (p. 2734).

7

As required, add unmanaged sites to NGE domains, and apply encryption; see 82.17 “To add unmanaged sites to an NGE domain” (p. 2737).

8

If required, manually execute a rekeying scheduled task; see 82.18 “To manually execute a rekeying scheduled task” (p. 2739).

9

View the results of one or more rekeying operations; see 82.19 “To view rekeying results and statistics” (p. 2739).

10

Remove the NGE security from one or more objects; see 82.20 “To disable encryption on an object” (p. 2741).

82.11 Workflow for migration of NGE management from CLI to NFM-P

82.11.1 Stages

The following is the sequence of high-level actions required to migrate NGE management from CLI to NFM-P. Some steps may not be needed depending on the CLI and NFM-P configuration of the services and key group; see 82.2.2 “Migration scenarios” (p. 2719).

1

Configure the global encryption label; see 82.12 “To create the NGE global encryption label” (p. 2730).

2

Perform the prerequisite steps. These steps must be completed before starting to discover CLI managed NGE nodes because migration is automatic when discovery starts.

Perform the following:

1. Ensure the Global Encrypt label used on the CLI managed nodes is identical to that configured in the NFM-P.
2. Choose Manage→Network Group Encryption from the NFM-P main menu. The Manage Network Group Encryption form opens.

   Choose Key Group (NetworkGroupEncryption) from the drop-down menu and click Search to display the list of key groups.

3. Verify that both encryption and authentication algorithms of key groups on CLI managed nodes are identical to those configured on the NFM-P.
4. Disable re-keying for all key groups currently managed by the NFM-P if re-keying is enabled.
5. Choose Manage→Network Group Encryption from the NFM-P main menu and choose Cleanup Scheduled Task from the drop-down menu. Select the NGE Scheduled Task and click Shut Down to disable the task.
6. Check the list of Active Outbound Security Associations in the key group list against the CLI allocated SPIs to verify that there are no SPI conflicts on the CLI managed nodes.
7. If SPI or algorithm conflicts are found, resolve them in CLI.

3

Discover the nodes in the NFM-P; see 9.10 “Workflow for device discovery” (p. 288).

4

If needed, create a key group with the same ID as configured in the CLI; see 82.13 “To create an NGE key group” (p. 2730).

5

If needed, add the services to the key group and enable encryption:

1. Choose Manage→Network Group Encryption from the NFM-P main menu. The Manage Network Group Encryption form opens.

   Choose Key Group (NetworkGroupEncryption) from the drop-down menu and click Search to display the list of key groups.
2. Select a key group and click Properties. The Key Group (Edit) form opens.
3. Click on the Encryption tab, then the sub-tab for the type of service you need to add.
4. Click Add and use the form that opens to choose one or more objects.
5. Add any other services that are configured to the key group.
6. Click Encrypt Services to enable encryption.

6

Perform the following post-requisite steps:

1. Choose Manage→Network Group Encryption from the NFM-P main menu and choose Cleanup Scheduled Task from the drop-down menu. Select the NGE Cleanup Scheduled Task.
2. Click Turn Up to re-enable the NGE cleanup scheduled task, and Execute to run it.

   Nokia recommends running the NGE Cleanup Scheduled Task before re-keying is enabled. This will remove unused key groups and remove unused SPIs from the key group, allowing room for the new keys.
3. Enable any re-keying schedules you disabled in Stage 2.

82.12 To create the NGE global encryption label

82.12.1 Steps

1

Choose Manage→Network Group Encryption from the NFM-P main menu. The Manage Network Group Encryption form opens.

2

Click Create→Group Encryption Label. The Group Encryption Label (Create) form opens.

3

Configure the Group Encryption Label parameter.

4

Click OK. The Group Encryption Label (Create) form closes.

5

Close the Manage Network Group Encryption form.

END OF STEPS

82.13 To create an NGE key group

82.13.1 Steps

1

Choose Manage→Network Group Encryption from the NFM-P main menu. The Manage Network Group Encryption form opens.

2

Click Create→Key Group. The Key Group (Create) form opens.

3

Configure method of rekey operations: check the Force Rekey or Progressive Rekey check box, or leave both boxes unchecked to choose (default) rekey.

4

Configure the Encryption Algorithm and Authentication Algorithm parameters.

5

Click Apply. The NFM-P generates the encryption and authentication keys; the key values are displayed in the Security Associations panel.

6

Click on the Encryption tab.

7

Add one or more service objects to the key group.

1. Click on the sub-tab for the type of object that you need to add.

   Note the following:
   - The terminating site of an SDP must support NGE and be managed by the NFM-P.
   - A PW template must have the Use GRE Delivery parameter set to True.
2. Click Add and use the form that opens to choose one or more objects.

8

To apply the NGE encryption keys, perform one of the following: to one or more objects, select the objects and click Encrypt.

- To apply the NGE encryption keys to SDPs or VPRNs, click Encrypt Services.
- To apply the NGE encryption keys to other objects, select the objects and click Encrypt.

9

Click Yes to confirm the action. The NFM-P deploys the key group and keys to the participating NEs. The indicators in the Execution Status panel on the General tab display the status of the operation.

If the deployment is successful, the indicators appear as follows:

- Execution State—Encryption
- Last Execution Status—Success

10

To create a rekeying scheduled task, perform the following steps.

For maximum security, Nokia recommends that you create a rekeying scheduled task, which ensures that the keys in a key group are updated regularly.

1. Click on the Rekey Schedule tab.
2. Click Create. The Rekey Schedule, Key Group (Create) form opens.
3. Configure the parameters.
4. In the Schedule panel, click Select and use the form that opens to choose or create a schedule.

   You cannot use a schedule that has a Frequency value of Per Second or Per Minute.
5. Click OK to save your changes and close the form. A rekeying scheduled task is created.

11

Click OK to save your changes and close the Key Group (Create) form.

12

Close the Manage Network Group Encryption form.

END OF STEPS

82.14 To add an object to a key group

82.14.1 Purpose

Perform this procedure to add an NGE compatible object to an existing key group.

82.14.2 Steps

1

Choose Manage→Network Group Encryption from the NFM-P main menu. The Manage Network Group Encryption form opens.

2

Choose Key Group from the drop-down menu and click Search. The NFM-P NGE key groups are listed.

3

Select a key group and click Properties. The Key Group (Edit) form opens.

4

Click on the Encryption tab.

5

Click on the sub-tab for the type of object that you need to add.

The far-end site of an SDP must support NGE and be managed by the NFM-P.

6

Click Add and use the form that opens to choose one or more objects.

7

To apply the NGE encryption keys to the objects, click Encrypt Services.

8

Click Yes to confirm the action. The NFM-P deploys the key group and keys to the participating NEs. The indicators in the Execution Status panel on the General tab display the status of the operation.

If the deployment is successful, the indicators appear as follows:

- Execution State — Enable Encryption

- Last Execution Status — Success

9

Close the Key Group (Edit) form.

10

Close the Manage Network Group Encryption form.

END OF STEPS

82.15 To create an NGE domain on a key group

82.15.1 Steps

1

Choose Manage→Network Group Encryption from the NFM-P main menu. The Manage Network Group Encryption form opens.

2

Choose Key Group from the drop-down menu and click Search. The NFM-P NGE key groups are listed.

3

Select a key group and click Properties. The Key Group (Edit) form opens.

4

Click on the Encryption tab.

5

Click on the NGE Domains sub-tab.

6

Click Create. The NGE Domain (Create) form opens.

7

Configure the parameters in the General tab.

8

Click OK.

9

Save your changes and close the forms.

END OF STEPS

82.16 To configure an NGE domain

82.16.1 Steps

1

Choose Manage→Network Group Encryption from the NFM-P main menu. The Manage Network Group Encryption form opens.

2

Choose Key Group from the drop-down menu and click Search. The NFM-P NGE key groups are listed.

3

Select a key group and click Properties. The Key Group (Edit) form opens.

4

Click on the Encryption tab.

5

Click on the NGE Domains sub-tab.

6

Choose an NGE domain and click Properties. The NGE Domain (Edit) form opens.

7

Add one or more managed sites to the domain:

1. Click on the Domain Sites tab.
2. Click Add→Add Managed Sites. The Select Managed Sites window opens.
3. Click Search. The available NEs are listed.
4. Select an NE and click OK.

   The site is added to the domain.

When two or more sites are added to the domain, the L3 Router Interfaces in the same subnet will be populated in the L3 Router Interfaces tab. The Ethernet ports associated with interfaces in the L3 Router Interfaces tab will be populated in the L2 Ethernet Ports tab.

You can add unmanaged sites to a domain; see 82.17 “To add unmanaged sites to an NGE domain” (p. 2737).

8

If needed, add interfaces or ports to the domain manually. When an L3 Router Interface is added, the Ethernet ports associated with the interface will be populated in the L2 Ethernet Ports tab.

To add an interface or port manually:

1. Click on the L3 Router Interfaces or L2 Ethernet Ports tab.
2. Click Add.
3. Select the interfaces or ports and click OK.

The objects are added to the domain.

9

If needed, you can bind a manually created ACL IP Exception filter to an L3 interface for L3 encryption exemption.

See 51.7 “To configure an ACL IP exception filter policy” (p. 1683) to create the policy.

To bind an ACL IP Exception Filter to a gateway L3 interface:

1. Click on the L3 Router Interfaces.
2. Select an interface and click Properties. The Key Group Routing Interface Binding (Edit) form opens.
3. Click on the Select button for the Inbound IP Exception or Outbound IP Exception fields and select a policy.
4. Save your changes and close the Key Group Routing Interface Binding (Edit) form.

10

To apply the NGE encryption keys to one or more objects:

- To encrypt interfaces:
  1. Select a domain and click Properties.
  2. Click on the L3 Router Interfaces tab.
  3. Select one or more interfaces and click Encrypt.
- To encrypt ports:
  1. Select a domain and click Properties.
  2. Click on the L2 Ethernet Ports tab.
  3. Select one or more ports and click Encrypt.
- To encrypt all ports or interfaces in a domain, select a domain and click Encrypt→L3 Router Interfaces or Encrypt→L2 Ethernet Ports.

11

To disable encryption on one or more objects:

- To disable encryption on an interface:
  1. Select a domain and click Properties.
  2. Click on the L3 Router Interfaces tab.
  3. Select one or more interfaces and click Disable Encryption.
- To disable encryption on a port:
  1. Select a domain and click Properties.
  2. Click on the L2 Ethernet Ports tab.
  3. Select one or more ports and click Disable Encryption.
- To disable encryption on all ports or interfaces in a domain, select a domain and click Disable Encryption→L3 Router Interfaces or Disable Encryption→L2 Ethernet Ports.

12

To remove a port or interface from the domain:

1. Disable encryption on the ports or interfaces you need to delete; see Step 11.
2. From the NGE Domains tab, select a domain and click Properties. The NGE Domain (Edit) form opens.
3. Click on the L3 Router Interfaces or L2 Ethernet Ports tab.
4. Select an interface or port and click Delete.
5. Click OK to close the NGE Domain (Edit) form.

13

To remove a site from the domain:

1. Disable encryption on all ports and interfaces on the site; see Step 11.
2. From the NGE Domains tab, select a domain and click Properties. The NGE Domain (Edit) form opens.
3. Click on the Domain Sites tab.
4. Select a site and click Delete.
5. Click OK to close the NGE Domain (Edit) form.

14

To delete a domain:

1. Disable encryption on the all ports and interfaces in the domain; see Step 11.
2. From the NGE Domains tab, select a domain and click Delete.

15

Close the forms.

END OF STEPS

82.17 To add unmanaged sites to an NGE domain

82.17.1 Steps

1

Choose Manage→Network Group Encryption from the NFM-P main menu. The Manage Network Group Encryption form opens.

2

Choose Key Group from the drop-down menu and click Search. The NFM-P NGE key groups are listed.

3

Select a key group and click Properties. The Key Group (Edit) form opens.

4

Click on the Encryption tab, then on the NGE Domains sub-tab.

5

Choose an NGE domain and click Properties. The NGE Domain (Edit) form opens.

6

Configure at least one site and interface in the domain as a gateway. At least one gateway must be present before an unmanaged site can be added to the domain.

To configure a gateway:

1. Click on the Gateways tab, then on the Sites sub-tab.
2. Click Add and select a site.
3. Click OK to add the site to the list of gateway sites.
4. Click on the Interfaces sub-tab.
5. Click Add and select an L3 interface.
6. Click OK to add the interface to the list.

7

Add one or more unmanaged sites to the domain.

To add an unmanaged site:

1. Click on the Domain Sites sub-tab.
2. Click Add→Add Unmanaged Sites. The NGE Domain Site (Create) form opens.
3. Configure the parameters.

   If you need to discover a VSR which is managed by a VSR-a, configure the Managed by VSR-a check box and enter the VSR-a IP address. The VSR will be discovered as part of discovering the VSR-a.
4. Click OK.

The unmanaged site is added to the list of sites in the domain.

Repeat this step as required to add other sites.

8

Verify that the Unmanaged Site check box is enabled for all unmanaged sites.

Select the unmanaged sites and click NGE Discovery. The IP addresses of the unmanaged sites are added to the discovery rule specified in Step 7.

When NGE discovery is triggered, the NFM-P inserts the IP address of the unmanaged NE to the specified discovery rule. ACL IP exception filters will then be created on the gateway interface, in preparation for successful encryption on the interface of the newly discovered NE.

9

Wait for the NGE discovery process to complete an NE resynchronization. When the resynchronization is complete, the discovered sites become managed sites in the NGE domain and the Unmanaged Site check box is disabled.

If the NGE Discovery Execution Status is Failed, check the NGE Discovery Execution State for the failure reason.

10

Enable encryption on interfaces of the newly discovered NE by following Step 10 of 82.16 “To configure an NGE domain” (p. 2734).

After encryption has been enabled, the ACL IP exception filters are removed by the NFM-P.

11

Close the forms.

END OF STEPS

82.18 To manually execute a rekeying scheduled task

82.18.1 Steps

1

Choose Manage→Network Group Encryption from the NFM-P main menu. The Manage Network Group Encryption form opens.

2

Choose Key Group from the drop-down menu and click Search. The NFM-P NGE key groups are listed.

3

Select a key group and click Properties. The Key Group (Edit) form opens.

4

Click on the Rekey Schedule tab.

5

Click Execute→Rekey, Execute→Force Rekey or Execute→Progressive Rekey. The NFM-P performs the rekeying operation.

6

If required, view the rekeying results, as described in 82.19 “To view rekeying results and statistics” (p. 2739).

7

Close the Key Group (Edit) form.

8

Close the Manage Network Group Encryption form.

END OF STEPS

82.19 To view rekeying results and statistics

82.19.1 Steps

1

Choose Manage→Network Group Encryption from the NFM-P main menu. The Manage Network Group Encryption form opens.

2

Choose Key Group from the drop-down menu and click Search. The NGE key groups are listed.

3

Select a key group and click Properties. The Key Group (Edit) form opens.

4

Click on the Rekey Schedule tab.

5

To view results of a completed rekey scheduled task:

1. Click on the Results tab. The scheduled task results for all runs are listed.
2. To view a result, select the result and click Properties. The Rekey Schedule Result form opens.
3. View the information, as required.
4. Close the Rekey Schedule Result form.

6

To view results of an ongoing rekey operation:

1. From the Rekey Schedule tab, select a scheduled rekey task.
2. Click Rekey Progress.

   A Rekey Progress Info dialog box appears, showing the total number of sites to be rekeyed, and remaining sites to be rekeyed.
3. If necessary, you can intervene with the rekey process:
   - Click Force Rekey to switch to a force rekey process. The rekey will proceed as a forced rekey.
   - Click Stop/Fail to manually end the rekey process.
4. Click OK to close the dialog box.

7

To view statistics about the rekeying task runs, perform the following steps:

1. Click on the Rekey Times tab.
2. View the information, which describes the minimum, maximum, and average durations of new key set deployment and previous key set removal.

8

Close the Key Group (Edit) form.

9

Close the Manage Network Group Encryption form.

END OF STEPS

82.20 To disable encryption on an object

82.20.1 Purpose

Perform this procedure to remove the NGE encryption from an encrypted object.

82.20.2 Steps

1

Choose Manage→Network Group Encryption from the NFM-P main menu. The Manage Network Group Encryption form opens.

2

Choose Key Group from the drop-down menu and click Search. The NFM-P NGE key groups are listed.

3

Select a key group and click Properties. The Key Group (Edit) form opens.

4

Click on the Encryption tab.

5

Click on the sub-tab for the type of object on which you need to disable encryption.

6

Select one or more objects and click Disable Encryption. You can disable encryption only on objects with encryption enabled.

7

Click Yes to confirm the action. The NFM-P removes the service association between the key group and the object. The indicators in the Execution Status panel on the General tab display the status of the operation.

If the operation is successful, the indicators appear as follows:

- Execution State—Disable Encryption
- Last Execution Status—Success

8

Close the Key Group (Edit) form.

9

Close the Manage Network Group Encryption form.

END OF STEPS

83 Service PW template policies

83.1 Service PW template policies

83.1.1 Overview

Service PW templates policies enable you to automatically create SDP bindings on NEs that support BGP AD VPLS. PW templates contain the configuration to use when the NFM-P creates SDP bindings automatically through BGP AD. PW templates use the NFM-P policy distribution model to distribute the template to the NEs.

To prevent unwanted service disruptions, NEs do not automatically reconfigure SDP bindings when a change is made to the PW template from which they were generated. You can manually trigger a template re-evaluation to cause the NEs to re-configure SDPs to match the configuration in the template.

PW templates can be re-evaluated at three levels:

- service
- service site
- local definition of PW template policy

When you re-evaluate a PW template from the local definition of the PW template policy, the NFM-P re-evaluates the selected template for all of the VPLSs on the selected site.

When you re-evaluate a PW template from the service site, the NFM-P re-evaluates the selected template on the selected service site.

When you re-evaluate a PW template from the service, the NFM-P re-evaluates the selected template on all sites in the VPLS.

83.2 Workflow to configure and manage PW template policies

83.2.1 Purpose

The following workflow lists the high-level steps required to create and manage a service PW template policy.

83.2.2 Stages

1

Create a PW template policy. See 83.3 “To configure a PW template policy” (p. 2744) .

2

Release and distribute the PW template policy to each NE that is or will be a component of the VPLS or BGP VPLS. See 83.4 “To distribute a PW template policy” (p. 2746) .

3

Reevaluate PW template when a configuration change is made to the PW template. See 83.5 “To reevaluate a PW template policy on a local definition after a configuration change” (p. 2747) .

83.3 To configure a PW template policy

Note: Starting with NE release 15.1 R1, the Name parameter can only be configured during creation of the policy. It cannot be changed after the policy is created. However, the name can be changed if the NE release is 15.0, R4 or later.

83.3.1 Steps

1

Choose Manage→Service→Service PW Template Policies from the NFM-P main menu. The Manage Service PW Template Policies form opens.

2

Click Create. The Service PW Template (Create) form opens.

3

Perform one of the following:

a. To populate the Service PW Template form using an existing pseudowire (SDP Binding) as a base:

   1. Click Populate from Pseudowire and select a pseudowire. The Service PW Template (Create) refreshes with the pseudowire information.
   2. Go to Step 18 .

b. To manually configure the service PW template:

   1. Configure the required general parameters.
   2. Configure the required parameters in the Miscellaneous panel.

      The Block On Peer Fault parameter takes effect only when PW status signaling is enabled.

      The Block On Peer Fault parameter is not configurable on a spoke SDP that is on an MC LAG or an endpoint.

      You can set either the Enable Force-Vlan-VC Forwarding parameter or the Enable Force Q-in-Q-VC Forwarding parameter to true, but not both.
   3. Select an Accounting Policy in the Accounting Policy panel.

4

Click on the MAC tab and configure the required parameters.

5

Click on the Split Horizon Group tab and configure the required parameters.

6

Click on the Ingress Filters tab and configure the Ingress Filter Type parameter.

7

Click on the Egress Filters tab and configure the Egress Filter Type parameter.

8

Click on the IGMP tab and configure the required parameters.

9

Click on the STP tab and configure the required parameters.

10

Click on the QoS tab.

11

Configure the required parameters in the Ingress Forwarding Plane Redirect panel:

1. Select a Network Policy to assign a policy to the PW template.
2. Select an Ingress Queue Group Template Policy to assign a policy to the PW template.
3. Configure the Instance ID parameter.

12

Click on the Tunnel Admin Groups tab.

Note: You can apply the inclusion or exclusion of tunnel administrative groups only if you set the Use Provisioned SDP parameter to true in Step 3 b 1 .

13

Click on the tunnel administrative groups that you need to include in the PW template policy in the Included Admin Groups-Unassigned panel. You can choose multiple groups by holding down the Ctrl key when you click on the group.

14

Click on the right arrow to move the selected administrative groups into the Included Admin Groups-Assigned panel. You can move an assigned administrative group to the unassigned portion of the form if required, by selecting the group and clicking on the left arrow.

15

Click on the tunnel administrative groups that you need to exclude from the PW template policy in the Excluded Admin Groups-Unassigned panel. You can choose multiple groups by holding down the Ctrl key when you click on the group.

16

Click the right arrow to move the selected administrative groups into the Excluded Admin Groups-Assigned panel. You can move an assigned tunnel administrative group to the unassigned portion of the form, if required, by selecting the group and clicking the left arrow

17

Configure the required parameters in the Egress Port Redirect panel:

1. Select a Network Policy Select to assign a policy to the PW template.
2. Select an Egress Queue Group Template Policy to assign a policy to the PW template.
3. Configure the Instance ID parameter.

18

Save your changes and close the forms.

END OF STEPS

83.4 To distribute a PW template policy

83.4.1 Purpose

Use this procedure to manually distribute PW template policies that are used by BGP AD capable NEs and to configure the distribution mode of local policies.

When you distribute a global policy, local policies using the Sync With Global distribution mode allow the NE to receive the policy.

Note: Local policies using the Local Edit Only distribution mode do not allow the NE to receive the distribution of a global policy. You must ensure that the policy distribution mode for the local policy is set to Sync With Global if you need the NE to receive the distribution of a global policy.

83.4.2 Steps

1

Choose Manage→Service→Service PW Template Policies from the NFM-P main menu. The Manage Service PW Template Policies form opens.

2

Select the policy or policies that you need to distribute.

3

Perform 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the Service PW Template Policy.

END OF STEPS

83.5 To reevaluate a PW template policy on a local definition after a configuration change

83.5.1 Purpose

Perform the following procedure to cause the NEs to re-configure SDPs to match the configuration in the template when a PW template policy is modified. This causes a re-evaluation of the selected template for all VPLS services on the selected NE.

You can also reevaluate a PW template policy at the service and service site levels.

83.5.2 Steps

1

Choose Manage→Service→Service PW Template Policies from the NFM-P main menu. The Manage Service PW Template Policies form opens.

2

Choose a PW template policy and click Properties. The Service PW Template Policy (Edit) form opens.

3

Click on the Local Definitions tab.

4

Choose the NE on which you need to re-evaluate the PW template policy. The Service PW Template - Local Policy (Edit) form opens.

5

Click Re-evaluate PW Template to run an evaluation of the modified template. The NFM-P performs a re-evaluation of the selected template for all VPLS services on the selected NE.

6

A dialog box appears indicating if the re-evaluation was successful. If it was not, the reason for the failure is displayed. If you make any subsequent modifications, you can re-evaluate the template again. Click OK.

7

Save the changes and close the forms.

END OF STEPS

84 Service SAP template policies

84.1 Service SAP template policies

84.1.1 Overview

The epipe SAP template policy is used in Wi-Fi offload VLAN to anchor ISA configurations. It allows global ingress and egress qos policy configuration and traffic filtering for access SAPs, allowing users to shape traffic based on the Wi-Fi radio technology of an AP. For more information, see 39.1.7 “VLAN access to anchor ISA” (p. 1321) .

The VPLS SAP template policy is used in L2 wholesale-retail configurations. It provides global ingress/egress policy and other information for the creation of internal VPLS SAPs on a WLAN GW. For more information, see 39.1.8 “L2 wholesale” (p. 1321) .

84.2 To configure an epipe SAP template policy

84.2.1 Steps

1

Choose Manage→Service→SAP Template Policies from the NFM-P main menu. The Manage Service SAP Template Policies form opens.

2

Click Create→Epipe SAP Template or select an existing epipe SAP template policy and click Properties. The Epipe SAP Template (Create|Edit) form opens.

3

On the General tab, configure the Displayed Name parameter.

An epipe SAP template policy cannot share the same object name as a VPLS SAP template policy if both policies are distributed to the same NE. Although both policies could co-exist in the NFM-P database, the NE stores both policy types in the same MIB table, which would cause a conflict.

4

Click on the Egress tab and select the following objects for the epipe SAP template policy:

- IP filter
- IPv6 filter
- MAC filter
- QoS policy

5

Click on the Ingress tab.

1. Select the following objects for the epipe SAP template policy:
   - IP filter
   - IPv6 filter
   - MAC filter
   - QoS policy
2. Configure the Shared Queue parameters, if required.

6

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

84.3 To configure a VPLS SAP template policy

84.3.1 Steps

1

Choose Manage→Service→SAP Template Policies from the NFM-P main menu. The Manage Service SAP Template Policies form opens.

2

Click Create→VPLS SAP Template or select an existing VPLS SAP template policy and click Properties. The VPLS SAP Template (Create|Edit) form opens.

3

On the General tab, configure the required parameters.

An epipe SAP template policy cannot share the same object name as a VPLS SAP template policy if both policies are distributed to the same NE. Although both policies could co-exist in the NFM-P database, the NE stores both policy types in the same MIB table, which would cause a conflict.

4

Select a DoS protection policy, if required.

If you configure a DoS protection policy on the VPLS SAP template policy, you can configure the CPM Monitor MAC parameter or select ETH CFM Monitoring options.

5

Click on the Ingress tab to configure ingress filter, QoS, and scheduler policies for the VPLS SAP template policy.

1. Select the following policy types, as required:
   - IP filter
   - IPv6 filter
   - MAC filter
   - QoS
   - QoS scheduler
   - Policer control
2. Configure the remaining parameters.

6

Click on the Egress tab to configure egress filter, QoS, and scheduler policies for the VPLS SAP template policy.

1. Select the following policy types, as required:
   - IP filter
   - IPv6 filter
   - MAC filter
   - QoS
   - QoS scheduler
   - Policer control
2. Configure the remaining parameters.

7

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

85 Composite service management

85.1 Overview

85.1.1 Purpose

This chapter provides overview and procedural information on composite service management in the NFM-P.

85.1.2 Contents

Composite service management

85.2 Overview

85.2.1 General information

A composite service is a set of linked services. Composite service functionality supports complex applications that require a combination of services, such as VLAN connections to an HVPLS, an IES spoke into a VPLS, or a VPRN-to-VPLS interconnection.

Services that are owned by different customers can be connected to form a composite service. An example is an HVPLS in which the core VPLS belongs to one customer and the satellite VPLS instances belong to other customers. An HVPLS is considered to be a composite service by the NFM-P.

Composite services consist of customer services, called SCs in the context of a composite service, and connectors. A connector is a bidirectional logical link between two SCs, such as a pair of PW spokes that carry traffic in opposite directions between VLL and VPLS instances, a dot1q-encapsulated link between a VLAN and a VPLS, or an internal cross-connect.

The term SCP describes a type of connector endpoint. In the case of the services that are available on the 7210 SAS, 7450 ESS, 7750 SR, or the 7950 XRS, an SCP is a service interface or SAP. For L2 switches, an SCP may be a network interface, such as an uplink port.

Composite services exist only in the context of the NFM-P and are configured through the NFM-P GUI or an OSS application. They are unknown to individual network devices. To simplify composite service configuration and to ensure that non-NFM-P device configuration does not disrupt the management of composite services, the following rules apply to the creation, deletion, modification, and presentation of composite services.

- A composite service can have zero SCs.
- A composite service can have zero connectors.
- Two connected SCs can belong to only one composite service.
- A connector between two SCs belongs to only one composite service.
- An SC cannot be removed from a composite service until its connector to the composite service is removed.
- A group of connected services can be moved from one composite service to another.

The NFM-P supports composite-service configuration using the following methods.

- Tabbed configuration forms with an embedded navigation tree that provides a logical, hierarchical view of the composite service and acts as a configuration interface. When you right-click on an object In the service navigation tree, a menu specific to the object appears. When you choose an object in the menu, the related configuration form opens.
- Connector creation and configuration from within the composite service’s flat topology view

If a service that is specified for inclusion in a composite service does not currently belong to a composite service, it is added to the composite service regardless of its administrative or operational state. If the specified service is part of an existing composite service, it can be moved to a different composite service. However, SCs that are connected to the specified service are also

moved to the new composite service upon confirmation of the action by the NFM-P operator. The NFM-P performs no such action confirmation for OSS applications.

Services within a composite service can have the same service ID, service type, and customer ID. For example, a VPLS with service ID 5 on one NE and an IES service with service ID 5 on another NE can be combined to create a composite service.

85.2.2 Hierarchical organization of composite services

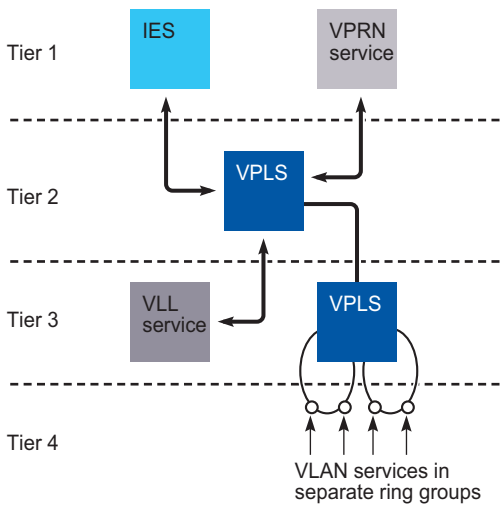
The NFM-P organizes the SCs in a composite service by tiers within a hierarchy during network discovery and for display purposes. When you add an SC to a composite service, the NFM-P assigns a default tier value to the SC according to the service type.

Table 85-1 Default tiers for service types

Service type	Default tier
IES and VPRN	1
VPLS and MVPLS	2
VLL	3
VLAN	4

The default tier values reflect common deployment configurations. The figure below shows a composite service hierarchy. SCs are not restricted to the default tiers, as in the case of the VPLS in Tier 3 that forms an HVPLS with the VPLS in Tier 2.

Figure 85-1 Default SC tier assignments



You can change the tier of an SC at any time and can specify a value other than one of the defaults that the NFM-P assigns; composite services can have many tiers.

The tier value of an SC determines the relative position of the SC within a composite service topology map. The NFM-P displays SCs in rows by tier, in numerical order from the top of the panel downward, beginning with tier 1.

You can move SC icons in a composite service topology map from one tier to another for a customized view, then use the Rearrange by Service Tiers button to organize the SC icons in the map panel according to tier. The composite service topology map is redrawn when you click on the Rearrange by Service Tiers button, and you cannot revert to the former layout of the composite service topology map.

See Chapter 4, “Topology map management” for more information about NFM-P map management.

85.2.3 Network discovery of composite services

The NFM-P associates SCs and connectors with composite services during network discovery. The following rules apply to this process.

- When the NFM-P discovers a valid connector between two services that do not belong to a composite service, a composite service that contains the services and connector is automatically created.
- When the NFM-P discovers a valid connector between two services and one of the services belongs to a composite service, the other service is added as an SC of the composite service.
- When the NFM-P discovers a valid connector between two services and the two services are SCs of different composite services, an alarm is raised and the connector is excluded from the NFM-P database.

The NFM-P assigns a default tier value to a service upon creation and to a new SC during network discovery. The tiered hierarchy provides a common framework for service configurations that are provisioned through the NFM-P and CLI. An NFM-P operator can assign a different tier value to an SC after discovery.

A composite service has Aggregated Operational State and Service Component Degraded status indicators. The General tab of the Composite Service management form displays these indicators.

The Aggregated Operational State indicator has four possible values: Up, Down, Partially Down, and Unknown. The value is derived from the aggregated SC operational states as follows.

- Up—All SCs are operationally up
- Partially Down—At least one SC is operationally down
- Down—All SCs are operationally down
- Unknown—The status of at least one SC is undetermined

The Service Component Degraded indicator shows whether there is an operational flag set on any of the service sites under this composite service.

85.3 Connector types

85.3.1 General information

The following types of connectors join SCs in a composite service:

- SCP-to-SCP
- internal cross-connect
- PW spoke
- routed VPLS
- VRF RT connections for VPRN services

Note: The NFM-P does not create connectors between mesh SDP bindings.

85.3.2 SCP-to-SCP connectors

SCP-to-SCP connectors can join any two SC types that have service interfaces on the same device or on different devices. A connector between VPLS and VPRN SAPs is an SCP-to-SCP connector, as is a connector between a dot1q-encapsulated VPLS SAP and L2 switch uplink port in a VLAN ring group. The table below describes the supported encapsulation types.

Table 85-2 Supported encapsulation types

SAP type	Encapsulation type
Ethernet[1]	dot1q
	QinQ
	Null
ATM	VPI/VCI
	VPI
FR	DLCI
SONET/SDH	BCP Null
	BCP dot1q
	IPCP
	PPP Auto
	cHDLC
	WAN Mirror
LAG	Null
	dot1q
	QinQ
	Null

Notes:

1. VLAN connection profiles are supported for Ethernet SAPs with dot1q and QinQ.

The operational status of an SCP-to-SCP connector depends on the operational status of its endpoints. An alarm raised against one of the endpoints causes an alarm to be raised against the connector. Such alarms are aggregated within the composite service.

85.3.3 Internal cross-connect connectors

An internal cross-connect connector can join any SC types. It uses a CCAG to join two SCs that have SAPs or network interfaces on the same device. This functionality is available in the 7450 ESS and 7750 SR. The following rules apply to internal cross-connect connectors.

- A SAP can be connected to another SAP or to a network interface using a CCAG.
- When a SAP or network interface is deleted, the connector associated with it is also deleted.
- The deletion of an internal cross-connect connector causes the associated interfaces and SAPs to be deleted.

The operational state of an internal cross-connect connector depends on the operational state of the CCAG. An alarm raised against the CCAG causes an alarm to be raised against the connector. Such alarms are aggregated within the composite service.

85.3.4 PW spoke connectors

A PW spoke connector generally joins VPLS instances to create an HVPLS. In the 7210 SAS, 7450 ESS, 7750 SR, and 7950 XRS, a PW spoke can, for example, connect IES and VPLS instances to provide distributed Internet access service. The endpoints of a PW spoke connector must be on different devices. PW spoke connectors are subject to restrictions on the SC types that they can join. The table below lists the SC types that can be linked by PW spoke connectors.

Table 85-3 Valid PW spoke interconnections

SC type	Valid PW spoke SC interconnections
VLL	IES, VPLS
VLAN	—
VPLS	IES, VLL, VPLS
MVPLS	MVPLS
IES	VLL, VPLS
VPRN	VLL, VPLS

The operational state of a PW spoke connector depends on the operational state of the underlying SDP bindings. An alarm raised against one of the SDP bindings causes an alarm to be raised against the connector. Such alarms are aggregated within the composite service.

85.3.5 Routed VPLS connectors

A routed VPLS connector joins an L3 access interface within an IES or VPRN service context to a VPLS or I-VPLS on the same site. When an IES or VPRN IP interface is bound to a VPLS site

name, the site name cannot be bound to another IP interface. Although an IES or VPRN IP interface can only be bound to a single VPLS site, the service context that contains the IP interface can have other IP interfaces bound to other VPLS sites. Both the IES or VPRN IP interface and VPLS site must be located on the same NE.

If a VPLS site name does not exist within the system, the binding between the IP interface and the VPLS site remains operationally down until a VPLS site name is assigned to the VPLS site. When an IP interface is bound to a VPLS site, the operational state of the binding depends on the operational state of the VPLS site, or whether the IP interface binding is enabled on the VPLS site.

The operational state of the routed VPLS connector depends on the operational state of the binding and the operational state of the L3 IP interface.

The routed VPLS connector function is supported for IOM3, or later, cards in the following devices:

- 7450 ESS in mixed mode
- 7750 SR
- 7750 SR-c4
- 7705 SAR, all variants
- 7950 XRS

85.3.6 VPRN RT connections

RT connectivity is the matching of import and export VRF targets for VPRN services, and is represented as a dotted line between the services with arrows indicating the direction. You can highlight the VRF targets between VPRN services within a composite service on the topology map and on the flat topology map. The flat topology map shows RT connections between all of the sites, whereas the topology map show RT details between services.

For VPRN RT connections within composite services, you can define:

- the VRF import and export targets on the sites (only one import and one export RT value on each site)
- the VRF target based on import and export policies, where multiple community members can be defined

Consider the following when you highlight the VRF targets between VPRN services within a composite service on the topology map:

- the RT connections are highlighted when the RT defined in the VRF import policy matches the VRF export policy on another site
- if a site is configured with VRF target values and with VRF import and export policies, the NFM-P uses the VRF import and export policy

See 79.27 “To configure a VRF instance on a VPRN site” (p. 2567) for more information about how to configure VRF instances on VPRN sites.

See 79.50 “To configure VRF import and export policies on a VPRN site” (p. 2615) for more information about how to configure VRF import and export policies on a VPRN site.

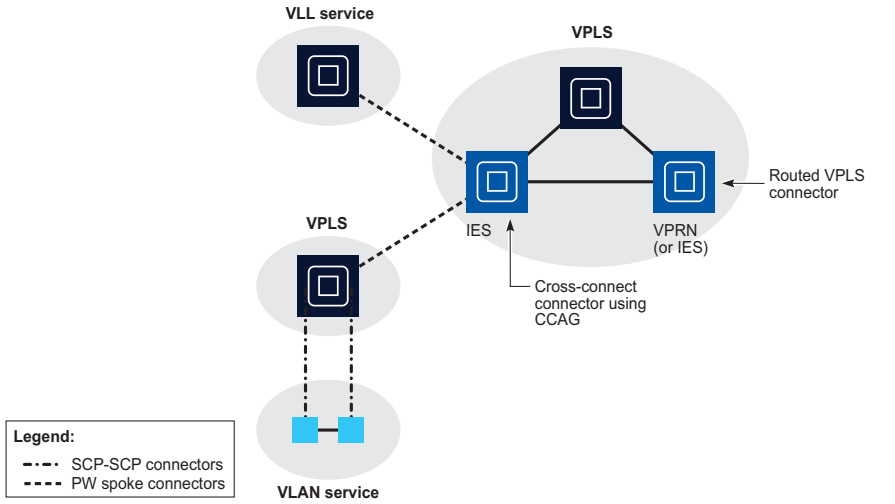
See Chapter 54, “Routing policies” for more information about routing policies.

85.4 Sample composite service configuration

85.4.1 General information

The figure below shows a sample composite service configuration that involves a variety of customer services and uses the three SC connector types.

Figure 85-2 Sample composite service configuration



85.4.2 Workflow to create a composite service

The following workflow lists the high-level steps required to create a composite service. As a prerequisite for creating a composite service, this workflow assumes the following:

- a group or customer with the required user access privileges has been configured.
- the IP or IP/MPLS core network exists.
- any required service tunnels are created including the static, dynamic or SR-TE LSP required to create the service tunnel; see 33.9 “To create an IP/MPLS service tunnel” (p. 1190) for more information.
- the access ports for the service are created; see Chapter 16, “Port and channel object configuration” for more information.
- any required pre-defined routing, QoS, scheduling, filter, accounting, and time of day suite policies are created; see Chapter 49, “Policies overview” for more information. You do not have to create pre-defined policies if policies are created on a per-service basis.
- any required MP-BGP for PE-to-PE routing is configured; see Chapter 28, “Routing protocol configuration” for more information about protocol configuration.
- the other network services that are to be the SCs of the composite service are created.

85.4.3 Stages

1

As required, modify the default system preferences for composite services such as specifying if composite services are auto-discovered or if service alarms are aggregated for composite services.

2

Create composite service.

1. Define the general properties for the composite service. See 85.5 “To create a composite service” (p. 2764) for more information.
2. Specify the services for inclusion in the composite service. You can specify multiple services in one operation. See 85.6 “To add services to a composite service” (p. 2764) for more information.
3. Create connectors to link the SCs of the composite service. See 85.7 “To create a cross connect connector” (p. 2765) , 85.8 “To create an SCP connector” (p. 2766) , 85.10 “To discover VRF route target connections” (p. 2768) , and 85.12 “To create a routed VPLS connector” (p. 2770) for more information.
4. Turn up the composite service.

3

As required, run an OAM validation test for the composite service. See 85.13 “To run an OAM validation test for a composite service” (p. 2771) for more information. Alternatively, you can

also run a One Time Validation on the composite service. See 90.55 “To run a one-time validation test on a service” (p. 3084) for more information.

4

As required, force a manual rediscovery of all composite services in the NFM-P to discover new service connectors that would add SCs to an existing composite service, or for new service connectors that would connect together two SCs to create a new composite service. See 85.14 “To rediscover composite services” (p. 2772) for more information.

5

Manage a composite service.

1. View the service topology map associated with a composite service. See 85.15 “To view the service topology map associated with a composite service” (p. 2773) for more information.
2. As required, modify a composite service:
   - using the navigation tree; see 85.16 “To modify a composite service using the navigation tree” (p. 2773) for more information
   - using the flat topology view; see 85.17 “To modify a composite service using the flat topology view” (p. 2774) for more information
3. As required, delete a composite service. See 85.18 “To delete a composite service” (p. 2778) for more information.

Composite service management procedures

85.5 To create a composite service

85.5.1 Steps

1

Choose Create→Service→Composite Service from the NFM-P main menu. The Composite Service (Create) form opens.

2

Configure the required general parameters.

The Composite ID parameter is configurable only if the Auto-Assign ID parameter is disabled.

3

Click Apply.

4

Save the changes and close the forms.

END OF STEPS

85.6 To add services to a composite service

85.6.1 Steps

1

Choose Manage→Service→Composite Services from the NFM-P main menu. The Manage Composite Services form opens.

2

Select a composite service and click Properties. The Composite Service (Edit) form opens.

3

In the service navigation tree, right-click on the Services icon and choose Add Services. The Add Services form opens.

Note: You can also create a service for inclusion in the composite service by right-clicking on the Services icon and choosing Create *Service Type*.

4

Select one or more services.

5

To add a connector to the composite service:

a. Create a cross connect connector. Perform Step 3 to Step 12 of 85.7 “To create a cross connect connector” (p. 2764) .

b. Create a routed VPLS connector. Perform Step 3 to Step 11 of 85.12 “To create a routed VPLS connector” (p. 2770) .

c. Create an SCP connector. Perform Step 3 to Step 12 of 85.8 “To create an SCP connector” (p. 2766) .

d. Create a Spoke Connector. Perform Step 3 to Step 14 of 85.9 “To create a spoke connector” (p. 2767) .

6

Save the changes and close the forms.

END OF STEPS

85.7 To create a cross connect connector

85.7.1 Steps

1

Choose Manage→Service→Composite Services from the NFM-P main menu. The Manage Composite Services form opens.

2

Select a composite service and click Properties. The Composite Service (Edit) form opens.

3

In the service navigation tree, right-click on the Connectors icon and choose Create CrossConnect. The Cross Connect (Create) form opens.

Note: The service endpoints of a cross-connect connector must be on the same NE.

4

Configure the required general parameters.

5

Select an SC to associate with the connector in the Service A panel.

6

Select an SC to associate with the connector in the Service B panel.

7

Select a site to associate with the connector in the Site A panel.

8

Select a site to associate with the connector in the Site B panel.

9

Click on the Transport tab.

10

Select a CCAG for the connector.

11

Configure the required parameters.

12

Save the changes and close the forms.

END OF STEPS

85.8 To create an SCP connector

85.8.1 Steps

1

Choose Manage→Service→Composite Services from the NFM-P main menu. The Manage Composite Services form opens.

2

Select a composite service and click Properties. The Composite Service (Edit) form opens.

3

In the service navigation tree, right-click on the Connectors icon and choose Create ScpConnector. The ScpConnector (Create) form opens.

4

Configure the required general parameters.

5

Select an SC to associate with the connector in the Service A panel.

6

Select an SC to associate with the connector in the Service B panel.

7

Select a site to associate with the connector in the Site A panel.

8

Select a site to associate with the connector in the Site B panel.

9

Click on the Service Connection Point tab.

10

Select an SCP to associate with the connector in the Service Connector Point A panel.

11

Select an SCP to associate with the connector in the Service Connector Point B panel.

12

Save the changes and close the forms.

END OF STEPS

85.9 To create a spoke connector

85.9.1 Steps

1

Choose Manage→Service→Composite Services from the NFM-P main menu. The Manage Composite Services form opens.

2

Select a composite service and click Properties. The Composite Service (Edit) form opens.

3

In the service navigation tree, right-click on the Connectors icon and choose Create ScpConnector. The SpokeConnector (Create) form opens.

Note: The service endpoints of a spoke connector must be on different NEs.

4

Configure the required general parameters.

5

Select an SC to associate with the connector in the Service A panel.

6

Select an SC to associate with the connector in the Service B panel.

7

Select a site from service A to associate with the connector in the Site A panel.

8

Select a site from service B to associate with the connector in the Site B panel.

9

Click on the Transport tab.

10

Configure the parameters.

The Transport Type parameter is configurable when the Auto Select Tunnels parameter is enabled.

11

Select a service tunnel to associate with the connector in the Tunnel A panel

12

Select a service tunnel to associate with the connector in the Tunnel B panel

13

If one of the SCs in the composite service is an IES, the First L3 Access Interface and Second L3 Access Interface panels are present. Select an access interface to associate with the spoke connector in the First L3 Access Interface and Second L3 Access Interface panels. Otherwise, go to Step 4 .

14

Save the changes and close the forms.

END OF STEPS

85.10 To discover VRF route target connections

85.10.1 Steps

1

Choose Administration→System Preferences and configure the Enable VRF Route Target

Connections parameter in the Composite Services panel on the Service tab. See the *NSP System Administrator Guide* for more information.

2

Choose Manage→Service→Composite Services from the NFM-P main menu. The Manage Composite Services form opens.

3

Click Rediscover Composite Services→VRF Route Target to update all of the VPRN Route Target connectors.

Any unidirectional RT connectivity between two different VPRN services are automatically moved into one composite service, if any route targets are highlighted.

4

Close the forms.

5

Perform 85.11 “To draw VRF targets between VPRN services” (p. 2768) to highlight VRF targets between VPRN services.

Note: If you disable the Enable VRF Route Target Connections parameter in the system preferences, the NFM-P removes all discovered composite services based on the VRF Route Target. You must repeat 85.10 “To discover VRF route target connections” (p. 2768) to re-discover the VRF route targets.

END OF STEPS

85.11 To draw VRF targets between VPRN services

85.11.1 Purpose

Use this procedure to draw VRF targets between VPRN services on a topology map associated with a composite service.

85.11.2 Steps

1

Choose Manage→Service→Composite Services from the NFM-P main menu. The Manage Composite Services form opens.

2

Select a composite service and perform one of the following steps:

a. Click on the Topology View button. A Composite Service Topology - *Service Name* map opens.

b. Click on the Topology View Flat button. A Composite Service Flat Topology - *Service Name* map opens. The Flat Topology map is a flattened view of a composite service, meaning that all the service objects are displayed simultaneously, along with the service sites, access interfaces, and the links or groups of links between them.

See Chapter 4, “Topology map management” for more information about composite service topology views.

3

Right-click on the composite services topology map composite services flat topology map and choose Highlight Route Target Topology.

4

Close the forms.

END OF STEPS

85.12 To create a routed VPLS connector

85.12.1 Steps

1

Choose Manage→Service→Composite Services from the NFM-P main menu. The Manage Composite Services form opens.

2

Select a composite service and click Properties. The Composite Service (Edit) form opens.

3

In the service navigation tree, right-click on Connectors and choose Create RoutedVplsConnector. The RoutedVplsConnector (Create) form opens.

4

Configure the required general parameters.

5

Select an SC to associate with the connector in the Service A panel.

6

Select an SC to associate with the connector in the Service B panel.

7

Select a site from service A to associate with the connector in the Site A panel.

8

Select a site from service B to associate with the connector in the Site B panel.

Note: The sites that you select in Step 7 and Step 8 must be located on the same NE.

9

Click on the Routed-VPLS L3 Connection Point tab.

10

Select an L3 access interface.

11

Save the changes and close the forms.

END OF STEPS

85.13 To run an OAM validation test for a composite service

85.13.1 Purpose

A validator test suite must be created for the tested entity. See Chapter 89, “Service Test Manager” for more information about how to create a validator test suite.

Note: As an alternative, you can also run an OAM validation test on the composite service by performing a One Time Validation. This is a mostly automated procedure and is described in 90.55 “To run a one-time validation test on a service” (p. 3084) .

85.13.2 Steps

1

Choose Manage→Service→Composite Services from the NFM-P main menu. The Manage Composite Services form opens.

2

Select a composite service and click Properties. The Composite Service (Edit) form opens.

3

Click Action and choose Validate. If a validator test suite is not associated to the composite service, a dialog box appears. Perform the following steps:

1. Click OK to associate the composite service with an existing validator test suite. The Choose Validator Test Suite form opens.
2. Select a validator test suite and click OK The Choose Validator Test Suite form closes.

4

View the Operational Flags indicators. If the validation test fails, a check mark appears beside the OAM Validation Failed indicator.

5

Click on the Tests tab.

6

Click on the Tested Entity Result tab.

7

Select an entry and click Properties. The Tested Entity Result form opens and displays information about the validation test.

8

Close the forms.

END OF STEPS

85.14 To rediscover composite services

85.14.1 Purpose

This procedure forces a manual rediscovery of all composite services in the NFM-P. The Rediscover Composite Services command performs a network discovery that looks for new service connectors that would add SCs to an existing composite service, or for new service connectors that would connect together two SCs to create a new composite service.

Note: If the Auto Discover Composite Services system preference is enabled, composite services are rediscovered as part of routine network discovery in the NFM-P. See 73.5 “To list the services associated with a customer” (p. 1982) for more information.

85.14.2 Steps

1

Choose Manage→Service→Composite from the NFM-P main menu. The Manage Composite Services form opens.

2

Click Rediscover Composite Services.

3

A warning dialog box appears. Click Yes to start the rediscovery.

4

A progress bar appears, indicating the status of the rediscovery process. Upon completion, an information form appears, indicating the number of composite services and connectors discovered. Close the form.

5

Close the Manage Composite Services form.

END OF STEPS

85.15 To view the service topology map associated with a composite service

85.15.1 Steps

1

Choose Manage→Service→Composite Services from the NFM-P main menu. The Manage Composite Services form opens.

2

Select a composite service and perform one of the following steps:

a. Click on the Topology View button. A Composite Service Topology - *Service Name* map opens.

b. Click on the Topology View Flat button. A Composite Service Flat Topology - *Service Name* map opens. The Flat Topology map is a flattened view of a composite service, meaning that all the service objects are displayed simultaneously, along with the service sites, access interfaces, and the links or groups of links between them.

See Chapter 4, “Topology map management” for more information about composite service topology views.

3

Close the forms.

END OF STEPS

85.16 To modify a composite service using the navigation tree

Note: Modifying parameters can be service-affecting.

Note: You can also modify composite service components and add service connectors from the flat topology view. See 85.17 “To modify a composite service using the flat topology view” (p. 2774) .

85.16.1 Steps

1

Choose Manage→Service→Composite Services from the NFM-P main menu. The Manage Composite Services form opens.

2

Select a composite service and click Properties. The Composite Service - *Service Name* (Edit) form opens.

3

In the service navigation tree, right-click on an item and choose Properties.

Using the contextual menu, you can also:

- Add SCs and connectors to a composite service
- Create services for inclusion in the composite service. When you create services by using the contextual menu, the services are automatically added to the composite service.
- Remove SCs and connectors from a composite service
- Move SCs to another composite service
- Delete SCs

  Deleting an SC is not the same as removing an SC from a composite service. Deleting an SC removes the service from the NFM-P database. To avoid a service outage, be certain of the action that you are taking.

4

Save the changes and close the forms.

END OF STEPS

85.17 To modify a composite service using the flat topology view

85.17.1 Purpose

You can modify composite service components and add service connectors from the flat topology view. The main advantage of creating connectors using the flat topology view is that most of the parameters in the associated configuration forms are automatically populated when you select an item in the map.

Note: Modifying parameters can be service-affecting.

Note: You can also modify and add composite service components using the navigation tree. See 85.16 “To modify a composite service using the navigation tree” (p. 2773) .

85.17.2 Steps

1

Choose Manage→Service→Composite Services from the NFM-P main menu. The Manage Composite Services form opens.

2

Select a composite service and click Properties. The CompositeService - *Service Name* (Edit) form opens.

3

Click Flat Topology View. The Composite Service Flat Topology map opens.

4

To configure parameters for any item on the map, right-click on the item and choose Properties. The configuration form for the item is displayed.

5

Edit the parameters as required. See 85.5 “To create a composite service” (p. 2764) for detailed configuration information on creating and configuring components.

6

Add service connectors to the composite service, if required.

Depending on the sites or ports you select, when you right-click on a component, the contextual menu contains one or more of the following choices:

- Create Cross Connect. Go to Step 7 .
- Create Routed Vpls Connector. Go to Step 8 .
- Create Scp Connector. Go to Step 9 .
- Create Spoke Connector. Go to Step 10 .

Click on the required item in the contextual menu and proceed to the associated step indicated in this list.

Note: If you need to modify any of the automatically-populated parameters in the associated configuration forms while creating these connectors, see 85.16 “To modify a composite service using the navigation tree” (p. 2773) for detailed information.

7

To create a Cross Connect Connector:

1. Select the two sites for which you want to create the Cross Connect Connector. These represent the same physical NE that exists in two separate services, since service endpoints of a Cross Connect Connector must be on the same NE.

2. Right-click on either of the NEs and choose Create Cross Connect.

   The CrossConnect (Create) form opens.
3. Configure the parameters.
4. Click on the Transport tab.
5. Select a CCAG for the connector.
6. Save the changes and close the form.
7. Go to Step 14 .

8

To create a Routed VPLS Connector:

1. Select a VPLS site and an L3 Access Interface for which you want to create the Routed Vpls Connector. The site and access interface must be on the same NE.
2. Right-click on either of the icons and choose Create Routed Vpls Connector. The RoutedVplsConnector (Create) form opens.
3. Configure the parameters.
4. Save the changes and close the form.
5. Go to Step 14 .

9

To create an SCP Connector:

1. Select the ports for the two sites for which you want to create the SCP Connector.
2. Right-click on either of the of the ports and choose Create Scp Connector. The ScpConnector (Create) form opens.
3. Configure the parameters.
4. Save the changes and close the form.
5. Go to Step 14 .

10

To create a Spoke Connector:

1. Select the two sites for which you want to create the Spoke Connector. These sites must be two different NEs that exist in two separate services.
2. Right-click on either of the sites and choose Create Spoke Connector. The SpokeConnector (Create) form opens.
3. Configure the parameters.
4. Save the changes and close the form.

11

To create new services within the composite service view:

1. Right-click on the flat topology map background and choose Create. A list of services appears.
2. Choose the service type you want to create. The *Service* (Create) form opens.
3. Configure the required parameters for the service and save the changes and close the form.

   See the appropriate service management chapter for information about creating a specific service type.

12

To add services to the composite service:

1. Right-click on the flat topology map background and choose Add→Service(s). The Add Services - Composite Services form opens.
2. Select a service. The service is displayed on the map. If the service includes service sites, the sites are also displayed on the map.

13

To add service sites to an existing service in the composite service:

1. Right-click on the flat topology map background and choose Add→Service Site(s). The Find Service form opens.
2. Select a service.
3. Select one or more NEs. The *Service* Site (Create) form opens. If you select more than one NE, the *Service* Site, Multiple Instances (Create) form opens.
4. Configure the service site and save and close the form. The new service site is displayed on the map.

   See the appropriate service management chapter for information about configuring a specific service site type.

14

Save the changes and close the forms.

END OF STEPS

85.18 To delete a composite service

CAUTION

Service disruption

Deleting a service may result in a service disruption for customers.

Consider the implication of deleting the service before proceeding.

85.18.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

As required, configure the filter criteria to locate the service or range of services to be deleted. A list of services appears at the bottom of the Manage Services form.

3

Choose a service or a range of services from the list.

4

Click Delete. A warning form appears. This form is dynamic based on the priority of the service. Perform one of the following:

a. For services with a low priority, go to Step 5 .

b. For services with a medium priority, configure the “Enter the highest priority of the service being deleted” text field by typing: Medium. Go to Step 5 .

c. For services with a high priority, configure the “Enter the highest priority of the service being deleted” text field by typing: High. Go to Step 5 .

5

For all services regardless of how their priority is configured, acknowledge the check box that prompts you confirm that you understand the implications of deleting the service.

Note: If you select multiple services with different priorities, you must enter the highest priority level of selected services before you can delete the services.

6

Click Yes to confirm the action. The service is deleted and removed from the list.

7

Close the Manage Services form.

END OF STEPS

86 Dynamic service management

86.1 Overview

86.1.1 Purpose

This chapter provides overview and procedural information on dynamic service management in the NFM-P.

86.1.2 Contents

Dynamic service management

86.2 Overview

86.2.1 General information

A dynamic service is a service in which sites are created using information contained in RADIUS Change of Authorization messages instead of manual operator input.

You can configure dynamic services for the following service types:

- Epipe
- IES
- VPLS
- VPRN

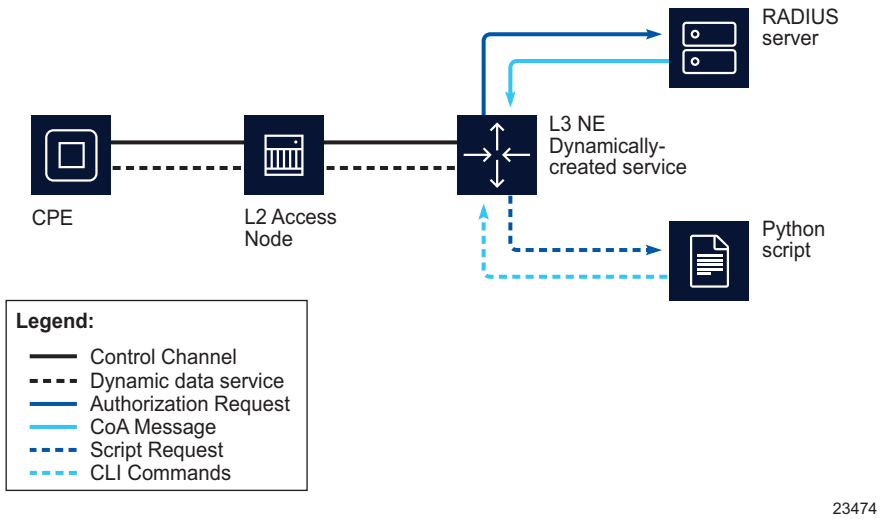
86.2.2 Dynamic service structure

The creation of a dynamic service is triggered by a CPE device establishing a control channel (PPPoE, IPoE, or DHCP) with an L3 NE. The control channel is authenticated using RADIUS, and the RADIUS server sends Access-Accept or Change of Authorization messages that contain the parameters for the dynamic service required by the triggering device.

The L3 NE passes the information from the RADIUS messages to a Python script, which returns CLI commands that create the required dynamic sites on the NE.

Data-triggered RADIUS authentication is possible through association of the dynamic service policy with a VPLS capture SAP, allowing dynamic service policy binding to an MSAP. The dynamic service policy is associated with a RADIUS server policy for authentication purposes. In deployments where RADIUS is used for accounting and dynamic changes (CoA) but cannot provide actual service provisioning parameters, you can configure a local authentication database object and associate it with the dynamic services policy, in place of a RADIUS server policy. In this case, the local authentication database is also associated with the dynamic service-enabled NE.

Figure 86-1 Basic dynamic service



When the control channel fails - for example, when the CPE device is removed - the NE deletes any dynamic services that were created for the control channel.

86.3 Dynamically-created objects

86.3.1 General information

Network objects in a dynamic service are read-only on the NE and in the NFM-P, and cannot be modified except through RADIUS CoA messages. As a result, some operations are not supported on dynamically-created sites. When a dynamic object is created or deleted, the action is recorded in the dynamic service activity log. This section describes the unsupported operations, and the dynamic service activity log.

Dynamically created service sites are discovered and synchronized with the NFM-P in the same manner as manually created service sites. A service that contains a dynamically created object has the Contains Dynamically Created Sites parameter enabled, and cannot be deleted until the dynamically created object is removed from the service.

86.3.2 Unsupported operations

Table 86-1 Unsupported operations on dynamically created objects

Operation	Description
Object configuration operations	
Delete	You cannot delete dynamically created objects. A RADIUS CoA message must request their deletion, or the control channel for the dynamic service that created the object must be disconnected.

Table 86-1 Unsupported operations on dynamically created objects (continued)

Operation	Description
Create child objects	You cannot create objects within dynamically created sites; for example, subscriber interfaces or spoke SDP bindings.
Topology map actions	You cannot interact with dynamically-created objects that appear on the service topology map, except to display their parameters.
SAP copy/move	Dynamically created SAPs are not included in SAP copy or move operations. The operations proceed normally, but skip any dynamically created SAPs.
MDA or card removal	You cannot delete MDAs or cards with dynamic sites.
Automated operations	
Automatic MEP/MIP creation	MEGs skip MEP or MIP creation on SAPs and SDP bindings that are on a dynamically-created site.
SDP binding auto-completion	Dynamically-created sites are skipped during SDP binding auto-completion.
Service Throughput site list	Dynamically-created sites do not appear on the Service Throughput form

86.3.3 Dynamic services activity log

The NFM-P maintains a log of dynamic service actions for each NE, adding an entry whenever an object is created or deleted on the NE. Log entries are deleted after a configurable amount of time, as specified by the ageout constraint policy defined in the NFM-P. For information about configuring the ageout constraint policy, see the *NSP System Administrator Guide*; for information about viewing the dynamic services activity log, see 86.9 “To view the dynamic services activity log” (p. 2789) .

86.3.4 ID range behavior

Each NE that is configured for dynamic service must specify an ID range for dynamically-created sites. Dynamically-created sites can only use IDs from the specified range, and non-dynamic sites cannot use IDs from that range. When a dynamic service is created on an NE, the next available ID from the specified range is used.

86.4 Workflow to create dynamic services

86.4.1 Purpose

The following workflow lists the high-level steps required to configure an NE to process dynamic service requests. As a prerequisite for creating a dynamic service, this workflow assumes that the following appropriate preconfigurations have been performed:

- pre-discovery CLI modifications
- discovery including mediation configuration with CLI user name and password
- creation of python scripts to be called by the NE; for more information about creating dynamic service python scripts, and CLI operations supported for python scripts, see the *7750 SR OS Triple Play Guide*.
- creation of RADIUS policies

86.4.2 Stages

1

Configure a RADIUS script policy; see 64.23 “To configure a RADIUS script policy” (p. 1865).

2

Configure a dynamic service policy; see 86.5 “To configure a dynamic service policy” (p. 2786).

3

Where required, configure a local authentication database, with binding to the dynamic service policy; see 86.6 “To configure a local authentication database” (p. 2787).

4

Configure the NE for dynamic service; see 86.7 “To configure an NE for dynamic service” (p. 2788).

5

Where data-triggered authentication is required, configure the dynamic service policy on a VPLS capture SAP; see 74.26 “To configure a capture SAP” (p. 2049).

6

Configure a RADIUS-authenticated control channel. See the *7750 SR OS Triple Play Guide* for more information about dynamic service control channels.

Dynamic service management procedures

86.5 To configure a dynamic service policy

86.5.1 Steps

1

Choose Policies→Dynamic Services→Dynamic Service Policy from the NFM-P main menu. The Dynamic Service Policy form opens.

2

Click Create or choose a dynamic service policy and click Properties. The Dynamic Service Policy (Create|Edit) form opens.

3

Configure the required general parameters.

4

Select a RADIUS script policy for the dynamic service policy.

5

Select a CLI user for the dynamic service policy.

6

To configure RADIUS or local authentication for the dynamic services policy:

RADIUS authentication and local authentication are mutually exclusive.

1. Click on the Authentication tab and do one of the following:
   - Select a RADIUS server policy and configure the RADIUS Password parameter.
   - Select a local authentication database.
2. Save your changes and close the form.

7

To configure the accounting instances of the dynamic services policy:

1. Click on the Accounting tab. Each dynamic services policy has two accounting instances.
2. Choose an accounting instance and click Properties. The Accounting Instance form opens.
3. Configure the parameters.
4. Select a RADIUS server policy for the accounting instance.
5. Configure the parameters in the Update Interval panel.
6. Save your changes and close the form.

8

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs

END OF STEPS

86.6 To configure a local authentication database

86.6.1 Steps

1

Choose Policies→Dynamic Services→Local Authentication Database from the NFM-P main menu. The Local Authentication Database form opens.

2

Click Create or choose a local authentication database and click Properties. The Local Authentication Database (Create|Edit) form opens.

3

Configure the required general parameters.

4

To configure users in the local authentication database:

1. Click on the Users tab.
2. Click Create or select an existing user and click Properties. The Dyn Svc Local Auth Db User form opens.
3. Configure the required general parameters.
4. Click on the SAP User tab to configure per-SAP users for the database user.
5. Click Create or select an existing SAP user and click Properties. The Dyn Svc Local Auth Db Sap form opens
6. Configure the required general parameters.
7. Select a dynamic service policy.
8. Click on the Accounting tab to configure accounting instances for the SAP user.
9. Click Create or select an existing accounting instance and click Properties. The Dyn Svc Local Auth Db Acct form opens.
10. Configure the required parameters.
11. Save your changes and close the forms.

5

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs

END OF STEPS

86.7 To configure an NE for dynamic service

86.7.1 Steps

1

Choose Manage→Service→Dynamic Service NE Configuration from the NFM-P main menu. The Dynamic Service NE Configuration form appears.

2

Choose an NE and click Properties. The Dynamic Service NE Configuration (Edit) form opens.

3

Disable the Disable Creation parameter to allow the dynamic creation of network objects on the NE.

4

Define an ID range using the Start and End parameters. Dynamically-created objects are created using IDs from within the specified range.

5

Configure the Access-Accept parameter in the Timers panel.

6

Save the changes and close the form.

END OF STEPS

86.8 To list dynamically created objects on an NE

86.8.1 Steps

1

Choose Manage→Service→Dynamic Service NE Configuration from the NFM-P main menu. The Dynamic Service NE Configuration form appears.

2

Configure the filters and click on the Search button. A list of NEs that support dynamic services appears.

3

Choose an NE and click Properties. The Dynamic Service NE Configuration (Edit) form opens.

4

Click on one of the following tabs to search for and list the related dynamically created objects on the NE:

Click on one of the following tabs to search for and list the related dynamically created objects on the NE:

- Dynamic SAP Info
- Root Objects
- Script Snippets
- Service Sites

Note: The list of objects in the Dynamic SAP Info tab is automatically updated.

5

Close the forms.

END OF STEPS

86.9 To view the dynamic services activity log

86.9.1 Steps

1

Choose Manage→Service→Dynamic Service NE Configuration from the NFM-P main menu. The Dynamic Service NE Configuration form appears.

2

Choose an NE and click Properties. The Dynamic Service NE Configuration (Edit) form opens.

3

Click on the Dynamic Service Activity tab.

4

Configure the filter and click Search. A list of dynamic service actions appears.

5

Close the forms.

END OF STEPS

87 Application assurance

87.1 Overview

87.1.1 Purpose

This chapter provides overview and procedural information about the NFM-P application assurance functions.

87.1.2 Contents

Application assurance

87.2 Overview

87.2.1 General information

Application Assurance (AA) is a service-enabling technology that enhances QoS functions by providing additional traffic control, traffic diversion, application identification, statistics collection, and data reporting.

AA and dynamic subscriber policy control allow a broadband network to provide application-based subscriber management for Internet access.

The fundamental elements of AA processing are:

- identification of the traffic on a per-flow or per-session basis
- policy-based treatment of the identified traffic

Shallow packet inspection (SPI), inspects Layer 1 to Layer 3 traffic information and does not provide application-based QoS information. AA enables deep packet inspection (DPI) of subscriber traffic using policies that define the action to perform for specific traffic types on a per-subscriber basis.

Subscriber traffic is selected for processing by AA, then inspected by an ISA-AA MDA or ESA VM in a logical group. See 87.3 “ISA-AA groups and partitions” (p. 2794) for more information about ISA-AA groups and partitions.

Note: AA policies can be configured on an NE only when an ISA-AA group exists on the NE.

The benefits of AA for residential and business service providers are:

- enhanced application-level QoS using policy-based traffic management
- traffic flow thresholds and threshold-crossing notifications
- application-aware reporting and performance analysis
- greater network security
- high scalability and flexibility to control network costs

The NFM-P supports AA functions on the 7450 ESS and 7750 SR.

Note: AA is not supported on a single-slot chassis.

87.3 ISA-AA groups and partitions

87.3.1 General information

The NFM-P supports the configuration of ISA-AA groups and partitions. An ISA-AA partition is a unique child object of an ISA-AA group. The partition can be assigned an AA policy. There is no relationship between partitions of different ISA-AA groups. You can configure up to 128 partitions per group.

You can divide an ISA-AA group into partitions that are dedicated to VPN-specific AA services. A partition can have a set of VPN-specific custom protocols, applications, application group definitions, policy definitions, and reporting. Each partition policy can be divided into multiple application QoS policies using ASOs.

To apply one policy to multiple groups or partitions, use a policy sync group; see 87.16 “Policy sync groups” (p. 2808).

87.3.2 ISA-AA groups

You can perform the following operations on an ISA-AA group:

- Assign ISA-AA MDAs or ESA VMs and create AA partitions.
- Specify FCs to be diverted for inspection, and choose the AA policy to apply to the group.
- Configure redundancy and a bypass mode to protect against equipment failure.
- Configure QoS on IOMs that host ISA-AA traffic.
- Configure ISA capacity planning using low and high thresholds.

Residential services are an example where all AA services can be configured as part of a single group that includes all ISA-AAs. The configuration provides the management of common applications and reporting for all subscribers and services, with common or per-customer AQP using ASO characteristics to divide the AQP of the ISA-AA into per-application profile QoS policies.

Multiple ISA-AA groups can also be used to create separate services based on different sets of common applications, traffic diversion needs, or different redundancy models.

Multiple ISA-AA groups can be used for:

- a mix of residential and business customers
- different business VPN verticals
- business services with a common template base but different levels of redundancy, FC diversion, or scaling per group

See 13.5 “To configure an ISA-AA group and ISA-AA partitions” (p. 415) for information about configuring ISA-AA groups.

87.3.3 ISA-AA partitions

ISA-AA groups and partitions improve the scaling of policies. When partitions are configured, application identification and policy configuration apply only to the specified partitions in the ISA-AA group, and not to any other partition in the AA group. When partitions are not configured, the ISA-AA group acts as a single partition.

Although the definition of application profiles and related ASO characteristics is in the context of a partition, each application profile name in an NE configuration must be unique. Application, application group, and AQP definitions are specific to a partition.

ISA-AA partitions support accounting and customized reporting for every AA subscriber associated with a partition, and allow you to do the following:

- Define different types of reporting and accounting policies for different partitions in a single AA group.

- Display AA group protocol statistics with partition visibility; for example, you can view protocol counts for each partition in a group.

When you create or delete an ISA-AA partition, a default AA accounting policy is automatically created in or deleted from the ISA-AA partition.

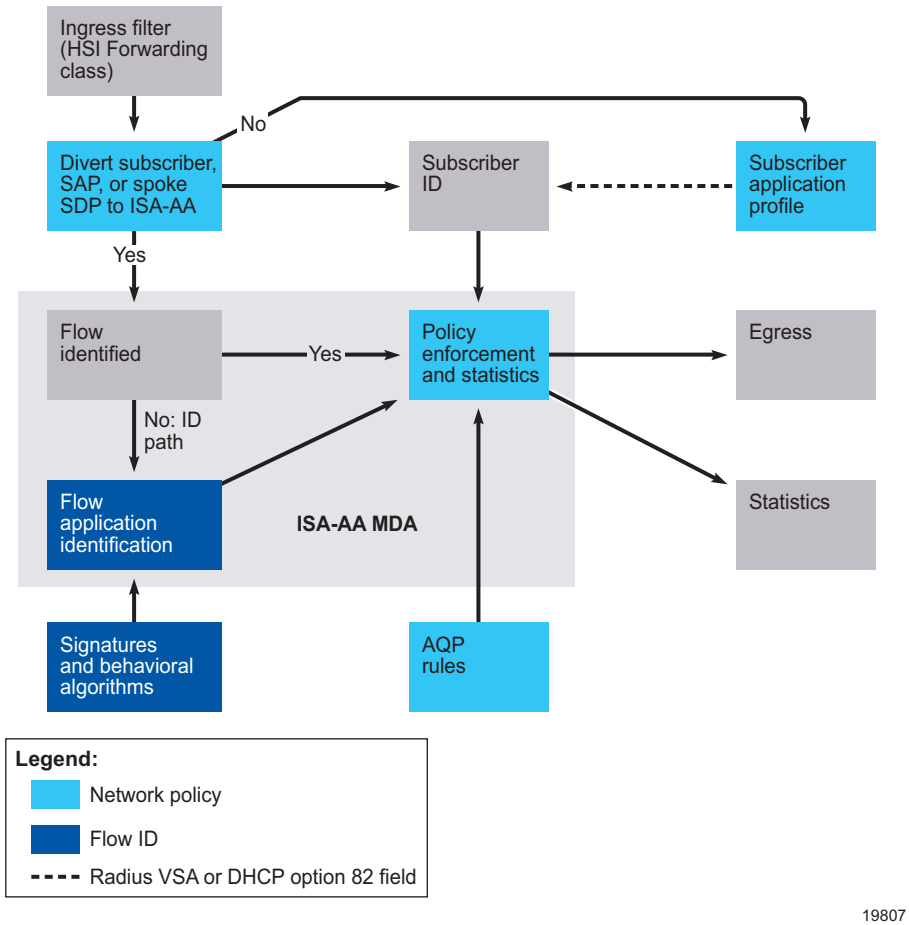
See 13.5 “To configure an ISA-AA group and ISA-AA partitions” (p. 415) for information about configuring ISA-AA partitions.

87.4 AA components

87.4.1 General information

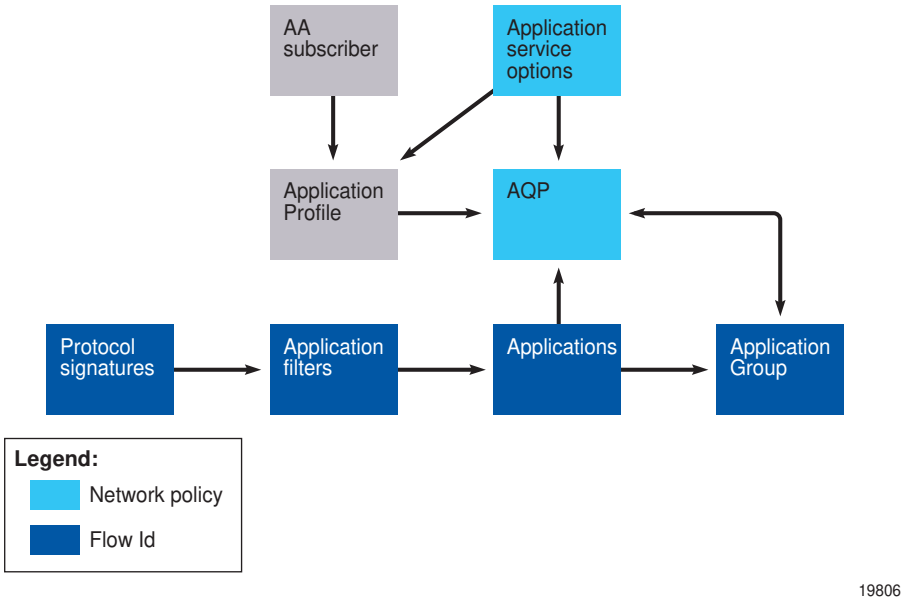
The NFM-P supports AA component creation and configuration using configuration forms and scripts. The following figure shows the AA components.

Figure 87-1 AA components



The following figure shows the relationship between AA components.

Figure 87-2 AA policy structure



87.5 AA group policies

87.5.1 Components

An AA group policy includes the following components, as required:

- applications
- application groups
- charging groups
- application profiles
- application filters
- application service options (ASOs)
- application QoS policies (AQPs)
- custom protocols

The following table describes the components.

Component	Description
Application	Identifies the type of IP payload in the subscriber flow An application provides a definition and description to the application names supported by an application filter.
	Defaults One predefined application (“unknown”) is provided. The unknown application cannot be modified. All other applications must be configured.
	Examples/use cases Webscale companies, CORBA, DNS Server
	Notes The application name is a key match criterion within the AQP rules that are applied to the IP traffic of a subscriber. The application name is also the unique identifier of the application object for reporting systems such as NSP Analytics Reports. Network operators can change the application group that an application is associated with, or view the application filters that define the application.
Application group	A container for multiple applications
	Defaults A set of default application groups is provided. At least one default application group (“unknown”) must be associated with each NE. The default application groups cannot be modified.
	Examples/use cases File hosting, gaming, mail, peer to peer
	Notes Multiple applications can be assigned to an application group. An application can only belong to one group. Applications that are not assigned to an application group are automatically placed in the “unknown” application group.

Component	Description
Charging group	A set of applications that you need to bill for in a specific way, such as usage-based billing
	Defaults If an application is not associated with a charging group, a default charging group is assigned. If tethering detection or flow attribute matching is in use with 7450 ESS, a default tethered charging group can be configured.
	Examples/use cases Applications that are free to the end user can all be associated with a zero-rate charging group. A use case for charging groups is bill-shock avoidance.

Component	Description
Application profile	Enables AA service for traffic to and from an ESM subscriber, ESM subscriber host, SAP, or spoke SDP. Each application profile is unique and defines the AA service that the AA subscriber receives. The type of traffic is configured in the system-wide configuration of QoS FCs to be diverted to the ISA-AA MDA for subscribers with AA enabled. The FC is used for any subscriber traffic that a service provider needs to inspect using AA. A subscriber can be assigned an application profile that affects every host of the subscriber. For SAP or spoke SDP AA subscribers, an application profile can be assigned that affects the traffic originating from or destined for the SAP or spoke SDP. For subscribers with application profiles that enable AA, traffic is diverted to the active ISA-AA MDA using ingress QoS policy filters. The filters identify classes that can be diverted for AA. The system identifies and diverts traffic for any subscriber to the ISA-AA MDA, according to the application profile. Diversion to the ISA-AA MDA depends on the ISA-AA MDA status. If a subscriber is not configured to divert traffic to the ISA-AA MDA, normal ingress forwarding occurs.
	Defaults One predefined application profile (“default”) is provided. By default, subscribers are not assigned to an application profile and traffic is not diverted for AA analysis.
	Notes • Application profiles are customer-defined and created using the configured ASO characteristics. • Application profiles allow ASO characteristics to be associated with AA subscribers. • Local instances of the application profile are configured to bind to specific objects of an NE (for example, L2 access interface, SAP, local subscriber explicit map entry, and so on). • Application profiles can be assigned only when ISA-AA cards are assigned to an ISA-AA group. • Global application profiles must be manually distributed to the NEs. • Application profiles can be assigned a capacity cost for subscriber load balancing among ISAs within the AA group.

Component	Description
Application filter	Application filters are provided as an indirect action between protocols and applications to allow the addition of variable parameters, for example, port numbers and IP addresses, to an application definition. An application filter contains numbered entries that define the use of protocol signatures and other application criteria. Multiple filter entries can be used to define an application, but each application filter entry maps to one application.
	Notes A traffic flow may have multiple filter entries. The entries are applied to the flow sequentially, and the matching entry with the lowest ID value is applied first. A traffic flow can be assigned to only one application. You can accommodate the insertion of new entries in a list of entries by renumbering one or more of the existing entries using a GUI or OSS client. See87.31 “To renumber application filter entries” (p. 2842) for information about renumbering application filter entries using the GUI. An application must be configured before the associated application filter is defined.

Component	Description
Application service option (ASO)	A series of operator-defined application characteristics that define the service provider and customer network functions that are common to sets of subscribers ASOs prevent subscribers from requiring each subscriber-specific entry in the application QoS policies for standard network services. ASOs are assigned one or more characteristic values to define service offerings to customers. ASO characteristics are used: • as input to application profiles • by application QoS policies to influence how specific traffic is checked and how policies are applied
	Examples/use cases • Entry for each managed application group; for example, VoIP, P2P, and HTTP • Multiple entries where specific applications in an application group can be individually managed as service parameters; for example, HTTP content from a specific content provider, or streaming video from network television or games • HSI tiers, for example, Gold, Silver, and Bronze, that specify bandwidth levels • Bandwidth parameters for each service option
	Notes You can configure ASO characteristics for a subscriber using an AA subscriber policy override. An AA subscriber policy override can be configured for a SAP or spoke SDP binding. The AA subscriber must have an application profile assigned, or the subscriber policy override is rejected. You can retrieve on demand the ASO values that are assigned to a SAP or spoke SDP binding subscriber from the properties form of the subscriber. In a typical application, ASOs define the HSI service parameters. • ASOs are optional; AA can check the subscriber IP traffic without the use of application service options. • ASOs can be configured for each AA group policy. • ASO characteristics are used to define application profiles and operator-defined AQP rules. • The set of ASOs represent network-wide menus of service capabilities that are available to subscribers.

Component	Description
Application QoS policy (AQP)	List of rules that define the match criteria and action to be performed on all traffic flows. The AQP rules use the application groups, applications, and so on, as the match criteria. The output of the AQP rules defines the policy actions to perform.
	Notes AQP rules consist of match and action criteria: • Match—Refers to the criteria used to identify a flow in order to apply actions such as dropping, forwarding, mirroring, and policing of bandwidth and flow. Matches cannot be made against protocols. Match criteria can be a combination of the following: - applications or application groups - ASO characteristics - flow direction - AA subscribers - flow source or destination IP address and/or port - flow attributes • Action—Defines AA actions to be applied to traffic. For example, you can apply a set of actions such as bandwidth policing, packet discards, QoS remarking, and rate limiting to a flow.
Custom protocols	Configurable strings of up to 16 hexadecimal octets for pattern-matched application identification in the payload of TCP- and UDP-based applications The match applies to the client-to-server, server-to-client, or any direction for TCP-based applications, and to any direction for UDP-based applications.
	Notes You can configure a custom protocol description, custom protocol ID, and shutdown. When a custom protocol is administratively disabled, traffic is identified as though the protocol is not configured. Custom protocols and Nokia protocols are distinct; the span of a custom protocol is limited to the group or partition associated with an AA policy. Nokia protocols span all groups and partitions. All application filter entries, except strings, are supported. Custom protocol statistics collection on an ISA-AA partition group or special study subscriber is supported.

87.6 AA Cflowd

87.6.1 Data collection

ISA-AA groups and partitions support Cflowd sampling and TCP performance data collection for AA applications and application groups. AA Cflowd statistics are collected by the NSP, if flow collection

is enabled in the NSP deployment. The NSP can forward the data to an OSS or to NSP Analytics Reports for reporting and analysis.

Cflowd analysis is performed on a per-flow basis. Statistics are created at the end of a flow session. Standard Cflowd sampling collects the source and destination addresses and the protocol used, AA Cflowd also collects the start time, duration, and context IP address. This additional information can be used to customize network usage reporting.

If an NFM-P deployment includes an auxiliary database, you can store the AA Cflowd statistics for use as the source data for reports in NSP Analytics Reports.

An ISA-AA group supports one Cflowd instance. See Chapter 13, "Logical group object configuration" for information about configuring AA Cflowd on an ISA-AA group, and the *NSP Statistics Management Guide* for AA flow configuration information.

AA Cflowd policies

You can use the NFM-P to create AA Cflowd group policies for AA groups and partitions. The parameters in an AA Cflowd group policy are the same as the Cflowd parameters that you configure on an ISA-AA group.

When you use an AA Cflowd group policy to specify the AA Cflowd collection criteria, you can apply the policy to multiple AA sites. You can also use the policy as the master policy in a policy sync group to ensure that the distributed AA Cflowd group policies remain synchronized with the master, and to facilitate the deployment of a policy update to multiple local policy instances at one time.

AA Cflowd templates

You can apply a cflowd template to an AA Cflowd policy on the 7750 SR NE. The policy must either be for an ISA-AA group with partitions disabled, or be a group level policy for an ISA-AA group with partitions enabled. Templates are not available for a partition level AA Cflowd policy. Cflowd template allows for groups of parameters and fields to be collected together under a combined heading such as Volume.

See 87.33 "To configure an AA Cflowd group policy" (p. 2844) for AA Cflowd group policy configuration information. See 87.16 "Policy sync groups" (p. 2808) for information about policy sync groups.

87.7 AA protocol signatures

87.7.1 Protocol signature set

The NFM-P generates a set of signatures that identify AA protocols.

The signature set includes:

- protocol support summary—list of protocols that can be identified with the load using a combination of pattern and behavioral techniques. The protocols are used to generate statistics by protocol and as input in combination with other information to identify applications.
- pattern signatures—set of pattern-match signatures used in analysis
- behavior signatures—set of diagnostic techniques used in analysis

Because protocol signatures are intended to be the most basic block of application identification, other AA components, such as application filters, are provided to further customize protocol signatures. Customization reduces the need for a new protocol signature load when a new application may need to be identified.

Each protocol can be referenced in the definition of one or more applications by the application filter definition. The assignment of each supported protocol to an application filter or application is optional, and allows the addition of new signature protocols without the need to update the application filter and applications.

Protocol signature upgrades

The NFM-P supports protocol signature upgrades without affecting policy behavior. You can obtain new protocol signatures by dynamically upgrading only the ISA-AA MDA software on an NE, if the new software is from the same major release. All new signatures in R2 or later of a major release are disabled during an upgrade to ensure that policies and services are not affected. See 26.16 “To upgrade the ISA-AA MDA software” (p. 795) for information about how to upgrade the ISA-AA MDA software.

If the software is from a different major release, you must upgrade the entire device to obtain the new signatures. See “NE software upgrade overview” (p. 771) for information about performing device software upgrades.

The protocols in R1 of a release are designated as parent signatures and cannot be disabled. The protocols must be enabled on a per-protocol basis to take effect. See 87.70 “To enable an AA protocol signature” (p. 2884) for information about enabling AA protocols.

87.8 Dynamic experience management

87.8.1 ANL capacity monitoring

Dynamic Experience Management (DEM) employs DPI and congestion control to maintain QoE. For each ANL, or bandwidth bottleneck point, the system continuously monitors the capacity at the ANL. If congestion is predicted or detected at an ANL, the DEM gateway uses bandwidth policers to give priority to delay-sensitive applications.

Multiple ANLs can be configured when multiple ISAs are configured within an ISA-AA group; see 87.36 “To configure an AA Access Network Location” (p. 2849).

87.9 AA policers

87.9.1 Bandwidth or flow limitation

Policers allow IP traffic on an interface to be limited.

AA policers can be bandwidth or flow limiting, and can have one of the following scopes:

- system scope—limits all traffic entering an ISA-AA MDA
- subscriber scope—limits apply only to the traffic of a subscriber

After a policer is assigned by an AQP for one traffic direction, the same policer cannot be assigned in the other direction. AQP rules with policer actions must specify a traffic direction other than “both”.

Congestion override

Congestion override can be configured on an AA policer with a subscriber scope. The policer is triggered when the subscriber ANL is in a congestion state. You can configure the congestion thresholds in the policer configuration form. Congestion override configuration can assist with DEM.

Note: If both congestion override and ToD override are configured and conflict, the congestion override will take precedence.

See 87.26 “To configure an AA policer” (p. 2830) for configuration information.

87.10 AA GTP firewalls

87.10.1 Stateless GTP firewall

You can use the NFM-P to create a stateless GTP firewall using GTP and SCTP traffic filters, and enforce a GTP flow count limit in an AA flow-count policer. See 87.27 “To configure an AA GTP firewall” (p. 2831) for information about AA GTP firewall configuration.

You can view the local GTP and SCTP filter statistics from the Statistics tab of a local filter properties form. The GTP firewall statistics for an ISA-AA group or partition are available on the Statistics tab of the group or partition properties form.

87.10.2 GTP-c firewall for S8 and Gn

You can use the NFM-P to create a firewall for AA on Gn or S8 interfaces. This type of firewall ensures that total traffic to or from the SGSN is enforced at a configured rate.

See 87.28 “To configure an AA GTP-c firewall for S8 or Gn” (p. 2835) for information about AA GTP-c firewall configuration.

You can view the local GTP filter statistics from the Statistics tab of a local filter properties form. An ISA card has to be assigned as a group member for the statistics to be collected. The GTP firewall statistics for an ISA-AA group or partition are available on the Statistics tab of the group or partition properties form.

87.11 AA statistics TCAs

87.11.1 Threshold-crossing alarms

Threshold-crossing alarms (TCAs) can be raised for events related to excessive flow counts or flow rates on an ISA-AA group or partition. The TCA mechanism enhances firewall security using AA policers and the watermarks specified in GTP, SCTP, or session filters. See 87.41 “To configure an AA statistics TCA” (p. 2854) for configuration information.

87.12 AA flow watermarks

87.12.1 Flow-table consumption monitoring

AA supports the configuration of high and low thresholds (known as “watermarks”) to monitor flow-table consumption by traps and logs, and also to monitor data path CPU usage. The thresholds are established to alert operators when the flow table approaches maximum capacity, or when AA CPU usage is excessive. When a high threshold is reached, the NFM-P raises an alarm that clears when the alarm condition is no longer present. The alarm is viewable from the Faults tab of the associated ISA-AA group properties form.

AA flow watermark statistics are available from the Statistics tab of an ISA-AA group properties form.

See 87.39 “To configure an AA flow watermark” (p. 2852) for configuration information.

87.13 AA transit IP and transit prefix policies

87.13.1 Transit subscriber discovery

AA transit IP and transit prefix policies define how AA transit subscribers are created by an NE. Transit IP policies can be configured to discover dynamic transit subscribers via DHCP or RADIUS, and can also be configured with a list of static transit subscribers. Transit IP policies can also be configured to discover dynamic transit subscribers when traffic is detected on a parent SAP or spoke SDP binding.

Transit prefix policies allow you to specify transit subscribers by using network or subscriber IP ranges.

AA transit subscribers can persist in the NFM-P database. Transit subscriber aggregators allow you to aggregate multiple database persisted transit subscriber instances for VPN sites.

Because of the potentially high rate at which AA transit subscribers are created and deleted, a throttling mechanism is available on the NE for the associated creation and deletion traps. See 87.50 “To configure trap throttling for AA transit subscriber creation and deletion” (p. 2864) .

87.14 AA HTTP redirect policies

87.14.1 HTTP/HTTPS redirection

AA HTTP redirect policies allow you to configure HTTP/HTTPS redirection, specify templates for local NE termination of HTTP errors, and configure web browser redirection to customized error pages according to HTTP error codes. See “Application assurance procedures” (p. 2819) for configuration information.

87.15 AA URL Filter policies

87.15.1 URL filtering

AA URL filter policies allow you to configure filtering of URL access by category. This will allow for parental controls for household internet access, and control of access to the Internet for smart devices.

An AA URL filter can filter based on an AA URL list, or use an ICAP server or a web service to communicate with an external server or database to determine filtering decisions. See 87.68 “To configure an AA URL filter” (p. 2880) for configuration information.

87.16 Policy sync groups

87.16.1 Centrally defined policy components

Policy sync groups allow AA group policy or AA Cflowd policy components to be centrally defined and applied to multiple ISA-AA groups and partitions. A policy sync group includes a master policy that defines a set of common policy components, and a list of member AA group or AA Cflowd policies that are synchronized with the master.

A synchronization action that you perform using a policy sync group affects only the classes named in the group, and applies to each AA group and partition that is a member of the policy sync group.

The following synchronization options are available:

- The master policy classes override the member policy classes.
- The master policy classes are added to each member policy.

After you create a policy sync group, you can use the policy sync group to do the following:

- Distribute AA group policy or AA Cflowd group policy updates to all members using the Synchronize function.
- Audit the member policies to identify variances from the master policy settings.
- Compare two member policies.

If a policy audit identifies a difference between the master policy and a member policy, the NFM-P raises an alarm. The differences are listed as the affected objects of the alarm.

See 87.34 “To configure a policy sync group” (p. 2846) for policy sync group configuration information. See 87.35 “To audit, compare, or synchronize policies using a policy sync group” (p. 2848) for information about how to use a policy sync group to compare, audit, or synchronize member policies.

AA reporting

87.17 Overview

87.17.1 General information

AA reporting attributes are metadata parameters that specify how application performance data is reported to systems such as NSP Analytics Reports; the parameters are not deployed to NEs.

The parameters are configurable on the following object properties forms:

- AA application
- AA application group
- subscriber objects:
  - subscriber instance
  - service
  - SAP
  - customer
  - spoke SDP binding
  - transit subscriber

See 87.54 “To enable application performance reporting on a service” (p. 2867) , 87.55 “To configure application performance reporting on a SAP or SDP binding” (p. 2868) , 87.56 “To configure application performance reporting for a transit subscriber” (p. 2869) , and 87.57 “To disable application performance reporting on a service” (p. 2870) for configuration information.

87.17.2 Enabling reporting

Application performance reporting enables AA performance and flow-based volume reporting to functions such as NSP Analytics Reports.

For increased reporting granularity, and to reduce the amount of reported information, you can use default DCP groups to segregate the Internet or intranet traffic of an entire network, an IP address range, or a single IP address.

You can create custom DCP groups for service objects to report only the required business application data for a service that has an application profile. See “Default and custom DCP groups” (p. 2811).

A reporting system can use the collected data to perform Apdex analysis. Apdex measures the quality of end-user experience with respect to Internet applications.

See “AA reporting” (p. 2809) for more information about application performance reporting.

87.17.3 Apdex reporting

Application performance index, or Apdex reporting, is a standard method of estimating the end-user satisfaction associated with online application delivery; for example, you can configure Apdex to monitor a VoIP or video stream, which requires very low delay.

Apdex measures quality indicators that include the following:

- round-trip time
- mean delay
- standard deviation delay
- packet loss

Visit the Apdex Alliance website for detailed Apdex information.

The NFM-P supports Apdex threshold configuration based on the following:

- application type
- application delay sensitivity
- application tier level

The NFM-P uses tiers to classify the application types. An Apdex tier signifies the traffic importance and specifies which set of application performance thresholds are in effect.

Each tier has default end-user frustration and tolerance thresholds for quantifying the application performance. You can modify the threshold values for each tier to attain the desired quality of end-user experience.

For residential Apdex, the thresholds are configurable for an AA group or partition, application group, and application. A child object, for example, an application, can inherit the threshold values from the parent application group or AA partition. A child object can also override the parent thresholds.

You can also configure tier-based Apdex reporting for the following service objects:

- spoke SDP bindings
- access interfaces
- business transit subscribers

Note: You must associate an application profile with an object in order to configure AA reporting on the object.

87.17.4 IP detail reporting

You can configure service-level IP detail reporting, which collects information about the most active end users, by volume, of applications and applications groups.

The following service types support IP detail configuration:

- IES
- VLL Epipe
- VLL Ipipe

- VPLS
- VPRN

87.17.5 Usage-based billing

The NFM-P supports application-specific reporting to systems such as NSP Analytics Reports based on configurable charging groups. You create charging groups as child objects of an AA group policy and can assign them to the following:

- applications
- application groups
- charging group thresholds
- AA subscriber statistics objects

You can assign one charging group to multiple applications or application groups, and can associate an application or application group with only one charging group.

You can configure charging groups with specific usage quotas and notification thresholds, and assign the thresholds to application profiles.

87.17.6 DCP groups

An NFM-P operator can configure business or residential DCP groups that specify how to summarize the collected reporting data for upstream reporting systems, which use the group specifications as an aggregation framework for analysis.

A DCP group organizes subscriber traffic based on the IP address range in a subnet rule that represents a subscriber address range or the server address range of a content provider. A DCP group can contain up to 100 subnet rules.

A residential DCP group is configured in an AA group policy. A business DCP group is configured as part of a service, for example, on the Application Assurance tab of an Epipe. Either can contain up to 65 535 DCP groups.

You can use DCP groups to help identify traffic patterns such as the following:

- the volume of application traffic delivered to a specific regional market, for product management or policy development
- the application performance in a specific regional market; for example, how streamed video that is external in origin affects a local video-on-demand service
- the source of continuous high-volume traffic that is external in origin

You can use the NFM-P policy sync group function to synchronize the DCP groups in one AA group policy with other AA group policies. See 87.16 “Policy sync groups” (p. 2808) in 87.4 “AA components” (p. 2796) for more information.

Default and custom DCP groups

When you enable application performance reporting in an AA group policy or service, the NFM-P creates default IPv4 and IPv6 Intranet and Internet DCP groups that separately aggregate all

subscriber and content-server traffic. You can add DCP subnet rules to a default DCP group, or create multiple custom DCP groups per service.

You can associate one of the following subscriber objects with a custom DCP group in a service:

- service
- SAP
- customer
- spoke SDP binding
- business transit subscriber

A SAP or spoke SDP binding requires an application profile before you can associate it with a custom DCP group; a business transit subscriber is associated with an AA group that is configured for use in the VPN context.

If application performance reporting is disabled in a global AA group policy, the NFM-P retains the associated default and custom DCP groups for future use.

87.18 Flow attributes

87.18.1 Additional AA classification

Flow attributes allow for further classification of flows, other than according to application or application group. Flow attributes can be marked against packets of a flow.

Attributes are assigned to a flow based on characteristics of the flow. A flow may have zero or more attributes assigned to it including competing or conflicting attribute values such as Video and Video ABR.

Flow attributes can be based on the following:

- application filter provisioned: the flow attribute is based on the application filter definition
- flow state derived: the flow attribute is derived by an algorithm based on the protocol in use

Including flow attributes in an AQP allows match criteria and actions based on flow attribute, for example, application of a bandwidth policer or usage-based billing. To include flow attributes in an AQP, flow attribute matching must be enabled in the ISA-AA Group.

AA accounting statistics collection

87.19 Overview

87.19.1 General information

AA accounting statistics provide information about application use in a network. You can configure AA accounting to collect and report statistics when at least one ISA-AA MDA is active. The AA accounting statistics provide information about application use on a SAP or spoke SDP, or by a subscriber.

Note: You cannot use a local AA accounting policy on an NE of a different release to update a global policy using the policy synchronization function; you must use a local policy from the same release of an NE.

AA accounting collects statistics on traffic flows. The NFM-P can collect the following AA statistics types:

- AA application
- AA application group
- AA protocol
- AA subscriber protocol (special study)
- AA subscriber application (special study)
- AA subscriber custom record

The statistics data can be viewed in graphical or tabular form using the NFM-P GUI, or forwarded for reporting and analysis to systems such as a third-party server, and used to create reports in NSP Analytics Reports. You can also configure the NFM-P to export the data to XDR-encoded IPDR files for OSS client retrieval. See 87.19.2 “IPDR data export” (p. 2813) in this section for more information.

AA uses the NFM-P and NE accounting statistics and logging capabilities to collect AA accounting statistics. See “Statistics collection in the NFM-P” in the *NSP NFM-P Statistics Management Guide* for general information about configuring and collecting accounting statistics. See 87.37 “To configure an AA accounting policy” (p. 2849) for information about configuring an AA accounting policy.

The NFM-P can be configured to collect statistics for each protocol and application of a specific subscriber. For more comprehensive traffic monitoring, you can enable AA statistics collection on a specific NE for a subset of subscribers. An NE can have only one policy for each AA statistics type that is enabled.

87.19.2 IPDR data export

To support data analytics and reporting functions, the NFM-P can export AA accounting statistics data to files on a main or auxiliary server station in one or both of the following formats:

- IPDR format, using XDR encoding
- format for NSP Analytics Reports

The exported files are stored in the aaAccountingStats directory under the OSS XML output directory on a main or auxiliary server station. Each filename has an AA_*type* prefix, where *type* represents the statistics type. Each filename also includes the associated NE IP address.

Note: The tethering statistics type is modeled and represented differently in each format:

- IPDR:
  TETHER—filename prefix is AA_TETHER
- NSP Analytics Reports::
  SUMMARY—filename prefix is AA_SUMMARY

You can enable and configure the export function during an NFM-P system installation or upgrade, or afterward, using 87.38 “To configure AA accounting file export” (p. 2850).

87.19.3 Special study statistics

The AA subscriber protocol and AA subscriber application statistics are special study statistics for detailed accounting statistics collection on a limited number of subscribers, SAPs, or spoke SDPs on an NE. The number of subscribers, SAPs, or spoke SDPs is limited to constrain the volume of generated statistics.

Special study statistics collection is required for certain reports in NSP Analytics Reports.

Special study statistics are enabled by adding subscribers, SAPs, or spoke SDPs to a list in an ISA-AA group or partition on an NE for detailed traffic monitoring. When a subscriber is on a special study list, the ISA-AA creates one statistics record for each application and application group that is associated with the subscriber. When a SAP or spoke SDP is on a special study list, the ISA-AA creates one statistics record for each application, application group, and protocol flow on the SAP or spoke SDP. See 13.5 “To configure an ISA-AA group and ISA-AA partitions” (p. 415) for information about configuring special study objects in an ISA-AA group.

87.19.4 Subscriber custom record statistics

An AA subscriber custom record accounting policy applies to all subscribers, SAPs, and spoke SDPs in an ISA-AA group or partition for a specified set of AA protocols, applications, and application groups. The policy enables statistics collection on only the specified objects, which limits the volume of collected data and the statistics collection processing load. For example, an NFM-P operator may require statistics for only three application groups and 10 applications. You can view and configure the AA statistics objects of an AA group or partition from the AA Subscriber Stats Objects tab of an application, application group, or charging group properties form.

DSM AA statistics export

When the Subscriber Scale of an ISA-AA Group is set to Lightweight Internet, you can enable the export of AA statistics according to the settings in a RADIUS accounting policy. You enable the function in the application, application group, and charging group configured as subscriber statistics objects in an AA group policy, and in the AA Subscriber Custom Record accounting policy configuration of an AA accounting policy.

87.19.5 Monitoring usage by charging group

You can enable usage monitoring in an AA Subscriber Custom Record accounting policy, and optionally export the usage statistics to a RADIUS accounting policy. See 87.73 “To configure subscriber usage monitoring” (p. 2887) for configuration information.

Workflows to configure AA

87.20 Workflow to perform hardware procedures for AA configuration

87.20.1 Stages

1

Configure the required ISA-AA groups and partitions on NEs. See 13.5 “To configure an ISA-AA group and ISA-AA partitions” (p. 415) .

2

Configure AARP instances on an NE. See 87.25 “To configure an AARP instance on an NE” (p. 2829) .

87.21 Workflow to manage AA policies

87.21.1 Stages

1

Configure AA group policies using 87.23 “To configure an AA group policy” (p. 2819) .

As required, configure the following components:

- ASOs and ASO overrides
- application profiles
- application groups
- charging groups
- applications
- application filters
- custom protocols

2

Configure AQPs for AA group policies. See 87.24 “To configure an AQP” (p. 2825) .

3

Configure AA policers. See 87.26 “To configure an AA policer” (p. 2830) .

4

Create a policy sync group. See 87.34 “To configure a policy sync group” (p. 2846) .

5

Configure an AA flow watermark policy. See 87.39 “To configure an AA flow watermark” (p. 2852) .

6

Configure AA transit IP policies and transit prefix policies as required.

1. Configure AA transit IP policies. See 87.46 “To configure an AA transit IP policy” (p. 2860) .
2. Configure AA transit prefix policies. See 87.47 “To configure an AA transit prefix policy” (p. 2861) .
3. Configure database persisted transit subscriber aggregators. See 87.48 “To configure a database persisted transit subscriber aggregator” (p. 2862) .
4. Associate database persisted transit subscribers with aggregators. See 87.49 “To associate a database persisted transit subscriber with an aggregator” (p. 2863) .
5. As required, view the database persisted transit subscriber information. See 87.51 “To view database persisted transit subscriber information” (p. 2864) .

7

Configure usage-based billing as required:

1. Enable usage-based billing at the application profile level. See 87.52 “To configure usage-based billing for an application profile” (p. 2865) .
2. Associate applications with charging groups. See 87.53 “To associate an application with a charging group” (p. 2866) .

8

Configure HTTP policies as required:

1. Configure AA HTTP redirect policies. See 87.59 “To configure an AA HTTP redirect policy” (p. 2872) .
2. Configure AA HTTP error redirect policies. See 87.58 “To configure an AA HTTP error redirect policy” (p. 2871) .

9

Configure AA protocol signatures and enable inactive protocols, as required. See 87.70 “To enable an AA protocol signature” (p. 2884) .

10

As required, delete AA objects or records.

a. Delete an AA application, application group, or custom protocol; see 87.77 “To delete an AA application, application group, or custom protocol” (p. 2892) .

b. Remove the record of an inactive AA transit subscriber from the NFM-P database; see 87.78 “To delete an inactive AA transit subscriber instance” (p. 2893) .

87.22 Workflow to manage AA reporting

87.22.1 Purpose

This workflow provides general information about configuring AA reporting. See the *NSP Statistics Management Guide* for additional information about statistics collection, and the *NSP Analytics Report Catalog* for information about NSP Analytics Reports.

87.22.2 Stages

1

Create an AA accounting policy to specify when statistics are collected from the ISA-AA MDA. See 87.37 “To configure an AA accounting policy” (p. 2849) .

2

Configure application performance reporting on a service, and configure DCP groups for application performance reporting, if required. See 87.54 “To enable application performance reporting on a service” (p. 2867) .

3

Configure application performance reporting on SAPs and SDP bindings, as required. See 87.55 “To configure application performance reporting on a SAP or SDP binding” (p. 2868) .

4

Configure reporting attributes for AA reporting on a database persisted transit subscriber. See 87.56 “To configure application performance reporting for a transit subscriber” (p. 2869) .

5

As required, view AA results.

a. View AA summary information for subscribers, transit subscribers, SAPs, and spoke SDPs on ISA-AA MDAs; see 87.72 “To view AA summary information for an ISA-AA group or partition” (p. 2886) .

b. View AA special study statistics data on an ISA-AA MDA; see 87.75 “To view AA special study statistics data” (p. 2889) .

c. View application filter hit counts on local definitions of AA group policies; see 87.74 “To view AA statistics data for an ISA-AA group or partition” (p. 2888) .

d. View application filter hit counts on local definitions of AA group policies; see 87.76 “To view AA statistics data for application filters” (p. 2891) .

Application assurance procedures

87.23 To configure an AA group policy

Note: AQP creation for an AA group policy is described separately in 87.24 “To configure an AQP” (p. 2825) .

87.23.1 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Click Create→AA Group Policy or select an AA group policy and click Properties. The AA Group Policy (Create | Edit) form opens.

3

Configure the parameters.

Note: You can set the Minimum ISA Generation parameter to 2 only if the ISA-AA group contains exclusively revision 2 ISA-AA MDAs.

4

Select a default charging group and default tethered charging group, as required.

Configure default Apdex thresholds

5

An Apdex threshold in an application or application group overrides a default threshold.

To modify a default Apdex threshold:

1. Click on the NSP Analytics Parameters tab, then on the Default Apdex Configuration tab.
2. Select an Apdex entry and click Create. The Apdex Configuration (Edit) form opens.
3. Click on the Thresholds tab.
4. Select a tier entry and click Properties. The Apdex Threshold (Edit) form opens.
5. Configure the parameters.

   A threshold value of -1 means that no value is specified.

   A frustrated threshold must be greater than the associated tolerated threshold, unless one or both values are inherited.
6. Save your changes and close the forms.

6

Repeat Step 5 to modify an additional threshold set, if required.

Create application groups

7

You can also manage application groups using the right-click contextual menu options for the Application Groups object on the AA Identification Components tab.

To create one or more application groups:

1. Click on the Application Groups tab.
2. Click Create. The Application Group (Create) form opens.
3. Configure the parameters.

   You must select the check box beside the Export ID parameter in order to configure that parameter.
4. Click on the Charging Group tab.
5. Select a charging group.
6. To configure Apdex thresholds for the application group, click on the NSP Analytics Parameters tab. Otherwise, go to 12 .

   An Apdex threshold in an application group overrides the associated default threshold configured in Step 5 .
7. Click Create. The Apdex Configuration (Create) form opens.
8. Configure the parameters.
9. Click on the Thresholds tab.
10. Select a tier entry and click Properties. The Apdex Threshold (Create) form opens.
11. Configure the parameters.

    A threshold value of -2 means that the value is inherited.

    A threshold value of -1 means that no value is specified.

    A frustrated threshold must be greater than the associated tolerated threshold, unless one or both values are inherited.
12. Save your changes and close the forms.

Create charging groups

8

To create one or more charging groups:

1. Click on the Charging Groups tab.
2. Click Create. The Charging Group (Create) form opens.
3. Configure the parameters.

You must select the check box beside the Export ID parameter before you can configure that parameter.

4. Save your changes and close the forms.

Create applications

9

You can also manage applications using the right-click contextual menu options for the Applications object on the AA Identification Components tab.

To create one or more applications:

1. Click on the Applications tab.
2. Click Create. The Application (Create) form opens.
3. Configure the parameters.

   You must select the check box beside the Export ID parameter before you can configure that parameter.
4. Click on the Application Group tab.
5. Select an application group.
6. Click on the Charging Group tab.
7. Select a charging group.
8. To configure Apdex thresholds for the application group, click on the NSP Analytics Parameters tab. Otherwise, go to 16 .

   An Apdex threshold in an application overrides the associated application group threshold configured in Step 7 .
9. Configure the Threshold Administrative State parameter on the General tab.
10. Click on the Apdex Configuration tab.
11. Click Create. The Apdex Configuration (Create) form opens.
12. Configure the parameters.
13. Click on the Thresholds tab.
14. Select a tier entry and click Properties. The Apdex Threshold (Create) form opens.
15. Configure the parameters.

    A threshold value of -2 means that the value is inherited.

    A threshold value of -1 means that no value is specified.

    A frustrated threshold must be greater than the associated tolerated threshold, unless one or both values are inherited.
16. Save your changes and close the forms.

Create application filters

10

You can also manage application filters using the right-click contextual menu options for the Application Filters object on the AA Identification Components tab.

To create one or more application filters:

1. Click on the Application Filters tab.
2. Click Create. The Application Filter (Create) form opens.
3. Configure the parameters.
4. Click on the General Properties tab.
5. Configure the Flow Set-up Direction and HTTP Match All Requests parameters.
6. Configure the parameters in the IP Protocol panel.
7. To specify an application protocol, configure the parameters in the Protocol panel and select a protocol.
8. You can specify server address properties or network address properties in an application filter, but not both.

   To specify server address properties, configure the Server Address Operator parameter. You can specify one server address range by configuring the Server Address and Server Address Mask parameters, or choose an IP prefix list to specify multiple server address ranges.

   Specify server address with netmask by configuring the Masked IP Address and Masked IP Address Mask parameters.You can specify server address properties or masked IP address properties in an application filter, but not both.

   Choose a DNS IP cache, if required, and go to Step 10 10 .
9. To specify network address properties, configure the Network Address Operator parameter. You can specify one network address range by configuring the Network Address and Network Address Mask parameters, or choose an IP prefix list to specify multiple network address ranges.
10. Configure the parameters in the Server Port panel.
11. Configure the parameters in the HTTP Port panel.
12. Click on the Application tab and choose an application.
13. To create one or more application filter expressions, click on the Application Filter Expressions tab and click Create. The Application Filter Expression (Create) form opens.
14. Configure the parameters.
15. Save your changes and close the forms.

Create ASOs

11

To create one or more ASOs:

1. Click on the Application Service Options tab.
2. Click Create. The Application Service Option (Create) form opens.
3. Configure the parameters.

   The Displayed Name of an ASO cannot contain a forward slash (/) character.
4. To create one or more ASO value entries, click on the Application Service Option Value Entries tab.
5. Click Create. The Application Service Option Value Entry (Create) form opens.
6. Configure the ASO Characteristic Value parameter.
7. Save your changes and close the form.

Create application profiles

12

To create an application profile:

1. Click on the Application Profiles tab.
2. Click Create. The Application Profile (Create) form opens.
3. Configure the parameters.
4. Click on the NSP Analytics Parameters tab.
5. Configure the Billing Reset Date parameter.
6. Configure the parameters.
7. Click on the Charging Group Thresholds tab.
8. Click Create. The Charging Group Thresholds (Create) form opens.
9. Configure the parameters.
10. Select a charging group.
11. Save your changes and close the form.
12. Click on the Characteristics tab to create one or more application profile characteristics.
13. Click Create. The Application Profile Characteristic (Create) form opens.
14. Choose an ASO characteristic.
15. Choose an ASO characteristic value.
16. Save your changes and close the forms.

Create AQPs

13

To configure one or more AQPs, perform 87.24 “To configure an AQP” (p. 2825) .

Create custom protocols

14

To create one or more custom protocols:

1. Click on the Custom Protocols tab.
2. Click Create. The Custom Protocol (Create) form opens.
3. Configure the parameters.
4. Click on the Custom Protocol Expressions tab.
5. Click Create. The Custom Protocol Expressions (Create) form opens.
6. Configure the parameters.
7. Save your changes and close the forms.

Configure default DCP group address rules

15

To configure one or more address rules for a default DCP group:

1. Click on the NSP Analytics Parameters tab, then on the Default DCP Groups tab.
2. Select a group and click Properties. The Default DCP Group (Edit) form opens.
3. Click on the Address Rules tab.
4. Click Create. The DCP Address Rule (Create) form opens.
5. Configure the parameters.
6. Save your changes and close the form.

Configure custom DCP groups

16

To configure one or more custom DCP groups:

1. Click on the NSP Analytics Parameters tab, then on the Custom Residential DCP Groups tab.
2. Configure the parameters.
3. Click on the Address Rules tab.
4. Click Create. The DCP Address Rule (Create) form opens.
5. Configure the parameters.

6. Save your changes and close the form.

Configure IP address-based application identification assistance

17

To enable AA to assign an application to a traffic session based on the IP addresses in the session:

1. Click on the IP Identification Assist tab.
2. Configure the parameters on the General tab.
3. Click on the DNS Trust Servers tab.
4. Click Create. The IP Identity Assist DNS Server (Create) form opens.
5. Configure the parameters.

18

Save your changes and close the forms.

END OF STEPS

87.24 To configure an AQP

87.24.1 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Select an AA group policy and click Properties. The AA Group Policy (Edit) form opens.

3

Click on the Application QoS Entries tab.

4

Click Create. The Application QoS Policy (Create) form opens.

5

Configure the parameters.

6

Click on the Match Criteria tab.

7

To configure General Attributes:

1. Configure the Traffic Direction parameter.
2. To specify an application as a criterion:
   a. Configure the Application Operator parameter.
   b. Choose an application.
3. To specify an application group as a criterion:
   a. Configure the Application Group Operator parameter.
   b. Choose an application group.
4. To specify DSCP criteria, configure the parameters in the DSCP panel.
5. To specify IP criteria, configure the parameters in the IP Protocol panel.
6. To specify a charging group as a criterion:
   a. Configure the Charging Group Operator parameter.
   b. Choose a charging group.

8

To configure subscriber criteria:

1. Click on the AA Subscriber tab.
2. Configure the parameters.

   The SAP and Spoke SDP Binding options for the Subscriber Type parameter are selectable only during local AQP entry creation.

   If the Subscriber Type parameter is set to None, the other parameters on the AA Subscriber tab are reset to the default values.
3. Perform one of the following.
   - If the Subscriber Type parameter is set to ESM, configure the ESM Subscriber parameter.
   - If the Subscriber Type parameter is set to SAP, configure the SAP Subscriber parameter.
   - If the Subscriber Type parameter is set to Spoke SDP Binding, configure the Spoke Subscriber parameter.
   - If the Subscriber Type parameter is set to Transit, configure the Transit Subscriber parameter.
   - If the Subscriber Type parameter is set to ESM-MAC, configure the ESM Subscriber Host parameter.

9

To configure source or destination criteria:

1. Click on the Source and Destination tab.
2. To configure source criteria, configure the Address Operator parameter in the Source Address panel. You can specify a single IP prefix or address by configuring the Address and Address Length parameters, or select an IP prefix list.

3. Configure the parameters in the Source Port panel.
4. To configure destination criteria, configure the Address Operator parameter in the Destination Address panel. You can specify a single IP prefix or address by configuring the Address and Address Length parameters, or select an IP prefix list.
5. Configure the parameters in the Destination Port panel.

10

To configure ASO characteristic criteria:

1. Click on the Characteristics tab.
2. Click Create. The Application QoS Policy Characteristic (Create) form opens.
3. Configure the parameters.
4. Save your changes and close the form.

11

Click on the Action tab and configure the Drop parameter. If you select the Drop parameter, go to Step 28 .

12

Configure flow attribute criteria if required.

To include flow attribute criteria in an AQP, the Flow Attributes parameter must be enabled in the ISA-AA group associated with the AA Group policy.

To configure flow attribute criteria:

1. Click on the Flow Attributes tab.
2. Click Create. The Application QoS Flow Attribute (Create) form opens.
3. Click Select to choose a flow attribute name.
4. Configure the parameters.
5. Save your changes and close the form.

13

Choose one or more agents in any or all of the following panels.

- Bandwidth Limit Policer
- Flow Rate Limit Policer
- Flow Count Limit Policer
- HTTP Error Redirect

14

To configure HTTP redirect:

1. Choose an HTTP redirect policy.

2. Configure the Flow Type parameter.

15

Choose an HTTP enrichment policy, if required.

16

Choose an HTTP notification policy, if required.

17

Choose a session filter, if required.

18

If required, configure the Subscriber Cut Through and Mirror Source All Inclusive parameters.

Note: The Mirror Source All Inclusive parameter is configurable only when you configure an AQP entry in a local definition of the AA group policy.

19

Choose a mirror service, if required.

Note: You can specify a mirror service only when you configure an AQP entry in a local definition of the AA group policy.

20

Choose a URL filter, if required.

21

Choose an ASO characteristic name, if required. The name is correlated to the ICAP Custom X-Header value in an AA URL filter.

22

Choose a DNS IP cache, if required.

23

Choose a GTP filter, if required.

24

Choose an SCTP filter, if required.

25

Configure the remarking parameters in the Remark panel.

26

Choose a Multi-Path TCP Proxy policy, if required.

27

If required, enable and configure the Value parameter in the TCP Maximum Segment Size panel.

28

Save your changes and close the forms.

END OF STEPS

87.25 To configure an AARP instance on an NE

87.25.1 Purpose

Application Assurance Redundancy Protocol (AARP) provides data-plane connectivity to dynamically maintain dual-homed AA subscriber traffic on the same ISA-AA for processing. An AARP instance is configured between dual-homed routers to establish connectivity with the same AARP instance number on each NE. See the *7750 SR Advanced Configuration Guide* and *7750 SR Multiservice Integrated Service Adapter Guide* for more information about AARP instances. See 78.18 “To add an AARP interface to an IES or a VPRN site” (p. 2448) for information about how to configure an AARP interface in an IES or VPRN service.

87.25.2 Steps

1

Choose Manage→ISA Functions→ISA-AA from the NFM-P main menu. The Manage ISA-AA form opens.

2

Click Create→AARP. The Select Network Elements form opens.

3

Select a Network Element and click OK. The AARP (Create) form opens.

4

Configure the required parameters.

a. If the AARP instance endpoint is a SAP:

1. Set the Peer Endpoint Type parameter to SAP.
2. If the SAP has a name, click on the L3 Access Interface tab and choose the SAP. Otherwise, configure the SAP Terminating Port, SAP Encapsulation Type, SAP Outer Encapsulation Value, and SAP Inner Encapsulation Value parameters.

The SAP Outer Encapsulation Value parameter is configurable when the SAP Encapsulation Type parameter is set to Dot1 Q:

The SAP Inner Encapsulation Value parameter is configurable when the SAP Encapsulation Type parameter is set to Q in Q:

b. If the AARP instance endpoint is a spoke SDP binding:
   1. Set the Peer Endpoint Type parameter to Spoke SDP Binding.
   2. If the spoke SDP binding has a name, click on Spoke SDP Bindings tab and choose the spoke SDP binding. Otherwise, configure the Spoke SDP Bind ID parameter.

5

Click Apply.

6

View the Operational Flag and Peer Operational Flag indicators to ensure that the configuration is correct.

7

Modify the configuration, if required.

8

Save your changes and close the forms.

END OF STEPS

87.26 To configure an AA policer

87.26.1 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Click Create→AA Policer or select an AA policer and click Properties. The AA Policer (Create | Edit) form opens.

3

Configure the parameters.

4

Save your changes and close the forms.

END OF STEPS

87.27 To configure an AA GTP firewall

87.27.1 Purpose

Perform this procedure to configure a firewall for AA GTP traffic associated with an AQP that is bound to an ISA-AA group or partition.

87.27.2 Steps

Configure AA GTP filter

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Click Create→AA GTP Filter or select an AA GTP filter and click Properties. The AA GTP Filter (Create | Edit) form opens.

3

Configure the parameters.

4

Click on the Message Type tab.

5

Click Create, or select an entry and click Properties. The AA GTP Message Type (Create | Edit) form opens.

6

Configure the parameters.

7

Click OK to save your changes and close the form.

8

Click on the General tab.

9

Click Apply.

10

Distribute the policy to NEs, as required.

11

Close the AA GTP Filter (Create | Edit) form.

Configure AA SCTP filter

12

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

13

Click Create→AA SCTP Filter or select an AA SCTP filter and click Properties. The AA SCTP Filter (Create | Edit) form opens.

14

Configure the parameters.

15

Click on the PPID tab.

16

Click Create, or select an entry and click Properties. The AA SCTP Message Type (Create | Edit) form opens.

17

Configure the parameters; click Select or type a value to specify a PPID.

18

Click OK to save your changes and close the form.

19

Click on the General tab.

20

Click Apply.

21

Distribute the policy to NEs, as required.

22

Close the AA SCTP Filter (Create | Edit) form.

Bind GTP and SCTP filters to AQP

23

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

24

Choose AA Group Policy (Application Assurance) from the drop-down menu and click Select. A list of AA group policies is displayed.

25

Select a policy and click Properties. The AA Group Policy (Edit) form opens.

26

Click on the Application QoS Entries tab.

27

Select an entry and click Properties. The Application QoS Policy (Edit) form opens.

28

Click on the Action tab.

29

Use the Select buttons to specify the GTP and SCTP filters.

30

Click OK to save your changes and close the form.

31

Click Apply.

32

Distribute the policy to NEs, as required.

33

Close the AA Group Policy (Edit) form.

Configure GTP flow count monitoring in AA policer

34

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

35

Choose AA Policer (Application Assurance) from the drop-down menu and click Select. A list of AA policers is displayed.

36

Select a policer and click Properties. The AA Policer (Edit) form opens.

37

Configure the GTP Flow Count Limit parameter.

38

Click Apply.

39

Distribute the policer to NEs, as required.

40

Close the AA Policer (Edit) form.

41

Close the Application Assurance Policies form.

Configure firewall on AA group or partition

42

Right-click on an ISA-AA group in the Equipment view of the network navigation tree and choose Properties. The ISA-AA Group (Edit) form opens.

43

To configure the GTP firewall for the group, configure the parameters in the GTP panel.

You can configure a GTP firewall for an ISA-AA group only if the group is not partitioned.

44

To configure the GTP firewall for a partition:

1. Click on the ISA-AA partitions tab.
2. Select a partition and click Properties. The ISA-AA Group Partition (Edit) form opens.
3. Configure the parameters in the GTP panel.
4. Click OK to save your changes and close the form.

45

Click OK to save your changes and close the ISA-AA Group (Edit) form.

END OF STEPS

87.28 To configure an AA GTP-c firewall for S8 or Gn

87.28.1 Purpose

Perform this procedure to configure a firewall for AA GTP-c traffic associated with an S8 or Gn interface that is bound to to an ISA-AA group or partition.

87.28.2 Steps

Configure GTP parameters on the ISA-AA group and partition

1

Configure the GTPC Database parameter:

1. On the Equipment tree, expand *[NE]*→Logical Groups→ISA-AA Groups→ISA-AA Group *n*.
2. Right-click on the ISA-AA Group *n* icon and choose Properties. The ISA-AA Group (Edit) form opens.
3. On the General tab, in the Group panel, change the GTP Tunnel Database parameter value from 0 to 100 or vice versa.

2

If you are using 7750 SR NEs, configure the Minimum ISA Generation parameter value to 2.

This configuration is not required for VSR NEs.

3

Click on the ISA-AA Partitions tab.

4

Click Create or select an existing partition entry and click Properties. The ISA-AA Group Partition (Create|Edit) form opens.

5

On the General tab, in the GTP panel, configure the GTPC Inspection parameter value to Enabled.

6

Close the ISA-AA Group and ISA-AA Group Partition forms.

Configure AA GTP filter

7

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

8

Click Create→AA GTP Filter or select an AA GTP filter and click Properties. The AA GTP Filter (Create | Edit) form opens.

9

Configure the following parameters to Enabled:

- Validate GTP Tunnels
- Validate Sequence Number
- Validate Source IP Address

10

Click on the GTP in GTP tab and configure the default action for GTP in GTP packets.

11

Click on the GTP V2 Message Type tab and configure the default action for packets that do not match any GTP V2 message type entries.

12

Configure GTP V2 message type entries:

1. Click on the Entries subtab.
2. Click Create and configure the parameters.
3. Create additional GTP V2 message type entries as needed.

13

Click on the IMSI APN Filter tab and configure the default action for packets that do not match any IMSI APN filter entries.

14

Configure IMSI APN Filter entries:

1. Click on the Entries subtab.
2. Click Create and configure the parameters.
3. Create additional IMSI APN Filter entries as needed.

15

Distribute the policy to NEs, as required.

16

Close the AA GTP Filter (Create | Edit) form.

END OF STEPS

87.29 To configure AA TCP validation

87.29.1 Purpose

Perform this procedure to configure AA to monitor TCP packet discards on an ISA-AA group or partition for reasons such as packet corruption, malformation, or incorrect sequencing. The NFM-P can use the collected statistics to raise AA statistics TCAs.

87.29.2 Steps

Configure AA TCP validation policy

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Click Create→AA TCP Validation, or select an AA TCP validation policy and click Properties. The AA TCP Validation (Create | Edit) form opens.

3

Configure the parameters.

4

Click Apply.

5

Distribute the policy to NEs, as required.

6

Close the AA TCP Validation (Create | Edit) form.

Configure AA TCP validation TCA

7

Click Create→AA Statistics TCA→TCP Validation, or select a TCP validation AAsStatistics TCA

and click Properties. The AA Statistics TCA TCP Validation (Create | Edit) form opens.

8

Use the Select button to choose the new AA TCP validation policy.

9

Configure the parameters.

10

Click Apply.

11

Distribute the policy to NEs, as required.

Note: You can view the TCAs for an NE from the Faults tab of the local policy definition, which is listed on the Local Definitions tab of the AA TCP Validation form.

12

Close the AA Statistics TCA TCP Validation (Create | Edit) form.

Bind TCA to AQP entry

13

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

14

Choose AA Group Policy (Application Assurance) from the drop-down menu and click Select. A list of AA group policies is displayed.

15

Select a policy and click Properties. The AA Group Policy (Edit) form opens.

16

Click on the Application QoS Entries tab.

17

Select an entry and click Properties. The Application QoS Policy (Edit) form opens.

18

Click on the Action tab.

19

Use the Select button in the TCP Validation panel to specify the new TCP validation policy.

20

Click OK. The Application QoS Policy (Edit) form closes, and the AA Group Policy (Edit) form is again displayed.

21

Click Apply.

22

Click on the General tab..

23

Distribute the policy to NEs, as required.

24

Close the AA Group Policy (Edit) form.

Enable TCP validation statistics collection

25

Click Create→AA Accounting Policy, or select an AA accounting policy and click Properties. The AA Accounting Policy (Create | Edit) form opens.

26

If you are creating a policy, configure the parameters and click Apply.

27

Click on the Accounting Policies tab.

28

Select the AA Admit Deny entry and click Properties. The AA Accounting Configuration - AA Admit Deny (Create | Edit) form opens.

29

Select the Include TCP Validation Statistics parameter.

30

Click OK. The AA Accounting Configuration — AA Admit Deny (Create | Edit) form closes, and the AA Accounting Policy (Edit) form is again displayed.

31

Click on the General tab.

32

Distribute the accounting policy to NEs, as required.

Note: You can view the collected statistics for an NE from the Statistics tab of the local policy definition, which is listed on the Local Definitions tab of the AA TCP Validation form.

33

Close the AA Accounting Policy (Edit) form.

34

Close the Application Assurance Policies form.

END OF STEPS

87.30 To configure AA TCP optimization

87.30.1 Steps

Configure TCP optimization policy

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Click Create→AA TCP Optimization, or select an AA TCP optimization policy and click Properties. The AA TCP Optimization (Create | Edit) form opens.

3

Configure the parameters.

Note: To configure a dynamic initial slow start threshold, enter 1000001 for the initial slow start threshold parameter. This will set the initial slow start threshold to Auto on the NE.

4

Click Apply.

5

Distribute the policy to NEs, as required.

6

Click OK. The AA TCP Optimization (Create | Edit) form closes.

Bind policy to AA session filter

7

Click Create→AA Session Filter, or select an AA session filter and click Properties. The AA Session Filter (Create | Edit) form opens.

8

If you are creating an AA session filter, configure the parameters and click Apply.

9

Click on the Entries tab.

10

Click Create, or select a session filter and click Properties. The AA Session Filter Params (Create | Edit) form opens.

11

Set the Action parameter to TCP Optimizer.

12

Use the Select button in the TCP Optimization panel to specify the new TCP optimization policy.

13

Click OK. The AA Session Filter Params (Edit) form closes, and the AA Session Filter (Create | Edit) form is again displayed.

14

Click on the General tab.

15

Click Apply.

16

Distribute the policy to NEs, as required.

17

Close the AA Session Filter (Create | Edit) form.

18

Close the Application Assurance Policies form.

END OF STEPS

87.31 To renumber application filter entries

87.31.1 Purpose

The application filter entries in an AA group policy are applied to a traffic flow sequentially; the matching entry with the lowest ID value is applied first. Perform this procedure to assign new ID values to one or more application filter entries in an AA group policy.

Note: The NFM-P renumbers a filter entry ID only when the following are true.

- The new value is unused.
- The new value is less than or equal to the maximum allowed value.
- The renumbering does not change the filter order.

87.31.2 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Select an AA group policy and click Properties. The AA Group Policy (Edit) form opens.

3

Click on the Application Filters tab. The application filter entries are listed.

4

To renumber one filter entry:

1. Select the entry and click Renumber ID. The Renumber Entry ID form opens.
2. Configure the New Entry ID parameter.
3. Save your changes and close the form. The NFM-P renumbers the entry.

5

To renumber multiple filter entries:

1. Select the lowest-numbered entry that you want to renumber and click Renumber IDs. The Renumber Entry ID form opens.
2. Configure the Start Entry ID and End Entry ID parameters.

An End Entry ID value of 0 specifies that there is no ending entry ID; the range of entry IDs to renumber extends to the highest-numbered entry.

3. Perform one of the following:
   - Select Add Factor to add an offset to each entry ID in the specified range.
   - Select Multiply Factor to multiply the ID of the selected entry and each higher-numbered entry in the specified range by an offset.
4. Configure the Factor Value parameter by specifying the required addition or multiplication offset.
5. Save your changes and close the form. The NFM-P renumbers the entries.

6

Close the open forms.

END OF STEPS

87.32 To bind an application filter to an AA Port List Policy

87.32.1 Purpose

An AA Port List Policy can be bound to an application filter configured for the same ISA-AA Group and Partition.

87.32.2 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Choose AA Group Policy (Application Assurance) from the object drop-down menu.

3

Enter the ISA-AA Group ID and ISA-AA Partition ID in the fields and click Search. The AA group policies for the ISA-AA Group and Partition are listed.

4

Select an AA group policy and click Properties. The AA Group Policy (Edit) form opens.

5

Click on the Application Filters tab. The application filter entries are listed.

6

Click Create or select an application filter and click Properties. The Application Filter (Create | Edit) form opens.

7

Configure the parameters.

8

Click on the General Properties tab.

9

Configure the Server Port parameters:

1. Set the Server Port Value Type parameter to List.
2. Set the Server Port Operator parameter to Equal or Not Equal
3. Click Select for the Server Port List parameter and choose a policy from the list of released AA Port List (Application Assurance) Policies.

10

Configure the HTTP Port parameters:

1. Set the HTTP Port Value Type parameter to List.
2. Set the Server Port Operator parameter to Equal or Not Equal
3. Click Select for the Server Port List parameter and choose a policy from the list of released AA Port List (Application Assurance) Policies.

11

Close the open forms.

END OF STEPS

87.33 To configure an AA Cflowd group policy

87.33.1 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Click Create→AA Cflowd Group Policy, or select an AA Cflowd group policy and click Properties. The AA Cflowd Policy (Create | Edit) form opens.

3

Configure the parameters.

When you configure the ISA-AA Partition ID parameter, the Partitions parameter is automatically set to Enabled.

4

Click Apply.

5

If the Partitions parameter is set to Enabled and you specified an ISA-AA Partition ID value, go to Step 14 .

6

Click on the Cflowd tab and configure the parameters.

7

Specify the Cflowd collectors.

1. Click on the Collector tab.
2. Click Create or select an existing collector entry and click Properties. The Cflowd Collector (Create | Edit) form opens.
3. Configure the parameters.
4. Save your changes and close the form.

   An ISA-AA group can contain a maximum of sixteen Cflowd collectors.

8

If the Partitions parameter on the General tab is set to Disabled, go to Step 9 .

9

To add an AA application or application group for Cflowd performance monitoring, click on the Performance tab. Otherwise, go to Step 12 .

10

To add an AA application for Cflowd performance monitoring, perform the following steps.

1. Click Add Applications Comprehensive, or Add Applications TCP. The Select Applications form opens.
2. Select one or more applications and click OK.

11

To add an AA application group for Cflowd performance monitoring, perform the following steps.

1. Click Add Application Groups Comprehensive, or Add Application Groups TCP. The Select Application Groups form opens.
2. Select one or more application groups and click OK.

12

To set the Cflowd sampling administrative states, click on the State tab and configure the required parameters.

13

To configure a template:

1. Click on the Template tab.
2. Select a template and click Properties.
3. In the form that opens, configure the General parameters.
4. Click on the Dynamic Fields tab and click Create.
5. In the Create form, click Select to choose a dynamic field and click OK to add it to the template.
6. Add additional fields as needed and click OK.

14

Save your changes and close the forms.

END OF STEPS

87.34 To configure a policy sync group

87.34.1 Steps

1

Choose Policies→Policy Sync Group from the NFM-P main menu. The Policy Sync Groups form opens.

2

Click Create→Policy Sync Group or select a policy sync group entry and click Properties. The Policy Sync Group (Create | Edit) form opens.

3

Configure the Policy Type parameter.

4

Use the Select button to choose a master policy.

5

Configure the remaining parameters.

6

Specify the AA group policy or AA Cflowd group policy classes to include in the policy sync group.

1. Click on the Included Classes tab. The tab lists the classes that are included in the policy sync group.

   The Sync Members, Add to Members, and Update Master actions performed on an AA group policy affect only the classes listed on the Included Classes tab.
2. To add one or more classes, click Add and specify the classes.
3. To delete one or more classes, select the classes and click Delete.

7

Add one or more member AA group or AA Cflowd group policies.

1. Click on the Members tab.
2. Click Add and select one or more policies. The Confirm form opens.

   The form displays the following options: “Listed master policy classes will overwrite member classes” and “Listed master policy classes will be added to member classes.”

   The Sync Members button performs the same function as the “Listed master policy classes will overwrite member classes” option.

   The Add to Members button performs the same function as the “Listed master policy classes will be added to member classes” option.
3. Choose an option and click OK.

8

To remove a member AA group policy:

1. Click on the Members tab.
2. Select a member policy.
3. Click Delete. The member policy is removed from the list.

9

Save your changes and close the forms.

END OF STEPS

87.35 To audit, compare, or synchronize policies using a policy sync group

87.35.1 Steps

1

Choose Policies→Policy Sync Group from the NFM-P main menu. The Policy Sync Groups form opens and lists the policy sync groups.

2

Select a policy sync group and click Properties. The Policy Sync Group (Edit) form opens.

3

To display the differences between the master policy and the policy members, click Audit.

Alarms are raised against member policies if mismatches in the included classes exist.

4

To compare two member policies, or compare the master policy to a member policy:

1. From the Members tab, select two policies and click Compare. The Compare - AA Group Policy or Compare - AA Cflowd Policy form opens.

   You can use the Swap button to switch Policy A and Policy B.
2. Click Compare to view the differences between Policy A and Policy B.
3. Choose a result and click Properties. The Difference - AA Group Policy (*class type*) or Difference - AA Cflowd Policy (*class type*) form opens.
4. View the differences between the two policies.

5

To add the classes defined in the master policy to each member policy, click Add To Members. The master policy classes are added to each member policy.

Note: After you click Add to Members, the member policy mode changes to Draft.

6

To add the contents of a selected AA group policy to the included classes of the master policy, click Update Master. The member policy classes are added to the master policy.

7

To synchronize each member policy with the master policy, click Sync Members. The master policy class list overwrites the class list in each member policy.

Note: After you click Sync Members, the member policy mode changes to Draft.

END OF STEPS

87.36 To configure an AA Access Network Location

87.36.1 Before you begin

An ISA-AA group must be configured; see 13.5 “To configure an ISA-AA group and ISA-AA partitions” (p. 415).

87.36.2 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Click Create or select an AA Access Network Location entry and click Properties. The AA Access Network Location (Create | Edit) form opens.

3

Configure the required parameters.

4

If the Source Level parameter is set to Cell or mac-vlan, configure RTT Threshold parameters.

Note: The Source Level parameter cannot be changed after the policy is created.

5

Save your changes and close the forms.

END OF STEPS

87.37 To configure an AA accounting policy

Note: See “Statistics collection in the NFM-P” in the *NSP NFM-P Statistics Management Guide* for general information about configuring and collecting accounting statistics.

87.37.1 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Click Create or select an AA accounting policy entry and click Properties. The AA Accounting Policy (Create | Edit) form opens.

3

Configure the parameters.

4

Click on the Accounting Policies tab. The accounting policies are listed.

5

To configure an accounting policy:

1. Select the accounting policy and click Properties. The AA Accounting Configuration form opens.
2. Configure the parameters.

   Enabling the Export Using parameter enables aggregate counter export using the method specified in the parameter options; for example, Accounting Policy.
3. Choose an accounting policy.
4. Configure the required policy-specific parameters.

   The Collect Usage Monitoring Statistics parameter is configurable only for a 7450 ESS or 7750 SR, and only when the accounting policy type is AA Subscriber Custom Record.
5. Click OK.

6

Save your changes and close the forms.

END OF STEPS

87.38 To configure AA accounting file export

87.38.1 Purpose

Perform this procedure to configure the export of AA accounting statistics to files on NFM-P main or auxiliary server stations.

CAUTION

Service Disruption

If you are enabling or disabling the export function, performing this procedure requires a server restart, which is service-affecting.

Perform this procedure only during a scheduled maintenance period.

Note: If the statistics are to be exported to a main server, and the NFM-P system is redundant, you must perform the procedure on each main server in the system, and must perform the procedure on the standby main server station first.

87.38.2 Steps

1

Log in to the main or auxiliary server station as the nsp user.

2

Open a console window.

3

Enter one of the following:

- On a main server station:
  `bash$ cd /opt/nsp/nfmp/server/nms/config ↵`
- On an auxiliary server station:
  `bash$ cd /opt/nsp/nfmp/auxserver/nms/config ↵`

4

Enter the following to make a backup copy of the server configuration file:

`bash$ cp nms-server.xml nms-server.xml.backup ↵`

5

Open the nms-server.xml file with a plain-text editor such as vi.

6

Locate the <aaStatsProcessing section.

7

To enable or disable the export function, set the following parameter to true or false, as required; for example, to enable the function:

`enabled="true"`

8

Specify the file format by editing the following line, as required:

`fileFormat="`*`format`*`"`

where *format* is one of the following:

- ipdr—IPDR format
- ram—format for NSP Analytics Reports
- ipdr, ram—IPDR and ram formats

9

Save and close the nms-server.xml file.

10

If you are configuring the standby main server in a redundant system, go to Step 12 .

11

If you changed only the fileFormat value, enter one of the following to put the configuration change into effect:

- On a main server station:

  bash$ **/opt/nsp/nfmp/server/nms/bin/nmsserver.bash read_config** ↵
- On an auxiliary server station:

  bash$ **/opt/nsp/nfmp/auxserver/nms/bin/auxnmsserver.bash auxread_config** ↵

The server reads the updated configuration, and saves subsequently collected AA accounting statistics to files on the server station.

12

If you are enabling or disabling the function, or are configuring the standby main server in a redundant system, enter one of the following to restart the server:

- On a main server station:

  bash$ **/opt/nsp/nfmp/server/nms/bin/nmsserver.bash force_restart** ↵
- On an auxiliary server station:

  bash$ **/opt/nsp/nfmp/auxserver/nms/bin/auxnmsserver.bash auxforce_restart** ↵

The server restarts, reads the updated configuration, and saves subsequently collected AA accounting statistics to files on the server station.

13

Close the console window.

END OF STEPS

87.39 To configure an AA flow watermark

87.39.1 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Select AA Flow Watermark (Application Assurance) from the object drop-down menu and click Search.

3

Select an AA flow watermark entry and click Properties. The AA Flow Watermark (Edit) form opens.

4

Configure the parameters.

5

Click Apply. The Configuration Mode changes to Draft.

6

Distribute the flow watermark to NEs, as required.

7

Close the forms.

END OF STEPS

87.40 To configure an AA RADIUS accounting policy

87.40.1 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Click Create or select an AA RADIUS accounting policy entry and click Properties. The AA RADIUS accounting policy (Create | Edit) form opens.

3

Configure the parameters.

You must select the Enable check box beside the IP and Value (minutes) parameters before you can configure the parameters.

4

If you set the Router Instance parameter to VPRN, choose a VPRN service to associate the policy with.

5

Click on the RADIUS Accounting Servers tab and click Create. The AA RADIUS Accounting Server (Create) form opens.

6

Configure the parameters.

7

To add another RADIUS accounting server, click Apply and repeat Step 6 .

8

Save your changes and close the forms.

END OF STEPS

87.41 To configure an AA statistics TCA

87.41.1 Steps

1

Create an accounting policy and distribute the policy to the NEs that require the TCA configuration. See the *NSP NFM-P Statistics Management Guide* for information about creating accounting policies.

Note: You must set the accounting policy Type to AA Admit Deny.

2

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

3

Click Create→AA Accounting Policy, or select an AA accounting policy and click Properties. The AA Accounting Policy (Create | Edit) form opens.

4

Configure the parameters.

5

Click Apply.

6

Click on the Accounting Policies tab.

7

Select the AA Admit Deny entry and click Properties. The AA Accounting Configuration — AA Admit Deny (Edit) form opens.

Note: If the AA Admit Deny entry is not listed, you must synchronize the global policy with a local policy definition that has the AA Admit Deny policy type configured using a CLI.

8

Click Select and choose the previously configured AA Admit Deny accounting policy.

9

Click OK. The AA Accounting Configuration — AA Admit Deny (Edit) form closes.

10

Click OK. The AA Accounting Policy (Create | Edit) form closes.

11

Click Create→AA Statistics TCA Config, or select an AA statistics TCA and click Properties. The AA Statistics TCA Config (Create | Edit) form opens.

12

Configure the parameters.

13

Click OK to save your changes and close the AA Statistics TCA Config (Create | Edit) form.

14

Perform 87.42 “To configure an AA statistics TCA policer” (p. 2856).

15

Perform 87.43 “To configure an AA statistics TCA filter” (p. 2856).

16

Perform 87.44 “To configure an AA statistics TCA filter entry” (p. 2858).

17

Close the Application Assurance Policies form.

END OF STEPS

87.42 To configure an AA statistics TCA policer

87.42.1 Steps

1

Configure an AA policer; see 87.26 “To configure an AA policer” (p. 2830) for information.

Note: You must set the policer Type to Flow Rate Limit or Flow Count Limit.

2

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

3

Click Create→AA Statistics TCA Policer Config, or select an AA TCA policer and click Properties. The AA Statistics TCA Policer Config (Create | Edit) form opens.

4

Click Select and choose the previously created policer.

5

Configure the parameters.

6

Click OK to save your changes and close the AA Statistics TCA Policer Config (Create | Edit) form.

7

Close the Application Assurance Policies form, if required.

END OF STEPS

87.43 To configure an AA statistics TCA filter

87.43.1 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Click Create→AA Statistics TCA Filter Config, or select an AA TCA filter and click Properties. The AA Statistics TCA Filter Config (Create | Edit) form opens.

3

Configure the TCA Config Filter Type parameter.

4

Click Select and choose a filter.

Note: Only filters of the type specified as the TCA Config Filter Type are listed.

5

Configure the Watermark Type parameter.

If the TCA Config Filter Type is set to GTP Filter, the valid options are the following:

- Payload Range
- Filter Default Action
- Header Sanity

Note: If you select Payload Range, the Max Payload Length parameter must be set on the GTP filter associated with the AQP.

If the TCA Config Filter Type is set to SCTP Filter, the valid options are the following:

- PPID Range
- Filter Default Action
- Packet Sanity

Note: If you select PPID Range, the PPID Range parameter must be set on the SCTP filter associated with the AQP.

If the TCA Config Filter Type is set to Session Filter, the valid option is Filter Default Action.

6

Configure the remaining parameters.

7

Click OK to save your changes and close the AA Statistics TCA Filter Config (Create | Edit) form.

8

Close the Application Assurance Policies form, if required.

END OF STEPS

87.44 To configure an AA statistics TCA filter entry

87.44.1 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Click Create→AA Statistics TCA Filter Entry Config, or select an AA TCA filter entry and click Properties. The AA Statistics TCA Filter Entry Config (Create | Edit) form opens.

3

Configure the following parameters:

- TCA Config Filter Type
- ISA-AA Group ID
- ISA-AA Partition ID

4

Click Select and choose a filter entry.

Note: Only filter entries for the type specified as the TCA Config Filter Type are listed, and only if the filters contain at least one:

- message type, for GTP filters
- PPID, for SCTP filters
- protocol entry, for session filters

5

Configure the remaining parameters.

6

Click OK to save your changes and close the AA Statistics TCA Filter Config (Create | Edit) form.

7

Close the Application Assurance Policies form, if required.

END OF STEPS

87.45 To configure an AA Tether Detection policy

87.45.1 Purpose

An AA Tether Detection policy is created automatically when an ISA-AA group and its associated AA Group policy is created on a 7450 ESS NE. The Subcriber Scale parameter of the ISA-AA group must be configured to Mobile Gateway or another Gateway setting, depending on the NE release.

See 13.5 “To configure an ISA-AA group and ISA-AA partitions” (p. 415) to create an ISA-AA group. Use this procedure to complete the configuration.

87.45.2 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Select an AA Tether Detection policy and click Properties.

3

Configure the required parameters on the General tab.

4

Click on the TTL Monitoring tab.

5

Configure the required parameters.

6

Click on the Single Device Expected TTLs tab.

7

Click Create. The Expected TTL, Global Policy (Create) form opens.

8

Configure up to 16 TTLs.

9

Click Apply.

10

Distribute the policy to NEs, as required.

11

Close the forms.

END OF STEPS

87.46 To configure an AA transit IP policy

87.46.1 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Click Create→AA Transit IP Policy or select an AA transit IP policy and click Properties. The AA Transit IP Policy (Create | Edit) form opens.

3

Configure the parameters.

4

Choose a default application profile.

Only application profiles with the same Group ID and Partition ID values as the AA transit IP policy are listed.

5

Choose a subscriber identification policy.

6

Configure the following required parameters.

The following parameters cannot be enabled at the same time:

- DHCP, and RADIUS or Seen IP
- Auto Create, and DHCP or RADIUS

7

If the RADIUS parameter is set to Enabled, select a subscriber authentication policy and an AA RADIUS accounting policy.

8

If the Diameter parameter is set to Enabled, select a diameter application policy.

9

To add one or more static subscribers to the AA transit IP policy:

1. Click on the Subscribers tab.
2. Click Create. The Transit Subscriber (Create) form opens.
3. Configure the Displayed Name parameter.
4. Choose an application profile.
5. Click on the IP Addresses tab.
6. Click Create. The Transit IP Address (Create) form opens.
7. Configure the Address parameter.
8. Save your changes and close the form.

10

Save your changes and close the forms.

END OF STEPS

87.47 To configure an AA transit prefix policy

87.47.1 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Click Create→AA Transit Prefix Policy or select an AA Transit Prefix Policy entry and click Properties. The AA Transit Prefix Policy (Create | Edit) form opens.

3

Configure the parameters.

4

To configure one or more transit prefix subscribers:

1. Click on the Subscribers tab and click Create. The Transit Prefix Subscriber (Create) form opens.
2. Configure the parameters.
3. Choose an application profile.
4. Save your changes and close the form.

5

Note: Each entry ID must be assigned according to the following hierarchy, or the configuration fails:
local IPv4 < remote IPv4 < local IPv6 < remote IPv6
For example:

- Each local IPv6 entry ID must be higher than all IPv4 entry IDs.
- Local IPv4 entry IDs are lowest; remote IPv6 entry IDs are highest.

To create one or more transit prefix entries:

1. Click on the Entries tab and click Create. The Transit Prefix Entry (Create) form opens.
2. Choose a subscriber.
3. Configure the parameters.

   The Subscriber Address and Network Address values must both be IPv4 or IPv6; you cannot configure one address as IPv4 and the other as IPv6.
4. Save your changes and close the form.

6

Save your changes and close the forms.

END OF STEPS

87.48 To configure a database persisted transit subscriber aggregator

87.48.1 Steps

1

Choose Manage→AA Transit Subscribers from the NFM-P main menu. The Manage AA Transit Subscribers form opens.

2

Click Create→Transit Subscriber Aggregator or select a transit subscriber aggregator entry and click Properties. The Database Persisted Transit Subscriber Aggregator (Create | Edit) form opens.

3

Configure the parameters.

4

Save your changes and close the forms.

END OF STEPS

87.49 To associate a database persisted transit subscriber with an aggregator

Note: You can associate an aggregator only with database persisted business transit subscribers. A business transit subscriber is associated with an AA group that is configured for use in the VPN context.

87.49.1 Steps

1

Choose Manage→AA Transit Subscribers from the NFM-P main menu. The Manage AA Transit Subscribers form opens.

2

Choose a database persisted transit subscriber entry and click Properties. The Database Persisted Transit Subscriber (Edit) form opens.

3

Click on the NSP Analytics Parameters tab.

4

Click Select. The Select Database Persisted Transit Subscriber Aggregator form opens.

5

Configure the filter for the Keyword List column and click Search.

6

Select an aggregator and click OK.

7

Repeat Step 2 to Step 8 to associate more database persisted transit subscribers with aggregators, as required.

8

Save your changes and close the forms.

END OF STEPS

87.50 To configure trap throttling for AA transit subscriber creation and deletion

87.50.1 Purpose

Perform this procedure to specify the trap throttling rate on one or more NEs for AA transit subscriber creation and deletion events. When the trap rate exceeds the specified rate, the NFM-P resynchronizes the AA transit subscriber table on the NE to obtain the updated list of AA transit subscribers.

87.50.2 Steps

1

To enable the default rate limit of ten traps per second, create a CLI script that contains the following lines:

```
configure log event-control "application_
assurance" tmnxBsxTransIpPolAaSubCreated generate disable-specific-throttle
configure log event-control "application_
assurance" tmnxBsxTransIpPolAaSubDeleted generate disable-specific-throttle
```

2

To specify a different rate limit, create a CLI script that contains the following lines:

```
configure log event-control "application_
assurance" tmnxBsxTransIpPolAaSubCreated generate throttle specific-throttle-rate traps interval int

configure log event-control "application_
assurance" tmnxBsxTransIpPolAaSubDeleted generate throttle specific-throttle-rate traps interval int
```

where

traps is the number of traps

interval is the number of seconds over which the traps are generated

3

Use Workflows to execute workflows on one or more NEs, as required.

END OF STEPS

87.51 To view database persisted transit subscriber information

87.51.1 Steps

1

Choose Manage→AA Transit Subscribers from the NFM-P main menu. The Manage AA Transit Subscribers form opens.

2

Choose a database persisted transit subscriber entry and click Properties. The Database Persisted Transit Subscriber (Edit) form opens.

3

View the subscriber information, as required.

4

Close the Database Persisted Transit Subscriber (Edit) form.

5

Close the Manage AA Transit Subscribers form.

END OF STEPS

87.52 To configure usage-based billing for an application profile

87.52.1 Purpose

Perform this procedure to associate a charging group with an application profile. You can perform 87.53 “To associate an application with a charging group” (p. 2866) to assign an application to a charging group, if required.

87.52.2 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Choose an AA group policy entry and click Properties. The AA Group Policy (Edit) form opens.

3

Click on the Application Profiles tab.

4

Select an application profile and click Properties. The Application Profile (Edit) form opens.

5

Click on the NSP Analytics Parameters tab.

6

Configure the Billing Reset Date parameter.

7

Configure the parameters in the Apdex Thresholds and MOS Thresholds panels.

8

Click on the Charging Group Thresholds tab.

9

Click Create or select a charging group threshold and click Properties. The Charging Group Thresholds (Create | Edit) form opens.

10

Configure the parameters.

11

Select a charging group.

12

Save your changes and close the forms.

END OF STEPS

87.53 To associate an application with a charging group

87.53.1 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Choose an AA group policy entry and click Properties. The AA Group Policy (Edit) form opens.

3

Click on the Applications tab.

4

Select an application and click Properties. The Application (Edit) form opens.

5

Click on the Charging Group tab.

6

Choose a charging group.

7

Save your changes and close the forms.

END OF STEPS

87.54 To enable application performance reporting on a service

87.54.1 Purpose

Perform this procedure to enable application performance reporting on a service, and to configure default and custom DCP groups.

87.54.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a service and click Properties. The *service_type* Service (Edit) form opens.

3

Click on the Application Assurance tab.

4

Click on the NSP Analytics Parameters tab.

5

Select the Enable Application Performance Reporting parameter.

6

Click Apply. The NFM-P creates default IPv4 and IPv6 Internet and Intranet DCP subnet groups, which are listed on the Default DCP Groups tab.

7

To configure one or more address rules for a default DCP group:

1. Click on the Default DCP Groups tab.
2. Select a group and click Properties. The Default DCP Group (Edit) form opens.
3. Click on the Address Rules tab.

4. Click Create. The DCP Address Rule (Create) form opens.
5. Configure the parameters.
6. Save your changes and close the form.

8

To configure one or more custom DCP groups:

1. Click on the Custom DCP Groups tab.
2. Configure the parameters.
3. Click on the Address Rules tab.
4. Click Create. The DCP Address Rule (Create) form opens.
5. Configure the parameters.
6. Save your changes and close the form.

9

Save your changes and close the forms.

END OF STEPS

87.55 To configure application performance reporting on a SAP or SDP binding

87.55.1 Purpose

Perform this procedure to configure an Apdex tier value and the associated thresholds on a service object.

87.55.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a service and click Properties. The *service_type* Service (Edit) form opens.

3

Click on the Application Assurance tab.

4

Click on the NSP Analytics Parameters tab.

5

Select the Enable Application Performance Reporting parameter.

6

Click Apply.

7

Open the SAP or spoke SDP binding properties form.

8

Click on the Application Assurance tab.

9

Choose an application profile.

10

Click on the NSP Analytics Parameters tab.

11

Click Create. The AA Reporting (Create) form opens.

12

Configure the parameters.

13

Save your changes and close the forms.

END OF STEPS

87.56 To configure application performance reporting for a transit subscriber

87.56.1 Purpose

Perform this procedure to configure an Apdex tier value and the associated thresholds for a transit subscriber.

Note: You can perform this procedure only for a business transit subscriber. A business transit subscriber has an associated AA group policy with a Subscriber Scale setting of VPN.

87.56.2 Steps

1

Choose Manage→AA Transit Subscribers from the NFM-P main menu. The Manage AA Transit Subscribers form opens.

2

Choose a database persisted transit subscriber and click Properties. The Database Persisted Transit Subscriber (Edit) form opens.

3

Click on the NSP Analytics Parameters tab.

4

Click on the Reporting tab.

5

Click Create. The AA Reporting (Create) form opens.

6

Configure the parameters.

7

Save your changes and close the forms.

END OF STEPS

87.57 To disable application performance reporting on a service

87.57.1 Purpose

Perform this procedure to disable application performance reporting on a service and to delete the default DCP subnet groups.

87.57.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a service and click Properties. The *service_type* Service (Edit) form opens.

3

Click on the Application Assurance tab.

4

Deselect the Enable Application Performance Reporting parameter.

5

Click Apply.

6

Click on the Default DCP Groups tab.

7

Click Delete All Result. The default DCP subnet groups are deleted.

8

Save your changes and close the forms.

END OF STEPS

87.58 To configure an AA HTTP error redirect policy

87.58.1 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Click Create→AA HTTP Error Redirect or select an AA HTTP error redirect policy entry and click Properties. The AA HTTP Error Redirect (Create | Edit) form opens.

3

Configure the parameters.

4

Choose a template.

5

To configure an HTTP error code:

1. Click on the HTTP Error Codes tab.
2. Click Create. The HTTP Redirect Error Code (Create) form opens.

3. Choose an error code.
4. Configure the Message Size (octets) parameter.
5. Save your changes and close the form.

6

Save your changes and close the forms.

END OF STEPS

87.59 To configure an AA HTTP redirect policy

87.59.1 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Click Create→AA HTTP Redirect or select an AA HTTP redirect policy entry and click Properties. The AA HTTP Redirect (Create | Edit) form opens.

3

Configure the parameters.

Note: The TCP Client Reset parameter is configurable only for a 7750 SR.

4

Configure the Redirect URL parameter to specify the location to which the subscriber hosts are redirected. If required, click Insert Macros to add keywords that specify an associated identifier such as the subscriber ID.

5

Choose a template.

6

Save your changes and close the forms.

END OF STEPS

87.60 To configure an AA HTTP Enrichment (Application Assurance) policy

87.60.1 Purpose

Perform this procedure to create an AA HTTP Enrichment (Application Assurance) policy for an AQP.

HTTPS enrichment is supported for connection to auto-authentication services with web portals that use HTTPS. If an HTTP TLS extension is configured, a customized extension is inserted in the message sent by the client to the server during the TLS handshake. The web portal should include an add-on that will remove the extension and perform integrity checks on the packet without the extension.

Note: HTTP enrichment policy restrictions may differ considerably between NE types and releases. To avoid deployment failures, Nokia recommends that you create a global HTTP enrichment policy for each combination of NE type and release in your network.

For example, create one global policy for each of the following:

Different NE types:	Different NE revisions:
• 7750 SR	• 7750 SR, Release *x* R*y* • 7750 SR, Release *x* R*z*

87.60.2 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Click Create→AA HTTP Enrichment or select an AA HTTP Enrichment (Application Assurance) policy entry and click Properties. The AA HTTP Enrichment (Create | Edit) form opens.

3

Configure the parameters.

4

Click on the HTTP Enrichment Fields tab.

5

Click Create. The HTTP Enrichment Field (Create) form opens.

6

Perform one of the following.

a. Choose a field.

b. Configure the Name parameter.

7

Configure the remaining parameters and select a certificate profile.

The Static String parameter is configurable when the Name parameter is set to static-string.

8

To create an HTTP Enrichment field with a certificate profile, select Certificate for the Encode Type parameter and choose a certificate profile.

Note: If the certificate profile is associated with an HTTP Enrichment field, the association must be removed before the certificate profile can be deleted.

9

Repeat Step 5 to Step 7 to add another field, if required.

10

To configure HTTPS enrichment, click on the HTTP Enrichment TLS Extension tab. The HTTP Enrichment TLS Extension (Create) form opens.

11

Click Select.

12

Choose one or more subtypes and click OK.

13

To configure HTTP RAT enrichment, click on the HTTP RAT Enrichment tab and perform the following to create RAT-type entries:

1. Click Create. The HTTP RAT Enrichment form opens.
2. Configure the RAT Type and RAT String, then click OK.

14

Save your changes and close the forms.

END OF STEPS

87.61 To configure an AA Certificate Profile

87.61.1 Purpose

Use this procedure to create a certificate for use in certificate based encryption. When certificate based encryption is configured for HTTP header encryption, the NE extracts the key from the certificate and uses it to perform encryption.

87.61.2 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Click Create→AA Certificate Profile or select an AA Certificate Profile (Application Assurance) policy entry and click Properties. The AA Certificate Profile (Create | Edit) form opens.

3

Configure the parameters.

The certificate profile is added to the lists in the Application Assurance Policies form and the ISA AA Group (Edit) form.

4

Save your changes and close the forms.

END OF STEPS

87.62 To configure an HTTP notification policy

87.62.1 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Click Create→AA HTTP Notification or select an AA HTTP notification policy entry and click Properties. The AA HTTP Notification (Create | Edit) form opens.

3

Configure the parameters.

The Interval (minutes) parameter is configurable when the Interval Type parameter is set to Minimum Interval.

4

Choose a template.

5

Save your changes and close the forms.

END OF STEPS

87.63 To configure an AA Port List Policy

87.63.1 Purpose

Use this procedure to create an AA Port List Policy. A port list can contain a maximum of 32 port members. Members can be either an individual port or a range of ports.

87.63.2 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Click Create→AA Port List Policy, or select an AA Port List policy and click Properties. The AA Port List Policy (Create | Edit) form opens.

3

Configure the parameters in the General tab.

4

Specify the port list members.

1. Click on the Port List Members tab.
2. Click Create or select an existing collector entry and click Properties. The AA Port List Member (Create | Edit) form opens.
3. Configure the parameters.
4. Save your changes and close the form.

5

Save your changes and close the forms.

END OF STEPS

87.64 To configure an AA IP prefix list policy

87.64.1 Purpose

Perform this procedure to create a policy that contains a list of IP prefixes. You can associate a prefix list with an IP session filter, application filter, or AQP.

87.64.2 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Click Create→AA IP Prefix List Policy or select an AA IP prefix list policy entry and click Properties. The AA IP Prefix List Policy (Create | Edit) form opens.

3

Configure the parameters.

4

Click on the IP Prefix tab.

5

Click Create. The AA Prefix Entry (Create) form opens.

6

Configure the parameters.

7

Save your changes and close the form.

8

Repeat Step 5 to Step 7 to create another prefix entry, if required.

END OF STEPS

87.65 To configure an AA Multi-path TCP policy

87.65.1 Purpose

Perform this procedure to create a policy for multi-path TCP scheduling. You can associate a prefix list with an AQP.

87.65.2 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Click Create→AA Multi-Path TCP Policy or select an AA multi-path TCP policy entry and click Properties. The AA Multi-Path TCP Policy (Create | Edit) form opens.

3

Configure the parameters.

4

Save your changes and close the form.

END OF STEPS

87.66 To configure an AA session filter

87.66.1 Purpose

Perform this procedure to create an AA session filter for an AQP. See 87.24 “To configure an AQP” (p. 2825) for information about configuring an AQP.

87.66.2 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Click Create→AA Session Filter or select an AA session filter entry and click Properties. The AA Session Filter (Create | Edit) form opens.

3

Configure the parameters.

4

Click on the Entries tab and click Create. The AA Session Filter Params (Create) form opens.

5

Configure the parameters.

6

If you set the Action parameter to HTTP Redirect, choose an HTTP redirect policy.

7

Click on the Match Criteria tab and configure the Protocol Number parameter.

8

Perform one of the following in either or both of the Source Address and Destination Address panels.

a. Specify a single IP address or prefix by configuring the Address and Length parameters.

b. Choose an IP prefix list.

9

If required, choose a DNS IP cache in the Destination Address panel.

10

If the Protocol Number parameter is set to SCTP, TCP, or UDP, configure the parameters in the Source Port and Destination Port panels.

11

Save your changes and close the form.

12

Repeat Step 5 to Step 11 to add another filter entry, if required.

13

Save your changes and close the forms.

END OF STEPS

87.67 To configure and manage an AA URL list policy

87.67.1 Purpose

Perform this procedure to configure a URL list policy for an AA URL filter. An AA URL list is a list of URLs that is stored locally in a file on an NE.

87.67.2 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Click Create→AA URL List Policy, or select an AA URL list policy entry and click Properties. The AA URL List Policy (Create | Edit) form opens.

3

Configure the parameters.

Note: You can set the File Size parameter to Extended only when the Minimum ISA Generation value on the associated ISA-AA group is greater than 1.

4

Click Apply.

5

Distribute the policy to NEs, as required.

6

To check the status of a local policy instance, or remove a local decryption key:

1. Click on the Local Definitions tab.
2. Select a local instance and click Properties. The AA URL List Policy form (Edit) opens.
3. View the general status shown by the Operational Flags indicators on the General tab.
4. To remove the local decryption key, click Remove Decrypt Key.
5. Click on the Status tab.
6. Click Search, select an entry, and click Properties. The AA URL List Status Entry form opens. The form displays detailed, NE-specific status information.

7

Close the forms.

END OF STEPS

87.68 To configure an AA URL filter

87.68.1 Purpose

Perform this procedure to configure a URL filter and optional ICAP server or web service for an AQP.

Web services are supported on the following NEs: 7750 SR and 7450 ESS in mixed mode.

Note: To use a web service for AA URL filtering on an ISA-AA Group, the following parameters must be configured on the ISA-AA group:

- For 7450 ESS or 7750 SR NEs, the Minimum ISA Generation parameter should be set to 2.
  For VSR or VMG NEs, the parameter is set by default.
- The Web Service Cache Size parameter should be set to 100.

87.68.2 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Click Create→AA URL Filter or select a URL filter entry and click Properties. The AA URL Filter (Create | Edit) form opens.

3

Configure the parameters.

4

If the Default Action parameter is set to Block Http Redirect, choose an HTTP Redirect policy.

5

Choose an ICAP HTTP Redirect policy, if required.

6

If a web service will be used, configure a Web Server Classify ID and Category Set ID and click Apply.

7

To configure a local filtering allow list:

1. Click Select in the Local Filtering panel.
2. Click Search to populate the list of available URL List policies.
3. Select a list, or click Create and configure the parameters to create a URL list.
4. Click OK.

8

To configure a local filtering deny list:

1. Click on the Local Filtering Deny List tab.
2. Click Create. The AA URL Filter Deny List (Create) form opens.
3. Click Select to select a URL List policy, an HTTP Redirect policy, or both.

Notes:

The deny list cannot be the same as the allow list.

To block HTTP Redirect, the Default Action parameter must be set to Block Http Redirect.

4. Click OK.

9

To create an ICAP server entry:

1. Click on the ICAP Server tab.
2. Click Create. The AA ICAP Server Entries form opens.
3. Configure the parameters.

10

Repeat Step 9 to create an additional ICAP server entry.

11

To create a web service profile:

1. Click on the Web Service Profile tab and click Create.
2. Configure the General parameters.
3. Click on the Web Service Category sub-tab and click Create.
4. Click Select and select the URL categories to block.

12

Repeat Step 11 to create an additional web service profile if needed.

13

To configure a web service classification override:

1. Configure the Classifier ID parameter in the Web Service panel on the General tab.
2. Click on the Web Service Classification Overrides tab.
3. Click Create. the AA URL Filter Web Service Classification Override (Create) form opens.
4. Configure the parameters and click OK.

14

On the General tab, select a Web Service profile as the default profile.

15

Click Apply to save your changes.

16

Distribute the policy to NEs, as required.

17

Close the forms.

END OF STEPS

87.69 To configure an AA DNS IP cache

Note: You can specify an AA DNS IP cache in an application filter or AQP of an AA group policy.

87.69.1 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Click Create→AA DNS IP Cache, or select an AA DNS IP cache and click Properties. The DNS IP Cache (Create | Edit) form opens.

3

Configure the parameters.

4

Specify one or more cache servers.

1. Click on the AA DNS Cache Server tab and click Create. The AA DNS IP Cache Server (Create) form opens.
2. Configure the parameters.
3. Save your changes and close the form.

5

Specify one or more DNS domains and domain substrings.

1. Click on the AA DNS IP Cache Domain tab and click Create. The AA DNS IP Cache Domain (Create) form opens.
2. Configure the parameters.
3. Save your changes.

6

Distribute the policy to NEs, as required.

7

Close the forms.

END OF STEPS

87.70 To enable an AA protocol signature

87.70.1 Purpose

Perform this procedure to administratively enable an AA protocol signature for use by AA functions.

87.70.2 Steps

1

Choose Manage→ISA Functions→ISA-AA from the NFM-P main menu. The Manage ISA-AA form opens.

2

Select an AA protocol entry and click Properties. The AA Protocol (Edit) form opens.

3

Configure the Protocol Administrative State parameter.

You can configure the Protocol Administrative State parameter only for a local protocol.

4

Save your changes and close the form.

END OF STEPS

87.71 To update the AA application database on multiple NEs

87.71.1 Purpose

Perform this procedure to distribute an updated AA application database to multiple NEs using the NFM-P policy synchronization function.

87.71.2 Steps

1

Contact Nokia technical support to obtain the required application database delta file.

2

Using a CLI, execute the delta file on an NE.

Note: If the “Switch Distribution Mode to Local Edit Only on CLI Change” parameter on the System Preferences form is enabled, the distribution mode of each local policy changes to Local Edit Only. Otherwise, the distribution mode remains Sync With Global.

Each local policy on the NE is updated with the delta content, and differs from the global policy.

3

Perform an NE resync audit to ensure that the application database content on the NE and in the local NE policies is synchronized.

4

Perform the following steps to update the global policy from the local policy.

1. Navigate to the global policy by choosing Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.
2. Select AA Group Policy (Application Assurance) from the object drop-down menu and click Search.
3. Select the required global AA group policy and click Synchronize. The Synchronize form opens and the global policy is listed in the Destination Policy Instance(s) panel.
4. In the Available Local Policies list, select the NE that has the updated local policy with the delta content and click the right-pointing arrow. The NE moves to the Selected Source Local Policy panel.
5. Click Synchronize. The NFM-P synchronizes the global policy with the local policy, and the global policy distribution mode changes to Draft.
6. Close the Synchronize form.

5

Perform the following steps to distribute the global policy to one or more NEs.

1. Select the global policy in the Application Assurance Policies form and click Properties. The AA Group Policy (Edit) form opens.
2. Click Switch Mode. The Release - AA Group Policy form opens with the associated NEs listed in the Select Objects panel.
3. Click Distribute. The NFM-P distributes the policy to the NEs.
4. Close the forms.

Note: If a local policy is in Local Edit Only distribution mode, the release has no effect on the local policy; if the distribution mode of a local policy is Sync With Global, the global policy overwrites the local definition.

6

Perform the following steps to switch any local policies in Local Edit Only mode to Sync With Global mode.

1. Choose Local from the Policy scope drop-down menu on the Application Assurance Policies form. The local policies are listed.
2. Select the required policies and click Switch Distribution Mode. The Distribute form opens.
3. Choose Local Edit Only from the drop-down menu. The NEs that have policies in Local Edit Only mode are listed in the Available Nodes with Local Policies panel.
4. Select the NEs in the Available Nodes with Local Policies panel and click the right-pointing arrow. The NEs move to the Selected Nodes with Local Policies panel.
5. Click Synch With Global. The distribution mode of each policy changes to Synch With Global.

7

Close the forms.

END OF STEPS

87.72 To view AA summary information for an ISA-AA group or partition

87.72.1 Purpose

CAUTION

Service Disruption

The AA summary information on the NE may be slightly out of synchronization with the NFM-P database. Before you attempt to resynchronize an ISA-AA group, Nokia recommends that you consider the effect of resynchronizing an ISA-AA group; such an operation may require the retrieval of a large volume of information, and may affect NE performance.

Perform this procedure to view the AA summary information for the following objects associated with an ISA-AA group or partition:

- subscribers
- transit subscribers
- SAPs
- spoke SDP bindings

AA summary information is typically used for AA debugging purposes. You can view debug statistics information on the Statistics tab of an AA object.

87.72.2 Steps

1

In the equipment view navigation tree, expand Network→NE→Logical Groups→ISA-AA Group→ISA-AA Group.

2

Right-click on the ISA-AA Group icon and choose Properties. The ISA-AA Group (Edit) form opens.

3

If partitions are enabled in the ISA-AA group:

1. Click on the Partitions tab. The AA group partitions are listed.
2. Select a partition and click Properties. The ISA-AA Group Partition (Edit) form opens.

4

To view the summary information for an object:

1. Click on the AA Summary tab. The following tabs are displayed; each tab lists the corresponding objects in the ISA-AA group: Subscribers, SAPs, Spoke SDP Bindings, and Transit Subscribers.
2. Click on the appropriate tab.
3. Select an object and click Properties. The AA *object_type* (Edit) form opens.
4. View the information.

5

Close the forms.

END OF STEPS

87.73 To configure subscriber usage monitoring

87.73.1 Purpose

Perform this procedure to configure usage monitoring for a subscriber instance associated with an AA Subscriber Custom Record accounting policy.

87.73.2 Steps

1

Configure the Collect Usage Monitoring Statistics parameter in the AA Subscriber Custom Record accounting policy, as described in Step 5 of 87.37 “To configure an AA accounting policy” (p. 2849) .

2

Distribute the accounting policy to NEs, as required.

3

To configure the export method for a local policy instance:

1. Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.
2. Select AA Group Policy from the object drop-down menu and click Search.
3. Select a policy and click Properties. The AA Group Policy (Edit) form opens.
4. Click on the Local Definitions tab.
5. Select an instance and click Properties. The properties form of the local policy instance opens.
6. Click on one of the following tabs, as required: Application, Application Group, Charging Group.
7. Select an entry and click Properties. The properties form of the entry opens.
8. Click on the AA Subscriber Stats Objects tab.
9. Select a statistics object and click Properties. The AA Subscriber Stats Object Config form opens.
10. Deselect the Enable Selection parameter.
11. Save your changes and close the form.

END OF STEPS

87.74 To view AA statistics data for an ISA-AA group or partition

87.74.1 Steps

1

In the equipment view, expand Network→NE→Logical Groups→ISA-AA Groups-ISA-AA Group.

2

Right-click on the ISA-AA Group icon and choose Properties. The ISA-AA Group (Edit) form opens.

3

Perform one of the following.

a. View AA statistics data for an ISA-AA group.
   1. Click on the Statistics tab.
   2. Choose an AA statistics class from the object drop-down menu.

b. View AA statistics data for an ISA-AA partition.
   1. Click on the ISA-AA Partitions tab. The ISA-AA partitions are listed.
   2. Select an entry and click Properties. The ISA-AA Group Partition (Edit) form opens.
   3. Click on the Statistics tab.
   4. Choose an AA statistics class from the object drop-down menu.

4

Perform one of the following.

a. Click Collect to perform an on-demand collection of the current performance statistics data. The collected statistics entries are listed on the form.

b. Click Collect All to collect one on-demand statistics record for each statistic type that the object supports. The collected statistics entries are listed on the form.

5

Select an entry and click Properties. The Statistics Record form opens.

6

View the statistics data.

7

Close the forms.

END OF STEPS

87.75 To view AA special study statistics data

87.75.1 Purpose

Perform this procedure to view the AA special study statistics data on an ISA-AA MDA. If the ISA-AA group is partitioned, the AA special study tabs are on the partition properties form.

87.75.2 Steps

1

In the equipment view, expand Network→NE→Logical Groups→ISA-AA Groups-ISA-AA Group.

2

Right-click on the ISA-AA Group icon and choose Properties. The ISA-AA Group (Edit) form opens.

3

Click on the AA Special Study tab. The following tabs are displayed; each tab lists the corresponding objects in the ISA-AA group:

- Subscribers
- SAPs
- Spoke SDP Bindings
- Transit Subscribers
- ESM Subscriber Host

4

Click on the appropriate tab. A list of objects is displayed.

5

Select an object and click Properties. The AA *object_type* Config (Edit) form opens.

6

Click on the Statistics tab.

7

Choose an AA statistics class.

8

Perform one of the following.

a. Click Collect to perform an on-demand collection of the current performance statistics data. The collected statistics entries are listed on the form.

b. Click Collect All to collect one on-demand statistics record for each statistic type that the object supports. The collected statistics entries are listed on the form.

9

Select an entry and click Properties. The Statistics Record form opens.

10

View the statistics data.

11

Close the forms.

END OF STEPS

87.76 To view AA statistics data for application filters

87.76.1 Purpose

Perform this procedure to view the application filter hit counts for a local AA group policy.

87.76.2 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Choose AA Group Policy (Application Assurance) from the object drop-down menu.

3

Click Search. The AA group policies are listed.

4

Select an AA group policy and click Properties. The AA Group Policy - Global Policy (Edit) form opens.

5

Click on the Local Definitions tab.

6

Click Search. The local policy instances are listed.

7

Select a policy and click Properties. The AA Group Policy - Local Policy (Edit) form opens.

8

Click on the Application Filters tab.

9

Click Search. The application filters are listed.

10

Select an application filter and click Properties. The Application Filter - Local Policy (Edit) form opens.

11

Click on the Statistics tab and click Collect All.

12

Click Search. The collected statistics records are listed.

13

Select a statistics object and click Properties. The Statistics Record - AA Application Filter Stats form opens.

14

View the statistics data.

15

Close the forms.

END OF STEPS

87.77 To delete an AA application, application group, or custom protocol

87.77.1 Steps

1

Choose Policies→ISA Policies→Application Assurance from the NFM-P main menu. The Application Assurance Policies form opens.

2

Choose AA Group Policy (Application Assurance) from the object drop-down menu and click Search. The AA group policies are listed.

Note: The NFM-P does not create or delete a local AA group policy on each applicable managed NE. A local AA group policy is created or deleted when the ISA-AA group is created or deleted.

3

Select a policy and click Properties. The AA Group Policy (Edit) form opens.

4

Click on the Applications, Application Groups, or Custom Protocols tab, as required.

5

Select an entry and click Delete.

6

Click View Dependencies to review the dependencies, if required.

When an entry is associated with a global AA group policy, the dependency count includes all dependencies on the global and local policy instances. When an entry is in a local AA group policy, the counts include the dependencies on the local policy instance only.

7

Save your changes and close the form.

8

Distribute the updated policy to each NE that has a local definition of the policy.

END OF STEPS

87.78 To delete an inactive AA transit subscriber instance

87.78.1 Purpose

Perform this procedure to remove the record of an inactive AA transit subscriber from the NFM-P database. An AA transit subscriber instance become inactive when the subscriber is deleted from an AA transit IP policy.

Note: You can use an ageout constraint policy to ensure that the number of inactive AA transit subscriber instances in the NFM-P database remains at a manageable level. See the *NSP System Administrator Guide* for information about ageout constraint policies.

AA statistics data can be lost when you delete an AA transit subscriber instance before the NFM-P finishes collecting and processing the AA statistics. Nokia recommends that you wait at least two statistics collection intervals before you delete an inactive AA transit subscriber instance.

87.78.2 Steps

1

Choose Manage→AA Transit Subscribers from the NFM-P main menu. The Manage AA Transit Subscribers form opens.

2

Click Search. The AA transit subscriber instances are listed.

3

Click on the Active column header to sort the list. An inactive AA transit subscriber instance has no check mark in the Active column.

4

Select the AA transit subscriber instance to delete and click Delete. The AA transit subscriber instance is removed from the list.

5

Close the Manage AA Transit Subscribers form.

END OF STEPS

88 Tunnel administrative groups

88.1 Overview

88.1.1 Purpose

The NFM-P supports SDP admin groups—or steering parameters—on all NEs and on all service tunnel types. However, steering parameters are NFM-P objects that are not deployed to NEs. The 7750 SR supports the use of SDP admin groups, which enable services to use PW templates for automatic inclusion or exclusion of specific SDPs.

See the 7750 SR documentation for information about SDP admin groups

In the context of NFM-P management, steering parameters are called tunnel administrative groups. A tunnel administrative group uses steering parameter and SDP admin group concepts.

Tunnel administrative groups use the NFM-P policy distribution model. You can create a global tunnel administrative group and distribute it locally to NEs. Consider the following when you create a tunnel administrative group:

- you can create a maximum of 32 tunnel administrative groups
- the group value is uniquely associated with the group name
- an SDP can be added to more than one tunnel administrative group
- tunnel administrative groups are supported on:
  - GRE service tunnels
  - MPLS:BGP service tunnels
  - MPLS:LDP service tunnels
  - RSVP-LSP service tunnels
  - mixed LSP mode service tunnels
- you cannot assign tunnel administrative groups to an SDP using an LDP IPv6 FEC

SDPs that share a specific characteristic or attribute can be made members of the same tunnel administrative group. When you create a service PW template, you can include and exclude one or more tunnel administrative groups. When a service is bound to the template, the SDP selection rules enforce the specified tunnel administrative group inclusion and exclusion constraints. Tunnel administrative groups allow you to control the SDP, or set of SDPs, that are selected while spokes are established among service sites using PW templates in BGP-AD, BGP-VPLS, or MS-PW applications. Tunnel administrative groups can be assigned to services that use the PW template policy, such as BGP-AD VPLS services, BGP-VPLS services, and Epipe spoke SDP FEC services. See Chapter 83, “Service PW template policies” for more information about PW template policies.

In addition, you can apply tunnel administrative groups to tunnel selection profiles. Tunnel selection profiles assign transport tunnels for a service when the service has been configured for automatic SDP binding creation. When a tunnel selection profile is used within a service to create SDP bindings, any tunnels that include the tunnel administrative group in that profile become eligible for consideration in the tunnel selection process. See Chapter 33, “Service tunnels” for more information about tunnel selection profiles.

88.1.2 Contents

Tunnel administrative group procedures

88.2 Workflow to configure tunnel administrative groups

88.2.1 Overview

The following workflow describes the high-level tasks required to create and configure tunnel administrative groups.

88.2.2 Stages

1

Create a tunnel administrative group. See 88.3 “To create a tunnel administrative group” (p. 2897) .

2

Release and distribute the tunnel administrative group to the NEs. See 88.3 “To create a tunnel administrative group” (p. 2897) .

3

Assign the tunnel administrative group to one or more of the following:

- A service tunnel. See 33.9 “To create an IP/MPLS service tunnel” (p. 1190) in Chapter 33, “Service tunnels” .
- A tunnel selection profile. See 33.13 “To create a tunnel selection profile” (p. 1201) in Chapter 33, “Service tunnels” .
- A service PW template. Ensure that the Use Provisioned SDP parameter on the service PW template is enabled. See 83.3 “To configure a PW template policy” (p. 2744) in Chapter 83, “Service PW template policies” .
- A BGP or BGP AD VPLS. See 77.113 “To assign tunnel administrative groups to a BGP or BGP AD VPLS” (p. 2418) in Chapter 77, “VPLS management ” .

88.3 To create a tunnel administrative group

88.3.1 Steps

1

Choose Manage→Service Tunnels from the NFM-P main menu. The Manage Service Tunnels form opens.

2

Click Create→Tunnel Admin Group. The Tunnel Admin Group, Global Policy (Create) form opens.

3

Configure the required general parameters and click Apply.

4

Click Switch Mode to release the policy for distribution. The Release - Tunnel Admin Group form opens.

5

Choose the NEs in the Available Objects to which you want to distribute the tunnel admin group and click on the arrow button to move the NEs to the Selected Objects panel.

6

Click Distribute and close the form.

7

Save the changes and close the forms.

END OF STEPS

88.4 To list and view tunnel administrative groups

88.4.1 Steps

1

Choose Manage→Service Tunnels from the NFM-P main menu. The Manage Service Tunnels form opens.

2

Choose Tunnel Admin Group (Service Tunnel Management) from the object drop-down menu and click Search.

3

Choose a tunnel administrative group and click Properties. The Tunnel Admin Group - Global Policy (Edit) form opens.

4

Click on the following tabs for additional information:

- Local Definitions
- Service Tunnels—lists the service tunnels to which this tunnel administrative group is assigned, based on ID only
- Tunnel Selection Profiles— lists the tunnel selection profiles that include or exclude this tunnel administrative group, based on ID only

- Service PW Templates— lists the service PW templates that include or exclude this tunnel administrative group, based on ID only
- Faults—lists the alarms raised for the policy

5

Close the forms.

END OF STEPS

Part VII: Service assurance

Overview

Purpose

This part provides information about service assurance using the NFM-P.

Contents

89 Service Test Manager

89.1 Overview

89.1.1 Purpose

This chapter describes the NFM-P Service Test Manager, and provides information about configuring and using the STM.

89.1.2 Contents

Service Test Manager description

89.2 STM concepts and components

89.2.1 OAM diagnostic tests

The NFM-P Service Test Manager (STM) provides access to a set of configurable in-band or out-of-band, packet-based OAM diagnostic tests that allow you to perform on-demand or scheduled verifications of SLA compliance and for network troubleshooting.

You can perform the following tasks with the STM:

- Create on-demand OAM diagnostic tests to provide proactive detection of service degradation and SLA verification and to verify end-to-end service performance. See Chapter 90, “OAM diagnostic tests”for information about each OAM diagnostic test that can be configured with the NFM-P STM.
- Run discrete OAM diagnostic tests on concurrent groups of objects.
- Group OAM tests in an integrated STM test suite for concurrent execution to provide continual performance feedback such as latency, delay, packet loss, and threshold-crossing alerts. The test results are logged for monitoring and trend analysis.
- STM test suites can be immediately processed, scheduled for the automatic execution of tasks using NFM-P-based schedules at designated times, or retained for future use. An NFM-P schedule is configurable for one-time or ongoing task execution.
- Configure threshold-crossing parameters to generate alarms when rising or falling threshold values are reached due to the reach, latency, or jitter issues discovered by the OAM diagnostic tests.
- Automatically generate OAM tests based on object or topology changes.

Note: You can customize some STM-specific user and system preferences to change the default STM settings to meet your operational requirements. See the workflow in 89.9 “STM workflow” (p. 2945) for additional information.

Note: The NFM-P STM allows the deployment of the maximum number of tests to a 7450 ESS, 7750 SR, or 7950 XRS. The NFM-P raises an alarm when the number of tests on an NE is 60% of the configured maximum. Attempts to create or execute a test using the NFM-P fail when the number of deployed tests on an NE is too high.

Note: OAM tests on 7705 SAR-Hm NEs will not execute if the packet size is greater than 1600 octets.

89.2.2 STM test policies

To enable the automatic generation of tests within an STM test suite, the NFM-P requires that the STM test policy contains a set of test definitions that defines the pre- and post-processing rules. An STM test policy also specifies the order of execution for the generated tests. An STM test policy is

applied to an STM test suite during test suite creation. See 89.10 “To configure an STM test policy” (p. 2947) for information about how to create an STM test policy.

You can re-apply an STM test policy under the following conditions:

- by clicking Generate on the Test Policy (Create|Edit) form when any test entities have changed
- by clicking Update Test Suites on the Test Policy (Create|Edit) form

An STM test policy can be used by multiple STM test suites but an STM test suite can have only one associated STM test policy.

Note: You can apply changes made to an STM test policy to all referencing STM test suites by clicking Update Test Suites on the Test Policy (Create|Edit) form.

STM test policy parameters can be configured to only display test results if a test fails or generates a threshold-crossing alarm. In large networks, this can substantially reduce the amount of test data that the NFM-P needs to collect.

An STM test policy is specific to one type of entity; for example, a VLL service or service tunnel. The test definitions in the policy are restricted to the tests that apply to the entity type specified in the policy.

89.2.3 STM test suites

The grouping of OAM diagnostic tests into an STM test suite allows an NFM-P operator to use one schedule for the periodic execution of multiple tests against multiple network objects; for example, services, NEs, or transport components.

An operator can choose to include existing tests, use the NFM-P to generate the OAM diagnostic tests that comprise an STM test suite, or both. Groups of tests in a suite can be configured to execute sequentially or concurrently. In addition, you can configure an STM test suite as an OAM validator to verify the operational status of a service. This can also be done on a one-time basis using the one-time service validation test; see “OAM diagnostic tests” (p. 2980) for more information.

A test suite contains three test groups:

- **First-run tests**

  First-run tests are the tests in a suite that the NFM-P executes before the tests in the other groups. First-run tests are chosen from a list of existing tests and might typically include high-level diagnostics; for example, a service site ping or VPRN ping. No restrictions apply to the types of tests that are selectable as first-run tests.
- **Generated tests**

  Generated tests are created by the NFM-P for use against a specific network entity, based on the entity type specified in the suite and the specific tested entities that are named in the associated test policy. For example, a service site ping test policy associated with a three-site VPRN test suite causes the NFM-P to generate six tests: one site ping test from each site in the VPRN to the other two sites. When you change the configuration of a network entity, such as a service, you must regenerate the generated tests that apply to the entity. Test regeneration removes previously generated tests from a test suite.
- **Last-run tests**

Last-run tests are the tests in a suite that the NFM-P executes after the tests in the other groups. Last-run tests are chosen from a list of existing tests and might typically include transport-layer diagnostics; for example, an LSP trace or a tunnel ping. No restrictions apply to the types of tests that are selectable as last-run tests.

Note: First-run and last-run tests do not apply to STM test suites where the MEF35 Mode parameter is enabled. See 89.12 “To create an STM test suite” (p. 2951) for more information.

To create an STM test suite that contains tests for different entity types, you can specify that the test suite applies to no specific entity type. In this way, you can create a group of disparate tests to which no test policy restrictions apply. Specifying None as the entity type in a test suite has the following effects:

- It allows you to choose any predefined test as a first-run or last-run test.
- It disables test generation in the test suite, because test generation requires a test policy that is based on a specific entity type.

Note: The NFM-P does not attempt to discover tests or test suites that are configured locally on an NE, for example, using a CLI.

Note: By default, the NFM-P suppresses alarms for suspended NEs. See 9.3.3 “Suspending device management” (p. 280) for more information. If you attempt to modify an OAM test or test suite that is deployed to a suspended NE, the NFM-P raises an alarm.

To manage the system resources that test execution consumes, the NFM-P assigns a weight value to a test. When the NFM-P executes a test, it attempts to reserve the test weight from a resource pool, performs the test, then returns the test weight to the pool. The weight of a test suite is the sum of the weights of the individual tests in the suite. The NFM-P attempts to reserve the weight of the whole suite for the duration of suite execution. If the required weight for a test or test suite is unavailable, execution is halted and the Status value contained in the test result is set to Not Enough Resources.

You can create an OAM service validation test to verify the operational status of a service. The operational status of a service depends on the operational states of its service sites or instances. It is possible for a service to be operationally up when communication between sites is not operational. For example, a VRF can be operationally up but the routes to its peers might not be populated because of the routing policy, route target, or ACL configuration. The State Cause of the service indicates the success or failure of the OAM validation test, and therefore, service connectivity.

You can configure an OAM validator when you create a test suite and run the OAM validation test from the service configuration form.

Note: OAM validation tests are not supported for HVPLS.

89.2.4 STM test suite design considerations

Consider the following when you create, schedule, or run STM test suites.

- **General design considerations:**
  - A test, whether pre-existing or generated, is associated with only one STM test suite.

- You can execute a generated test on demand, not just in the context of a test suite.
- An NFM-P user who is assigned the admin or QoS/ACL management scope of command role can create and modify all tests, test policies, and test suites. A user who is assigned the service management scope of command role can create and modify only STM components that are related to services. A user who is assigned the topology management role can create and modify only STM components that are related to network transport elements.

- **STM Test Suite (Create) form parameter considerations**
  - OAM test suites in which the Validation Test Suite parameter is enabled are used to test the operational status of a service or service-related entity such as a service tunnel. The result of this validator test is indicated by the OAM Validation Failed state cause indicator on the General tab of the management form for the object.
  - The Entity Type parameter specifies that only test policies created for the same entity type are available for the test suite. The parameter also restricts the predefined tests that are available as first-run or last-run tests to those that apply to the entity type.
  - To create a test suite that includes tests for different entity types, specify None as the Entity Type parameter value. This allows you to choose any predefined test as a first-run or last-run test.
  - Specifying None as the Entity Type parameter value disables the generation of tests in a test suite; the policy the STM uses to generate tests must be associated with a specific entity type.
  - The Validation Test Suite parameter specifies that the test suite is used to validate the connectivity of the tested service entity to which it is applied. This is also referred to as a validator test suite. OAM validation tests are not supported for HVPLS. See 90.55 “To run a one-time validation test on a service” (p. 3084) for information about how to run a one-time validation test on a service. See 33.26 “To run an OAM validation test on a service tunnel” (p. 1225) for information about how to run a one-time validation test on a service tunnel.
  - If you are creating a test suite that contains an Ethernet CFM test definition, you must enable the NE Schedulable parameter.
- **Scheduling and execution considerations:**
  - The execution of STM test suites can be configured as scheduled tasks. See Chapter 5, “NFM-P-based schedules” for additional design consideration information about using the NFM-P to schedule STM test suites.
  - Using an NE schedule does not ensure that the target NEs perform the actions in an associated STM scheduled task in the order specified; the NEs that execute an NE scheduled task operate independently and are not directed by the NFM-P. As soon as an NE completes an action in an NE scheduled task, it performs the next action.
  - First-run and last-run tests that have the Continuously Executed and Accounting Files options enabled can be added to test suites.
  - When issuing an Execute or Stop Execution command for a test suite that has the Continuously Executed and Accounting Files options enabled, the execution or stopping of the first-run and last-run tests will be triggered.
  - You must click Validate on the associated service or service tunnel configuration form to run the OAM validator test suite. The result of this OAM validation is indicated by the OAM Validation Failed operational flag. See 90.55 “To run a one-time validation test on a service” (p. 3084) for information about how to run a one-time validation test on a service. See

33.26 “To run an OAM validation test on a service tunnel” (p. 1225) for information about how to run a one-time validation test on a service tunnel.

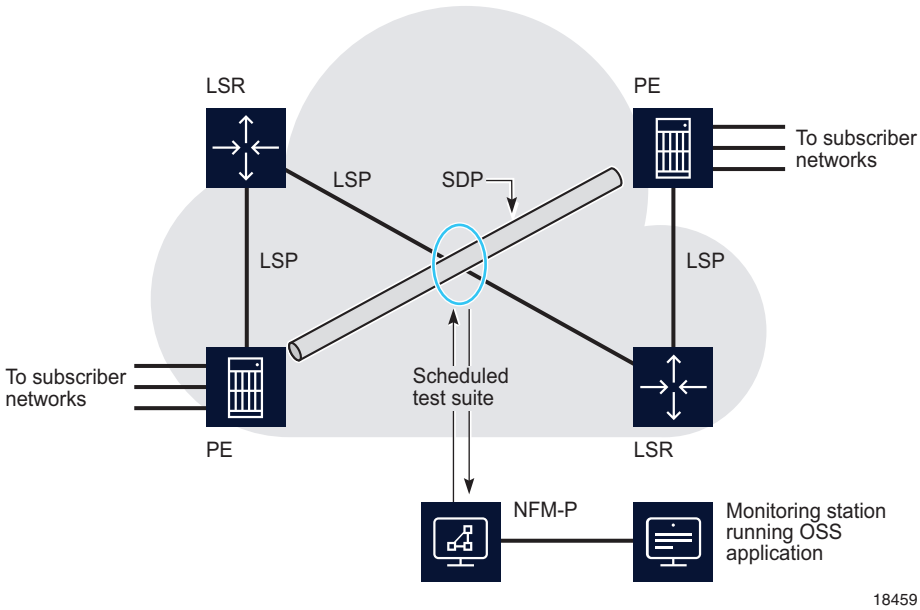
- **Test result considerations:**
  - You can view test suite results for an object from the Tests tab of the configuration form for the object.
  - The NFM-P database logs test results only for scheduled test suites that are associated with NFM-P-defined schedules. Logging for test suites that are associated with NE schedules is performed locally on each target NE.
  - Size constraint policies control the number of historical records that the NFM-P retains in the database. You can configure size constraint policies to limit the number of database objects that are associated with specific test types. See the *NSP System Administrator Guide* for information about size constraint policies.

89.3 Sample STM implementation

89.3.1 STM test suites

The following figure shows a sample STM implementation that illustrates how you can use STM suites to verify service operation and identify network problems.

Figure 89-1 Sample STM implementation



In the sample network, two scheduled STM test suites run constantly to ensure that the transport elements are functioning properly. One test suite monitors the SDPs, and the other test suite monitors the LSPs. An NFM-P administrator can quickly update the test suites, as required, to

reflect network topology changes by revising the list of tested entities in the suite and regenerating the tests. An OSS application collects the test result information which is then available for monitoring by NOC staff.

Note: This sample configuration uses an NFM-P schedule to create a scheduled task. See Chapter 5, “NFM-P-based schedules” for information about NFM-P schedules.

The SDP test suite contains the following generated tests for each SDP:

- tunnel ping
- MTU ping

The LSP test suite contains the following generated test for each LSP path:

- LSP ping (tested entity type is LSP path)

The NOC monitoring staff become aware that tunnel ping operations fail occasionally on one SDP. Packet loss is not yet significant enough to affect SLAs, but threatens to become so, based on the observed trend. NOC staff run a test suite against the LSPs in the affected LSP path.

The test suite contains the following generated test for each LSP in the LSP path:

- LSP ping (tested entity type is LSP)

Test results show that the packet loss is related to a specific LSP in the path. Investigation of the LSP traffic pattern indicates that a recently provisioned service is causing the LSP to be oversubscribed. The problem is addressed by a network designer and is corrected through configuration changes.

The following table lists the high-level tasks necessary to configure and use the STM elements in this sample.

Table 89-1 Sample STM implementation configuration sequence

Task	Description
1. Scheduled STM test suite creation	Create STM test policies for transport-layer elements. • Create a test policy for the SDPs. Specify Tunnel (SDP) as the Entity Type for the policy, and choose Tunnel Ping and MTU Ping as the test definitions. Create separate tunnel ping definitions for different forwarding classes, as required. • Create a test policy for the LSP paths. Specify LSP as the Entity Type for the policy and choose LSP Ping as the test definition. In the test definition, specify LSP Path as the Target Type. Create separate LSP ping definitions for different forwarding classes, as required. Create STM test suites for transport-layer elements. • Create a test suite for the SDPs. Specify Tunnel (SDP) as the Entity Type for the suite, choose the SDP test policy, choose the SDPs against which the suite is to run, and use the NFM-P to generate the tests in the suite. Create a schedule for the test suite according to network monitoring requirements, and apply the schedule to the test suite to create a scheduled task. • Create a test suite for the LSP paths. Specify LSP as the Entity Type for the suite, choose the LSP test policy, choose the LSP paths against which the suite is to run, and use the NFM-P to generate the tests in the suite. Create a schedule for the test suite according to network monitoring requirements, and apply the schedule to the test suite to create a scheduled task.

Table 89-1 Sample STM implementation configuration sequence (continued)

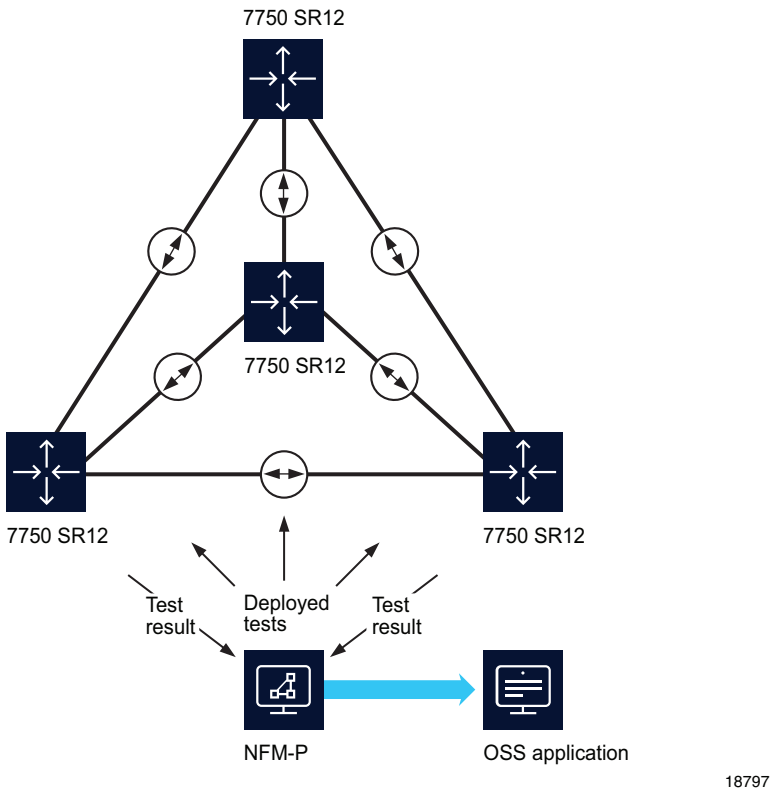
Task	Description
2. Data presentation	Customize the tabular display of test results in the NFM-P, or create an OSS application that retrieves test-result data from the NFM-P and presents it as information in graphical format for NOC staff.
3. Creation of non-scheduled STM test suite or individual OAM tests for network troubleshooting	Create an STM test policy for the LSPs for use during network troubleshooting. • Create a test policy for the LSPs. Specify LSP as the Entity Type for the policy and choose LSP Ping as the test definition. In the test definition, specify LSP as the Target Type. Create separate LSP ping definitions for different forwarding classes, as required. Create a non-scheduled STM test suite (or individual OAM tests, depending on the number of LSPs involved) for the LSPs in the LSP path. • Specify LSP as the Entity Type for the suite, choose the created LSP test policy, choose the LSPs in the LSP path against which the suite is to run, and use the NFM-P to generate the tests for the suite.
4. Network monitoring	Use the NFM-P to display the scheduled test results in tabular format, or use an OSS application to monitor the LSP ping, tunnel ping, and MTU ping diagnostic results in real time. Record inconsistencies and trends, and troubleshoot the network as required. Use the threshold-crossing alarm capabilities to raise alarms when traffic characteristics rise above or fall below specific values.
5. Network troubleshooting	When potential trouble arises, use a non-scheduled STM test suite or individual STM tests to help identify the cause. • Create individual tests or edit the existing non-scheduled test suite. Include as tested entities the LSPs that comprise the LSP path and regenerate the tests for the suite, as required. • Execute the non-scheduled test suite and monitor the test results. • Edit the test definition in the test policy. Change test parameter values as required, regenerate the tests in the suite, and re-execute the suite. Continue to refine the diagnostic test results until the problem manifests itself in the test results.

89.4 Sample STM network SLA monitoring configuration

89.4.1 Continual network topology monitoring

The following figure shows the high-level flow of tests and test results in a simple network topology that the network provider wants to continually monitor using the STM. See the sample network monitoring configuration steps that follow for the steps required to create the STM configuration.

Figure 89-2 Continual network topology monitoring



An NFM-P administrator creates and schedules an STM test suite to monitor the LSP mesh and identify potential overloading and reachability problems before they affect service traffic. The test suite contains ping and trace test definitions for three different classes of in-profile traffic and is scheduled to run every 15 min.

Note: This sample configuration uses an NFM-P schedule to create a scheduled task. See Chapter 5, “NFM-P-based schedules” for information about NFM-P schedules.

Because the same group of tests is to be run on multiple entities of the same type, the test suite consists of generated tests only.

The test policy that the NFM-P uses to generate the tests contains the following six test definitions:

- LSP ping - be in
- LSP ping - af in
- LSP ping - nc in
- LSP trace - be in
- LSP trace - af in
- LSP trace - nc in

The NFM-P generates 72 tests for the test suite—3 ping tests and 3 trace tests for each of the 12 LSPs and LSP paths. Every 15 min., the NFM-P scheduler executes the tests and stores the results. An OSS application periodically retrieves the test results, performs trend analysis, and provides the transport utilization information to NOC monitoring staff.

The NFM-P generates an alarm in the event of an LSP ping probe failure or an LSP trace path change, as specified in the test policy, so NFM-P operators become aware of new transport faults as they arise.

89.4.2 Sample network monitoring configuration steps

The following steps describe the configuration of the network monitoring sample shown in Figure 89-1, “Sample STM implementation” (p. 2909). For clarity, only the configuration steps required for the sample are described. See the procedures in “Procedures to use the STM” (p. 2945) for complete STM configuration information.

89.4.3 Stages

Create a test policy

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager (STM) form opens.

2

Click Create and choose Test Policy. The Test Policy (Create) form opens.

3

Configure the parameters in Table 89-2, “Test policy General tab parameters” (p. 2913), using the supplied values.

Table 89-2 Test policy General tab parameters

Parameter	Value	Comment
Name	LSP Test Policy	—
NE Schedulable	disabled	NE-schedulable test results are not returned to the NFM-P.
Entity Type	LSP	—

4

Click on the Test Definitions tab.

5

To add LSP Ping test definitions to the test policy, click Add and choose MPLS→Add LSP Ping. The LSP Ping Definition (Create) form opens.

In the sample configuration, the operator creates a separate LSP Ping test definition for each of the following forwarding classes:

- be (best effort - low priority, delivery not guaranteed)
- af (assured forwarding - medium priority, delivery guaranteed)
- nc (network control - high priority, delivery guaranteed)

6

Configure the parameters for each test definition using the values supplied in Table 89-3, “LSP Ping Definition parameters” (p. 2913).

Table 89-3 LSP Ping Definition parameters

Parameter	Value	Comment
General tab		
Name	LSP Ping - be in LSP Ping - af in LSP Ping - nc in	Create three LSP Ping test definitions, one for each Name value.
Target Type	LSP	—
Test parameters tab		
Number of Test Probes	5	A value of 5 provides more analysis granularity than a single test probe, without affecting network performance.
Size (octets)	108	This is the minimum packet size for this type of test on the 7450 ESS and 7750 SR. The minimum packet size varies, depending on the type and release of device against which a test runs.
Forwarding Class	be af nc	For LSP Ping - be in test definition For LSP Ping - af in test definition For LSP Ping - nc in test definition To cover a range of traffic streams and to test different network queues, multiple test definitions are necessary. The sample configuration uses three LSP ping definitions that differ only by forwarding class.
Forwarding Profile	in	All test packets are marked in-profile. This means that they follow the same path as service traffic.
Results configuration tab		
Probe History Size (rows)	100	—
Trap Generation	Probe Failure	Test-probe failures provide early notification of LSP congestion or reachability issues to an NFM-P operator. OSS analysis of the results indicates trends for further investigation.

7

For each LSP Ping test Definition you create, click OK to save the changes and close the form. The Test Policy (Create) form is displayed, with the LSP Ping test definitions listed.

8

To add LSP Trace test definitions to the test policy, click Add and choose MPLS→Add LSP Trace. The LSP Trace Definition (Create) form opens.

In the sample configuration, the operator creates a separate LSP Trace test definition for each of the following forwarding classes:

- be (best effort - low priority, delivery not guaranteed)
- af (assured forwarding - medium priority, delivery guaranteed)
- nc (network control - high priority, delivery guaranteed)

9

Configure the parameters for each test definition using the values supplied in Table 89-4, “LSP Trace Definition parameters” (p. 2914).

Table 89-4 LSP Trace Definition parameters

Parameter	Value	Comment
General tab		
Name	LSP Trace - be in LSP Trace - af in LSP Trace - nc in	For first test definition For second test definition For third test definition
Target Type	LSP Path	—
Test parameters tab		
Number of Test Probes	5	A value of 5 provides more analysis granularity than a single test probe, without affecting network performance.
Size (octets)	108	This is the minimum packet size for this type of test on the 7450 ESS and 7750 SR. The minimum packet size varies, depending on the type and release of device against which a test runs.
Forwarding Class	be af nc	For LSP Trace - be in definition For LSP Trace - af in definition For LSP Trace - nc in definition To cover a range of traffic streams and to test different network queues, multiple test definitions are necessary. The sample configuration uses a different LSP Trace definition for each forwarding class.
Forwarding Profile	in	All LSP Trace test definitions in the sample involve in-profile traffic.
Results configuration tab		

Table 89-4 LSP Trace Definition parameters (continued)

Parameter	Value	Comment
Probe History Size (rows)	100	—
Trap Generation	Test Failure Path Change	A test failure trap may indicate a routing or congestion issue, but it also indicates test misconfiguration when the Maximum Time to Live parameter value is too low to allow a test probe to reach the destination LSP. A path change trap may indicate an intermittently congested or unresponsive LSP.

10

For each LSP Trace test Definition you create, click OK to save the changes and close the form. The Test Policy (Create) form is displayed, with the LSP Trace test definitions listed.

11

Click OK to save your changes and close the Test Policy (Create) form. The Service Test Manager (STM) form is displayed.

Create a schedule

12

Choose Tools→Schedules→Schedule from the NFM-P main menu. The Schedule form opens.

13

Click Create. The NFM-P Schedule (Create) form opens.

14

Configure the parameters in Table 89-5, “NFM-P Schedule parameters” (p. 2916) using the supplied values.

Table 89-5 NFM-P Schedule parameters

Parameter	Value	Comment
Name	LSP Assurance	—
Current Client Start Time	a future time	Specify the date and time at which the schedule is to be first triggered. This value is used to calculate the times of subsequent tests, based on the Frequency parameter value. Compare this value and the Frequency parameter value with those in other NFM-P schedules to ensure that the scheduled test times are staggered and the resulting NE task load is balanced.
Ongoing	enabled	This setting tells the NFM-P to repeatedly trigger execution of the task associated with the schedule.

Table 89-5 NFM-P Schedule parameters (continued)

Parameter	Value	Comment
Frequency	Per Minute / 15	Select the Run Every Minutes radio button and specify 15 as the number of minutes for the triggering frequency.

15

Save your changes and close the form.

16

Close the Schedule form.

Create an STM test suite

17

Click Create on the Service Test Manager form and choose Test Suite. The Test Suite (Create) form opens.

18

Configure the parameters in Table 89-6, “Test suite parameters” (p. 2917)using the supplied values.

Table 89-6 Test suite parameters

Parameter	Value	Comment
Name	LSP Test Suite	—
Entity Type	LSP	—
NE Schedulable	disabled	NE-schedulable test results are not returned to the NFM-P.

19

Choose a test policy to govern the generation of tests.

1. Click on the Test Policy tab and click Add.
2. Choose the LSP Test Policy entry you configured in Stage 3 and click OK. The test policy is listed on the Test Policy tab.

20

Choose the LSPs for the test suite to assess.

1. Click on the Tested Entities tab and click Add.
2. Choose the required LSPs and click OK. The LSPs are listed on the Tested Entities tab.

21

Click Apply to save the changes. Additional buttons appear and the form name changes to Test Suite (Edit).

22

Click on the Generated Tests tab.

23

Click Generate Tests. The NFM-P generates a test for each LSP listed on the Tested Entities tab. The tests are listed on the form as they are generated.

24

Apply a span of control to the test suite.

1. Click on the Spans tab and click Add.
2. Choose one or more configured spans to apply to the test suite, and click OK.

Create a scheduled task

25

Click Schedule at the bottom of the Test Suite form. The STM Scheduled Task (Create) form opens. LSP Test Suite is displayed in the Task panel.

26

Configure the parameters in Table 89-7, “NFM-P scheduled task parameters” (p. 2917) using the supplied values.

Table 89-7 NFM-P scheduled task parameters

Parameter	Value	Comment
Scheduled Task Name	Periodic LSP Check	—
Administrative State	Enabled	The NFM-P executes the scheduled task at regular intervals based on the specified Current Client Start Time and Frequency.

27

In the Schedule panel, click Select and choose the LSP Assurance schedule you configured in Stage 14.

28

Save your changes and close the forms.

89.5 Sample STM SAA accounting files configuration

89.5.1 SAA accounting file configuration scenario

This sample describes the configuration of SAA accounting files that are to be collected following the generation of an NE schedulable test of VLL services.

A network provider wants to use the NFM-P to view test result information for an NE schedulable test of VLL services, and wants the NFM-P to process the OAM results MIB entries and produce a compressed XML record that is stored in SAA accounting files on the nodes.

To perform this task, an NFM-P administrator creates an NE schedulable test for VLL services that records test result information in SAA accounting files. The administrator creates one accounting policy, one file policy, one test policy, and one test suite.

89.5.2 Sample SAA accounting files configuration steps

The following steps describe the end-to-end configuration for this sample. For clarity, only the configuration steps required for the sample are described. See the procedures in "Procedures to use the STM" (p. 2945) for complete STM configuration information.

Create an accounting policy

1

Choose Tools→Statistics→Accounting Policies from the NFM-P main menu. The Accounting Policies form opens.

2

Click Create. The Accounting Policy (Create) form opens.

3

Configure the parameters in Table 89-8, "Accounting policy parameters" (p. 2919) using the supplied values.

Table 89-8 Accounting policy parameters

Parameter	Value	Comment
Displayed Name	SAA Accounting Policy	—
Type	NE Schedulable Tests	You must choose this value to allow the configuration of SAA accounting files

4

Create a file policy.

1. Click Select in the File panel, The Select a File Policy form opens.
2. Click Create. The File Policy (Create) form opens.

3. Configure the required parameters. For this sample, enter SAA File Policy as the Displayed Name.
4. Click OK. The form closes and the policy is listed on the Select a File Policy form.

5

Select the newly-created SAA File Policy entry and click OK. The Accounting Policy (Create) form displays the new file policy in the File panel.

6

Click Apply, then click Switch Mode to change the configuration mode to Released.

7

Distribute the SAA Accounting policy to the NEs for which you require the SAA accounting statistics records. See 49.6 “To release and distribute a policy” (p. 1476).

8

Close the forms.

Create a test policy

9

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager (STM) form opens.

10

Click Create and choose Test Policy. The Test Policy (Create) form opens.

11

Configure the parameters in Table 89-9, “Test policy parameters” (p. 2920) using the supplied values.

Table 89-9 Test policy parameters

Parameter	Value	Comment
Name	SAA Test Policy	—
NE Schedulable	enabled	You must enable this parameter to allow the configuration of SAA accounting files.
Entity Type	VLL Service	—
Accounting Files	enabled	You must enable this parameter to allow the configuration of SAA accounting files.

12

Add a test definition to the policy.

1. Click on the Test Definitions tab.
2. Click Add and choose Service→Add VCCV Ping. The VCCV Ping Definition (Create) form opens.
3. Configure the required parameters on the General, Test Parameters, and Results Configuration tabs.
4. Click OK to close the form. The VCCV Ping test definition is listed on the Test Policy (Create) form.

13

Click OK to close the Test Policy (Create) form. The Service Test Manager (STM) form is displayed.

Create a test suite

14

Click Create on the Service Test Manager (STM) form and choose Test Suite. The Test Suite (Create) form opens.

15

Configure the parameters in Table 89-10, “Test suite parameters” (p. 2920) using the supplied values.

Table 89-10 Test suite parameters

Parameter	Value	Comment
Name	SAA Test Suite	—
Entity Type	VLL Service	—
NE Schedulable	enabled	You must enable this parameter to allow the configuration of SAA accounting files.

16

Add the test policy you configured in Stage 11.

1. Click on the Test Policy tab, then click Add.
2. Choose the SAA Test Policy entry and click OK. The test policy is listed on the Test Policy tab.

17

Choose the NEs for which you require the SAA accounting statistics records.

1. Click on the Tested Entities tab, then click Add.
2. Choose the NEs that were selected for accounting policy distribution in Stage 7 and click OK. The NEs are listed on the Tested Entities tab.

18

Click Apply to save the changes. Additional buttons appear and the form name changes to Test Suite (Edit).

19

Click on the Generated Tests tab.

20

Click Generate Tests. The NFM-P generates a test for each NE listed on the Tested Entities tab. The tests are listed on the form as they are generated.

89.6 Sample STM threshold-crossing alarm configuration

89.6.1 Threshold-crossing alarm configuration scenario

The following sample configuration focuses on the configuration of a threshold-crossing alarm that is to be included in a test suite. It does not describe the configuration of the test suite, schedule or scheduled task associated with the sample. No test policy is required for the configuration, as it does not involve generated tests.

A network provider needs to use the NFM-P to monitor a customer VPLS named VPLS 17 that carries VoIP traffic. The goal is to have the NFM-P raise an alarm when the round-trip jitter value rises above a specified threshold.

Network jitter values typically range from 10 to 15 ms, but are occasionally as high as 25 ms. Jitter buffers in the end-user VoIP sets can accommodate up to 80 ms of jitter. A network engineer determines that a jitter test threshold of 30 ms is low enough to allow NOC operators sufficient time for investigating a jitter increase, yet high enough to exclude spurious jitter events.

An NFM-P administrator wants to create a scheduled CPE ping test suite for the VPLS that periodically measures the round-trip jitter between each VPLS site and an end device. The administrator creates one CPE ping test for each site in the VPLS.

89.6.2 Sample threshold-crossing alarm configuration steps

The following procedure defines the configuration steps required for this sample. See 89.4 “Sample STM network SLA monitoring configuration” (p. 2911) for information about sample test suite, test policy, or scheduling configurations. See the procedures in “Procedures to use the STM” (p. 2945) for complete STM configuration information. For conciseness, the procedure lists only the configuration steps that are specific to and necessary for the sample.

Create CPE ping test with threshold-crossing criteria

1

Click Create on the Service Test Manager (STM) form and choose L2 Service→CPE Ping. The CPE Ping (Create) form opens.

2

Configure the parameters in Table 89-11, “General CPE Ping test parameters” (p. 2922) using the supplied values.

Table 89-11 General CPE Ping test parameters

Parameter	Value	Comment
General tab		
Name	CPE Ping Test - VPLS 17, Site A	A descriptive name such as this is helpful for quickly identifying the entity under test when viewing the test results.
NE Schedulable	enabled	You must enable this parameter to allow the configuration of threshold-crossing criteria.
Select (in the Service panel)	VPLS 17	Click Search on the Select Service - CPE Ping form, then choose a service.
Select (in the Site panel)	Site A	Click Search on the Select Site - CPE Ping form, then choose a service.
Destination Path Address	*IP address of an end device connected to Site A*	Defines the IP address to which the CPE ping packets are sent.
Source IP Address	*IP address of the NE that originates the test packets*	This IP address must be in the same subnet as the Destination IP Address.
Source MAC Address	*MAC address of the NE that originates the test packets*	—
Test parameters tab		
Number of Test Probes	5	A value of 5 provides more analysis granularity than a single test probe, without affecting network performance.
Results configuration tab		
Probe History Size (rows)	100	This value provides a greater retained test-result history for occasional monitoring by an NFM-P operator.
Trap Generation	Probe Failure	Test-probe failures provide early notification of congestion or reachability issues to an NFM-P operator for troubleshooting purposes.

3

Click Apply. Additional buttons and tabs are displayed, and the form name changes to CPE Ping *Test Name* (Edit).

4

Click on the Threshold Alarms tab.

5

Click Add to add threshold criteria. The NE Threshold Event (Create) form opens.

6

Configure the parameters in Table 89-12, “Threshold-crossing CPE Ping test parameters” (p. 2923) using the supplied values.

Table 89-12 Threshold-crossing CPE Ping test parameters

Parameter	Value	Comment
Type	Round-Trip Jitter	—
Generate Alarm on Rising Threshold	enabled	This is the default setting. Alternatively or additionally, by enabling the Generate Alarm on Rising Threshold parameter, you can configure the NFM-P to generate an alarm when a test-result value falls below a specified threshold. You can also configure the NFM-P to clear a rising-threshold alarm when the test-result value falls below the value configured for the falling threshold.
Rising Threshold tab		
Threshold Value	30	This value specifies that the NFM-P is to generate an alarm when an individual test result contains a round-trip jitter value greater than 30 ms.

7

Save your changes and close the forms.

89.7 STM Y.1564 test configuration

89.7.1 ITU-T Y.1564 tests

The NFM-P supports the ITU-T Y.1564 test methodology, which is used to assess the proper configuration and performance of an Ethernet service before customer notification and delivery. The Y.1564 standard provides for measuring throughput, latency, frame loss, and jitter to assess if the service complies with an SLA. In the STM, Y.1564 tests are configured either as Y.1564 bidirectional tests, or Y.1564 service tests.

The Y.1564 bidirectional tests are supported on the 7705 SAR and 7210 SAS (except the 7210 SAS-E). These tests use a testhead profile for configuration of the test criteria. A variety of test types is supported, including bandwidth availability: see 89.7.2 “ITU-T Y.1564 bidirectional test” (p. 2925).

The Y.1564 service tests are supported on the 7210 SAS-K, supported FP4 or FP5 7x50, and 7250 IXR. These tests provide an enhanced configuration that differs from the bidirectional test configuration, using separate profiles or templates for acceptance criteria and payload, and allowing configuration of multiple test streams; see 89.7.8 “Y.1564 service tests” (p. 2935).

89.7.2 ITU-T Y.1564 bidirectional test

The Y.1564 bidirectional service tests are supported on the 7705 SAR and 7210 SAS (except the 7210 SAS-E). Support for specific functions varies depending on the device type and release; see the NE documentation for more information.

You can perform Y.1564 tests on VLL Epipe services configured on 7705 SAR NEs, and on VPLS and VLL Epipe services on 7210 SAS NEs, except for the following service types:

- PBB Epipe
- B-VPLS
- MVPLS
- I-VPLS

You can configure a supported NE as a testhead for performing Y.1564 tests. The testhead generates test data for various test types and sends it through the service from the source SAP to the remote destination SAP. The remote SAP performs a port loopback with MAC swap and returns the test data to the source SAP. The testhead analyzes the data and produces the test results.

For 7210 SAS NEs, you can assign a no-service access port or a virtual port as a testhead port. The source SAP for the service you are testing must reside on the same NE. For 7210 SAS-R devices, the testhead port and source SAP must reside on the same card.

For 7705 SAR NEs, you do not specify a testhead port; instead, test traffic is identified by a testhead MAC address specifically configured on the NE.

A testhead profile specifies the parameters for the test, including duration, line rate (CIR), burst size (PIR), frame payload details, and acceptance criteria. The values configured for acceptance criteria determine whether a test execution fails or succeeds. Profiles are created and distributed using the NFM-P policy framework. See Chapter 49, “Policies overview” for more information.

To prevent service disruptions when other services share the ports on which the test source SAP and remote SAP are configured, the NFM-P provides a function to move the SAPs to target ports where no services are configured. See Chapter 96, “Service throughput configuration” for more information.

You can use the NFM-P STM to create, save, and execute Y.1564 bidirectional tests for a configured service. You can add the Y.1564 bidirectional test to an NFM-P STM test suite as a first-run or last-run test, and you can use the test suite to schedule the test. Alternatively, you can use the Tests tab of the properties form for the service.

You can also use the NFM-P service topology map to configure or select Y.1564 bidirectional tests and view test results; see 4.2.2 “Managing OAM diagnostics from the topology view” (p. 176). Each test type displays results on a separate tab, except for step-load and bandwidth availability tests which display on one tab. A message is displayed when the number of results exceeds the available tabs; delete older results to allow new results to display.

Consider the following when you add the Y.1564 bidirectional test to an STM test suite.

- Test policies are not supported.
- Generated tests are not supported.
- The Y.1564 bidirectional test is not NE-schedulable.

- Parallel tests are not supported. You can run only one Y.1564 bidirectional test at a time. However, multiple test types can be run sequentially as a single test. See 89.7.5 “Y.1564 bidirectional test types” (p. 2926) in this section.
- You cannot include CIR step-load and CIR step-load color-aware tests as part of an STM test suite.

89.7.3 7210 SAS considerations

The system resource profile for the 7210 SAS testhead NE must be configured appropriately. You must allocate a minimum of six entries to the ingress internal ACL MAC resource pool, and a minimum of two entries to the egress internal resource pool (ACL MAC, IPv4 or IPv6 64-bit criteria). The testhead tool uses resources from these resource pools; if no resources are available, the testhead tool cannot function. You must not allocate resources to the egress internal ACL 128-bit IPv6 criteria. See 6.5.13 “System resource profile” (p. 220) in 6.5 “7210 SAS” (p. 216) and 12.50 “To configure the global system resource profile on a 7210 SAS or 7250 IXR” (p. 380) for more information about configuring the system resource profile.

You must configure a port loopback with MAC swap on the test source port before you initiate the test; see 16.24 “To configure Ethernet ports” (p. 599). Set the Type parameter to Internal.

When you configure a testhead profile for the 7210 SAS, the Profile ID value cannot be greater than 10.

You cannot choose an L2 uplink SAP as the source SAP.

If the service you are testing is a VPLS, you must assign a static MAC to the SAP or SDP (service circuit) on the source site; see 77.29 “To add or modify FIB entries associated with a VPLS” (p. 2290). Static MAC configuration is not required for Y.1564 tests on Epipe services.

For 7210 SAS-D NEs, if more than one mirror service is configured, you cannot run a Y.1564 bidirectional test.

The 7210 SAS-K supports the enhanced Y.1564 service test functionality in addition to the standard Y.1564 bidirectional test functionality. Configuration of the enhanced functionality (also called the service test testhead OAM tool) differs from the bidirectional test configuration; see 89.7.8 “Y.1564 service tests” (p. 2935).

89.7.4 7705 SAR considerations

You must configure a port loopback with MAC swap on the test destination SAP before you initiate the test; see 76.47 “To configure Ethernet loopback for a VLL Epipe L2 access interface on a 7705 SAR” (p. 2189). Set the Mode parameter to Internal, and enable the MAC Swap function.

Egress/Ingress scheduler mode must be set to 16-priority; see 76.44 “To configure scheduling on a VLL L2 access interface” (p. 2186).

For more information about Y.1564 bidirectional tests, including restrictions and configuration guidelines, see the NE documentation.

89.7.5 Y.1564 bidirectional test types

The following test types are supported:

- Single CIR

- Single CIR color-aware
- CIR step-load
- Traffic policing color-aware
- Single PIR
- Single PIR color-aware
- CIR step-load color-aware
- Bandwidth availability

When color-aware tests are selected, the NFM-P provides separate test results for in-profile and out-of-profile traffic. To execute color-aware tests, the Dot1P-In and Dot1P-Out parameters must be set to values other than the default values.

CIR step-load and CIR step-load color-aware tests are run in multiple iterations based on a user-defined percentage of the configured CIR value. With each iteration, the tested CIR value is increased. The percentage determines the number of steps to run. For example, if the configured CIR is 10000 kb/s, and the CIR Step (%) is 25, then the first iteration runs a test for a CIR of 2500 kb/s (25% of the 10000 kb/s line rate). The next iteration increases the test CIR by another 25% of the configured CIR, and so on for each iteration. In this example, the test runs four iterations, until the configured line rate is tested. Each iteration runs for 3 min, regardless of the setting of the test duration. If the first iteration fails, no further iterations are performed.

When a Traffic policing color-aware test is executed, the NFM-P uses a PIR that is calculated according to the formula:

PIR = CIR + 1.25 × (configured PIR value − configured CIR value).

The original configured PIR value is restored when the Traffic policing color-aware test is complete.

Traffic policing color-aware, Single PIR, and Single PIR color-aware tests will not execute if PIR (Admin) is disabled.

Configured test parameter values can change during test execution, depending on the type of test being executed. For example, when the Traffic policing color-aware test is executed, the PIR value is modified to suit the requirements of the test. When test execution is complete, the NFM-P restores the test parameter values to their original configuration.

You can select multiple test types to run in a single test execution, except for the Bandwidth availability test. Bandwidth availability tests must be run separately.

Bandwidth availability tests

The Bandwidth availability test measures the line rate for the service. The NFM-P manages the rate values and accuracy for the test, instructs the testhead to perform test iterations, and ends the test.

The first iteration of the test uses a rate of 960,000 kb/s by default. If the first iteration succeeds, the test ends. If the first iteration does not succeed, the test runs additional iterations to narrow in on a bandwidth that approaches the maximum available rate.

When acceptance criteria are at default values, a tested rate is successful when no packets are dropped. Otherwise, acceptance criteria settings influence the success or failure of an iteration.

A user-configured accuracy value determines the end of the test. When the difference between the highest successful test rate and the lowest failed rate is within the accuracy value, the test ends.

The last successful rate is displayed as the Available Bandwidth on the Y1564 Bi-Directional Test form. Each iteration of the Bandwidth availability test runs for three min, regardless of the test duration configured in the test profile. Lower values for the Accuracy parameter typically produce more iterations of the test. The NFM-P automatically ends a Bandwidth availability test if no SNMP traps are received from the testhead within a calculated time-out period.

89.7.6 Workflow to configure and run Y.1564 bidirectional tests

This workflow describes the high-level steps required to configure Y.1564 bidirectional tests on the NFM-P. For detailed Y.1564 bidirectional test configuration steps, see the sample procedure that follows this workflow. The service to be tested must be fully configured before running the test.

1. For a 7210 SAS testhead NE, configure the system resource profile. Allocate a minimum of six entries to the ingress internal ACL MAC resource pool, and a minimum of two entries to the egress internal resource pool (ACL MAC, IPv4 or IPv6 64-bit criteria). See 12.50 “To configure the global system resource profile on a 7210 SAS or 7250 IXR” (p. 380).
2. For 7210 SAS NEs, configure a port loopback with MAC swap on the test source port; see 16.24 “To configure Ethernet ports” (p. 599). Set the Type parameter to Internal.

   If you are configuring a test on a 7210 SAS-K site, enable the MAC-Swap-Enable parameter on the L2 access interface. For a VLL service, see 76.40 “To create a VLL L2 access interface on a terminating site” (p. 2174) ; for a VPLS, see 77.67 “To create a VPLS or MVPLS L2 access interface” (p. 2332).

   For configuration of enhanced Y.1564 service tests (also called the service test testhead OAM tool) on the 7210 SAS-K, see 89.7.8 “Y.1564 service tests” (p. 2935).

   For 7705 SAR NEs, configure an Ethernet loopback on the destination L2 access interface; see 76.47 “To configure Ethernet loopback for a VLL Epipe L2 access interface on a 7705 SAR” (p. 2189).
3. If the service you are testing is a VPLS, assign a static MAC to the SAP or SDP (service circuit) on the source site; see 77.29 “To add or modify FIB entries associated with a VPLS” (p. 2290).
4. Set the OLC state of the service to Maintenance. See the *NSP System Administrator Guide* for more information.
5. Configure the testhead.

   For the 7210 SAS, select a testhead port on the test source NE.

   For the 7705 SAR, configure the Marker Source MAC Address parameter on the test source NE.
6. Create a testhead profile and distribute the profile to the NE that contains the test-head port and the source SAP of the service to be tested.

   For 7210 SAS NEs, the Profile ID value cannot be greater than 10.
7. Configure the Y.1564 bidirectional test in the NFM-P STM.
8. Move SAPs as required; see Chapter 96, “Service throughput configuration” for more information.
9. Add the Y.1564 bidirectional test to an STM test suite, if required; see 89.12 “To create an STM test suite” (p. 2951) and the overview to 89.7 “STM Y.1564 test configuration” (p. 2924).
10. Execute the test and view the results.

11. Restore the original SAP configuration, if required.

89.7.7 Sample Y.1564 bidirectional test configuration steps

The following procedure lists the configuration steps that are required for this sample. See the procedures in "Procedures to use the STM" (p. 2945) for complete STM configuration information. For configuration of enhanced Y.1564 service tests on the 7210 SAS-K, see 89.7.8 "Y.1564 service tests" (p. 2935).

Prepare the service for the test

1

If the test source NE is a 7705 SAR, configure Ethernet loopback on the destination SAP; see 76.47 "To configure Ethernet loopback for a VLL Epipe L2 access interface on a 7705 SAR" (p. 2189).

If the test source NE is a 7210 SAS, configure a port loopback with MAC swap on the test source port; see 16.24 "To configure Ethernet ports" (p. 599). Set the Type parameter to Internal.

When you configure a test on a 7210 SAS-K, MAC swap address configuration is not required. However, if you are configuring a test on a 7210 SAS-K site, enable the MAC-Swap-Enable parameter on the L2 access interface. For a VLL service, see 76.40 "To create a VLL L2 access interface on a terminating site" (p. 2174) ; for VPLS, see 77.67 "To create a VPLS or MVPLS L2 access interface" (p. 2332).

2

For 7705 SAR NEs, ensure that the egress and ingress scheduler mode for the test SAPs is set to 16-priority; see 76.44 "To configure scheduling on a VLL L2 access interface" (p. 2186).

3

If the service you are testing is a VPLS, assign a static MAC to the SAP or SDP (service circuit) on the source site; see 77.29 "To add or modify FIB entries associated with a VPLS" (p. 2290).

When you configure the test on a 7210 SAS-K, static MAC configuration is not required for VPLS.

4

Set the OLC state of the service to Maintenance. See the *NSP System Administrator Guide* for more information.

Select a testhead port (7210 SAS only)

5

Note: You must configure the testhead port on the 7210 SAS NE that contains the source SAP of the service you need to test. For 7210 SAS-R NEs, the test-head port and source SAP must reside on the same card.

Open the properties form for the 7210 SAS NE that you need to configure.

6

Click on the Globals tab, then click on the Service tab.

7

Note: If you select a physical port as a no-service port, the port cannot contain any SAPs.

Note: Not all chassis types support virtual no-service ports. The number of available virtual ports and the port names vary depending on the chassis type. Virtual ports are not displayed on the navigation tree.

Note: You cannot select the same no-service port for more than one function.

Select a loopback no-service testhead port. Perform one of the following:

a.

Select a physical test-head port.

1. In the TestHead Port panel, click Clear if required, then click Select. The Select TestHead Port form opens.
2. Choose a port and click OK.

b.

Select a virtual testhead port.

1. Enable the Use Virtual TestHead Port parameter.
2. In the Virtual TestHead Port panel, click Clear if required, then click Select. The Select Virtual TestHead Port form opens.
3. Choose a port and click OK.

   The available virtual ports vary depending on the chassis type and card type.

8

Save your changes and close the form.

Configure a testhead MAC address (7705 SAR only)

9

Open the properties form for the NE that you need to configure; choose the 7705 SAR NE that contains the source SAP of the service you need to test.

10

Click on the Globals tab, then click on the OAM tab.

11

On the General tab, configure the Marker Source MAC Address parameter.

Nokia recommends that you use a non-zero MAC address that is unique in the tested network.

Create a testhead profile

12

Note: The testhead profile is distributed to the NE using the NFM-P policy distribution framework; see Chapter 49, “Policies overview”. You must distribute the testhead profile for the Y.1564 bidirectional test to the source site for the service that you are testing.

Choose Tools→Y1564 Profiles→Y1654 Test Head Profile from the NFM-P main menu. The Y1564 Test-Head Profiles form opens.

13

Click Create. The Y1564 Test-Head Profile (Create) form opens.

14

Configure the required general parameters.

For 7210 SAS NEs, the Profile ID value cannot be greater than 10.

The configured PIR value must be greater than the configured CIR value.

To execute color-aware tests, the Dot1P-In and Dot1P-Out parameters must be set to values other than default.

Traffic Policing Color-Aware, Single PIR, and Single PIR Color-Aware tests will not execute if the Disable PIR check box is selected.

15

Configure frame payload details. You can create up to eight frame payload configurations for each testhead profile.

1. Click on the Frame Payload tab, then click Create. The Y1564 Test-Head Payload (Create) form opens.
2. Configure the required parameters.

   The available parameters vary depending on the option you choose for the Type parameter.

   Additional parameters are available when you configure the VLAN Tag 1 and VLAN Tag 2 parameters.
3. Save your changes and close the form. The Y1564 Test-Head Profile (Create) form is displayed.

16

Configure acceptance criteria. You can create up to eight acceptance criteria configurations for each testhead profile.

1. Click on the Acceptance Criteria tab, then click Create. The Y1564 Test Head Acceptance Criteria (Create) form opens.
2. Configure the required parameters.

   Disable the Default check boxes to configure values other than the default values.
3. Save your changes and close the form. The Y1564 Test-Head Profile (Create) form is displayed.

17

Click Apply to save the configured profile. The Y1564 Test-Head Profile (Create) form is displayed with additional buttons.

18

Click on the General tab, then click Switch Mode to change the configuration mode to released.

19

Distribute the profile to the NE that is the testhead and source site for the service to be tested. See 49.6 “To release and distribute a policy” (p. 1476).

You cannot distribute a testhead profile to 7210 SAS NEs if the Profile ID value is greater than 10.

Configure and execute the test using the NFM-P STM

20

Note: You can only execute tests for VPLS or VLL Epipe services that are fully configured in the NFM-P.

Configure initial test settings.

1. Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager (STM) form opens.

   Alternatively, you can configure tests from the service topology map, or from the Tests tab of the properties form for the service you need to test.
2. Click Create and choose Service →Y1564 BiDirectional Test from the drop-down menu. The Y1564 Bi-Directional Test (Create) form opens.
3. Configure the parameters on the General tab.

   You can select and execute multiple test types in a single test, except for the Bandwidth availability test. When the Bandwidth availability test type is selected, you cannot select other test types. See 89.7.5 “Y.1564 bidirectional test types” (p. 2926).

21

Choose a service for the test.

1. Click Select in the Service panel. The Select Service - Y1564 Bi-Directional Test form opens.
2. Choose the service that you need to test and click OK. The Y1564 Bi-Directional Test (Create) form reappears with the service information and additional panels.

22

Configure the Source Site and SAP.

1. Click Select in the Source Site panel. The Select Source Site - Y1564 Bi-Directional Test form opens.
2. Choose the 7210 SAS site that contains the source SAP for the service and click OK. The Y1564 Bi-Directional Test (Create) form reappears with the Source Site information and additional panels.
3. Click Select in the Source Test SAP section of the Source SAPs panel. The Select Source Test SAP - Y1564 Bi-Directional Test form opens.
4. Choose the port that contains the source SAP for the service and click OK. The Y1564 Bi-Directional Test (Create) form reappears with the Source Test SAP information displayed.

23

Note: Configuration of the Remote Site and SAP is optional in an Epipe service because the second terminating site becomes the remote site and SAP by default. However, you must perform this step if you need to select a Remote SAP Target Port in order to move SAPs; see Stage 25.

Configure the Remote Site and SAP, if required.

1. Click Select in the Remote Site panel. The Select Remote Site - Y1564 Bi-Directional Test form opens.
2. Choose the site that contains the remote SAP for the service and click OK. The Y1564 Bi-Directional Test (Create) form reappears with an additional panel and the Remote Site information displayed.
3. Click Select in the Remote Test SAP section of the Remote SAPs panel. The Select Remote Test SAP - Y1564 Bi-Directional Test form opens.
4. Choose the port that contains the remote SAP for the service and click OK. The Y1564 Bi-Directional Test (Create) form reappears with the Remote SAP information displayed.

24

Configure the Forwarding Class parameter, if required.

25

Note: When the ports that contain the source SAP or remote SAP also contain SAPs for services other than the service you are testing, the test may have an impact on those other services. If service impact is a concern, you can choose to move the test source SAP or remote SAP to other ports that will not have an impact on services. When you move SAPs, leave the Ignore Service Impact Validations check box unselected. See Chapter 96, “Service throughput configuration” for more information.

If required, move the SAPs to prevent service disruptions.

1. If service impact is not a concern, enable the Ignore Service Impact Validations parameter and go to Stage 26.
2. Click Select in the Target Port section of the Source SAPs panel. The Select Target Port - Y1564 Bi-Directional Test form opens.
3. Choose a port that does not have an associated service and click OK. The Y1564 Bi-Directional Test (Create) form reappears with the Target Port name displayed.
4. Click Select in the Target Port for Remote SAP section of the Remote SAPs panel. The Select Target Port for Remote SAP- Y1564 Bi-Directional Test form opens.
5. Choose a port that does not have an associated service and click OK. The Y1564 Bi-Directional Test (Create) form reappears with the Target Port for Remote SAP name displayed.

26

Choose and configure a testhead profile for the test.

1. Click on the Test Parameters tab.
2. Click Select in the Profile panel. The Select Profile - Y1564 Bi-Directional Test form opens.
3. Choose a profile and click OK. The Y1564 Bi-Directional Test (Create) form reappears with the profile information and an additional panel.
4. If the site for the service to be tested service is a 7705 SAR, configure the Performance Monitoring parameter.

   When Performance Monitoring is enabled, time-stamped test packets are generated and the test measures latency and jitter. Performance monitoring can affect throughput results for some tests.
5. Click Select in the Payload section of the Payload and Acceptance Criteria panel. The Select Payload - Y1564 Bi-Directional Test form opens.
6. Choose a Frame Payload configuration and click OK. The Y1564 Bi-Directional Test (Create) form reappears with the Payload information displayed.

   For services configured on 7705 SAR NEs, you can choose up to four frame payload configurations per test.
7. If required, click Select in the Acceptance Criteria section of the Payload and Acceptance Criteria panel. The select Acceptance Criteria - Y1564 Bi-Directional Test form opens.
8. Choose an Acceptance Criteria configuration and click OK. The Y1564 Bi-Directional Test (Create) form reappears with the Acceptance Criteria ID displayed.

27

Click Apply. The Prepare and Execute buttons are activated.

28

If you configured a target port to perform a SAP move in Stage 25, click on the General tab, then click Prepare. The Source Test SAP and Remote Test SAP are moved to the Target ports; see Chapter 96, “Service throughput configuration” for more information.

29

Click Execute to run the test. The Results tab of the Y1564 Bi-Directional test is displayed. The test appears in the list.

30

Choose the test from the list to view the results. The Y1564 Bi-Directional Test - Results (View) form opens. The Result Status field displays Pending until the test is complete. The test duration is configured in the test profile and is displayed in the Test Duration panel. When the test is complete, the test information is displayed.

Note: When multiple tests are selected, the Current Test Type in Execution is displayed on the General tab of the Y1564 Bi-Directional Test form. When tests are complete, the current test type displayed is None.

Note: You can stop the test execution at any time by clicking Stop Execution. The NFM-P stops the current test type and runs the next selected test type, if any.

Note: Configured test parameter values can change during test execution, depending on the type of test being executed. For example, when the Traffic policing color-aware test is executed, the PIR value is modified to suit the requirements of the test. When test execution is complete, the NFM-P restores the test parameter values to their original configuration.

31

To restore the moved SAPs to their original ports, click on the General tab, then click Restore; see 96.6 “To restore a service after a throughput configuration” (p. 3255).

89.7.8 Y.1564 service tests

The NFM-P supports enhanced Y.1564 service test functionality on the 7210 SAS-K, supported FP4 or FP5 7x50, and 7250 IXR. For the 7210 SAS-K, the enhanced functionality is also called the service test testhead OAM tool. Y.1564 service tests are configured using separate profiles or templates for acceptance criteria, frame mix and payload. The tests allow for the configuration of multiple streams (also called flows), for which service performance metrics can be obtained.

Each stream can contain the following test types:

- CIR
- CIR-PIR

- Policing
- Performance
- Bandwidth Availability (NFM-P-only test, not present in CLI)

Two options are available for selecting the stream order, which determines how the tests in each stream are executed. The options are:

- Ordered
- Parallel

When Ordered is selected, tests are executed in sequence by test type, but within each test type the tests are executed in numerical order by stream ID. For example, all CIR tests are executed, beginning with the test configured in stream 1, then stream 2, and so on. Then all CIR-PIR tests are executed, again beginning with the lowest-numbered stream ID.

When Parallel is selected, tests are executed in sequence by test type, but within each test type, the tests are executed concurrently for all streams. For example, CIR tests are executed on both stream 1 and stream 2 at the same time, followed by CIR-PIR tests on both streams.

The Performance test type always executes in parallel, regardless of the stream order option selected.

If any of the test types fails, further execution of the remaining test types is halted, and a failed result is shown for the service test.

The NFM-P provides easily-viewed test results for the overall test, and for test types and streams. You can choose to collect and manage test results as accounting statistics, using an accounting policy.

The Y.1564 service test is configured, saved, and executed in the NFM-P STM using menu options and forms that are different from the Y.1564 bidirectional tests; see 89.7.10 “Sample Y.1564 service test configuration” (p. 2937).

See the NE OAM guides for configuration guidelines and more information about the service test testhead OAM tool.

89.7.9 Workflow to implement Y.1564 service tests

The following workflow outlines the basic steps required to perform Y.1564 service tests using the STM.

1

If required, configure an accounting policy for test results collection.

2

Configure profiles or templates for acceptance criteria, frame mix, and payload.

3

Configure the service test general parameters, to select the testhead NE stream order and test durations. Assign an accounting policy if required.

4

Configure service test streams to define test types and to select the required profiles or templates.

5

Execute the test.

6

View the results.

89.7.10 Sample Y.1564 service test configuration

The following sample procedure lists the detailed configuration steps required to configure a Y.1564 service test using the STM. See the procedures in “Procedures to use the STM” (p. 2945) for complete STM configuration information.

1

If required, configure an accounting policy to collect and manage test results, and distribute the policy to the testhead NE; see “To configure an accounting policy” in the *NSP NFM-P Statistics Management Guide*. You must choose Service TestHead for the Type parameter.

Configure test profiles or templates

2

Note: You must distribute the test profiles or templates for the Y.1564 service test to the source site for the services that you are testing. Test profiles and templates are distributed to the NE using the NFM-P policy distribution framework; see Chapter 49, “Policies overview”.

If you are configuring tests for a supported FP4 or FP5 7x50 site or a 7250 IXR site, go to Stage 5

For 7210 SAS-K NEs, configure an acceptance criteria profile.

1. Choose Tools→Y1564 Profiles→Y1564 Acceptance Criteria Profile from the NFM-P main menu. The Y1564 Acceptance Criteria Profiles form opens.
2. Choose a profile from the list, or click Create. The Y1564 Acceptance Criteria Profile (Create|Edit) form opens.
3. Configure the required parameters.
4. Save your changes and close the forms.

3

For 7210 SAS-K NEs, configure a frame mix profile.

1. Choose Tools→Y1564 Profiles→Y1564 Frame Mix Profile from the NFM-P main menu. The Y1564 Frame Mix Profiles form opens.
2. Choose a profile from the list, or click Create. The Y1564 Frame Mix Profile (Create|Edit) form opens.

3. Configure the required parameters. The default size values are defined by ITU-T Y.1564.
4. Save your changes and close the forms.

4

For 7210 SAS-K NEs, configure a payload profile.

1. Choose Tools→Y1564 Profiles→Y1564 Payload Profile from the NFM-P main menu. The Y1564 Payload Profiles form opens.
2. Choose a profile in the list, or click Create. The Y1564 Payload Profile (Create|Edit) form opens.
3. Configure the required parameters.
4. Save your changes and close the forms.

5

For supported FP4 or FP5 7x50 NEs, or 7250 IXR NEs, configure an acceptance criteria template.

1. Choose Tools→Y1564 Profiles→Acceptance Criteria Template from the NFM-P main menu. The Acceptance Criteria Template form opens.
2. Choose a template from the list, or click Create. The Acceptance Criteria Template, Global Policy(Create|Edit) form opens.
3. Configure the required parameters.
4. Save your changes and close the forms.

6

For supported FP4 or FP5 7x50 NEs, or 7250 IXR NEs, configure a frame size template.

1. Choose Tools→Y1564 Profiles→ Frame Size Template from the NFM-P main menu. The Frame Size Template form opens.
2. Choose a template from the list, or click Create. The Frame Size Template, Global Policy(Create|Edit) form opens.
3. Configure the required parameters.
4. Save your changes and close the forms.

Configure general service test settings

7

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager (STM) form opens.

8

Choose a test from the list, or click Create and choose Service →Y1564 Service Test from the drop-down menu. The Y1564 Service Test (Create) form opens.

9

Configure the parameters on the General tab.

Select the site that contains the service SAPs to be tested, and click Apply. The selected site becomes the testhead for generating test traffic.

If required, select the accounting policy configured in Stage 1.

The parameters and configurations available for a test vary depending on the type of NE that is configured for the Site.

Configure service test streams

10

Click on the Service Test Streams tab, where a list of service test streams is displayed.

11

Choose a stream from the list, or click Create. The Y1564 Service Test Stream (Create|Edit) form opens.

12

Configure the required parameters, and assign the required profiles (for 7210 SAS) or templates (for supported FP4 or FP5 7x50 or 7250 IXR).

13

Save your changes and close the form.

Execute the test and view the results

14

Click on the Execute button. The test runs for the duration configured in “Configure general service test settings” (p. 2938), unless a failed result is returned for a stream. Test execution stops when a test fails.

15

When the test is complete, click on the Results tab. A list of test results is displayed.

16

Choose a result from the list, and click Properties. The Y1564 Service Test Result (View) form opens.

17

View the overall test results.

18

To view the service test stream results, click on the Streams tab. A list of streams is displayed.

19

Choose a result from the list, and click Properties. The Y1564 Service Test Stream Result (View) form opens.

20

View the stream results.

21

Close the form.

89.8 Sample OmniSwitch device SLA testing

89.8.1 CPE SLA Test-Head OAM test

You can use the NFM-P STM to perform a CPE SLA Test-Head OAM test to validate and test customer SLAs used on select OmniSwitch devices in Metro Ethernet networks. The test is critical for provisioning or troubleshooting network services between customer endpoints. The CPE SLA Test-Head OAM test supports unidirectional traffic and IPv4.

You can perform the following tasks on the NFM-P without an external test-head device:

- Generate specific flow-based traffic across the network to help identify flow-based issues.
- Identify the impact of QoS settings (for example, SAP profile or QoS policies) on the overall traffic.
- Check the throughput across a provider network. The throughput is displayed on the NFM-P GUI for each iteration of the test.
- Debug flow-specific traffic forwarding across the provider network.
- Analyze the behavior of various user-defined traffic patterns across the provider network.
- Perform the handover testing after the initial deployment.
- Perform on-demand testing and results monitoring using a central entity.

You can perform a CPE SLA Test-Head OAM test using one CPE test-head profile or a group of profiles. You can also run several tests for one CPE Test-Head profile or group of profiles.

The following conditions are applicable to the creation of a CPE SLA Test-Head profile or a group of profiles and their execution:

- A CPE SLA Test-Head Group profile can contain up to eight stream/flows.
- A CPE SLA Test-Head Group profile can contain up to eight analyzers.
- When you configure the STM test execution details, the analyzer test name and the generator test name must be the same.
- If the analyzer has a test (flow) which is not in the generator group profile, the test is not valid.
- When you run a CPE SLA test or test group, only one test can be run at a time. You cannot run

concurrent tests on the same device.

89.8.2 Sample CPE SLA Test-Head profile configuration

The following configuration steps describe how to create a CPE SLA Test-Head profile or a group of profiles on supporting OmniSwitch devices. For information about device support, see the NE documentation.

Note: For OS 6400, OS 6850E, OS 6855 U24X, and OS 9000E NEs running AOS Release 6.4.5, CPE SLA Test-Head profiles and CPE SLA Test-Head Group profiles can only be distributed if the profile has a Tx Rate of 64 kbps or above. If running AOS Release 6.4.6 or later, the Tx Rate must be 88 kbps or above.

89.8.3 CPE SLA Test-Head profile configuration steps

The procedure lists only the configuration steps that are required for this sample. See the procedures in "Procedures to use the STM" (p. 2945) for complete STM configuration information.

Create a CPE SLA Test-Head profile

1

Choose Tools→Y1564 Profiles→AOS CPE Test-Head Profile from the NFM-P main menu. The AOS CPE Test-Head Profiles form opens.

2

Click Create. The AOS CPE Test-Head Profile (Create) form opens.

3

Configure the required parameters.

Additional panels and parameters are available when you configure the Frame Type parameter or set the L2 Saa parameter to true.

4

Click Apply, then click Switch Mode to change the configuration mode to Released.

5

Distribute the CPE Test-Head profile to the required NEs. See Chapter 49, "Policies overview" for more information about policies and policy distribution.

6

Configure the local VLAN and port settings for the CPE Test-Head profile.

1. Click on the Local Definitions tab, then click Search. A list of the NEs to which you distributed the profile in Stage 5 is displayed.
2. Choose an NE and click Properties. The CPE Test-Head Profile form opens.

3. In the VLAN panel, click on the Select button for the Service ID parameter. The Select vlanSitePointer - CPE Test-Head Profile form opens.
4. Click Search and choose a VLAN site.
5. Click Local Audit On to change the mode to Local Edit only.
6. Click on the Select button for the Port parameter. The Select vlan port - CPE Test-Head Profile form opens.
7. Click Search and choose a port.
8. Click Apply and close the form.

7

As required, repeat Stage 1 to Stage 6 to create additional CPE SLA Test-Head profiles.

The CPE SLA test OAM diagnostic test on the STM (see Stage 10), can utilize the following profile types:

- Generator profile
- Analyzer profile
- Loopback profile

You can also group profiles as described in Stage 8 ; otherwise, go to Stage 10.

Create an AOS CPE SLA Test-Head Group profile

8

If required, create an AOS CPE SLA Test-Head Group profile which can be use to bind individual CPE Test-Head profiles to form a group of tests.

Perform the following:

1. Choose Tools→Y1564 Profiles→AOS CPE Test-Head Group Profile from the NFM-P main menu. The AOS CPE Test-Head Group Profile form opens.
2. Click Create. The AOS CPE Test-Head Group Profile (Create) form opens.
3. Configure the required parameters.

   If the Role parameter is set to the Generator option, perform Stage 9. Otherwise, continue with Stage 8.
4. Click on the CPE Test Group Member tab, then click Create. The Select Port - AOS CPE Test Group Profile form opens.
5. Choose the required CPE Test-Head profiles and click OK. The AOS CPE Test-Head Group Profile (Create) form opens displaying the selected profiles.
6. Click OK to save the AOS CPE Test-Head Group profile.
7. Click Search to display the AOS CPE Test-Head Group profile.
8. Choose the AOS CPE Test-Head Group profile and perform Stage 4, Stage 5, and Stage 6.
9. Go to Stage 10.

9

Configure the required feeder port for the generator.

1. Open the Properties form for the required NE.
2. Click on the Globals tab, then on the AOS OAM tab.
3. Click on the Select button for the Feeder Port Name parameter. The Select Feeder Port form opens.
4. Choose the required feeder port and click OK. The NE Properties form reappears.
5. Save your changes and close the form.
6. Perform the rest of the substeps in Stage 8.

Configure the CPE SLA test execution details on the STM

10

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager (STM) form opens.

11

Click Create and choose one of the following options:

a. AOS CPE→CPE SLA Test. This option allows you to run a test on a CPE test-head profile or a group of profiles. The CPE SLA Test (Create) form opens. Perform Stage 12 to Stage 16, and Stage 18 to configure this option.

b. AOS CPE→CPE SLA Test Group. This option allows you to run several tests on a on a CPE test-head profile or group of profiles. The CPE SLA Test Group (Create) form opens with the General tab displayed. Complete Stage 12, Stage 13, Stage 16, Stage 17, and Stage 18 to configure this option.

12

Configure the required parameters.

13

Click Select in the Generator panel and choose a generator profile.

14

Click Select in the Analyzer panel and choose an analyzer profile.

15

Click Select in the Loopback panel and choose an loopback profile.

16

Click on the Test Parameters tab and configure the required parameters.

17

Click on the CPE SLA Test Group Members tab, then click Create. The CPE Test-Head Group Profile form opens.

1. Click Search to display the CPE Test-Head Group profiles.
2. Choose the required CPE Test-Head Group profiles and click OK.

18

Save your changes and close the forms.

Run the STM test and analyze the results

19

On the Service Test Manager (STM) form, choose one of the following options from the object drop-down menu, then click Search.

a. CPE SLA Test (AOS SAS). This option displays all single CPE test-head profile tests that have been created.

b. CPE SLA Test Group (AOS SAS). This option displays all group CPE test-head profile tests that have been created.

20

Choose the appropriate CPE SLA test and click Execute to run the test.

21

To view the test results, click on the Results tab.

Procedures to use the STM

89.9 STM workflow

89.9.1 Stages

1

As required, change the STM default settings to meet your operational requirements when creating or running OAM diagnostics tests with the STM.

a. Enable the debug STM mode parameter on the NFM-P user preferences form to access additional forms on the STM that can be used to configure OAM diagnostic test limits and view additional test configuration information. See 1.23 “To configure NFM-P user preferences” (p. 116) for more information.

b. Customize the NFM-P system preferences such as the default retention time for db test results and log file. See the *NSP System Administrator Guide* for more information.

2

As required, review the appropriate workflow for the OAM diagnostic test you need to run with the STM to determine if any prerequisite steps are required.

a. Review “Procedures to configure and perform OAM diagnostic tests” (p. 3006)in Chapter 90, “OAM diagnostic tests”.

b. Review 89.7.6 “Workflow to configure and run Y.1564 bidirectional tests” (p. 2928) in this chapter.

c. Review “Procedures to configure Ethernet CFM” (p. 3107)in Chapter 91, “Ethernet CFM”.

3

Create the individual OAM diagnostic tests to be run as a discrete test or to be used in an STM test policy or STM test suite. See Table 90-1, “NFM-P supported OAM diagnostic tests and configurations” (p. 2981) for a list of all NFM-P supported OAM diagnostic tests that can be configured using the STM and their applicable procedures.

4

Create or modify an STM test policy to specify which OAM test definitions are to be included in the STM test suite; see 89.10 “To configure an STM test policy” (p. 2947).

5

As required, configure threshold-crossing alarms or NM threshold-crossing alarms as a post-STM OAM diagnostic test or STM test policy creation exercise; see 89.11 “To configure threshold-crossing alarms or NM threshold-crossing alarms for an OAM diagnostic test or STM test policy” (p. 2949).

6

Create or modify an STM test suite; see 89.12 “To create an STM test suite” (p. 2951) or 89.13 “To modify an STM test suite and view additional information” (p. 2955).

7

As required, configure test limits before running the OAM diagnostic test or test suite to view additional test configuration information after performing the test; see 89.14 “To configure OAM diagnostic test limits on the STM and view additional test configuration information” (p. 2957).

8

Run individual or multiple OAM diagnostic tests from the STM and immediately view the test results; see 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959).

9

As required, view and compare OAM diagnostic test results on the STM as a post-analysis exercise; see 89.16 “To view and compare OAM diagnostic test results on the STM” (p. 2960).

10

As required, schedule the execution of an STM test suite as a one-time event or as an ongoing task.

1. Create an NFM-P-based schedule before you schedule the execution of an STM test suite; see 5.6 “To configure an NFM-P-based schedule” (p. 193).
2. Associate an STM test suite with an NFM-P-based schedule; see 5.7 “To associate a task with an NFM-P-based schedule” (p. 194).
3. As required, view which STM test suites are associated with an NFM-P-based schedule; see 5.8 “To view scheduled tasks associated with an NFM-P-based schedule” (p. 195).
4. Turn up the STM test suite scheduled task to allow the test suite to execute as per the schedule details; see 5.10 “To turn up or shut down an NFM-P-based scheduled task” (p. 196).

11

Run an STM test suite from the STM; see 89.17 “To execute an STM test suite” (p. 2961). Alternatively, perform 5.11 “To immediately execute an NFM-P-based scheduled task” (p. 197) to immediately execute the STM test suite from the Scheduled Task form.

12

Monitor the diagnostic results from the scheduled test suite and the alarm list for indications of network or service faults and threshold-crossing alarms.

a. View the STM test suite results; see 89.18 “To view STM test suite results” (p. 2962).

b. View and compare the STM test suite results for a tested entity; see 89.19 “To view and compare STM test suite results for a tested entity” (p. 2963).

13

Interpret OAM diagnostic test results on the STM; see 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964).

14

As required, edit or delete an OAM diagnostic test or test suite; see 89.21 “To edit an OAM diagnostic test” (p. 2975), 89.22 “To delete an OAM diagnostic test” (p. 2975), and 89.23 “To delete an STM test suite” (p. 2976).

89.10 To configure an STM test policy

89.10.1 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager (STM) form opens.

2

Perform one of the following:

a. Create an STM policy. Click Create and choose Test Policy. The Test Policy (Create) form opens.

b. Modify an exiting STM policy. Perform the following:

1. Choose Test Policy (Assurance) from the object menu, then click Search.
2. Choose a test policy and click Properties. The Test Policy (Edit) form opens.

Note: If you modify a test policy that is associated with a test suite, you must click Generate to regenerate the tests in the test suite.

Note: You can apply changes made to an STM test policy to all associated STM test suites by clicking Update Test Suites at the bottom of the Test Policy (Create|Edit) form.

3

Configure the required parameters.

Some parameters are configurable only during test policy creation, and cannot be modified for existing test policies.

The NE Schedulable and MEF35 parameters are mutually exclusive. The NE Schedulable parameter must be selected for SAA-type STM test policies. The MEF35 parameter must be selected for PM Session-type STM test policies.

The Test Family parameter is available when the MEF35 Mode parameter is selected. Configure the Test Family parameter as follows:

- Choose the Ethernet option to enable configuration of DMM, SLM, and LMM PM Session tests for Entity Types of VLL, VPLS, or Composite services.
- Choose the IP option to enable configuration of a TWAMP Light PM Session test for Entity Types of VPRN Service or Router.
- Choose the MPLS option to enable configuration of an MPLS DM Session Test for Entity Types of LSP or LSP (MPLS-TP). The LSP entity type includes RSVP and RSVP Auto LSPs.

You must select the NE Schedulable parameter if the test you are creating will be used in a test suite that requires an NE-scheduled policy.

The Strategy parameter in the Test Generation panel is available when the Entity Type parameter is set to VLL Service or VPRN Service.

The Types parameter in the Address Types panel is configurable when the Entity Type parameter is set to VPRN Service.

The Accounting Files parameter is configurable when the NE Schedulable parameter is selected.

The Continuously Executed and Test Result Storage parameters are configurable when the Accounting Files parameter is selected.

4

Click on one of the following:

a. Test Definitions tab. This tab is available when the MEF35 Mode parameter is not selected. Use this tab to add all OAM test definitions to a test policy except for PM Session OAM test types.

b. PM Session Test Definitions tab. This tab is available when the MEF35 Mode parameter is selected. Use this tab to add all PM Session OAM test definitions to a test policy.

5

Add one or more test definitions to the policy.

1. Click Add and choose an option from the cascading menu, for example, Services→Add Site Ping or PM Session Test→Add CFM SLM Session Test. The selected test definition form opens.

   The available options and test categories vary, depending on the settings specified for the Entity Type, NE Schedulable, or other parameters in Step 3.

2. Configure the required parameters.

   The available parameters depend on the type of test you chose in 1. See the XML API Reference to view information about configurable parameters and their applicability.

3. Click on each of the remaining tabs on the selected test definition creation form, for

instance: Test Parameters, Results Configuration, CFM Details, Bin Group Details, Measurement Interval Details, and so on. Configure the required parameters on each tab. The available tabs vary, depending on the type of test you chose in 1.

4. As required, configure threshold-crossing alarms for the test definition by performing Step 4 to Step 9 of 89.11 “To configure threshold-crossing alarms or NM threshold-crossing alarms for an OAM diagnostic test or STM test policy” (p. 2949).

   Note: Configuration of threshold-crossing alarms is optional, and can be performed either during test definition creation, or later; see 89.11 “To configure threshold-crossing alarms or NM threshold-crossing alarms for an OAM diagnostic test or STM test policy” (p. 2949).

6

Save your changes and close the form. The Test Policy (Create|Edit) form is displayed, with test definitions listed on the Test Definitions tab.

7

CAUTION

Service Disruption

Do not modify the test policy while a scheduled task for the suite is enabled

The operation of scheduled test suites that use the test policy may be adversely affected if you modify the test policy while a scheduled task for the suite is enabled.

If you are configuring an existing test policy, click Update Test Suites to apply the test policy changes to all associated test suites.

You can click on the Usages tab to view a list of the test suites that use the test policy.

8

Save your changes and close the forms.

END OF STEPS

89.11 To configure threshold-crossing alarms or NM threshold-crossing alarms for an OAM diagnostic test or STM test policy

89.11.1 Purpose

Perform this procedure to configure threshold-crossing alarms or NM threshold-crossing alarms as a post-STM OAM diagnostic test or STM test policy creation exercise.

You can configure threshold-crossing alarms or NM threshold-crossing alarms for OAM diagnostic tests based on the following requirements:

- within an discrete OAM diagnostic test or for a test definition within an STM test policy
- for tests that are NE-schedulable or non-NE-schedulable

An alarm is raised when a threshold is crossed, either because the value rose above or fell below the configured level.

Note: The NM threshold-crossing alarms are not configurable for service site ping, VPRN trace, MTU ping, Mrinfo and Mtrace tests. The type of NM threshold-crossing event available for selection depends on the test type.

Note: Configuring threshold-crossing alarms on a test definition within the test policy creates a threshold definition that applies to generated tests. Configuring threshold-crossing alarms directly on a test that is NE-schedulable applies just to the test.

Note: If you modify a test policy associated with a test suite, you must regenerate the generated tests in the test suite.

89.11.2 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager (STM) form opens.

2

Perform one of the following:

a. Choose Test (Assurance) from the object menu to configure threshold alarms for a discrete OAM diagnostic test.

b. Choose Test Policy (Assurance) from the object menu to configure threshold alarms in a test definition within a test policy.

3

Click Search and perform one of the following:

a. Choose an NE-schedulable or non-NE-schedulable test and click Properties. The Test (Edit) form opens.

b. Choose an NE-schedulable or non-NE-schedulable policy and click Properties. The Test Policy (Edit) form opens.

4

Perform one of the following:

a. Click on the Thresholds tab for a discrete OAM diagnostic test.

b. Click on the Test Definition tab for a test definition within a test policy.

5

Perform one of the following:

a. Click Create for a discrete OAM diagnostic test. The NE Threshold Event (Create) form opens.

b. Click Add for a test definition within a test policy. The NE Threshold Event (Create) form opens.

6

Configure the required parameters.

The Clear Alarm on Falling Threshold parameter is configurable when the Include Falling Threshold is enabled.

7

Click on the Rising Threshold tab and configure the Threshold Value parameter.

8

Click on the Falling Threshold tab and configure the Threshold Value parameter.

Note: The Falling Threshold tab can be accessed when the Include Falling Threshold parameter is enabled on the General tab of the NM Threshold Event (Create) form.

9

Click OK to save your changes and close the form.

10

Repeat Step 4 to Step 9 to configure threshold events on additional tests.

11

Select a test and click Execute. A threshold-crossing alarm appears on the dynamic alarm list if the threshold rises above or falls below the configured level.

12

Save your changes and close the forms.

END OF STEPS

89.12 To create an STM test suite

89.12.1 Before you begin

As required, review the 89.2.4 “STM test suite design considerations” (p. 2907) information in this chapter before starting this procedure.

Before performing this procedure, you must configure the STM test policy and test definitions to be included in the STM test suite.

89.12.2 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager (STM) form opens.

2

Click Create and choose Test Suite. The Test Suite (Create) form opens.

3

Configure the required parameters.

The MEF35 and NE Schedulable parameters are mutually exclusive. The MEF35 parameter must be selected if the test suite will contain a test policy that uses PM Session Test Definitions. The NE Schedulable, Validation Test Suite, and Timeout parameters are configurable when the MEF35 Mode parameter is not selected.

You must select the NE Schedulable parameter if the test suite you are creating will use an NE-schedulable test policy.

The Validation Test Suite parameter is configurable when the Entity Type parameter is set to a type that supports validation, for example a VLL service.

The First-run Execution Sequence and Last-run Execution Sequence parameters are configurable when the MEF35 Mode parameter is not selected.

The Accounting Files parameter is configurable when the NE Schedulable parameter is selected.

The Continuously Executed and Test Result Storage parameters are configurable when the Accounting Files parameter is selected.

4

If you chose None as the option for the Entity Type parameter in Step 3, go to Step 8. Otherwise go to Step 5.

5

Add a test policy to the test suite.

1. Click on the Test Policy tab, then click Add.
2. Choose a test policy and click OK. The policy is listed on the Test Policy tab.

   The available policies depend on the option specified for the Entity Type parameter in Step 3.

6

Define the network entities for the test suite.

1. Click on the Tested Entities tab, then click Add.

2. Choose one or more entities and click OK. The selected entities are listed on the Tested Entities tab.

   The available entities depend on the option specified for the Entity Type parameter in Step 3.

   The Test Suite Count column in the Search form indicates the number of configured test suites that a specific test entity is currently associated with. The counter includes test suites that do not contain generated tests.

3. Select any required entities and click Lock Test Generation.

   Locking the test generation means that the initial settings you specify when creating the test suite will be retained, even if later on you change some attributes (for instance, if you are testing SDP tunnels and you extend the tested entities by selecting another SDP tunnel). All customized test attributes are retained when re-generating the tests.

   The NFM-P auto-locks tested entities when generated tests are modified or deleted.

   The Test Re-generation locked field in the list displays a check mark to indicate that the lock is enabled, and the name of the button changes to Unlock Test Generation. If you do not want to lock the test, click Unlock Test Generation. The Test Re-generation locked field in the list will not display a check mark.

7

If you selected the MEF35 Mode parameter in Step 3, go to Step 12.

8

Define first-run tests.

1. Click on the First-run Tests tab, then click Add.
2. Choose one or more tests and click OK.
3. Reorder the first-run test execution sequence, if required. When there is more than one test in the first-run list, the Move Up and Move Down buttons are available. Select a test entry and use the buttons to reorder the tests.

9

Define last-run tests.

1. Click on the Last-run Tests tab, then click Add.
2. Choose one or more tests and click OK.
3. Reorder the last-run test execution sequence, if required. When there is more than one test in the last-run list, the Move Up and Move Down buttons are available. Select a test entry and use the buttons to reorder the tests.

10

Click Apply to save the changes. Additional buttons become available at the bottom of the form.

11

If you chose None as the option for the Entity Type parameter in Step 3, go to Step 16. Otherwise, go to Step 12.

12

Click on the Generated Tests tab or the Generated PM Sessions Tests tab, as applicable.

13

Click Generate Tests.

The Generate Tests button is available only when you have a policy and at least one entity associated with the STM test suite.

The NFM-P begins generating tests for the test suite based on the test policy. The tests appear in a list on the Generated Tests form as they are generated. The name of the originating tested entity for each test is also displayed on the list, for quick reference.

Note: When the test policy or the configuration of an entity on the Tested Entities tab changes, you must regenerate the tests in the test suite by clicking Generate Tests.

Note: When tests have been generated in a test suite which has a test policy already associated with it, these tests will not be altered (deleted and recreated, or set to default tests), when Generate Tests is clicked again.

Note: Any of the tests generated by a test suite can be deleted directly from the list on the Generated Tests tab. Select the tests that you want to delete and click Delete.

Note: For a test suite containing a P2MP LSP Ping Test Policy, the test suite generator will generate one test per S2L path (for P2MP LSP) or one test per leaf node address (for P2MP LDP).

14

Click on the Generation Error Logs tab to view the log files that the NFM-P creates before and during test generation. The Stage drop-down allows you to select the type of logs to examine, including pre-generation and deployment information.

Note: Generation Error Logs messages appear only when failures occur during the test generation process.

15

Click on the Generated Artifacts tab to view a list of all objects created at the time of Test Suite creation or while generating the contained tests. Objects include: MDs, MAs, Global MEGs, MEPs, Bin Groups, tests (including SAA and PM Session), and accounting policies. The Stage drop-down allows you to select the type of information to examine.

Note: The Generated Artifacts tab will not show objects that already existed prior to generating the tests and are just being reused by those tests. Only newly-created objects are displayed.

Note: If objects are manually deleted, they will also be removed from the Generated Artifacts list. For example, if a MEP is deleted, the MEP object and the tests originating from the MEP will all be deleted from the list. If a GMEG is deleted, then all MAs, MEPs, and tests associated with the GMEG will also be deleted from the list.

16

Close the forms. See 89.17 “To execute an STM test suite” (p. 2961) for information about executing a test suite.

END OF STEPS

89.13 To modify an STM test suite and view additional information

89.13.1 Steps

1

You can modify an STM test suite using two methods. Perform one of the following:

a. Modify the test suite using the STM. Go to Step 2.

b. Add an entity to the test suite from the entity to be tested. Go to Step 9.

2

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager (STM) form opens.

3

Choose Test Suite (Assurance) from the object drop-down menu and click Search. A list of test suites appears.

4

Choose a test suite and click Properties. The Test Suite (Edit) form opens.

5

Configure the required parameters on the General tab.

Some parameters are configurable only during test suite creation, and cannot be modified for existing test suites.

6

Modify the components of the test suite.

The following tabs list components of a test suite. Add, remove, or modify components as required.

- Test Policy tab — displays the test policy that is associated with the test suite
- Tested Entities tab — lists the entities that are the subjects of the tests in the test suite

- First-run Tests tab — lists the group of tests in the test suite that run first
- Generated Tests tab — lists the generated tests that are included in the test suite
- Last-run Tests tab — lists the group of tests in the test suite that run last

To configure a test suite component list item, select the item and click Properties.

7

View additional information.

The following tabs display information about the creation and execution of the test suite:

- Results tab — lists the per-run results that are returned by each execution of the test suite
- Individual Test Results tab — lists all individual test results. This is similar to what is displayed when a Tested Entity is chosen and you click on Show Results.
- Generation Error Logs tab — lists the log entries that are created before and during test generation for the test suite. The Stage drop-down menu allows you to select the type of logs to examine, including pre-generation and deployment information.
- Generated Artifacts tab - Lists all objects created at the time of Test Suite creation or while generating the contained tests. Objects include: MDs, MAs, Global MEGs, MEPs, Bin Groups, tests (including SAA and PM Session), and accounting policies. The Stage drop-down menu allows you to select the type of information to examine.
- Faults tab — displays the faults associated with the test suite

Note: Generation Error Logs messages only appear if any failures occur during the test generation process.

Note: The Generated Artifacts tab will not show objects that already existed prior to generating the tests and are just being reused by those tests. Only newly-created objects are displayed.

Note: If objects are manually deleted, they will also be removed from the Generated Artifacts list. For example, if a MEP is deleted, the MEP object and the tests originating from the MEP will all be deleted from the list. If a GMEG is deleted, then all MAs, MEPs, and tests associated with the GMEG will also be deleted from the list.

Note: You can use the Quick Filter on the test result tab pages to narrow down and limit the displayed results.

8

Save your changes and close the forms.

9

Open the Properties form of a supported entity that you want to add to a test suite; for example, a VLL or VPRN service or VPLS.

10

Click on the Tests tab. The Test Suite tab is displayed.

11

Click Add. The Add form appears.

12

Click Search to display a list of test suites. Only test suites applicable to this type of entity will be displayed.

13

Choose a test suite and click OK. The Add form closes and the selected test suite appears in the Test Suite tab.

The entity has now been added to this test suite. You can confirm this by clicking Properties to display the Test Suite (Edit) form. The added entity will appear on the list in the Tested Entities tab. You can also modify any other parameters of the test suite here, as detailed in Step 2 to Step 6 above.

Note: Once you have added the entity, you can also run the test suite from the Test Suite sub-tab by clicking Execute. See 89.17 “To execute an STM test suite” (p. 2961) for information about executing a test suite.

END OF STEPS

89.14 To configure OAM diagnostic test limits on the STM and view additional test configuration information

89.14.1 Purpose

Using the STM, you can optionally configure some limits for OAM diagnostic tests. For example, you can specify the maximum number of pings and traces performed on managed devices during the execution of a test, or you can limit the number of tests that can be performed. The default is to allow an unlimited number of tests.

You can also perform this procedure to see additional information about OAM tests configured on managed devices, such as deployment and schedule information.

Note: Limiting the number of tests does not raise an alarm on the NFM-P, or an SNMP trap on the managed device. The indication that the limit is reached is that no further test results are returned.

89.14.2 Steps

1

Ensure that the Debug STM Mode parameter on the NFM-P User Preferences form is selected. Choose Application→User Preferences from the NFM-P main menu, or see 1.23 “To configure NFM-P user preferences” (p. 116) for more information.

The drop-down options specified in this procedure are available only when Debug STM Mode is enabled.

2

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager (STM) form opens.

3

Choose one of the following options from the object menu.

a. NE Test Agent (Assurance). You can specify the maximum number of pings and traces allowed to be performed on individual managed devices during the execution of a test, or limit the number of tests that can be performed on all managed devices. This option also provides information about the node ID, concurrent ping and trace information, LTT concurrent requests, deployed test counts, and alarm status.

b. Deployed Test (Assurance). You can view additional deployment information about each configured OAM diagnostic test on managed devices such as the node ID, name and description, management ownership, deployment and execution state, schedule status and start time, and alarm status.

c. NE Schedulable Test (Assurance). You can view additional information about NE schedulable tests on managed devices, such as the node ID, name and description, management ownership, test deployed, mode, state, runs and failures, accounting policy ID, accounting suppression, card TCA profile, and alarm status.

4

Click Search. A list of policies or tests appears, depending on the option chosen in Step 3.

5

Choose an item and click Properties. A form opens showing the current configuration and information.

6

As required, view the deployment information, or change the test limits for the managed device to meet your operational requirements.

7

Save your changes and close the forms.

END OF STEPS

89.15 To run one or more OAM diagnostic tests from the STM and view the test results

89.15.1 Purpose

You can run a single OAM diagnostic test from the properties form associated with the test, or from the Service Test Manager (STM) form. To run multiple tests simultaneously, or to add them to an STM test suite, you must use the Service Test Manager (STM) form.

You can view the test results immediately after the test is complete, as outlined in this procedure, or you can view and compare the results of multiple tests, as outlined in 89.16 “To view and compare OAM diagnostic test results on the STM” (p. 2960).

89.15.2 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager (STM) form opens.

2

Click on the object drop-down and expand the Test (Assurance) menu item until the required test type appears.

3

Choose the test type from the menu and click Search. A list of pre-configured tests is displayed.

4

Run the tests. Choose one or more tests in the list and click Execute.

Note: You can select and execute multiple tests from the test list, except for CCM Tests. If multiple tests including CCM tests are selected, the Execute button is not available.

5

View the test results.

1. Select a test in the list and click Properties. The Test (Edit) form opens.
2. Click on the Results tab. A list of test results is displayed.

6

Archive the results, if required. Select one or more of the test results and click Archive.

Archived test results are stored indefinitely. They can only be removed by manually selecting and deleting them.

7

Close the forms.

END OF STEPS

89.16 To view and compare OAM diagnostic test results on the STM

89.16.1 Steps

Perform this procedure to view the results of multiple OAM diagnostic tests accessible on the STM. You can also use this procedure to compare two test results from the same type of test.

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager (STM) form opens.

2

Choose the required test result type. Click on the object drop-down and expand one of the following menu item until the required test results type appears.

a. Test Result (Assurance) — contains the test results from almost all test types that have been run.

b. Test Suite Result (Assurance) — contains the test results from all STM test suites that have been run.

c. Archived Test Results (Assurance) — contains the test results from all individual tests that have been run and archived.

d. One Time Validation Results (Assurance) — contains the test results from all One Time Validation tests that have been run.

3

Choose the required test results type and click Search. The list of test results is displayed.

4

Choose a test result and click Properties. The test results form opens.

5

Click on the tabs to view the test results. You can click View beside an object to open the properties form for that object. Alternatively, click View Test, or View Test Object, to view the required information.

6

To compare results from two tests of the same type, perform one of the following:

a. Choose two test results and click Compare. The Compare form opens. Go to Step 8.

b. Choose one test result and click Compare. This allows you compare the selected test result with a test result from a test results archive. The Compare form opens.

c. Click Compare without choosing any test results. This allows you to select two test results for comparison from a test results archive. The Compare form opens.

The Compare form displays two object fields at the top. If you performed Step 6 a, then these two fields will be populated with the names of the chosen tests. If you performed either of Step 6 b or Step 6 c, then one or both of the fields will be blank.

7

Select the test results to assign as Object A and Object B, as required.

1. Click Select beside the required field. The Select Object form opens.
2. Choose the Test Result type from the drop-down selector and click Search. You can choose a regular or archived test result. A list of test results is displayed.
3. Choose a test result and click OK. The Select Object form closes and the Compare form displays the selection.

   When one of the Object fields is populated and you want to populate the other, then the list displays only the required type of test results, either regular or archived.

8

Click Compare. The comparison is performed and an entry appears in the list.

The Swap button allows you to interchange the names in the Object fields without having to reselect the test results. This is useful when organizing the order in which results are compared in the list.

9

Choose the entry and click Properties. The Difference form is displayed, with the differences between specific properties listed. The Value A column shows the property value in Object A and the Value B column shows the value of the same property in Object B.

The names of the test (Class Name) and test objects are displayed in the field on the right.

10

View the information and close the forms.

END OF STEPS

89.17 To execute an STM test suite

89.17.1 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager (STM) form opens.

2

Choose Test Suite (Assurance) from the object menu.

3

Click Search, then choose a test suite in the list and click Properties. The Test Suite (Edit) form opens with the General tab displayed.

4

Click Execute. The test suite begins to run. You can view the test results when the test is complete.

Note: You can run an OAM validation test from the properties form of a service tunnel or an applicable service. See the applicable service management chapter for more information.

Note: When you execute a test suite from the properties form of an applicable service, only the tests belonging to that service will be executed. Tests within the suite, but not associated with the current tested entity, will not be executed.

Note: When you execute a test suite under the tested entity (by clicking Execute under the entity's Tests>Test Suite sub-tab), NFM-P will create a Tested Entity Result under the entity's Tests>Tested Entity Result sub-tab.

Note: You can click Delete All Result in either the Results tab or the Individual Test Results tabs to remove all listed test results. Alternatively, you can use the Quick Filter on the test result tab pages to narrow down and limit the displayed results. Clicking Delete All Result will then only delete the filtered results. If no filter condition is specified, then clicking Delete All Result will delete all the pages of results, not just the currently displayed page.

Note: If the list under either of these tabs contains more than 1000 entries, only 1000 entries are displayed at a time, with paging available for the remainder. However, clicking Delete All Result deletes all pages of results, not just the currently displayed page.

5

Close the Test Suite (Edit) form.

END OF STEPS

89.18 To view STM test suite results

89.18.1 Purpose

Perform this procedure to view STM test suite results from the Test Suite Result form.

Note: You can also view the test suite results for an object from the Tests tab of the configuration form for the object.

89.18.2 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager (STM) form opens.

2

Choose Test Suite Result (Assurance) from the object menu.

3

Click Search, then select a test suite result and click Properties. The Test Suite Result form opens.

4

View the information and statistics on the General tab.

5

To view test results, click on the Results tab and perform one of the following:

a. Use the horizontal scroll bar at the bottom of the list to view the tabular information about the listed tests.

b. Choose an entry from the list and click Properties. The results form for the selected test opens.

6

Close the forms.

END OF STEPS

89.19 To view and compare STM test suite results for a tested entity

89.19.1 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager (STM) form opens.

2

Choose Test Suite (Assurance) from the object menu and click Search. A list of test suites is displayed.

3

Choose a test suite in the list and click Properties. The Test Suite (Edit) form opens.

4

Click on the Tested Entities tab to view a list of entities tested by the test suite.

Note: The Test Generation State column displays the overall test state of each entity. The possible values are:

- Not Generating — No test generation is applicable; for example, the test suite type is set to none.
- No Test Generated — Generation did not produce any tests.
- Policy Distribution — Required policies are being distributed in preparation for test generation.
- Pre-Generation — Prerequisite tasks and object configurations are being performed.
- Test Generation — Tests are being generated.
- Generation Complete — Test suite has successfully generated.
- Generation Failed — Test generation failed; test suite configuration should be reviewed.

5

Choose a tested entity and click Show Results. The Tested Entity (Edit) form opens.

6

Click Search, then choose a test result and click Properties. The results form for the selected test opens.

7

To compare two test results from the same type of test, choose the two test results and click Compare. The Difference form opens.

8

Close the forms.

END OF STEPS

89.20 To interpret OAM diagnostic test results on the STM

89.20.1 Steps

1

Perform the appropriate OAM diagnostic test. See Table 90-1, “NFM-P supported OAM diagnostic tests and configurations” (p. 2981) for a list of supported OAM diagnostic tests and their applicable procedures.

2

Perform 89.16 “To view and compare OAM diagnostic test results on the STM” (p. 2960) to view OAM diagnostic test results.

3

The General and Response Packets tabs display the key information about OAM diagnostic results.

When no packet information is required, as for an OAM ping, the information appears on the Packets Results form without any tabs. For example, status and return code information appears directly on the Packets Results form.

You can view test packet information by performing the following:

1. Click on the Response Packets tab. A list of test objects appears.
2. Choose an object and click Properties. The Packets Results form opens.

4

Interpret the results, based on the status and return code information.

a. For MTU OAM diagnostics, the key information is how many frames were sent and incrementally increased in size before the frames could not be sent.

   When the frame cannot be sent because it is too large, that results in a request timeout message. The largest frame that was sent is the last frame size with an associated success response.

b. For tunnel OAM diagnostics, the key information is the result of the diagnostic, displayed in the status message. The following table lists the displayed messages and descriptions.

Table 89-13 Tunnel OAM diagnostics results

Displayed message	Description
Request Timeout	The request timed out with a reply.
Orig-SDP Non-Existent	The request was not sent because the originating SDP does not exist.
Orig-SDP Admin-Down	The request was not sent because the originating SDP administrative state is operationally down.
Orig-SDP Oper-Down	The request was not sent because the originating SDP operational state is down.
Request Terminated	The operator terminated the request before a reply could be received or before the timeout of the request could occur.
Far End: Originator-ID Invalid	The request was received by the far end, but the far end indicates that the originating SDP ID is invalid.
Far End: Responder-ID Invalid	The request was received by the far end, but the responder ID is not the same destination SDP ID that was specified.
Far End:Resp-SDP Non-Existent	The reply was received, but the return SDP ID used to respond to the request does not exist

Table 89-13 Tunnel OAM diagnostics results (continued)

Displayed message	Description
Far End:Resp-SDP Invalid	The reply was received, but the return SDP ID used to respond to the request is invalid.
Far End:Resp-SDP Down	The reply was received, but the return SDP ID indicates that the administrative or operational state of the SDP is down.
Success	The tunnel is in service and working as expected. A reply was received without any errors.

c. For service site OAM diagnostics, the key information is the result of the diagnostic, which is displayed in the status message and with the other records from the General tab.

As the diagnostic traverses the service across the originating and destination IP addresses, the service tunnels, and the used VCs, the status of each portion of the service is displayed. The following table lists the displayed messages and descriptions.

Table 89-14 Service site OAM diagnostics results

Displayed message	Description
Sent - Request Timeout	The request timed out with a reply.
Sent - Request Terminated	The request was not sent because the diagnostic was terminated by the operator.
Sent - Reply Received	The request was sent and a successful reply message was received.
Not Sent - Non-Existent Service-ID	The configured service ID does not exist.
Not Sent - Non-Existent SDP for Service	There is no SDP for the service being tested.
Not Sent - SDP For Service Down	The SDP for the service is down.
Not Sent - Non-Existent Service Egress Label	There is a service label mismatch between the originator and responder.

d. For MAC, VPRN, and multicast FIB ping OAM diagnostics, the key information is the result of the diagnostic. The following table lists the return codes and descriptions.

Table 89-15 MAC, VPRN, multicast FIB ping OAM diagnostics results

Displayed message	Description
notApplicable (0)	The OAM diagnostic message does not apply to the OAM diagnostic performed.
fecEgress (1)	The replying router is an egress for the FEC.
fecNoMap (2)	The replying router has no mapping for the FEC.
notDownstream (3)	The replying router is not a downstream router.
downstream (4)	The replying router is a downstream router, and the mapping for this FEC on the router interface is the specified label.

Table 89-15 MAC, VPRN, multicast FIB ping OAM diagnostics results (continued)

Displayed message	Description
downstreamNotLabel (5)	The replying router is a downstream router, and the mapping for this FEC on the router interface is not the specified label.
downstreamNotMac (6)	The replying router is a downstream router, but it does not have the specified MAC address.
downstreamNotMacFlood (7)	The replying router is a downstream router, but it does not have the specified MAC address and cannot flood the request to other routers.
malformedEchoRequest (8)	The received echo request is malformed.
tlvNotUnderstood (9)	One or more TLVs were not understood.
downstreamNotInMFib (10)	The replying router is a downstream router, but it is not part of the MFIB.
downstreamMismatched (11)	The downstream mapping is mismatched.
upstreamIfIdUnkn (12)	The upstream interface index is unknown.
noMplsFwd (13)	The label switched successfully but MPLS forwarding did not occur at stack-depth.
noLabelAtStackDepthh (14)	The label entry at stack-depth did not occur.
protoIntfMismatched (15)	The protocol is not associated with the interface at FEC stack-depth.
terminatedByOneLabel (16)	The ping was terminated prematurely due to the label stack shrinking to a single label.
seeDDMapForRetCodeSubCode (17)	See DDMap TLV for the return code and sub-return code.
fecStackChange (18)	The label switched with an FEC stack change.

e. For multicast router OAM diagnostics, the key information includes information that is related to adjacent routers, supported protocols, traffic metrics, and time-to-live thresholds. Administrators can use this information to identify bidirectional adjacency relationships.

f. For multicast trace OAM diagnostics, the key information is the result of the diagnostic, displayed in the status message. The following table lists the displayed messages and descriptions.

Table 89-16 Multicast trace OAM diagnostics results

Displayed message	Description
noError (0)	No error.
wrongIf (1)	The router is not forwarding the multicast source or group traffic because the router is not part of the multicast path.
pruneSent (2)	The router sent a prune request upstream that impacts the multicast source and group in the trace request.

Table 89-16 Multicast trace OAM diagnostics results (continued)

Displayed message	Description
pruneRecvd (3)	The router stopped forwarding traffic for the multicast source and group in response to a request from the next hop router.
scoped (4)	The multicast group is subject to administrative scoping.
noRoute (5)	The router has no route for the multicast source or group and no way to determine a potential route.
wrongLastHop (6)	The router is not the correct last-hop router.
notForwarding (7)	The router is not forwarding the multicast source or group traffic for an unspecified reason.
reachedRP (8)	Request arrived on the rendezvous point or core.
rpfIf (9)	The request arrived on the expected RPF interface.
noMulticast (10)	The request arrived on an interface that is not enabled for multicast traffic.
infoHidden (11)	One or more hops are hidden from the trace.
fatalError (12)	Fatal error.
noSpace (129)	There is insufficient room to insert another response data block in the packet.
oldRouter (130)	The previous router hop cannot process the multicast trace request.
adminProhib (131)	The multicast trace was administratively prohibited.
unknown (132)	Unknown error.

g. For most diagnostics, common return codes are used. The return codes indicate the status of OAM tests, usually when there was a problem performing the test. The following table lists return codes and descriptions.

Table 89-17 OAM diagnostics return codes

Return code	Description
notApplicable (0)	A response was received on the device which is not applicable to the OAM diagnostic performed.
responseReceived (1)	A response to the OAM diagnostic was received on the device.
unknown (2)	The OAM diagnostic failed for an unknown reason.
internalError (3)	An internal error on the device caused the diagnostic to not be performed.
maxConcurrentLimitReached (4)	The device cannot perform the OAM diagnostics because there are too many OAM diagnostic operations already running.
requestTimedOut (5)	The OAM diagnostic could not be completed because no reply was received within the allocated timeout period.
unknownOrigSdpId (6)	Indicates an invalid or non-existent originating service tunnel.
downOrigSdpId (7)	The originating service tunnel is operationally down.
requestTerminated (8)	The OAM diagnostic was canceled before the timeout or reply period was reached.

Table 89-17 OAM diagnostics return codes (continued)

Return code	Description
invalidOriginatorId (9)	The far-end device replied indicating that the originating ID was invalid.
invalidResponderId (10)	The far-end device replied with an invalid responding ID.
unknownRespSdpId (11)	The far-end device replied with an invalid response service tunnel ID.
downRespSdpId (12)	The responding service tunnel with the given ID is operationally or administratively down.
invalidServiceId (13)	An invalid or non-existent service ID.
invalidSdp (14)	An invalid or non-existent service tunnel for the service.
downServiceSdp (15)	The service tunnel bound to the service is down.
noServiceEgressLabel (16)	The egress label for the service does not exist.
invalidHostAddress (17)	The IP address for the host is invalid, for example, in the case of a broadcast or multicast IP address.
invalidMacAddress (18)	The MAC address specified in the OAM diagnostic is invalid.
invalidLspName (19)	The LSP name specified in the OAM diagnostic is invalid.
macIsLocal (20)	The MAC address is the local SAP or device MAC address, not the MAC address of the downstream SAP or device, therefore the MAC ping or trace cannot be sent.
farEndUnreachable (21)	No route is available to the far-end GRE service tunnel.
downOriginatorId (22)	The originating ping device is operationally down.
downResponderId (23)	The device responding to the ping is operationally down.
changedResponderId (24)	The ID of the device responding to the ping has changed.
downOrigSvcId (25)	The originating service identified by the ID is operationally down.
downRespSvcId (26)	The service responding to the ping identified by the ID is operationally down.
noServiceIngressLabel (27)	The ingress label for the service does not exist.
mismatchCustId (28)	The subscriber ID identified with the service differs between the originating device and the responding device.
mismatchSvcType (29)	The service type identified with the service differs from one device to another.
mismatchSvcMtu (30)	The service MTU size associated with the service differs between the originating device and the responding device.
mismatchSvcLabel (31)	The service label identified with the service differs between the originating device and the responding device.
noSdpBoundToSvc (32)	There is no service tunnel bound to the service.
downOrigSdpBinding (33)	The service tunnel associated with the originating device's service is operationally down.
invalidLspPathName (34)	The LSP path name specified in the OAM diagnostic is invalid.
noLspEndpointAddr (35)	There is no LSP endpoint address specified in the OAM diagnostic.
noActiveLspPath (36)	There is no active LSP path.
downLspPath (37)	The far end of the LSP is operationally down.

Table 89-17 OAM diagnostics return codes (continued)

Return code	Description
invalidLspProtocol (38)	The LSP protocol is not valid or is not supported.
invalidLspLabel (39)	The LSP label is invalid.
routeIsLocal (40)	For a VPRN ping, the route is a local route.
noRouteToDest (41)	For a VPRN ping, there is no route available to the destination of the OAM diagnostic.
localExtranetRoute (42)	For a VPRN ping, the route is a local extranet route.
srcIpInBgpVpnRoute (43)	For a VPRN ping, the source IP address belongs to a BGP VPN route.
srcIpInvalid (44)	For a VPRN ping, the source IP address is invalid or no route is available to the source IP address.
bgpDaemonBusy (45)	For a VPRN trace, the BGP routing process is busy on the device, and VPRN route target information cannot be retrieved.
mcastNotEnabled (46)	Multicast is not enabled on the device, so the diagnostic cannot be performed.
mTraceNoSGFlow (47)	No (*,G)/(S,G) flow on the router. The multicast trace cannot be initiated.
mTraceSysIpNotCfg (48)	The system IP address is not configured. The address is required for a response to a multicast trace.
noFwdEntryInMfib (49)	No forwarding entry could be found for the specified source and destination addresses in the MFIB.
dnsNameNotFound (50)	The domain name specified in the dns query does not exist.
noSocket (51)	For icmp-ping, unable to get socket.
socketOptVprnIdFail (52)	For icmp-ping, unable to set SO_VPRNID for socket.
socketOptIfIndexFail (53)	For icmp-ping, unable to set IP_IFINDEX for socket.
socketOptNextHopFail (54)	For icmp-ping, unable to set IP_NEXT_HOP for socket.
socketOptMtuDiscFail (55)	For icmp-ping, unable to set IP_MTU_DISC for socket.
socketOptSndbufFail (56)	For icmp-ping, unable to set SO_SNDBUF for socket.
socketOptHdrincFail (57)	For icmp-ping, unable to set IP_HDRINCL for socket.
socketOptTosFail (58)	For icmp-ping, unable to set IP_TOS for socket.
socketOptTtlFail (59)	For icmp-ping, unable to set IP_TTL for socket.
bindSocketFail (60)	For icmp-ping, unable to bind socket.
noRouteByIntf (61)	For icmp-ping, no route to destination via the specified interface.
noIntf (62)	For icmp-ping, no interface specified.
noLocalIp (63)	For icmp-ping, unable to find local IP address.
sendtoFail (64)	For icmp-ping, the send to function failed.
rcvdWrongType (65)	For icmp-ping, received packet of wrong ICMP type.
noDirectInterface (66)	For icmp-ping, no direct interface to reach destination.

Table 89-17 OAM diagnostics return codes (continued)

Return code	Description
nexthopUnreachable (67)	For icmp-ping, unable to reach the next-hop.
socketOptHwTimeStampFail (68)	For icmp-ping, unable to set IP_TIM_TIME for socket.
noSpokeSdpInVll (69)	For vccv-ping, unable to find spoke-sdp given SdpId:vc-id.
farEndVccvNotSupported (70)	For vccv-ping, far end does not support the VCCV options.
noVcEgressLabel (71)	For vccv-ping, no VC egress label to send vccv-ping
socketOptIpSessionFail (72)	For icmp-ping, unable to set IP_SESSION for socket.
rcvdWrongSize (73)	For icmp-ping, received packet of wrong size.
dnsLookupFail (74)	For icmp-ping, dns lookup failed.
noIpv6SrcAddrOnIntf (75)	For icmp-ping, no ipv6 source on the interface.
multipathNotSupported (76)	For lsp-trace, downstream NE does not support multipath.
nhIntfNameNotFound (77)	For lsp-ping/trace, given next-hop interface name not found.
msPwInvalidReplyMode (78)	For vccv-ping, MS-PW switching NE supports ip-routed reply mode only.
ancpNoAncpString (79)	ANCP string unknown to the system.
ancpNoSubscriber (80)	Subscriber unknown to the system.
ancpNoAncpStringForSubscriber (81)	Subscriber has no associated ANCP string.
ancpNoAccessNodeforAncpString (82)	No access NE is found for the given ANCP string.
ancpNoAncpCapabilityNegotiated (83)	ANCP capability not negotiated with the involved DSLAM.
ancpOtherTestInProgress (84)	Another ANCP test is running for this ANCP string.
ancpMaxNbrAncpTestsInProgress (85)	Maximum number of concurrent ANCP tests reached.
spokeSdpOperDown (86)	For vccv-ping, spoke-sdp is operationally down.
noMsPwVccvInReplyDir (87)	Switching NE in MS-PW with no VCCV support in echo reply direction.
p2mpLspNameOrInstInvalid (88)	P2MP LSP name or instance provided is not valid.
p2mpLspS2LPathDown (89)	LSP path to S2L is down.
p2mpLspS2LAddressInvalid (90)	One or more S2L addresses is not valid.
p2mpLspNotOperational (91)	P2MP LSP is operationally down.
p2mpLspTrMultipleReplies (92)	Probe returned multiple responses. Result may be inconsistent.
invalidMepId (93)	The user-configured MEP identifier is not valid.
multipleReplies (94)	More than one reply received, when only one was expected.
packetSizeTooBig (95)	Packet size is too big.
gtpPingError (96)	General GTP Ping error.
gtpPingRsrcUnavailable (97)	GTP Path management resource unavailable.

Table 89-17 OAM diagnostics return codes (continued)

Return code	Description
gtpPingDupRequest (98)	Duplicate request for the same peer.
gtpPingCleanUpInProg (99)	GTP Path management clean up in progress.
invalidInterface (100)	The specified egress interface does not exist.
p2mpLspNotFound (101)	The P2MP-LSP not found given LDP-ID or sender-address.
ethCfmSlmInLoss (102)	Synthetic Loss Measurement (SLM) probe lost in transit from far-end node to local agent.
ethCfmSlmOutLoss (103)	SLM probe lost on transmit from local agent to far-end node.
ethCfmSlmUnacknowledged (104)	SLM probe lost but unable to identify loss reason.
spokeSdpFecNoBndFound (105)	Spoke-sdp-fec is invalid or has no associated SDP binding yet.
mtraceNotSupportedP2mp (106)	Mtrace not supported in base routing context when incoming interface is P2MP.
useFec129Parameters (107)	Specify FEC129 parameters for FEC129 PW instead of sdp-id:vc-id.
dnsServerUnexpectedResponse (108)	The nameserver received an unexpected response.
dnsServerResponseFormErr (109)	The nameserver responded with FORMERR.
dnsServerResponseServFail (110)	The nameserver responded with SERVFAIL.
dnsServerResponseNotImp (111)	The nameserver responded with NOTIMP.
dnsServerResponseRefused (112)	The nameserver responded with REFUSED.
sendFailUndefinedServiceId (113)	The OAM test cannot be performed because the associated service does not exist.
sendFailWrongServiceType (114)	The OAM test cannot be performed because the associated service is of the wrong type.
sendFailSubnettedService (115)	The OAM test cannot be performed on a service with a specified mac subnet length.
invalidRespServiceId (116)	Invalid or non-existent responder Service-ID.
adminDownOrigSdpBind (117)	SDP binding is administratively down on the originator side.
operDownRespSdpBind (118)	SDP binding is operationally down on the responder side.
adminDownRespSdpBind (119)	SDP binding is administratively down on the responder side.
sdpBindVcidMismatch (120)	SDP binding VC ID mismatch between originator and responder.
sdpBindTypeMismatch (121)	SDP binding type mismatch between originator and responder.
sdpBindVcTypeMismatch (122)	SDP binding VC type mismatch between originator and responder.
sdpBindVlanVcTagMismatch (123)	SDP binding VLAN VC tag mismatch between originator and responder.
adminDownOrigSvc (124)	Service on the originator side is administratively down.
adminDownRespSvc (125)	Service on the responder side is administratively down.
adminDownOrigSdpId (126)	The originating SDP-ID is administratively down.
adminDownRespSdpId (127)	The responding SDP-ID is administratively down.
mTraceSourceIsNotRemote (128)	The multicast trace route test cannot be performed because the source address is not remote.

Table 89-17 OAM diagnostics return codes (continued)

Return code	Description
invalidVirtualRouterId (129)	The OAM test cannot be performed because the associated virtual router ID is invalid.
ldpPrefixIsLocal (130)	The OAM test cannot be performed because the associated LDP prefix is local to the system.
sourceIpIsNotLocal (131)	The OAM test cannot be performed because the associated source address is not local to the system.
nextHopIpIsLocal (132)	The OAM test cannot be performed because the associated next hop address is local to the system.
targetIpIsLocal (133)	The OAM test cannot be performed because the associated target address is local to the system.
invalidControlPlaneOption (134)	The OAM test cannot be performed because the control plane send or receive option is not allowed with the specified service.
iomRevisionNotSupported (135)	The OAM test cannot be performed due to a mismatch in supported revision with the provisioned IOMs.
invalidSourceMacOption (136)	The OAM test cannot be performed because the source MAC option is not allowed with the specified service.
sendFailSpbMgdService (137)	The OAM test cannot be performed on a service which is managed by SPB.
useStaticPwParameters (138)	The spoke SDP is configured for static PW.
type1Fec129PwNotSupported (139)	The OAM test is not supported on type 1 FEC129 pseudowires.
mplsTpLspPathNotOperational (140)	The OAM test cannot be performed because the MPLS-TP LSP path is not operational.
invalidStaticMplsTpLsp (141)	The OAM test only supports static MPLS-TP LSPs.
controlWordNotValid (142)	The control-word for the spoke-SDP is not valid for this OAM test.
pwPathIdNotConfigured (143)	The pw-path-id provisioning is not complete.
notSupportedOnVcSwitchService (144)	The OAM test is not supported on a VC-switching service.
sdpFarEndNotSupported (145)	The OAM test does not support the SDP far-end value.
mplsTpLspPathShutdown (146)	The MPLS-TP path is currently shut down.
forceOptionIsBlocked (147)	The force option is currently blocked because of the configuration of a related entity.
intfForLspPathIsNotOperational (148)	The interface for the LSP path is not operational.
ttlExpired (149)	The destination could not be reached because the time-to-live (IPv4) or hop limit (IPv6) was too small. This results from an ICMPv4 type 11 code 0 or ICMPv6 type 3 code 0 message.
networkUnreachable (150)	The network specified by the destination address is unreachable. This results from an ICMPv4 type 3 code 0 or ICMPv6 type 1 code 0 message.
hostUnreachable (151)	The host specified by the destination address is unreachable. This results from an ICMPv4 type 3 code 1 or ICMPv6 type 1 code 3 message.
bgpLabelPrefixIsLocal (152)	The OAM test cannot be performed because the associated BGP Label Route prefix is local to the system.

Table 89-17 OAM diagnostics return codes (continued)

Return code	Description
bgpLabelPrefixUnknown (153)	The OAM test cannot be performed because the BGP target FEC prefix entry is not found in the Routing Table.
ldpPrefixUnknown (154)	The OAM test cannot be performed because the LDP target FEC prefix entry is not found in the routing table.
l2tpv3DeliveryTypeUnsupported (155)	The OAM test cannot be performed because the L2TPv3 delivery type is unsupported.
vPingPeerCvNoLspPing (156)	The OAM test cannot be performed because the peer CV bits do not support LSP ping.
vPingPeerCcNoCtrlWord (157)	The OAM test cannot be performed because the peer CC bits do not support control word.
sendFailEvpnCfgdServiceX (158)	The OAM test cannot be performed on a VPLS service that has EVPN configured.
sendFailEvpnCfgdServiceX (158)	The OAM test cannot be performed on a VPLS service that has EVPN configured.
sendFailed (159)	The OAM test cannot send the test packet.
minimumPacketSizeNotMet (160)	The OAM test cannot send the test packet as the minimum required packet size exceeds the user supplied packet size.
invalidTargetFecType (161)	The OAM test does not support this FEC type.
p2mpLspPingNotSupportedOnMgmtRtr (162)	The OAM p2mpLspPing test is not supported on the management router.
ipv4SdpFarEndsOnly (163)	The OAM test only supports bindings and SDPs using an IPv4 far end.
vxlanEgrBndSvcMismatch (164)	The OAM test cannot send packets to a VXLAN egress binding not owned by the same service as the one sending.
vxlanNoMatchingTep (165)	The OAM test can only send to VTEPs that have been configured.
vxlanEvpnUnconfigured (166)	The OAM test can only send on a service with EVPN configured.
ipv6SdpFarEndsNotSupported (167)	The OAM test does not support bindings and SDPs using an IPv6 far end.
oamTestOverSRTunNotSupported (168)	The OAM test is not supported on SR tunnels.
sendFailEvpnCfgdPbbService (169)	The OAM test cannot be performed on a VPLS/Epipe service that is associated with a b-vpls that has EVPN configured.
txPortDown (170)	The transmit port is operationally down.
noTxPort (171)	No transmit port.
parentAdminDown (172)	The parent (SPOKE, SAP, SVC or PORT) of the MEP is admin shutdown.
destMacResolveFail (173)	Unable to resolve the remote-mepid to a unicast layer2 MAC address.
vxlanIpV6TermUnsupported (174)	The OAM test does not support IPv6 tunnel termination points.
ipPrefixIsLocal (175)	The OAM test cannot be performed because the associated IP prefix is local to the system.
ipPrefixUnknown (176)	The OAM test cannot be performed because the Target FEC prefix entry is not found in the Routing table.
greEthBrdgdDelvryTypeUnsupported (177)	The OAM test cannot be performed because the GRE Ethernet Bridged delivery type is unsupported.

Table 89-17 OAM diagnostics return codes (continued)

Return code	Description
mtrace2Disabled (178)	The mtrace2 test cannot be performed because mtrace2 is disabled at the system level.

END OF STEPS

89.21 To edit an OAM diagnostic test

89.21.1 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager (STM) form opens.

2

Choose Test (Assurance) or PM Session Test (Assurance) from the object menu and click Search. A list of tests is displayed.

3

Choose a test and click Properties. The properties form for the test opens.

4

Configure the required parameters.

5

Save your changes and close the forms.

END OF STEPS

89.22 To delete an OAM diagnostic test

89.22.1 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager (STM) form opens.

2

Choose Test (Assurance) or PM Session Test (Assurance) from the object menu and click Search. A list of tests is displayed.

3

Choose one or more tests and click Delete.

4

Confirm the action. The test or tests are deleted from the list of available OAM diagnostic tests.

5

Close the form.

END OF STEPS

89.23 To delete an STM test suite

89.23.1 Before you begin

If the STM test suite is scheduled to run, you must remove the scheduled task associated with the test suite before you can delete the test suite. See Chapter 5, “NFM-P-based schedules” for more information.

89.23.2 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager (STM) form opens.

2

Choose Test Suite (Assurance) from the object menu and click Search. A list of test suites is displayed.

3

Select a test suite and click Delete.

4

Confirm the action. The test suite is deleted and removed from the list.

5

Close the form.

END OF STEPS

90 OAM diagnostic tests

90.1 Overview

90.1.1 Purpose

This chapter describes the NFM-P OAM diagnostic tests, and provides information about configuring and performing OAM diagnostic tests.

90.1.2 Contents

OAM diagnostic tests

90.2 OAM diagnostic test overview

90.2.1 Introduction to OAM diagnostic tests

The NFM-P provides a set of configurable in-band or out-of-band, packet-based OAM diagnostic tests that allows you to pro-actively manage networks and customer SLAs including:

- on-demand or scheduled service performance monitoring, and SLA verification to ensure that a service meets its guaranteed performance settings in a controlled test time
- networking troubleshooting activities including fault detection, fault verification, and fault isolation

This chapter provides information about each OAM diagnostic test that can be configured using the NFM-P. See Chapter 89, “Service Test Manager” for information about higher-level functions that can be performed with each OAM diagnostic test using the STM, such as creating STM test policies and STM test suites.

The correct delivery of services requires that a number of operations must occur correctly at different levels in the service. For example, operations such as the association of packets to a service, VC labels to a service, and each service to a service tunnel, must be performed successfully for the service to pass traffic to subscribers according to their SLAs. Even when tunnels are operating correctly and are correctly bound to services, incorrect information may cause connectivity issues.

For in-band, packet-based testing, the OAM packets closely resemble customer packets to effectively test the forwarding path. However, these packets are distinguishable from customer packets, so they are kept within the service provider network and not forwarded to the customer. For out-of-band testing, OAM packets are sent across a portion of the transport network; for example, across LSPs to test reachability.

90.2.2 On-demand OAM diagnostic test configuration

You can create, manage, and run most OAM diagnostic tests on-demand from the NFM-P STM as a single test entity.

Some OAM diagnostic tests can be configured from alternate launch points on the NFM-P GUI, including the following:

- from a network object or NE Properties form; for example, LSP pings from the LSP Properties form
- from a service tunnel or service form
- from the service topology or composite service flat topology view on service flat topology maps; see Chapter 4, “Topology map management” for information.
- using a user-defined CLI script; for example, creating a device-specific ping and traceroute script for troubleshooting issues on an OmniSwitch

The following table lists the OAM diagnostic tests that are accessible from the NFM-P GUI and provides a link to the appropriate test description and applicable procedure.

Table 90-1 NFM-P supported OAM diagnostic tests and configurations

OAM test category / test type	Test network object or service level	Network level	See Procedure
Ethernet CFM OAM diagnostic tests			
91.2.2 “Global MEG check” (p. 3089)	Ethernet	Port	91.19 “To create and run a Global MEG OAM diagnostic test from the STM” (p. 3120)
91.2.3 “Continuity check” (p. 3089) (includes 91.2.4 “CFM dual-ended loss test” (p. 3089))			91.20 “To create and run a Continuity Check OAM diagnostic test from the STM” (p. 3122)
91.2.5 “CFM loopback” (p. 3090)			91.21 “To create and run a CFM loopback OAM diagnostic test from the STM” (p. 3123)
91.2.6 “CFM link trace” (p. 3090)			91.22 “To create and run a CFM link trace OAM diagnostic test from the STM” (p. 3125)
91.2.7 “CFM Eth test” (p. 3090)			91.23 “To create and run a CFM Eth OAM diagnostic test from the STM” (p. 3127)
91.2.8 “CFM two way delay test” (p. 3090)			91.24 “To create and run a CFM two way delay OAM diagnostic test from the STM” (p. 3128)
91.2.9 “CFM one way delay test” (p. 3091)			91.25 “To create and run a CFM one-way delay OAM diagnostic test from the STM” (p. 3130)
91.2.10 “CFM single ended loss test (7705 SAR only)” (p. 3091)			91.26 “To create and run a CFM single-ended loss OAM diagnostic test from the STM” (p. 3131)
91.2.11 “CFM two way SLM” (p. 3091)			91.27 “To create and run a CFM two way SLM OAM diagnostic test from the STM” (p. 3132)
91.2.12 “CFM LM test” (p. 3091)			91.28 “To create and run a CFM LM OAM diagnostic test from the STM” (p. 3134)
Performance Monitoring OAM diagnostic tests			
92.2.2 “PM session test support and configuration” (p. 3138)	Ethernet	Network element	92.6 “To configure a PM session OAM diagnostic test from the STM” (p. 3146)
92.2.3 “CFM DMM session test” (p. 3139)			92.7 “To configure a CFM DMM session OAM diagnostic test from the STM” (p. 3149)
92.2.4 “CFM SLM session test” (p. 3139)			92.8 “To configure a CFM SLM session OAM diagnostic test from the STM” (p. 3150)
92.2.5 “CFM LMM session test” (p. 3139)			92.9 “To configure a CFM LMM session OAM diagnostic test from the STM” (p. 3151)

Table 90-1 NFM-P supported OAM diagnostic tests and configurations (continued)

OAM test category / test type	Test network object or service level	Network level	See Procedure
92.2.6 “TWAMP Light session test” (p. 3140)	IP Layer 3 interface	Network element	92.11 “To configure a TWAMP Light reflector” (p. 3153)
92.2.6 “TWAMP Light session test” (p. 3140)			92.12 “To configure a TWAMP Light session OAM diagnostic test from the STM” (p. 3154)
92.2.7 “TCC test” (p. 3140)			92.13 “To configure a TCC OAM diagnostic test from the STM” (p. 3155)
92.2.8 “MPLS DM session test” (p. 3140)	MPLS	LSP	92.10 “To configure an MPLS DM session OAM diagnostic test from the STM” (p. 3152)
Service OAM diagnostic tests			
“Service site ping” (p. 2986)	Service transport binding (level 5)	Network element	90.7 “To create and run a service site ping OAM diagnostic test from the STM” (p. 3007)
“VCCV ping” (p. 2986)	Service (level 6)	VPRN site	90.8 “To create and run a VCCV ping OAM diagnostic test from the STM” (p. 3008)
“VCCV trace” (p. 2988)			90.9 “To create and run VCCV trace OAM diagnostic test from the STM” (p. 3009) 90.10 “To create and run a VCCV trace OAM diagnostic from a static PW to a dynamic PW segment from the STM” (p. 3010) (static PW to a dynamic PW segment) 90.11 “To create and run a VCCV trace OAM diagnostic from a dynamic PW to a static PW segment from the STM” (p. 3012) (dynamic PW to a static PW segment)
“Y.1564 bidirectional tests” (p. 2988)		Network element	89.7 “STM Y.1564 test configuration” (p. 2924)
L2 service OAM diagnostic tests			

Table 90-1 NFM-P supported OAM diagnostic tests and configurations (continued)

OAM test category / test type	Test network object or service level	Network level	See Procedure
"MAC populate" (p. 2989)	Service (level 6)	VPLS site Epipe VLL site VLL	90.12 "To create and run a MAC populate OAM diagnostic test from the STM" (p. 3013)
"MAC purge" (p. 2989)			90.13 "To create and run a MAC purge OAM diagnostic test from the STM" (p. 3014)
"MAC ping" (p. 2989)			90.14 "To create and run a MAC ping OAM diagnostic test from the STM" (p. 3015)
"MAC trace" (p. 2990)			90.15 "To create and run a MAC trace OAM diagnostic test from the STM" (p. 3016)
"CPE ping" (p. 2991)		VPLS site Epipe VLL site	90.16 "To create and run a CPE ping OAM diagnostic test from the STM" (p. 3017)
"ANCP loopback" (p. 2991)		Network element	90.17 "To create and run an ANCP loopback OAM diagnostic test from the STM" (p. 3018)
"VXLAN ping" (p. 2992)		VPLS site	90.18 "To create and run a VXLAN ping OAM diagnostic test from the STM" (p. 3019)
L3 service OAM diagnostic tests			
"VPRN ping" (p. 2992)	Service (level 6)	VPRN site	90.19 "To create and run a VPRN ping or VPRN trace OAM diagnostic test from the STM" (p. 3022) (STM method) 90.20 "To create and run a VPRN Ping, VPRN Trace, ICMP Ping, or ICMP Trace OAM diagnostic test from a service manager form" (p. 3023) (from a service)
"VPRN trace" (p. 2992)			
Service transport OAM diagnostic tests			
"Tunnel ping" (p. 2993)	Service transport (level 4)	Service tunnel (SDP)	90.21 "To create a tunnel ping OAM diagnostic test from the STM" (p. 3026) (STM method) 90.22 "To create and run a tunnel ping OAM diagnostic test from a service tunnel" (p. 3026) (service tunnel method)
"MTU ping" (p. 2994)			90.23 "To create and run an MTU ping OAM diagnostic test from the STM" (p. 3028) (STM method) 90.24 "To create and run an MTU ping OAM diagnostic test from a service tunnel" (p. 3028) (service tunnel method)
MPLS OAM diagnostic tests			

Table 90-1 NFM-P supported OAM diagnostic tests and configurations (continued)

OAM test category / test type	Test network object or service level	Network level	See Procedure
"LSP ping" (p. 2995)	Transport (level 3)	LSP LSP path MPLS-TP LSP	90.25 "To create and run a MPLS LSP ping OAM diagnostic test from the STM" (p. 3030)
"LSP trace" (p. 2996)			90.26 "To create and run a MPLS LSP trace OAM diagnostic test from the STM" (p. 3031)
"LDP tree trace" (p. 2996)		MPLS site LDP site	90.27 "To create and run a MPLS LDP tree trace OAM diagnostic test from the STM" (p. 3032)
"P2MP LSP ping" (p. 2997)		P2MP LSP, P2MP mLDP P2MP path	90.28 "To create and run a MPLS P2MP LSP ping OAM diagnostic test from the STM" (p. 3033)
"P2MP LSP trace" (p. 2997)			90.29 "To create and run a MPLS P2MP LSP trace OAM diagnostic test from the STM" (p. 3037)
L1/L2 OAM diagnostic tests			
"ATM ping" (p. 2998)	Layer 1 or Layer 2 (level 1)	ATM PVC connection	90.30 "To create and run an ATM ping OAM diagnostic test from the STM" (p. 3039) (STM method) 90.31 "To configure an ATM OAM loopback from a device Properties form" (p. 3040) (Properties form method)
Multicast OAM diagnostic tests			
"BIER ping" (p. 2998)	Routed network (level 2)	IP multicast traffic	90.32 "To create and run a BIER ping OAM diagnostic test from the STM" (p. 3040)
"BIER trace" (p. 2998)	Routed network (level 2)	IP multicast traffic	90.33 "To create and run a BIER trace OAM diagnostic test from the STM" (p. 3042)
"MFIB ping" (p. 2999)	Service (level 6)	VPLS site Epipe VLL site	90.34 "To create and run an MFIB ping OAM diagnostic test from the STM" (p. 3043)
"Mrinfo" (p. 2999)	Routed network (level 2)	IP multicast traffic	90.35 "To create and run an Mrinfo OAM diagnostic test from the STM" (p. 3044)
"Mtrace" (p. 2999)			90.36 "To create and run an Mtrace OAM diagnostic test from the STM" (p. 3044)
"Mtrace2" (p. 2999)			90.37 "To create and run an Mtrace2 OAM diagnostic test from the STM" (p. 3045)
ICMP OAM diagnostic tests			

Table 90-1 NFM-P supported OAM diagnostic tests and configurations (continued)

OAM test category / test type	Test network object or service level	Network level	See Procedure
"ICMP ping" (p. 3000)	Service (level 6)	VPRN site	90.38 "To create and run an ICMP ping OAM diagnostic test from the STM" (p. 3046)
"ICMP trace" (p. 3000)			90.39 "To create and run an ICMP trace OAM diagnostic test from the STM" (p. 3047)
"DNS ping" (p. 3000)			90.40 "To create and run an ICMP DNS ping OAM diagnostic test from the STM" (p. 3048)
VMN OAM diagnostic tests			
"PRBS test" (p. 3000)	1830 VWM TLU/ITP	Port	90.41 "To create and run a PRBS test" (p. 3048)
AOS CPE OAM diagnostic tests			
"CPE SLA test" (p. 3001)	Ethernet	Port or NE	89.8 "Sample OmniSwitch device SLA testing" (p. 2940)
"CPE SLA test group" (p. 3001)			89.8 "Sample OmniSwitch device SLA testing" (p. 2940) 90.42 "To create and run a OmniSwitch CPE SLA diagnostic test from the STM" (p. 3051)
Non-STM OAM diagnostic tests			
"OmniSwitch ping and traceroute OAM test" (p. 3001)	Ethernet	Port or NE	90.44 "To create an OmniSwitch ping or traceroute OAM diagnostic test using a CLI script" (p. 3058) 90.45 "To configure and run an OmniSwitch OAM diagnostic ping test CLI script" (p. 3062) 90.46 "To configure and run an OmniSwitch OAM traceroute test CLI script" (p. 3064)
"OmniSwitch advanced loopback test" (p. 3002)	Ethernet	Port	90.47 "To configure an advanced loopback test on an OmniSwitch from a device Properties form" (p. 3067)
"F5 OAM loopback test (7705 SAR-M/ME)" (p. 3002)	Ethernet	Port	90.48 "To run the F5 OAM loopback diagnostic test from a 7705 SAR-M/ME Properties form" (p. 3068)
"802.3ah EFM OAM diagnostic test" (p. 3002)	Ethernet	Port	90.49 "To configure an 802.3ah EFM OAM diagnostic test from an NE Properties form" (p. 3069) (Properties form method) 90.50 "To configure an 802.3ah EFM OAM diagnostic test on an OmniSwitch Properties form" (p. 3074) (OmniSwitch specific)

Table 90-1 NFM-P supported OAM diagnostic tests and configurations (continued)

OAM test category / test type	Test network object or service level	Network level	See Procedure
"One-time service validation test" (p. 3003)	Service (level 6)	VLL, VPLS, and VPRN services Composite services Dynamic LSPs Service tunnels	90.55 "To run a one-time validation test on a service" (p. 3084)

90.2.3 Multiple OAM diagnostic test configuration

You can also create, schedule, and run test suites that contain groups of OAM diagnostic tests using the NFM-P STM. The use of test suites is especially valuable when multiple objects of the same type require testing. Test suites can be scheduled to run on a regular basis to provide continual network performance feedback.

See Chapter 89, "Service Test Manager" for information about configuring multiple OAM diagnostic tests as part of a test suite using the STM.

See Chapter 5, "NFM-P-based schedules" for information about scheduled tasks.

90.3 OAM diagnostic test descriptions

90.3.1 Introduction

This section provides a description of supported NFM-P OAM diagnostic test functionality grouped by their functional area on the STM. Unless where noted, all test are accessible from the STM. See Table 90-1, "NFM-P supported OAM diagnostic tests and configurations" (p. 2981) for a list of all supported OAM diagnostic tests and their applicable procedures.

90.3.2 Ethernet CFM OAM diagnostic tests

Use the Ethernet CFM (Connectivity Fault Management) OAM diagnostic tests to detect, isolate, and report connectivity faults for L2 objects in Ethernet networks. The NFM-P Ethernet CFM function is implemented based on the IEEE 802.1ag OAM standard.

See Chapter 91, "Ethernet CFM" for a description of each Ethernet CFM OAM diagnostic test and applicable configuration procedure.

90.3.3 PM OAM diagnostic tests

Use the Performance Monitoring (PM) OAM diagnostic tests to assess the configuration and performance of Carrier Ethernet services such as Ethernet frame delay, frame delay variation, frame loss, and frame throughput measurements as specified by the ITU-T Y-1731 standard.

See Chapter 92, "Performance Monitoring tests" for a description of each PM OAM diagnostic test and applicable configuration procedure.

90.3.4 Service OAM diagnostic tests

Use the Service OAM diagnostic tests to assess the configuration and performance of an Ethernet service before customer notification and delivery, and to troubleshoot and resolve problems that are related to an individual service within the provider network.

Service site ping

The service site ping OAM diagnostic test, which is called svc-ping in CLI, provides end-to-end connectivity testing for an individual service within the provider network.

This diagnostic test operates at a higher level than the tunnel ping OAM because it verifies connectivity for an individual service rather than connectivity across the service tunnel. This allows you to isolate a problem within the service rather than at the port, which is the endpoint of the service tunnel.

The test verifies a service ID for correct and consistent provisioning between two service endpoints.

The following information can be verified from a service site ping OAM:

- local and remote service sites exists
- current state of the local and remote service sites
- local and remote service types are correlated
- same customer is associated with the local and remote service sites
- service-to-circuit association at both the local and remote service sites using the Use Local Tunnel and Use Remote Tunnel options, to check the circuit between service sites
- local and remote ingress and egress service labels match

See 90.7 “To create and run a service site ping OAM diagnostic test from the STM” (p. 3007) for information about how to create and run a service site ping OAM diagnostic test from the STM.

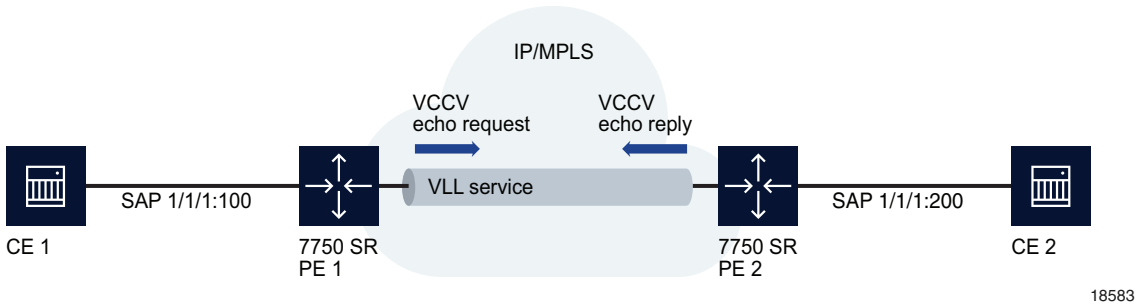
Note: The OAM messages, which operate over an LDP LSP, and/or over a PW signaled by T-LDP, and which require a response using the IP path, must use a source IP address that is reachable within the same routing domain as that of the LSR ID of the LDP or T-LDP session. The messages of the service site ping OAM diagnostic test use the T-LDP local LSR ID as the source IP address. Previously, the NE’s system interface address was used for this purpose.

VCCV ping

The VCCV ping OAM diagnostic test, which is called vccv-ping in the CLI, performs in-band connectivity tests. It can be used for VPLS, MVPLS, HVPLS, and all types of VLLs.

When applied to a VLL service, the test supports cross-circuit tests as long as the circuit types match; for example, an Epipe-to-Epipe connector, or an Epipe-to-VPLS/MVPLS site connector. The purpose of the ping is to determine that the destination PE device is the egress for the L2 FEC. The following figure shows a sample VCCV ping OAM diagnostic test.

Figure 90-1 VCCV ping OAM diagnostic



In Figure 90-1, “VCCV ping OAM diagnostic” (p. 2988) , the ping test packet or packets are sent with the destination IP address of PE 2. The request is encapsulated in a VLL packet and is forwarded to PE 2. PE 2 replies to the source device IP address. The packets are sent using the same encapsulation and along the same path as user packets in the VLL. This test provides a check of both the control plane and the data plane.

Note: The OAM messages which operate over an LDP LSP, and/or over a PW signaled by T-LDP, and which require a response using the IP path, must use a source IP address which is reachable within the same routing domain as that of the LSR ID of the LDP or T-LDP session. The messages of the VCCV ping OAM diagnostic test use the T-LDP local LSR ID as the source IP address. Previously the NE’s system interface address was used for this purpose.

When this test is applied to a VPLS, MVPLS or HVPLS, downstream SDP bindings are not configurable as they are in VLL services. Downstream bindings are typically related to switching sites and these are not relevant to VPLS. In VPLS, only the first SDP binding is configured, and this can be either a mesh or spoke binding.

Also, since an HVPLS comprises a mixture of active and standby spokes, the VCCV ping test execution will only be successful on active spokes that have associated active return spokes. A test suite will generate all the required VCCV ping tests, but only active spokes with active return spokes are counted in the statistics results. This also includes any service connector used in a composite service, provided that the connector is a spoke connector between a VPLS and an Epipe service.

See 90.8 “To create and run a VCCV ping OAM diagnostic test from the STM” (p. 3008) for information about how to create and run a VCCV ping OAM diagnostic test from the STM.

VCCV trace

The VCCV trace OAM diagnostic test, which is called vccv-trace in the CLI, displays the hop-by-hop path used by a VLL. VCCV trace can trace the entire path of a PW with a single command issued at the T-PE or at an S-PE. It is an iterative process by which the ingress T-PE or T-PE sends successive VCCV-Ping messages with incrementing the TTL value, starting from TTL=1. The process is terminated when the reply is from the egress T-PE or when a timeout occurs.

Note: The OAM messages which operate over an LDP LSP, and/or over a PW signaled by T-LDP, and which require a response using the IP path, must use a source IP address which is reachable within the same routing domain as that of the LSR ID of the LDP or T-LDP session. The messages of the VCCV Trace OAM diagnostic test use the T-LDP local LSR ID as the source IP address. Previously the NE’s system interface address was used for this purpose.

See 90.9 “To create and run VCCV trace OAM diagnostic test from the STM” (p. 3009) for information about how to create and run a VCCV trace OAM diagnostic test from the STM. To create a VCCV trace OAM diagnostic test from a static PW to a dynamic PW segment, perform 90.10 “To create and run a VCCV trace OAM diagnostic from a static PW to a dynamic PW segment from the STM” (p. 3010) . To create a VCCV trace OAM diagnostic test from a dynamic PW to a static PW segment, perform 90.11 “To create and run a VCCV trace OAM diagnostic from a dynamic PW to a static PW segment from the STM” (p. 3012) .

Y.1564 bidirectional tests

Y.1564 bidirectional tests allow you to assess the configuration and performance of an Ethernet service before customer notification and delivery. Y.1564 provides a standard for measuring throughput, latency, frame loss, and jitter to assess if the service complies with an SLA. Multiple test types are supported. See 89.7 “STM Y.1564 test configuration” (p. 2924) in Chapter 89, “Service Test Manager” for more information.

90.3.5 L2 service OAM diagnostic tests

Use the L2 service OAM diagnostic tests to troubleshoot and resolve problems that are related to FIBs, MAC addressing, or hostname in a VLAN. These tests are generally used in combination; for example, MAC populate to inject a MAC address into the network, MAC ping to determine where the address was learned, MAC trace to determine the path, CPE ping to test the VPLS, and MAC purge to remove the injected MAC address.

MAC populate

The MAC populate OAM diagnostic test, which is called mac-populate in CLI, is used to:

- determine if the FIB table is accurate by testing forwarding plan correctness. This is done by populating a service FIB with an OAM-tagged MAC entry. This MAC entry indicates that the NE is the egress NE for the MAC address of a service. You can then use the FIB manager to see the OAM-tagged MAC entry.

- send a message through the flooding domain to learn a MAC address, as if a customer packet with that source MAC address had flooded the domain from that ingress point of the service.

You can:

- force an existing MAC address to become OAM-tagged
- distinguish, in the FIB manager, MAC addresses that are OAM-tagged
- age an OAM-tagged MAC address

In a MAC populate, the OAM-tagged MAC address is populated on the egress point of the service. You can specify whether to flood this OAM-tagged MAC address to other devices so that the same OAM-tagged entry is added to the FIB tables of other devices.

See 90.12 “To create and run a MAC populate OAM diagnostic test from the STM” (p. 3013) for information about how to create and run a MAC populate OAM diagnostic test from the STM.

MAC purge

The MAC purge OAM diagnostic test, which is called mac-purge in CLI, is used to delete an OAM-tagged entry from a FIB, which was generated using the MAC populate OAM diagnostic test. This clears the FIB of any learned information for a specific MAC address, allows the FIB to be populated only by a MAC populate request, and can be used to flush all devices in a service domain.

See 90.13 “To create and run a MAC purge OAM diagnostic test from the STM” (p. 3014) for information about how to create and run a MAC purge OAM diagnostic test from the STM.

MAC ping

The MAC ping OAM diagnostic test, which is called mac-ping in CLI, is used to test connectivity in a VLL or VPLS by verifying a remote MAC address at the far end of a service. The MAC ping determines the existence of the far-end egress point of the service. MAC pings can be sent in-band or out-of-band.

You must specify either:

- the target (far-end) MAC address
  OR
- the broadcast address

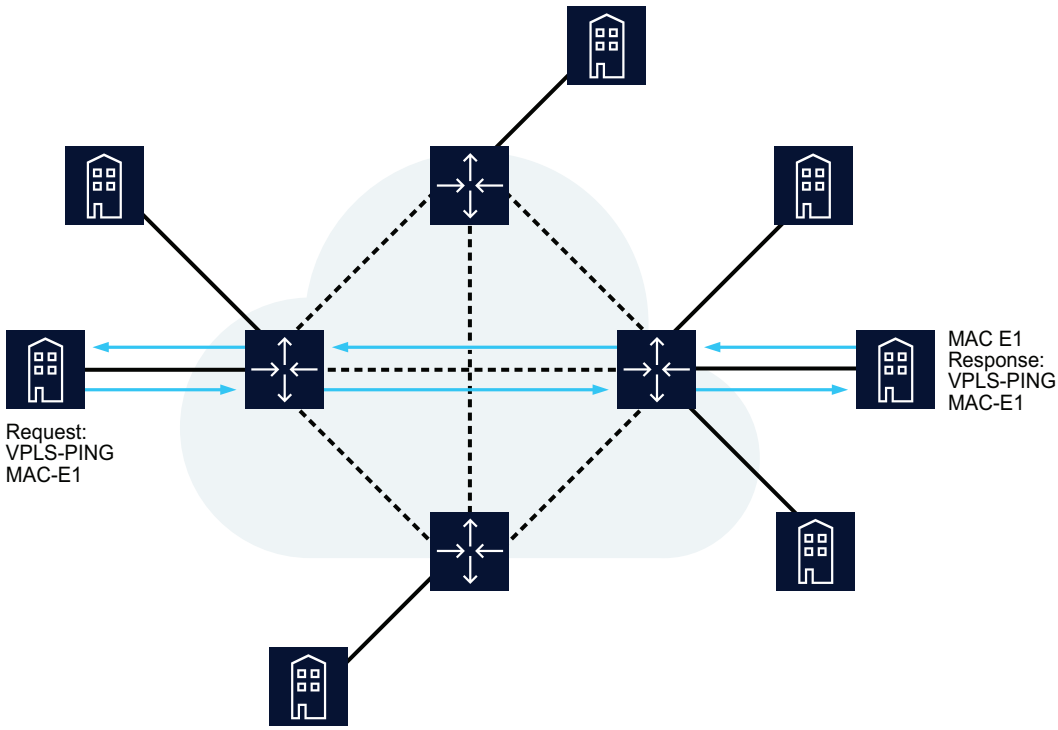
In a MAC ping that is out-of-band, the ping is forwarded along the flooding domain when no MAC address bindings exist or is sent along the bindings if MAC address bindings exist. A response ping is sent from the far-end device when there is an egress binding for the service.

In a MAC ping that is in-band, the ping is sent with a VC label TTL of 255. The ping packet goes across each hop, and when it reaches the egress router, it is identified by the OAM label and the response is sent back along the management plane.

Figure 90-2, “Sample MAC ping OAM diagnostic test” (p. 2990) shows a sample MAC ping OAM diagnostic test from one end of a service to the far-end MAC address of the service.

See 90.14 “To create and run a MAC ping OAM diagnostic test from the STM” (p. 3015) for information about how to create and run a MAC ping OAM diagnostic test from the STM.

Figure 90-2 Sample MAC ping OAM diagnostic test



MAC trace

The MAC trace OAM diagnostic test, which is called mac-trace in CLI, displays the hop-by-hop route of MAC addresses used to reach the target MAC address at the far end of a service. MAC traces can be sent in-band or out-of-band.

You must specify either:

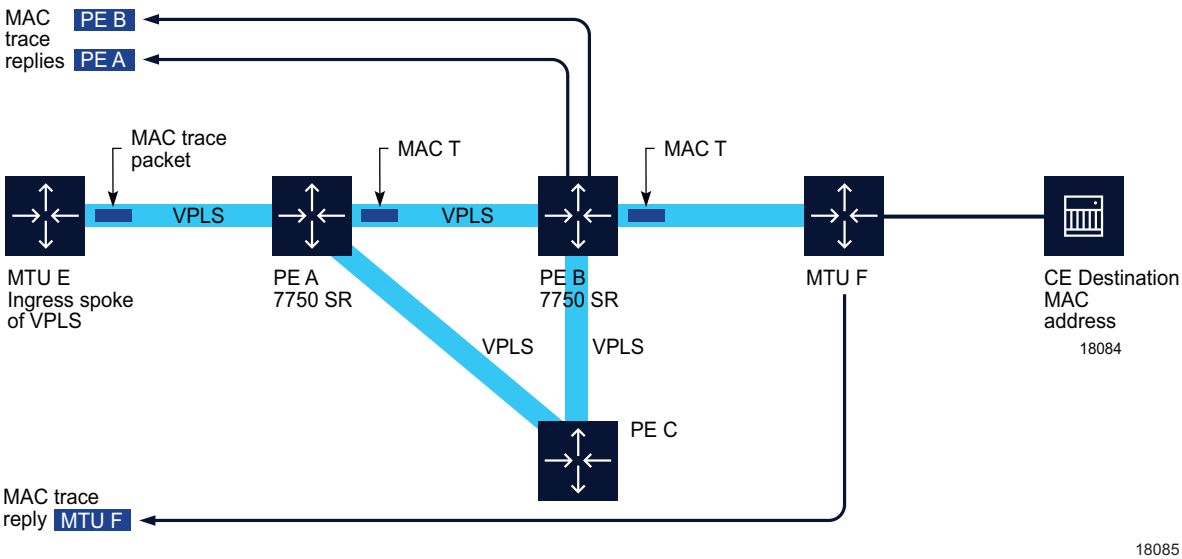
- the target (far-end) MAC address
  OR
- the broadcast address

In a MAC trace that is out-of-band, the destination IP address is specified by mapping the destination MAC address. If the destination MAC address is known to be a specific site, the far-end IP address of the service tunnel is used. If the destination MAC address is not known, the packet is sent to all service tunnels in the service.

In a MAC trace that is in-band, the trace request contains tunnel encapsulation, VC label, OAM, and other information. If the destination MAC address is known, the appropriate tunnel encapsulation and VC label is used. If the destination MAC address is not known, the packet is sent to all service tunnels, including all necessary tunnel encapsulation and egress VC labels for each bound service tunnel.

The following figure shows a sample MAC trace OAM diagnostic test. See Figure 90-3, “MAC trace OAM diagnostic test” (p. 2991) for information about how to create and run a MAC trace OAM diagnostic test from the STM.

Figure 90-3 MAC trace OAM diagnostic test



CPE ping

The CPE ping OAM diagnostic test, which is called cpe-ping in the CLI, is used to trace the end-to-end switching of specified MAC addresses of customer premises equipment. This ping extends the functionality of the MAC ping beyond the egress (customer-facing) port by allowing a ping to the SAP of a VPLS or a VLL Epipe service over a VPLS PBB backbone.

See 90.16 “To create and run a CPE ping OAM diagnostic test from the STM” (p. 3017) for information about how to create and run a CPE ping OAM diagnostic test from the STM.

ANCP loopback

The ANCP loopback OAM diagnostic test, which is called oam ancp in the CLI, is used to send DSL OAM commands to complete an OAM test to the access NE from a centralized point or when operational boundaries prevent direct access to the DSLAM. The ANCP loopback test raises an alarm that generates a log event displaying both successful and failed results.

See 90.17 “To create and run an ANCP loopback OAM diagnostic test from the STM” (p. 3018) for information about how to create and run an ANCP loopback OAM diagnostic test from the STM.

VXLAN ping

VXLAN is the overall Layer 2 tunneling mechanism used to connect services in data center architectures. The VXLAN connection is a point-to-point Layer 2 connection that has only two Virtual Tunnel Endpoints (VTEPs). From a transport perspective, the VXLAN tunnels are similar in

nature to a GRE SDP binding. The VXLAN connections are part of the subscriber's VPLS services connecting the Virtual Machine to the data center. Each subscriber has their own VPLS instance.

The VXLAN ping test is used to confirm that the Virtual Tunnel is operational by using Echo Request/Reply functions, as well as query the status of the Virtual Network Instance (VNI).

See 90.18 “To create and run a VXLAN ping OAM diagnostic test from the STM” (p. 3019) for information about how to create and run a VXLAN ping OAM diagnostic test from the STM.

90.3.6 L3 service OAM diagnostic tests

Use the L3 service OAM diagnostic tests to troubleshoot and resolve problems related to VPRN services provisioned on the NFM-P.

VPRN ping

The VPRN ping OAM diagnostic test determines the existence of the far-end egress point of the service. This allows testing of whether a specific destination can be reached. VPRN pings can be sent in-band or out-of-band. When a VPRN ping test packet is sent, a reply is generated if the targeted prefix is reachable over a VPRN SAP or VPRN spoke interface; otherwise the test packet is dropped in CPM. This also applies in the case of a routed VPLS interface.

You can perform a VPRN ping OAM diagnostic test from the STM, as described in 90.19 “To create and run a VPRN ping or VPRN trace OAM diagnostic test from the STM” (p. 3022) . You can also perform this test from a VPLS/MVPLS or VLL service form, as described in 90.20 “To create and run a VPRN Ping, VPRN Trace, ICMP Ping, or ICMP Trace OAM diagnostic test from a service manager form” (p. 3023) , or from a service flat topology map.

VPRN trace

The VPRN trace OAM diagnostic test displays the hop-by-hop path for a destination IP address within a VPRN service. This allows operators to know the destination path of customer traffic. VPRN traces can be sent in-band or out-of-band. When a VPRN trace test packet is sent, a reply is generated if the targeted prefix is reachable over a VPRN SAP or VPRN spoke interface. Otherwise the test packet is dropped in CPM. This also applies in the case of a routed VPLS interface.

You can perform a VPRN trace OAM diagnostic test from the STM, as described in 90.19 “To create and run a VPRN ping or VPRN trace OAM diagnostic test from the STM” (p. 3022) . You can also perform this test from a VPLS/MVPLS or VLL service form, as described in 90.20 “To create and run a VPRN Ping, VPRN Trace, ICMP Ping, or ICMP Trace OAM diagnostic test from a service manager form” (p. 3023) , or from a service flat topology map.

90.3.7 Service transport OAM diagnostic tests

Use the service transport OAM diagnostic tests to troubleshoot and resolve problems related to VPRN services provisioned on the NFM-P.

Tunnel ping

The tunnel ping OAM diagnostic test, which is called sdp-ping in the CLI, performs in-band unidirectional or bidirectional connectivity tests on service tunnels (also called an SDP). Use tunnel ping to troubleshoot and resolve tunnel and service problems that are related to issues that circuits may have transmitting traffic across the GRE or MPLS network.

The OAM packets are sent in-band in the tunnel encapsulation, so they follow the same path as the service traffic. The response can be received out-of-band in the control plane or in-band using the data plane for a bidirectional test.

For a unidirectional test, tunnel ping OAM tests:

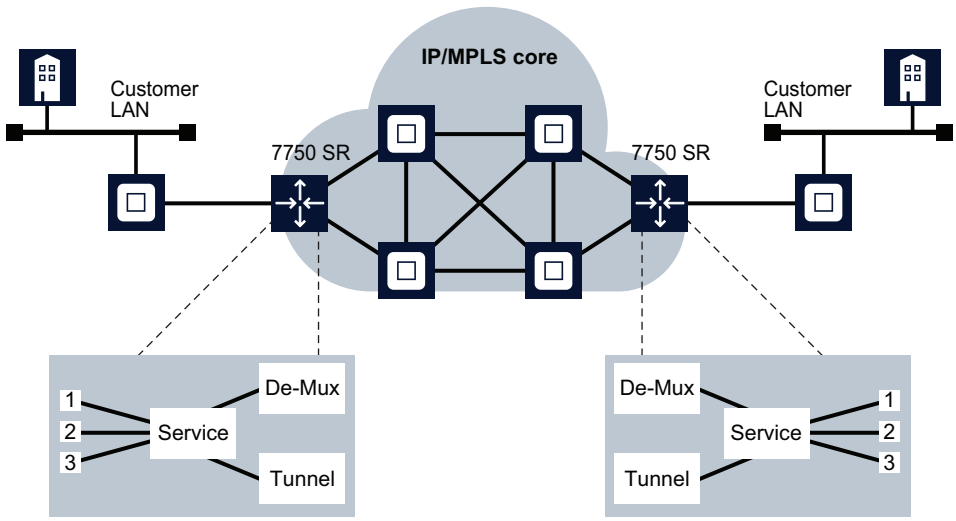
- egress service tunnel ID encapsulation
- whether the packet can reach the far-end IP address destination of the service tunnel ID within its encapsulation
- whether a packet of the specified size goes to the far-end IP address of the service tunnel ID within its encapsulation
- forwarding class mapping to ensure that the test packet is treated the same as the customer traffic
- determine whether SLA delay metrics are met

For a bidirectional test, tunnel OAM uses a local egress service tunnel ID and an expected remote service tunnel ID, so the user can specify where the returned messages should be sent from based on the far-end tunnel ID.

Figure 90-4, “Sample tunnel ping OAM diagnostic test” (p. 2993) shows how a tunnel OAM packet can be inserted to test the connectivity between two customer LANs across the IP/MPLS core.

See 90.21 “To create a tunnel ping OAM diagnostic test from the STM” (p. 3026) for information about how to create and run an tunnel ping OAM diagnostic test from the STM.

Figure 90-4 Sample tunnel ping OAM diagnostic test



Note: The OAM messages which operate over an LDP LSP, and/or over a PW signaled by T-LDP, and which require a response using the IP path, must use a source IP address which is reachable within the same routing domain as that of the LSR ID of the LDP or T-LDP

session. The messages of the tunnel ping OAM diagnostic test use the T-LDP local LSR ID as the source IP address. Previously the NE's system interface address was used for this purpose.

MTU ping

The MTU ping OAM diagnostic test, which is called sdp-mtu in CLI, provides a tool for service providers to:

- determine the maximum frame (MTU) size supported between the service ingress and the service termination point on a service tunnel (also called an SDP), to within one byte
- solve troubleshooting issues that are related to equipment used across the network core that may not be able to handle large frame sizes

In a large network, network devices can support a variety of packet sizes, up to a limit, that are transmitted across its interfaces. This size limit is referred to as the MTU of network interfaces. You must consider the MTU of the entire service tunnel end-to-end when you provision services, especially for VLL services in which the service must support the ability to transmit the largest customer packet.

Note: The OAM messages which operate over an LDP LSP, and/or over a PW signaled by T-LDP, and which require a response using the IP path, must use a source IP address which is reachable within the same routing domain as that of the LSR ID of the LDP or T-LDP session. The messages of the MTU ping OAM diagnostic test use the T-LDP local LSR ID as the source IP address. Previously the NE's system interface address was used for this purpose.

See 90.23 "To create and run an MTU ping OAM diagnostic test from the STM" (p. 3028) for information about how to create and run an MTU ping OAM diagnostic test from the STM. See 90.24 "To create and run an MTU ping OAM diagnostic test from a service tunnel" (p. 3028) for creating and running an MTU ping OAM diagnostic test from a service tunnel.

90.3.8 MPLS OAM diagnostic tests

Use the MPLS OAM diagnostic tests to test OAM functionality for MPLS provisioned networks based on RFC 4379.

LSP ping

The LSP ping OAM diagnostic test, which is called lsp-ping in CLI, performs in-band MPLS LSPs, MPLS-TP LSPs, LDPs, and MPLS path connectivity tests.

You can use an LSP ping to:

- detect data plane failures in LSPs or MPLS-TP LSP and with LSP or MPLS-TP LSP connectivity
- test whether the LSP or MPLS-TP LSP tunnels are working in both directions

In an LSP or MPLS-TP LSP ping, the originating router creates an MPLS echo request packet for the LSP and MPLS path to be tested. The MPLS echo request packet is sent and awaits an MPLS echo reply packet from the router that terminates the LSP. The status of the LSP is displayed when the MPLS echo reply packet is received. Figure 90-5, "LSP ping OAM diagnostic test" (p. 2995) shows an example of an LSP ping OAM diagnostic test.

See 90.25 “To create and run a MPLS LSP ping OAM diagnostic test from the STM” (p. 3030) for information about how to create and run an LSP ping OAM diagnostic test from the STM.

Figure 90-5 LSP ping OAM diagnostic test

Note: The OAM messages which operate over an LDP LSP, and/or over a PW signaled by T-LDP, and which require a response using the IP path, must use a source IP address which is reachable within the same routing domain as that of the LSR ID of the LDP or T-LDP session. The messages of the LSP Ping use the T-LDP local LSR ID as the source IP address. Previously the NEs system interface address was used for this purpose.

LSP trace

The LSP trace OAM diagnostic test, which is called lsp-trace in CLI, displays the hop-by-hop route used by MPLS LSPs, MPLS-TP LSPs, LDPs, and the MPLS path. You can use an LSP trace to isolate a data plane failure to a particular router and to provide LSP path tracing.

The following information can be determined from the test:

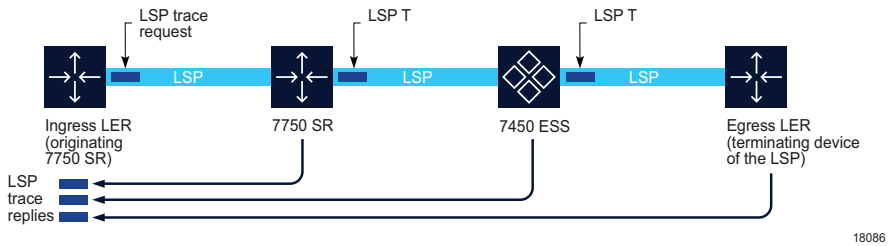
- hop-by-hop path
- destination path of the packets

When performing an MPLS LSP or MPLS-TP LSP trace, the originating router creates an MPLS echo request packet for the LSP to be tested. The packet contains increasing TTL values. The MPLS echo request packet is sent and awaits a TTL exceeded response or the MPLS echo reply packet from the router that terminates the LSP. The devices along the hop-by-hop route reply to the MPLS echo request packets with TTL and MPLS echo reply information.

Figure 90-6, “LSP Trace diagnostic test” (p. 2996) shows an example of an LSP trace OAM diagnostic test.

See 90.26 “To create and run a MPLS LSP trace OAM diagnostic test from the STM” (p. 3031) for information about how to create and run an LSP trace OAM diagnostic test from the STM.

Figure 90-6 LSP Trace diagnostic test



Note: The OAM messages which operate over an LDP LSP, and/or over a PW signaled by T-LDP, and which require a response using the IP path, must use a source IP address which is reachable within the same routing domain as that of the LSR ID of the LDP or T-LDP session. The messages of the LSP trace OAM diagnostic test use the T-LDP local LSR ID as the source IP address. Previously the NE's system interface address was used for this purpose.

LDP tree trace

The LDP tree trace OAM diagnostic test, which is called ldp-treetrace in CLI, is used to detect and discover the ECMP routing paths for an LSP between egress and ingress routers.

The following information is determined from the test:

- number of ECMP paths
- number of failed hops

In an LDP tree trace, the originating router creates an MPLS echo request packet. The packet contains a set of IP header destination addresses. Routers along the path reply to the request with information about themselves and neighboring routers in the downstream path. The originating router uses this information to probe the downstream routers until it discovers a bit map setting common to all routers along the path. The result is a tree of available routers that the originating router can use for next hops. After discovery, the paths are tested using LSP ping and LSP trace.

Note: The OAM messages which operate over an LDP LSP, and/or over a PW signaled by T-LDP, and which require a response using the IP path, must use a source IP address which is reachable within the same routing domain as that of the LSR ID of the LDP or T-LDP session. The messages of the LDP tree trace use the T-LDP local LSR ID as the source IP address. Previously the NE's system interface address was used for this purpose.

See 90.27 "To create and run a MPLS LDP tree trace OAM diagnostic test from the STM" (p. 3032) for information about how to create and run an LDP tree trace OAM diagnostic test from the STM.

P2MP LSP ping

The PSMP LSP ping OAM diagnostic test, which is called p2mp-lsp-ping in CLI, performs in-band LSP connectivity tests.

The echo request message is sent on the active P2MP instance and is replicated in the data path over all branches of the P2MP LSP instance. By default, all egress LER devices that are leaves of the P2MP LSP instance will reply to the echo request message.

You can reduce the scope of the echo reply messages by entering a list of addresses for the egress LER devices that are required to reply. A maximum of 5 addresses can be specified in a single run of the p2mp-lsp-ping command. If all 5 egress LER devices are 7x50 NEs, they will be able to parse the list of egress LER addresses and will reply. The p2mp-lsp-ping command specifies that only the top address in the P2MP Egress Identifier TLV must be inspected by an egress LER. When interoperating with other implementations, a 7x50 egress LER will respond if its address is anywhere in the list. Furthermore, if another vendor implementation is the egress LER, only the egress LER matching the top address in the TLV may respond.

If you enter the same egress LER address more than once in a single p2mp-lsp-ping command, the head-end NE displays a response to a single one and displays a single error warning message for the duplicate ones. When queried over SNMP, the head-end NE issues a single response trap and issues no trap for the duplicates.

See 90.28 “To create and run a MPLS P2MP LSP ping OAM diagnostic test from the STM” (p. 3033) for information about how to create and run a P2MP LSP ping OAM diagnostic test from the STM.

P2MP LSP trace

The PSMP LSP trace OAM diagnostic test, which is called p2mp-lsp-trace in CLI, performs in-band LSP connectivity tests.

The LSP trace capability allows you to trace the path of a single S2L path of a P2MP LSP. Its operation is similar to that of the p2mp-lsp-ping command, but the sender of the echo reply request message includes the Downstream Detailed Mapping TLV to request the downstream branch information from a branch LSR or BUD LSR. The branch LSR or BUD LSR will then also include the Downstream Detailed Mapping TLV to report the information about the downstream branches of the P2MP LSP. An egress LER must not include this TLV in the echo response message.

The parameter probe-count operates in the same way as in the LSP trace on a P2P LSP. It represents the maximum number of probes sent per TTL value before giving up on receiving the echo reply message. If a response is received from the traced NE before reaching maximum number of probes, then no more probes are sent for the same TTL. The sender of the echo request then increments the TTL and uses the information it received in the Downstream Detailed Mapping TLV to start sending probes to the NE downstream of the last NE that replied. This continues until the egress LER for the traced S2L path replies.

See 90.29 “To create and run a MPLS P2MP LSP trace OAM diagnostic test from the STM” (p. 3037) for information about how to create and run a P2MP LSP trace OAM diagnostic test from the STM.

90.3.9 L1/L2 OAM diagnostic tests

Use the L1/L2 OAM diagnostic tests to test ATM PVC connections.

ATM ping

The ATM ping OAM diagnostic test, which is called atmoam-ping in CLI, performs an ATM ping on an ATM PVC from the PVC endpoint using ATM OAM loopback cells. An ATM ping test verifies VC integrity and endpoint connectivity for PVCs using OAM loopback capabilities.

See 90.30 “To create and run an ATM ping OAM diagnostic test from the STM” (p. 3039) for information about how to create and run an ATM ping OAM diagnostic test from the STM. See 90.31 “To configure an ATM OAM loopback from a device Properties form” (p. 3040) for creating and running a ATM ping OAM diagnostic test from an NE Properties form.

90.3.10 Multicast OAM diagnostic tests

Use the multicast OAM diagnostic tests to troubleshoot and resolve problems with the multicast component of a VPLS or a VPRN service.

BIER ping

The BIER ping OAM diagnostic test, which is called bier-ping in CLI, confirms connectivity within a BIER-enabled multicast network. Test packets are generated and sent in a specified sub-domain. Bier ping tests can be configured to specify a BFR ID, a range of BFR IDs, or a BFR prefix.

See 90.32 “To create and run a BIER ping OAM diagnostic test from the STM” (p. 3040) for information about how to create and run a BIER ping OAM diagnostic test from the STM.

BIER trace

The BIER trace OAM diagnostic test, which is called bier-trace in CLI, identifies the hop-by-hop route within a BIER-enabled multicast network. Test packets are generated and sent in a specified sub-domain from any BFR to any other BFR. BIER trace tests can be configured to specify a BFR ID or a BFR prefix.

See 90.33 “To create and run a BIER trace OAM diagnostic test from the STM” (p. 3042) for information about how to create and run a BIER trace OAM diagnostic test from the STM.

MFIB ping

The multicast FIB (MFIB) ping OAM diagnostic test, which is called mfib-ping in CLI, identifies the SAPs that egress an IP multicast stream within a multicast component of a VPLS. This diagnostic test can also be used to display the SAPs that are operationally up in the VPLS.

See 90.34 “To create and run an MFIB ping OAM diagnostic test from the STM” (p. 3043) for information about how to create and run an MFIB ping OAM diagnostic test from the STM.

Mrinfo

The Mrinfo (multicast router information) OAM diagnostic test, which is called mrinfo in CLI, identifies VPRN multicast information for the target router. The information includes details that are related to adjacent routers, supported protocols, traffic metrics, and time-to-live thresholds. Administrators can use this information to identify bidirectional adjacency relationships.

See 90.35 “To create and run an Mrinfo OAM diagnostic test from the STM” (p. 3044) for information about how to create and run a Mrinfo OAM diagnostic test from the STM.

Mtrace

The Mtrace (multicast trace) OAM diagnostic test, which is called mtrace in CLI, identifies the hop-by-hop route used by VPRN multicast traffic to reach the target router. This diagnostic gathers the hop address, routing error conditions, and packet statistics at each hop. The NFM-P attempts to trace the receiver-to-sender route for the traffic. The destination of the diagnostic can be any PIM-enabled interface in the routing instance.

In this test, the command sends a ping to the head of the specified multicast group (which can be one or more hops away from the launch NE). If that ping fails, the command will ping the neighboring NE, then the neighbor's neighbor, and so on up the multicast group chain to determine which NE fails to respond.

See 90.36 “To create and run an Mtrace OAM diagnostic test from the STM” (p. 3044) for information about how to create and run an Mtrace OAM diagnostic test from the STM.

Mtrace2

The Mtrace2 (multicast trace version 2) OAM diagnostic test, which is called mtrace2 in CLI, is similar to the Mtrace OAM test, but with added functionality for isolating packet loss problems and configuration problems. Tests are initiated from an Mtrace2 client toward a specified source, or a Rendezvous Point (RP) if no source address is specified. In the STM configuration, there is an option for StarG, which allows initiation from any source. Mtrace2 uses UDP-based messages, and supports base router and VPRN instances. Both IPv4 and IPv6 are supported.

See 90.37 “To create and run an Mtrace2 OAM diagnostic test from the STM” (p. 3045) for information about how to create and run an Mtrace2 OAM diagnostic test from the STM.

90.3.11 ICMP

Use the ICMP OAM diagnostic tests to troubleshoot and resolve IP reachability problems; for example, to send error messages indicating that a requested VPRN service is not available or that a host or router could not be reached.

ICMP ping

The ICMP ping OAM diagnostic test, which is called icmp-ping in CLI, identifies the reachability of a remote host across the IP network. The test is used with ICMP trace to detect and localize faults in IP networks.

You can also enable the ICMP ping OAM diagnostic test from the VRF site of a subscriber VPRN service. An ICMP ping determines the existence of the far-end egress point of the service. This allows testing of whether a specific destination can be reached. ICMP pings can be sent in-band or out-of-band.

ICMP ping tests can be used to control the operational state of L3 service SAPS. On supporting NEs, users can configure a policy-based ICMP ping template and apply it to all required IES and VPRN L3 interfaces. The interfaces can use the template to populate ICMP ping test configuration values. For more information about ICMP ping templates, see 90.51 “To configure an ICMP Ping template” (p. 3079).

See 90.38 “To create and run an ICMP ping OAM diagnostic test from the STM” (p. 3046) for information about how to create and run an ICMP ping OAM diagnostic test from the STM.

ICMP trace

The ICMP trace OAM diagnostic test, which is called icmp-trace in CLI, identifies the diagnostic used to trace the ICMP traceroute control table. The tool is used with ICMP ping to detect and localize faults in IP networks.

ICMP trace displays the hop-by-hop path for a destination IP address within a VPRN service. This allows operators to know the destination path of subscriber traffic. ICMP traces can be sent in-band or out-of-band.

See 90.39 “To create and run an ICMP trace OAM diagnostic test from the STM” (p. 3047) for information about how to create and run an ICMP trace OAM diagnostic test from the STM.

DNS ping

The DNS ping OAM diagnostic test, which is called dns-ping in CLI, identifies the diagnostic used to ping the DNS name, if a DNS name resolution is configured. See 90.40 “To create and run an ICMP DNS ping OAM diagnostic test from the STM” (p. 3048) for information about how to create and run a DNS ping OAM diagnostic test from the STM.

90.3.12 VWM diagnostic test

Use the VWM OAM diagnostic tests to detect signal failures between two 1830 VWM TLUs or two 1830 VWM ITPs.

PRBS test

You can verify the data path between two 1830 VWM TLUs or two 1830 VWM ITPs by performing the PRBS test. The test is performed by generating PRBS signals, transmitting the signals through a daisy chain of interfaces, and looping them back to detect signal failures.

The NFM-P allows you to run the PRBS test and view the results. The PRBS measurements are performed on client or line ports of the 1830 VWM TLU and 1830 VWM ITP devices and loopbacks are configured on client or line ports of the 1830 VWM TLU and 1830 VWM ITP devices. The administrative state of both ports is set to Maintenance before the PRBS test is performed.

You can stop the test manually at any time or automatically after the configured duration has elapsed. On the same port, a new measurement can only be started after the previous measurement is stopped. The result of a measurement on a specific port is lost when a new measurement is started on the same port.

The result of the test is obtained by reading the number of errors detected in the received PRBS signal in the 1830 VWM TLU or 1830 VWM ITP.

See 90.41 “To create and run a PRBS test” (p. 3048) for more information about performing the PRBS test.

90.3.13 AOS CPE OAM diagnostic tests

Use the AOS CPE OAM diagnostic tests to perform L2 ping and link traces on select OmniSwitch devices in Metro Ethernet networks. See 89.8 “Sample OmniSwitch device SLA testing” (p. 2940) in Chapter 89, “Service Test Manager” for more information.

CPE SLA test

The NFM-P STM allows you to perform a CPE SLA OAM diagnostic test to validate and test customer SLAs used on select OmniSwitch devices in Metro Ethernet networks. The test is critical for provisioning or troubleshooting network services between customer endpoints. The NFM-P STM allows you to test supports unidirectional traffic and IPv4.

See 89.8 “Sample OmniSwitch device SLA testing” (p. 2940) for information about how to configure a CPE SLA OAM diagnostic test using the STM.

CPE SLA test group

The CPE SLA test group allows you to perform a CPE SLA test-head test using one CPE test-head profile or a group of profiles. You can also run several tests for one CPE test-head profile or group of profiles.

See 89.8 “Sample OmniSwitch device SLA testing” (p. 2940) for information about how to create a CPE SLA test-head Group profile using the STM, which can be use to bind individual CPE test-head profiles to form a group of tests.

90.3.14 Non-STM OAM diagnostic and validation tests

The following OAM diagnostic and validation tests are configured from alternate launch points on the NFM-P GUI other than the STM.

OmniSwitch ping and traceroute OAM test

The OmniSwitch ping and traceroute OAM diagnostic test uses user-defined CLI scripts to allow you to troubleshoot and resolve problems with IP reachability on an OmniSwitch.

See 90.44 “To create an OmniSwitch ping or traceroute OAM diagnostic test using a CLI script” (p. 3058) for information about creating an OmniSwitch ping or traceroute OAM diagnostic test using a CLI script.

See 90.45 “To configure and run an OmniSwitch OAM diagnostic ping test CLI script” (p. 3062) and 90.46 “To configure and run an OmniSwitch OAM traceroute test CLI script” (p. 3064) for information about configuring and running an OmniSwitch ping and traceroute CLI scripts.

OmniSwitch advanced loopback test

The OmniSwitch advanced loopback test allows you to troubleshoot and resolve network faults on OmniSwitch ports to isolate the network segments where errors have occurred. See 90.47 “To configure an advanced loopback test on an OmniSwitch from a device Properties form” (p. 3067) for information about configuring an OmniSwitch advanced loopback test.

F5 OAM loopback test (7705 SAR-M/ME)

The F5 OAM loopback test allows you to validate ATM bonding on DSL ports on a 7705 SAR-M/ME device equipped with a DSL module. The parameters for the F5 OAM loopback test are only visible when a DSL module is connected to an ISAM device with the bonding type of ATM and the device is operationally up.

See 90.48 “To run the F5 OAM loopback diagnostic test from a 7705 SAR-M/ME Properties form” (p. 3068) for information about configuring an F5 OAM loopback test.

802.3ah EFM OAM diagnostic test

An 802.3ah EFM OAM diagnostic test addresses three key operational issues when deploying Ethernet across geographically disparate locations: link monitoring, fault signaling, and remote loopback.

Link monitoring provides some basic error definitions for Ethernet so entities can detect failed and degraded connections. Fault signaling provides mechanisms for one entity to signal another that it has detected an error. Remote loopbacks allows one NE to put another NE into a state whereby all inbound traffic is immediately reflected back onto the link.

The 802.3ah EFM OAM test supports:

- EFM OAM capability discovery
- active and passive modes
- remote failure indication
- local and remote loopbacks
- EFM OAMPDU tunneling
- high-resolution EFM OAM timers

You can configure a 802.3ah EFM OAM diagnostic test on Ethernet ports in network mode on the 7210 SAS, 7450 ESS, 7705 SAR, 7750 SR, and 7950 XRS. See 90.49 “To configure an 802.3ah EFM OAM diagnostic test from an NE Properties form” (p. 3069) for more information.

For OmniSwitch NEs, the 802.3ah EFM OAM diagnostic test is supported at the NE level or at the Ethernet port level on the Ethernet ports in network mode. See 90.50 “To configure an 802.3ah EFM OAM diagnostic test on an OmniSwitch Properties form” (p. 3074) for more information.

One-time service validation test

A one-time service validation test provides a mechanism to quickly test a service or composite service either at the time it is provisioned or when it is already in service.

A variety of services and transport components can be tested using this function including:

- VLL, VPLS, and VPRN services
- composite services
- dynamic LSPs
- service tunnels

A one-time service validation test operates like a Validator test suite however the temporary objects that are automatically created for this method are deleted upon its completion. Items deleted include the test suite, tests, MEGs, and MEPs. No user action is required to do this.

Another significant difference with the One-time service validation test is that no results file is created. Instead, all tests and results are stored as archived objects that remain after the test is finished. The results can be viewed in the NFM-P GUI. See the XML API Reference (oneTimeValidate under sas.TestManager) for the required syntax to view the results using the XML API.

Executing a one-time service validation test also updates the OAM Validation Failed state field as required, indicating whether or not the validation was successful.

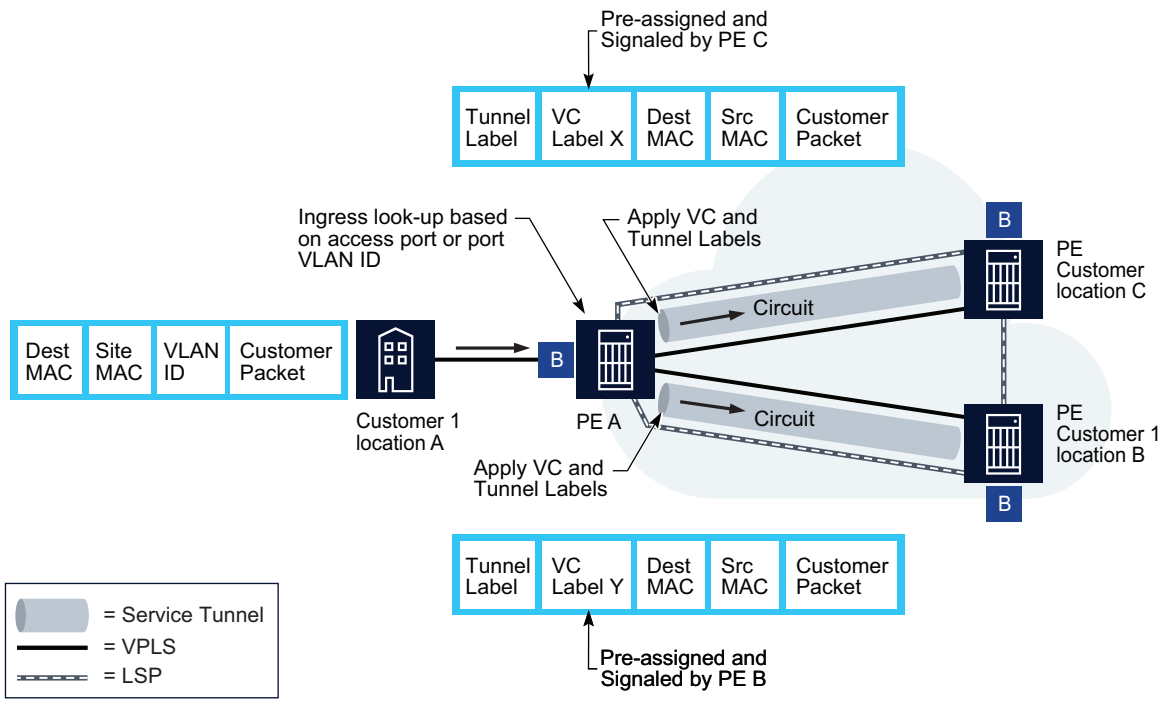
See 90.55 “To run a one-time validation test on a service” (p. 3084) for information about configuring a one-time service validation test.

90.4 Sample OAM diagnostic test configuration

90.4.1 Sample OAM diagnostic sequence

The following figure shows a sample OAM diagnostic sequence illustrating how you can use multiple OAM tests to verify service creation and diagnose service problems. This sample shows a VPLS diagnostic sequence.

Figure 90-7 Sample OAM diagnostic sequence for a VPLS



90.4.2 Sample OAM diagnostic configuration tasks for a service

The following table lists the high-level tasks necessary to configure the sample in Figure 90-7, “Sample OAM diagnostic sequence for a VPLS” (p. 3004).

Table 90-2 Sample OAM diagnostic configuration tasks for a service

Task	Description
Service creation and OAM validation	

Table 90-2 Sample OAM diagnostic configuration tasks for a service (continued)

Task	Description
1. MPLS and LSP creation	Create an MPLS network and LSPs for use by the service tunnels connecting the VPLS sites. Test the validity of the LSPs using LDP tree trace or LSP ping. If the results indicate a problem with the path, use LSP trace to check the specific MPLS path for the device causing the ping failure.
2. Service tunnel creation	Create a service tunnel that uses the MPLS LSP created earlier and perform a tunnel ping on the service tunnel to verify tunnel connectivity. Create all tunnels necessary to interconnect the VPLS sites, and repeat the tunnel ping to ensure tunnel connectivity. After all of the tunnels are created, use the tunnel ping remote tunnel option and specify the return tunnel path. Verify bidirectional tunnel connectivity.
3. Service creation	Create a service using the service tunnels to interconnect the VPLS sites, either using mesh or spoke service tunnel bindings. Use a service site ping between each VPLS site device and its neighboring sites to verify service configuration consistency.
4. MAC diagnostics	Connect the CPE devices to the VPLS and verify traffic. Use MAC trace from the edge devices to verify MAC address learning by the VPLS sites and to ensure that the correct associations are made between MAC addresses and the service tunnels or SAPs to which they are bound. Use MAC ping against an unknown MAC address to verify that no response is returned. Use MAC populate to create an OAM-specific MAC address. Use MAC ping and MAC trace against the created MAC address to verify that customer traffic is not affected by the additional MAC address. Use MAC purge to remove the created OAM MAC address.
Service OAM diagnostics	
5. Diagnose traffic flow problems at a specific MAC address	Use MAC ping against the MAC address to which traffic is not flowing. Use the source and destination MAC address to simulate customer traffic routes as closely as possible. Use MAC trace to pinpoint the location of the traffic failure. Check for MAC filter rules or MAC table sizes to identify possible causes of the failure; for example, incorrect configurations.
6. Diagnose the components of the service	Use service site ping to test the potential next hops to ensure consistent configuration. Use tunnel ping to the far end of the tunnel using the remote tunnel option and specify the return tunnel path. Verify bidirectional tunnel connectivity. Use LSP ping to determine if the tunnel is working. Use an LSP trace to determine if an intervening device is down.

90.5 OSS client OAM diagnostic test results file retrieval

90.5.1 Method to receive OAM logs

XML API clients can use the <registerSasLogToFile> method to receive OAM logs that are based on specific class types. Clients must register to receive the logs, and if no client registers, no logs are created. See the *NSP NFM-P XML API Developer Guide* for detailed information about XML API client methods.

The OAM data is exported to the file after the data is read from the NE. The file is saved to a specified directory on the NFM-P server.

Before you configure XML API clients to receive Test Results files, it is recommended that you configure the DB Test Result Retention Time (hours), Default Test Result Storage, and Log Retention Time (minutes) parameters as required. These are accessed by clicking Administration→System Preferences and then clicking the Test Manager tab.

Procedures to configure and perform OAM diagnostic tests

90.6 OAM diagnostic test workflow

90.6.1 Stages

Note: The tests mentioned in this workflow are generally used on an as-required (on-demand) basis. However, certain tests (for example, PM Session tests) can also be run on a scheduled (proactive) basis.

There are some user and system preferences that can change the operational behavior of OAM diagnostic tests such as specifying the default retention time for db test results or specifying OAM diagnostic test limits. See the STM chapter workflow in 89.9 “STM workflow” (p. 2945) for more information.

Not all service assurance tools are applicable to every NE managed by the NFM-P.

1

Create the transport network and customer services that you want to monitor or troubleshoot. See the appropriate service management chapter in this guide.

2

Review a typical OAM diagnostic test configuration that illustrates how you can use multiple OAM tests to verify service creation and diagnose service problems; see 90.4 “Sample OAM diagnostic test configuration” (p. 3004) .

3

As required, review both the generic and device-specific STM implementation samples in Chapter 89, “Service Test Manager” to help you understand how the various OAM diagnostics tests can be used to verify or monitor service operation, monitor and identify network problems.

4

If the OAM diagnostic test being configured is part of an STM test policy or STM test suite, review the STM chapter workflow to determine any prerequisite or post-requirement configuration requirements; see 89.9 “STM workflow” (p. 2945) . Also see Chapter 92, “Performance Monitoring tests” for information regarding the PM Session tests.

5

If a service needs to be tested or monitored for SLA compliance, or a customer service is compromised and corrective action is required, use the appropriate OAM diagnostic test to analyze, verify, or troubleshoot the problem. See Table 90-1, “NFM-P supported OAM diagnostic tests and configurations” (p. 2981) for a list of all NFM-P supported OAM diagnostic tests and their applicable procedures (covers 91.19 “To create and run a Global MEG OAM diagnostic test from the STM” (p. 3120) to 90.55 “To run a one-time validation test on a service” (p. 3084) in this chapter and 92.7 “To configure a CFM DMM session OAM diagnostic test from the STM” (p. 3149) to 92.12 “To configure a TWAMP Light session OAM diagnostic test from the STM” (p. 3154) in Chapter 92, “Performance Monitoring tests”).

6

If a running OAM diagnostic test needs to be halted, you can click Stop Execution available on the test form. The test's Result Status will indicate Skipped. The Stop Execution button is also available when running PM Session tests and on test suite forms.

90.7 To create and run a service site ping OAM diagnostic test from the STM

90.7.1 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose Service→Create Service Site Ping. The Service Site Ping (Create) form opens.

3

Configure the required parameters.

4

Click on the Test Parameters tab and configure the required parameters.

When you set the target IP address, then choose a service ID, only service IDs from the selected site are available. When you set the Use Local Tunnel and Use Remote Tunnel parameters, the test becomes a ping that tests the service tunnel bindings between the service sites.

5

Click on the Results Configuration tab and configure the required parameters.

6

Save the changes and close the forms.

7

To run the OAM diagnostic test and view the results, perform 89.15 "To run one or more OAM diagnostic tests from the STM and view the test results" (p. 2959) . See 89.20 "To interpret OAM diagnostic test results on the STM" (p. 2964) for information about how to interpret the test results.

END OF STEPS

90.8 To create and run a VCCV ping OAM diagnostic test from the STM

90.8.1 Steps

You can perform this test from a VPLS/MVPLS or VLL service form, or from the service flat topology map.

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose Service→VCCV Ping. The VCCV Ping (Create) form opens.

3

Configure the required parameters.

4

Set the Test Type parameter in the Test Object panel.

To create a VCCV ping from a static PW to a dynamic PW segment, set the Test Type parameter to Static and configure the required parameters in the MPLS-TP VCCV Ping panel.

To create a VCCV ping from a dynamic PW to a static PW segment, set the Test Type parameter to Regular.

If you set the Test Type parameter to FEC 128, configure the required parameters in the FEC 128 Configurations panel.

5

Select the required spoke or mesh SDP binding in the First Spoke/Mesh SDP Binding panel.

Note: The selection of spoke bindings is applicable to both VPLS and VLL services; mesh bindings are only applicable to VPLS and MVPLS. However, when creating this test for MVPLS and VPLS, the concept of downstream spoke SDP bindings does not apply.

6

To configure this test for a VLL, select the required downstream spoke SDP binding in the Downstream SDP Binding panel.

7

Set the Target FEC Type parameter.

If creating a VCCV ping from a static PW to a dynamic PW segment, and the next segment is a dynamic PW, set the Target FEC Type parameter to FEC 129 and configure the required parameters in the Test Multi-Segment PW (FEC 129) panel for the dynamic PW. The PW ID parameter is the Service ID of the service that contains the dynamic PW between the source and destination NEs in this segment.

If creating a VCCV ping from a dynamic PW to a static PW segment, set the Target FEC Type parameter to Static and configure the required parameters in the Test Multi-Segment PW (Static) panel for the dynamic PW.

8

Click on the Test Parameters tab and configure the required parameters.

The Probe History parameter is only configurable when the NE Schedulable parameter is enabled.

If you are configuring a VCCV ping test for a VLL with a switching site, you must set the Reply Type parameter to IP.

9

Click on the Results Configuration tab and configure the required parameters.

10

Save the changes and close the forms.

11

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

End of steps

90.9 To create and run VCCV trace OAM diagnostic test from the STM

90.9.1 Steps

You can also perform this diagnostic test from a VLL service form, or from the service flat topology map. To create a VCCV trace OAM diagnostic test from a static PW to a dynamic PW segment, perform 90.10 “To create and run a VCCV trace OAM diagnostic from a static PW to a dynamic PW segment from the STM” (p. 3010) . To create a VCCV trace OAM diagnostic test from a dynamic PW to a static PW segment, perform 90.11 “To create and run a VCCV trace OAM diagnostic from a dynamic PW to a static PW segment from the STM” (p. 3012) .

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose Service→VCCV Trace. The VCCV Trace (Create) form opens.

3

Configure the required parameters.

4

Set the Test Type parameter in the Test Object panel to Regular.

5

Select a spoke SDP binding in the First Spoke SDP Binding panel.

6

Configure the required parameters.

7

Set the Target FEC Type parameter to None.

8

Click on the Test Parameters tab and configure the required parameters.

The Probe History parameter is only configurable when the NE Schedulable parameter is enabled.

If you are configuring a VCCV trace test for a VLL with a switching site, you must set the Reply Type parameter to IP.

9

Click on the Results Configuration tab and configure the required parameters.

10

Save the changes and close the forms.

11

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

END OF STEPS

90.10 To create and run a VCCV trace OAM diagnostic from a static PW to a dynamic PW segment from the STM

90.10.1 Steps

You can perform this test from a VPLS/MVPLS or VLL service form, or from the service flat topology map.

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose Service→VCCV Trace. The VCCV Trace (Create) form opens.

3

Configure the required parameters.

4

Set the Test Type parameter in the Test Object panel to Static.

5

Configure the required parameters.

6

Configure the Send Mode parameter in the MPLS-TP VCCV Trace panel.

7

Select the required spoke or mesh SDP binding in the First Spoke/Mesh SDP Binding panel.

Note: The selection of spoke bindings is applicable to both VPLS and VLL services; mesh bindings are only applicable to VPLS and MVPLS. However, when creating this test for MVPLS and VPLS, the concept of downstream spoke SDP bindings does not apply.

8

To configure this test for a VLL, select the required downstream spoke SDP binding in the Downstream SDP Binding panel.

9

Set the FEC Type parameter to FEC 128.

10

Configure the required parameters in the Test Multi-Segment PW (FEC 128) panel for the dynamic PW.

The PW ID parameter is the Service ID of the service that contains the dynamic PW between the source and destination NEs in this segment.

11

Click on the Test Parameters tab and configure the required parameters.

The Probe History parameter is only configurable when the NE Schedulable parameter is enabled.

If you are configuring a VCCV trace test for a VLL with a switching site, you must set the Reply Type parameter to IP.

12

Click on the Results Configuration tab and configure the required parameters.

13

Save the changes and close the forms.

14

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

End of steps

90.11 To create and run a VCCV trace OAM diagnostic from a dynamic PW to a static PW segment from the STM

90.11.1 Steps

You can perform this test from a VPLS/MVPLS or VLL service form, or from the service flat topology map.

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose Service→VCCV Trace. The VCCV Trace (Create) form opens.

3

Configure the required parameters.

4

Set the Test Type parameter in the Test Object panel to Regular.

5

Select the required spoke or mesh SDP binding in the First Spoke/Mesh SDP Binding panel.

Note: The selection of spoke bindings is applicable to both VPLS and VLL services; mesh bindings are only applicable to VPLS and MVPLS. However, when creating this test for MVPLS and VPLS, the concept of downstream spoke SDP bindings does not apply.

6

To configure this test for a VLL, select the required downstream spoke SDP binding in the Downstream SDP Binding panel.

7

Set the FEC Type parameter to Static.

8

Configure the required parameters in the Test Multi-Segment PW (Static) panel for the dynamic PW.

9

Click on the Test Parameters tab and configure the required parameters.

The Probe History parameter is only configurable when the NE Schedulable parameter is enabled.

If you are configuring a VCCV trace test for a VLL with a switching site, you must set the Reply Type parameter to IP.

10

Click on the Results Configuration tab and configure the Required parameters.

11

Save the changes and close the forms.

12

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

END OF STEPS

90.12 To create and run a MAC populate OAM diagnostic test from the STM

90.12.1 Steps

You can also perform this diagnostic test from the Tests tab on a VPLS or Epipe VLL service form.

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose L2 Service→MAC Populate. The MAC Populate (Create) form opens.

3

Configure the required parameters.

When the Service Name parameter is configured, you can configure the Name parameter for the site.

4

Click on the Results Configuration tab and configure the required parameters.

5

Save the changes and close the forms.

6

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

END OF STEPS

90.13 To create and run a MAC purge OAM diagnostic test from the STM

90.13.1 Steps

You can also perform this diagnostic test from the Test tab of a VPLS or an Epipe VLL.

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose L2 Service→MAC Purge. The MAC Purge (Create) form opens.

3

Configure the required parameters.

When the Service Name parameter is configured, you can configure the Name parameter for the site.

4

Click on the Results Configuration tab and configure the required parameters.

5

Save the changes and close the forms.

6

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

END OF STEPS

90.14 To create and run a MAC ping OAM diagnostic test from the STM

90.14.1 Steps

You can also perform this diagnostic test from the Test tab of a VPLS or an Epipe VLL.

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose L2 Service→MAC Ping. The MAC Ping (Create) form opens.

3

Configure the required parameters.

When the Service Name parameter is configured, you can configure the Name parameter for the site.

4

Click on the Test Parameters tab and configure the required parameters.

The Probe History parameter is only configurable when the NE Schedulable parameter is enabled.

5

Click on the Results Configuration tab and configure the required parameters.

6

Save the changes and close the forms.

7

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

END OF STEPS

90.15 To create and run a MAC trace OAM diagnostic test from the STM

90.15.1 Steps

You can also perform this diagnostic test from the Test tab of a VPLS or an Epipe VLL.

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose L2 Service→MAC Trace. The MAC Trace (Create) form opens.

3

Configure the required parameters.

When the Service Name parameter is configured, you can configure the Name parameter for the site.

4

Click on the Test Parameters tab and configure the required parameters.

The Probe History parameter is only configurable when the NE Schedulable parameter is enabled.

5

Click on the Results Configuration tab and configure the required parameters.

6

Save the changes and close the forms.

7

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

END OF STEPS

90.16 To create and run a CPE ping OAM diagnostic test from the STM

90.16.1 Additional information

You can also perform this diagnostic test from:

- the Test tab→CPE Ping sub-tab of the required VPLS or VLL Epipe service provisioned over a VPLS PBB backbone
- the topology view of the required VPLS or VLL Epipe service

This test can also be added to the FirstRun/LastRun in a test suite.

If the Epipe or the B-VPLS (in the case of PBB Epipe) uses SDP bindings, the system configuration must be network chassis mode D compatible.

To run this test for a VLL Epipe over a VPLS PBB backbone, the NEs involved must be at IOM3 or above.

90.16.2 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose L2 Service→CPE Ping. The CPE Ping (Create) form opens.

3

Configure the required parameters.

When the Service Name parameter is configured, you can configure the Name parameter for the site.

The Source MAC Address parameter is only displayed and configurable when you are creating this test for a VPLS.

4

Click on the Test Parameters tab and configure the required parameters.

The Probe History parameter is only configurable when the NE Schedulable parameter is enabled.

The Send Via Control Plane and Reply Via Control Plane parameters are only configurable for a VPLS.

5

Click on the Results Configuration tab and configure the required parameters.

6

Click on the NM Thresholds tab to configure threshold-crossing alarms.

Note: The NM Thresholds tab will only be displayed and configurable when the NE Schedulable parameter is not enabled. See 89.11 “To configure threshold-crossing alarms or NM threshold-crossing alarms for an OAM diagnostic test or STM test policy” (p. 2949) for more information.

7

Save the changes and close the forms.

8

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

END OF STEPS

90.17 To create and run an ANCP loopback OAM diagnostic test from the STM

90.17.1 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose L2 Service→ANCP Loopback. The ANCP Loopback (Create) form opens.

3

Configure the required parameters.

4

Select the originating NE in the From IP Address panel.

5

Click on the Test Parameters tab.

6

To configure the ANCP loopback diagnostic for a subscriber ID:

1. Set the Target Type parameter to Subscriber Ident String.
2. Configure the Subscriber Ident String parameter in the ANCP Target Type Details panel.

7

To configure the ANCP loopback diagnostic for an ANCP string:

1. Set the Target Type parameter to ANCP String.
2. Configure the ANCP String parameter in the ANCP Target Type Details panel.

8

Configure the required parameters in the ANCP Details panel.

9

Click on the Results Configuration tab and configure the required parameters.

Note: The ANCP OAM test returns a result trap only if it can locate the subscriber line ANCP string. In this case, it correctly returns the failure or success message. If the ANCP string (i.e., the subscriber line) does not exist on the DSLAM, the network element cannot ping it and does not return a trap. The OAM test in NFM-P remains in the Pending state until the request times out. This behavior differs from the behavior of the other OAM tests. To correct the problem, check the Trap Generation: Probe Failure check box.

10

Save the changes and close the forms.

11

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

End of steps

90.18 To create and run a VXLAN ping OAM diagnostic test from the STM

90.18.1 Steps

Perform this test to run a VXLAN ping test to confirm that a virtual tunnel is operational using the echo request/reply functions, as well as query the status of the Virtual Network Instance (VNI). VXLAN exists only on VPLS and this test is used to ping from site to site in the service. The VXLAN ping test can also be created from a VPLS service and from VPLS sites under the OAM→Tests→VXLAN tab. This functionality is also available in the VPLS service topology map.

1

Choose Manage→Service→Services from the NFM-P main menu. The Service Manager form opens.

2

Choose the required service from the list and click Properties. The *Service* (Edit) form opens.

3

Choose a site from the navigation tree. The Site information is displayed.

4

Click on the BGP tab, then on the General sub-tab.

1. Enable the Enable BGP parameter.
2. Configure the Route Distinguisher parameter.
3. Click RT and PW Template Configuration to open the BGP Configuration form.
4. Click the VSI Import Policies tab and configure required Import Route Target.
5. Click the VSI Export Policies tab and configure required Export Route Target.

5

Click on the EVPN tab.

6

Configure the required parameters.

Note: The Enable BGP EVPN parameter must be enabled for this test.
The CFM MAC Advertisement parameter allows the advertisement through BGP of any configured Up MEP, vMEP and MIP MAC addresses on SAPs and SDP bindings. These are not advertised by default. When this parameter is enabled, locally-generated ETH-CFM PDUs utilize the TEP and VTEP connections as transport for EVPN services. CFM will inform and keep the STM up to date on MEP and MIP MAC addresses, including any additions, deletions, and changes. If the CFM MAC Advertisement parameter is disabled, the Up MEP, vMEP and MIP MAC addresses will be withdrawn in BGP.

7

Click Create in the VXLAN panel. The VXLAN (Create) form opens.

8

Configure the Network Identifier parameter and close the form.

Note: The Network Identifier parameter must have the same value for all sites to be included in the test.

9

Repeat Step 4 to Step 8 for all sites in the service which are to be included in the test.

10

Close the service form.

11

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

12

Click Create and choose L2 Service→VXLAN Ping. The VXLAN Ping (Create) form opens.

13

Configure the required parameters on the General tab.

Note: The Outer IP Destination parameter determines which site in the service to test.

14

Click on the Test Parameters tab and configure the required parameters.

Note: Enabling the I-Flag parameter specifies that the OAM PDUs contain a valid VNI. If it is not enabled, the OAM PDUs are prevented from being forwarded beyond the terminating Virtual Tunnel Endpoints (VTEPs).

Note: You must set the Relay Mode parameter to the Overlay option when the test uses non-system IP addressing.

15

Click on the Results Configuration tab and configure the required parameters.

16

Click Execute to run the test.

17

Click on the Results tab and select the test, then click Properties.

The VXLAN Ping Result form opens. Test results are displayed on the General, Response Probes, and Details tabs.

18

See 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) for additional information on running OAM diagnostic tests and 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

19

Save the changes and close the forms.

END OF STEPS

90.19 To create and run a VPRN ping or VPRN trace OAM diagnostic test from the STM

90.19.1 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose L3 Service→VPRN Ping or VPRN Trace. The VPRN Ping (Create) form or VPRN Trace (Create) opens.

3

Configure the required parameters.

4

Select a VPRN site In the Test Object Panel.

5

Click on the Test Parameters tab.

6

Configure the parameters in the Execution Details panel.

7

Configure the parameters in the Test Probe panel.

The Time To Live parameter only applies to VPRN ping tests.

The Initial Time to Live, DiffServ Field and Maximum Time to Live parameters only apply to VPRN trace tests.

8

Click on the NM Thresholds tab to configure threshold-crossing alarms. See 89.11 “To configure threshold-crossing alarms or NM threshold-crossing alarms for an OAM diagnostic test or STM test policy” (p. 2949) for more information.

9

Save the changes and close the forms.

10

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

END OF STEPS

90.20 To create and run a VPRN Ping, VPRN Trace, ICMP Ping, or ICMP Trace OAM diagnostic test from a service manager form

90.20.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Service Manager form opens.

2

Choose a service from the list and click Properties. The *Service* (Edit) form opens.

3

Click on the Sites tab.

4

Choose a site or sites from the list and click Properties. The Site (Edit) form opens.

5

Click on the OAM tab, then the Tests tab.

6

Configure and run a VPRN ping or VPRN trace OAM diagnostic.

a. To create and run a VPRN ping:

1. Click on the VPRN Ping tab. A list of VPRN diagnostics appears.
2. Double-click on a row in the list to edit an existing test, or click Create to create a new test. The VPRN ping form opens.
3. Configure the required parameters.
4. Select a VPRN site.
5. Click on the Test Parameters tab and configure the required parameters.

The Probe History parameter is only configurable when the NE Schedulable parameter is enabled.

6. Click on the Results Configuration tab and configure the required parameters.
7. Click Apply to save the changes and confirm the action.
8. Click Execute. A deployed test is created and run. Open the deployed test from the Deployed Tests tab to view its current state. When the test is complete, the deployed test is removed, and you can view the results.

b. To create and run a VPRN trace:

1. Click on the VPRN Trace tab. A list of VPRN trace diagnostics appears.
2. Double-click on a row in the list to edit an existing test, or click Create to create a new test. The VPRN Trace (Create) form opens.
3. Configure the required parameters.
4. Select a VPRN site.
5. Click on the Test Parameters tab and configure the required parameters.

   The Probe History parameter is only configurable when the NE Schedulable parameter is enabled.
6. Click on the Results Configuration tab and configure the required parameters.
7. Click Apply to save the changes and confirm the action.
8. Choose the diagnostic from the list.
9. Click Execute. A deployed test is created and run. Open the deployed test from the Deployed Tests tab to view its current state. When the test is complete, the deployed test is removed, and you can view the results.

7

Configure and run an ICMP ping or ICMP trace OAM diagnostic.

a. To create and run ICMP ping:

1. Click on the ICMP Ping tab. A list of ICMP diagnostics appears.
2. Double-click on a row in the list to edit an existing test, or click Create to create a new test. The ICMP Ping form opens.
3. Configure the required parameters.
4. Configure the IP Address and VPRN interface in the Source panel.
5. Configure the Target IP Address and VPRN interface in the Target IP Address panel.
6. Click on the Test Parameters tab and configure the required parameters.

   The Probe History parameter is only configurable when the NE Schedulable parameter is enabled.

   The Continuous Execution option is only applicable when the Packet Interval is set to 1 second or greater.

   The Continuous Execution and Rapid options are mutually exclusive.
7. Click on the Results Configuration tab and configure the required parameters.

8. Click Apply to save the changes and confirm the action.
9. Click Execute. A deployed test is created and run. Open the deployed test from the Deployed Tests tab to view its current state. When the test is complete, the deployed test is removed, and you can view the results.

b. To create and run ICMP trace:

1. Click on the ICMP Trace tab. A list of ICMP trace diagnostics appears.
2. Double-click on a row in the list to edit an existing test, or click Create to create a new test. The ICMP Trace form opens.
3. Configure the required parameters.
4. Configure the IP Address and VPRN interface in the Source panel.
5. Configure the Target IP Address and VPRN interface in the Target IP Address panel.
6. Click on the Test Parameters tab and configure the required parameters.

   The Probe History parameter is only configurable when the NE Schedulable parameter is enabled.
7. Click on the Results Configuration tab and configure the required parameters.
8. Click Apply to save the changes and confirm the action.
9. Choose the diagnostic from the list.
10. Click Execute. A deployed test is created and run. Open the deployed test from the Deployed Tests tab to view its current state. When the test is complete, the deployed test is removed, and you can view the results.

8

View the test results on the Results tab. The results depend on the type of test. See 89.16 “To view and compare OAM diagnostic test results on the STM” (p. 2960).

Result information includes:

- Number of Probes Sent
- Time Last Response
- Number of Responses Received

Note: Results of individually run ICMP Trace tests are viewed on the Results tab. The Results tab displays only the result of the last individually run ICMP Trace test, any previous individually run test results are overwritten.
Results from ICMP Trace tests that are scheduled or part of a test suite are also stored on the Results tab. The number of scheduled test results stored corresponds to the value configured in the Probe History Size (rows) parameter. Scheduled ICMP Trace test results do not overwrite individually run test results or previously run scheduled test results.

END OF STEPS

90.21 To create a tunnel ping OAM diagnostic test from the STM

90.21.1 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose Service Transport→Tunnel Ping. The Tunnel Ping (Create) form opens.

3

Configure the required parameters.

4

Select the source of the service tunnel.

5

Save the changes and close the forms.

6

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

END OF STEPS

90.22 To create and run a tunnel ping OAM diagnostic test from a service tunnel

90.22.1 Steps

1

Choose Manage→Service Tunnels from the NFM-P main menu. The Manage Service Tunnels form opens.

2

Filter to list only the source and destination routers of the service tunnel and click Search. The list of service tunnels opens.

3

Double-click on a service tunnel from the list. The Tunnel (Edit) form opens.

4

Click on the Tests tab.

5

Click on the Tunnel Ping tab.

6

Click Create. The Tunnel Ping (Create) form opens. The form displays information about the circuit being tested, including the originating tunnel ID.

7

Configure the required parameters.

8

Click on the Test Parameters tab and configure the required parameters.

The Packet Interval (seconds) parameter has an effect only when multiple probes are to be sent.

The Probe History parameter is only configurable when the NE Schedulable parameter is enabled.

Ensure that you configure the Forwarding Class parameter to work with the services that use the tunnel.

9

Click on the Results Configuration tab and configure the required parameters.

10

Click Apply to save the changes and confirm the action.

11

Perform the tunnel ping OAM diagnostic:

1. Click Execute on the Tunnel Ping (Edit) form. A deployed test is created and run. Open the deployed test from the Deployed Tests tab to view its current state. When the test is complete, the deployed test is removed, and you can view the results. The diagnostic is complete.
2. Click on the Results tab. The list of tunnel ping OAM packets sent is displayed.
3. Click on the row or rows to view diagnostic information.
4. Click Properties. The OAM results form opens.

See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about the diagnostic status messages. Use the status message to interpret the diagnostic results.

5. Close the form.

12

Close the Tunnel (Edit) form when the OAM diagnostics are complete.

END OF STEPS

90.23 To create and run an MTU ping OAM diagnostic test from the STM

90.23.1 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose Service Transport→MTU Ping. The MTU Ping (Create) form opens.

3

Configure the required parameters.

4

Select the source of the service tunnel.

5

Save the changes and close the forms.

6

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

END OF STEPS

90.24 To create and run an MTU ping OAM diagnostic test from a service tunnel

90.24.1 Steps

Use the MTU ping diagnostic test to find the largest valid frame size.

1

Choose Manage→Service Tunnels from the NFM-P main menu. The Manage Service Tunnels form opens.

2

Filter to list only the source and destination routers of the service tunnel and click Search. The list of service tunnels appears.

3

Double-click on a service tunnel from the list. The Tunnel (Edit) form opens.

4

Click on the Tests tab.

5

Click on the MTU Ping tab.

6

Click Create. The MTU Ping (Create) form opens. The form displays information about the service tunnel being tested and the originating tunnel ID.

7

Configure the required parameters.

8

Click on the Test Parameters tab and configure the required parameters.

Note: If the step size is small but the end message size is large, the amount of time to complete the MTU ping may be many minutes. Ensure that you have an appropriate step size that reflects the range of MTU packet sizes that you want to test.

9

Click on the Results Configuration tab and configure the required parameters.

10

Click Apply to save the changes.

11

Perform the MTU ping.

1. Click execute in the MTU Ping (Edit) form. The MTU ping diagnostic starts. A deployed test is created and run. Open the deployed test from the Deployed Tests tab to view its current state. When the test is complete, the deployed test is removed, and you can view the results. The diagnostic is complete.

2. Click on the Results tab. The list of MTU ping OAM probes sent is displayed.
3. Click on the row(s) to view diagnostic information.
4. Click Properties. The OAM results form opens.

   See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about the diagnostic status messages. Use the status message to interpret the diagnostic results. For example, the status message Response Received indicates that the MTU OAM diagnostic completed successfully.
5. Close the form.

12

Close the Tunnel (Edit) form when the OAM diagnostics are complete.

END OF STEPS

90.25 To create and run a MPLS LSP ping OAM diagnostic test from the STM

90.25.1 Steps

The MPLS LSP Ping OAM diagnostic test is supported on both IPv4 and IPv6 source and destination addresses.

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose MPLS→LSP Ping. The LSP Ping (Create) form opens.

3

Configure the required parameters. The available parameters change depending on the option specified for the Target Type parameter. Information about NFM-P parameters is available in the XML API Reference.

4

Click on the Test Parameters tab and configure the required parameters.

5

Click on the Results Configuration tab and configure the required parameters.

6

As required, click on the NM Thresholds tab to configure threshold-crossing alarms.

Note: The NM Thresholds tab will only be displayed and configurable when the NE Schedulable parameter is not enabled. See 89.11 “To configure threshold-crossing alarms or NM threshold-crossing alarms for an OAM diagnostic test or STM test policy” (p. 2949) for more information.

7

Save the changes and close the forms.

8

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

END OF STEPS

90.26 To create and run a MPLS LSP trace OAM diagnostic test from the STM

90.26.1 Steps

The MPLS LSP Trace OAM diagnostic test is supported on both IPv4 and IPv6 source and destination addresses.

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose MPLS→LSP Trace. The LSP Trace (Create) form opens.

3

Configure the required parameters. The available parameters change depending on the option specified for the Target Type parameter. Information about NFM-P parameters is available in the XML API Reference.

4

Click on the Test Parameters tab and configure the required parameters.

The Probe History parameter is only configurable when the NE Schedulable parameter is enabled.

5

Click on the Results Configuration tab and configure the required parameters.

6

As required, click on the NM Thresholds tab to configure threshold-crossing alarms.

Note: The NM Thresholds tab will only be displayed and configurable when the NE Schedulable parameter is not enabled. See 89.11 “To configure threshold-crossing alarms or NM threshold-crossing alarms for an OAM diagnostic test or STM test policy” (p. 2949) for more information.

7

Save the changes and close the forms.

8

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

END OF STEPS

90.27 To create and run a MPLS LDP tree trace OAM diagnostic test from the STM

90.27.1 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose MPLS→LDP Tree Trace. The LDP Tree Trace (Create) form opens.

3

Configure the required parameters.

4

Click on the Test Parameters tab and configure the required parameters.

5

Click on the Results Configuration tab and configure the required parameters.

6

As required, click on the NM Thresholds tab to configure threshold-crossing alarms.

Note: The NM Thresholds tab will only be displayed and configurable when the NE Schedulable parameter is not enabled. See 89.11 “To configure threshold-crossing alarms or NM threshold-crossing alarms for an OAM diagnostic test or STM test policy” (p. 2949) for more information.

7

Save the changes and close the forms.

8

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

END OF STEPS

90.28 To create and run a MPLS P2MP LSP ping OAM diagnostic test from the STM

90.28.1 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose MPLS→P2MP LSP Ping. The P2MP LSP Ping (Create) form opens.

3

Configure the required parameters.

4

Perform one of the following:

a. If you selected P2MP RSVP as your Target Type:

1. Select a P2MP dynamic LSP in the P2MP Dynamic LSP panel.
2. Select a P2MP Instance in the P2MP Instance panel.
3. Configure the Select All S2L Paths parameter.

   If you enabled the parameter, go to Step 5 .
4. Click on the S2L Paths tab.
5. Click Add and select one or more S2L paths (up to a maximum of five).

b. If you selected P2MP mLDP as your Target Type:

Note: For the test to execute successfully, ensure the following:

- The LDP protocol must be enabled on all NEs between the source and destination, including any intermediate NEs.
- LDP interfaces must be in place between the source and destination NEs.
- LDP interfaces must be up, and the Multicast Forwarding parameter must be enabled on each interface. This also applies to all intermediate NEs. See 28.52 “To configure an LDP interface” (p. 944) for information about configuring LDP interfaces.

Perform the following:

1. Configure the required parameters.
2. Select the P2MP ID you want to test in the P2MP LDP panel.
3. Click on the LDP Leaf Addresses tab.
4. Click Add and select up to five leaf NEs.

c. If you selected P2MP mLDP-SSM as your Target Type:

Note: For the test to execute successfully, ensure the following:

- The LDP protocol must be enabled on all NEs between the source and destination, including any intermediate NEs.
- LDP interfaces must be in place between the source and destination NEs.
- LDP interfaces must be up, and the Multicast Forwarding parameter must be enabled on each interface. This also applies to all intermediate NEs. See 28.52 “To configure an LDP interface” (p. 944) for information about configuring LDP interfaces.

Perform the following:

1. Select the System ID (Loopback IP Address) in the P2MP LDP SSM panel.
2. Configure the Router Instance type (either a base router or a VPRN service). If you select Service, then you must also select the required VPRN Instance.
3. Select the Source Address. The Group Address field will be automatically populated, depending on your choice of Source Address. However, you can also manually enter a multicast address in the Group Address field, as required.
4. If you selected Service as the Router Instance type, then go to Step 5 .
5. Select a Sender Address.
6. Click on the LDP Leaf Addresses tab.
7. Click Add and select up to five leaf NEs.

d. If you selected P2MP Policy as your Target Type, perform the following:

1. Select a System ID (Loopback IP Address).
2. Select the Root Address, Root Tree Id, and Root Tree Instance Id.
3. Click on the Leaf Addresses tab.
4. Click Add and select up to five leaf addresses.

5

Click on the Test Parameters tab and configure the required parameters.

The Time To Live parameter is only displayed if you selected P2MP RSVP as your Target Type.

6

Click on the Results Configuration tab and configure the required parameters.

7

As required, click on the NM Thresholds tab to configure threshold-crossing alarms. See 89.11 “To configure threshold-crossing alarms or NM threshold-crossing alarms for an OAM diagnostic test or STM test policy” (p. 2949) for more information.

8

Click OK to save the changes. The Service Test Manager form opens.

9

Choose the created test from the list of OAM diagnostics and click Properties.

The P2MP LSP Ping (Edit) form opens.

10

Click Execute to start the P2MP LSP ping. A deployed test is created and run. Open the deployed test to view its current state. When the test is complete, the deployed test is removed, and you can view the results.

Note: When this test is performed on an existing Point-to-Multipoint LSP, up to five S2L paths (for a P2MP RSVP target type) or five LDP leaf addresses (for a P2MP mLDP or P2MP mLDP-SSM target type) can be selected. If none are selected, all available paths or addresses up to the limit of five will be pinged.

11

Click on the Results tab in the P2MP LSP Ping (Edit) form.

The Results tab will show an entry for each S2L path (RSVP) or leaf address (mLDP or mLDP-SSM) tested.

12

Select the test from the list and click on Properties. The P2MP LSP Ping Packet Result form opens.

The General tab displays the test parameters you configured, along with time the test was executed, its status, and the following test information:

- Number of Packets Sent
- Packet Timeouts
- Number of Responses Received

- Number of Packets Lost
- Loss Percentage
- Last Good Packet Time

Note: The test results depend on the type of test you run. See 89.16 “To view and compare OAM diagnostic test results on the STM” (p. 2960) for more information.

13

Click on the Details tab.

14

View the test results for the:

- Round Trip Time
- Outbound One Way Time
- Inbound One Way Time

15

Click on the Response Packets tab.

16

Select a response packet from the list and click on Properties. The P2MP LSP Ping Packet Result form opens.

Note: The test results depend on the type of test you run. See 89.16 “To view and compare OAM diagnostic test results on the STM” (p. 2960) for more information.

17

View details on the response packet, including:

- Status
- Round-Trip Time
- Response sequence

18

Repeat Step 12 to Step 17 for all tested S2L paths (RSVP) or leaf addresses (mLDP).

END OF STEPS

90.29 To create and run a MPLS P2MP LSP trace OAM diagnostic test from the STM

90.29.1 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose MPLS→P2MP LSP Trace. The P2MP LSP Trace (Create) form opens.

3

Configure the required parameters.

4

Click Select in the P2MP Dynamic Lsp panel to choose the P2MP Dynamic LSP you want to test.

5

Click on Select in the P2MP Instance panel to choose the P2MP Instance you want to test.

6

Click on Select in the S2L Destination Address panel to choose the S2L Destination Address you want to test.

7

Click on the Test Parameters tab and configure the required parameters.

8

Click on the Results Configuration tab and configure the required parameters.

9

As required, click on the NM Thresholds tab to configure threshold-crossing alarms. See 89.11 “To configure threshold-crossing alarms or NM threshold-crossing alarms for an OAM diagnostic test or STM test policy” (p. 2949) for more information.

10

Click OK to save the changes. The Service Test Manager form opens.

11

Choose the created test from the list of OAM diagnostics and click Properties.

The P2MP LSP Trace (Edit) form opens.

12

Click execute to start the P2MP LSP trace. A deployed test is created and run. Open the deployed test to view its current state. When the test is complete, the deployed test is removed, and you can view the results.

13

Click on the Results tab.

14

Select the test from the list and click on Properties. The P2MP LSP Trace Result form opens.

The General tab displays the test parameters you configured, along with time the test was executed and its status.

Note: The test results depend on the type of test you run. See 89.16 “To view and compare OAM diagnostic test results on the STM” (p. 2960) for more information.

15

Click on the Hops and Probes tab.

A tree view of the Hops and Probes associated with this test is provided.

16

Right-click on a Hop from the tree view and click on Properties.

The P2MP LSP Trace Hop (Edit) form is displayed, showing the General tab.

17

View the test results for the following:

- Response Probe
- Round Trip Details
- Outbound One Way Trip Details
- Inbound One Way Trip Details

18

Right-click on a Probe from the tree view and click on Properties.

The P2MP LSP Trace Probe (Edit) form is displayed, showing the General tab.

19

View details on the probe, including:

- Response Probe

- LSP Details

20

Repeat this test for all required S2L paths. The test only evaluates one S2L path per execution.

END OF STEPS

90.30 To create and run an ATM ping OAM diagnostic test from the STM

90.30.1 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose L1/L2→ATM Ping. The ATM Ping (Create) form opens.

3

Configure the required parameters.

The VCI parameter is only configurable when the Connection Type is set to VCC Connection.

4

Click on the Test Parameters tab and configure the required parameters.

5

Click on the Results Configuration tab and configure the required parameters.

6

Save the changes and close the forms.

7

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

END OF STEPS

90.31 To configure an ATM OAM loopback from a device Properties form

90.31.1 Steps

The ATM OAM loopback settings are configured globally on supported devices. However, a loopback must be enabled on an IES or VPRN SAP.

1

Choose Equipment from the navigation tree view selector. The navigation tree displays the Equipment view.

2

Right-click on the device where you want to configure an ATM OAM loopback and select Properties. The Network Element (Edit) form opens.

3

Click on the ATM tab.

4

Configure the required parameters.

5

Save your changes and close the form.

END OF STEPS

90.32 To create and run a BIER ping OAM diagnostic test from the STM

90.32.1 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose Multicast→BIER Ping. The BIER Ping (Create) form opens.

3

Configure the required parameters on the General tab.

4

Select a source site in the Site panel.

5

Depending on the option selected for the BIER Target Type parameter in Step 3, perform one of the following:

a. For the BFR ID option:
   1. Configure the Sub-Domain ID parameter.
   2. Select a destination BFR ID in the BFR ID panel.

      The BFR ID must be in the configured sub-domain.

b. For the BFR ID Range option:
   1. Configure the Sub-Domain ID parameter.
   2. Configure a starting ID for the range. Click Select for the BFR ID Start parameter and choose a BFR ID from the list.
   3. Configure an ending ID for the range. Click Select for the BFR ID End parameter and choose a BFR ID from the list.

      All BFR IDs in the range must be in the configured sub-domain.

c. For the BFR Prefix option:
   1. Configure the Sub-Domain ID parameter.
   2. Click on the BFR Prefix tab.
   3. Click Create. The BIER Ping BFR Prefix (Create) form opens.
   4. Configure the parameters and select a Prefix address.

      The BFR prefix must be in the configured sub-domain.
   5. Close the BIER Ping BFR Prefix (Create) form.
   6. Configure additional BFR prefixes as required. You can configure up to 16 BIER BFR prefixes.

6

Click on the Test Parameters tab and configure the required parameters.

7

Click on the Results Configuration tab and configure the required parameters.

8

Save the changes and close the forms.

9

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

End of steps

90.33 To create and run a BIER trace OAM diagnostic test from the STM

90.33.1 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose Multicast→BIER Trace. The BIER Trace (Create) form opens.

3

Configure the required parameters on the General tab.

4

Select a source site in the Site panel.

5

Depending on the option selected for the BIER Target Type parameter in Step 3, perform one of the following:

a. For the BFR ID option:
   1. Configure the Sub-Domain ID parameter.
   2. Select a destination BFR ID in the BFR ID panel.

      The BFR ID must be in the configured sub-domain.

b. For the BFR Prefix option:
   1. Configure the Sub-Domain ID parameter.
   2. Select a destination prefix in the BFR Prefix panel.

      The BFR prefix must be in the configured sub-domain.

6

Click on the Test Parameters tab and configure the required parameters.

7

Click on the Results Configuration tab and configure the required parameters.

8

Save the changes and close the forms.

9

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

END OF STEPS

90.34 To create and run an MFIB ping OAM diagnostic test from the STM

90.34.1 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose Multicast→MFIB Ping. The MFIB Ping (Create) form opens.

3

Configure the required parameters on the General tab.

When the Service Name parameter is configured, you can configure the Name parameter for the site.

When you set the target IP address, then choose a service ID, only service IDs from the selected site are available.

4

Click on the Test Parameters tab and configure the required parameters.

5

Click on the Results Configuration tab and configure the required parameters.

6

Save the changes and close the forms.

7

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

END OF STEPS

90.35 To create and run an Mrinfo OAM diagnostic test from the STM

90.35.1 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose Multicast→Mrinfo. The Mrinfo (Create) form opens.

3

Configure the required parameters.

4

Click on Select to choose a PIM interface. The Select PIM Interface form opens.

5

Select a PIM interface in the list and click OK. The Select PIM Interface form closes, and the interface information is displayed on the Mrinfo (Create) form.

6

Click on the Results Configuration tab and configure the required parameters.

7

Save the changes and close the forms.

8

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

End of steps

90.36 To create and run an Mtrace OAM diagnostic test from the STM

90.36.1 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose Multicast→Mtrace. The Mtrace (Create) form opens.

3

Configure the required parameters.

4

Click on the Test Parameters tab and configure the required parameters.

5

Click on the Results Configuration tab and configure the required parameters.

6

Save the changes and close the forms.

7

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

End of steps

90.37 To create and run an Mtrace2 OAM diagnostic test from the STM

90.37.1 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose Multicast→Mtrace2. The Mtrace2 (Create) form opens.

3

Configure the required parameters.

4

Click on the Test Parameters tab and configure the required parameters.

5

Click on the Results Configuration tab and configure the required parameters.

6

Save the changes and close the forms.

7

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959). See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

END OF STEPS

90.38 To create and run an ICMP ping OAM diagnostic test from the STM

90.38.1 Steps

You can also perform an ICMP ping test from the Test tab of a VPRN or EIS service configuration form.

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose ICMP→ICMP Ping. The ICMP Ping (Create) form opens.

3

Configure the required parameters.

4

Click on the Test Parameters tab and configure the required parameters.

The Probe History parameter is only configurable when the NE Schedulable parameter is enabled.

The Continuous Execution option is only applicable when the Packet Interval is set to 1 second or greater.

The Continuous Execution and Rapid options are mutually exclusive.

5

Click on the Results Configuration tab and configure the required parameters.

6

Save the changes and close the forms.

7

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

END OF STEPS

90.39 To create and run an ICMP trace OAM diagnostic test from the STM

90.39.1 Steps

You can also perform an ICMP trace test from the Test tab of a VPRN or EIS service configuration form.

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose ICMP→ICMP Trace. The ICMP Trace (Create) form opens.

3

Configure the required parameters.

4

Click on the Test Parameters tab and configure the required parameters.

The Probe History parameter is only configurable when the NE Schedulable parameter is enabled.

5

Click on the Results Configuration tab and configure the required parameters.

6

Save the changes and close the forms.

7

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

END OF STEPS

90.40 To create and run an ICMP DNS ping OAM diagnostic test from the STM

90.40.1 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose ICMP→DNS Ping. The DNS Ping (Create) form opens.

3

Configure the required parameters.

4

Click on the Test Parameters tab and configure the required parameters.

The Probe History parameter is only configurable when the NE Schedulable parameter is enabled.

5

Click on the Results Configuration tab and configure the required parameters.

6

Save the changes and close the forms.

7

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

END OF STEPS

90.41 To create and run a PRBS test

90.41.1 Before you begin

Ensure that the administrative state of the port where the test is run and the port where the loopback is configured are set to Maintenance.

90.41.2 Steps

Set the administrative state to Maintenance

1

On the equipment tree, expand Network→1830 VWM→Shelf 1830 VWM TLU →Card Slot TLU.

2

Right-click on the port object where the PRBS test will be executed and choose Properties. The Physical Port (Edit) form opens.

3

Click on the States tab and set the Administrative State parameter to Maintenance.

4

Save your changes and close the form.

5

Repeat Step 1 to Step 4 for the port where you need to configure loopback.

Configure loopback

6

On the equipment tree, expand Network→1830 VWM→Shelf 1830 VWM TLU →Card Slot TLU.

7

Right-click on the port object where you need to configure the loopback and choose Properties. The Physical Port (Edit) form opens.

8

Click on the Port Specifics tab. In the Loop Back panel, set the appropriate LoopBack Status parameter to Enabled.

9

Save your changes and close the form.

Start the PRBS test

10

Perform one of the following:

a. From the main menu:
   1. Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager (STM) form opens.
   2. Click Create→VWM→PRBS Test. The PRBS Test (Create) form opens.

b. From the port:
   1. On the equipment tree, expand Network→1830 VWM→Shelf 1830 VWM TLU →Card Slot TLU.
   2. Right-click on the port object where you need to perform the PRBS test and choose Properties. The Physical Port (Edit) form opens.
   3. Click PRBS Test. The PRBS Test (Create) form opens.

11

Configure the required parameters and click on the PRBS tab.

12

Configure the required parameters.

Note: The parameters are populated when the test is performed from the Physical Port (Edit) form.

13

Click Apply. The PRBS Test (Create) form closes and the PRBS Test (Edit) form appears.

14

Click Execute to run the test.

Stop the PRBS test

15

Perform one of the following to stop the test:

a. Click Stop Test Execution to stop the test manually.

b. Perform the following to stop the test automatically:
   1. Click on the PRBS tab and configure the Auto Stop and Auto Stop Duration parameters.
   2. Click Apply.

View the results

16

Click on the Results tab and click search. The results are listed.

17

Choose an entry and click Properties. The PRBS Test Result form opens.

Result: The results of the test are obtained by reading the number of errors detected in the received PRBS signal in the 1830 VWM TLU or 1830 VWM ITP.

END OF STEPS

90.42 To create and run a OmniSwitch CPE SLA diagnostic test from the STM

90.42.1 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose L1/L2→ATM Ping. The ATM Ping (Create) form opens.

3

Configure the required parameters.

4

Click on the Test Parameters tab and configure the required parameters.

5

Click on the Results Configuration tab and configure the required parameters.

6

Save the changes and close the forms.

7

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

END OF STEPS

90.43 To configure and run OAM tests contextually

90.43.1 Reference

A number of the OAM diagnostic tests for objects and services described in this chapter can be contextually configured and executed from various entry points in the GUI. Specifically, VPLS, VPRN, Epipe, and Composite services, in addition to SAPs (access interfaces), SDP tunnels, SDP bindings, and LSPs can all be tested contextually. All of the tests are available in both Quick and Scheduled runs. Some test types also support a continuous run option. Scheduled tests use SNMP and continuous tests use accounting.

Contextual test creation and execution is available from:

- Service topology maps and flat maps (for Composite services)
- Sites and Interfaces tabs within a service properties form
- Service Tree within a service properties form
- Manage Service Tunnels form
- Applicable Manage LSP forms

This procedure is applicable to all of these access modes, since the contextual test forms that are opened are the same, regardless of the access mode you use.

Contextual tests can be created between selected service sites or between or on specific entities. The tests are accessed by selecting single or multiple entities, then right-clicking and choosing Run OAM Tests.

Refer to the following procedures for additional detailed information on configuring the tests using the STM, if required:

- CFM Loopback - 91.21 “To create and run a CFM loopback OAM diagnostic test from the STM” (p. 3123)
- CFM Link trace - 91.22 “To create and run a CFM link trace OAM diagnostic test from the STM” (p. 3125)
- CFM Two-way delay - 91.24 “To create and run a CFM two way delay OAM diagnostic test from the STM” (p. 3128)
- CFM Two-way SLM - 91.27 “To create and run a CFM two way SLM OAM diagnostic test from the STM” (p. 3132)
- VCCV Ping - 90.8 “To create and run a VCCV ping OAM diagnostic test from the STM” (p. 3009)
- VCCV Trace- 90.9 “To create and run VCCV trace OAM diagnostic test from the STM” (p. 3010)
- VPRN Ping and VPRN Trace- 90.19 “To create and run a VPRN ping or VPRN trace OAM diagnostic test from the STM” (p. 3023)
- Tunnel Ping- 90.21 “To create a tunnel ping OAM diagnostic test from the STM” (p. 3027). Either a single or multiple tunnels can be selected to run the OAM tests contextually.
- MTU Ping- 90.23 “To create and run an MTU ping OAM diagnostic test from the STM” (p. 3029). Either a single or multiple tunnels can be selected to run the OAM tests contextually.
- LSP Ping- 90.25 “To create and run a MPLS LSP ping OAM diagnostic test from the STM” (p. 3031)

- LSP Trace- 90.26 “To create and run a MPLS LSP trace OAM diagnostic test from the STM” (p. 3032)
- ICMP Ping- 90.38 “To create and run an ICMP ping OAM diagnostic test from the STM” (p. 3047)
- ICMP Trace- 90.39 “To create and run an ICMP trace OAM diagnostic test from the STM” (p. 3048)

Refer also to 4.2.3 “Working with Ethernet CFM objects” (p. 177) in Chapter 4, “Topology map management” and 4.8 “To use OAM diagnostic functions on service topology and composite service flat topology maps” (p. 181) for additional information on accessing OAM functionality from a service topology view.

Refer to the following service chapters for additional information, if required:

- VPLS - Chapter 77, “VPLS management ”
- VPRN - Chapter 79, “VPRN service management”
- VLL (for Epipe services) - Chapter 76, “VLL service management”
- Composite Services- Chapter 85, “Composite service management”
- LSPs- Chapter 31, “MPLS”
- SDPs- Chapter 33, “Service tunnels”

Additional procedural points:

- To test SAPs, the SAPs must be operationally Up.
- If you select SAPs or sites with resources such as Global MEGs and MEPs already present, you can utilize these objects and run the tests on top of them.
- To test SDP bindings, the bindings must be operationally Up. The following types are supported:
  1. Regular Spoke SDP Bindings on VPLS, MVPLS, and Epipe services
  2. Regular Spoke SDP Bindings with source interfaces on VPRN services
  3. Mesh SDP Bindings on VPLS and MVPLS with V-sites and B-sites
  4. Static Spoke SDP Bindings on VPLS
  5. Spoke FEC 128 on Epipe services. Testing these types is only available from the table or tree view. The topology view is not supported.
- Contextually-created test policies cannot be used to create regular test suites. When a contextually-created test suite is deleted, the associated test policy is also deleted.
- Contextually-created OAM tests cannot be created between VPLS B-L2 Access Interfaces.
- Contextually-created OAM tests cannot be created between Epipe sites.
- For non-CFM entities, multiple OAM Context windows can be opened to run tests on different entities at the same time.

90.43.2 Steps

To demonstrate the contextual OAM configuration and execution workflow generally, this procedure covers the testing of two SAPs or sites as examples. Testing different entities follows the same basic process. The procedure assumes that you have already accessed either a service form or service topology view.

1

Perform one of the following:

a. Select two or more SAPs and right click on one of them.

b. Select two or more sites and right click on one of them.

2

Select Run OAM Tests from the contextual menu. The OAM Contextual Test form opens.

3

Configure the OAM Test Type parameter for the type of test you want to run.

4

Configure the Test Level and Number of Test Probes, as applicable.

5

Configure and run one of the following test execution modes:

a. Quick Run. Go to Step 6 .

b. Scheduled Run. Go to Step 14 .

c. Continuous Run. Go to Step 26 .

Quick Run tests

6

Configure the Test Execution Mode for Quick Run.

Quick Run tests provide a one-time immediate test result.

7

Click Execute to run the test.

Note: When you execute a test, all required test resources are automatically created by NFM-P. After the test has been executed, the created test resources are automatically deleted. Pre-existing resources that were used for the test are not deleted.

8

To view the test results, click on the Quick Run Results tab and select an entry.

9

Click Properties. The One Time Validation Result form opens. Results for each of the selected test objects are available in the Results tab.

Note: The test results are archived for future reference.

10

Close the form.

11

Click the SAPs or Sites tab to view the objects you chose to run the test. Click View Service to open the property form of the service associated with the selected objects.

12

Click the Test Generation Log tab to view any error messages generated by the test.

13

Close the form.

Scheduled Run tests

14

Configure the Test Execution Mode for Scheduled Run.

15

Enter a Test Suite Name. This name will be used for the automatically-created test suite required for the test. The created test suite can be viewed in the STM after test execution, if required.

16

Click Select for the Test Suite Scheduler and perform one of the following in the Select OAM Context Schedules form:

a. Select an existing schedule form and go to Step 17.

b. Click Create and perform the following:

1. Configure the required parameters in the NFM-P Schedule (Create) form.

   Note:

   CFM scheduled tests do not support a schedule with a frequency less than per minute.

2. Click OK. The NFM-P Schedule (Create) form closes.
3. Click Select for the Test Suite Scheduler and select the newly-created schedule.

17

Click Execute. Tests will be executed as scheduled and the progress bar shows the current test status.

18

To view the test results, click on the Test Suite Results tab and select an entry.

19

Click Properties. The Test Suite Result form opens. General information regarding the test suite results is provided.

20

To view individual test results, select an entry in the Results tab and click Properties. The Test Result form opens. Review the test results.

21

To view the details of the test suite created for the test, click Test Suite View at the lower left-hand corner of the form. The OAM Contextual Test form closes and the Test Suite (Edit) form opens.

You can also view the SAPs or sites you selected for the test in the Contextual Tested Entity tab of the Test Suite (Edit) form.

22

Close the Test Suite (Edit) form.

23

Click the SAPs or Sites tab to view the objects you chose to run the scheduled test. Click View Service to open the property form of the service associated with the selected objects.

24

Click the Test Generation Log tab to view any error messages generated by the test.

25

Close the forms.

Continuous Run tests

26

Configure the Test Execution Mode for Continuous Run.

Continuous Run tests are accounting policy based tests.

27

Enter a Test Suite Name. This name will be used for the automatically-created test suite required for the test. The created test suite can be viewed in the STM after test execution, if required.

28

Click Execute. Tests will be run at 15-minute intervals and the progress bar shows the current test status.

29

To view the test results, click on the Test Suite Results tab and select an entry. If the continuously run test has yet not been run, its Status in the Test Suite Results tab shows as Request Sent.

30

Click Properties. The Test Suite Result form opens. General information regarding the test suite results is provided.

31

To view individual test results, select an entry in the Results tab and click Properties. The Test Result form opens. Review the test results.

32

To view the details of the test suite created for the test, click Test Suite View at the lower left-hand corner of the form. The OAM Contextual Test form closes and the Test Suite (Edit) form opens.

You can also view the SAPs or sites you selected for the test in the Contextual Tested Entity tab of the Test Suite (Edit) form.

33

Close the Test Suite (Edit) form.

34

Click the SAPs or Sites tab to view the objects you chose to run the scheduled test. Click View Service to open the property form of the service associated with the selected objects.

35

Click the Test Generation Log tab to view any error messages generated by the test.

36

Close the forms.

END OF STEPS

90.44 To create an OmniSwitch ping or traceroute OAM diagnostic test using a CLI script

WARNING

Network Damage

Scripts that are not correctly created or applied can cause serious damage to the network.

Nokia recommends that system administrators clearly define user responsibilities for CLI script usage, and ensure that scripts are verified and validated before they are executed on devices in a live network.

90.44.1 Steps

Perform this procedure to create an OmniSwitch ping or traceroute OAM diagnostic test using a using the sample CLI scripts in Code Figure 90-8, “Sample OmniSwitch OAM ping script” (p. 3059) and Code Figure 90-9, “Sample OmniSwitch traceroute script” (p. 3060) .

1

Choose Tools→Scripts from the NFM-P main menu. The Scripts form opens.

2

Choose CLI Script (Scripting) from the object drop-down menu and click Create. The CLI Script (Create) form opens.

3

Configure the required parameters.

Enable the Use Latest Version parameter to associate all of the targets of the script with the latest version of the CLI script.

You must set the Content Type parameter to Velocity.

4

Perform the following steps to specify the script target types.

1. Click Add in the NE Types panel. The Select Property - CLI Script form opens.
2. Select one or more OmniSwitch NE types in the list and click OK. The Select Property - CLI Script form closes, and the NE types are listed on the CLI Script (Create) form.

5

Click Apply to apply the configuration.

6

Click on the Versions tab.

7

Create the script by clicking Create. The Script Editor *script_name* form opens.

8

Create the CLI script text by performing one of the following steps.

a. Import an existing text file with a CLI script. You can create a text file by copying and pasting the text from the sample OmniSwitch ping shown in Figure 90-8, “Sample OmniSwitch OAM ping script” (p. 3059) or the sample traceroute script shown in Figure 90-9, “Sample OmniSwitch traceroute script” (p. 3060) into a text editor.

   Perform the following steps:

   1. Choose File→Import from the Editor menu. The Import dialog box appears.
   2. Choose the file to be imported and click on Import. The script appears in the Script Editor workspace.
   3. Modify the script as required.

b. Enter or copy and paste the CLI script text from the sample OmniSwitch ping shown in Figure 90-8, “Sample OmniSwitch OAM ping script” (p. 3059) or the sample traceroute script shown in Code Figure 90-9, “Sample OmniSwitch traceroute script” (p. 3060) into the Script Editor workspace.

Note: The following ping and traceroute scripts are sample CLI scripts that can be used to run ping and traceroute tests.

  </tab>
</velocityProperties>

traceroute $ip_address max-hop $maxHopValue
```

9

Perform one of the following.

a. Save the script to the Scripts tool.

1. Choose File→Save from the Editor menu or click Save. The Comment form opens.
2. Configure the required parameters.
   - Network Element Version Information
   - Bundle ID
3. Click OK.

b. Export the script to a local or network text file.

1. Choose File→Export from the Editor menu, or click Export. A dialog box appears and prompts you to choose a file storage location in the network.
2. Scroll to the location in which you want to save the text file, and enter a filename in the appropriate field.
3. Click Export. The script version text file is saved in the specified location.

10

Choose File→Close from the Editor menu. The Script Editor form closes, and the CLI Script (Edit) form reappears with the Version tab displayed. The new version of the script appears in the list.

11

Close the forms.

See 90.45 “To configure and run an OmniSwitch OAM diagnostic ping test CLI script” (p. 3062) and 90.46 “To configure and run an OmniSwitch OAM traceroute test CLI script” (p. 3064) for information about configuring and running OmniSwitch ping and traceroute OAM scripts.

End of steps

90.45 To configure and run an OmniSwitch OAM diagnostic ping test CLI script

WARNING

Network Damage

Scripts that are not correctly created or applied can cause serious damage to the network.

Nokia recommends that system administrators clearly define user responsibilities for CLI script usage, and ensure that scripts are verified and validated before they are executed on devices in a live network.

90.45.1 Steps

The following procedure describes how to create and run an OmniSwitch OAM diagnostic ping test using the script created using 90.44 “To create an OmniSwitch ping or traceroute OAM diagnostic test using a CLI script” (p. 3059) .

1

Ensure that the mediation policy for each OmniSwitch target is configured with the correct user name and password for CLI communication. See 9.17 “To configure device mediation” (p. 301) .

2

Choose Tools→Scripts from the NFM-P main menu. The Scripts form opens.

3

Choose CLI Script (script) from the object drop-down menu.

4

Configure the filter criteria. A list of scripts appears at the bottom of the Scripts form.

5

Double-click on the OmniSwitch ping script that you created using 90.44 “To create an OmniSwitch ping or traceroute OAM diagnostic test using a CLI script” (p. 3059) . The CLI Script (Edit) form opens.

6

Click on the Targets tab.

7

Click Create. The Target Configuration form opens.

8

Click Create. The Select Network Elements form opens.

9

Choose one or more OmniSwitch devices and click OK. The Select Network Elements form closes, and the OmniSwitch NEs are listed on the Target Configuration form.

10

Configure the test parameters.

1. Choose a target from the Target List panel.
2. Configure the required parameters.
3. Click Apply To Selected.
4. Repeat Step 10 1 to Step 10 3 to configure additional targets, if required.
5. Click OK to close the Target Configuration form. The CLI Script (Edit) form opens with the Targets tab displayed.

11

To run the script on specified targets, choose one or more entries from the list.

12

Click execute. The results of the test appear in the form.

13

Perform one of the following to view the results of the scripts:

a. Choose a target from the list. The results of the script that was run on the specified target appears in the panel below the list.

   Perform the following:

   1. Click Save Result to save the results to the result manager. A dialog box appears. Click OK.

      Note:

      You can save the results of multiple scripts to the result manager simultaneously; choose the entries in the list and click Save Result.

   2. Export the results to a local or network text file.
   3. Click Export. A dialog box appears and prompts you to choose a file storage location on the network.
   4. Scroll to the location in which you want to save the text file, and enter a filename in the appropriate field.

5. Click Export. The results text file is saved in the specified location.

b. Choose one or more entries from the list and click View Selected. The View Selected form opens and displays the results of the script. The results for each target are separated by a comment that indicates the script version, associated target, script status, run time and date, and script parameters.

Perform the following:

1. Export the results of the script to a local or network text file. Choose File→Export from the Editor menu, or click Export. A dialog box appears and prompts you to choose a file storage location in the network. Scroll to the location in which you want to save the text file, and enter a filename in the appropriate field. Click Export. The results text file is saved in the specified location.
2. Choose File→Close from the View Selected form to close the View Selected form.

14

Click OK or Cancel to close the CLI Script (Edit) form.

15

Close the Scripts form.

END OF STEPS

90.46 To configure and run an OmniSwitch OAM traceroute test CLI script

WARNING

Network Damage

Scripts that are not correctly created or applied can cause serious damage to the network.

Nokia recommends that system administrators clearly define user responsibilities for CLI script usage, and ensure that scripts are verified and validated before they are executed on devices in a live network.

90.46.1 Steps

The following procedure describes how to configure and run an OmniSwitch traceroute using the script created using 90.44 “To create an OmniSwitch ping or traceroute OAM diagnostic test using a CLI script” (p. 3059) .

1

Ensure that the mediation policy for each OmniSwitch target is configured with the correct user name and password for CLI communication. See 9.17 “To configure device mediation” (p. 301) .

2

Choose Tools→Scripts from the NFM-P main menu. The Scripts list form opens.

3

Choose CLI Script (script) from the object drop-down menu.

4

Configure the filter criteria. A list of scripts appears at the bottom of the Scripts form.

5

Double-click on the OmniSwitch traceroute script that you created using 90.44 “To create an OmniSwitch ping or traceroute OAM diagnostic test using a CLI script” (p. 3059) . The CLI Script (Edit) form opens.

6

Click on the Targets tab.

7

Click on Add. The Target Configuration form opens.

8

Click Add in the target list to add an OmniSwitch to the list. The Select Network Elements form opens with a list of OmniSwitch NEs.

9

Choose one or more OmniSwitch NEs and click OK. The Select Network Elements form closes, and the OmniSwitch NEs appear in the target list panel of the Target Configuration form.

10

Configure the test parameters.

1. Choose a target from the Target List panel.
2. Configure the required parameters.
3. Click Apply To Selected.
4. Repeat Step 10 1 to Step 10 3 to configure additional targets.
5. Click OK to close the Target Configuration form. The CLI Script (Edit) appears with the Targets tab displayed.

11

To run the script on the specified targets, choose one or more entries from the list.

12

Click Execute. The test results appear.

13

Perform one of the following to view the results of the scripts:

a. Choose a target from the list. The results of the script that was run on the specified target appears in the panel below the list.

   Perform the following:

   1. Click Save Result to save the results to the result manager. A dialog box appears. Click OK.

      Note:

      You can save the results of multiple scripts to the result manager simultaneously; choose the entries in the list and click Save Result.

   2. Export the results to a local or network text file.
   3. Click Export. A dialog box appears and prompts you to choose a file storage location on the network.
   4. Scroll to the location in which you want to save the text file, and enter a filename in the appropriate field.
   5. Click Export. The results text file is saved in the specified location.

b. Choose one or more entries from the list and click View Selected. The View Selected form opens and displays the results of the script. The results for each target are separated by a comment that indicates the script version, associated target, script status, run time and date, and script parameters.

   Perform the following:

   1. Export the results of the script to a local or network text file. Choose File→Export from the Editor menu, or click Export. A dialog box appears and prompts you to choose a file storage location in the network. Scroll to the location in which you want to save the text file, and enter a filename in the appropriate field. Click Export. The results text file is saved in the specified location.
   2. Choose File→Close from the View Selected form to close the View Selected form.

14

Click OK or Cancel to close the CLI Script (Edit) form.

15

Close the form.

END OF STEPS

90.47 To configure an advanced loopback test on an OmniSwitch from a device Properties form

90.47.1 Steps

Note: Only one test profile per port can be created, up to a maximum of 8 ports on an NE. The test profile cannot be created on a port that is part of a LAG.

1

Choose Equipment from the navigation tree. The navigation tree displays the Equipment view.

2

Expand the OmniSwitch NEs icon.

3

Right-click on the device where you want to configure an advanced loopback test and select Properties. The Network Element (Edit) form opens.

4

On the Network Element (Edit) form navigation tree, expand the Shelf icon.

5

Expand to the port level and click on a port object. The Physical Port (Edit) form opens.

6

Click on the Advanced Loopback tab. Click Create. The AOS Advanced Loopback (Create) form opens.

7

Configure the required parameters.

Note: For OS 6250 and OS 6450 NEs, when the Traffic Type parameter value is set to Outward, the user can specify the SAP Id, provided the SAP Id already exists on the NE. If a loopback profile is created with the Traffic Type parameter value set to Outward, the SAP Id parameter will be provided with the default value of 0. If the loopback profile is created with a SAP Id, the SAP Id must exist on the NE.

8

Save your changes.

9

Choose a test entry on the Physical Port (Edit) form. Click apply. A dialog box appears.

10

Click Yes.

11

Choose a test entry on the Physical Port (Edit) form. Click Properties.

12

The AOS Advanced Loopback (Edit) form opens. Configure the Status parameter.

13

Save your changes and close the forms.

END OF STEPS

90.48 To run the F5 OAM loopback diagnostic test from a 7705 SAR-M/ME Properties form

90.48.1 Procedure support

This procedure is only supported on the 7705 SAR-M/ME equipped with a DSL module.

Note: The parameters for the F5 OAM loopback test are only visible when the DSL module for the 7705 SAR-M/ME is connected to an ISAM device with the bonding type of ATM and the device is operationally up.

90.48.2 Steps

1

Choose Equipment from the navigation tree view selector. The navigation tree displays the Equipment view.

2

Navigate to the port object where you want to configure an Ethernet port. The path is Network→*NE*→Shelf→Card Slot→Daughter Card Slot→Port *n/n/n*.

3

Right-click on the Port icon and choose Properties. The Physical Port (Edit) form opens.

4

Click on the DSL tab.

5

Choose Active for the F5 Oam Loopback parameter.

6

Click Apply to save your changes. A confirmation window opens.

7

Click Yes. The loopback test is executed.

If the test was successfully executed, the F5 Oam Loopback Status field displays Pass and the F5 Oam Loopback Time field displays the time it took for the test to execute in milliseconds.

8

View the results from the F5 OAM Loopback test by opening a Telnet session on the NE, if required. See 10.4 “To open and close an NFM-P device CLI session” (p. 329) .

END OF STEPS

90.49 To configure an 802.3ah EFM OAM diagnostic test from an NE Properties form

CAUTION

Service Disruption

Performing an 802.3ah EFM diagnostic is service-affecting.

Ensure that you consider the implications of performing this test before you proceed.

90.49.1 Steps

Note: For the 802.3ah EFM diagnostic to be successful, the local and peer ports must support the 802.3ah protocol, and be operationally and administratively up.

When a port is in loopback mode, service mirroring does not work if the port is a mirror source or a mirror destination.

Satellite ports support virtually all OAM functionality. The only exception is that no EFM-OAM link monitoring is available for such ports.

1

Choose Equipment from the navigation tree view selector. The navigation tree displays the Equipment view.

2

Right-click on the device where you want to configure an 802.3ah EFM OAM diagnostic and select Properties. The Network Element (Edit) form opens.

3

On the Network Element (Edit) form navigation tree, expand the Shelf icon.

4 Expand to the port level and click on a port object. The Physical Port (Edit) form opens.

5 Click on the Ethernet tab. The Ethernet port configuration form opens.

6 Click on the EFM-OAM tab. The EFM-OAM form opens.

7 Configure the required parameters.

8 Click Apply. A dialog box appears.

9 Click Yes.

10 Click Resync.

The EFM-OAM form is updated with the results of the 802.3ah EFM diagnostic. The values that are displayed on the form depend on the configuration of the local and peer ports.

Table 90-3, “802.3ah EFM OAM results” (p. 3070), Table 90-4, “802.3ah EFM OAM Statistics” (p. 3072) and Table 90-5, “802.3ah EFM OAM peer information” (p. 3073) describe the displayed information.

Table 90-3 802.3ah EFM OAM results

Parameter	Value	Description
Operational Status (dot3OamOperStatus)	Disabled	The Administrative State parameter on the local port is set to Disabled.
	Active Send Local	The Mode parameter is set to Active and the local port is discovering the peer port EFM OAM capabilities.
	Passive Wait	The Mode parameter is set to Passive and the local port is waiting to receive OAMPDUs from the peer device.
	Send Local and Remote	The local port discovered the peer but has not yet accepted or rejected the configuration of the peer. The local port may determine that the peer port is not compatible and decline OAM peering.
	OAM Peering Locally Rejected	The local port declined OAM peering.
	Send Local and Remote Ok	The local port accepted OAM peering.
	OAM Peering Remotely Rejected	The remote port declined OAM peering.
	Operational	The local and remote ports accepted the OAM peering.
	Non-operational Half Duplex	The Administrative State parameter is set to Enabled but the local port is in half-duplex mode.
	Link Fault	The link detected a fault and is transmitting OAMPDUs with a link fault indication.
Max. PDU Size (dot3OamMaxOamPduSize)	PDU size	The largest OAMPDU size, in bytes, that is supported by the local port: Minimum is 64 Maximum is 1518 Default is 1514
Configuration Revision (dot3OamConfigRevision)	0 to 65 535	The configuration revision of the OAM entity obtained from the latest OAMPDU sent by the OAM entity. The value is used by OAM entities to indicate that configuration changes occurred that may require the peer OAM entity to re-evaluate whether OAM peering is allowed.

Table 90-3 802.3ah EFM OAM results (continued)

Parameter	Value	Description
Functions Supported (dot3OamFunctionsSupported)	Event Support	The port can send and receive event notification OAMPDUs.
	Loopback Support	The port can initiate and respond to loopback commands.
	Unidirectional Support	The port supports the transmission of OAMPDUs on links that operate in unidirectional mode.
	Variable Support	The port can send and receive variable request and response OAMPDUs.
Loopback Status (dot3OamLoopbackStatus)	No Loopback	The port is not in a loopback condition.
	Initiating Loopback	The local device initiated a loopback, sent a loopback OAMPDU and is waiting for a response from the peer port.
	Remote Loopback	The peer port is in loopback mode.
	Terminating Loopback	The local port is in the process of terminating a loopback on the peer port.
	Local Loopback	The peer port has put the local port into loopback mode.
	Unknown	An OAMPDU that contains an unexpected message was received by the local port.

Table 90-4 802.3ah EFM OAM Statistics

Statistics	Displayed Value	Description
Frames Lost Due to OAM(dot3OamFramesLostDueToOam)	*Number of frames*	The number of frames that were dropped by the OAM multiplexer. Discontinuities of this counter can occur under some conditions.
Information Rx (dot3OamInformationRx)	*Number of OAMPDUs*	The number of information OAMPDUs received on this interface
Information Tx (dot3OamInformation Tx)	*Number of OAMPDUs*	The number of information OAMPDUs transmitted on this interface. Discontinuities of this counter can occur can occur under some conditions.
Loopback Control Rx (dot3OamLoopbackControlRx)	*Number of OAMPDUs*	The number of loopback control OAMPDUs received on this interface
Loopback Control Tx (dot3OamLoopbackConrolTx)	*Number of OAMPDUs*	The number of loopback control OAMPDUs transmitted on this interface
Unsupported Codes Rx (dot3OamUnsupportedCodesRx)	*Number of OAMPDUs*	The number of OAMPDUs received on this interface with an unsupported opcode

Table 90-4 802.3ah EFM OAM Statistics (continued)

Statistics	Displayed Value	Description
Unsupported Codes Tx (dot3OamUnsupportedCodesTx)	*Number of OAMPDUs*	The number of OAMPDUs transmitted on this interface with an unsupported opcode

Table 90-5 802.3ah EFM OAM peer information

Peer Information	Displayed Value	Description
Peer MAC Address (dot3OamPeerMacAddress)	*MAC address*	The MAC address of the peer port. The MAC address is contained in the received OAMPDU.
Peer Vendor OUI (dot3OamPeerVendorOui)	*OUI*	The OUI of the OAM peer. The OUI is part of the peer MAC address contained in the received OAMPDU. The OUI can be used to identify the vendor of the remote OAM device.
Peer Vendor Info (dot3OamPeerVendorInfo)	*Vendor information text*	The vendor information field is in the local information TLV, and can be used to determine additional information about the peer device.
Peer Mode (dot3OamPeerMode)	Active or Passive	See Mode
Peer Max PDU Size (dot3OamPeerMaxOamPduSize)	*PDU size*	The largest OAMPDU value, in bytes, that is supported by the peer port. Minimum is 64 Maximum is 1518 Default is 1514
Peer Configuration Revision (dot3OamPeerConfigRevision)	0 to 65 535	The configuration revision of the OAM device as identified in the latest OAMPDU sent by the OAM peer. The configuration revision is used by OAM devices to indicate that configuration changes have occurred which might require the peer OAM device to re-evaluate whether OAM peering is allowed.
Peer Functions Supported (dot3OamPeerFunctSupported)	Event Support	The peer port can send and receive Event Notification OAMPDUs.
	Loopback Support	The peer port can initiate and respond to loopback commands.
	Unidirectional Support	The peer port supports the transmission of OAMPDUs on links that are operating in unidirectional mode.
	Variable Support	The peer port can send and receive Variable Request and Response OAMPDUs.

11

Close the EFM-OAM form when you have completed the EFM OAM diagnostic.

END OF STEPS

90.50 To configure an 802.3ah EFM OAM diagnostic test on an OmniSwitch Properties form

90.50.1 802.3ah EFM OAM diagnostic considerations

CAUTION

Service Disruption

Performing an 802.3ah EFM diagnostic is service-affecting.

Ensure that you consider the implications of performing this test before you proceed.

Link OAM (802.3ah) is not supported on mirroring ports.

When a port is in loopback mode, service mirroring does not work if the port is a mirror source or a mirror destination.

Note: For the 802.3ah EFM OAM diagnostic to be successful, the local and peer ports must support the 802.3ah protocol, and be operationally and administratively up.

The EFM OAM diagnostic is supported at the NE level or at the Ethernet port level on the Ethernet ports in network mode.

To configure Link OAM at the NE level, go to Step 1 .To configure Link OAM and 802.3ah EFM OAM diagnostics at the port level, go to Step 6 .

90.50.2 Steps

1

Choose Equipment from the navigation tree view selector. The navigation tree displays the Equipment view.

2

Expand the OmniSwitch NEs icon.

3

Right-click on the OmniSwitch device where you want to configure an 802.3ah EFM OAM diagnostic and select Properties. The Network Element (Edit) form opens.

4

Click on the Globals tab.

5

Click on the EFM-OAM tab. The EFM-OAM form opens.

6

Configure the required parameters.

7

On the Network Element (Edit) form navigation tree, expand the Shelf icon.

8

Expand to the port level and click on a port object. The Physical Port (Edit) form opens.

9

Click on the Ethernet tab. The Ethernet port configuration form opens.

10

Click on the EFM-OAM tab. The EFM-OAM form opens.

11

Configure the required parameters.

12

Save your changes.

13

Click Yes.

The EFM-OAM form is updated with the results of the 802.3ah EFM diagnostic. The values that are displayed on the form depend on the configuration of the local and peer ports.

Table 90-6, “802.3ah EFM OAM results” (p. 3075), Table 90-7, “802.3ah EFM OAM Statistics” (p. 3077) and Table 90-8, “802.3ah EFM OAM peer information” (p. 3078) describe the displayed information.

Table 90-6 802.3ah EFM OAM results

Parameter	Value	Description
Operational Status (dot3OamOperStatus)	Disabled	The Administrative State parameter on the local port is set to Disabled.
	Active Send Local	The Mode parameter is set to Active and the local port is discovering the peer port EFM OAM capabilities.
	Passive Wait	The Mode parameter is set to Passive and the local port is waiting to receive OAMPDUs from the peer device.
	Send Local and Remote	The local port discovered the peer but has not yet accepted or rejected the configuration of the peer. The local port may determine that the peer port is not compatible and decline OAM peering.
	OAM Peering Locally Rejected	The local port declined OAM peering.
	Send Local and Remote Ok	The local port accepted OAM peering.
	OAM Peering Remotely Rejected	The remote port declined OAM peering.
	Operational	The local and remote ports accepted the OAM peering.
	Non-operational Half Duplex	The Administrative State parameter is set to Enabled but the local port is in half-duplex mode.
	Link Fault	The link detected a fault and is transmitting OAMPDUs with a link fault indication.
Max. PDU Size (dot3OamMaxOamPduSize)	PDU size	The largest OAMPDU size, in bytes, that is supported by the local port: Minimum is 64 Maximum is 1518 Default is 1514
Configuration Revision (dot3OamConfigRevision)	0 to 65 535	The configuration revision of the OAM entity obtained from the latest OAMPDU sent by the OAM entity. The value is used by OAM entities to indicate that configuration changes occurred that may require the peer OAM entity to re-evaluate whether OAM peering is allowed.

Table 90-6 802.3ah EFM OAM results (continued)

Parameter	Value	Description
Functions Supported (dot3OamFunctionsSupported)	Event Support	The port can send and receive event notification OAMPDUs.
	Loopback Support	The port can initiate and respond to loopback commands.
	Unidirectional Support	The port supports the transmission of OAMPDUs on links that operate in unidirectional mode.
	Variable Support	The port can send and receive variable request and response OAMPDUs.
Loopback Status (dot3OamLoopbackStatus)	No Loopback	The port is not in a loopback condition.
	Initiating Loopback	The local device initiated a loopback, sent a loopback OAMPDU and is waiting for a response from the peer port.
	Remote Loopback	The peer port is in loopback mode.
	Terminating Loopback	The local port is in the process of terminating a loopback on the peer port.
	Local Loopback	The peer port has put the local port into loopback mode.
	Unknown	An OAMPDU that contains an unexpected message was received by the local port.

Table 90-7 802.3ah EFM OAM Statistics

Statistics	Displayed Value	Description
Frames Lost Due to OAM(dot3OamFramesLostDueToOam)	*Number of frames*	The number of frames that were dropped by the OAM multiplexer. Discontinuities of this counter can occur under some conditions.
Information Rx (dot3OamInformationRx)	*Number of OAMPDUs*	The number of information OAMPDUs received on this interface
Information Tx (dot3OamInformation Tx)	*Number of OAMPDUs*	The number of information OAMPDUs transmitted on this interface. Discontinuities of this counter can occur can occur under some conditions.
Loopback Control Rx (dot3OamLoopbackControlRx)	*Number of OAMPDUs*	The number of loopback control OAMPDUs received on this interface
Loopback Control Tx (dot3OamLoopbackConrolTx)	*Number of OAMPDUs*	The number of loopback control OAMPDUs transmitted on this interface
Unsupported Codes Rx (dot3OamUnsupportedCodesRx)	*Number of OAMPDUs*	The number of OAMPDUs received on this interface with an unsupported opcode

Table 90-7 802.3ah EFM OAM Statistics (continued)

Statistics	Displayed Value	Description
Unsupported Codes Tx (dot3OamUnsupportedCodesTx)	*Number of OAMPDUs*	The number of OAMPDUs transmitted on this interface with an unsupported opcode

Table 90-8 802.3ah EFM OAM peer information

Peer Information	Displayed Value	Description
Peer MAC Address (dot3OamPeerMacAddress)	*MAC address*	The MAC address of the peer port. The MAC address is contained in the received OAMPDU.
Peer Vendor OUI (dot3OamPeerVendorOui)	*OUI*	The OUI of the OAM peer. The OUI is part of the peer MAC address contained in the received OAMPDU. The OUI can be used to identify the vendor of the remote OAM device.
Peer Vendor Info (dot3OamPeerVendorInfo)	*Vendor information text*	The vendor information field is in the local information TLV, and can be used to determine additional information about the peer device.
Peer Mode (dot3OamPeerMode)	Active or Passive	See Mode
Peer Max PDU Size (dot3OamPeerMaxOamPduSize)	*PDU size*	The largest OAMPDU value, in bytes, that is supported by the peer port. Minimum is 64 Maximum is 1518 Default is 1514
Peer Configuration Revision (dot3OamPeerConfigRevision)	0 to 65 535	The configuration revision of the OAM device as identified in the latest OAMPDU sent by the OAM peer. The configuration revision is used by OAM devices to indicate that configuration changes have occurred which might require the peer OAM device to re-evaluate whether OAM peering is allowed.
Peer Functions Supported (dot3OamPeerFunctSupported)	Event Support	The peer port can send and receive Event Notification OAMPDUs.
	Loopback Support	The peer port can initiate and respond to loopback commands.
	Unidirectional Support	The peer port supports the transmission of OAMPDUs on links that are operating in unidirectional mode.
	Variable Support	The peer port can send and receive Variable Request and Response OAMPDUs.

14

Close the EFM-OAM form when you have completed the EFM OAM diagnostic.

END OF STEPS

90.51 To configure an ICMP Ping template

90.51.1 Before you begin

ICMP ping templates are used to populate values for ICMP ping tests when the tests are used on L3 interfaces to control the operational state. ICMP ping templates are supported for IPv4 only.

Using the NFM-P policy framework, ICMP ping templates are assigned to L3 interfaces for IES and VPRN services; see the following procedures:

- 78.50 “To assign an ICMP ping template to an IES L3 access interface” (p. 2495)
- 79.105 “To assign an ICMP ping template to a VPRN L3 access interface” (p. 2679)

Nokia recommends that you assign an NE DoS protection policy configured with ICMP-Ping-Check as the protocol to the affected interfaces; see 78.45 “To assign a DoS protection policy or DDoS protection policy to an IES L3 access interface” (p. 2491) and 79.100 “To assign an NE DoS or DDoS protection policy to a VPRN L3 access interface” (p. 2675).

90.51.2 Steps

1

Click Tools→OAM Templates→ICMP Ping Template on the NFM-P main menu. The ICMP Ping Template form opens.

2

Click Create, or select an existing template and click Properties. The ICMP Ping Template (Create|Edit) form opens.

3

Configure the required parameters.

4

Click OK to save the policy and close the form, or click Apply to save the policy.

5

Perform 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

90.52 To configure a link measurement template

90.52.1 Purpose

The link measurement template includes common test parameters that can be synchronized with the Global policy. The link measurement template can be associated with a routing instance. When that association is established the interface will execute a process to determine the operational state and detect and defect conditions that may prevent proper test execution.

90.52.2 Steps

1

Click Tools→OAM Templates→Link Measurement Template on theNFM-P main menu. The Link Measuremen Templates form opens.

2

Click Create, or select an existing template and click Properties. The Link Measurement Template, Global Policy (Create|Edit) form opens.

3

Configure the required parameters.

4

Click OK to save the template and close the form, or click Apply to save the template.

5

Perform 27.2 “To configure a routing instance or a VRF instance” (p. 826) to associate the template to a routing instance.

END OF STEPS

90.53 To configure link monitoring on an Ethernet port

90.53.1 Steps

Note: Ethernet link monitoring works between directly-connected Ethernet ports and monitors link level errors, such as Ethernet frame errors, and for a subset of MDAs, Ethernet symbol errors as well. In the event that error levels exceed configured thresholds, a signal degradation error log, or in more severe cases, a signal failure error log can be generated. In the case of signal failure error, the peer port may be notified, and the local (and peer) ports may be disabled until the error log is manually cleared.

Satellite ports support virtually all OAM functionality. The only exception is that no EFM-OAM link monitoring is available for such ports.

1

Choose Equipment from the navigation tree view selector. The navigation tree displays the Equipment view.

2

Right-click the device on which you want to configure link monitoring and select Properties. The Network Element (Edit) form opens.

3

Navigate to the port on which you want to configure link monitoring. The path is Network→*NE*→Shelf→Card Slot→Daughter Card Slot→Port *n/n/n*.

4

Right-click on the Port icon and choose Properties. The Physical Port (Edit) form opens.

5

Click on the Ethernet tab and then on the EFM-OAM tab.

6

Configure the Administrative State to Enabled.

7

Configure the Transmit Interval (x100ms) and Multiplier (Intervals) parameters to determine the transmit rate for the link monitoring PDUs.

8

Configure the Dying Gasp Notify and Critical Event Notify parameters to determine the reporting of a signal failure to the far-end device.

9

Configure the parameters in the Link Event Configuration panel.

The general parameters in this panel are used to enable the link monitoring capability and to determine the port's response to local and remote signal degradation (SD) and signal failure (SF) events. The parameters in the Errored Frame, Errored Frame Period, Errored Frame Seconds Summary, and Errored Frame Symbols sub-panels are used to enable and configure their respective link monitoring variants. These monitoring variants can operate concurrently.

10

Expand the Counters panel to view link monitoring communications counters between the local and peer Ethernet ports. These counters are not automatically updated. Click Refresh to resynchronize the MIBs related to these counters.

11

Expand the Peer Information panel to view information learned from PDUs sent by the directly-connected peer. The Peer Vendor OUI attribute is used by routers to correctly interpret the meaning of attributes sent during dying gasp or critical events when the peer experiences a signal failure threshold crossing event.

12

Expand the Link Monitoring Error Event Logs panel to view signal failure and signal degradation event logs issued from local or remote link monitoring peer ports.

Perform the following:

1. Click Refresh to obtain current event logs from the NE.
2. Select a log from the list under either the Signal Failure or Signal Degradation sub-tabs and click Properties to view the contents.
3. Click Clear to clear local, remote, or all the event logs.

   Note:

   Clearing event logs cannot be undone.

13

Save your changes and close the form.

END OF STEPS

90.54 To configure system and port level ETH-OAM Dying Gasp notification

90.54.1 Reference

Ethernet First Mile OAM 802.3ah is deployed heavily at E-NNI and UNI connections. These connection points are typically multi-vendor and have resilient connectivity. Signaling the pending removal of a link when a soft reset could interrupt service on such ports is critical in reducing unacceptably long outages for known maintenance conditions. This signaling is accomplished by setting the Dying Gasp flag in the Information OAMPDU when a soft reset message is received by EFM for those ports that will be affected by the soft reset. The Dying Gasp flag can be enabled at both the port and system levels.

90.54.2 Steps

1

Choose Equipment from the navigation tree view selector. The navigation tree displays the Equipment view.

2

Right-click the device on which you want to configure dying gasp notification and select Properties. The Network Element (Edit) form opens.

3

Click on the Globals tab and then on the OAM sub-tab.

4

Enable the System Dying Gasp Tx on Reset Enable parameter. The default state is disabled.

Both the system level and port level dying gasp functionality must be enabled for the notification capability to be active on a port.

Note: You can click on Show system EFM-OAM Information to display additional EFM-OAM details.

5

Navigate to the port on which you want to configure the dying gasp notification. The path is Network→*NE*→Shelf→Card Slot→Daughter Card Slot→Port *n/n/n*.

6

Right-click on the Port icon and choose Properties. The Physical Port (Edit) form opens.

7

Click on the Ethernet tab and then on the EFM-OAM sub-tab.

8

Configure the Administrative State to Enabled.

9

Enable the Dying Gasp on Reset Enable and the Dying Gasp Notify parameters. The Dying Gasp Notify parameter determines whether or not the local OAM entity attempts to report a dying gasp to its peer OAM entity when a dying gasp event occurs.

10

Configure the Trigger Fault parameter as required. Enabling the Trigger Fault function allows an operator to invoke an ETH-OAM fault (either Dying Gasp or Critical Event) before shutting down the port.

11

Configure the remaining parameters as required.

12

Configure the required parameters in the Link Event Configuration panel. See 90.53 “To configure link monitoring on an Ethernet port” (p. 3081) for detailed information on configuring link monitoring.

Note: The Reaction to Peer Dying Gasp parameter specifies how the local port will be impacted when it receives an Information OAMPDU from a peer with the Dying Gasp flag set.

13

Expand the Link Monitoring Error Event Logs panel to view signal failure and signal degradation event logs issued from local or remote link monitoring peer ports. The event logs on a remote peer will record active error events when receiving the trigger fault command from the source node.

Perform the following:

1. Click Refresh to obtain current event logs from the NE.
2. Select a dying gasp log from the list under the Signal Failure sub-tab and click Properties to view the contents.
3. Click Clear to clear local, remote, or all the event logs.

   Note: Clearing event logs cannot be undone.

14

Save your changes and close the form.

END OF STEPS

90.55 To run a one-time validation test on a service

90.55.1 Steps

Perform the following steps to run the one-time validation test on a service:

1

Select the required test entity using the appropriate item under the NFM-P Manage menu item, and then click Properties. The entity's property form opens.

Entities that you can test using this function include:

- VLL, VPLS, and VPRN services (Manage→Service→Services)
- Composite services (Manage→Service→Composite Services)
- Dynamic LSPs (Manage→MPLS→Dynamic LSPs)
- Service tunnels (Manage→Service Tunnels)

2

Click One Time Validation.

Note: If a regular OAM validation is currently running on the selected test entity, the One Time Validation function will not be executed.

The Choose Validator Test Policy form is displayed and lists all test policies that are applicable to the selected test entity.

3

Select the required policy from the list and click OK.

Note: A default read-only test policy (Validation-Default-Policy) is supplied for this purpose. You can copy this policy but not modify it. Modify the cloned copy as required, or you can select a test policy you have previously created. See 89.10 “To configure an STM test policy” (p. 2947) to create an STM test policy.

The One Time Validation function proceeds after you click OK.

The automated operations that occur are as follows:

1. The One Time Validation test suite is created.
2. The selected test entity is added to the test suite.
3. Any tests, MEGs, and MEPs that are appropriate to the test entity and that are required to run the validation are created.
4. The generated tests are executed.
5. The test entity’s OAM Validation Failed state indicator is updated as required (a checkmark indicates the OAM validation failed whereas a blank checkbox indicates that the validation succeeded).
6. Test results for each individual test that was created and executed to perform the validation are copied to new test result objects.
7. The test suite, tests, and any required OAM objects that were created to run the validation are deleted.

4

To view the test results, click on the tested entity’s Test tab and then on the One Time Validation Result sub-tab.

Note: These archived test results are also available through the STM. They can be viewed by selecting the One Time Validation Result (Assurance) item from the object drop-down menu. See 89.19 “To view and compare STM test suite results for a tested entity” (p. 2963) for more information.

5

Select one of the test results in the list and click Properties. The One Time Validation Result (Edit) form opens.

6

Review the results as required and then close the One Time Validation Result (Edit) form.

Note: The archived test results are not deleted after viewing. They will remain available until manually deleted by the user.

7

Close the form.

END OF STEPS

91 Ethernet CFM

91.1 Overview

91.1.1 Purpose

This chapter describes the Ethernet CFM (Connectivity Fault Management) OAM diagnostic tests, and provides information about configuring and performing Ethernet CFM diagnostic tests.

91.1.2 Contents

Ethernet CFM

91.2 Ethernet CFM test descriptions

91.2.1 Introduction

This section provides a description of NFM-P supported Ethernet CFM OAM diagnostic tests. Unless noted, all tests are accessible from the STM. See Table 90-1, “NFM-P supported OAM diagnostic tests and configurations” (p. 2981) for a list of all supported OAM diagnostic tests and their applicable procedures.

91.2.2 Global MEG check

A global MEG check detects connectivity failures between pairs of local and remote maintenance endpoints, or MEPs, in a MEG. A MEG consists of the maintenance entities that belong to the same service inside a common service OAM domain.

See 91.19 “To create and run a Global MEG OAM diagnostic test from the STM” (p. 3120) for information about how to create and run a global MEG check from the STM.

91.2.3 Continuity check

Continuity check messages are multicast messages that a MEP transmits periodically to remote MEPs in the same MEG. CCMs are used to discover a remote endpoint, check the health of a site, and detect cross-connect misconfigurations. A CFM continuity check test is automatically generated when you create an MD. When you execute the test and a connectivity fault is present, the MEP that detects the fault raises an alarm.

See 91.20 “To create and run a Continuity Check OAM diagnostic test from the STM” (p. 3122) for information about how to create and run a continuity check from the STM.

The loss of three consecutive CCMs or the receipt of a CCM with incorrect information, indicates a fault.

Note: If a service is modified after you associate it with an MD; for example, a new site is added, you must manually add new MEPs.

If a CFM continuity check test is running on a service when you add a new MEP to the service, you must stop the test and execute it again to make the new MEP active.

When a service is modified after a CFM continuity check is created; for example, a new B-VPLS site is added to the service, you must manually add a virtual MEP to the site.

91.2.4 CFM dual-ended loss test

A CFM dual-ended loss test functions as an optional extension of a CFM continuity check. It applies only to Y.1731 MEPs that are configured on the 7705 SAR. This type of test is used to calculate the rate of frame loss in each direction for Ethernet packets sent between two MEPs.

When a continuity check test is executed with the dual-ended loss option enabled, the option is replicated on all participating MEPs that support the test, along with the accompanying alarm threshold values. If a MEP detects that the local or remote frame loss ratio has exceeded the alarm threshold for a remote MEP, the MEP raises an alarm against the remote MEP.

See 91.20 “To create and run a Continuity Check OAM diagnostic test from the STM” (p. 3122) for information about how to configure the CFM dual-ended loss test option as part of creating and running a CFM continuity check from the STM.

91.2.5 CFM loopback

CFM loopback messages are sent to a unicast destination MAC address. The MEP at the destination responds to the loopback message with a loopback reply. A MEP or a MIP can reply to a loopback message if the destination MAC address matches the MAC address of the MEP or MIP. CFM loopback tests verify connectivity to a specific MEP or MIP.

See 91.21 “To create and run a CFM loopback OAM diagnostic test from the STM” (p. 3123) for information about how to create and run a CFM loopback from the STM.

You can also perform multicast loopbacks by providing a multicast address (class 1 multicast destination) that aligns with the level that the originating MEP is configured on. Only one multicast test can be run at a time per NE, and results from the previous test are deleted when a new test is started. The stored values include the responding MEP MAC address, the sequence number, and a locally-assigned rx index (allowing you to detect out-of-order responses).

91.2.6 CFM link trace

CFM link trace messages that contain a target unicast MAC address are sent to multicast destination MAC addresses. Each MIP at the same MD level replies with a link trace response. Messages are forwarded to the next hop until they reach the destination MAC address.

See 91.22 “To create and run a CFM link trace OAM diagnostic test from the STM” (p. 3125) for information about how to create and run a CFM link trace from the STM.

91.2.7 CFM Eth test

The CFM Eth test applies only to Y.1731 MEPs. This one-way test originates on a source MEP and terminates on a destination MEP. The target of a CFM Eth test is a MAC address. The test is used to perform one-way in-service diagnostic test that include verifying bandwidth throughput, frame loss, and bit errors. To perform the test, a MEP inserts frames with Eth-test information that includes specific throughput, frame size, and transmission patterns. A MIP is transparent to Eth-test frames.

See 91.23 “To create and run a CFM Eth OAM diagnostic test from the STM” (p. 3127) for information about how to create and run a CFM Eth test from the STM.

91.2.8 CFM two way delay test

The CFM two way delay test applies only to Y.1731 MEPs. In this test, the frame delay is defined as the time elapsed since the start of transmission of the first bit of the frame by the source site until the frame is received by the same site after passing through the destination site. The frame delay represents the round-trip time between the source and destination sites.

See 91.24 “To create and run a CFM two way delay OAM diagnostic test from the STM” (p. 3128) for information about how to create and run a CFM two way delay test from the STM.

91.2.9 CFM one way delay test

The CFM one way delay test applies only to Y.1731 MEPs. The test originates on one MEP and terminates on a target MEP. The results are read from the target MEP. In the test, frame delay is defined as the time elapsed since the start of transmission of the first bit of the frame by a source site until the frame is received by the destination site. The frame delay represents the one-way trip time between the source and destination sites.

See 91.25 “To create and run a CFM one-way delay OAM diagnostic test from the STM” (p. 3130) for information about how to create and run a CFM one way delay test from the STM.

91.2.10 CFM single ended loss test (7705 SAR only)

The CFM single ended loss test applies only to Y.1731 MEPs. This one-way test originates on a source MEP and terminates on a destination MEP. The target of a single-ended loss test is a destination MAC address. The test is used to calculate the rate of frame loss in each direction for Ethernet packets sent between the two MEPs.

See 91.26 “To create and run a CFM single-ended loss OAM diagnostic test from the STM” (p. 3131) for information about how to create and run a CFM single ended loss test from the STM.

91.2.11 CFM two way SLM

The CFM two way SLM test provides Synthetic Loss Measurement and is used to check packet loss for a particular MEP. See 91.27 “To create and run a CFM two way SLM OAM diagnostic test from the STM” (p. 3132) for information about how to create and run a CFM two way SLM test from the STM.

Note: On the 7705 SAR, SLM is only supported on Epipe services under the following conditions:

- single-ended (two way) loss measurement using optional TLV with a timestamp on the near-end and far-end for combined loss and delay measurement
- unicast destination addresses only
- DOWN MEP direction for Spoke-SDPs only (UP and DOWN MEP direction for SAPs)

91.2.12 CFM LM test

The CFM LM (loss measurement) test measures the counter values applicable for ingress and egress service frames where the counters maintain a count of transmitted and received data frames between a pair of MEPs.

See 91.28 “To create and run a CFM LM OAM diagnostic test from the STM” (p. 3134) for information about how to create and run a CFM LM test from the STM.

91.2.13 CFM Statistics

The Ethernet CFM statistics are used for viewing and analyzing the current overall processing requirements for CFM. Any packet that is counted against the CFM resource will be included in the statistics counters.

The Ethernet CFM statistics are available per NE and per MEP, with a per-OpCode breakdown. Use the **`show eth-cfm statistics`** command to display the statistics at the system level. Use the

show eth-cfm mep mep-id domain md-index association ma-index statistics command to view the per-MEP statistics.

From the NFM-P GUI, Ethernet CFM statistics can be retrieved:

- at the network level
  - Network Element (Edit) →Statistics tab
- at the MEP level
  - Tool →Service Test Manager (STM) →CFM opcodes tab

For ETH-CFM statistics at the NE level, the record types include:

- CFM Global Opcode Stats (Ethernet OAM)
- Ethernet CFM Packet Count (Ethernet OAM)
- Ethernet CFM Resource Limits (Ethernet OAM)
- OAM General Stats (Ethernet OAM)
- OAM Performance Req Types Stats (Ethernet OAM)

At the individual MEP level, CFM Opcodes → OAM_MEP_statistics can be displayed. Click Resync to see the changes in the NFM-P.

These statistics help operators to determine the busiest active MEPs on the system with a breakdown of per-OpCode processing at the system and MEP level. For eth-cfm oper up statistics collection, create an MD and a MEG and attach a service with up/down MEP. See 91.14 “To configure an automatic MEP ID assignment on an NE” (p. 3108) and 91.15 “To configure an Ethernet CFM MD policy and subordinate objects” (p. 3109).

91.3 Ethernet CFM concepts and components

91.3.1 Ethernet CFM function

The NFM-P Ethernet Connectivity Fault Management, or Ethernet CFM, function is implemented based on the IEEE 802.1ag OAM standard. This standard describes protocols for detecting, isolating, and reporting connectivity faults in an Ethernet network.

You can use Ethernet CFM for the following:

- path discovery
- fault detection
- fault isolation
- fault notification

Ethernet CFM diagnostic tests are configured using the NFM-P Service Test Manager. See Chapter 89, “Service Test Manager” for more information about the STM. See Chapter 90, “OAM diagnostic tests” for more information about CFM diagnostic tests.

91.3.2 MDs

The IEEE 802.1ag OAM standard partitions a network into eight hierarchical levels called maintenance domains, or MDs. An MD is a network, or part of a network, that is provisioned with a set of maintenance entity groups, or MEGs, which are groups of service sites.

91.4 MEGs

91.4.1 MEG description

Typically, a MEG represents one service and consists of a group of maintenance end points, or MEPs. Only one MEG can be associated with a service, but one service can be associated with multiple MEGs. MDs and MEGs are distributed to NEs using NFM-P policy distribution.

Within a MEG, MEPs can be sorted into logical groupings called MEG subgroups. A MEG that contains subgroups is called a Global MEG. By default, a Global MEG has one subgroup. MEG subgroups allow you to group managed MEPs and unmanaged remote MEPs so that Ethernet CFM can be directed to a specific area of a system, a MEG subgroup, rather than the entire system.

91.5 MEPs

91.5.1 MEP description

The MEPs are configured at the edge of an MD and perform the following functions:

- periodically send CFM continuity check messages
- validate CFM PDU replies
- discard CFM PDU messages that are not in the MEP configuration
- initiate and respond to CFM test messages

MEPs can be added to services automatically or manually. When a MEP is assigned to a service manually, it associates its MEG with a single site on the service. When a MEP is assigned to a service automatically, it associates its MEG with all sites on the service. MEPs which are generated automatically can inherit test generation options from the SAP or service site. See 91.15 “To configure an Ethernet CFM MD policy and subordinate objects” (p. 3109) for more information.

You can configure an initial MEP ID for automatic MEP ID assignment on an NE.

You can also add MEPs to services during Ethernet CFM test configuration from the Service Topology map. See 4.2.3 “Working with Ethernet CFM objects” (p. 177) in Chapter 4, “Topology map management” for more information.

Each MEP is assigned an up or down direction. An up MEP is provisioned on an ingress port, and monitors the forwarding path inside a bridge NE to the egress port. A down MEP is provisioned on an egress port, and monitors the forwarding path between bridge NEs.

You can assign roles to managed MEPs and unmanaged remote MEPs during OAM test suite configuration. A MEP can be designated as a hub or spoke, and as a test source, a test target, or both. Assigning roles to MEPs in test suites can reduce the total number of automatic tests generated. See 91.15 “To configure an Ethernet CFM MD policy and subordinate objects” (p. 3109)
.

MEPs can inherit their roles from the SAP or service site. You can propagate test generation role settings to all unmanaged remote and managed MEPs on a SAP or service site using the Propagate to MEPs button on the ETH-CFM tab of the Access Interface (Edit) and Site (Edit) forms.

91.5.2 MEP association

An up MEP can be associated with the following object types:

- Epipe and VPLS SAPs
- Epipe spoke SDP bindings
- VPLS mesh and spoke SDP bindings
- VPLS and MVPLS B-sites, as virtual MEPs
- B-L2 access interfaces
- OmniSwitch VLAN SAPs

A down MEP can be associated with the following object types:

- Epipe, Ipipe, IES, VPLS, and VPRN SAPs
- Epipe and IES spoke SDP bindings
- VPLS mesh and spoke SDP bindings
- B-L2 access interfaces
- MVPLS access interfaces
- OmniSwitch VLAN SAPs
- Network interfaces
- Ports
- LAGs

91.5.3 Virtual MEPs

A virtual MEP is an up MEP that is created on a VPLS site when a CFM continuity check test is run. Each virtual MEP transmits a CFM continuity check stream on all SAPs and SDPs of the site. A virtual MEP uses the site MAC address, if configured; otherwise, it uses the shelf MAC address. See Chapter 77, “VPLS management ” for information about assigning virtual MEPs to a VPLS.

The following rules apply to virtual MEP management:

- One virtual MEP can be configured on a VPLS or MVPLS B-site.
- All regular MEPs on SAPs and SDP bindings in the same MEG as a virtual MEP must be configured as up MEPs.
- Regular MEPs in the same MEG and on the same B-site as a virtual MEP cannot be enabled when the virtual MEP is enabled.
- Virtual MEPs can be created in a MEG only when MIP creation in the MEG is disabled.

91.5.4 Facility MEP

A facility MEP is a MEP that is down and is created on a router interface, network interface, port, or LAG. A facility MEP detects failure conditions for an Ethernet transport network using ETH-CCM or AIS and, where appropriate, propagates alarm conditions so that the services that share this common transport are aware of the failure.

A virtual tunnel facility MEP is created by configuring a LAG MEP or a port MEP with a VLAN ID. In this instance the VLAN ID must match the outer encapsulation value of the SAP that is associated with the Tunnel MEP.

The following rules apply to facility MEP management:

- Only one facility MEP can be configured on a port, a LAG, or a network interface.
- A facility MEP can be configured on a port only if the MD level is 0.
- A facility MEP must be configured in the down direction.
- A facility MEP ID must be unique within the same device.
- Port facility MEPs are supported on ports in access, hybrid, or network mode with dot1q encapsulation, and on ports in access or hybrid mode with Q in Q encapsulation.
- Port facility MEPs cannot be configured on network elements that support Ethernet tunnels.
- Tunnel facility MEPs are supported on LAG ports configured with Q in Q encapsulation in access or hybrid mode.
- Tunnel facility MEPs must have a lower MD level than any service MEPs that are created on the same LAG.
- A tunnel facility MEP VLAN ID must be unique within the same port.
- Tunnel facility MEPs cannot be configured on LAGs with a VLAN ID of 0.
- Tunnel port facility MEPs cannot be configured on LAG members.
- Fast facility MEPs, which are MEPs with a CCM interval of 10 ms or 100 ms, cannot be configured when CCM padding is enabled.
- There must be 2 facility MEPs in a MEG subgroup to execute a CCM test.

91.5.5 Unicast MEPs

The following rules apply to Unicast MEP management:

- When a CCM test is executed, the NFM-P will deploy remote MEPs (with unicast-da) to spokes for NEs that support unicast CCM.
- MEG sub-groups will ignore Unicast remote MEP lists when discovering MEG sub-groups and only use the hub remote MEPs list.
- Remote MEPs configured as unicast will update the appropriate Unicast Hub MEP’s Operational MAC Address. If an appropriate Unicast Hub MEP cannot be found, the remote MEPs will auto-create an unmanaged remote MEP with the Unicast Hub’s target pointer set.
- An unmanaged remote MEP without a MAC Address configured cannot be used as a Unicast Hub.

- Hub MEPs should be configured with remote lists that target all regular (non-unicast) MEPs and only the unicast MEPs that point to the hub. This allows a mixture of unicast and regular MEPs for CCM testing.
- You can use a multi-selection of MEPs to set a Unicast Hub MEP pointer.
- A MEP cannot point to itself as a Hub.
- A MEP cannot point to a Hub on the same site.
- If a MEG site has more than one MEP, the NFM-P sets all the MEPs to have the same Hub pointer.
- The remote MEP list of a Hub will not include spokes that do no point to it.
- When listing available Hubs, the NFM-P will also list unmanaged remote MEPs that have a MAC address from the same sub-group.
- When the NFM-P discovers a remote MEP it manages that has an appropriate MAC address, it will update the hub pointer.
- When the managed MEPs point to a hub, then regardless of what other remote MEPs or unmanaged remote MEPs are deployed, NFM-P will only deploy the hub's MEP ID with the Operational MAC Address. No other MEP IDs will be deployed.
- No local MEP is allowed when there is a remote MEP with a MAC address.
- No remote MAC address is allowed if multiple remote MEPs exist.
- If a MEP with a hub pointer exists on a MEG site, NFM-P will auto-populate the hub pointer when a new MEP is create
- When you create a remote MEP with a MAC address, the NFM-P creates an unmanaged remote MEP. This unmanaged remote MEP will be in the same sub-group as the spoke.
- Where MC-LAG redundant MEPs exist, the hub will point to the active one.

91.6 MIPs

91.6.1 MIP description

Maintenance intermediate points, or MIPs, are internal points in an MD that perform the following functions:

- validate received CFM PDUs
- validate and respond to link trace messages
- validate and respond to loopback messages

A MIP consists of two half-function objects that allow the MIP to be recognized as a MIP in one MD level and as a MEP on a higher level.

91.7 Allocating bandwidth resources for Ethernet CFM LBM/LBR SAT

91.7.1 Description

Service Activation Testing (SAT) is a critical operational task that is performed prior to service handoff to a subscriber. SAT can be performed up to speeds of 10 Gbps. To support SAT on the NFM-P, you can configure the following GUI objects to facilitate high-speed Ethernet-CFM LBMs (Loopback messages)-to-LBRs (Loopback responses) processing typically used during SAT.

- Use the Service Activation Response parameter on the MEP Properties form to specify if the MEP uses standard bandwidth processing or if additional bandwidth processing is applied for processing service activation requests/stream encapsulated in the ETH-LBM (Ethernet-Loopback message) format. When enabled, additional bandwidth resources are allocated to rapidly respond to this stream of LBM messages; the MEP will not validate any type-length-value (TLV)s, and will not increment or compute any loopback statistics. When disabled, the MEP ETH-LBMs uses standard bandwidth processing. You can configure the Service Activation Response parameter on SAPs, Spoke or Mesh bindings, and Network Interfaces MEPs associated with VLL Epipe and VPLS services.
- Use the LBM Service Activation Responder Info button on the NE Properties form (Globals tab; OAM sub-tab), to execute the “show eth-cfm lbm-svc-act-responder” CLI command. This command displays all the MEPs that have the Service Activation Response parameter enabled.
- The LBM responder is supported for both the service-based MEPs and the MEPs on the router interface.

91.8 Configuring ITU-T Y.1731 ETH-ED grace period notifications

91.8.1 ETH-ED grace period notification description

ITU-T Y.1731 performance monitoring provides standards-based Ethernet performance monitoring that encompasses the measurement of Ethernet frame delay, frame delay variation, and frame loss and throughput as outlined in the ITU-T Y-1731 specification and interpreted by the Metro Ethernet Forum (MEF).

The ETH-ED (Ethernet Expected Defect) function of the ITU-T Y.1731 standard is used by a MEP to signal to its peer MEPs, the transmission of CCM frames is expected to be interrupted, without any interruption to data frames. The consequent loss of continuity defects at the peer MEPs is also suppressed. Frames with ETH-ED information carry the MEP ID of the MEP and the expected duration of the interruption.

You can enable ETH-ED grace period notification for MEPs using the Grace Period TX Enabled parameter located on the NE Properties form (Globals tab, OAM sub-tab); see 12.5 “To modify NE properties” (p. 343).

When grace period notification is enabled, you can perform specific ITU-T Y.1731 ETH-ED protocol configurations using the following parameters located on the supported object Grace panel: Eth VSM Rx Enable, Eth VSM Tx Enable, Rx Enable, Tx Enable, Max Rx Defect Window, and Priority. See the XML API Reference for information about configurable parameters and their applicability. See Table 91-1, “Supported objects and configuration guideline for Grace ETH-ED period notifications” (p. 3097) for supported object types for grace period notifications and configuration guidelines.

Table 91-1 Supported objects and configuration guideline for Grace ETH-ED period notifications

Supported network object	Configuration guidelines
Ethernet Tunnel	See ...33.14 “To configure an Ethernet tunnel endpoint” (p. 1203) Navigate to: Service Tunnels→Ethernet Tunnel→Create→Tunnel Properties→Tunnel End points→Ethernet Tunnel Path Endpoint→MEPs→General tab (Grace panel)
Ethernet Ring Element	See ...33.16 “To configure an Ethernet Ring Element” (p. 1208) Navigate to: Ring Element→MEP tab→Create ETH-CFM Global→MEPs→General tab (Grace panel)
Routing Instance Interface	See ...27.2 “To configure a routing instance or a VRF instance” (p. 826) Navigate to: NE Routing Instance→Router Interface Properties→MEPs→General tab (Grace panel) Note -- Ensure the port is associated with the Router Interface
SAP MEPs associated with EPIPE, IPIPE, VPLS, IES, and VPRN services	See ...74.25 “To configure a MEP on a SAP” (p. 2048) Navigate to: Service type→Sites→L2 (or L3) Access Interface→SAP Properties→OAM tab→ETH-CFM tab→Create MEP→MEPs (Grace panel)
Subscriber Interface MEPs associated with IES, and VPRN services	See ...78.16 “To configure a subscriber interface on an IES” (p. 2444) or 79.47 “To configure a subscriber interface on a VPRN” (p. 2610) Navigate to: Service type→Sites→Subscriber Interfaces→Group Interfaces→Service Access Points Properties→OAM tab→ETH-CFM tab→Create MEP→MEPs (Grace panel)
Spoke SDP Binding or Mesh SDP MEP associated with EPIPE, VPLS, IES, and VPRN services	See ...77.99 “To create a MEP on a VPLS SDP binding” (p. 2398) Navigate to: Service type→Sites→Spoke SDP Bindings Properties→OAM tab→ETH-CFM tab→Create MEP→MEPs (Grace panel)
LAG MEP	See ...13.16 “To create a LAG” (p. 431) or 13.17 “To modify a LAG” (p. 435) Navigate to: NE→Logical Groups→LAGS→Properties→MEPs→Create MEP→MEPs (Grace panel)
Port/Facility MEPs	See ...91.5.4 “Facility MEP” (p. 3095) Navigate to: Port Properties→Ethernet tab→MEPs (Grace panel)

91.8.2 ETH-ED enforcement rules

The NFM-P applies the following enforcement rules for ETH-ED grace period notifications:

- When a soft-reset occurs on the node, if ETH-ED transmit and receive are both enabled, then Grace ETH-ED takes precedence over Grace ETH-VSM. CCM should be enabled when a soft-reset occurs. Only when is CCM is enabled will the grace protocols be applied.
- Transmitting Grace field will read the protocol ETH-ED for the maximum Rx defect window value.
- Any MEP transmitting the Grace ETH-ED defect protocol must have CCM enabled.
- When a soft-reset occurs, no configurations can be added or changed either on the node or using the NFM-P.
- When a soft-reset occurs on the node, if ETH-VSM transmit and receive are both enabled, then Grace ETH-VSM takes precedence over Grace ETH-ED.

91.9 Ethernet-CFM redundancy

91.9.1 Ethernet-CFM redundancy description

When you configure Ethernet-CFM redundancy, you can link MEPs to the state of the resiliency mechanism that is supported in MC-LAGs. The state of the MEP does not affect the state of resiliency mechanism.

Ethernet-CFM redundancy is configured at the NE level. When you configure Ethernet-CFM redundancy, the state of a MEP is the same as the state of the SAP, LAG, or MC-LAG with which it is associated. For example, if the redundant MC-LAG is in standby state, the MEP is also in standby state. When a MEP is in standby state, the MEP is idle, CCMs are not exchanged, and the MEP does not respond to CFM tests.

Note: The MEP, SAP, and LAG must reside within an MC-LAG that has Ethernet-CFM redundancy configured. See 43.5 “To create an MC LAG group” (p. 1365) to configure MC-LAGs.

When Ethernet-CFM redundancy is configured and the active state of an MC-LAG changes, the MC-LAG Inactive state on the MEP changes and any defects on the MEP are flagged.

The state of MEPs, SAPs, and LAGs that are configured for Ethernet-CFM redundancy appears in the MC-LAG Inactive field. The status of MC-LAGs that are configured for Ethernet-CFM redundancy appears in the Is Active field.

In addition to configuring Ethernet-CFM redundancy at the NE level, you can configure Ethernet-CFM redundancy on tunnel MEPs. See 12.5 “To modify NE properties” (p. 343) to configure Ethernet-CFM redundancy at the NE level. See 13.17 “To modify a LAG” (p. 435) to configure Ethernet-CFM redundancy on a tunnel MEP.

91.10 Sample Ethernet CFM implementation

91.10.1 MDs, MEPs, and MIPs in an IEEE 802.1ag network

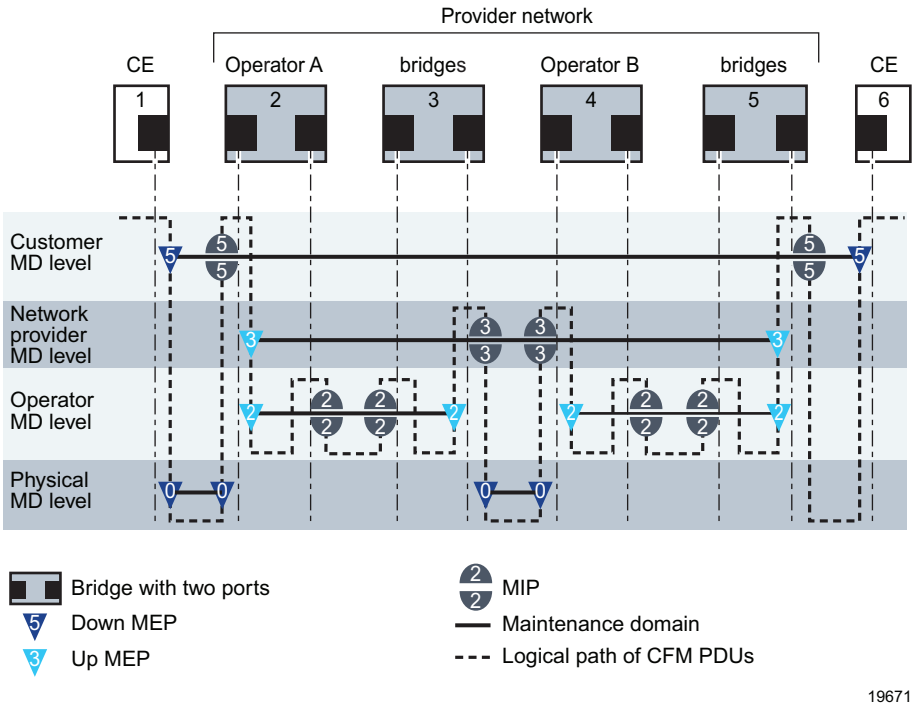
Figure 91-1, “Ethernet CFM objects in example network” (p. 3100) shows an example of MDs, MEPs, and MIPs in an IEEE 802.1ag network that consists of two operator areas, for example, services in the provider network, that are joined to create a network path for customer traffic.

The number on an object identifies the associated MD, which is one of the following:

- MD 5—end-to-end customer path
- MD 3—end-to-end network provider path
- MD 2—paths within services
- MD 0—physical path

MD 5 provides access to a down MEP on each CE device, and to a MIP on each PE bridge. MD 3 provides access to an up MEP on each PE bridge, and to a MIP on each bridge between groups of operator bridges. MD 2 provides access to the up MEPs and MIPs in each service. MD 0 provides access to MEPs for checking the physical connectivity between NEs.

Figure 91-1 Ethernet CFM objects in example network



91.11 Ethernet CFM implementation for composite services

91.11.1 Composite service description

End-to-end test suite generation for composite services is available for VPLS and VLL Epipe services. In this context, a composite service is a set of services connected by one or more of the following:

- VLAN uplinks
- Spoke bindings
- CCAG connectors

Creating test suites and test policies for composite services is very similar to creating these for a regular service. Test generation options can be applied to modify the roles of managed and remote unmanaged up MEPs. See 91.15 “To configure an Ethernet CFM MD policy and subordinate objects” (p. 3109) . The Accounting Files and Continuously Executed options are also available when you create a test policy for a composite service.

Once tests have been ordered to generate, a MEG is created on each eligible endpoint SAP. Tests are then generated for this MEG that target other eligible endpoint SAPs within the composite service. Results for individual tests can then be reviewed.

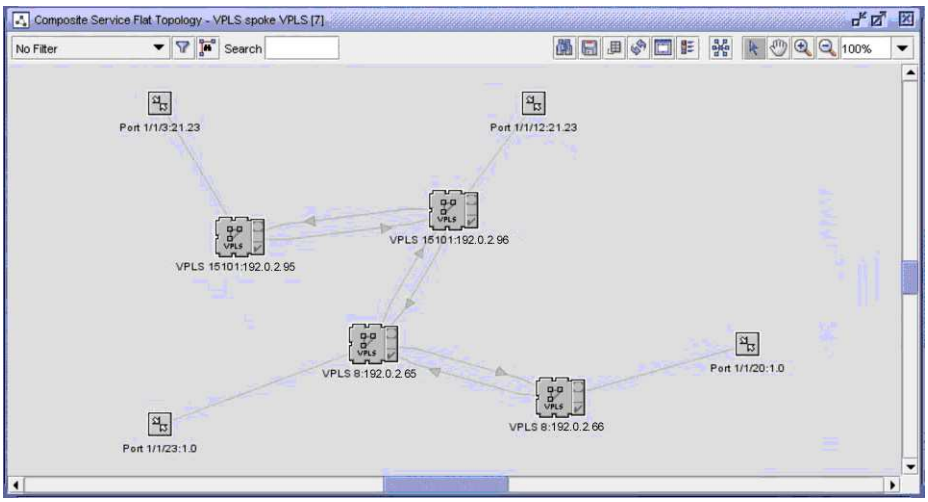
Note: If there is a previously created MEG on one of the service sites (for example, a MEG created for a service before the service was included in a composite service) and the Generate Tests button is selected, tests are not generated. When a MEG with only a subset of the composite service already exists on one of the service SAPs, the generation of tests is blocked. The MEG must be deleted before the CFM tests are generated.

91.11.2 Examples of Ethernet CFM tests for composite services

The following are examples of how the Ethernet CFM test generation rules for composite services are structured to operate.The examples are based on the default test roles for MEPs. The default roles are Hub and both Test Source and Test Target.

The following figure shows a flat topology view of a simple configuration of two VPLSs (VPLS 8 and VPLS 15101) that are connected by a pair of spoke bindings between sites 192.0.2.96 and 192.0.2.65.

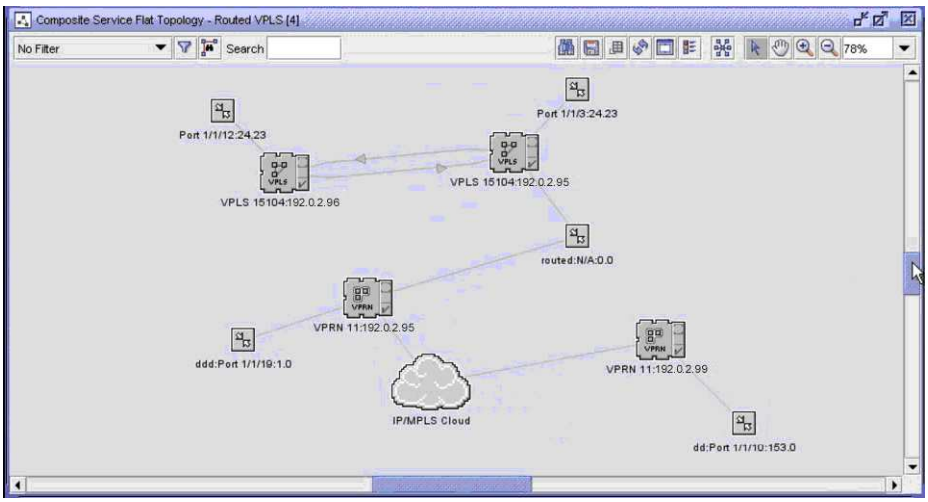
Figure 91-2 Composite service connected by spoke bindings



In this configuration, all four SAPs are considered as endpoints. Therefore MEPs are generated on each SAP and they all target each other. A total of twelve tests are generated. Double-clicking on an endpoint opens the interface configuration form and the MEP generated for this particular endpoint is displayed under the MEPs tab. If you then query the MEP's properties, the Tests tab in the MEP's configuration form displays the three tests that target the other MEPs in this composite service.

The following figure shows an example of a routed VPLS configuration with a VPLS (VPLS 15104) and a VPRN (VPRN 11). The services are connected by a routed VPLS interface (shown as routed:N/A:0.0).

Figure 91-3 Routed VPLS composite service



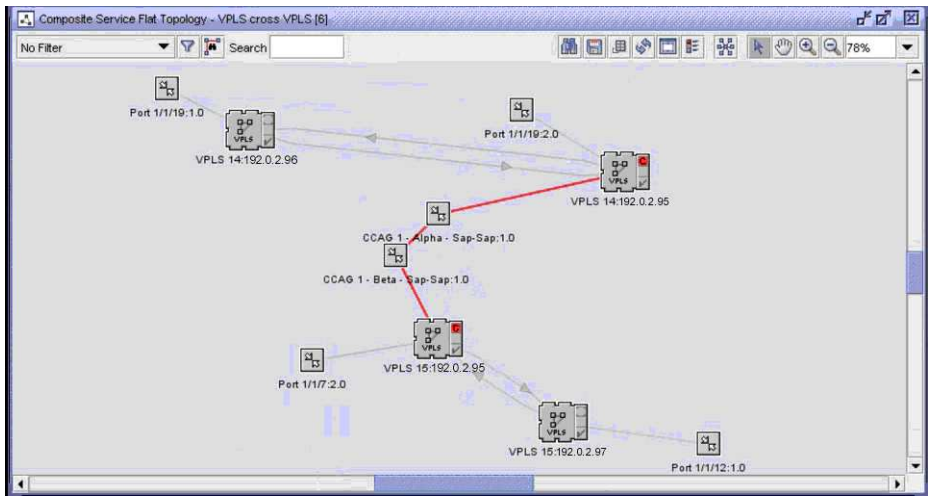
In this configuration, site 192.0.2.95 exists on both the VPLS and VPRN service. This is an overlapping site. The test generation rules would normally skip an overlapping site and no MEGs or tests would be generated for that site.

However in this case, the overlap for this site occurs in an unsupported service. The test generation rules for such a configuration will skip the unsupported VPRN service entirely and only generate tests for the supported VPLS, including site 192.0.2.95. Therefore, two MEPs and two tests (targeting each other) will be generated here, one for each of the SAPs on sites 192.0.2.96 and 192.0.2.95.

The test generation logs available in the test suite configuration form (under the Generation Error Logs tab) provide an explanation whenever the test generation rules cause items to be excluded from the tests. In this case, the log would state: “The CFM Composite Services Test Suite skipped the unsupported service”.

The following figure shows an example of a cross-connected VPLS composite service.

Figure 91-4 Cross-connected VPLS composite service



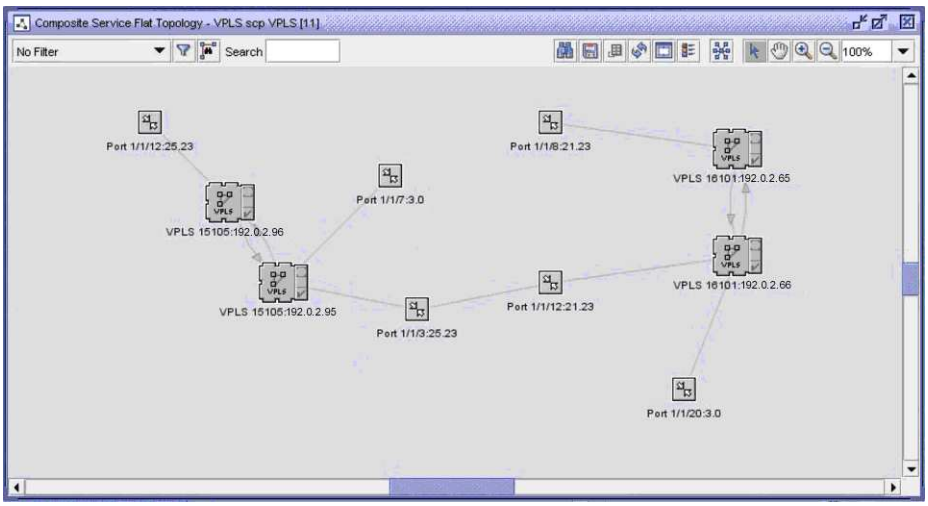
In this configuration, the two VPLSs (VPLS 14 and VPLS 15) are cross-connected by the SAPs CCAG 1-Alpha and CCAG 1-Beta. Both these SAPs originate from site 192.0.2.95, which exists in both services. It is therefore an overlapping site. The test generation rules skip overlapping sites, so no MEGs or tests are generated for any SAPs associated with that site.

Therefore, two MEPs and two tests (targeting each other) will be generated here, one for each of the SAPs on sites 192.0.2.96 and 192.0.2.97.

In addition, there will be two test generation logs available in the Generation Error Logs tab of the test suite configuration form. In this case, the logs would be identical, one stemming from each of the supported VPLSs. The logs would state: “Skipped overlapping service site”.

The following figure shows an example of an SCP-connected VPLS composite service.

Figure 91-5 SCP-connected VPLS composite service



In this configuration, the two VPLSs (VPLS 15105 and VPLS 16101) are joined by an SCP connector between sites 192.0.2.95 and 192.0.2.66. The test generation rules skip any SAPs identified as part of a connector, since they are not endpoints. So no MEGs or tests are generated for either connector SAP.

MEGs and tests will however, be generated for each of the other four SAPs shown in the example. In total, four MEGs and twelve tests will be generated.

In addition, there will be two test generation logs available in the Generation Error Logs tab of the test suite configuration form. In this case again, the logs would be identical, one stemming from each of the supported VPLSs. The logs would state: “Skipped service connecting SAPs”.

91.12 Primary VLAN support for Ethernet CFM

91.12.1 Primary VLAN feature description

A VLAN assigned for service monitoring is considered the Primary VLAN. By setting a Primary VLAN identifier, you can perform additional ETH-CFM extraction checking.

By default, the ETH-CFM processing uses a SAP or SDP binding configuration to determine the proper offset for the start of the ETH-CFM e-type 0x8902 PDU. Any packet that includes ETH-CFM (e-type 0x8902) at the appropriate offset will be subjected to the extraction routines for MEPs or MIPs provided the Primary VLAN is enabled. If the ETH-CFM is not at the appropriate offset, the packets pass as user data. When a MEP is configured without a Primary VLAN, only the classic extraction is performed.

The default mapping of the ingress packet is based on the Layer 2 mapping which in turn, is mapped to the appropriate MEP. If the mapping does not match, as in the case of ambiguous or additional VLAN tags beyond the SAP or SDP binding delineation, then additional lookups for ETH-CFM are possible.

This is applicable where a single VLAN or aggregate is transporting many VLANs underneath that aggregate function. It is also applicable to dot1q networks that carry multiple tags without using the default SAP. Fully-qualified SAPs/SDP binding are also able to use the Primary VLAN function. The extraction function is the same for either fully-qualified or ambiguous SAPs/SDP binding.

A MEP or MIP must be configured on a particular SAP or SDP binding to perform any ETH-CFM extraction. The classic extraction (which is the matching of the ETH-CFM packets immediately following the SAP/SDP binding configuration) is performed first. If the Ethernet encapsulation is set to dot1q and the SAP configuration is x/y/z:*, then the ETH-CFM extraction looks for ETH-CFM to appear in the header with no VLAN tags preceding it. If there is a match on this classic extraction, then no further extraction routines are invoked. If the classic extraction fails and a second MEP is configured with Primary VLAN enabled, then the additional extraction will check to see if ETH-CFM immediately follows the specified Primary VLAN. If that is true, then the VLAN will be used as an index into the primary VLAN table and the extraction is performed based on normal criteria following the ETH-CFM rules.

The Primary VLAN function is supported for up and down MEPs, as well as ingress and egress MIPs on an Ethernet SAP for VPLS and Epipe service MEPs (including Local Switched PBB ePipe with PBB Tunnel backup). Primary VLAN support is only applicable to service MEPs and not facility MEPs (specifically, not tunnel MEPs). Facility MEPs are meant to validate the transport and not the switching capability of a network element.

Primary VLAN support for 7210 SAS NEs varies depending on chassis type, release version, and card type. See the NE documentation for more information.

When enabling this function, an operator can specify the VLAN ID for generated MEG sites, and also whether or not the MEP should be a Primary VLAN MEP or MIP (only applicable to SAP/SDP binding MEPs or MIPs on VPLS and Epipe services).

The CCM test execution routine checks if all MEPs in the MEG or MEG Sub-group match before allowing the test execution to proceed.

Points to consider when enabling the Primary VLAN function:

- A unique MA should be employed for each Primary VLAN.
- The Primary VLAN function is only applied to SAPs and spoke and mesh SDP bindings. Virtual MEPs are not supported.
- The MHF-Creation parameter must be set to the static option to force the generation of Primary VLAN MIPs.
- Primary VLAN MEPs can only be assigned at creation time.
- Primary VLAN MEPs must have an MA Service VLAN ID correctly set.
- The MA Service VLAN ID cannot be changed if Primary VLAN MEPs exist.
- Multiple Primary VLAN MEPs per SAP or SDP bindings are supported. There is no restriction on the number of MEPs that are allowed on SAPs/SDP binding for this feature. Both the classic extraction context and every Primary VLAN on the SAPs/SDP binding can support up to 16 MEPs (8 Up and 8 Down), one per MD level.
- All eight MD levels can be configured on all MEPs (0-7) that are configured on a SAP/SDP binding, within their specific context (classic or Primary VLAN). This allows an operator to have

the complete range of eight MD levels for use in the specified Primary VLAN. This avoids conflicts when the same MD Level and Layer 2 encapsulation maps to two different MEPs in the different contexts.

- Levels are specific within each of the contexts (classic and all the Primary VLANs configured on the same SAP/SDP binding). Therefore each lookup can have overlapping levels. The hierarchy is maintained within the extraction context.
- Primary VLAN MEPs and Fault Propagation are mutually exclusive.
- Primary VLAN MEPs and Fast CCM Interval are mutually exclusive.
- There is no sub-second CCM support for Primary VLAN enabled MEPs.

Procedures to configure Ethernet CFM

91.13 Ethernet CFM diagnostic test workflow

91.13.1 Stages

This workflow outlines the procedures that describe how to configure, manage and perform Ethernet CFM OAM diagnostic tests, as well as how to view the results the tests generate. The PM session tests are generally configured through the Service Test Manager. See Chapter 89, “Service Test Manager” for more information on working with the STM.

1

If the Ethernet CFM diagnostic test being configured is part of an STM test policy or STM test suite, review the STM chapter workflow to determine any prerequisite configuration requirements. See Chapter 89, “Service Test Manager” for more information on the STM.

2

Configure the initial MEP ID value on an NE for automatic MEP creation; see 91.14 “To configure an automatic MEP ID assignment on an NE” (p. 3108) .

3

Create an Ethernet CFM MD policy and subordinate objects associated with the MD such as a Global MEG, MEG, and MEP for each level at which Ethernet connectivity is to be monitored; see 91.15 “To configure an Ethernet CFM MD policy and subordinate objects” (p. 3109).

4

As required, create identical MEPs on service SAPs that are part of an MC-LAG; see 91.16 “To automatically create identical MEPs on a redundant pair of service SAPs” (p. 3118).

5

As required, change the MEG sub-group association for managed MEPs or unmanaged remote MEPs; see 91.17 “To change the MEG sub-group association for managed MEPs or unmanaged remote MEPs” (p. 3119) .

6

As required, configure a default NE-level MD on an OmniSwitch; see 91.18 “To configure a default MD on an OmniSwitch” (p. 3120).

7

As required, configure one of the following CFM Ethernet diagnostic tests:

- Global MEG check; see 91.19 “To create and run a Global MEG OAM diagnostic test from the STM” (p. 3120)
- Continuity check and CFM dual-ended loss test; see 91.20 “To create and run a Continuity Check OAM diagnostic test from the STM” (p. 3122)

- CFM loopback; see 91.21 “To create and run a CFM loopback OAM diagnostic test from the STM” (p. 3123)
- CFM link trace; see91.22 “To create and run a CFM link trace OAM diagnostic test from the STM” (p. 3125)
- CFM Eth test; see 91.23 “To create and run a CFM Eth OAM diagnostic test from the STM” (p. 3127)
- CFM two way delay test; see 91.24 “To create and run a CFM two way delay OAM diagnostic test from the STM” (p. 3128)
- CFM one way delay test; see 91.25 “To create and run a CFM one-way delay OAM diagnostic test from the STM” (p. 3130)
- CFM single ended loss test; see 91.26 “To create and run a CFM single-ended loss OAM diagnostic test from the STM” (p. 3131)
- CFM two way SLM; see 91.27 “To create and run a CFM two way SLM OAM diagnostic test from the STM” (p. 3132)
- CFM LM test; see 91.28 “To create and run a CFM LM OAM diagnostic test from the STM” (p. 3134)

8

Create an STM test policy specifying at least one Ethernet CFM test definition; see 89.10 “To configure an STM test policy” (p. 2947).

9

Create an STM test suite; see 89.12 “To create an STM test suite” (p. 2951).

10

As required, execute the generated Ethernet CFM test suite; see 89.17 “To execute an STM test suite” (p. 2961).

11

As required, view and compare CFM Ethernet test results: See 89.18 “To view STM test suite results” (p. 2962) , and 89.19 “To view and compare STM test suite results for a tested entity” (p. 2963) ,

91.14 To configure an automatic MEP ID assignment on an NE

91.14.1 Steps

Perform this procedure to configure an initial MEP ID value and associated MEP parameters on an NE for automatic MEP creation.

1

On the equipment tree, right-click on a device and select Properties. The Network Element (Edit) form opens with the General tab displayed.

2

Click on the Globals tab and on the OAM tab.

3

Configure the MEP ID parameter.

4

Save your changes and close the form.

END OF STEPS

91.15 To configure an Ethernet CFM MD policy and subordinate objects

91.15.1 Related information

Many of the forms accessed in this procedure can also be accessed using the Service Topology map. See 4.2 “Working with topology maps” (p. 176) for information about working with maps.

Note: You can only perform this procedure when a service exists to associate with the MD policy or subordinate objects.

91.15.2 Steps

This policy defines the MD for Ethernet-based services such as VPLS, Epipe, VPRN, and IES, including SAPs and SDP bindings, for use in Ethernet CFM OAM diagnostic tests.

1

Choose Tools→Ethernet CFM→Maintenance Domain Policies from the NFM-P main menu. The Maintenance Domain Policies form opens.

2

Click Create or select an existing MD and click Properties. The Maintenance Domain - Global Policy (Create|Edit) form opens.

3

Configure the general parameters.

4

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

Add a Global MEG to an MD

5

To add a Global MEG to an MD:

1. Click on the Global Maintenance Entity Group tab and click Create. The Global Maintenance Entity Group (Create) form opens with the General tab displayed.
2. Configure the general parameters.
3. Configure the Name Format and Name parameters in the Maintenance Entity Group panel.

   If you select icc-based as the Name Format, then the associated Name value must be 8 to 13 characters long.
4. Configure the parameters in the Initial MEG Configuration panel.

   When you are creating a Global MEG for a 7750 SR-c4, 7750 SR-c12, or 7450 ESS-6, the Initial CCM Interval must be set to 1s.

   For Wavence nodes, the value *static* is not supported for the Initial MHF-Creation parameter. If static is selected during MEP configuration, then the default value *none* gets assigned to the node.

   You can only configure the Initial CFM Hold Down Timer (Centiseconds) parameter when the Initial CCM Interval is set to 10 ms or 100 ms.

   When the Initial CCM Interval parameter is set to 10 ms or 100 ms, you cannot configure automatic MEP creation in Step 7 .

   Note:

   When a Global MEG is created and applied, you can open the Global Maintenance Entity Group form at any time and view on the General tab two information fields that display the number of local MEGs and the number of MEPs currently associated with the Global MEG.
5. Save your changes.

Add a MEG sub-group to a Global MEG

6

To add a MEG sub-group to a Global MEG, perform one of the following:

a. Add a new MEG sub-group to a Global MEG.
   1. Select a Global MEG and click Properties. The Global Maintenance Entity Group (Edit) form opens with the General tab displayed.
   2. Click on the MEG Sub-Group tab and click Create. The MEG Sub-Group (Create) form opens.
   3. Configure the required parameters.
   4. Save your changes.

b. Automatically create a new MEG sub-group based on existing remote MEP lists.

Note: You can only create MEG sub-groups using this method when a valid remote MEP list exists and the remote MEPs on the list are CCM enabled.

Perform the following:

1. Select a Global MEG and click Properties. The Global Maintenance Entity Group (Edit) form opens with the General tab displayed.
2. Click Discover MEG Sub Groups. If this button is not visible, click More Actions and choose Discover MEG Sub Groups. When remote MEPs on valid lists are CCM enabled, new MEG sub-groups are created from the remote MEP lists. The new MEG sub-groups are listed on the Global Maintenance Entity Group (Edit) form.
3. Save your changes.

Associate a service with a Global MEG

7

To associate a service with a Global MEG, perform one of the following:

a. Automatically associate all NEs in a service with a Global MEG.

1. Select an MD and click Properties. The Maintenance Domain - Global Policy (Edit) form opens.
2. Click on the Global Maintenance Entity Group tab and click Create. The Global Maintenance Entity Group (Create) form opens with the General tab displayed.
3. Click on the Service tab and click Create. The Service (Create) form opens.
4. Select a Service.
5. Configure the Follow Service Topology Changes parameter, if required.

   Note:

   Enabling this parameter will cause relevant Ethernet OAM objects in the MEG and MEG sub-groups to automatically change in response to topology changes in the service or composite service you selected in 4 . Such changes include the addition or deletion of sites, SDP bindings, and access interfaces. Applicable CFM tests (as specified in a test suite) will also be automatically generated and/or deleted, as required. The specific Ethernet OAM objects that will respond to a service topology change are dependent on the selections you make in 7 below.
6. Configure the required parameters in the Auto-Creation of MEG(s) panel.
7. Configure the required parameters in the Auto-Creation of MEP(s) panel.

   Note:

   You cannot configure the MEP(s) Creation on Access Interfaces, MEP(s) Creation on SDP Bindings, or Virtual MEP(s) Creation on VPLS Sites parameters when the Initial CCM Interval parameter in Step 5 is set to 10 ms or 100 ms.

   For 7210 SAS-K NEs, to enable the Primary VLAN Enable parameter, you must enable the Primary VLAN parameter in the system resource profile for the device; see 12.50 “To configure the global system resource profile on a 7210 SAS or 7250 IXR” (p. 380).
8. Configure the required parameters in the Auto-Creation of MIP(s) panel.

9. Save your changes.

b. Associate a single NE on a service with a Global MEG.

1. Select an MD and click Properties. The Maintenance Domain Global Policy (Edit) form opens.
2. Click on the Global Maintenance Entity Group tab, select a Global MEG, and click Properties. The Global Maintenance Entity Group (Edit) form opens.
3. Click on the NE Maintenance Entity Group tab and click Create. The NE Maintenance Entity Group (Create) form opens with the General tab displayed.
4. Select a site.
5. Configure the required parameters.

   You can only configure the CFM Hold Down Timer (Centiseconds) parameter when the CCM interval is set to 10 ms or 100 ms.

   You cannot choose the 10 ms and 100 ms options for the CCM interval parameter when the CCM Padding Packet Size(Bytes) parameter is enabled.

   Note:

   Only the parameters that are supported on the selected site are displayed when you open the form.
6. Click on the Service tab.

   If the selected site supports only the service ID as the key identifier in an NE maintenance group, click on the Service ID tab, then click Create. The MEG Service (Create) form opens.

   If the selected site supports the service name as the key identifier in an NE maintenance group, both the Service ID and Service Name tabs are available. Click on the required tab, then click Create. The MEG Service (Create) form opens.

   On supporting NEs, you can choose either the service ID or the service name as the identifier for the associated service. To change from ID to name, or from name to ID, select the required tab, click Create, and configure the change. The previous configuration is removed, and the updated identifier is used.
7. Configure the required parameters.
8. Save your changes.

   Note:

   When an NE Maintenance Entity Group is created and applied, you can open the NE Maintenance Entity Group (Edit) form at any time and view on the General tab an information field that displays the number of MEPs currently associated with the NE Maintenance Entity Group.

Add an Ethernet path to the Global MEG

8

To add an Ethernet path to the Global MEG:

1. On the Global Maintenance Entity Group (Edit) form, click on the Ethernet Path tab and click Create. The Ethernet Path (Create) form opens.

   Note:

   You must specify an Ethernet tunnel path or Ethernet ring path on this form.
2. Select an Ethernet tunnel path or an Ethernet Ring Path.
3. Configure the required parameters.
4. Save your changes.

Add an NE MEG to the MD

9

To add an NE MEG to the MD:

1. Click on the NE Maintenance Entity Group tab and click Create. The Maintenance Entity Group (Create) form opens with the General tab displayed.
2. Select a site for the NE MEG.
3. Select a Unicast Hub MEP for the NE MEG. The Unicast Hub MEP panel is only displayed when the site you selected in 2 is a 7450 ESS, 7750 SR, or 7950 XRS NE.

   Configuring this parameter allows you to add a unicast MEP to the remote MEPs list. This enables the deployment of a hub-and-spoke topology where multiple MEPs acting as spokes can communicate with one hub MEP. In this scenario, the remote MEP has a MEP Mac Address which is the Operational MAC Address of the Unicast Hub MEP.

   See the MEP ID parameter description for additional information and constraints on configuring a unicast CCM hub.
4. Configure the required parameters. The following restrictions apply:
   - The VLAN ID parameter is configurable only when the selected NE is an OmniSwitch.
   - The CFM Hold Down Timer (Centiseconds) parameter is only configurable when the CCM interval is set to 10 ms or 100 ms.
   - The 10 ms and 100 ms options of the CCM interval parameter cannot be configured when the CCM Padding Packet Size(Bytes) parameter is enabled.
5. Click OK.
6. To associate a template with the NE MEG, select an NE MEG and click Properties. The Maintenance Entity Group (Edit) form opens. Otherwise, go to 8 .
7. Click on the Templates tab and select an associated template.
8. Click on the Service tab and click Create. The MEG Service (Create) form opens.
9. Configure the required parameters.

On supporting NEs, you can specify a user-defined ID in the Sender ID TLV of LBM and LTM PDUs. To use this option, set the ID-Permission parameter to the chassis option, and perform Procedure 12.44 “To configure the Sender-ID TLV of a CFM PDU for an NE” (p. 376).

10. Save your changes.

Add a managed MEP to the Global MEG

10

To add a managed MEP to the MEG:

1. Click on the Managed MEP tab and click Create. The MEP (Create) form opens.
2. Select a MEG.
3. Configure the required parameters. The following considerations apply:
   - The Interface Type parameter is configurable when the Type parameter is set to Regular.
   - The Interface Type Port is only available if the MD level is 0.
   - For facility MEPs, the Direction parameter must be set to Down.
4. Configure the required parameters in the Fault Alarm/Reset Time panel and the CCM panel.
5. Select a MEG subgroup to associate with the managed MEP.

   Note:

   If a MEG subgroup is not selected, the managed MEP is automatically associated with the default MEG subgroup.
6. Configure the required parameters in the Test Generation Options panel.

   Note:

   The Role, Use as Test Source, and Use as Test Target parameters are configurable only when you set the Direction parameter to Up.

   You can propagate test generation role settings to all MEPs on a SAP or service site using the Propagate to MEPs button on the ETH-CFM tab of the Access Interface (Edit) and Site (Edit) forms.
7. If the Type parameter you configured in 3 is set to Virtual, go to 12 .
8. If the Interface Type parameter you configured in 3 is set to LAG or Port, configure the Facility Fault Notify parameter.
9. If the Interface Type parameter you configured in 3 is set to LAG, configure the Facility VLAN ID.

   Note:

   If you are configuring a tunnel facility MEP, the Facility VLAN ID parameter value must match the outer encapsulation value of the SAP to which you are connecting the tunnel facility MEP.
10. In the bottommost panel, select an object of the type specified by the Interface Type parameter you configured in 3 . The Select *object_type* form opens.
11. Go to 13 .

12. Select a service site for the virtual MEP in the Service Site panel.
13. If the MD for the MEP has a Name Type of none and its Maintenance Association has a Name Format of icc-based, the Y.1731 Tests and AIS tabs are configurable. Otherwise, go to 15 .
14. Click on the Y.1731 TEST tab and AIS tab and configure the required parameters.
15. Click on the ETH-CSF tab and configure the required parameters.

    The CSF Rx Multiplier parameter is configurable when the Enable Client Signal Fault parameter is enabled.

    Note:

    ETH-CSF acts as one of the triggers for fault propagation on the receiving MEP, when the Fault Propagation parameter is enabled in 4 .

    When the CSF Rx Multiplier is 0 (meaning that CSF will never timeout) and you need to manually clear the CSF state, you must first disable and then re-enable the Enable Client Signal Fault parameter. Otherwise, CSF must receive a C-DCI flag in a PDU to clear the state automatically, whenever the multiplier is 0.

    If the CSF Rx Frame State read-only indicator displays anything other Client Defect Clear Indication, then a fault exists.

11

Save your changes.

Add a remote MEP to the MEG

12

Add a remote MEP to the MEG.

Note: When you execute a CCM test or synchronize the managed and unmanaged remote MEP lists, the NFM-P automatically distributes the local MEP and the remote MEP to the remote MEP list, except for 7705 SAR NEs, which are excluded from automatic MEP -distribution.
If you enabled the Enable Auto Remote MEP Discovery parameter in Step 7 b , the auto-discovered remote MEPs will populate this list when CCM is running on the network. You can clear the list of auto-discovered MEPs if required, by clicking on Clear Auto Discovered Remote MEPS.
When you execute a CCM test or synchronize the managed and unmanaged remote MEP lists within a MEG sub-group, the NFM-P automatically distributes the local MEP and the remote MEP within that MEG sub-group.
If the remote MEP you are adding is to act as a Unicast Hub MEP, the remote MEP's MEP Mac Address will become the Operational MAC Address of the Unicast Hub MEP. If you subsequently delete the remote MEP, the Operational MAC Address of the configured Unicast Hub MEP will also be cleared.
You can add only one entry to the remote MEP list for a 7705 SAR.

If a local MEP and the corresponding remote MEP are on the same OmniSwitch, deleting the remote MEP results also deletes the corresponding local MEP.

Perform the following:

1. Click on the Remote MEP tab. The Remote MEP (Create) form opens.
2. Configure the required parameters.

   See the MEP ID parameter description for additional information and constraints when configuring a remote MEP to act as a unicast CCM hub.
3. Save your changes.
4. You can also convert an existing remote MEP on this list that was previously automatically discovered to a static remote MEP by clicking the entry's Auto Discovered Remote Mep checkbox. The Remote MEP (Edit) form for that entry opens with the General tab displayed.
5. Disable the Auto Discovered Remote Mep checkbox and click OK. The Remote MEP (Edit) form closes.

13

Save your changes.

Add an unmanaged remote MEP to the Global MEG

14

To add an unmanaged remote MEP to the Global MEG:

1. Click on the Unmanaged Remote MEP tab and click Create. The Unmanaged Remote MEP (Create) form opens.
2. Configure the required parameters.
3. Select a MEG Sub-Group to associate the unmanaged remote MEP.

   Note:

   If a MEG sub-group is not selected, the unmanaged remote MEP is automatically associated with the default MEG subgroup.

   The outline color of a MEP icon indicates the MEG subgroup to which the MEP belongs.
4. Configure the required parameters in the Test Generation Options panel. The following considerations apply:
   - The Role, Use as Test Source, and Use as Test Target parameters are configurable only when you set the Direction parameter to Up.
   - You can only configure Test Generation Options when the unmanaged MEP has a MAC address.
   - You can propagate test generation role settings to all MEPs on a SAP or service site using the Propagate to MEPs button on the ETH-CFM tab of the Access Interface and Site (Edit) forms.
5. Save your changes.

15

Click Synchronize Remote MEPs to distribute the MEPs to the NEs, if required.

Note: If the managed MEP or unmanaged remote MEP belongs to a MEG sub-group, the remote MEP synchronization will only occur within the MEG sub-group.

16

Click Resync Remote MEP DB to re-synchronize the Remote MEPs database, if required.

Optionally, you can also view the DB state of any Remote MEP under a Managed MEP. Otherwise, go to Step 17 .

1. Click on the Managed MEP tab in the Global MEG form, select a Managed MEP, and click Properties. The MEP (Edit) form opens.
2. Click on the Remote MEP DB State tab, select a Remote MEP, and click Properties. The Remote MEP DB State (View) form opens, with the General tab displayed.

   The presented information includes:

   - MEP ID
   - Remote State
   - Grace Period RX
   - MAC Address
   - Rdi
   - Port Status
   - Interface Status
   - Last CCM

17

Click the Audit Unicast CCM item in the More Actions menu to automatically populate all the Hub pointers, if required.

Note: For discovered networks with CCM and a remote MEP list configured, Nokia highly recommends the use of this button to set up a correct HUB-spoke topology in NFM-P before executing a CCM test.
The Audit Unicast CCM action will use the remote lists from all NEs to automatically set the Hub MEP pointers to the appropriate MEPs. If an appropriate MEP is not found, an unmanaged MEP with MEP ID and MEP MAC Address matching the unicast remote MEP entry will be created. The Hub MEP pointer is then set to this unmanaged MEP.
If duplicate managed and unmanaged MEPs are detected, the unmanaged MEP is deleted and the managed MEP is used as the unicast Hub MEP. This action also ensures that the Hub MEP is in the same sub-group as the spoke pointing to it.

18

Save your changes and close the forms.

END OF STEPS

91.16 To automatically create identical MEPs on a redundant pair of service SAPs

91.16.1 LAG creation reference

See 13.16 “To create a LAG” (p. 431) for information on creating LAGs. See Chapter 43, “MC LAG groups” for more information about creating MC-LAGs.

91.16.2 Steps

Perform this procedure to create identical MEPs on service SAPs that are part of an MC-LAG. The procedure assumes that the service has been configured with MC-LAGs and redundant SAPs. The pair of redundant SAPs must have identical inner and outer encapsulations configured and they must be in the same service.

1

Select Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select a service and click Topology View. The Service Topology map opens.

3

Select the OAM check box at the bottom left of the map window. MEG and MEP objects are added to the map.

4

Perform one of the following:

a. If you are creating a Global MEG:

1. Right-click on the topology map background and select Create CFM Global MEG. The Global Maintenance Entity Group (Create) form opens. See 91.15 “To configure an Ethernet CFM MD policy and subordinate objects” (p. 3109) for information about configuring a Global MEG.
2. When the Global MEG is created, a purple triangular MEP icon appears above each of the SAPs. Right-click on one of the MEP icons associated with the redundant pair of SAPs. The MEP (Edit) form for that SAP opens.
3. Click Properties in the Redundancy panel.

   This action automatically populates the Properties page of the redundant partner, creating identical MEPs on both members of the redundant pair. Leave the MEP (Edit) form open.
4. Right-click on the other MEP icon associated with the redundant pair of SAPs. The MEP (Edit) form for that SAP opens.
5. Confirm that the ID and Operational Mac Address parameters in the Redundant MEP panel for both MEPs are identical.

   Note:

If the redundant SAPs are in a VPRN or IES service, only the ID parameter will be synchronized between the two SAPs. MAC addresses are not supported for these services.

b. If you are working with an existing Global MEG where a MEP is missing from one of the SAPs in a redundant pair:

1. Right-click on the MEP icon that is present for a SAP in the redundant pair. The MEP (Edit) form for that SAP opens.
2. Enable the Create Redundant MEP check box in the Redundancy panel and click Apply. A new MEP icon appears above the other SAP of the redundant pair.

   This action automatically populates the Properties page of the redundant partner which was missing its MEP, thereby creating identical MEPs on both members of the redundant pair. Leave the MEP (Edit) form open.
3. Right-click on the new MEP icon. The MEP (Edit) form for that SAP opens.
4. Confirm that the ID and Operational Mac Address parameters in the Redundant MEP panel for both MEPs are identical.

   Note:

   If the redundant SAPs are in a VPRN or IES service, only the ID parameter will be synchronized between the two SAPs. MAC addresses are not supported for these services.

5

Save your changes and close the forms.

END OF STEPS

91.17 To change the MEG sub-group association for managed MEPs or unmanaged remote MEPs

91.17.1 Steps

Note: The outline color of a MEP icon indicates the MEG sub-group to which the MEP belongs.

1

Select Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select a service and click Topology View. The Service Topology map opens.

3

Select the OAM check box at the bottom left of the map window. MEG and MEP objects are added to the map.

4

Right-click on the interface object that includes the MEP that you wish to move to another MEG sub-group and choose Ethernet CFM→Edit MEP. The Select MEP (Edit) form opens.

5

In the MEG Sub-Group panel, click Clear to remove the current MEG sub-group association.

6

Select a MEG sub-group.

7

Save your changes and close the form.

END OF STEPS

91.18 To configure a default MD on an OmniSwitch

91.18.1 Steps

1

On the equipment tree, expand an OmniSwitch NE icon, right-click on the device and select Properties. The Network Element (Edit) form opens with the General tab displayed.

2

Click on the Globals tab and on the CFM tab.

3

Configure the required parameters.

4

Save your changes and close the form.

END OF STEPS

91.19 To create and run a Global MEG OAM diagnostic test from the STM

91.19.1 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose Ethernet CFM→Create Global MEG. The Global Maintenance Entity Group, Test (Create) form opens.

3

Configure the required general parameters.

4

Perform one of the following:

a. To choose an existing MD, select an MD in the Maintenance Domain panel.

b. To create a new MD:

1. Click Create. The Maintenance Domain, Global Policy (Create) form opens.
2. Configure the required parameters.
3. Save the changes, close the form and select the MD you created.

5

Configure the required parameters in the Maintenance Entity Group panel.

If you select icc-based as the Name Format, the associated Name value must be 8 to 13 characters.

6

Configure the required parameters in the Initial MEG Configuration panel.

When you are creating a Global MEG for a 7750 SR-c4, 7750 SR-c12, or 7450 ESS-6, the Initial CCM Interval must be set to 1s.

You can only configure the Initial CFM Hold Down Timer (Centiseconds) parameter when the Initial CCM Interval is set to 10 ms or 100 ms.

When the Initial CCM Interval parameter is set to 10 ms or 100 ms, you cannot configure automatic MEP creation.

7

As required, associate a Service to the Global MEG. Perform Step 7 of 91.15 “To configure an Ethernet CFM MD policy and subordinate objects” (p. 3109) .

8

As required, add an Ethernet path to the Global MEG. Perform Step 8 of 91.15 “To configure an Ethernet CFM MD policy and subordinate objects” (p. 3109) .

9

As required, add a managed MEP to the Global MEG. Perform Step 10 of 91.15 “To configure an Ethernet CFM MD policy and subordinate objects” (p. 3109) .

10

Save the changes and close the form.

11

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

END OF STEPS

91.20 To create and run a Continuity Check OAM diagnostic test from the STM

91.20.1 Steps

Note: The NFM-P automatically creates a Continuity Check OAM diagnostic test when you create an MD and global MEG. You can execute an automatically created test using the STM, or from the Tests tab of a MEG.

If a service is modified after you associate it with an MD, you must manually add new MEPs; for example, when a new site is added.

If a continuity check test is running on a service when you add a new MEP to the service, you must stop the test and execute it again to make the new MEP active.

When a service is modified after a continuity check is created, you must manually add a virtual MEP to the site; for example, when a new B-VPLS site is added to the service.

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose Ethernet CFM→Create Continuity Check. The CFM Continuity Check Test (Create) form opens.

3

Configure the required parameters.

4

Select a MEG in the Maintenance Entity Group panel.

5

Configure the Duration (minutes) parameter in the Connectivity Check Timer panel.

6

If you are configuring the test for a 7705 SAR, configure the required parameters in the Initial Dual Ended Loss Test Options panel.

7

Save the changes and close the form.

8

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

END OF STEPS

91.21 To create and run a CFM loopback OAM diagnostic test from the STM

91.21.1 Steps

Note: The maximum number of continuous CFM loopback tests that can be executed is 300, provided that the SAA packet per second rate of 200 pps is not exceeded. The total number of continuous tests must share this maximum rate of 200 pps.

You can also run this test contextually for VPLS, Epipe, and Composite services. See 90.43 “To configure and run OAM tests contextually” (p. 3053) for more information.

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose Ethernet CFM→CFM Loopback. The CFM Loopback Test (Create) form opens.

3

Configure the required parameters.

4

Select a global MEG next to the Global ID parameter.

5

Select the originating MEP next to the ID parameter.

6

To select the test destination using the target MEP ID:

1. Enable the Enable Target MEP ID parameter.
2. Configure the Target MEP ID parameter or select the target MEP ID to choose the destination MEP.

   Note:

   MEP ID selection is only supported for OmniSwitch NEs. The NE Schedulable parameter must be enabled in Step 3 .

7

In the MEP Transmit Information panel, choose one of the following for the service destination test endpoint:

a. Select a MEP, MIP, or Unmanaged MEP for the Target MAC Address parameter.

Note: You must select a Maintenance Entity Group ID and Originating MEP prior to configuring this parameter for the Select buttons to function.

Note: The MIP selection is not supported for OmniSwitch NEs.

b. Click the Enable Target MEP ID checkbox if you want to specify a remote Maintenance Entity Point ID (MEP ID) endpoint.

Note: With both options, you have the choice to either enter a value manually for the Target MEP ID or Target MAC Address parameter or use the selected value.

8

If you enabled the NE Schedulable parameter in Step 3 , go to Step 9 . Otherwise, configure the MEP Transmit LBM Information parameters.

9

Click on the Test Parameters tab and configure the required parameters.

The Probe History parameter is only configurable when the NE Schedulable parameter is enabled.

10

Click on the Results Configuration tab and configure the required parameters.

The Trap Generation parameter is only configurable when the Accounting Files parameter is disabled.

The Test Result Storage parameter is only configurable when the Accounting Files parameter is enabled.

11

Save the changes and close the form.

12

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

END OF STEPS

91.22 To create and run a CFM link trace OAM diagnostic test from the STM

91.22.1 Steps

Note: The maximum number of continuous CFM link trace tests that can be executed is 300, provided that the SAA packet per second rate of 200 pps is not exceeded. The total number of continuous tests must share this maximum rate of 200 pps. However, it is recommended that the number of continuous CFM link trace tests executed be kept well below the maximum allowed limit.

You can also run this test contextually for VPLS, Epipe, and Composite services. See 90.43 “To configure and run OAM tests contextually” (p. 3053) for more information.

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose Ethernet CFM→CFM Link Trace. The CFM Link Trace (Create) form opens.

3

Configure the required parameters.

If you enable the NE Schedulable parameter, two additional tabs are displayed for the form: Test Parameters and Results Configuration.

4

Select a global MEG in the Test Object panel.

5

Select an originating MEP in the Test Object panel.

Note: MEPs can be added to services automatically or manually. If no MEPs are listed when you perform this step, see “Ethernet CFM” (p. 3089) for information about how to configure a MEP that is required for this step.

6

In the MEP Transmit Information panel, choose one of the following for the service destination test endpoint:

a. Select a MEP, MIP, or Unmanaged MEP for the Target MAC Address parameter.

Note: You must select a Maintenance Entity Group ID and Originating MEP prior to configuring this parameter for the Select buttons to function.

Note: The MIP selection is not supported for OmniSwitch NEs.

b. Click the Enable Target MEP ID checkbox if you want to specify a remote Maintenance Entity Point ID (MEP ID) endpoint.

Note: With both options, you have the choice to either enter a value manually for the Target MEP ID or Target MAC Address parameter or use the selected value.

7

If you enabled the NE Schedulable parameter in Step 3 , go to Step 8 . Otherwise, configure the MEP Transmit LBM Information parameters.

8

Click on the Test Parameters tab and configure the REQUIRED parameters.

The Probe History parameter is only configurable when the NE Schedulable parameter is enabled.

9

Click on the Results Configuration tab and configure the required parameters.

The Trap Generation parameter is only configurable when the Accounting Files parameter is disabled.

The Test Result Storage parameter is only configurable when the Accounting Files parameter is enabled.

10

Save the changes and close the form.

11

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

END OF STEPS

91.23 To create and run a CFM Eth OAM diagnostic test from the STM

91.23.1 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose Ethernet CFM→CFM Eth Test. The CFM Eth Test (Create) form opens.

3

Configure the required parameters.

4

Select a global MEG in the Test Object panel.

5

Select an originating MEP in the Test Object panel.

Note: MEPs can be added to services automatically or manually. If no MEPs are listed when you perform this step, see “Ethernet CFM” (p. 3089) for information about how to configure a MEP that is required for this step.

6

In the MEP Transmit Information panel, choose one of the following for the service destination test endpoint:

a. Select a MEP, MIP, or Unmanaged MEP for the Target MAC Address parameter.

Note: You must select a Maintenance Entity Group ID and Originating MEP prior to configuring this parameter for the Select buttons to function.

Note: The MIP selection is not supported for OmniSwitch NEs.

b. Click the Enable Target MEP ID checkbox if you want to specify a remote Maintenance Entity Point ID (MEP ID) endpoint.

Note: With both options, you have the choice to either enter a value manually for the Target MEP ID or Target MAC Address parameter or use the selected value.

7

Configure the MEP Transmit LBM Information parameters.

8

Save the changes and close the forms.

9

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

END OF STEPS

91.24 To create and run a CFM two way delay OAM diagnostic test from the STM

91.24.1 Steps

Note: The maximum number of continuous CFM two way delay tests that can be executed is 300, provided that the SAA packet per second rate of 200 pps is not exceeded. The total number of continuous tests must share this maximum rate of 200 pps.

You can also run this test contextually for VPLS, Epipe, and Composite services. See 90.43 “To configure and run OAM tests contextually” (p. 3053) for more information.

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose Ethernet CFM→CFM Two Way Delay Test. The CFM Two Way Delay Test (Create) form opens.

3

Configure the required parameters.

If the NE Schedulable parameter is enabled, two additional tabs are displayed for the form, Test Parameters and Results Configuration.

4

Select a global MEG in the Test Object panel.

5

Select an originating MEP in the Test Object panel.

Note: MEPs can be added to services automatically or manually. If no MEPs are listed when you perform this step, see “Ethernet CFM” (p. 3089) for information about how to configure a MEP that is required for this step.

6

To select the test destination using the target MEP ID:

1. Enable the Enable Target MEP ID parameter.
2. Configure the Target MEP ID parameter or select the target MEP ID to choose the destination MEP.

   Note:

   MEP ID selection is only supported for OmniSwitch NEs. The NE Schedulable parameter must be enabled in Step 3 .

7

In the MEP Transmit Information panel, choose one of the following for the service destination test endpoint:

a. Select a MEP, MIP, or Unmanaged MEP for the Target MAC Address parameter.

Note: You must select a Maintenance Entity Group ID and Originating MEP prior to configuring this parameter for the Select buttons to function.

Note: The MIP selection is not supported for OmniSwitch NEs.

b. Click the Enable Target MEP ID checkbox if you want to specify a remote Maintenance Entity Point ID (MEP ID) endpoint.

Note: With both options, you have the choice to either enter a value manually for the Target MEP ID or Target MAC Address parameter or use the selected value.

8

If you enabled the NE Schedulable parameter in Step 3 , go to Step 9 . Otherwise, configure the MEP Transmit LBM Information parameters.

9

If the NE Schedulable parameter was enabled in Step 3 , go to Step 11 . Otherwise, go to Step 10 .

10

Configure the MEP Transmit DMM Information VLAN Priority parameter. Go to Step 13 .

11

Click on the Test Parameters tab and configure the required parameters.

The Probe History parameter is only configurable when the NE Schedulable parameter is enabled.

12

Click on the Results Configuration tab and configure the required parameters.

The Trap Generation parameter is only configurable when the Accounting Files parameter is disabled.

The Test Result Storage parameter is only configurable when the Accounting Files parameter is enabled.

13

Save the changes and close the forms.

14

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

End of steps

91.25 To create and run a CFM one-way delay OAM diagnostic test from the STM

91.25.1 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose Ethernet CFM→CFM One Way Delay Test. The CFM One Way Delay Test (Create) form opens.

3

Configure the required parameters.

4

Select a global MEG in the Test Object panel.

5

Select an originating MEP in the Test Object panel.

Note: MEPs can be added to services automatically or manually. If no MEPs are listed when you perform this step, see “Ethernet CFM” (p. 3089) for information about how to configure a MEP that is required for this step.

6

In the MEP Transmit Information panel, choose one of the following for the service destination test endpoint:

a. Select a MEP, MIP, or Unmanaged MEP for the Target MAC Address parameter.

Note: You must select a Maintenance Entity Group ID and Originating MEP prior to configuring this parameter for the Select buttons to function.

Note: The MIP selection is not supported for OmniSwitch NEs.

b. Click the Enable Target MEP ID checkbox if you want to specify a remote Maintenance Entity Point ID (MEP ID) endpoint.

Note: With both options, you have the choice to either enter a value manually for the Target MEP ID or Target MAC Address parameter or use the selected value.

7

Configure the Priority parameter in the MEP Transmit LBM Information panel.

8

Save the changes and close the forms.

9

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

End of steps

91.26 To create and run a CFM single-ended loss OAM diagnostic test from the STM

91.26.1 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose Ethernet CFM→CFM Single Ended Loss Test. The CFM Single Ended Loss Test (Create) form opens.

3

Configure the required parameters.

4

Select a global MEG in the Test Object panel.

5

Select an originating MEP in the Test Object panel.

Note: MEPs can be added to services automatically or manually. If no MEPs are listed when you perform this step, see “Ethernet CFM” (p. 3089) for information about how to configure a MEP that is required for this step.

6

To select a MEP as the test destination, click Select MEP.

7

Configure the required parameters in the MEP Transmit LMM Information panel.

8

Save the changes and close the forms.

9

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

END OF STEPS

91.27 To create and run a CFM two way SLM OAM diagnostic test from the STM

91.27.1 Steps

Note: The maximum number of continuous CFM two way SLM tests that can be executed is 300, provided that the SAA packet per second rate of 200 pps is not exceeded. The total number of continuous tests must share this maximum rate of 200 pps.

You can also run this test contextually for VPLS, Epipe, and Composite services. See 90.43 “To configure and run OAM tests contextually” (p. 3053) for more information.

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose Ethernet CFM→CFM Two Way SLM. The CFM Two Way SLM Test (Create) form opens

3

Configure the required parameters.

If the NE Schedulable parameter is enabled, two additional tabs are displayed for the form, Test Parameters and Results Configuration.

4

Select a global MEG in the Test Object panel.

5

Select an originating MEP in the Test Object panel.

Note: MEPs can be added to services automatically or manually. If no MEPs are listed when you perform this step, see “Ethernet CFM” (p. 3089) for information about how to configure a MEP that is required for this step.

6

To select the test destination using the target MAC Address:

a. To select a MEP as the test destination, click Select MEP.

b. To select a MIP as the test destination, click Select MIP.

Note: MIP selection is not supported for OmniSwitch NEs.

c. To select an unmanaged MEP as the test destination, click Select Unmanaged MEP.

7

If the NE Schedulable parameter was not enabled in Step 3 , configure the REQUIRED parameters in the MEP Transmit SLM Information panel and go to Step 10 . Otherwise, go to Step 8 .

8

Click on the Test Parameters tab and configure the required parameters.

The Probe History parameter is only configurable when the NE Schedulable parameter is enabled.

9

Click on the Results Configuration tab and configure the required parameters.

The Trap Generation parameter is only configurable when the Accounting Files parameter is disabled.

The Test Result Storage parameter is only configurable when the Accounting Files parameter is enabled.

10

Save the changes and close the forms.

11

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

END OF STEPS

91.28 To create and run a CFM LM OAM diagnostic test from the STM

91.28.1 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager form opens.

2

Click Create and choose Ethernet CFM→CFM LM Test. The CFM LM Test (Create) form opens.

3

Configure the required parameters.

4

Disable the NE Schedulable parameter.

5

Select a global MEG in the Test Object panel.

6

Select an originating MEP in the Test Object panel.

Note: MEPs can be added to services automatically or manually. If no MEPs are listed when you perform this step, see “Ethernet CFM” (p. 3089) for information about how to configure a MEP that is required for this step.

7

To select the test destination using the target MAC Address:

a. To select a MEP as the test destination, click Select MEP.

b. To select a MIP as the test destination, click Select MIP.

Note: MIP selection is not supported for OmniSwitch NEs.

c. To select an unmanaged MEP as the test destination, click Select Unmanaged MEP.

8

Configure the required parameters in the MEP Transmit LM Information panel.

9

Save the changes and close the forms.

10

To run the OAM diagnostic test and view the results, perform 89.15 “To run one or more OAM diagnostic tests from the STM and view the test results” (p. 2959) . See 89.20 “To interpret OAM diagnostic test results on the STM” (p. 2964) for information about how to interpret the test results.

END OF STEPS

92 Performance Monitoring tests

92.1 Overview

92.1.1 Purpose

This chapter describes PM (Performance Monitoring) OAM diagnostic tests, and provides information about configuring and performing PM diagnostic tests.

92.1.2 Contents

PM testing overview

92.2 PM session tests

92.2.1 Introduction

This section describes NFM-P supported PM OAM diagnostic test functionality. Unless noted, all tests are accessible from the STM. See Table 90-1, “NFM-P supported OAM diagnostic tests and configurations” (p. 2981) for a list of all supported OAM diagnostic tests and their applicable procedures.

92.2.2 PM session test support and configuration

The NFM-P supports PM session tests for Ethernet CFM, IP TWAMP Light, and MPLS DM.

You can configure PM session related objects from several areas in the NFM-P, including:

- STM; see 92.6 “To configure a PM session OAM diagnostic test from the STM” (p. 3146)
- Service Topology maps; see 4.2.3 “Working with Ethernet CFM objects” (p. 177)
- Layer 3 routing instances for IP-based PM sessions; see 27.2 “To configure a routing instance or a VRF instance” (p. 826)
- VPRN service site form for IP-based PM sessions; see 79.76 “To create a TWAMP Light reflector on a VPRN site” (p. 2647)
- VPRN service form (OAM tab→TWAMP sub-tab) for IP-based PM sessions. Perform the required steps in this procedure to create a PM session and then perform 92.12 “To configure a TWAMP Light session OAM diagnostic test from the STM” (p. 3154) to create a TWAMP Light test session.
- Dynamic LSP properties form for MPLS DM PM sessions (for dynamic LSP types only); see 31.13 “To configure a Dynamic or segment routing TE LSP” (p. 1132) .

Ethernet CFM

PM session CFM testing is based on Metro Ethernet Forum Specification 35 - Service OAM Performance Monitoring Implementation Agreement, which details a standardized method to test and report network delay and loss using CFM messaging. This testing is performed in Layer 2 networks.

TWAMP IP level monitoring

The PM session testing framework can also be utilized in the IP domain to perform TWAMP (Two-Way Active Measurement Protocol) IP level monitoring, and runs over IPv4 and IPv6 addresses. The TWAMP Light and TCC tests target Layer 3 interfaces. They provide options to monitor IP SLA performance as related to KPI.

The TCA events and their associated statistics can be configured on all PM session test types.

PM session results

Results reporting occurs at standardized measurement intervals (5 minutes, 15 minutes, 1 hour, and 1 day), and comprises statistical summaries of individual test frame results. Statistical

summaries include minimum, maximum, and average values of specific test criteria. SNMP-mediated statistics can be collected to display real-time results for in-progress measurement intervals. Additionally, a histogram can be generated to characterize the distribution of test results over the same measurement intervals. Statistics can be viewed using the individual test forms, the STM, or the Statistics Manager.

PM session test suite support

While PM session tests may be configured individually, test suite support allows for repeatable, policy driven auto-generation of PM sessions and associated tests, which are ideally suited to larger scale environments. See 89.12 “To create an STM test suite” (p. 2951) for information about how to configure PM session tests as part of an STM test suite.

92.2.3 CFM DMM session test

For CFM DMM (Delay Measurement Message) tests, calculations are made to report on three criteria: frame delay, frame delay range, and interframe delay variation. DMM test frames are issued at regular intervals from a source MEP. Delay measurement information for the forward, backward, and round trip path is determined from the DMR frames received from the destination MEP.

See 92.7 “To configure a CFM DMM session OAM diagnostic test from the STM” (p. 3149) for information about configuring a CFM DMM test.

92.2.4 CFM SLM session test

The CFM SLM (Synthetic Loss Measurement) session test is an extension of the Y.1731 standard that provides a method of exchanging transmit and receive counters to determine frame loss between a MEP and the destination MAC address or remote MEP ID of another node in the network. This test is used to verify MEP-MEP connectivity in the network and can be used to approximate the frame loss of actual data traffic. CFM SLM session tests measure frame loss using synthetic frames, rather than data traffic. Frame loss is measured by calculating the difference between the number of synthetic frames that are sent and received.

See 92.8 “To configure a CFM SLM session OAM diagnostic test from the STM” (p. 3150) for information about configuring a CFM SLM session test.

92.2.5 CFM LMM session test

The CFM LMM (Loss Measurement Message, single-ended) session test is a method of exchanging transmit and receive counters between peer MEPs to determine exact loss on a point-to-point Ethernet virtual circuit.

Note: LMM tests are limited to MEPs in the Down direction only. The following validations are performed:

- The LMM test suite tests can only be created or executed for MEG subgroups with exactly two MEPs.
- The LMM test suite tests can only be executed if the source and target MEPs are not already the source or target MEPs (respectively) of a currently running LMM test.

See 92.9 “To configure a CFM LMM session OAM diagnostic test from the STM” (p. 3151) for information about configuring a PM CFM LMM test.

92.2.6 TWAMP Light session test

The TWAMP Light session test targets Layer 3 interfaces and requires a TWAMP reflector in order to execute properly. See 92.11 “To configure a TWAMP Light reflector” (p. 3153) .

You can configure a TWAMP Light session test on the following network objects:

- STM; see 92.12 “To configure a TWAMP Light session OAM diagnostic test from the STM” (p. 3154)
- VPRN service site; see 79.76 “To create a TWAMP Light reflector on a VPRN site” (p. 2647)
- Base routing instance; see 27.2 “To configure a routing instance or a VRF instance” (p. 826)

92.2.7 TCC test

A TWAMP server is a combination of control server and session reflector, but requires an external probe called the TWAMP controller (testing head). The TWAMP Light test supports both a session sender and session reflector. TWAMP Light does not have a separate control plane, and the session reflector is configured in the NFM-P.

The TCC (TWAMP and TWAMP Light Control Client) test allows a TWAMP Light NE launch point (base router) to test TWAMP functionality against any TWAMP server that does not support TWAMP Light. The NFM-P creates the required TCP control channel with the TWAMP server, as well as the PM sessions and tests on the TWAMP Light launch point. The NFM-P also provides a report on a managed TWAMP server's capabilities (based on SNMP queries), which is accessible on the Globals→OAM sub-tab of the NE's properties form.

For managed RFC5938–compliant TWAMP servers, individual session control allows start and stop control messaging. This permits the client to define new tests and to start or stop specific tests while the TWAMP connection is active. The following operational points apply:

- When executing a test, a Supports Individual Test Control indicator on the General tab dynamically reports on server RFC5938 compliance.
- The Execute All and Stop All buttons at the bottom of the form affect all of the test sessions.
- Selective test session control is performed on the TWL Session tab, using the Execute or Stop Test Execution buttons at the right side of the form. Selected sessions must be administratively enabled to allow stopping and administratively disabled to start. A test's administrative status can be configured on its properties form, available from this tab.

See 92.13 “To configure a TCC OAM diagnostic test from the STM” (p. 3155) for information about configuring a TCC test.

92.2.8 MPLS DM session test

The MPLS DM (Delay Measurement) session test is based on RFC 6374, and provides calculations for LSPs for frame delay, frame delay range, and interframe delay variation. Measurements are one-way for dynamic RSVP and RSVP-auto LSP types, and round-trip for MPLS-TP Static LSP types. Test frame intervals are configurable from 1000 to 8000 ms, in 1000 ms increments. As a security feature, a global setting in the NE properties must be enabled for test packets to be transmitted or reflected.

See 92.10 “To configure an MPLS DM session OAM diagnostic test from the STM” (p. 3152) for information about configuring an MPLS DM test.

Workflow to configure and perform performance monitoring testing

92.3 PM diagnostic test workflow

92.3.1 Stages

This workflow outlines the procedures that describe how to configure, manage, and perform PM OAM diagnostic tests, as well as how to view the results the tests generate. PM tests are typically configured through the Service Test Manager. See Chapter 89, “Service Test Manager” for more information on working with the STM. You can also configure some PM-related objects from the Service Topology map. See 4.2.3 “Working with Ethernet CFM objects” (p. 177) in Chapter 4, “Topology map management” .

1

If the PM diagnostic test being configured is part of an STM test policy or STM test suite, review the STM chapter workflow to determine any prerequisite configuration requirements. See Chapter 89, “Service Test Manager” for more information on the STM.

2

Create and distribute a PM bin group policy that configures the statistical bins used by the various PM tests to collect their data. Perform 92.4 “To configure a PM bin group policy” (p. 3144) .

3

Create and distribute a new accounting policy, required to configure a PM session. Choose “Complete-PM” for the Type parameter. See “To configure an accounting policy” in the *NSP NFM-P Statistics Management Guide* for information on creating an accounting policy. See 49.6 “To release and distribute a policy” (p. 1476) for information on distributing a policy.

4

Configure a TWAMP Light reflector; see 92.11 “To configure a TWAMP Light reflector” (p. 3153). This is only required for proper operation of a PM TWAMP Light test session.

5

Configure a PM session to provide the session framework; see 92.6 “To configure a PM session OAM diagnostic test from the STM” (p. 3146) .

6

To generate accounting statistics, associate the accounting policy to the PM session. If the accounting policy is not associated with the PM session, the test results will be collected as performance statistics.

To associate the accounting policy with the PM Session:

1. Click Tools→Service Test Manager (STM) on the NFM-P main menu. The Service Test Manager (STM) form opens.
2. Select a PM Session and click Properties. The PM Session (Edit) form opens.
3. Click on the Components tab.
4. Right-click on Measurement Intervals and choose Create. The Measurement Interval (Create) form opens.
5. In the Accounting Policy panel, click Select and choose a policy.
6. Click OK.
7. Close the open forms.

7

As required, configure one of the following PM diagnostic tests:

- CFM DMM session test; see 92.7 “To configure a CFM DMM session OAM diagnostic test from the STM” (p. 3149) .
- CFM SLM session test; see 92.8 “To configure a CFM SLM session OAM diagnostic test from the STM” (p. 3150) .
- CFM LMM session test; see 92.9 “To configure a CFM LMM session OAM diagnostic test from the STM” (p. 3151) .
- MPLS DM session test; see 92.10 “To configure an MPLS DM session OAM diagnostic test from the STM” (p. 3152).
- TWAMP Light session test; see 92.12 “To configure a TWAMP Light session OAM diagnostic test from the STM” (p. 3154) .
- TCC test; see 92.13 “To configure a TCC OAM diagnostic test from the STM” (p. 3155) .

8

Create an STM test policy, specifying at least one PM diagnostic test definition.

See 89.10 “To configure an STM test policy” (p. 2947) for more information.

9

Create an STM test suite; see 89.12 “To create an STM test suite” (p. 2951).

10

As required, execute the generated PM test suite; see 89.17 “To execute an STM test suite” (p. 2961) .

11

As required, view and compare PM diagnostic test results:

- From a specific PM diagnostic test form; see92.14 “To collect and view PM statistics from a test form” (p. 3156) .
- From the STM; see92.15 “To view PM test results in the STM” (p. 3157) .
- From the Statistics Manager; see92.16 “To view PM test statistics in the Statistics Manager” (p. 3159) .
- For OAM PM event server performance statistics; see92.17 “To view OAM PM Event server performance statistics” (p. 3160) .
- To view STM test suite results; see 89.18 “To view STM test suite results” (p. 2962) .
- To view and compare STM test suite results; see 89.18 “To view STM test suite results” (p. 2962) .

92.3.2 Hardware configuration requirements

The PM session testing functionality requires the following hardware configurations to operate properly:

- Platform: 7750 SR 7/12, 7450 ESS 7/12, 7750 SRc 4/12 and 7950 XRS all require CPM3 or above for binning. The 7705 SAR does not support the creation of PM session tests.
- IOM support: IOM3/IMM and above
- Chassis mode: All SAPs executing this function must reside on IOM3/IMM and above. However, not every SAP in an affected service needs to be configured on IOM3/IMM or above. All active network ports on the affected NE must exist only on IOM3/IMM and above. The term given to this mode of operation is Network Chassis Mode D.

92.3.3 Recording test results

In addition to the procedures for viewing the OAM PM test results, you can also use the LogToFile method to record test results for transfer to external OSS applications. See the *NSP NFM-P XML API Developer Guide* for more information.

Procedures to configure and perform PM testing

92.4 To configure a PM bin group policy

92.4.1 General information

You must configure and distribute a PM bin group policy to define the structure of the statistical bins and delay counts used to collect statistical data by the various PM session tests.

92.4.2 Steps

1

Click Tools→PM Bin Group Policies on the NFM-P main menu. The PM Bin Group Policies form opens.

2

Click Create or select an existing bin group and click Properties. The Bin Group (Create|Edit) form opens.

3

Configure the required parameters.

4

Click on the Bins tab. A list of pre-configured default bins is displayed.

1. Click Create or select an existing bin object and click Properties. The Bin (Create|Edit) form opens.
2. Configure the required parameters.
3. Save your changes and close the form.

5

Click on the Delay-events tab to collect TCA event statistics.

1. Select a Bin Type from the list and click Properties. The TCA Config form opens.
2. Configure the required parameters.

   As an example of the bin exclusion logic, if you configure the Lowest Bin = 4, the Lowest Bin to Exclude = Bin 5, and enable Bin 0 and Bin 6 in the Excluded Bins for Average block, then the following will occur:

   - Bins 5 and 6 will be excluded from triggering a threshold crossing alarm for this Bin Group.
   - Bins 0 and 6 will be excluded when the calculation of average delay is performed for an OAM-PM measurement interval.
3. Save your changes and close the form.

6

Click OK to save the policy and close the form, or click Apply to save the policy.

7

Perform 49.6 “To release and distribute a policy” (p. 1476) to associate the policy to NEs.

END OF STEPS

92.5 To configure a streaming delay template

92.5.1 Before you begin

Streaming delay templates are associated under CFM DMM, MPLS DM, and TWAMP Light sessions to allow telemetry to collect PM streaming via gNMI.

92.5.2 Steps

1

Click Tools→OAM Templates→Streaming Delay Template on theNFM-P main menu. The Streaming Delay Template form opens.

2

Click Create, or select an existing template and click Properties. The Streaming Delay Template, Global Policy (Create|Edit) form opens.

3

Configure the required parameters.

4

Create streaming metrics.

1. Click the Streaming Delay Metrics tab and click Create. The Streaming Measurement (Create) form opens.
2. Configure the required parameters.
3. Save your changes and close the form.

5

Click OK to save the template and close the form, or click Apply to save the template.

6

Associate the template to a CFM DMM, MPLS DM, or TWAMP Light session by setting the Streaming Delay Template parameter on the associated session test configuration form.

END OF STEPS

92.6 To configure a PM session OAM diagnostic test from the STM

92.6.1 Steps

Configure the PM session framework

1

Click Tools→Service Test Manager (STM) on the NFM-P main menu. The Service Test Manager (STM) form opens.

2

Click Create→Performance Monitoring→PM Session or select an existing PM session and click Properties. The PM Session (Create|Edit) form opens.

Note: A bin group with ID 1 must exist before you can create a PM session. See 92.4 “To configure a PM bin group policy” (p. 3144) for information about creating bin groups.

3

Configure the required parameters.

If you configure the Test Family Type as IP, then you can also select an existing TCC test in the TWAMP panel. See 92.13 “To configure a TCC OAM diagnostic test from the STM” (p. 3155) for information on configuring a TCC test.

4

Select a System ID in the Network Element panel.

If you are creating a PM session from a Routing Instance form, the Network Element System ID is automatically populated.

5

Select a Bin Group policy in the Bin Group panel.

6

Depending on the Test Family Type selected in Step 3, perform one of the following:

a. Click on the Ethernet Session tab.
   1. Configure the Priority parameter.
   2. Select a Maintenance Entity Group ID in the Source (Controller) MEP information panel.
   3. Choose an originating MEP using the ID Select button.
   4. In the Destination (Responder) MEP information panel, choose one of the following for the service destination test endpoint:

- Select a MEP, MIP, or Unmanaged MEP for the Target MAC Address parameter.
  Note: You must select a Maintenance Entity Group ID and Originating MEP prior to configuring this parameter for the Select buttons to function.

- Click the Enable Target MEP ID checkbox if you want to specify a remote Maintenance Entity Point ID (MEP ID) endpoint.

  Note: With both options, you have the choice to either enter a value manually for the Target MEP ID or Target MAC Address parameter or use the selected value.

b. Click on the IP Session tab.

1. Configure the IP Session Target Type parameter. If you select the VPRN Service option, you must also select a VPRN service for the selected NE.

   If you are creating a PM session from a VPRN service form, the Service ID is automatically populated. If the PM session is created from the VPRN site context, the Network Element System ID, IP Session Target Type, and VPRN Service ID parameters are automatically configured.

2. Select source and destination IP addresses in the Source and Destination Addresses panel.

   The source IP and destination IP addresses are required to create a working TWAMP Light or TCC test. The source IP address is selected from a list of IP addresses on the NE specified in the VPRN service or routing instance. The destination IP address is selected from all IP addresses that are not configured on the NE in the VPRN service or routing instance. The destination IP address and destination UDP port specify the location of the TWAMP Light reflector that a TWAMP Light test will use. See 92.11 “To configure a TWAMP Light reflector” (p. 3153) for information on creating TWAMP reflectors.

   If you are creating the TWAMP Light or TCC test from a service topology map, the OAM option must be enabled in the map. Selecting two L3 access interfaces automatically populates both the Source IP and Destination IP fields, based on the SAPs you select. Selecting just one SAP populates only the Source IP field.

3. Configure the required parameters in the Session Details panel.

   The Bypass Routing, Egress IF Name, and Next Hop IP parameter are used to determine what kind of forwarding is used. You can only configure one of these parameters.

   The Source UDP Port parameter should only be specified when configuring the PM session for use in a PM TCC test.

   The DSCP Name, DSCP Egress Remark, Do Not Fragment, Use Pattern, Tunnel, and Mpls Tunnel parameters are specified when configuring the PM session for use in a TWAMP Light session test.

c. Click on the MPLS Session tab.

1. Configure the LSP Type parameter.

   The panels and parameters that appear vary depending on the LSP Type selected.

2. Select an LSP in the resulting panel.

   MPLS-TP Static LSPs are bidirectional and allow forward, backward, and round-trip delay metric calculation.

   RSVP and RSVP Auto LSPs require configuration of the Return Address parameter.

3. Configure the parameters in the Details panel.

   The Force Enable MPLS-DM parameter automatically enables transmission of test frames on test NEs, and reflection of test frames on supported destination NEs. If you do not enable the Force Enable MPLS-DM parameter, you must manually enable the

MPLS-DM Admin Status parameter on the NE properties form; see 92.10 “To configure an MPLS DM session OAM diagnostic test from the STM” (p. 3152).

7

Click Apply.

Configure and enable the PM session tests

8

Click on the Components tab.

1. Right-click the Measurement Intervals item and select Create Measurement Interval. The Measurement Interval form opens.

   A PM session test will record results information to a “raw” bin by default. This is a measurement interval with infinite duration. However, one or more finite measurement intervals may also be configured for the same PM session and associated tests. Measurement intervals can be configured as 5 minutes, 15 minutes, 1 hour, or 1 day in length. If you create more than one measurement interval, the Interval Duration must be different for each one.

2. Configure the required parameters.

   The Enable events, Delay Events, and Loss Events parameters are required to collect TCA event statistics. The Loss Events parameter is not configurable for MPLS DM tests.

3. Select an accounting policy.

9

Perform one of the following:

a. If you configured the Test Family parameter in Step 3 for Ethernet, right-click the Test Sessions icon and select one of the following tests from the contextual menu:

   - Create CFM DMM Test Session. Perform 92.7 “To configure a CFM DMM session OAM diagnostic test from the STM” (p. 3149) .
   - Create CFM SLM Test Session. Perform 92.8 “To configure a CFM SLM session OAM diagnostic test from the STM” (p. 3150) .
   - Create CFM LMM Test Session. Perform 92.9 “To configure a CFM LMM session OAM diagnostic test from the STM” (p. 3151) .

   You can create one of each type of these Ethernet tests for a single PM session.

b. If you configured the Test Family parameter in Step 3 for IP, right-click the Test Sessions icon, select Create TWAMP Light Test Session, and perform 92.12 “To configure a TWAMP Light session OAM diagnostic test from the STM” (p. 3154) .

c. If you configured the Test Family parameter in Step 3 for MPLS, right-click the Test Sessions icon, select Create MPLS DM Test Session, and perform 92.10 “To configure an MPLS DM session OAM diagnostic test from the STM” (p. 3152).

10

Save your changes and close the PM Session form.

If the Administrative State of either or both of the test sessions is set to Enabled, the tests will begin to execute automatically when the changes are applied. They continue to run until manually stopped.

Additional operations

11

To stop a test from running, select the test in the STM's PM Session Test (Assurance) list and click Stop Execution. You can also set the Administrative State of a test session to Disabled.

12

To include a PM session in a test policy, perform 89.10 "To configure an STM test policy" (p. 2947) .

13

To include a PM session in a test suite, perform 89.12 "To create an STM test suite" (p. 2951) .

END OF STEPS

92.7 To configure a CFM DMM session OAM diagnostic test from the STM

92.7.1 Steps

1

Click Tools→Service Test Manager (STM) on the NFM-P main menu. The Service Test Manager (STM) form opens.

2

Click Create→Performance Monitoring→CFM DMM Session Test or select an existing CFM DMM session test object and click Properties. The CFM DMM Test Session (Create|Edit) form opens.

3

Configure the required parameters.

4

Select a PM session.

5

To view the bins configured for the test by your choice of PM sessions, perform the following:

1. Click Properties for the selected PM session name. The PM Session (Edit) form opens.
2. Click Properties for the displayed Bin Group Mgr Object ID. The Bin Group (Edit) form opens.
3. Click on the Bins tab.
4. Select the bin you want to view and click Properties. The Bin (Edit) form opens.

6

Save your changes and close the forms.

END OF STEPS

92.8 To configure a CFM SLM session OAM diagnostic test from the STM

92.8.1 Steps

1

Click Tools→Service Test Manager (STM) on the NFM-P main menu. The Service Test Manager (STM) form opens.

2

Click Create→Performance Monitoring→CFM SLM Session Test or select an existing CFM SLM session test object and click Properties. The CFM SLM Test Session (Create|Edit) form opens.

3

Configure the required parameters.

4

Select a PM session.

5

Click on the Loss-events tab to collect TCA event statistics.

1. Select a direction type object and click Properties. The TCA Configuration form opens.
2. Configure the required TCA parameters.

   Note: The Clear threshold should always be lower than the Raise threshold.

6

Save your changes and close the forms.

END OF STEPS

92.9 To configure a CFM LMM session OAM diagnostic test from the STM

92.9.1 Steps

1

Click Tools→Service Test Manager (STM) on the NFM-P main menu. The Service Test Manager (STM) form opens.

2

Click Create→Performance Monitoring→CFM LMM Session Test or select an existing CFM LMM test session object and click Properties. The CFM LMM Test Session (Create|Edit) form opens.

3

Configure the required parameters.

The CFM LMM test must be disabled to make any changes to the session, including the Timing panel options.

When you configure the parameters in the Timing panel, the product of (Interval) x (Frames Per Delta-T) x (Consec Delta-T's) must not exceed 100 seconds.

The Availability parameter governs whether or not the test results will contain the availability information.

4

Select a PM session.

5

Click on the Loss-events tab to collect TCA event statistics.

1. Select a direction type object and click Properties. The TCA Configuration form opens.
2. Configure the required TCA parameters.

   Note: The Clear threshold should always be lower than the Raise threshold.

6

Save your changes and close the forms.

7

To collect LMM statistics, you must set an option to do so on the object with which the MEP is associated. Enable the Enable LMM Session Stats Collection parameter, either on the OAM tab (ETH-CFM sub-tab) or the MEPs tab in the following contexts, as required:

- IES and VPRN L3 access interfaces
- Spoke and Mesh SDP bindings
- IES and VPRN subscriber interfaces

- VLL and VPLS L2 access interfaces
- LAG member ports
- Non-LAG member ports

END OF STEPS

92.10 To configure an MPLS DM session OAM diagnostic test from the STM

92.10.1 Before you begin

Before you can execute an MPLS DM session test, the NE must be enabled to transmit or reflect the test frames. You can enable tests on NEs in the following two ways:

- Manually, by enabling the MPLS-DM Admin Status parameter on the NE properties form, Globals tab, OAM subtab, in the OAM-PM MPLS panel. See 12.5 “To modify NE properties” (p. 343).
- Automatically, by enabling the Force Enable MPLS-DM parameter on the MPLS Session tab during configuration of the PM session for the test; see 92.6 “To configure a PM session OAM diagnostic test from the STM” (p. 3146).

92.10.2 Steps

1

Choose Tools→Service Test Manager (STM) from the NFM-P main menu. The Service Test Manager (STM) form opens.

2

Choose Create→Performance Monitoring→MPLS DM Session Test or select an existing MPLS DM test session object, and click Properties. The MPLS DM Test Session (Create|Edit) form opens.

3

Configure the required parameters.

4

Select a PM session.

5

To view the bins configured for the test by your choice of PM sessions, perform the following:

1. Click Properties for the selected PM session name. The PM Session (Edit) form opens.
2. Click Properties for the displayed Bin Group Mgr Object ID. The Bin Group (Edit) form opens.

3. Click on the Bins tab.
4. Select the bin you want to view and click Properties. The Bin (Edit) form opens.
5. Close the form after viewing the bin.

6

Save your changes and close the forms.

END OF STEPS

92.11 To configure a TWAMP Light reflector

92.11.1 Steps

A TWAMP Light test needs to be pointed at a reflector on the correct UDP port in order to execute properly and generate valid results. A TWAMP Light reflector can be configured on a base routing instance or on a VPRN site. There can only be one reflector on a particular base routing instance or a VPRN site.

1

Perform one of the following:

a. 27.2 “To configure a routing instance or a VRF instance” (p. 826) for information on creating a TWAMP Light reflector on a base routing instance.

b. 79.76 “To create a TWAMP Light reflector on a VPRN site” (p. 2647) to create a TWAMP Light reflector on a VPRN site.

c. Step 6 in 92.6 “To configure a PM session OAM diagnostic test from the STM” (p. 3146) to create a TWAMP Light reflector while creating a PM session. When you specify a source IP address, destination IP address, and destination UDP port on a PM session, the NFM-P automatically creates a new reflector on the appropriate target type at the destination IP address and port if one does not already exist. A prefix matching the source IP address of the PM session is also created if one does not already exist. If you later delete the PM session, the NFM-P will also delete the associated prefix.

2

Refer to Step 6 in 92.6 “To configure a PM session OAM diagnostic test from the STM” (p. 3146) to see how the reflector information is incorporated into the PM session test.

END OF STEPS

92.12 To configure a TWAMP Light session OAM diagnostic test from the STM

92.12.1 Steps

1

Click Tools→Service Test Manager (STM) on the NFM-P main menu. The Service Test Manager (STM) form opens.

2

Click Create→Performance Monitoring→TWAMP-Light Session Test or select an existing TWAMP Light test session object and click Properties. The TWAMP Light Test Session (Create|Edit) form opens.

3

Configure the required parameters.

The Frames Per Delta-T, Consec Delta-T's, CHLI Threshold, and FLR Threshold parameters are only displayed when the TWAMP Light Statistics Type to Collect parameter is set to either Loss or Delay And Loss.

The Consecutive High Loss Interval (CHLI) Threshold parameter must be set to a value less than the Consec Delta-T's parameter value.

4

Select a PM session.

5

To view the bins configured for the test by your choice of PM sessions, perform the following:

1. Click Properties for the selected PM session name. The PM Session (Edit) form opens.
2. Click Properties for the displayed Bin Group Mgr Object ID. The Bin Group (Edit) form opens.
3. Click on the Bins tab.
4. Select the bin you want to view and click Properties. The Bin (Edit) form opens.
5. Close the form after viewing the bin.

6

Click on the Loss-events tab to collect TCA event statistics.

1. Select a direction type object and click Properties. The TCA Configuration form opens.
2. Configure the required TCA parameters.

7

Save your changes and close the forms.

END OF STEPS

92.13 To configure a TCC OAM diagnostic test from the STM

92.13.1 Steps

1

Click Tools→Service Test Manager (STM) on the NFM-P main menu. The Service Test Manager (STM) form opens.

2

Click the Create→Performance Monitoring→TCC Test or select an existing TCC test object and click Properties. The TCC Test (Create|Edit) form opens.

3

Configure the required parameters.

The Always configure TWAMP Server parameter defines how the NFM-P can modify the operation and configuration of a TWAMP server configured on a managed SR NE. When enabled, on execution of a TCC test, the NFM-P queries the prefix list for the TWAMP server. If no current prefix exists for the server and TWAMP test session client IP addresses, the NFM-P operationally disables the TWAMP server, add the required prefixes, and then re-enables the server.

4

Select a TWAMP server IP address in the TWAMP Server panel.

The displayed list shows system IP addresses for managed NEs. If NEs cannot be managed using in-band communication (for example, when the NFM-P has no route to the system IP address), the SR management interface must be manually entered as the TWAMP Server IP Address.

5

Click Apply.

6

Click on the PM Session tab.

7

Select a PM session or click Create to configure a PM session specifically associated to the TCC test. See 92.6 “To configure a PM session OAM diagnostic test from the STM” (p. 3146) for information on configuring PM sessions and bin groups.

When the test client and TWAMP server NEs are specified, the NFM-P automatically populates the PM session's IP session attributes. Test session IP source and destination addresses default to their respective system interface addresses. The Source UDP port is also chosen from the first one available from the range 64374-64383. If required, the addresses may be cleared and selected from a filtered list of available interfaces on the respective NEs. TWAMP Light tests may also be configured to use specific interfaces on egress, define a static next-hop IP address, or manipulate the IP TOS forwarding class, IP profile and IP TTL fields for TWAMP test packets.

8

Save your changes and close the form.

END OF STEPS

92.14 To collect and view PM statistics from a test form

92.14.1 Steps

You can generate and view PM statistics directly from the test form.

1

Click Tools→Service Test Manager (STM) on theNFM-P main menu. The Service Test Manager (STM) form opens.

2

Select a PM session test and click Properties. The test Properties form opens.

3

Click on the Statistics tab.

4

Select the required statistics record type from the object drop-down menu.

A list of all statistics record types for each PM session test type is provided in 92.15 "To view PM test results in the STM" (p. 3157) .

5

Configure the required time interval from the object menu.

6

Click Collect or Collect All to collect the associated statistics. Clicking Collect All will cause the statistics from all applicable record types to be collected. A list of statistics records is displayed.

7

Select a record entry and click Properties. The Statistics Record form opens.

8

Review the provided information on the General and Bin Stats tabs. The Bin Stats tab is only displayed for applicable record types.

9

Close the Statistics Record form.

END OF STEPS

92.15 To view PM test results in the STM

92.15.1 Steps

1

Click Tools→Service Test Manager (STM) on the NFM-P main menu. The Service Test Manager (STM) form opens.

2

Choose the PM Session (Assurance) entry from the object drop-down menu.

3

Click on the Search button. The list of PM sessions is displayed.

4

Select a PM session entry and click Properties. The PM Session (Edit) form opens.

5

Click on the Components tab.

6

Right-click on the required test under Test Sessions and choose Properties from the contextual menu. The test form opens.

You can also view the statistics for individual bin types for DMM and TWAMP Light tests from this point. Right click on the bin you want to examine under the required test, then select Properties for that bin. The bin statistics can be viewed on the Properties form Statistics tab.

7

Click on the Statistics tab. The statistics records for the selected test are displayed in the list. Statistics utilizing an accounting policy include “Accounting” in the record name (as opposed to SNMP-based statistics).

For CFM DMM test statistics, the record types include:

- CFM DMM Bin Accounting Stats (SAS PM)

- CFM DMM Bin Stats (Ethernet OAM)
- CFM DMM Session Accounting Stats (SAS PM)
- CFM DMM Session Stats (Ethernet OAM)

  These statistics are duplicated in two rows except the monitored object name is changed. For example, one row shows the data and the session name as monitored object and the other row shows the same data but the session bin type as the monitored object.
- Delay TCA Stats (Assurance)
- PM Session Base Stats (Assurance)

For accounting-based statistics, the DMM base statistics data are incorporated into the DMM Bin Stats or DMM Session Stats fields.

For CFM SLM test statistics, the record types include:

- CFM SLM Accounting Stats (SAS PM)
- CFM SLM Session Stats (Ethernet OAM)
- Loss TCA Aggregate Stats (Assurance)
- Loss TCA FWBW Stats (Assurance)
- PM Session Base Stats (Assurance)

Data from SNMP-based SLM base statistics are incorporated into the SLM accounting-based statistics.

For CFM LMM test statistics, the record types include:

- CFM LMM Accounting Stats (SAS PM)
- CFM LMM Session Stats (Ethernet OAM)
- Loss TCA FWBW Stats (Assurance)
- PM Session Base Stats (Assurance)

Data from SNMP-based LMM base statistics are incorporated into the LMM accounting-based statistics.

For TWAMP Light test statistics, the record types include:

- Delay TCA Stats (Assurance)
- Loss TCA Aggregate Stats (Assurance)
- Loss TCA FWBW Stats (Assurance)
- PM Session Base Stats (Assurance)
- TWAMP Light Bin Accounting Stats (SAS PM)
- TWAMP Light Bin Stats (Assurance)
- TWAMP Light Loss Accounting Stats (SAS PM)
- TWAMP Light Loss Session Stats (Assurance)
- TWAMP Light Session Accounting Stats (SAS PM)
- TWAMP Light Session Stats (Assurance)

For accounting-based statistics, TWAMP Light base statistics data are incorporated into the TWAMP Light Bin or TWAMP Light Session Stats fields.

8

Select a record entry and click Properties. The Statistics Record form opens.

9

Review the information on the General and related tabs, then close the forms.

END OF STEPS

92.16 To view PM test statistics in the Statistics Manager

92.16.1 Steps

You can review the OAM PM test results as statistics using the Statistics Manager. You can also use the Statistics Manager plotting function to obtain a graphical representation of the data.

1

Click Tools→Statistics→Statistics Manager in the NFM-P main menu. The Statistics Manager opens.

2

Configure the Statistics Type parameter for the required information type.

3

Select the required statistics type from the menu.

The collected bin and session statistics records for each test type are grouped under the category PM Stats (Assurance). PM Session Base statistics can also be accessed by selecting the PM Session Base Stats (Assurance) category.

4

Refer to the *NSP NFM-P Statistics Management Guide* for the required procedures on viewing statistics and also graphing statistics using the plotter function. Both historical and real-time plots are supported in OAM PM.

You can also access the plotting function for specific tests by clicking the Plotter button on the Statistics tab of a test Properties form. This capability is also available within a PM session Property form by right-clicking a specific test on the Components tab.

Additionally, a summary of the rate of PM session DB record collection is viewable via Tools -> Statistics -> Server Performance Manager (OAM PM Event) NFM-P Performance Statistics.

The tracked attributes include: time captured, periodic time, monitored object name, files received, files received periodic, results processed, and results processed periodic.

END OF STEPS

92.17 To view OAM PM Event server performance statistics

92.17.1 Steps

1

Click Tools→Statistics→Server Performance Statistics on the NFM-P main menu. The Server Performance Statistics form opens.

2

Select OAM PM Event (NFM-P Performance Statistics) from the menu.

The tracked attributes for each OAM PM event are displayed. They include: time captured, periodic time, monitored object name, files received, files received periodic, results processed, and results processed periodic.

END OF STEPS

93 Mirror services

93.1 Mirror service overview

93.1.1 Traffic packet mirroring

CAUTION

Service Disruption

Service mirroring can affect performance.

Service mirroring can affect performance across the network and in the source and destination devices, so must be planned accordingly.

The NFM-P GUI implementation of service mirroring provides mirroring of service traffic packets from any service type.

In a mirror service, packets from one or more sources are forwarded to their normal destinations and a copy of the entire packet, or a specified portion of the packet, is sent to the mirror destination. The mirrored packet can be viewed using a packet-decoding device, typically called a sniffer, that is attached to the destination port. The NFM-P does not limit the number of destination and source sites added under a mirror service. The mirrored packets are transported unidirectionally through the core network using IP or MPLS tunneling.

With pseudo-wire redundancy support, an ICB can be enabled in the mirror service spoke and remote source, which can provide bidirectional service that enables support for active and standby PE redundancy. An endpoint can be used to group the redundant objects, which may be of mirror SDP bindings or SDP and SAP. In the mirror map view, the color for the active and backup states of the redundant mirror SDP differ.

Service mirroring can be used to do the following:

- Troubleshoot problems with customer packet delivery and content.
- Help service providers meet regulations by providing itemized call records and wiretaps, as authorized by investigative authorities.
- Simplify the complex traffic-analysis networks that are often implemented as overlays to the customer-facing network.

93.1.2 Configuration methods

The NFM-P supports end-to-end mirror service configuration using the following methods:

- Tabbed configuration forms with an embedded navigation tree. The navigation tree provides a logical view of the service and acts as a configuration interface.
- Preconfigured template. A user who has the Administrator scope of command role, or the Mirror Service Management and Template Script Management roles, can create a mirror service template.

93.1.3 Operational status

The mirror service operational status is aggregated based on the status of each site.

- Aggregate status is down if all destination sites are down.
- Aggregate status is up if one of the redundant destination site is up.
- Aggregate status is down if all source sites are down.
- Aggregate status is up if one of the redundant source sites is up.
- Aggregate status is unknown if no sites are added to the service.

93.1.4 Implementation considerations

Consider the following before you implement a mirror service:

- You must be assigned the administrator or mirror service management scope of command role to create or modify a mirror service, or to view any mirror-related objects in the NFM-P.
- The default customer is automatically associated with a mirror service. You cannot associate a different customer with a mirror service.
- You can only configure one endpoint per mirror site.
- You can configure the endpoint in the destination site with SAP and SDP with ICB.
- An endpoint cannot have more than one SAP.
- You can create a mirror SDP under the endpoint in the destination site.
- You can create up to four mirror SDPs under the endpoint in the source site. One mirror SDP must have ICB. Alternatively, you can create one mirror SDP under the source site.
- When the mirror SDP binding is under an endpoint, the STP cannot be enabled on the spoke.
- Mirror sites with valid SAPs are considered as destination sites during discovery.
- You can configure a site as a destination without a SAP in the mirror service. During re-synchronization, the site type remains destination.
- Auto-SDP creation is restricted to one destination.
- You can change the redundancy setting of a mirror SDP binding by deleting and adding the mirror SDP binding on an endpoint.
- You cannot delete an MC-LAG SAP if an ICB is on the same endpoint.
- You cannot have a SAP with a non-ICB mirror spoke on the same endpoint.
- The destination of a mirror service must be an L2 SAP.
- You can mirror the ingress or egress traffic on SAPs and ports.
- You can mirror the ingress or egress traffic that is associated with one or more subscriber hosts.
- You can specify match criteria, such as IP addresses, MAC addresses, or MPLS ingress labels, to filter the mirrored traffic.
- You can configure forwarding classes and profiles for mirror service traffic on supported devices.
- Mirror service IDs are obtained from the same pool of IDs that is used by other services. When you manually assign an ID value, ensure that you do not assign an ID that belongs to another service.

- Use the packet-slicing option to copy a specific packet size from each frame. This option is useful for monitoring network usage without copying the customer data. It also limits the amount of mirrored traffic that travels through the core network.
- When the mirror destination is not on the same NE as the mirror source, a mirror service requires a service tunnel between the source and destination NEs.
- The NFM-P can automatically create a service tunnel between the source and destination sites.

  The following conditions must be met.
  - Automatic mesh SDP binding creation is enabled.
  - GRE or LDP is the transport type.
  - No other service tunnel is available between the source and destination sites.
- The mirror service source and destination encapsulation types must be the same.
- After an NE reboot or CPM activity switch, the debug configuration file for a mirror service is not by default reloaded on the NE. The NFM-P raises an alarm when this occurs. To ensure that the NE reloads the debug configuration file, you must specify the location of the file in the base NFM-P configuration. See the procedure to enable debug configuration file reloading on an NE for mirror services in the *NSP System Administrator Guide* for more information.
- When multiple mirror services reference the same packet, for example, from a SAP and from a port, the packet is mirrored only once.

  Apply these criteria in the following non-configurable order:
  - MAC or IP filters
  - MPLS ingress label
  - SAP
  - port
- For IP-only mirroring, specific considerations apply.

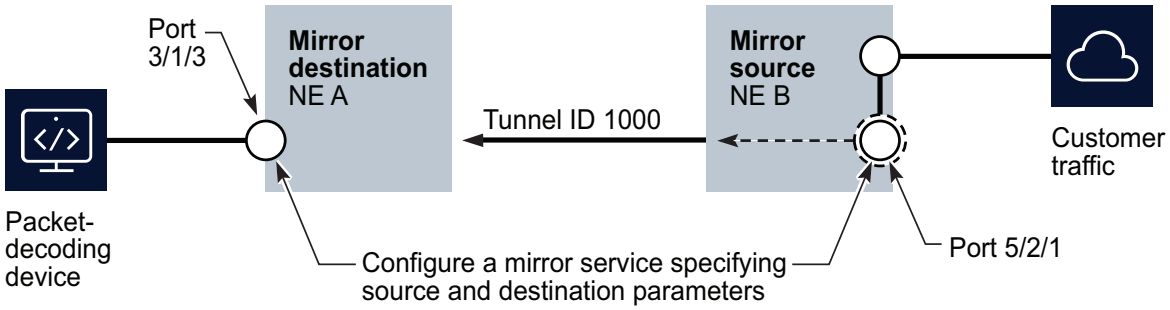
  Apply the following guidelines:
  - IP-only mirroring requires chassis mode C or D to be enabled.
  - By using “IP Only” as the encapsulation type, users can specify that only the IP packet is mirrored, without its original ATM/FR/POS/Ethernet DLC header.
  - When IP-only is configured on the source site, users can configure various mirroring sources, including subscribers and SAPs from Ipipe, IES, VPRN, VPLS, and MVPLS services. However, source ports and VLL services including Apipe, Epipe, and Fpipe cannot be configured.
  - For local IP-only mirroring, the source and destination MAC addresses must be configured.
  - For remote IP-only mirroring in a VPRN service, an IP mirror interface on the VPRN destination NE is used to receive the IP mirror packets and route them to the appropriate sniffer. If there are multiple sniffers connected to the VPRN using L3 interfaces, you must configure the routing policy to have IP mirror packets routed to the correct sniffer.

93.2 Sample mirror service

93.2.1 Sample mirror service configuration

The following figure shows a sample mirror service configuration.

Figure 93-1 Sample mirror service configuration



In this sample configuration, Router B is the mirror source that carries the customer packets. Router A is the mirror destination. The ingress and egress traffic on Port 5/2/1 is mirrored on the destination, Port 3/1/3. The following table lists the high-level tasks to configure the sample mirror service.

Table 93-1 Sample mirror service configuration

Task	Description
1. Connect the packet sniffer to the mirror destination.	The packet sniffer is attached to Router A, Port 3/1/3.
2. Configure the mirror destination parameters.	Port 3/1/3 on Router A is specified as the mirror destination. Specify the Tunnel ID 1000 as the transport tunnel to the mirror destination. All the parameters required to configure the type of mirroring, for example, slicing and mirror classification, are specified in the destination parameters.
3. Specify the source entity that is to be mirrored.	The egress and ingress traffic on Port 5/2/1 is to be mirrored.

93.3 Workflow to configure a mirror service

93.3.1 Prerequisites

The workflow lists the high-level steps required to configure a mirror service.

The workflow assumes the following:

- A group or a customer with the required user access privileges has been configured.
- The IP or IP/MPLS core network exists.
- Any required service tunnels are created including the static, dynamic or SR-TE LSP required to create the service tunnel; see 33.9 “To create an IP/MPLS service tunnel” (p. 1190) .
- The access ports for the service are created; see Chapter 16, “Port and channel object configuration” for more information.
- Any required pre-defined routing, QoS, scheduling, filter, accounting, and time of day suite

policies are created; see Chapter 49, “Policies overview” for more information. You do not have to create pre-defined policies if policies are created on a per-service basis.

- Any required MP-BGP for PE-to-PE routing is configured; see Chapter 28, “Routing protocol configuration” for more information about protocol configuration.
- The network services the mirror service will use are created.
- A packet-sniffing device at the L2 SAP that is the destination of the mirror service is configured.
- The SAP with the attached packet-sniffing device as the mirror destination is specified.
- The source of the packets to be mirrored is configured.

Note: Note: The functionalities described in these procedures are device-dependent. Not all functionalities described in these procedures are supported by all devices.

93.3.2 Stages

1

Create the mirror service. See 93.4 “To create a mirror service” (p. 3166) .

1. Define the general properties for the mirror service.
2. Specify the services for inclusion in the mirror service. You can specify multiple services in one operation.
3. Enable one or more routing protocols for the mirror site.
4. Create a destination site on the mirror service. See 93.5 “To create a destination site on a mirror service” (p. 3167) .
5. Create a source site on the mirror service, if required. See 93.6 “To create a source site on a mirror service” (p. 3169) .
6. Specify an endpoint on the site for redundancy, if required. See 93.9 “To create an endpoint for redundancy support on a mirror site” (p. 3173) .
7. Create an L2 access interface on the destination site, if required. See 93.10 “To create an L2 access interface on a destination site” (p. 3174) .
8. Specify one or more SAPs on the site as a mirror source, if required. See 93.11 “To specify a SAP on a mirror site as a mirror source” (p. 3177) .
9. Specify one or more ports on the site as a mirror source, if required. See 93.12 “To specify a port on a mirror site as a mirror source” (p. 3177) .
10. Specify one or more source IP filters, if required. See 93.13 “To specify a source IP filter entry as a mirror source” (p. 3178) .
11. Specify one or more source IPv6 filters, if required. See 93.14 “To specify a source IPv6 filter entry as a mirror source” (p. 3179) .
12. Specify one or more source MAC filters, if required. See 93.15 “To specify a source MAC filter entry for a mirror site” (p. 3180) .
13. Specify one or more source MPLS ingress labels, if required. See 93.18 “To specify an MPLS ingress label as a mirror source” (p. 3182) .
14. Turn up the mirror service.

2

As required, view mirror service information:

a. View the service topology map associated with a Mirror Service. See 93.20 “To view the service topology associated with a mirror service” (p. 3183) .

b. View the mirror service operational status. See 93.21 “To view mirror service operational status” (p. 3184) .

3

As required, run an OAM validation test for a mirror service. See 93.23 “To run an OAM validation test for a mirror service” (p. 3186) .

93.4 To create a mirror service

93.4.1 Before you begin

If you are configuring mirror services using dot1q or QinQ SAPs on a 7210 SAS (except for a 7210 SAS-D or 7210 SAS-K), then you must first assign a no-service mirror port. See 93.22 “To configure a mirror port on a 7210 SAS” (p. 3185) .

93.4.2 Steps

1

Choose Create→Service→Mirror from the NFM-P main menu. The Mirror Service (Create) form opens.

2

Configure the required general parameters.

The Service ID and SVC Mgr Service ID parameters are configurable when the Auto-Assign ID parameter is disabled.

3

If you enabled the Automatic SDP Binding Creation parameter, select a tunnel selection profile in the Auto SDP Binding Creation panel.

4

To configure a mirror source on a destination site, perform 93.5 “To create a destination site on a mirror service” (p. 3167) .

5

To configure a mirror source on a site other than the destination site, perform Step 3 to Step 12 of 93.6 “To create a source site on a mirror service” (p. 3169) . Otherwise, go to Step 6 .

6

Save the changes and close the forms.

END OF STEPS

93.5 To create a destination site on a mirror service

93.5.1 Steps

1

Choose Manage→Service→Mirror Services from the NFM-P main menu. The Manage Mirror Services form opens.

2

Select a mirror service and click Properties. The Mirror Service (Edit) form opens.

3

On the service navigation tree, right-click on Destination Sites and choose Create Destination Site to select an available site. The Mirror Site (Create) form opens.

4

Configure the required general parameters.

For mirror destination sites on network-enabled 7210 SAS NEs (except the 7210 SAS-K12 and 7210 SAS-K30 ETR), when you configure a mirror SDP as the source, you must set the Source Type parameter to Remote or Both.

5

Configure the Use Global Sampling Rate parameter to use the configured global rate. See 12.75 “To configure the global sampling rate on an NE” (p. 403) .

6

Click on the Mirroring Configuration tab and configure the required parameters.

Choose the default of 0 for the Slice Size parameter when you configure a destination mirror site, unless slicing at the destination is necessary. Packet slicing reduces the amount of mirrored traffic that traverses the network.

The Slice Size parameter is not displayed if the Encapsulation Type parameter is set to IP Only.

The Port Id Mirroring and remote source are mutually exclusive. If Enable Port ID Mirroring is set to true on the destination site, then a remote source site cannot be added to the service. If a remote source site is already on the service, then Enable Port ID Mirroring cannot be set to true. Also, if remote mirroring is used, then Enable Port ID Mirroring must be configured on all source sites.

The Enable Port ID Mirroring parameter is configurable only if the Encapsulation Type parameter is set to PPP.

For 7210 SAS NEs (except the 7210 SAS-K12 and 7210 SAS-K30 ETR), you can configure the Remote Source Capable parameter only when the Source Type parameter is set to Remote or Both in Step 4 .

7

Configure the remote source far end.

Note: The Remote Source Capable parameter configured in Step 6 must be set to True when you configure a remote source.

Perform the following:

1. Click on the Remote Source tab.
2. Click Create. The Remote Source (Create) form appears.
3. Configure the required parameters.
4. Save the changes and close the form.

8

Configure a remote source mirror SDP binding.

Note: The Remote Source Capable parameter configured in Step 6 must be set to True when you configure a remote source.
Remote source SDP bindings support only L2TPv3 or MPLS-TP tunnels. A remote source SDP binding is mutually exclusive to far end instances.

Perform the following:

1. Click on the Mirror SDP Bindings tab.
2. Click Create. The Mirror SDP Binding (Create) form opens.
3. If you are configuring an L2TPv3 tunnel for the SDP binding, go to 4 . Otherwise, configure the required parameters.
4. Specify a transport tunnel for the mirror SDP binding.

   First configure an MPLS-TP transport tunnel.
   - Select an MPLS-TP service tunnel for the spoke SDP binding in the Tunnel panel.
   - Click on the Pseudowire OAM tab and configure the Control Word parameter. If you are creating a mirror SDP binding using an MPLS-TP service tunnel for pseudowire static configuration, you must set the Control Word parameter to Preferred. See 93.8 “To configure an MPLS-TP static pseudowire on a mirror SDP binding” (p. 3172) .

   Then configure an L2TPv3 tunnel.
   - Select an L2TPv3 service tunnel for the spoke SDP binding in the Tunnel panel.
   - Configure the Ingress Cookie parameter. The Ingress Cookie parameter must match the Egress Cookie parameter that you configure on the SDP binding using L2TPv3 tunnel on the mirror source site in 93.6 “To create a source site on a mirror service” (p. 3169) .
5. Save the changes and close the form.

9

Save the changes and close the forms.

END OF STEPS

93.6 To create a source site on a mirror service

93.6.1 Steps

1

Choose Manage→Service→Mirror Services from the NFM-P main menu. The Manage Mirror Services form opens.

2

Select a mirror service and click Properties. The Mirror Service (Edit) form opens.

3

On the service navigation tree, right-click on Source Sites and choose Create Source Site to select an available site. The Mirror Site (Create) form opens.

4

Configure the required general parameters.

5

Click on the Mirroring Configuration tab.

6

Configure the required parameters.

The Slice Size parameter is not configurable if the Encapsulation Type parameter is set to IP Only in Step 4 .

The Enable Port ID Mirroring parameter is configurable only if you set the Encapsulation Type parameter to PPP in Step 4 .

The Port Id Mirroring and remote source are mutually exclusive. If Enable Port ID Mirroring is set to true on the destination site, then a remote source site cannot be added to the service. On the other hand, if a remote source site is already on the service, then Enable Port ID Mirroring cannot be set to true. Also, if remote mirror is used, then Enable Port ID Mirroring must be configured on all source sites.

7

Save the changes and close the form.

8

If you did not enable the Automatic SDP Binding Creation parameter in 93.4 “To create a mirror service” (p. 3166), then choose an SDP binding for the mirror source.

1. In the service navigation tree, expand the site object that you created.
2. Select Mirror SDP Binding under the source site in the service navigation tree, right-click and choose Create Mirror SDP Binding. The Mirror SDP Binding (Create) form opens.

   If you enabled the Automatic SDP Binding Creation parameter in 93.4 “To create a mirror service” (p. 3166) , go to Step 12 .

9

Specify a destination NE for the mirror SDP binding by selecting from a list of managed NEs for the Tunnel Termination Site parameter.

If the destination NE is not managed by the NFM-P, specify the system ID of the destination NE for the Tunnel Termination Site parameter.

Note: For a 7210 SAS destination site in a mirror service, you can either specify a mirror SDP binding or create a SAP, but not both.

10

If you are configuring an L2TPv3 tunnel for the SDP binding, go to Step 11 . Otherwise, configure the required parameters.

11

To specify a transport tunnel for the mirror SDP binding:

a. Let the NFM-P configure the transport tunnel automatically.
   1. Enable the Auto-Select Transport Tunnel parameter.
   2. Configure the Tunnel Auto-Selection Transport Preference parameter.

b. Configure the transport tunnel manually; select a tunnel in the Tunnel panel.

c. Configure an MPLS-TP transport tunnel.
   1. Select an MPLS-TP service tunnel for the spoke SDP binding in the Tunnel panel.
   2. Click on the Pseudowire OAM tab and configure the Control Word parameter.

      If you are creating a mirror SDP binding using an MPLS-TP service tunnel for pseudowire static configuration, then you must set the Control Word parameter to Preferred. See 93.8 “To configure an MPLS-TP static pseudowire on a mirror SDP binding” (p. 3172) .
   3. Save the changes and close the forms.

d. Configure an L2TPv3 tunnel.
   1. Select an L2TPv3 service tunnel for the spoke SDP binding in the Tunnel panel.
   2. Configure the Egress Cookie parameter. The Egress Cookie parameter must match the

Ingress Cookie parameter that you configured on the SDP binding using L2TPv3 tunnel on the mirror destination site in 93.5 “To create a destination site on a mirror service” (p. 3167) .

12

Save the changes and close the forms.

END OF STEPS

93.7 To configure a PCAP session for a mirror site

93.7.1 Steps

Mirrored packets can be captured in a PCAP file and viewed offline. A single capture provides all relevant protocol packets. Byte level details are also provided for each captured packet.

1

Create the mirror service. See 93.4 “To create a mirror service” (p. 3166) .

2

On the mirror service, create a source site. See 93.6 “To create a source site on a mirror service” (p. 3169) .

3

Select the source site and click Properties. The Mirror Service (Edit) form opens.

4

Click on the PCAP Sessions tab and click Create. The PCAP Session (Create) form opens.

5

Configure the Session Name, Capture Count, and File URL parameters.

The NFM-P can capture up to 250 packets from a mirror source.

You must provide a valid IP address for the generated PCAP file. If you want to use a new URL, you do not need to recreate the PCAP session. Delete the URL, apply any changes, and re-enter the new URL.

6

Click Apply. The new PcapSessions appears under the Mirror Service - Source Sites in the navigation tree.

7

On the MirrorPCAP session tab, click Start Pcap Session. The Session State parameter indicates the capture state of the PCAP session.

If you want to stop the PCAP session, you can use the Stop pcap capture option.

If you stopped and started a PCAP session without changing the file URL or PCAP file name, the previously captured information will be overwritten.

8

View the details of the PCAP file from the URL you specified.

Statistics for the PCAP session are available on the Statistics tab.

Scheduled statistics are not supported. PCAP session statistics are valid only when the PCAP session is in progress.

9

Save the changes and close the forms.

END OF STEPS

93.8 To configure an MPLS-TP static pseudowire on a mirror SDP binding

93.8.1 Steps

Perform this procedure to create an MPLS-TP static pseudowire on the mirror SDP binding. An MPLS-TP service tunnel must be used in the mirror SDP binding, and the Control Word parameter for pseudowire OAM must be set to Preferred in Step 11 of 93.6 “To create a source site on a mirror service” (p. 3169) .

1

Choose Manage→Service→Mirror Services from the NFM-P main menu. The Manage Mirror Services form opens.

2

Select a mirror service and click Properties. The Mirror Service (Edit) form opens.

3

On the navigation tree, expand the source site on which you want to configure the mirror SDP binding, expand Mirror SDP Bindings and click on the mirror SDP binding on which you want to configure the static MPLS-TP pseudowire. The Mirror SDP Binding (Edit) form opens.

4

Click on the Control Channel tab.

5

Configure the required parameters.

6

Click on the Static PW tab and click Create. The PW Path ID (Create) form opens.

7

Configure the Path AGI parameter.

8

Configure the parameters in the Source Attachment Individual Identifier panel.

9

Configure the parameters in the Target Attachment Individual Identifier panel.

10

Save the changes and close the forms.

END OF STEPS

93.9 To create an endpoint for redundancy support on a mirror site

93.9.1 Steps

1

Choose Manage→Service→Mirror Services from the NFM-P main menu. The Manage Mirror Services form opens.

2

Select a mirror service and click Properties. The Mirror Service (Edit) form opens.

3

Perform one of the following.

a. To create an endpoint on a destination site, expand the Destination Sites object to view the configured destination sites, and expand the destination site object on which you are creating the endpoint. Right-click on Endpoints and choose Create Endpoints. The Endpoint (Create) form opens.

b. To create an endpoint on a source site, expand the Source Sites object to view the configured source sites, and expand the source site object on which you are creating the endpoint. Right-click on Endpoints and choose Create Endpoints. The Endpoint (Create) form opens.

4

Configure the required general parameters.

5

Click OK.

For the destination site, the L2 Access Interface (Test Equipment Interface) and Mirror SDP Binding objects appear under the Endpoints object.

For the source site, the Mirror SDP Binding object now appears under the Endpoints object.

6

To create an L2 access interface as the mirror destination, expand Endpoints, right-click on L2 Access Interface (Test Equipment Interface) and choose Create L2 Access Interface. The L2 Access Interface (Create) form opens.

Note: You cannot create an L2 access interface on the endpoint if you create an L2 access interface in 93.10 “To create an L2 access interface on a destination site” (p. 3174) without selecting an endpoint for redundancy.

7

Click on the Port tab and select a port for the L2 access interface.

Note: Only ports in access or hybrid mode are listed. To choose a port that is not listed, you must set the Mode parameter for the port to Access or Hybrid. After you do this, the port is listed when you click Search.

8

Configure the required parameters.

9

Save the changes and close the form.

10

To create a mirror SDP binding on the endpoint, expand Endpoints, right-click on Mirror SDP Binding and choose Create Mirror SDP Binding. The Mirror SDP Binding (Create) form opens.

11

Configure the required general parameters.

12

Save the changes and close the forms.

END OF STEPS

93.10 To create an L2 access interface on a destination site

Note: You cannot create an L2 access interface on the site if you create an L2 access interface for redundancy in 93.9 “To create an endpoint for redundancy support on a mirror site” (p. 3173) .

For a 7210 SAS destination site in a mirror service, you can either create a SAP or specify a mirror SDP binding, but not both.

93.10.1 Steps

1

Choose Manage→Service→Mirror Services from the NFM-P main menu. The Manage Mirror Services form opens.

2

Select a mirror service and click Properties. The Mirror Service (Edit) form opens.

3

On the service navigation tree, expand Destination Sites→*destination_site*, right-click on L2 Access Interface (Test Equipment Interface), and choose Create L2 Access Interface. The L2 Access Interface (Create) form opens.

4

To configure an endpoint for redundancy, click on the Select button in the Redundancy panel to select the desired endpoint.

Note: If you select an endpoint for redundancy, the L2 access interface appears under the Endpoints object on the service navigation tree.

5

Click on the Port tab.

6

Select a port.

Note: The form lists only ports in access or hybrid mode. To choose a port that is not listed, you must set the Mode parameter for the port to Access or Hybrid. After you do this, the port is listed when you click on the Search button.
The form lists only ports that have the encapsulation type that you specified in the destination site creation, in 93.5 “To create a destination site on a mirror service” (p. 3167)

7

Configure the required parameters.

The Auto-Assign ID parameter is configurable if the port uses dot1q encapsulation. When the parameter is enabled, the NFM-P automatically configures the Outer Encapsulation Value parameter using the lowest unassigned value.

Note: You can set the Auto-Assign ID parameter to be the default parameter for dot1q encapsulation by enabling the Access Interface Encap Value (Dot1q only) parameter on the User Preferences form.

The Inner Encapsulation Value is configurable only when the port is an Ethernet or frame relay port with QinQ encapsulation.

8

To assign an egress QoS policy to the interface:

1. Click on the QoS tab.
2. Configure the Egress Mark QinQ Top Bits Only parameter.
3. Select an egress policy in the Egress Policy panel.

9

To assign a time of day suite to the interface:

1. Click on the TOD Suite tab.
2. Select a time of day suite.

10

To configure scheduling:

1. Click on the Schedulers tab.
2. Configure the Aggregate Rate Limit (kbps) parameter.

11

To configure local mirroring and if you chose IP Only as the encapsulation type in Step 4 of 93.5 “To create a destination site on a mirror service” (p. 3167) :

1. Click on the IP Mirror MAC Addresses tab.
2. Configure the required parameters.

   The Source and Destination MAC addresses on L2 Access Interface must be both null or neither null. Both null means that there are no source or destination MAC addresses configured on the interface.

   Note:

   If you want to configure remote mirroring in a VPRN service, you must create an IP Mirror Interface in that service. See Chapter 79, “VPRN service management” for more information.

12

To assign an ANCP policy to the interface:

1. Click on the ANCP Static Map tab.
2. Click Create. The ANCP Static Map (Create) form opens.
3. Configure the ANCP String parameter.
4. Select an ANCP Policy.
5. Save the changes and close the form.

13

Save the changes and close the forms.

END OF STEPS

93.11 To specify a SAP on a mirror site as a mirror source

93.11.1 Steps

1

Choose Manage→Service→Mirror Services from the NFM-P main menu. The Manage Mirror Services form opens.

2

Select a mirror service and click Properties. The Mirror Service (Edit) form opens.

3

In the service navigation tree, expand Site, right-click on the Source SAPs object and choose Create Source Interface. The Source Interface (Create) form opens.

4

Select an access interface to associate with the source interface.

5

Configure the required parameters.

6

Save the changes and close the forms.

END OF STEPS

93.12 To specify a port on a mirror site as a mirror source

93.12.1 Steps

1

Choose Manage→Service→Mirror Services from the NFM-P main menu. The Manage Mirror Services form opens.

2

Select a mirror service and click Properties. The Mirror Service (Edit) form opens.

3

Perform one of the following.

a. To create a source port on a destination site, expand Destination Sites→*destination_site*, right-click on Source Ports and choose Create Source Port. the Source Port (Create) form opens.

b. To create a source port on a source site, expand Source Sites→*source_site*, right-click on Source Ports and choose Create Source Port. The Source Port (Create) form opens.

4

Select a port.

A source port can be one of the following, depending on the NE:

- physical port
- channel
- LAG
- bundle
- CCAG

5

Configure the required parameters.

6

Save the changes and close the forms.

END OF STEPS

93.13 To specify a source IP filter entry as a mirror source

93.13.1 Steps

1

Choose Manage→Service→Mirror Services from the NFM-P main menu. The Manage Mirror Services form opens.

2

Select a mirror service and click Properties. The Mirror Service (Edit) form opens.

3

Perform one of the following.

a. To specify an IP filter entry on a destination site, expand Destination Sites→*destination_site*, right-click on Source IP Filters and choose Create Source IP Filter. The Source IP Filter (Create) form opens.

b. To specify an IP filter entry on a source site, expand the Source Sites→*source_site*, right-click on Source IP Filters and choose Create Source IP Filter. The Source IP Filter (Create) form opens.

4

Select an IP filter entry.

5

Save the changes and close the forms.

END OF STEPS

93.14 To specify a source IPv6 filter entry as a mirror source

93.14.1 Steps

1

Choose Manage→Service→Mirror Services from the NFM-P main menu. The Manage Mirror Services form opens.

2

Select a mirror service and click Properties. The Mirror Service (Edit) form opens.

3

Perform one of the following.

a. To specify an IPv6 filter entry on a destination site, expand Destination Sites→*destination_site*, right-click on Source IPv6 Filters and choose Create Source IPv6 Filter. The Source IPv6 Filter (Create) form opens.

b. To specify an IPv6 filter entry on a source site, expand the Source Sites→*source_site*, right-click on Source IPv6 Filters and choose Create Source IPv6 Filter. The Source IPv6 Filter (Create) form opens.

4

Select an IPv6 filter entry.

5

Save the changes and close the forms.

END OF STEPS

93.15 To specify a source MAC filter entry for a mirror site

93.15.1 Steps

1

Choose Manage→Service→Mirror Services from the NFM-P main menu. The Manage Mirror Services form opens.

2

Select a mirror service and click Properties. The Mirror Service (Edit) form opens.

3

Perform one of the following.

a. To specify a MAC filter entry on a destination site, expand Destination Sites→*destination_site*, right-click on Source MAC Filters and choose Create Source MAC Filter. The Source MAC Filter (Create) form opens.

b. To specify a MAC filter entry on a source site, expand the Source Sites→*source_site*, right-click on Source MAC Filters and choose Create Source MAC Filter. The Source MAC Filter (Create) form opens.

4

Select a MAC filter entry.

5

Save the changes and close the forms.

END OF STEPS

93.16 To specify a source filter as mirror source on 7250 IXR

93.16.1 Steps

A mirror service can contain multiple aggregate filter policies. However, each ACL aggregate filter policy must contain only one filter reference. A mirror service can have multiple aggregate filter policies attached. However, the aggregate filter policy can only have one source filter type attached. See 51.3 “To configure an ACL Aggregate filter policy” (p. 1668) to configure an ACL aggregate filter policy.

1

Choose Manage→Service→Mirror Services from the NFM-P main menu. The Manage Mirror Services form opens.

2

Select a mirror service and click Properties. The Mirror Service (Edit) form opens.

3

To specify a source filter on a destination site, expand Destination Sites→destination_site, right-click on Source Filters, and choose Create Source Filter. The Source Filter (Create) form opens.

4

From the Source Filter Type drop-down menu, select IP, IPv6, or MAC filter policy type.

5

Select the Aggregate Filter Name.

6

Select the IP/IPv6/MAC Filter Entry parameters.

7

Click on OK to save the changes and close the forms.

END OF STEPS

93.17 To specify a source subscriber as a mirror source

93.17.1 Steps

1

Choose Manage→Service→Mirror Services from the NFM-P main menu. The Manage Mirror Services form opens.

2

Select a mirror service and click Properties. The Mirror Service (Edit) form opens.

3

In the service navigation tree, expand Source Sites→*source_sites*, right-click on Source Subscribers and choose Create Source Subscriber. The Source Subscriber (Create) form opens.

4

Configure the required parameters.

5

You can further restrict the mirrored subscriber host traffic associated with the subscriber identification string by specifying SAP or SLA-profile criteria. To specify an SLA profile as a match criterion, go to Step 7 .

Note: You can configure parameters in the SAP/Subscriber Host Match Criteria panel or the SLA Profile Match Criteria panel, but you cannot configure parameters in both panels.

6

Specify a SAP on which to mirror subscriber host traffic.

Note: The form lists only dot1q- or QinQ-encapsulated SAPs that have subscriber management enabled.

Perform the following

1. Select a SAP in the SAP/Subscriber Host Match Criteria panel.
2. Configure the parameters in the SAP/Subscriber Host Match Criteria panel to specify the subscriber host match criteria for the SAP.

   Note:

   The NFM-P does not accept the parameter values unless a SAP is specified.

7

To specify an SLA profile as a match criterion, select an SLA profile in the SLA Profile Match Criteria panel.

8

Save the changes and close the forms.

END OF STEPS

93.18 To specify an MPLS ingress label as a mirror source

93.18.1 Steps

1

Choose Manage→Service→Mirror Services from the NFM-P main menu. The Manage Mirror Services form opens.

2

Select a mirror service and click Properties. The Mirror Service (Edit) form opens.

3

In the service navigation tree, expand Source Sites→*source_site*, right-click on Source MPLS Ingress Labels and choose Create Source Ingress Label. The Source Ingress Label (Create) form opens.

4

Configure the Ingress Label parameter.

5

Save the changes and close the forms.

END OF STEPS

93.19 To specify a source VLAN as a mirror source on the 7250 IXR

93.19.1 Steps

1

Choose Manage→Service→Mirror Services from the NFM-P main menu. The Manage Mirror Services form opens.

2

Select a mirror service and click Properties. The Mirror Service (Edit) form opens.

3

Right-click Source VLAN and click Create Source VLAN. The Source VLAN (Create) form opens.

4

In the Mirrored VLAN, select the port or LAG from the list.

5

Assign a Port ID.

6

Click on OK to save the changes and close the forms.

END OF STEPS

93.20 To view the service topology associated with a mirror service

93.20.1 Steps

1

Choose Manage→Service→Mirror Services from the NFM-P main menu. The Manage Mirror Services form opens.

2

Select a mirror service and click Topology View. A Topology View dialog box appears.

3

Click Yes to proceed. The Service Topology - *Service Name* map opens.

See Chapter 4, “Topology map management” for more information about service topology views.

End of steps

93.21 To view mirror service operational status

93.21.1 Steps

Note: The Aggregated Service Site Operational State and State Cause indicators on the General tab of the mirror service properties form display information about service faults.

1

Choose Manage→Service→Mirror Services from the NFM-P main menu. The Manage Mirror Services form opens.

2

Select a mirror service and click Properties. The Mirror *Service Name* (Edit) form opens.

3

View the Aggregated Service Site Operational State and State Cause indicators. When the Aggregated Operational State is Down or Partially Down, a check mark beside the appropriate State Cause indicator identifies the type of associated service fault.

4

Click on the appropriate tab to view or edit an object that is identified as faulty by a State Cause indicator.

5

Click on the Faults tab to view the alarms for the object. The alarms are grouped into various categories.

6

Close the Mirror Service (Edit) form.

7

Save the changes and close the forms.

End of steps

93.22 To configure a mirror port on a 7210 SAS

93.22.1 No-service ports on the 7210 SAS

For some implementations of mirror services on the 7210 SAS, you must configure a no-service port on the NE. You can select a physical port or a virtual port. Not all chassis types support virtual no-service ports.

If you select a physical port as a no-service port, the port cannot contain any SAPs.

For virtual no-service ports, the number of available ports and the port names vary depending on the chassis type. Virtual ports are not displayed on the navigation tree.

You cannot select the same no-service port for more than one function.

For more information about configuring no-service ports for mirror services, see the 7210 SAS OAM and Diagnostics documentation.

93.22.2 Steps

1

Open the properties form for the 7210 SAS NE that you need to configure.

2

Click on the Globals tab, then click on the Service tab.

3

Select a loopback no-service port. Perform one of the following:

a. Select a physical loopback no-service port.
   1. In the Mirror Port panel, click Clear if required, then click Select. The Select Mirror Port form opens.
   2. Choose a port and click OK.

b. Select a virtual loopback no-service port.
   1. Enable the Use Virtual Mirror Port parameter.
   2. In the Virtual Mirror Port panel, click Clear if required, then click Select. The Select Virtual Mirror Port form opens.
   3. Choose a port and click OK.

      The available virtual ports vary depending on the chassis type and card type.

4

Save your changes and close the forms.

END OF STEPS

93.23 To run an OAM validation test for a mirror service

93.23.1 Before you begin

An OAM validator test suite must be created for the tested entity. See Chapter 89, “Service Test Manager” for more information about how to create an OAM validator test suite.

93.23.2 Steps

1

Choose Manage→Service→Mirror Services from the NFM-P main menu. The Manage Mirror Services form opens.

2

Select a service and click Properties. The Mirror Service (Edit) form opens.

3

Click Validate. If an OAM validator test suite is not associated to the service, a dialog box appears. Perform the following steps:

1. Click OK to associate the service with an existing OAM validator test suite. The Choose Validator Test Suite form appears.
2. Select an OAM validator test suite and click OK. The Choose Validator Test Suite form closes.

4

View the State Cause indicators. When the validation test fails, a check mark appears beside the OAM Validation Failure indicator.

5

Click on the Tests tab.

6

Click on the Tested Entity Result tab.

7

Select an entry and click Properties. The Tested Entity Result form opens and displays information about the validation test.

8

Close the Tested Entity Result form.

9

Close the Mirror Service (Edit) form.

10

Save the changes and close the forms.

END OF STEPS

94 Lawful Intercept

94.1 Overview

94.1.1 Purpose

This chapter describes the NFM-P Lawful Intercept (LI) function, and includes LI configuration information.

94.1.2 Contents

Lawful Intercept overview

94.2 Lawful Intercept concepts

94.2.1 Overview

Lawful Intercept (LI) is a term that describes the interception and monitoring of network subscriber traffic by authorized agencies for law-enforcement purposes. A subscriber whose traffic is intercepted using LI is called a target. The LI target traffic is replicated by a service mirror that uses subscriber information as the match criteria.

94.2.2 Security assurances and restrictions

NFM-P has no native LI functions or legal interception capability, and can only enable, configure, and disable LI functions on NEs that have native LI functions, such as the 7750 SR.

NFM-P acts only as an optional remote LI controller, and has no view of any intercepted traffic; the target address is the only information available to NFM-P.

LI security constraints

LI uses the following constraints to enforce data security.

- LI is not detectable by a target subscriber.
- LI traffic is delivered separately from other network traffic.
- LI alarms are displayed only for authorized LI users.
- LI configuration information is stored in a separate and encrypted file.
- LI uses TLS to secure the required communication channels.

94.2.3 LI requirements

LI functions are managed separately from other NFM-P functions. LI mirroring is a special type of service mirroring that requires the following:

- on each LI NE in a mirror service:
  - SSH user security
  - an LI user profile
  - an NE user account that has LI privileges
- on the NFM-P:
  - TLS on the single-user GUI clients, client delegate servers, and JMS server
  - an NFM-P user account that has LI privileges
  - an assigned Lawful Interception Management scope of command role
  - an LI mediation policy

Note: The NFM-P blocks the association of LI mediation security with any 7750 SR whose software version descriptor includes -NL. An LI configuration on such an NE cannot be completed because the NE does not support LI mediation security.

94.3 LI functional tasks by user type

94.3.1 User authorization level

LI requires a dedicated user authorization level to setup the LI infrastructure on the NFM-P and corresponding NEs to configure and manage LI functions. The following user types are required to perform LI:

- NFM-P admin
- NE admin
- NE LI user
- NFM-P LI user or LI administrator

Note: For security, all LI functions in the NFM-P GUI, for example, menus, forms, parameters, policies, filters, and alarms, are hidden from view for all NFM-P user types except an LI user or LI administrator.

94.3.2 NFM-P admin LI tasks

The NFM-P admin user is responsible for the initial setup of the LI user or LI administrator accounts on the NFM-P. The setup includes the following tasks:

- create a LI user scope of command profile and associate a non-admin user account with the LI profile
- configure an LI user profile that restricts the LI user to LI activities only and does not allow system administrator activities
- create a password for the LI user
- configure CLI and SNMP access for the NE LI user account

The NFM-P admin cannot perform the following LI functions:

- assign LI privileges to a user who is associated with the admin profile
- delete an LI user
- view, create, modify, or delete LI objects
- view or modify LI security mediation policies or LI filter policies
- view LI-related alarms

94.3.3 NE admin tasks

The NE admin is responsible for the creation of an NE LI user profile and NE LI user account using a CLI on the NE that LI will be performed on. This is usually a one-time configuration.

94.3.4 NE LI user tasks

The NE LI user configures the NE LI user security on the NE using a CLI such as changing the password of the NE LI user account so it’s unknown to NE admin and to configure the SNMP data encryption used for the NE. This is usually a one-time configuration.

94.3.5 LI users or LI administrator tasks

CAUTION

Service Disruption

An LI user password cannot be modified unless it is known. When an LI user password is not known, the LI user account is unavailable.

An LI user or LI administrator can perform the following LI related tasks on the NFM-P:

- modify the LI user password
- configure an LI mediation security policy
- configure other LI-specific policy types that are used to filter or block traffic to non-LI users for LI mirror services including:
  - LI MAC filter policy
  - LI IP filter policy
  - LI IPv6 filter policy
  - Block reservation policy
- create, configure, and view LI sources that use IP, MAC, SAP, and subscriber filters
- create the LI mirror service
- view LI-related alarms

An LI administrator is an LI user who has been designated as the lead LI user who would normally create and maintain other LI user accounts once the NFM-P System admin has created the initial LI user account. This role is dependent/optional based on your NOC security requirements.

Note: Viewing or retrieving LI user activity records requires a user account with an assigned Lawful Interception Management scope of command role. The scope is restricted to the records of users in the same LI user group.

The NFM-P does not support LI user to execute CLI commands with LI user privilege on the node by using CLI scripts or by executing XML API API calls such as executeCLI or executeMultiCLI.

The following user account creation conditions apply to LI users and LI user groups.

- To configure LI, you must assign the Lawful Interception Management scope of command role for the user type.
- The Lawful Interception Management role can be assigned to only one scope of command profile.
- A scope of command profile that has an assigned Lawful Interception Management role can include other roles except for the admin role.
- You cannot change the scope of command profile assignment for a user group when the profile includes the Lawful Interception Management role.
- An LI user group must be created as an LI user group; you cannot change a non-LI user group to an LI user group.
- You cannot change an LI user group to a non-LI user group.

- A user account can have the Lawful Interception Management or the admin role, but not both.
- A user who belongs to an LI user group cannot be changed to a non-LI user.
- An LI span of control profile restricts LI user access to specific NEs.

94.4 LI service mirroring

94.4.1 LI target traffic

The LI target traffic is replicated by a service mirror that uses subscriber information as the match criteria. The LI service mirroring has a higher priority than non-LI mirroring. The LI service mirroring must be configured by an LI user with LI privileges and is hidden from users without LI permissions.

94.4.2 LI mirror sources

Only one mirror source, which can contain one or many LI source entries, can be associated with one mirror destination service. LI takes priority over debug mirror sources.

In the configuration of an LI source, when an LI user specifies that an entry must be used as an LI entry, it is hidden from all non-LI users.

94.4.3 LI filter policies

LI filter policies are used to filter out traffic to non-LI users for LI mirror services; these filters can only be viewed and configured by LI users.

Both non-LI filter entries and special purpose LI filter entries can be referenced in an LI mirror source. LI filters are associated with non-LI filters, and entries created in the LI filters are inserted into the associated non-LI filter before the filter is applied. A LI filter block reservation can be configured to reserve a range of entries in the non-LI filter into which the LI entries are inserted. See 94.18 “To configure a Block Reservation policy” (p. 3212) for more information.

LI filter policies include:

- LI MAC filter policy; see 94.15 “To configure an LI MAC filter policy” (p. 3208)
- LI IP filter policy; see 94.16 “To configure an LI IP filter policy” (p. 3209)
- LI IPv6 filter policy; see 94.17 “To configure an LI IPv6 filter policy” (p. 3211)
- Block Reservation filter policy; see 94.18 “To configure a Block Reservation policy” (p. 3212)

If a filter entry is associated with an LI source, the filter and the filter entry cannot be modified or deleted. unless the LI filter lock is configured. The filter lock configuration controls the behaviour of filters when they are used for LI. See 94.19 “To configure the LI filter lock” (p. 3214) for more information.

94.4.4 LI for NAT

LI for NAT mirrors the traffic of configured subscribers to a mirror-destination. All traffic for the specified subscriber, including traffic associated with static port forwarding, is mirrored. See 94.30 “To configure LI on a specific NAT subscriber” (p. 3225) for more information.

Procedures to configure LI

94.5 Workflow to configure LI

94.5.1 Stages

The following is the sequence of high-level activities required to setup the LI infrastructure on both the NFM-P and corresponding NEs, and to configure and manage LI functions.

Configure the LI user on the NFM-P

1

Create an LI user on the NFM-P.

1. Plan the NFM-P LI user account creation according to the requirements for LI user access to other NFM-P functional areas. See “User account and group management” in the *NSP System Administrator Guide* for more information.
2. Create an LI scope of command profile that has an assigned Lawful Interception Management role. See 94.6 “To create an LI scope of command profile on the NFM-P” (p. 3197) .
3. Create an LI user group that is associated with the new scope of command profile. See 94.7 “To create an LI user group on the NFM-P” (p. 3198).
4. Create an LI user account and assign it to the new user group. See 94.8 “To create an LI user on the NFM-P” (p. 3199) .
5. Provide the login credentials for the LI user account to the authorized LI administrator or LI user.
6. The LI user must change their LI user account password so that it is unknown to the NFM-P admin user.

Configure TLS for LI users

2

Assign SNMPv3 access privileges to the LI user group created in Stage 1 to each NE that the LI function will be performed on. You must enable TLS for the user group. See 9.11 “To enable SNMPv3 management of a device” (p. 291) .

Note: You cannot log in to the NFM-P as an LI user unless TLS is enabled for the LI user group.

3

NFM-P GUI access for LI users requires TLS between the NFM-P and the GUI clients. If TLS is disabled on the NFM-P XML API, TLS is also disabled for GUI access.

If TLS is disabled on the NFM-P XML API, enable TLS on the interface. The NFM-P section of the security chapter in the *NSP Installation and Upgrade Guide* describes how to enable TLS for NFM-P XML API clients.

Configure the LI user on the LI NE

4

Create an NE LI user on an NE where LI is being performed.

1. Create an NE LI user profile on the NE using a CLI. See 94.9 “To create an NE LI user profile on an NE using a CLI” (p. 3200) .
2. Create an NE LI user account on the NE that is associated with the LI user profile using a CLI. See 94.10 “To create an NE LI user account on an NE using a CLI” (p. 3201) .
3. Provide the login credentials for the LI NE user account to the NE LI user.
4. Configure NE LI user security on the NE such as the LI NE user account, password, and SNMP data encryption for the NE. See 94.12 “To configure NE LI user security” (p. 3204) .
5. Specify if the NE stores the LI source configuration locally or reconfigures the LI sources after a reboot. LI source configurations are saved on an NE when the polling policy for the NE specifies LI Local Save Allowed. See 8.10 “To configure polling for a 7250 IXR, 7450 ESS, 7705 SAR, 7750 SR, 7950 XRS, VSR, or Wavence SM” (p. 260) .

Configure the LI NE mediation policies and LI filter policies

5

Perform the following steps to configure an LI security mediation policy and the appropriate LI filter policies on the NFM-P.

1. Log out of the NFM-P GUI if you are logged in as a non-LI user and log back in as an LI user.
2. Synchronize the global NE user configuration profile with the local LI NE user configuration profile which is required prior to creating the LI mediation policy. See 94.13 “To synchronize the global NFM-P NE LI user configuration profile with the local NE LI user configuration profile” (p. 3206) .
3. Create an LI mediation security policy that defines the network security model used when creating LI mirror objects. See 94.14 “To configure an LI security mediation policy” (p. 3207) .
4. Create an LI MAC filter policy if you need to define the source and destination LI MAC filter entries used to filter out traffic to non-LI users for LI mirror services. See 94.15 “To configure an LI MAC filter policy” (p. 3208) .
5. Create an LI IP or IPv6 filter policy if you need to define the source and destination LI IP or IPv6 filter entries used to filter out traffic to non-LI users for LI mirror services. See 94.16 “To configure an LI IP filter policy” (p. 3209) and 94.17 “To configure an LI IPv6 filter policy” (p. 3211) .
6. Create a Block Reservation policy if you need to define the block reservation attributes of LI filter entries such as the block start/stop-entries and the block size in the base IPv4/IPv6 ACL filter. See 94.18 “To configure a Block Reservation policy” (p. 3212) .
7. Configure the LI Filter Lock if you need to configure who can modify base IPv4 and MAC filters referenced by an LI source. See 94.19 “To configure the LI filter lock” (p. 3214) .

6

Use the NFM-P to enable LI discovery of an NE. See 94.20 “To enable NE discovery for LI” (p. 3214) .

Configure LI mirror services

7

Perform the following steps to configure LI mirror services. See the “Workflow to create a mirror service” in Chapter 93, “Mirror services” for any non-LI configuration tasks that are required to configure a mirror service.

1. Create a mirror service. See 93.4 “To create a mirror service” (p. 3166) .
2. To specify an LI MAC filter created in Stage 5 5 as the LI source, see 94.23 “To specify an LI MAC filter entry as an LI source” (p. 3218) .
3. To specify an LI IPv4 or IPv6 filter created in Stage 5 6 as the LI source, see 94.25 “To specify an LI IP filter entry as an LI source” (p. 3220) and 94.26 “To specify an LI IPv6 filter entry as an LI source” (p. 3221) .
4. To specify an LI subscriber or subscriber host as the LI source, see 94.28 “To specify an LI subscriber as an LI source” (p. 3223) .
5. To specify an LI WLAN distributed subscriber as the LI source, see 94.29 “To specify an LI WLAN distributed subscriber as an LI source” (p. 3224) .
6. To specify an LI Source Port as the LI source, see 94.24 “To specify an LI Source Port as an LI source” (p. 3219).
7. To specify an LI SAP on a mirror site as the LI source, see 94.27 “To specify an LI SAP as an LI source” (p. 3222) .
8. To configure LI on a specific NAT subscriber, see 94.30 “To configure LI on a specific NAT subscriber” (p. 3225) .
9. To view LI mirrored subscriber host service information configured with a RADIUS server, see 94.31 “To view LI mirrored subscriber hosts configured with a RADIUS server” (p. 3227) .

Monitor LI user and system activity

8

View LI user and system logs to monitor LI activity. See the section on user activity logging in the *NSP System Administrator Guide* for more information about accessing user and system logs.

94.6 To create an LI scope of command profile on the NFM-P

94.6.1 Steps

You require NFM-P admin privileges to perform this procedure.

1

Using an account with an assigned User Management scope of command role, choose Administration→Security→NFM-P User Security from the NFM-P main menu. The NFM-P User Management (Edit) form opens.

2

Click on the Scope of Command tab.

3

Click Create→Profile. The Scope of Command Profile (Create) form opens.

4

Configure the required general parameters.

5

Assign one or more scope of command roles to the profile:

1. Click on the Roles tab.
2. Click Add and select one or more roles to include in the scope of command profile, where one of the roles is the Lawful Interception Management role.

   Note:

   You cannot include the Administrator role in an LI scope of command profile.

   The NFM-P allows the creation of only one scope of command profile that contains the Lawful Interception Management role.

6

Save the changes and close the form.

END OF STEPS

94.7 To create an LI user group on the NFM-P

94.7.1 Steps

You require NFM-P admin privileges to perform this procedure.

1

Using an account with an assigned User Management scope of command role, choose Administration→Security→NFM-P User Security from the NFM-P main menu. The NFM-P User Management (Edit) form opens.

2

Click on the User Groups tab.

3

Click Create. The User Group (Create) form opens.

4

Configure the required general parameters.

5

Select the LI scope of command profile you created in 94.6 “To create an LI scope of command profile on the NFM-P” (p. 3197) in the Scope of Command panel to assign the LI scope of command profile to the user group.

6

To assign a span of control profile to the user group select a profile ID in the Span of Control panel.

7

Save the changes and close the forms.

END OF STEPS

94.8 To create an LI user on the NFM-P

94.8.1 Steps

You require NFM-P admin privileges to perform this procedure.

1

Using an account with an assigned User Management scope of command role, choose Administration→Security→NFM-P User Security from the NFM-P main menu. The NFM-P User Management (Edit) form opens.

2

Click on the Users tab.

3

Click Create. The User (Create) form opens.

4

Configure the required general parameters.

5

Select the LI user group you created in 94.7 “To create an LI user group on the NFM-P” (p. 3198) to assign the LI user to the user group.

6

Configure the parameters in the Password panel.

7

Configure the parameters in the UI Session panel.

8

Configure the parameters in the OSS Session panel.

9

Configure the parameters in the Client IP Address panel.

10

Save the changes and close the forms.

END OF STEPS

94.9 To create an NE LI user profile on an NE using a CLI

94.9.1 Steps

You require NFM-P admin privileges to perform this procedure.

1

Open an SSH session on the NE as described in Chapter 10, “Device CLI sessions” .

2

Enter the following commands in sequence at the prompt to create an NE LI user profile. The following is a sample configuration:

```
configure system security profile li-prof ↲
default-action deny-all ↲
li ↲
entry 10 ↲
match "configure li" ↲
action permit ↲
exit ↲
entry 20 ↲
match "exit" ↲
action permit ↲
exit ↲
entry 30 ↲
```

```
match "help" ↲
action permit ↲
exit ↲
entry 40 ↲
match "back" ↲
action permit ↲
exit ↲
entry 50 ↲
match "show li" ↲
action permit ↲
exit ↲
entry 60 ↲
match "info" ↲
action permit ↲
exit ↲
entry 70 ↲
match "configure system security user" ↲
action permit ↲
exit ↲
entry 80 ↲
match "admin save" ↲
action permit ↲
exit ↲
exit all ↲
admin save ↲
```

3

Close the SSH session.

4

Right-click on the NE in the NFM-P topology map and choose Resync→Resync All MIBs from the contextual menu to update the NE configuration in the NFM-P.

END OF STEPS

94.10 To create an NE LI user account on an NE using a CLI

94.10.1 Steps

You require NFM-P admin privileges to perform this procedure.

1

Open an SSH session on the NE as described in Chapter 10, “Device CLI sessions” .

2

Enter the following commands in sequence at the prompt to create an LI user:

```
configure system security snmp ↲
access group "LI_group" security-model usm security-level privacy read
"iso" write "iso" notify "iso" ↲
access group "LI_group" security-model usm security-level privacy
context "li" exact read "li-view" write "li-view" notify "iso" ↲
exit all ↲
configure system security user LI_username ↲
password LI_password ↲
snmp group LI_group ↲
console member LI_profile ↲
console no member default ↲
exit all ↲
admin save ↲
```

where

LI_group is the name of the LI user group on the NE

LI_user is the name of the LI user account on the NE

LI_password is the password for the LI user account on the NE

LI_profile is the name of an LI user profile; see 94.9 “To create an NE LI user profile on an NE using a CLI” (p. 3200) for information about creating an LI user profile

3

Close the SSH session.

4

Right-click on the NE in the NFM-P topology map and choose Resync→Resync All MIBs from the contextual menu to update the NE configuration in the NFM-P.

END OF STEPS

94.11 To create additional NE LI user accounts using the NFM-P

94.11.1 Steps

Note: You require an LI user account to perform this procedure.
Before you can perform this procedure, at least one LI user account must exist on the NE.

Before you can perform this procedure, an NFM-P LI user must enable LI discovery for the NE using 94.20 “To enable NE discovery for LI” (p. 3214) .

1

Choose Administration→Security→NE User Configuration from the NFM-P main menu. The NE User Configuration form opens.

2

Click Create. The NE User (Create) form opens.

3

Configure the required parameters.

You must specify the li, snmp, and console values for the Access parameter.

Specify an MD5 authentication key for the Password parameter. See 94.12 “To configure NE LI user security” (p. 3204) for information about generating a user authentication key.

4

To assign one or more console profiles:

1. Click on the Console Profiles tab. The list of profiles numbered one through eight appears. A user can have up to eight console profiles.
2. Select a console profile for each of the profiles 1 through 8. See the procedure to configure a user account on a managed device in the *NSP System Administrator Guide* for information about creating console profiles.

5

Configure SNMPv3.

1. Click on the SNMPv3 tab.
2. Configure the authentication and privacy parameters. Ensure the NEs support a valid combination of authentication and privacy protocols.
3. Specify an authentication key generated using 94.12 “To configure NE LI user security” (p. 3204) for the New Authentication Password and Confirm New Auth Password parameters.
4. Specify an encryption key generated using 94.12 “To configure NE LI user security” (p. 3204) for the New Privacy Password and Confirm New Privacy Password parameters.

6

Save the changes and close the forms.

END OF STEPS

94.12 To configure NE LI user security

94.12.1 Steps

Note: You require NE LI user privileges to perform this procedure.

Perform this procedure to change the password for an LI user account on an NE and to configure LI user authentication and SNMP data encryption on the NE.

1

Use the NE LI user account to open an SSH session on the NE. See Chapter 10, “Device CLI sessions” for information about opening an SSH session on an NE.

2

Enter the following command to obtain the SNMP engine ID of the NE.

`show system info` ↵

The SNMP engine ID is displayed as SNMP Engine ID.

3

Record the SNMP engine ID for use in the following steps.

4

Generate an authentication key and a privacy key.

- An authentication key is used to encrypt a user password.
- A privacy key is used to encrypt the user SNMP packets.

Note: The key authentication method determines the key length.

1. Log in to an NFM-P single-user client, client delegate server, or main server station.

   Note:

   If you log in to a RHEL main or client delegate server station, you must log in as the nsp user.

   If you log in to a single-user client station, you must log in as the user who installed the client, or as a local administrator.
2. Open a console window.
3. On a RHEL station, navigate to the *install_directory*/nms/bin directory, where *install_directory* is one of the following:
   - the NFM-P main server installation location, /opt/nsp/nfmp/server
   - the NFM-P single-user client or client delegate server installation location, typically /opt/nsp/client
4. On a Windows station, navigate to the *install_directory*\nms\bin directory, where *install_directory* is the NFM-P single-user client or client delegate server installation location, typically C:\nsp\client.
5. Enter one of the following to create an authentication key:

- on a RHEL station:
  ./nmsclient.bash password2key *method password engine_ID* ↵
- on a Windows station:
  nmsclient.bat password2key *method password engine_ID* ↵

  where

  method is the authentication method, either MD5, SHA, SHA224, SHA256, SHA384 or SHA512

  password is the authentication key password

  engine_ID is the SNMP engine ID obtained in Step 2

  Note: You must enclose a password that contains a special character in single quotation marks; for example:

  password2key *method* 'Mypa$$word'

  Only use the authentication key from the output.

6. Enter the following to create a privacy key.
   - on a RHEL station:
     ./nmsclient.bash password2key *method password engine_ID* ↵
   - on a Windows station:
     nmsclient.bat password2key *method password engine_ID* ↵

     where

     method is the authentication method, either MD5, SHA, SHA224, SHA256, SHA384 or SHA512

     password is the privacy key password

     engine_ID is the SNMP Engine ID of the SR, in hexadecimal form with 10-64 hex digits (5-32 bytes)

     Note: You must enclose a password that contains a special character in single quotation marks; for example:

     password2key *method* 'Mypa$$word'

     The list of privacy keys for each privacy method is displayed.
7. Store the generated keys for your applicable authentication and privacy methods.

5

Using the keys generated in Step 4 , enter the following commands in sequence at the CLI prompt to change the LI user password and to configure LI security for the user account

1. Enter the following sequence of commands at the prompt:

   configure system security user *username* ↵

   password *new_LI_password* ↵

   snmp ↵

   authentication *auth_method authentication_key* privacy *priv_method privacy_key* ↵

   group *SNMPv3_group* ↵

   exit all ↵

where

username is the name of the LI user account on the NE

new_LI_password is the new password for the LI user account on the NE

auth_method can be:

hmac-md5-96 hmac-sha1-96 hmac-sha2-224 hmac-sha2-256 hmac-sha2-384 hmac-sha2-512

authentication_key is the authentication key value generated in Step 4

priv_method can be:

cbc-des cfb128-aes-128 cfb128-aes-192 cfb128-aes-256

privacy_key is the privacy key value generated in Step 4

2. Enter the following to save the configuration changes:

   admin save ↵

3. Close the CLI session.

END OF STEPS

94.13 To synchronize the global NFM-P NE LI user configuration profile with the local NE LI user configuration profile

94.13.1 Steps

Note: You require an LI user account to perform this procedure. If you do not synchronize the local profile with the global profile, the NE LI user does not appear in the list of users for SNMPv3 for the LI mediation policy.

You must perform this procedure before you can create an LI mediation policy.

1

Choose Administration→Security→NE User Configuration from the NFM-P main menu. The NE User Configuration form opens with a list of NE users.

2

Choose the NE LI user you created in 94.10 “To create an NE LI user account on an NE using a CLI” (p. 3201) and click Synchronize. The Synchronize - SR Local User form opens.

3

Choose the NE on which the local policy is defined from the Available Nodes panel and click on the right-arrow to move the NE to the Selected Node panel.

4

Click Synchronize.

5

Close the Synchronize -SR Local User form.

6

Close the NE User Configuration form.

END OF STEPS

94.14 To configure an LI security mediation policy

94.14.1 Steps

Note: You require an LI user account to perform this procedure.

The LI mediation security policy defines the network security model used when creating LI mirror objects for LI users. LI users do not use the standard mediation security policy. This policy identifies the NE LI user created specifically for LI purposes, the authentication and privacy protocol types, and the required passwords.

1

Choose Administration→Mediation from the NFM-P main menu. The Mediation (Edit) form opens.

2

Click on the LI Mediation Security tab.

3

Click Create. The LI Mediation Policy (Create) form opens.

4

Select the User Name you created in 94.10 “To create an NE LI user account on an NE using a CLI” (p. 3201) in the SNMPv3 panel.

5

The SNMP passwords in the NFM-P mediation policy must match the encrypted passwords generated for the NE LI user in 94.12 “To configure NE LI user security” (p. 3204) .

Set the mediation policy passwords.

1. Click Properties. The NE User Configuration form opens.
2. Click on the SNMPv3 tab.
3. Configure the authentication and privacy parameters. Ensure the NEs support a valid combination of authentication and privacy protocols.
4. Specify the password used to generate the authentication key in 94.12 “To configure NE LI user security” (p. 3204) for the New Authentication Password and Confirm New Auth Password parameters.

5. Specify the password used to generate the encryption key in 94.12 “To configure NE LI user security” (p. 3204) for the New Privacy Password and Confirm New Privacy Password parameters.
6. Save the changes and close the form.

6

Save the changes and close the forms.

END OF STEPS

94.15 To configure an LI MAC filter policy

94.15.1 Steps

Note: You are required to be an NFM-P user with LI privileges to access the LI MAC filter policy.

You require at least one ACL MAC filter policy to complete this procedure. See 51.4 “To configure an ACL MAC filter policy” (p. 1668) for more information.

You require at least one Block Reservation policy to complete this procedure. See 94.18 “To configure a Block Reservation policy” (p. 3212) for more information.

1

Choose Policies→Filter→LI Policies→LI MAC Filter from the NFM-P main menu. The LI MAC Filter Policies form opens.

2

Click Create or select a policy and click Properties. The LI MAC Filter, Global Policy (Create|Edit) form opens.

3

Configure the required general parameters.

4

Configure LI MAC filter entries:

1. Click on the LI MAC Filter Entries tab.
2. Click Create. The LI MAC Filter Entry, LI MAC Filter, Global Policy (Create) form opens.
3. Configure the required parameters.
4. Save the changes and close the form.

5

Configure the LI MAC filter association:

1. Click on the MAC Filter Association tab.
2. Click Create. The LI MAC Filter Association, LI MAC Filter form opens.

3. Select an ACL MAC filter to associate with the LI MAC filter policy.
4. Save the changes and close the form.

6

Click Apply.

7

Click on the General tab.

8

Click Switch Mode to release the policy for distribution. The Release - LI MAC Filter Policy form opens.

9

Choose the NEs in the Available Objects to which you want to distribute the policy and click the arrow to move the NEs to the Selected Objects panel.

10

Click Distribute and close the form.

11

Close the LI MAC Filter Policies form.

END OF STEPS

94.16 To configure an LI IP filter policy

94.16.1 Steps

Note: You are required to be an NFM-P user with LI privileges to access the LI IP filter policy.

You require at least one IP filter policy to complete this procedure. See 51.5 “To configure an ACL IP filter policy” (p. 1671) for more information.

You require at least one Block Reservation policy to complete this procedure. See 94.18 “To configure a Block Reservation policy” (p. 3212) for more information.

1

Choose Policies→Filter→LI Policies→LI IP Filter from the NFM-P main menu. The LI IP Filter Policies form opens.

2

Click Create or select a policy and click Properties. The LI IP Filter (Create|Edit) form opens.

3

Configure the required general parameters.

4

Configure one or more filter entries:

1. Click on the LI IP Filter Entries tab.
2. Click Create. The Entry, LI IP Filter (Create) form opens.
3. Configure the parameters.
4. Click on the Filter Properties tab.
5. Configure the Protocol parameter.
6. Configure the parameters in the Match Criteria panel.

   The Source Port and Dest Port parameters are configurable only when the Protocol parameter is set to TCP or UDP.
7. Save the changes and close the form.

5

Associate the base IP filter with the LI IP filter:

1. Click on the IP Filter Association tab.
2. Click Create. The LI IP Filter Association (Create) form opens.
3. Select an IP filter in the IP Filter panel.
4. Save the changes and close the form.

6

Click Apply.

7

Click on the General tab.

8

Click Switch Mode to release the policy for distribution. The Release - LI IP Filter Policy form opens.

9

Choose the NEs in the Available Objects to which you want to distribute the policy and click the arrow to move the NEs to the Selected Objects panel.

10

Click Distribute and close the form.

11

Close the LI IP Filter Policies form.

END OF STEPS

94.17 To configure an LI IPv6 filter policy

94.17.1 Steps

Note: You are required to be an NFM-P user with LI privileges to access the LI IPv6 filter policy.

You require at least one ACL IPv6 filter policy to complete this procedure. See 51.6 “To configure an ACL IPv6 filter policy” (p. 1677) for more information.

You require at least one Block Reservation policy to complete this procedure. See 94.18 “To configure a Block Reservation policy” (p. 3212) for more information.

1

Choose Policies→Filter→LI Policies→LI IPv6 Filter from the NFM-P main menu. The LI IPv6 Filter Policies form opens.

2

Click Create or select a policy and click Properties. The LI IPv6 Filter (Create|Edit) form opens.

3

Configure the required general parameters.

4

Configure one or more filter entries:

1. Click on the LI IPv6 Filter Entries tab.
2. Click Create. The Entry, LI IPv6 Filter (Create) form opens.
3. Configure the required general parameters.
4. Click on the Filter Properties tab.
5. Configure the Protocol parameter.
6. Configure the parameters in the Match Criteria panel:

   The Source Port and Dest Port parameters are configurable only when the Protocol parameter is set to TCP or UDP.
7. Save the changes and close the form.

5

Associate the base IPv6 filter with the LI IPv6 filter:

1. Click on the IPv6 Filter Association tab.
2. Click Create. The LI IPv6 Filter Association (Create) form opens.

3. Select an IPv6 filter in the IPv6 Filter panel.
4. Save the changes and close the form.

6

Click Apply.

7

Click on the General tab.

8

Click Switch Mode to release the policy for distribution. The Release - LI IPv6 Filter Policy form opens.

9

Choose the NEs in the Available Objects to which you want to distribute the policy and click the arrow to move the NEs to the Selected Objects panel.

10

Click Distribute and close the form.

11

Close the LI IPv6 Filter Policies form.

END OF STEPS

94.18 To configure a Block Reservation policy

94.18.1 Steps

Note: You are required to be an NFM-P user with LI privileges to access the Block Reservation policy.

You require at least one ACL MAC filter policy. See 51.4 “To configure an ACL MAC filter policy” (p. 1668) for more information.

You require at least one IP filter policy. See 51.5 “To configure an ACL IP filter policy” (p. 1671) for more information.

1

Choose Policies→Filter→LI Policies→Block Reservation from the NFM-P main menu. The Block Reservation Policies form opens.

2

Click Create or select a policy and click Properties. The Block Reservation, Global Policy (Create|Edit) form opens.

3

Configure the required general parameters.

4

Create a MAC filter LI block reservation association:

1. Click on the MAC Filters tab.
2. Click Create. The MAC Filter LI Block Reservation Association, Block Reservation, Global Policy (Create) form opens.
3. Select an ACL MAC filter to associate with the Block Reservation policy.
4. Save the changes and close the form.

5

Create an IPv4 or IPv6 filter LI block reservation association:

1. Click on the IP Filters tab.
2. Click Create. The IP Filter LI Block Reservation Association, Block Reservation, Global Policy (Create) form opens.
3. Select an IP filter to associate with the Block Reservation policy.
4. Save the changes and close the form.

6

Click Apply.

7

Click on the General tab.

8

Click Switch Mode to release the policy for distribution. The Release - Block Reservation Policy form opens.

9

Choose the NEs in the Available Objects to which you want to distribute the policy and click the arrow to move the NEs to the Selected Objects panel.

10

Click Distribute and close the form.

11

Close the Block Reservation Policies form.

END OF STEPS

94.19 To configure the LI filter lock

94.19.1 LI Filter Lock options

This procedure allows an NFM-P LI user to configure a parameter that permits base IPv4 and MAC filters referenced by an LI Source to be modified or deleted. The LI Filter Lock parameter specifies who can modify the LI filters. The available options are:

- Locked: no user can modify the LI filters
- Unlocked For LI Users: only users with LI privileges can modify the LI filters
- Unlocked For All: all users can modify the LI filters

94.19.2 Steps

Note: You require LI privileges to view the LI Configuration Status tab and to perform this procedure.

1

Right-click on a discovered device in the Equipment navigation tree and choose Properties. The Network Element (Edit) form is displayed.

2

Click on the LI Configuration Status tab.

3

Configure the LI Filter Lock parameter.

4

Save the changes and close the form.

END OF STEPS

94.20 To enable NE discovery for LI

94.20.1 Steps

Note: You require LI privileges to perform this procedure.

Perform this procedure to enable LI discovery of an NE. Before you can enable LI discovery for an NE, the NE must be successfully discovered. See Chapter 9, “Device discovery” for information about configuring NE discovery.

1

Choose Administration→Discovery Manager from the NFM-P main menu. The Discovery Manager (Edit) form opens with the Discovery Rules tab displayed.

2

Click on the Managed State tab. A list of discovered NEs is displayed.

3

Choose an NE on which 94.9 “To create an NE LI user profile on an NE using a CLI” (p. 3200) and 94.10 “To create an NE LI user account on an NE using a CLI” (p. 3201) have been performed, and click Properties. The Node Discovery Control (Edit) form opens.

4

Click on the LI Mediation Security tab.

5

Select the LI mediation policy created in 94.14 “To configure an LI security mediation policy” (p. 3207) in the Dual Read Access Mediation Policy panel.

6

Select the LI mediation policy created in 94.14 “To configure an LI security mediation policy” (p. 3207) in the Dual Write Access Mediation Policy panel.

7

Select the LI mediation policy created in 94.14 “To configure an LI security mediation policy” (p. 3207) in the Dual Trap Access Mediation Policy panel.

8

Save the changes and close the form.

9

On the Discovery Manager (Edit) form, click on the Resync Status tab.

10

Choose the NE and click Resync. The Resync Options form opens.

11

Select Choose MIB Entries and click Next. The Choose MIB Entries list form opens.

12

Select all TIMETRA-MIRROR-MIB entries in the list and click Finish.

Note: Resynchronizing only the TIMETRA-MIRROR-MIB entries resynchronizes only LI source objects and keeps the resynchronization time to the minimum required.

13

Close the forms.

END OF STEPS

94.21 To save the LI configuration of an NE

94.21.1 Steps

Note: You require LI privileges to view the LI Configuration Status tab and to perform this procedure.

This procedure allows an NFM-P LI user to save the LI configuration file (li.cfg) from the NFM-P for an NE. The li.cfg file is updated only when changes to the LI configuration are deployed to the NE.

1

Right-click on a discovered device in the Equipment navigation tree and choose Properties. The Network Element (Edit) form is displayed.

2

Click on the LI Configuration Status tab.

3

Click Save LI Configuration.

4

Close the form.

END OF STEPS

94.22 To configure Layer 3 encapsulation on a source site to allow LI-mirrored packets to be placed into a routable header

94.22.1 Related information

You can configure a Layer 3 encapsulation option to allow LI-mirrored packets to be placed into a routable header (either IP-UDP Shim or IP-GRE) and then forwarded in a routing context.

The following conditions apply if you configure the Layer 3 encapsulation option:

- Configuring Mirror SDP bindings and Mirror SAPs is mutually exclusive to the L3 Encapsulation
- You cannot configure the Session ID or Intercept ID of a source later on in this procedure if the L3 Encapsulation is not configured here.
- You cannot configure L3 Encapsulation if a mirror source object (such as: IP filter, MAC filter, and so on) is first configured for this service.

- You cannot change the routing instance of L3 Encapsulation if a gateway is first configured for this service.

You can configure L3 Encapsulation only on a source site on an NE in chassis mode D. See Chapter 15, “Shelf and card object configuration” for more information about chassis modes.

94.22.2 Steps

1

Choose Manage→Service→Mirror Services from the NFM-P main menu. The Manage Mirror Services form opens.

2

Select a mirror service and click Properties. The Mirror Service (Edit) form opens.

3

On the service navigation tree, expand Source Sites and click on the source site. The Mirror Site (Edit) form opens.

4

Click on the L3 Encapsulation tab and click Create. The Layer-3 Encapsulation null (Create) form opens

5

Configure the required parameters.

The Use Direction Bit parameter is only displayed if you configured the Header Type option for IP-UDP Shim.

6

Select a routing instance ID in the Routing Instance panel.

7

To configure a gateway:

1. Click Create in the Gateway panel. The Layer-3 Encapsulation Gateway null (Create) form opens.
2. Configure the required parameters in the IP Address panel.

   The gateway Source Address and Destination Address must either both be unconfigured or both configured. Similarly, the gateway Source Port and Destination Port must either both be unconfigured or both configured.

   The Source Port and Destination Port parameters are displayed only if you configured the Header Type option for IP-UDP Shim.
3. Save the changes and close the form.

8

Save the changes and close the forms.

END OF STEPS

94.23 To specify an LI MAC filter entry as an LI source

94.23.1 Steps

Specifying an LI MAC filter entry as the mirror source causes all the packets matching the filter to be mirrored to the mirror destination specified by the service ID of the mirror source.

1

Choose Manage→Service→Mirror Services from the NFM-P main menu. The Manage Mirror Services form opens.

2

Select a mirror service and click Properties. The Mirror Service (Edit) form opens.

3

Perform one of the following:

a. To specify an LI source LI IP filter entry on a destination site, expand the Destination Site object to view the configured destination sites, and expand the destination site object on which you are specifying the LI source LI IP filter entry.

b. To specify an LI source LI IP filter entry on a source site, expand the Source Site object to view the configured source sites, and expand the source site object on which you are specifying the LI source LI IP filter entry.

4

Right-click on LI Source LI IP Filters and choose Create LI Source LI IP Filter. The LI Source LI IP Filter (Create) form opens.

Note: A mirror site can be configured with debug or LI sources, but not both. LI source configuration takes priority over debug source configuration.

5

Select an LI source LI IP filter entry.

6

Configure the required parameters.

7

Save the changes and close the forms.

END OF STEPS

94.24 To specify an LI Source Port as an LI source

94.24.1 Purpose

Use this procedure to configure an LI Source Port mirror on a port or LAG. The LI Source Port can mirror Egress or Ingress traffic or both directions.

Note: The following considerations apply:

- The NE must be licensed to allow LI source port mirroring.
- When an LI Source Configuration is enabled, all Mirror Service sources (such as Interfaces, Ports, IP filter, or Subscribers) can no longer be provisioned on that Mirror Service.

  The admin user must create a new unique Service Mirror for non LI source types, and not share the same Mirror Service with and LI Mirror Service(both having the same service ID number).
- All existing Mirror Service sources will be removed if LI Source Configuration is enabled, or any type of LI Mirror source is provisioned.

94.24.2 Steps

1

Choose Manage→Service→Mirror Services from the NFM-P main menu. The Manage Mirror Services form opens.

2

Select a mirror service and Properties. The Mirror Service (Edit) form opens.

3

To specify an LI source port on a source site, expand Source Sites→*source_site*, right-click on LI Source Ports and choose Create Source Port. The Source Port (Create) form opens.

Note: An NFM-P operator with LI privileges can view, create, and delete LI source objects.
A mirror site can be configured with debug or LI sources, but not both. LI source configuration takes priority over debug source configuration.

4

Select a port.

An LI source port can be one of the following:

- physical port
- LAG

5

Configure the required parameters.

6

Save the changes and close the forms.

END OF STEPS

94.25 To specify an LI IP filter entry as an LI source

94.25.1 Steps

Specifying an LI IPv4 filter entry as the mirror source causes all the packets matching the filter to be mirrored to the mirror destination specified by the service ID of the mirror source.

1

Choose Manage→Service→Mirror Services from the NFM-P main menu. The Manage Mirror Services form opens.

2

Select a mirror service and Properties. The Mirror Service (Edit) form opens.

3

Perform one of the following:

a. To specify an LI source LI IP filter entry on a destination site, expand the Destination Site object to view the configured destination sites, and expand the destination site object on which you are specifying the LI source LI IP filter entry.

b. To specify an LI source LI IP filter entry on a source site, expand the Source Site object to view the configured source sites, and expand the source site object on which you are specifying the LI source LI IP filter entry.

4

Right-click on the LI Source LI IP Filters object below the site in the service navigation tree and choose Create LI Source LI IP Filter. The LI Source LI IP Filter (Create) form opens.

Note: An NFM-P operator with LI privileges can view, create, and delete LI source objects.

A mirror site can be configured with debug or LI sources, but not both. LI source configuration takes priority over debug source configuration.

5

Select an LI MAC filter entry.

6

Configure the required parameters.

7

Save the changes and close the forms.

END OF STEPS

94.26 To specify an LI IPv6 filter entry as an LI source

94.26.1 Steps

Specifying an LI IPv6 filter entry as the mirror source causes all the packets matching the filter to be mirrored to the mirror destination specified by the service ID of the mirror source.

1

Choose Manage→Service→Mirror Services from the NFM-P main menu. The Manage Mirror Services form opens.

2

Select a mirror service and Properties. The Mirror Service (Edit) form opens.

3

Perform one of the following:

a. To specify an LI source LI IPv6 filter entry on a destination site, expand the Destination Site object to view the configured destination sites, and expand the destination site object on which you are specifying the LI source LI IPv6 filter entry.

b. To specify an LI source LI IPv6 filter entry on a source site, expand the Source Site object to view the configured source sites, and expand the source site object on which you are specifying the LI source LI IPv6 filter entry.

4

Right-click on the LI Source LI IPv6 Filters object below the site in the service navigation tree and choose Create LI Source LI IPv6 Filter. The LI Source LI IPv6 Filter (Create) form opens.

Note: An NFM-P operator with LI privileges can view, create, and delete LI source objects.

A mirror site can be configured with debug or LI sources, but not both. LI source configuration takes priority over debug source configuration.

5

Select an LI source LI IPv6 filter entry.

6

Configure the required parameters.

7

Save the changes and close the forms.

END OF STEPS

94.27 To specify an LI SAP as an LI source

94.27.1 Steps

1

Choose Manage→Service→Mirror Services from the NFM-P main menu. The Manage Mirror Services form opens.

2

Select a mirror service and click Properties. The Mirror Service (Edit) form opens.

3

Right-click on the LI Source SAPs object below the site in the service navigation tree and choose Create LI Source Interface. The LI Source Interface (Create) form opens. Go to Step 4 .

Note: An NFM-P operator with LI privileges can view, create, and delete LI source objects.
A mirror site can be configured with debug or LI sources, but not both. LI source configuration takes priority over debug source configuration.

4

Select an access interface to associate with the source interface.

5

Configure the required parameters.

6

Save the changes and close the forms.

END OF STEPS

94.28 To specify an LI subscriber as an LI source

94.28.1 Steps

1

Choose Manage→Service→Mirror Services from the NFM-P main menu. The Manage Mirror Services form opens.

2

Select a mirror service and click Properties. The Mirror Service (Edit) form opens.

3

Expand the Source Site object to view the configured source sites, and expand the source site object on which you are specifying the subscriber as the mirror source.

4

Right-click on the LI Source Subscribers object below the site in the service navigation tree and choose Create LI Source Subscriber. The LI Source Subscriber (Create) form opens.

Note: An NFM-P operator with LI privileges can view, create, and delete LI source objects.
A mirror site can be configured with debug or LI sources, but not both. LI source configuration takes priority over debug source configuration.

5

Configure the required parameters.

6

You can further restrict the mirrored subscriber host traffic associated with the subscriber identification string by specifying SAP or SLA-profile criteria. To specify an SLA profile as a match criterion, go to Step 8 .

Note: You can configure parameters in the SAP/Subscriber Host Match Criteria panel or the SLA Profile Match Criteria panel, but you cannot configure parameters in both panels.

7

To specify a SAP:

1. Select a SAP on which to mirror subscriber host traffic in the SAP/Subscriber Host Match Criteria panel.

   You can select only dot1q- or QinQ-encapsulated SAPs that have subscriber management enabled.
2. Configure the parameters in the SAP/Subscriber Host Match Criteria panel to specify the subscriber host match criteria for the SAP.

   Note:

The NFM-P does not accept the parameter values unless a SAP is specified.

3. Go to Step 9 .

8

To specify SLA profile match criteria, select the SLA profile in the SLA Profile Match Criteria panel.

9

Save the changes and close the forms.

END OF STEPS

94.29 To specify an LI WLAN distributed subscriber as an LI source

94.29.1 Steps

1

Choose Manage→Service→Mirror Services from the NFM-P main menu. The Manage Mirror Services form opens.

2

Select a mirror service and Properties. The Mirror Service form opens.

3

Expand the Source Sites object to view the configured source sites, and expand the source site object on which you are specifying a WLAN distributed subscriber as the mirror source.

4

Right-click on the LI Source WLAN Distributed Subscribers object below the site in the service navigation tree and choose Create LI Source WLAN Distributed Subscriber. The LI Source WLAN Distributed Subscriber (Create) form opens.

Note: An NFM-P operator with LI privileges can view, create, and delete LI source objects.
A mirror site can be configured with debug or LI sources, but not both. LI source configuration takes priority over debug source configuration.

5

Configure the required parameters.

6

Save the changes and close the forms.

END OF STEPS

94.30 To configure LI on a specific NAT subscriber

94.30.1 Steps

1

Choose Manage→Service→Mirror Services from the NFM-P main menu. The Manage Mirror Services form opens.

2

Choose a mirror service and Properties. The Mirror *Service Name* (Edit) form opens.

3

Click on the Sites tab. A list of mirror service sites are displayed.

4

Choose a site and click Properties. The Mirror Site (Edit) form opens.

5

Click on the LI NAT Sources tab.

Note: The LI NAT Sources tab appears only if the Encapsulation Type parameter for the mirror site is set to Ethernet and the L3 encapsulation Header Type parameter is set to IP-UDP Shim. See 94.22 “To configure Layer 3 encapsulation on a source site to allow LI-mirrored packets to be placed into a routable header” (p. 3216) for more information about how to set the Header Type parameter.

6

Click Configure LI Source Configuration.

7

Click on the Ethernet Header tab.

8

Configure the required parameters.

9

Click on the L2 Aware Subscribers tab.

10

Click Create. The LI Source NAT L2 Aware Subscriber (Create) form opens.

11

Configure the required parameters.

12

Click OK. The LI Source NAT L2 Aware Subscriber (Create) form becomes a tab.

13

Click OK. The LI Source NAT L2 Aware Subscriber (Create) tab closes and the Mirror Service (Edit) form reappears with the Sites tab displayed.

14

Choose a site and click Properties. The Mirror Site (Edit) form opens.

15

Click on the LI NAT Sources tab. The Ethernet Header tab is displayed.

16

Click on the Dual Stack Lite LSN Subscribers tab.

17

Click Create. The LI Source Dual Stack Lite LSN Subscriber (Create) form opens.

18

Configure the required parameters.

19

Click OK. The LI Source Dual Stack Lite LSN Subscriber (Create) form becomes a tab.

20

Click OK. The LI Source Dual Stack Lite LSN Subscriber (Create) tab closes and the Mirror Service (Edit) form reappears with the Sites tab displayed.

21

Choose a site and click Properties. The Mirror Site (Edit) form opens.

22

Click on the LI NAT Sources tab. The Ethernet Header tab is displayed.

23

Click on the Classic LSN Subscribers tab.

24

Click Create. The LI Source Classic LSN Subscriber (Create) form opens.

25

Configure the required parameters.

26

Click OK. The LI Source Classic LSN Subscriber (Create) form becomes a tab.

27

Click OK. The LI Source Classic LSN Subscriber (Create) tab closes and the Mirror Service (Edit) form reappears with the Sites tab displayed.

28

Click on the NAT 64 LSN Subscribers tab.

29

Click Create. The LI Source NAT 64 LSN Subscriber (Create) form opens.

30

Configure the required parameters.

31

Click OK. The LI Source NAT 64 LSN Subscriber (Create) form becomes a tab.

32

Click OK. The LI Source NAT 64 LSN Subscriber (Create) tab closes and the Mirror Service (Edit) form reappears with the Sites tab displayed.

33

Save the changes and close the forms.

END OF STEPS

94.31 To view LI mirrored subscriber hosts configured with a RADIUS server

94.31.1 Steps

Note: You must have NFM-P LI user privileges to perform this procedure.

Before you can perform this procedure, at least one LI user account must exist on the NE.

Before you can perform this procedure, an NFM-P LI user must enable LI discovery for the NE using 94.20 “To enable NE discovery for LI” (p. 3214) .

Only PPPoE subscriber hosts can be mirrored with RADIUS.

1

Choose Manage→Service→Mirror Services from the NFM-P main menu. The Manage Mirror Services form opens.

2

Choose a mirror service and click Properties. The Mirror *Service Name* (Edit) form opens.

3

Click on the Sites tab. A list of mirror service sites is displayed.

4

Choose a site and click Properties. The Mirror Site (Edit) form opens.

5

If an LI source configuration object has not been created, the LI Source Configuration tab is dimmed. Click Create LI Source Configuration at the bottom of the form. A dialog box appears.

Note: You must create an LI source configuration object for the NE to mirror subscriber hosts for LI.
The Create LI Source Configuration button is a toggle that also lets you delete an LI source configuration object. If you delete an LI source configuration object, all associated LI source objects are deleted.
An LI source configuration object is automatically created when an LI source object is created.

6

Click OK. The LI Source Configuration tab is enabled, and an LI source configuration object is created.

7

Click on the LI Source Subscribers Via RADIUS tab.

8

Choose a subscriber and click Properties. The LI Source Subscriber Host form opens.

9

View the information on the form.

10

Close the LI Source Subscriber Host form.

END OF STEPS

95 RCA audit

95.1 Overview

95.1.1 Purpose

This chapter describes the NFM-P root cause analysis functionality, and provides information about configuring RCA.

95.1.2 Contents

RCA audit overview

95.2 RCA audit concepts

95.2.1 RCA audit description

You can perform on-demand or scheduled root cause analysis and verification of the configuration of routing instances, services, and other network objects to identify possible configuration problems. Except for physical links, the NFM-P provides a solution, which, at your request, can automatically be implemented to make all of the required configuration changes.

Note: The adjustments are made only to the NFM-P database and are not deployed to the network.

Only VPLS, VPRN, and VLL services RCA audits and golden configuration RCA audits can be scheduled.

95.2.2 RCA audit objects

You can perform RCA audits of the following objects:

- physical links
- VPLS, VPRN, and VLL services and service site memberships
- OSPF interfaces, areas, and area sites (NFM-P/CPAM integration only)
- IS-IS interfaces and sites (NFM-P/CPAM integration only)

95.3 NFM-P service audit

95.3.1 Service audit description

An NFM-P service is defined as a collection of service sites with the same customer ID, service type, and service ID. The NFM-P discovers services that are configured on a 7210 SAS, 7450 ESS, 7750 SR, or 7950 XRS, using the service ID on the NE. Configuration errors may occur in networks where the services were created and deployed on the NEs using CLI before the NEs were managed by the NFM-P.

For example, when two VPLSs with the same service ID and the same mesh VC ID on an NE are discovered by the NFM-P, they are discovered as a single service in the NFM-P.

Another example of a configuration error is when a switching Epipe has multiple Epipe sites and multiple VC IDs for different segments. If different service IDs are used when the sites are created, the NFM-P assumes that the sites are connected and creates multiple VLL services within a composite service.

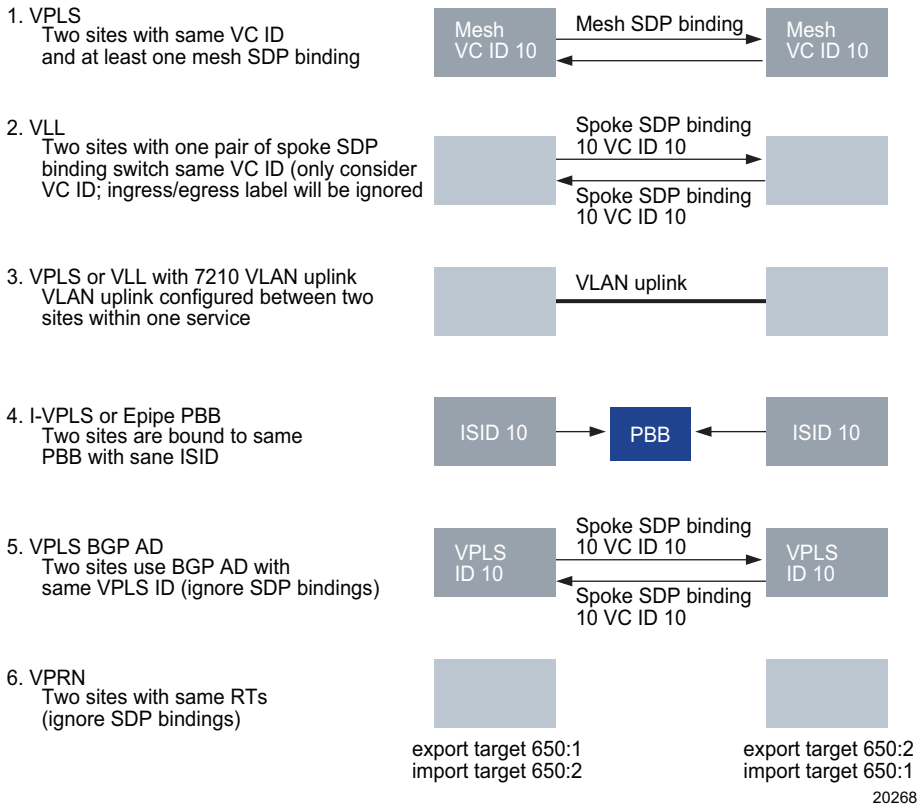
RCA audit policies allow you to modify the component membership of your NFM-P services to detect possible configuration problems. In addition, you can use the RCA audit to correct most configuration problems that are discovered in the audit.

Note: An NFM-P user who is assigned the Administrator or RCA scope of command role can create, modify, and execute all RCA audit policies. An NFM-P user who is assigned the Administrator or Service scope of command role can execute service audit adjustments.

95.3.2 Service membership rules

The NFM-P uses the rules outlined in the following figure to identify whether two service sites are connected. When two sites are identified as connected, they should belong to same service.

Figure 95-1 Rules to check whether two sites are connected



If service sites have different customer IDs, the NFM-P discovers the sites as belonging to different services. After the audit, the NFM-P generates a problem for each service. You can specify to which service the NFM-P should move the site and whether the empty service should be removed after the sites are moved.

For VPLS or VLL services, if the same service ID is used for two groups of sites that are not connected, the NFM-P detects a duplicate service ID. Two problems are generated for one of the group of sites, and the solution is to separate the services. If there are other groups of isolated sites, additional problems are generated for each group.

Consider the following when you perform an audit of a VPLS.

- Although different service IDs may be used, I-sites that are bound to same backbone VPLS and have the same ISID are considered to be in the same VPN.
- For VPLS sites that use BGP auto-discovery, the VPLS ID is used to determine service membership.
- H-VPLS is discovered as composite service in the NFM-P if different service IDs are used.

Consider the following when you perform an audit of a VLL service.

- Service sites with different customer IDs are discovered as two services, and can be reconfigured as one service.
- More than two groups of sites that are connected can be detected and can be separated into different services.
- Redundant VLLs are not affected by the audit and are considered correctly configured.
- If two Epipe sites are connected to the same PBB with same B-VPLS service ID, and the source and destination MAC addresses match, the NFM-P determines that the two sites are connected. If they are in different NFM-P services, a problem is generated during the audit.

Consider the following when you perform an audit of a VPRN service.

- VPRN service membership is based on the RTs defined in the VRFs.
- Sites that are in different services but have common import and export route targets. Import target of Site 1 is equal to the Export target of Site 2.

95.3.3 RCA audit for services with multi-vendor NE sites

The NFM-P attempts to place MV sites into the correct service during discovery. For MV sites which are not placed into the correct service, the MV Complete Service Topology function moves the MV sites and matches them with the service. When you click the MV Complete Service Topology button on the Manage Services form, the NFM-P performs a search for services containing MV sites. If a service does not contain any MV NEs, the NFM-P skips that service. For each service, the NFM-P performs an RCA audit and the following actions occur:

- Epipe service

  The NFM-P determines if an Epipe service has at least one MV site, and then checks all other Epipe services for a site with the same VC ID and with SDP bindings pointing to each other. If a matching site is found, the NFM-P moves the site from the first service to the second (matching) service. As a result, the two services are collated. If a service has two or more MV sites which do not meet the same criteria, one site is moved to either the correct matching service, or a new service. This action results in two services potentially assigned to different customers being merged into one service. No changes are made on the NE.

- VPLS service

  A VPLS service can have one or more sites. The RCA audit only supports mesh SDPs. The MV Complete Service Topology function does not support VPLS sites with spoke SDPs.

  When the NFM-P finds a VPLS service with at least one MV site, it checks all VPLS services for a site with the same mesh VC ID and the mesh SDPs pointing to each other. All of the matching sites that are in different services are moved to a single service. Any mismatched sites are moved to either the correct matching service, or a new service. This action results in two services potentially assigned to different customers being merged into one service. No changes are made on the NE.

- VPRN service

  Note: Do not re-use route targets on the NEs. Route targets must be unique because the RCA audit uses route targets to match VPRN sites that are in different NFM-P services or that have different service IDs. Reusing route targets causes the sites to be moved to the same service and the sites are physically separate.

  When the NFM-P finds a VPRN service with a MV site, it checks for all of the VPRN sites (MV or SR) that use the same RT value. The NFM-P then moves the MV sites from the first service to the second service that has other MV or SR sites. This step is repeated for all of the MV sites that have the same RT value. This action results in two services previously assigned to different customers being merged into one service.

95.4 Physical link audits

95.4.1 Physical link description

Physical links represent the actual physical configuration of network connections between ports. You can view and manage physical links from the equipment window, physical topology map, and the Manage Equipment list form of the NFM-P, on each router using the CLI. Because several key parameters on each end of the physical link depend on each other, configuration errors are possible. An RCA audit can identify configuration errors in physical links. The NFM-P does not provide a solution for configuration problems that the RCA audit identifies for physical links.

95.4.2 Configuration errors in physical links

By default, the RCA audit detects the following configuration errors in physical links:

- **physical port parameters**
  - mismatched MTU values
  - mismatched speeds
- **Ethernet port parameters**
  - Auto-negotiate parameter misconfiguration
  - Duplex parameter misconfiguration

You can configure the RCA audit policy for the physical link to include additional physical link properties in the audit.

95.5 Viewing and analyzing RCA audit results

95.5.1 RCA audit results

After you manually perform an RCA audit, or the RCA audit executes as per the schedule details, you can determine if problems were detected, when the last audit was performed, and view the correction plan for a problem. The RCA Audit Problem(s) indicator on the General tab of a network object properties form identifies whether configuration problems were detected in previous audits. The Last Audit Time indicator displays a timestamp of the last audit that was performed. The RCA Audit button is located at the bottom of the service properties form, or under the More Actions button.

After you associate an audit policy with the object, you can perform an RCA audit and view the results. If no problems are detected, the RCA Result tab does not appear.

The properties form of a problem displays the following information:

- problem severity
- probable cause
- description
- solution

The Caused By Objects tab lists the network objects that caused the problem. For service audits, the sites that should be moved out of a service, and the service they should move to, if there is only one destination service, are listed. If only one group of sites is listed, a new service is created and the sites are moved to the created service.

95.5.2 Correcting detected configuration problems

NOTICE

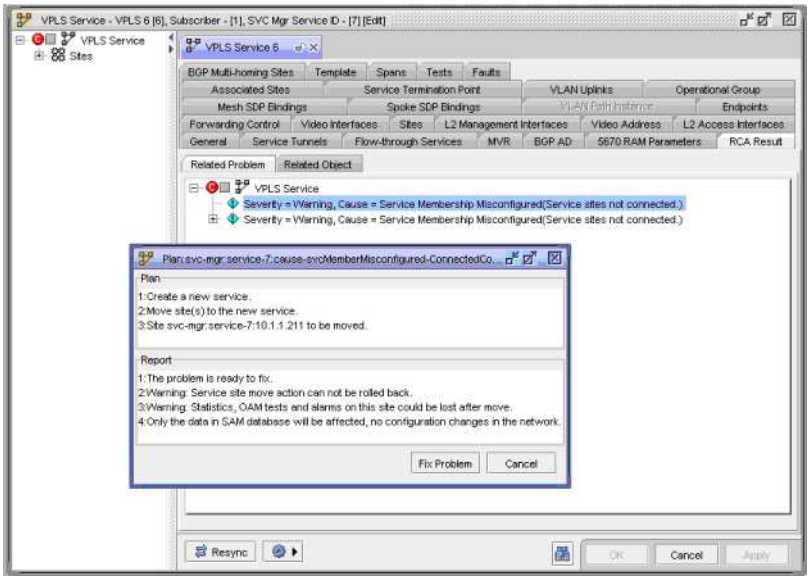
Service-disruption hazard

Modifying the nms-server.xml file can have serious consequences that can include service disruption.

To view the result in the server or client log, you need to enable the logging option in the nms-server.xml or nms-client.xml file. Contact your Nokia technical support representative before you attempt to modify the nms-server.xml file.

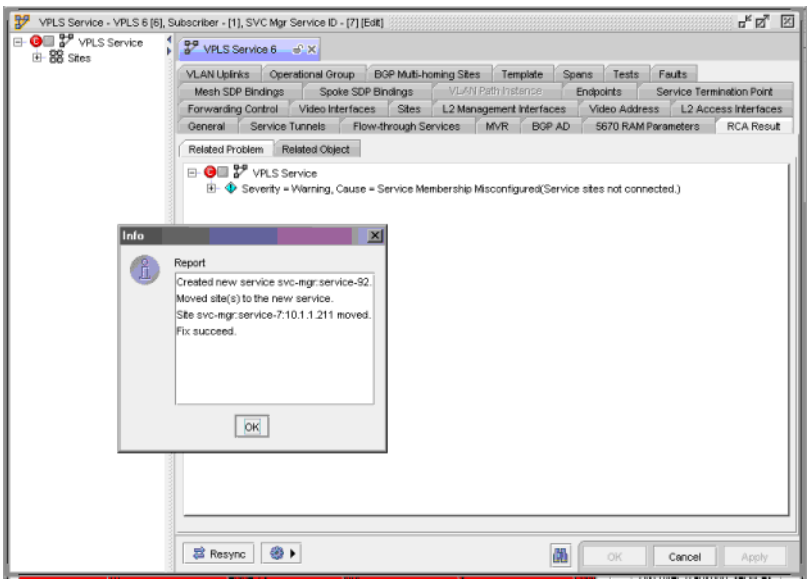
You can use an RCA audit to correct a detected configuration problem from the RCA Result tab on the network object properties form. The NFM-P lists the operations to fix the problem, as shown in the following figure.

Figure 95-2 Correction plan for a problem



When you accept the proposed solution, a summary of the correction operation that the NFM-P implemented appears, as shown in Figure 95-3, “Correction report” (p. 3235). To view the result in the server or client log, you must enable the logging option in the nms-server.xml or nms-client.xml file.

Figure 95-3 Correction report



The following table describes the probable causes of problems.

Table 95-1 Probable causes

Probable cause	Description
Admin Down	The object is administratively down.
Aggregated	Aggregated cause
B-VPLS Backbone Attributes misconfigured	One or more B-VPLS backbone parameters are not configured correctly.
Control B-VPLS SPB ECT-FID mapping configurations are not consistent across all sites in this B-VPLS	The ECT algorithm to FID range mapping in a control SPB B-VPLS is not consistent on all of the sites in the same service. Each B-site must have the same number of ECT-to-FID mappings. In addition, the following ECT-to-FID range mapping parameters must be the same on all of the sites in the SPB-enabled B-VPLS: • FID Range Start • FID Range End • FID Range Algorithm See 77.61 “To enable SPB on a control B-VPLS site” (p. 2323) for more information.
Misconfiguration	There is a misconfiguration error.
Missed service members for Multi-Segment PW	Missed service members for Multi-Segment PW
No members configured for this Multi-homing site	The BGP VPLS multi-homing site does not have other sites as members that share the same multi-homing ID in order to comprise a group.
No valid Route Targets configured for VPLS BGP Multi-homing	No valid Route Targets currently exist for a VPLS site that has BGP multi-homing sites configured under it.
One or more SPB SAP(s) or SPB Spoke SDP Binding(s) exist on User B-VPLS that do not exist on Control B-VPLS. These extra links are not fate shared with the Control B-VPLS	One or more SPB SAPs or spoke SDP bindings on the user B-VPLS are not on the control B-VPLS. You must remove the SAPs or spoke SDP bindings, or create them on the control SPB B-VPLS site.
Route Targets are misconfigured for VPLS BGP Multi-homing	One of the following misconfigurations exists: • No matching RT for peered multi-homing sites • There are multiple RTs configured for a VPLS site that has BGP multi-homing sites configured under it. Multiple RTs will make the BGP multi-homing sites appear under multiple topologies or multiple services. • Multi-homing sites have the same multi-homing ID but different RTs (different RTs mean the sites are in different topologies or services)
Service Membership Misconfigured	The service membership is not configured correctly.
One or more SPB SAP(s) or SPB Spoke SDP Binding(s) configured on Control B-VPLS are missing from the User B-VPLS	One or more SPB SAPs or spoke SDP bindings are configured on the control B-VPLS that do not exist on this user B-VPLS. You must remove the SAPs or spoke SDP bindings, or create them on the user SPB B-VPLS site.

Table 95-1 Probable causes (continued)

Probable cause	Description
SPB is not enabled on one or more B-Sites in this B-VPLS	The SPB Mode parameter is not set to Control or User on one or more of the sites in the SPB-enabled B-VPLS service. See 77.61 “To enable SPB on a control B-VPLS site” (p. 2323) and 77.62 “To enable SPB on a user B-VPLS site” (p. 2326) for more information.
SPB Sites within this B-VPLS service do not have their SPB Modes (Control/User) consistently configured	One or more B-sites in the SPB-enabled B-VPLS service do not have the same value configured for their SPB Mode parameter as the other sites within the service. See 77.61 “To enable SPB on a control B-VPLS site” (p. 2323) and 77.62 “To enable SPB on a user B-VPLS site” (p. 2326) for more information.
The B-VPLS SPB FIDs are not identical across all sites in this B-VPLS service	The Forwarding Identifier (FID) parameter is not the same for all the sites in the SPB B-VPLS service. See 77.61 “To enable SPB on a control B-VPLS site” (p. 2323) and 77.62 “To enable SPB on a user B-VPLS site” (p. 2326) for more information.
The Control B-VPLS SPB unicast forwarding tree topology configurations are not consistent across all sites in this B-VPLS	The Unicast Forwarding Tree Topology parameter is not configured consistently on all of the sites in the same control SPB B-VPLS service. See 77.61 “To enable SPB on a control B-VPLS site” (p. 2323) for more information.
Underlying Resource Operational Down	The underlying resource of the object is operationally down.
Underlying Resource Admin Down	The underlying resource of the object is administratively down.
Underlying Resource Missing	An underlying resource is missing.
Underlying Resource Problem	Problem with an underlying resource
Unknown	The probable cause could not be determined.
Within this Control B-VPLS, not all SAPs or Spoke-SDPs are SPB enabled	SPB is not enabled on one or more SAPs or spoke SDP bindings in the control B-VPLS service. You must add the SPB interface to the SAP or spoke SDP binding. See 77.61 “To enable SPB on a control B-VPLS site” (p. 2323) for more information.

Procedures to configure and schedule an RCA audit

95.6 Workflow to configure and schedule an RCA audit

95.6.1 Stages

1

Create or configure an RCA audit policy. See 95.7 “To configure an RCA audit policy” (p. 3238) .

2

Run the RCA audit policy for a specific service or object.

a. Perform an RCA audit of a service or multiple services. See 95.8 “To perform an RCA audit of a service or multiple services” (p. 3240) .

b. Perform an RCA audit of a physical link. See 95.9 “To perform an RCA audit of a physical link” (p. 3242) .

3

As required, schedule the RCA audit policy to perform the RCA audit at a designated time; see 95.10 “To schedule an RCA audit” (p. 3243) .

4

Identify the problems and view the suggested solutions. Solutions are not provided for physical links. See “Viewing and analyzing RCA audit results” for more information.

5

Implement the changes, as required.

6

Delete an RCA audit policy, as required. See 95.11 “To delete an RCA audit policy” (p. 3245).

95.7 To configure an RCA audit policy

95.7.1 Steps

1

Choose Policies→RCA Audits from the NFM-P main menu. The RCA Audits form opens.

2

Select Audit Policy (RCA) from the drop down list.

3

Click Create or choose a policy and click Properties. The Audit Policy (Create|Edit) form opens with the General tab displayed.

4

Configure the general parameters.

5

Select a policy type and click OK.

6

Click Apply.

7

Click on the Entry tab. Depending on the option specified in Step 5 , a list of RCA audit policy entries is displayed.

The RCA audit policy entry for a VLL RCA audit is: RCA Audit for VLL Service Membership.

The RCA audit policy entry for a VPRN RCA audit is: RCA Audit for VPRN Service Membership.

The following are the RCA audit policy entries for a VPLS RCA audit:

- RCA Audit for B-VPLS PBB
- RCA Audit for VPLS Service Membership
- RCA Audit for BGP Multi-homing
- RCA Audit for B-VPLS SPB

The following are the RCA audit policy entries for a physical link RCA audit:

- RCA Audit For Physical Ports of Physical Links
- RCA Audit For Ethernet Port Specifics of Physical Links

8

Choose an entry from the list and click Properties. The Audit Policy Entry - RCA Audit Policy - RCA Audit For *Network_Object* (Edit) form opens.

9

Configure the Enabled and Remove Empty Service parameters.

10

To configure an RCA audit policy for a physical link:

1. Click on the Attributes tab. A list of default attributes for the physical link entry is displayed.
2. Perform one of the following:
   - To configure default attributes, go to 3 .
   - To add an attribute, go to 5 .
3. Activate or deactivate the RCA audit for each attribute.

4. Choose one of the problem severity options for each attribute by clicking on the entry in the Severity column of the attribute.
5. Click Add to add an attribute. The Adding new Attribute(s) - RCA Audit For *entry_type* of Physical Links form opens with a list of attributes associated with the physical link entry.
6. Choose one or more attributes in the list and click OK.

11

Save your changes and close the form.

END OF STEPS

95.8 To perform an RCA audit of a service or multiple services

95.8.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a service or services that you want to audit and click RCA Audit. The Select RCA Policy to run the audit form opens with a list of configured policies.

Note: In addition to the standard audit checks, for BGP VPLS multi-homing sites, the audit also verifies:
Perform the following:

- if no valid Route Targets are configured under a VPLS site that has BGP multi-homing sites configured under it.
- if there are no matching RTs for peered multi-homing sites
- if there are multiple RTs configured under a VPLS site that has BGP multi-homing sites configured under it. Multiple RTs will make the BGP multi-homing sites appear under multiple topologies (or multiple services, since the RT defines the service)
- if multi-homing sites have the same multi-homing ID but different RTs (different RTs mean the sites are in different topologies or services)
- if a multi-homing site does not have other sites as members (sharing the same multi-homing ID to comprise a group)

In addition to the standard audit checks, for SPB- enabled B-VPLS sites, the audit also verifies that:

- all user B-VPLS SAPs or spoke SDP bindings are fate-shared with a control B-VPLS
- control and user B-VPLS instances in the same service on different sites have the same FID
- FID-to-ECT mapping is consistent on all of the sites for the active SPB B-VPLS services

- control B-VPLS SPB level Unicast Forwarding Tree Topology parameter is consistent on all of the sites in the same service

3

Choose an RCA audit policy and click OK. The Select RCA Policy form closes and a dialog box appears with the audit information.

4

Click OK.

5

If you selected multiple services to audit, perform the following. Otherwise, go to Step 6 .

1. Scroll to the RCA Audit Problem column and set the filter to = true.
2. Click Search. A list of services with problems appears.
3. Select a service and click Properties. The *Service* (Edit) form appears with the General tab displayed.

6

Click on the RCA Result tab. The RCA audit information is displayed on the Related Problem tab.

Note: The RCA Result tab appears only if the RCA audit detects one or more problems.

7

If required, expand the object in the problems tree to view the problems, the associated severity, and the cause.

8

Double-click on a problem icon to view information about the problem. The Problem (Edit) form opens with the General tab displayed.

9

Configure the Disable Fix Window parameter, if applicable.

10

Click on the Related Problem tab to view related problems.

Note: The NFM-P does not provide a solution for physical link configuration errors.

11

Click on the Caused By Objects tab to view a list of objects that are causing the problem.

12

Choose an entry from the list and click Properties. The properties form for the object opens.

13

Click on the tabs to view information about the configuration.

14

Configure the parameters, as required.

15

Save the configuration and close the forms.

16

To fix a problem:

1. Click on the Related Problem tab.
2. Right-click on a problem icon and choose Fix Problem. The Plan form appears.

   Note:

   The Fix Problem menu option is disabled if you set the Disable Fix Window parameter to Enabled in Step 9 .
3. Check the recommended plan to fix the problem in the Plan panel.
4. Check the report about fixing the problem in the Report panel.
5. Click Fix Problem.

17

Close the forms.

END OF STEPS

95.9 To perform an RCA audit of a physical link

95.9.1 Steps

1

Choose Manage→Equipment→Equipment from the NFM-P main menu. The Manage Equipment form opens.

2

Select Physical Link (Network) or Discovered Physical Link (Network) from the Select Object Type menu.

3

Choose an entry from the list and click Properties. The Physical Link (Edit) form opens with the General tab displayed.

4

Check the following indicators:

- RCA Audit Problem(s)
- Last Audit Time

5

Perform Step 6 to Step 15 in 95.8 “To perform an RCA audit of a service or multiple services” (p. 3240) .

END OF STEPS

95.10 To schedule an RCA audit

95.10.1 Steps

Note: Only VPLS, VPRN, and VLL services RCA audits and golden configuration RCA audits can be scheduled.

1

Choose Policies→RCA Audits from the NFM-P main menu. The RCA Audits form opens.

2

Choose a service audit policy and click Properties. The Audit Policy (Edit) form opens with the General tab displayed.

3

Click Schedule and choose Create RCA Audit Schedule Task. The Service Audit Scheduled Task (Create) form opens.

4

Configure the required parameters.

5

Click Select in the Schedule panel. The Select Schedule - Service Audit Scheduled Task form opens.

6

Perform one of the following:

a. Create a schedule to associate with the scheduled task.

b. Associate an existing schedule to the scheduled task. Go to Step 10 .

7

Click Create. The NFM-P Schedule (Create) form opens.

8

Configure the required parameters.

The Current Client End Time parameter is configurable when the Ongoing parameter is disabled and the Frequency parameter value is set to something other than Once.

When an NFM-P Schedule is not Ongoing and is assigned to a task, the NFM-P raises an alarm when the Current Client End Time expires.

Note: The Run Every parameter is not configurable when the Ongoing parameter is enabled.

9

Save your changes. The NFM-P Schedule (Create) form closes and the Select Schedule - Service Audit Scheduled Task form reappears.

10

Choose an entry from the list and click OK. The Select Schedule - Service Audit Scheduled Task form closes and the Service Audit Scheduled Task (Create) form reappears.

11

Ensure that the Administrative State parameter is set to Enabled and click OK. The Service Audit Scheduled Task (Create) form closes. The RCA Audit Policy form reappears with additional tabs.

12

To apply a filter to the schedule:

1. Click on the Schedule Filter tab.
2. Select a filter in the Audit Filter panel.

   Note:

   If no filters appear, click Audit Filter to create a new filter. See Chapter 1, “NFM-P GUI” for more information about how to create a filter.
3. Save your changes. The Select Audit Filter - Audit Policy form closes and the Audit Policy (Edit) form reappears with additional tabs.

13

Click on the Scheduled Objects to be Audited tab to view the services that are included in the audit.

14

Click on the Scheduled Result tab to view the results of the scheduled audit.

15

Click on the Problems tab to view the problems associated with the audit.

16

Close the forms.

END OF STEPS

95.11 To delete an RCA audit policy

95.11.1 Object deletion sequence

The following dependent objects must be deleted, in sequence, before you can delete an RCA audit policy:

- an associated scheduled task, if applicable
- any problems identified during the audit, if applicable

95.11.2 Steps

1

To delete the associated scheduled task:

1. Choose Tools→Schedules→Scheduled Task from the NFM-P main menu. The Scheduled Task form opens.
2. Choose NFM-P Scheduled Task (Schedule) from the Select Object Type menu.
3. Select the scheduled task, choose Task Action→Shut Down, and click Delete.
4. Confirm your changes and close the forms.

2

To delete the problems identified during the audit:

1. Choose Policies→RCA Audits from the NFM-P main menu. The RCA Audits form opens.
2. Choose Audit Policy (RCA) from the drop-down menu.
3. Select the RCA audit policy to be deleted, and click Properties. The Audit Policy (Edit) form opens.
4. Click on the Problems tab, select all of the problems, and click Delete.
5. Confirm your changes and close the forms.

3

To delete the RCA audit policy:

1. Choose Policies→RCA Audits from the NFM-P main menu. The RCA Audits form opens.
2. Choose Audit Policy (RCA) from the drop-down menu.
3. Select the RCA audit policy to be deleted, and click Delete.
4. Confirm your changes and close the forms.

END OF STEPS

96 Service throughput configuration

96.1 Overview

96.1.1 Purpose

This chapter describes the service throughput configuration, and provides information about configuring service throughput.

96.1.2 Contents

Service throughput configuration overview

96.2 Service throughput concepts

96.2.1 Throughput configuration description

The NFM-P allows you to create a copy of the SAP configuration of an end-user service that emulates the bandwidth, throughput, and QoS requirements of the service. You can perform any required OAM diagnostics on the service while sending the traffic through the NEs, to compare the customer SLA with current measurements and report the results.

96.2.2 Throughput configuration support

Throughput configurations are supported as shown in the following table.

NEs	Service types	Notes
• 7210 SAS • 7705 SAR • 7750 SR	• VLL Epipe, Apipe, and Cpipe • VPLS • composite services that contain VLL service (Epipe, Apipe, or Cpipe), VPLS, or both	—
7250 IXR	• VLL Epipe, Apipe, and Cpipe • VPLS • composite services that contain VLL service (Epipe, Apipe, or Cpipe), VPLS, or both	When the 7250 IXR is used as a source, the supported test methods are SAP-to-SAP Function and Mac Swap Loopback SAP/SDP Function. When the 7250 IXR is used as a destination, only the SAP-to-SAP Function is supported, with the Swap SAP option.

You can create a SAP based on the configuration of an existing SAP to prepare the service throughput configuration, where the port under the new SAP connects to the test entry or a loopback port as the destination.

Consider the following when you prepare a throughput test environment:

- The SAP to be replaced must reside under a VLL Epipe, Apipe or Cpipe site, including PBB Epipes, or a VPLS site including I-VPLS and B-VPLS.
- The following SAPs are not supported for the throughput test:
  - CCAGs
  - LAGs
  - SAPs that reside on an Ethernet tunnel element
  - SAPs that reside on an Ethernet ring element
  - SAPs used by a mirror service
- E-OAM objects, such as MEPs, are not copied to the test SAP.

You can view existing service throughput configurations on the Throughput Configuration tab of a service. Services and sites with a service throughput configuration have the Modified for Throughput Test parameter enabled on the General tab of the service or site.

Procedures to prepare for and restore from a service throughput configuration

96.3 Workflow to prepare for and restore from a service throughput configuration

96.3.1 Stages

The following workflow describes the high-level tasks required to prepare a throughput configuration. The workflow assumes that an NFM-P end user is challenging the offered SLA.

1

Open the service on which you need to create the test environment.

2

Set the Current OLC State parameter to Maintenance. See the *NSP System Administrator Guide* for more information.

3

Prepare the configuration. See 96.4 “To prepare an Epipe, Apipe, Cpipe, VPLS, or composite service throughput configuration” (p. 3249) .

4

Perform OAM diagnostics, as required. See Chapter 89, “Service Test Manager” for more information about the NFM-P service test manager.

5

Restore the service to the original configuration. See 96.6 “To restore a service after a throughput configuration” (p. 3255) .

6

Set the Current OLC State parameter to In Service. See the *NSP System Administrator Guide* for more information.

96.4 To prepare an Epipe, Apipe, Cpipe, VPLS, or composite service throughput configuration

96.4.1 Before you begin

The SAP that is replaced for the throughput configuration must exist under a supported VLL or VPLS site.

A throughput configuration cannot be performed on a SAP that:

- resides on CCAG or LAG

- resides on Ethernet tunnel element
- resides on Ethernet ring element
- is used by a mirror service

Nokia recommends that you set the Current OLC State parameter of the service to Maintenance before you prepare a throughput configuration. See the *NSP System Administrator Guide* for more information.

96.4.2 Steps

1

Perform one of the following:

a. To prepare a service throughput configuration on an Epipe, Apipe, Cpipe, or VPLS:
   1. Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.
   2. Choose a VPLS or VLL Epipe|Apipe|Cpipe and click Properties. The VPLS Service (Edit) or Epipe|Apipe|Cpipe (Edit) form opens.

b. To prepare a service throughput configuration on a composite service:
   1. Choose Manage→Service→Composite Services from the NFM-P main menu. The Manage Composite Services form opens.
   2. Choose a composite service and click Properties. The Composite Service (Edit) form opens.

2

Click on the Throughput Configuration tab and click Create. The Service Throughput Configuration form opens.

Note: Alternatively, you can choose a service throughput-capable service from the Manage Services or Manage Composite Services form, click on the Throughput Configuration button, and choose Create from the contextual menu.

3

Configure the required parameters.

4

In the Traffic Test Entry panel, select a SAP that is configured on the service that is to be replaced for testing.

5

Select a physical port or channel in the Traffic Test Entry panel that is connected to the test entry on which to create the SAP. You can choose an access or hybrid port on the service site on which the SAP that you selected in Step 4 resides that has the same encapsulation type as the selected SAP.

By default, the displayed port is the underlying port of the selected SAP. If you choose a different port, the NFM-P creates a SAP on the selected port by copying the configuration from the original SAP during the test preparation. E-OAM objects are not copied to the SAP.

6

Select a traffic destination site in the Traffic Test Destination panel.

7

To replace an existing SAP with a new SAP on a different port:

1. Set the Option parameter to Swap SAP.
2. Select a SAP in the Traffic Test Destination panel.
3. Select the port to which you need to switch in the Traffic Test Destination panel. The port must have the same encapsulation type as the selected SAP.

8

To loopback a port used by an existing SAP:

1. Set the Option parameter to Loopback Port Used By SAP.
2. Select the destination SAP in the Traffic Test Destination panel and configure the parameters on the port in the Loopback Parameters panel. The available parameters change depending on the NE on which the destination SAP is configured.

9

To replace an existing SAP with a new SAP on a different port and loopback the new port:

1. Set the Option parameter to Swap SAP and Loopback New Port.
2. Select the destination SAP and loopback port to which you need to swap in the Traffic Test Destination panel and configure parameters on the port. The available parameters change depending on the NE on which the destination SAP is configured.

10

To loopback an existing SAP:

1. Set the Option parameter to Loopback SAP.
2. Select the destination SAP in the Loopback SAP panel and configure the parameters in the Loopback Parameters panel.

11

To loopback an existing SDP binding:

1. Set the Option parameter to Loopback SDP Binding.
2. Select an SDP binding in the Loopback SDP Binding panel and configure the parameters in the Loopback Parameters panel.

12

Save the changes and close the form.

13

Click Apply on the VPLS Service (Edit) or Epipe|Apipe|Cpipe Service (Edit) form to:

- create a SAP on the selected port if the selected port differs from the port on the SAP
- configure the SAP with the same configuration as the original SAP, including all child objects that are copied over to the SAP
- delete the original SAP
- propagate port loopback parameter changes to the test port
- change the test SAP to a loopback SAP with the configured loopback parameters
- change the test SDP binding to a loopback SDP binding with the configured loopback parameters
- update the throughput information on the site
- update the throughput information on the service

Note: A site can only be used in one throughput configuration at a time. If a throughput configuration exists that uses a site as either a source or a destination, that site cannot be used in another throughput configuration.

14

Perform OAM diagnostics.

15

Save the changes and close the forms.

END OF STEPS

96.5 To configure an Epipe, Apipe, or Cpipe as a test service for MPLS-TP service tunnels

96.5.1 Preliminary considerations

Perform this procedure to create a site on a VLL Epipe, Apipe, or Cpipe service that is used exclusively for carrying test traffic for MPLS-TP service tunnels.

The admin lock test can be configured on a spoke SDP binding that is bound to a VLL Epipe, Apipe, Cpipe, and spoke termination on VPLS.

Consider the following:

- an MPLS-TP service tunnel must be used in the SDP binding, and the Control Word parameter on the Pseudowire OAM tab of the SDP binding must be set to Preferred
- the Control Channel Status parameter on the Control Channel tab of the spoke SDP binding must be set to Disabled

- a PW path must be created; see 76.15 “To configure an MPLS-TP static pseudowire on a VLL spoke SDP binding” (p. 2136)
- an ICB SDP binding must not be created on an endpoint
- no other service throughput configuration can exist on the site
- for Apipe and Cpipe services, the VC Type of the service and the test service must match

96.5.2 Steps

Create a test service site

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Create a VLL by clicking Create→VLL→Epipe|Apipe|Cpipe, or choose a VLL Epipe, Apipe, or Cpipe and click Properties. The Epipe|Apipe|Cpipe Service (Create|Edit) form opens.

3

If you are creating a service, configure the required general parameters.

4

On the navigation tree, right-click on the Sites icon and choose Create *Epipe*|*Apipe*|*Cpipe* Site. The Select Network Elements form opens.

5

Choose a site. The site you choose is also a service site on the host service of the throughput configuration you are configuring in Step 12 .

6

Click OK. The VLL Site (Create) form opens.

7

Configure the required general parameters.

8

Set the VLL Site Type to Terminating.

9

Enable the Test Service parameter .

Note: You must only create one site for a test service. This site defines a SAP that is the ingress and egress for test traffic.

The Test Service parameter is configurable only during site creation.

10

Save the changes and close the form.

Configure service throughput on the host service

11

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

12

Choose the VLL Epipe, Apipe, or Cpipe on which you want to configure the service throughput and click Properties. The Epipe|Apipe|Cpipe Service (Edit) form opens.

13

On the Epipe|Apipe|Cpipe Service (Edit) form of the host service, click on the Throughput Configuration tab and click Create. The Service Throughput Configuration form opens.

Note: Alternatively, you can choose a service throughput-capable service from the Manage Services form, click on the Throughput Configuration button, and choose Create from the contextual menu.

14

Configure the ID and Description parameters.

15

Set the Test Method parameter to MPLS-TP Lock Instruct Function.

Configure the Admin Lock test

16

A spoke SDP binding is administratively locked by locking the host service. Test traffic is injected into the spoke SDP binding using a test SAP, defined within the test service you created in Step 9 . When the admin lock is configured on a spoke SDP binding and a test service ID is specified, all of the traffic is forwarded to and from a SAP defined in the separate test service, which must be compatible with the spoke SDP binding. Traffic to and from the original SAP is dropped.

In the Traffic Test Entry panel, select a site on the host service. The Site ID is the site on which you are configuring the admin lock and the same site that you configured on the test service in Step 9 . The Admin Lock panel appears.

17

In the Admin Lock panel, select the spoke SDP binding to lock on the host site you selected in Step 16 .

18

In the Test Service panel in the Admin Lock panel, select the test service site you created in Step 5 to Step 10 .

Configure the Loopback test

19

If a loopback is configured on a spoke SDP binding, all traffic on the ingress direction of the spoke SDP binding and associated with the ingress VC-label is forwarded to the egress direction of the spoke SDP binding. The terminating site with the loopback configured to send test traffic back to the SDP binding you selected in Step 17 is automatically selected.

In the Traffic Test Destination panel, you can clear the selection or manually select the terminating, or destination, site.

20

In the Loopback panel, the spoke SDP binding on which you are configuring the loopback test is automatically selected. You can clear the selection or manually select an SDP binding.

21

Save the changes and close the form.

Note: A site can only be used in one throughput configuration at a time. If a throughput configuration exists that uses a site as either a source or a destination, that site cannot be used in another throughput configuration.

END OF STEPS

96.6 To restore a service after a throughput configuration

96.6.1 Service restoration considerations

The NFM-P performs the following when you restore the service:

- deletes the newly created SAPs
- re-creates the original SAPs
- on the loopback port: resets the loopback type to none if it was changed by the throughput configuration, and changes the loopback parameters to their default values
- updates the site throughput status information
- updates the service throughput status information

96.6.2 Steps

1

Perform one of the following:

a. Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

b. Choose Manage→Service→Composite Services from the NFM-P main menu. The Manage Services form opens.

2

Choose the service for which you need to restore the configuration and click Properties. The *Service_type* Service (Edit) form opens.

3

Click on the Throughput Configuration tab. A list of throughput configurations on the service appears.

4

Select the throughput configuration you need to remove, and click Delete.

Note: Alternatively, you can select a service or composite service that is modified for throughput configuration from the Manage Services form or Manage Composite Services, click on the Throughput Configuration button, and choose Delete (all) from the contextual menu. This removes all the service throughput configurations on the service.

5

Close the forms.

END OF STEPS

Part VIII: Appendices

Overview

Purpose

This part provides information about NFM-P user and system parameters that are not otherwise documented in the XML API Reference.

Contents

A Parameters

A.1 Overview

A.1.1 Purpose

This appendix lists and describes the NFM-P user and system parameters. Nodal parameters are not included in this appendix but can be found in the XML API Reference.

The parameters in this appendix are found on NFM-P forms and child forms that may be launched from the main menu or contextual menus related to the configurable object.

A.1.2 Contents

A.2 Alarm Settings parameters

A.2.1 Display Buffer Time (minutes)

The Display Buffer Time (minutes) parameter specifies the buffer time, in minutes, that will be applied to the time period for which current and historical alarms are displayed. The range is 1 to 59. The default is 5.

A.2.2 Reason for change

The Reason for change parameter specifies the justification for editing an existing note to an alarm. The options are:

- unspecified (default)
- unknown
- comment
- clarification
- update
- confirmation
- correction
- dispute

A.2.3 Search for Alarms

The Search for Alarms parameter specifies the search for historical alarms received during a specified time period. The Oldest Alarm Searched and the Oldest Alarm in Database fields are updated.

The options are:

- Past 1 hour
- Past 12 hours
- Past 1 Day
- Past 7 days
- Past 30 days
- All Available

A.2.4 Show Additional Text Button on Properties Forms

The Show Additional Text Button on Properties Forms parameter specifies whether the Additional Text Find icon is displayed on the object property forms, based on a client session.

The options are:

- Enabled
- Disabled (default)

A.3 Discovery Manager parameters

A.3.1 Ignore Timestamps

The Ignore Timestamps parameter specifies whether entries with unchanged last change timestamps are processed.

The options are:

- Enabled
- Disabled (default)

A.4 Generic NE Manager parameters

A.4.1 Use Default Additional Text

The Use Default Additional Text parameter specifies whether the alarm contains only the default additional text. When the parameter is enabled, the Additional Text parameter is set to the default value and cannot be configured.

The options are:

- Enabled (default)
- Disabled

A.5 NE CPM Filter parameters

A.5.1 MAX

The MAX parameter specifies whether the PIR (kbps) parameter or CIR (kbps) parameter is set to infinity or can be configured.

The options are:

- disabled (default)
- enabled

When the MAX parameter is set to enabled, you cannot configure the CIR or PIR parameters.

A.5.2 Service Id

The Service Id parameter specifies the service ID that is applied as a MAC filter match criterion in an NE CPM or management access filter.

A.5.3 Source IP Prefix

The Source IP Prefix parameter specifies a list of IP prefixes to use as sources for the filter policy. When the parameter is enabled, click on the Select button and choose a prefix list.

A.6 NE Maintenance parameters

A.6.1 Command to Apply After Backup

The Command to Apply After Backup parameter specifies whether to certify the configuration after a successful backup. The parameter is configurable only on an OmniSwitch.

The options are:

- Certify
- No command applied (default)

A.7 NFM-P User Security parameters

A.7.1 Enable

The Enable parameter specifies whether to enable or disable the ability to configure the Maximum Sessions Allowed parameter.

The options are:

- enabled
- disabled (default)

A.7.2 Password Change Required

The First Time Login Password Change parameter specifies whether a user is prompted to enter a new password before they can login for the first time.

The options are:

- disabled (default)
- enabled

A.7.3 Threshold Reporting State

The Threshold Reporting State parameter specifies whether to generate threshold alarms when the number of log entries exceeds Max Log Record parameter value.

The options are:

- Up (default)
- Down

A.7.4 User inactive greater than or equal to

The User inactive greater than or equal to parameter specifies the NFM-P user inactivity period, in days, for a custom user inactivity search. The range is 0 to 365. There is no default.

A.8 System Preferences parameters

A.8.1 Changing system preferences

CAUTION

Service Disruption

Changing the parameter value of a System Preference may affect the behavior of an existing NFM-P service.

Do not change the parameter value from the default without contacting Nokia technical support.

Note: The System Preferences parameters are configurable only by a user with administration privileges.

A.8.2 Create CSV files using UTF-8 with BOM (byte order mark) encoding

The Create CSV files using UTF-8 with BOM (byte order mark) encoding parameter specifies whether a BOM is added to CSV files. This is used to view CSV files in multi-language environments. By default, when the parameter is disabled, no BOM is added to CSV files. When the parameter is enabled, UTF-8 BOM will be added to all files created.

The options are:

- disabled (default)
- enabled

A.8.3 Maximum Number of Golden Config Audit Problems

The Maximum Number of Golden Config Audit Problems parameter specifies the maximum number of problems that a golden configuration audit can identify before the NFM-P automatically aborts the audit. The parameter is designed to preserve NFM-P system resources when comparing two extremely divergent NE configurations that may have been selected accidentally. The default is 500.

A.8.4 Propagate Name and Description of Site to Service

The Propagate Name and Description of Site to Service parameter specifies the default behavior when a site is added to a service with no other sites configured or a service with one site is found during node discovery. When the parameter is enabled, the service inherits the name and description parameters of the site configured on the service. Services with multiple sites or services with names and descriptions that are manually configured are not affected. The parameter is mutually exclusive with the A.8.6 “Whenever a site is added to a service in SAM, propagate the Service Name to Site Name” (p. 3266) parameter. The options are:

- disabled (default)
- enabled

A.8.5 Tabs

The Tabs parameter specifies the default behavior for tab customization on configuration forms.

Table A-1 Tabs parameter

Option	Description
Allow NFM-P to pre-hide some tabs on forms. Customization Allowed. (default)	Some tabs are automatically hidden by default. The user can customize the hidden tabs with the tab selector.
Always show all tabs on forms. No Customization Allowed.	All tabs are displayed by default. The tab selector is not available on configuration forms.
Initially show all tabs on forms. Customization Allowed.	All tabs are displayed by default. The user can customize the hidden tabs with the tab selector.

A.8.6 Whenever a site is added to a service in SAM, propagate the Service Name to Site Name

(propagateServiceNameToSites)

The “Whenever a site is added to a service in NFM-P, propagate the Service Name to Site Name” parameter specifies the default behavior of whether to populate the site name property on an NE using the service name when the NE is added as a service site. When the parameter is disabled, the site name property on the NE is unpopulated after the NE is added as a service site. The options are:

- disabled (default)
- enabled

A.9 Manage Workspaces parameters

A.9.1 Finished adding New Menu Items

When enabled, the Finished adding New Menu Items parameter specifies that the New Menu Items option no longer displays on the Menus tab of the Workspace (Edit) form, and that the Finished adding New Menu Items parameter also no longer displays. These functions remain inaccessible until a new upgrade is performed.

The options are:

- Enabled
- Disabled (default)

A.9.2 Overwrite Existing Workspace(s)

When enabled, the Overwrite Existing Workspace(s) parameter specifies that an imported workspace overwrites an existing workspace with the same name and scope.

The options are:

- Enabled
- Disabled (default)

A.9.3 Overwrite User Name

When enabled, the Overwrite User Name parameter specifies that the username of the currently logged-in user is assigned to the imported workspace. When the parameter is disabled, the username associated with the saved workspace is retained.

The options are:

- Enabled
- Disabled (default)

A.9.4 Scope

The Scope parameter on the Workspace form indicates the ownership of the custom workspace.

The options are:

- Private
- Public

A private workspace is visible only to the user that created the workspace, and to an administrator.

A public workspace is visible to all users.

A.9.5 Show Current OLC State

When enabled, the Show Current OLC State parameter specifies that navigation tree objects below the level of the NE display their current OLC state in their labels.

The options are:

- Enabled
- Disabled (default)

See the *NSP System Administrator Guide* for more information.

A.9.6 Tab Preferences

The Tab Preferences parameter specifies how tab preferences are derived for configuration forms in the workspace.

The options are:

- Local (default)
- Custom

Select an option by choosing one of the three buttons on the form.

Table A-2 Tab Preferences configuration buttons

Button	Description
Set to Local	Tab preferences are Local, and are derived from local tab selector settings for the current user. The workspace has no effect on tab display settings. Buttons on the tab selector are enabled and tab preferences can be changed manually.
Set to Current	Tab preferences are Custom, and are derived from the workspace. The workspace saves and uses the tab display settings in effect for the GUI client when Set to Current is selected. Buttons on the tab selector are disabled.
Set from Workspace...	Tab preferences are Custom, and are derived from the workspace. The workspace saves and uses tab display settings copied from another selected workspace. Buttons on the tab selector are disabled.

A.10 Task Manager parameters

A.10.1 autoRefreshInterval

The autoRefreshInterval parameter specifies how often, in s, the Task Manager searches for new tasks when the Task Manager is open. The range is 0, or 5 to 600. The default is 20. A value of 0 means the parameter is disabled. The parameter does not take effect until the client is restarted.

A.10.2 failedTasksPurgeInterval

The failedTasksPurgeInterval parameter specifies how often, in min, to remove all of the tasks that are not in the In Progress state. The range is 0, or 5 to 10 080. The default is 1440. A value of 0 means the parameter is disabled.

A.10.3 maxNumRetainedTasks

The maxNumRetainedTasks parameter specifies the maximum number of monitored tasks that the Task Manager displays. The count includes the top-level tasks and all sub-tasks. When the value is reached, the system automatically deletes successful tasks, starting with the earliest. The deleted tasks appear in XML format in the TaskTracker.log file, which is located in the log/taskmgmt directory on the NFM-P server. The range is 200 to 50 000 tasks. The default is 10 000.

A.10.4 numTasksToPurgeWhenFull

The numTasksToPurgeWhenFull parameter specifies the number of successful tasks to remove when the limit specified by the A.10.3 “maxNumRetainedTasks” (p. 3268) parameter is reached. The range is 20 to 500 tasks. The default is 100.

A.10.5 successfulTasksPurgeInterval

The successfulTasksPurgeInterval parameter specifies, in min, the interval at which tasks that are in the Succeeded state are removed. For a specific interval, the tasks from the previous interval that have a Succeeded state are removed. The range is 0, or 2 to 2880. The default is 10. A value of 0 means the parameter is disabled.

A.11 User Preferences parameters

A.11.1 Access Interface Encap Value (Dot1q only)

The Access Interface Encap Value (Dot1q only) parameter specifies whether the Auto-Assign ID parameter is the default parameter for dot1q encapsulation.

The options are:

- Enabled
- Disabled (default)

A.11.2 Apply User Span of Control

The Apply User Span of Control parameters specifies whether the GUI automatically filters list forms, trees, and maps to display only the objects in the user Edit Access spans.

The options are:

- Enabled
- Disabled (default)

A.11.3 Browser Path

The browser path parameter specifies the file path to the browser application that the NFM-P launches as a web portal. The browser path parameter can be configured manually or by clicking the Browse button and navigating to the file path.

A.11.4 Command Helper Key

The Command Helper Key parameter allows you to designate the key that activates the command helper function in the Script Editor.

A.11.5 Debug STM Mode

The Debug STM Mode parameter provides access to additional forms on the STM that can be used to configure OAM diagnostic test limits and view additional test configuration information on managed devices. The default is disabled.

When the parameter is enabled, you can select the following additional menus on the Service Test Manager (STM) form:

- NE Test Agent (Assurance): Allows you to specify the maximum number of pings and traces allowed to be performed on individual managed devices during the execution of a test, or limit the number of tests that can be performed on all managed devices. Also provides information about the node ID, concurrent ping and trace information, LTT concurrent requests, deployed test counts, and alarm status.
- Deployed Test (Assurance): Provides information about the node ID, name and description, management ownership, deployment and execution state, schedule status and start time, and alarm status.
- NE Schedulable Test (Assurance): Provides the node ID, name and description, management

ownership, test deployed, mode, state, runs and failures, accounting policy ID, accounting suppression, card TCA profile and alarm status.

A.11.6 Default Client Time Zone

The Default Client Time Zone parameter specifies the time zone that is applied to the NFM-P client by default. Choose a time zone from the drop-down menu. The default is the NFM-P server installation time zone. The Current Client Time Zone will automatically reflect any change made to the Default Client Time Zone.

A.11.7 Default Polling Interval (seconds)

The Default Polling Interval parameter specifies the default interval, in seconds, for the polling interval for real-time statistics in the Statistics Plotter form. The range is 10 to 3600. The default is 10.

A.11.8 Enable Command Helper

The Enable Command Helper parameter specifies whether the Command Helper function in the Script Editor is enabled.The Command Helper is a one-key function which completes commonly occurring script commands. The command helper key can be designated by the user.

A.11.9 Enable Confirmation for Bulk Change Actions

The Enable Confirmation for Bulk Change Actions parameter specifies whether a confirmation message is displayed before the NFM-P carries out a bulk change operation.

The options are:

- false
- true (default)

A.11.10 Enable properties forms with navigation trees when ‘View Alarmed Object’ button is applied

The Enable properties forms with navigation trees when ‘View Alarmed Object’ button is applied parameter, allows you to specify whether alarm information is displayed when you click on the View Alarmed Object button. The disabled option allows you to view the Properties form for an alarmed object.

The options are:

- Enabled (default)
- Disabled

A.11.11 GUI Builder in the Editor

The GUI Builder in the Editor parameter specifies whether the Velocity GUI Builder in the Script Editor is enabled.

The options are:

- Enabled (default)
- Disabled

A.11.12 Maximum Data Retention Time (seconds)

The Maximum Data Retention Time (Seconds) parameter specifies the number of seconds to keep statistics data in the Statistics Plotter form. The range is 3600 to 86400. The default is 43200.

A.11.13 Save To File Default Extension

The Save To File Default Extension parameter specifies the file type that is selected as default when saving list form information to file.

The options are:

- CSV (default)
- HTML

A.11.14 Show Alarm Flags

The Show Alarm Flags parameter specifies whether the monitoring flag panel toolbar at the top of the Dynamic alarm list Alarm Window is displayed.

The options are:

- Enabled
- Disabled (default)

A.11.15 Show Correlated Alarms

The Show Correlated Alarms parameter specifies whether correlated alarms are displayed in the alarm window. The parameter is automatically enabled when you enable the A.11.16 “Show Correlated Alarms by Default” (p. 3272) parameter. You can configure the parameter on a per-session basis.

The options are:

- Enabled (default)
- Disabled

A.11.16 Show Correlated Alarms by Default

The Show Correlated Alarms by Default parameter specifies whether the A.11.15 “Show Correlated Alarms” (p. 3271) parameter is enabled by default.

The options are:

- Enabled (default)
- Disabled

A.11.17 Show Toolbar

The Show Toolbar parameter specifies whether the toolbar at the top of the window is displayed.

The options are:

- Enabled (default)
- Disabled

A.11.18 Specify # of Items Per Page

The Specify # of Items Per Page parameter specifies the number of items returned per page by a search. The range is 1 to 9999. The default is 1000.

A.11.19 Suppress Containing Window Warning

The Suppress Containing Window Warning parameter specifies whether containing window warnings are suppressed.

The options are:

- Enabled
- Disabled (default)

When a child object configuration form is launched from a parent object, and the child object configuration is changed, a warning message opens. The warning message indicates that changes to the child form are not committed until they are applied in the parent object. You must acknowledge the message. You can suppress this warning message by enabling the parameter on the User Preferences form. You continue to receive a warning message that changes must be applied for parent objects before you can close the parent object configuration form.

A.11.20 Suppress Template Execution Warning

The Suppress Template Execution Warning specifies whether warning messages are suppressed when you execute a template.

The options are:

- Enabled
- Disabled (default)

A.11.21 Suppress Template Generation Message

The Suppress Template Generation Message parameter specifies whether template generation windows are suppressed.

The options are:

- Enabled
- Disabled (default)

A.11.22 Suppress Service and Composite Service Map Load Warning

The Suppress Service and Composite Service Map Load Warning parameter specifies whether the load time warnings for service and composite service maps are suppressed.

The options are:

- Enabled
- Disabled (default)

A.11.23 Turn on Audible Alarms

The Turn on Audible Alarms parameter specifies whether there is an alarm bell when an incoming alarm is registered.

The options are:

- Enabled (default)
- Disabled

A.12 Common Create menu parameters

A.12.1 Aggregated Service Site Operational State

The Aggregated Service Site Operational State parameter cannot be configured. The value is derived from the operational states of the sites that are part of the service.

The values are:

- Up—All sites are operationally up
- Partially Down—At least one site is operationally down
- Down—All sites are operationally down
- Unknown—The service has no provisioned sites

When the Aggregated Service Site Operational State is Partially Down or Down, a check mark appears beside the appropriate State Cause indicator to identify the type of fault to the NFM-P admin or mirror service management user. You can view alarms on the Faults page.

A.12.2 Enable

The Enable parameter specifies whether the Lease Populate parameter is configurable.

The options are:

- Enabled
- Disabled (default)

A.12.3 Enable WLAN GW

The Enable WLAN GW parameter specifies whether or not WLAN GW functionality is enabled on a routing instance. This parameter must be enabled in order to configure an APN Network Identifier or Mobile GW Address Map.

The options are:

- disabled (default)
- enabled

A.12.4 IPv6 Allow Unmatching Prefixes

The IPv6 Allow Unmatching Prefixes parameter specifies whether the interface allows unnumbered IPv6 prefixes that do not match the list of numbered prefixes configured on the NE.

The options are:

- enabled
- disabled (default)

A.12.5 Loopback Type

The Loopback Type parameter specifies the loopback configuration of the destination port in the service throughput test.

The options are:

- Internal
- Line
- None (default)

The options that are displayed depend on the NE on which you are configuring the port.

A.12.6 Loopback Time (seconds)

The Loopback Time (seconds) parameter specifies how long the selected destination port in the service throughput test remains as loopback. The parameter is configurable if the port is capable for timed loopback. The range is 30 to 86 400. The default is 0 (disabled).

A.12.7 No Egress Aggregate Rate Limit

The No Egress Aggregate Rate Limit parameter specifies that the transmission rate of all egress queues for the access interface is unlimited.

The options are:

- Enabled (default)
- Disabled

A.12.8 SHCV Enabled

The SHCV Enabled parameter specifies whether SHCV is enabled on the interface.

The options are:

- Enabled
- Disabled (default)

A.12.9 Template Description

The Template Description parameter specifies a description for the template type. The range is an interface name of 0 to 80 characters. The default is an empty string.

A.13 Physical Link parameters

A.13.1 Bandwidth (Mbps)

The Bandwidth parameter specifies the maximum bandwidth allowed for each specified CoS. The default value is derived from the speed of the physical port. Because there are eight classes of service, the default value for each CoS is the speed of the port divided by eight. The XML values are shown in Table A-3, “Bandwidth (Mbps) parameters” (p. 3274) .

Note: This parameter is only available if service CAC is configured. See the *NSP System Administrator Guide* for more information.

Table A-3 Bandwidth (Mbps) parameters

Bandwidth (Mbps) parameter name	XML string	Maximum bandwidth allowed for:
Bandwidth (Mbps) first field in column	cos0BW	CoS 0
Bandwidth (Mbps) second field in column	cos1BW	CoS 1
Bandwidth (Mbps) third field in column	cos2BW	CoS 2
Bandwidth (Mbps) fourth field in column	cos3BW	CoS 3
Bandwidth (Mbps) fifth field in column	cos4BW	CoS 4
Bandwidth (Mbps) sixth field in column	cos5BW	CoS 5
Bandwidth (Mbps) seventh field in column	cos6BW	CoS 6
Bandwidth (Mbps) eighth field in column	cos7BW	CoS 7

A.13.2 Booking Factor (%)

The Booking Factor parameter specifies the actual amount of bandwidth being booked on the physical link. For example, if a service requests 10 Mbps on CoS 0 and the booking factor on CoS 0 is 50%, then the actual amount of booked bandwidth is 5Mbs. The XML values are shown in Table A-4, “Booking Factor (%) parameters” (p. 3275) .

Note: This parameter is only available if service CAC is configured. See the *NSP System Administrator Guide* for information.

Table A-4 Booking Factor (%) parameters

Booking Factor (%) parameter name	XML string	Bandwidth being booked for:	Default value
Booking Factor (%) first field in column	cos0BookFactor	CoS 0	100
Booking Factor (%) second field in column	cos1BookFactor	CoS 1	100
Booking Factor (%) third field in column	cos2BookFactor	CoS 2	100
Booking Factor (%) fourth field in column	cos3BookFactor	CoS 3	100
Booking Factor (%) fifth field in column	cos4BookFactor	CoS 4	100
Booking Factor (%) sixth field in column	cos5BookFactor	CoS 5	100
Booking Factor (%) seventh field in column	cos6BookFactor	CoS 6	100
Booking Factor (%) eighth field in column	cos7BookFactor	CoS 7	100

A.13.3 Utilization Threshold (%)

The Utilization Threshold parameter specifies the percentage of bandwidth that, when exceeded, raises an alarm indicating that the used bandwidth has exceeded the maximum allowed bandwidth on the link. For example, if the threshold is set to 75% and the maximum allowed bandwidth is 20 Mbps, then an alarm will be raised when the used bandwidth value exceeds 15 Mbps. The XML values are shown in Table A-5, “Utilization Threshold (%) parameters” (p. 3276) .

Note: This parameter is only available if service CAC is configured. See the *NSP System Administrator Guide* for information.

Table A-5 Utilization Threshold (%) parameters

Utilization Threshold (%) parameter name	XML string	Bandwidth currently being used for:
Utilization Threshold (%) first field in column	cos0BWThreshold	CoS 0
Utilization Threshold (%) second field in column	cos1BWThreshold	CoS 1
Utilization Threshold (%) third field in column	cos2BWThreshold	CoS 2
Utilization Threshold (%) fourth field in column	cos3BWThreshold	CoS 3
Utilization Threshold (%) fifth field in column	cos4BWThreshold	CoS 4

Table A-5 Utilization Threshold (%) parameters (continued)

Utilization Threshold (%) parameter name	XML string	Bandwidth currently being used for:
Utilization Threshold (%) sixth field in column	cos5BWThreshold	CoS 5
Utilization Threshold (%) seventh field in column	cos6BWThreshold	CoS 6
Utilization Threshold (%) eighth field in column	cos7BWThreshold	CoS 7

A.14 Equipment Group parameters

A.14.1 Span

The Span parameter specifies whether span of control filtering is enabled.

Table A-6 Span parameter

Option	Description
Span Off (default, if span filtering is disabled on the User Preferences form)	Span of control filtering is disabled; objects in the View Access and Edit Access spans of the current user are displayed.
Span On (default, if span filtering is enabled on the User Preferences form)	Span of control filtering is enabled; only objects in the Edit Access spans of the current user are displayed.
User Preference	Span of control filtering is enabled or disabled, as configured on the User Preferences form.

A.15 IPsec VPN parameters

A.15.1 Delivery Service Interface Address

The Delivery Service Interface Address parameter specifies the IPv4 address, in dotted-decimal format, of the delivery service interface. The subnet for the parameter must be the same subnet as the A.15.3 “Local Gateway Address” (p. 3277) parameter.

A.15.2 ISA-Tunnel Group

The ISA-Tunnel Group parameter specifies the ISA-Tunnel group for the IPSEC VPN.

A.15.3 Local Gateway Address

The Local Gateway Address parameter specifies the IPv4 address, in dotted-decimal format, of the local NE of the IPsec tunnel. The subnet for the parameter must be the same subnet as the A.15.1 “Delivery Service Interface Address” (p. 3277) parameter.

A.15.4 Remote Gateway Address

The Remote Gateway Address parameter specifies the IPv4 address, in dotted-decimal format, of the remote gateway.

A.15.5 Secure Service Interface Address

The Secure Service Interface Address parameter specifies the IPv4 address for the secure service interface. The parameter is mandatory when the A.15.8 “Tunnel Type” (p. 3278) parameter is set to the Dynamic (Soft Client) option.

A.15.6 Static Route Address

The Static Route Address parameter specifies the IPv4 address, in dotted-decimal format, of the static route.

A.15.7 Static Route Prefix

The Static Route Prefix parameter specifies the prefix for the static route.

Table A-7 Static Route Prefix parameter

Option	Option description
24	Choose when the A.15.8 “Tunnel Type” (p. 3278) parameter is set to Dynamic (Site-to-Site) or Dynamic (Soft Client)
32	Choose when the A.15.8 “Tunnel Type” (p. 3278) parameter is set to Static

A.15.8 Tunnel Type

The Tunnel Type parameter specifies the tunnel type for the tunnel group.

The options are:

- Dynamic (Site-to-Site)
- Dynamic (Soft Client)
- Static

A.16 IES parameters

A.16.1 IES parameters overview

This section describes the parameters on the IES creation forms.

Note: This section also describes parameters common to the Service Template form and child forms. Service templates are intended for use in the NFM-P GUI. Nokia does not recommend using the XML API XML classes and methods associated with service templates.

A.16.2 Inherit from Network Element

The Inherit from Network Element check box specifies whether the interface inherits the value of the Operational State Transition Interval parameter from the NE.

The options are:

- Enabled (default)

- Disabled

When the check box is disabled, the Operational State Transition Interval parameter is configurable.

A.17 VLL parameters

A.17.1 VLL parameters overview

This section describes the parameters on the VLL service creation form and child forms.

Note: This section also describes parameters common to the Service Template forms. Service templates are intended for use in the NFM-P GUI. Nokia does not recommend using the XML API XML classes and methods associated with service templates.

A.17.2 Auto-Generate ID

The Auto-Generate ID parameter specifies the value used by each end of a service tunnel to identify the VC. The range is 0 to 4 294 967 295.

The options are:

- Enabled (default)
- Disabled

A.17.3 No Revert

The No Revert parameter specifies whether the VLL returns the primary spoke SDP to service after a failure. When the parameter is enabled, the VLL does not return the primary spoke SDP to service after a failure.

The options are:

- disabled (default)
- enabled

A.18 VPLS parameters

A.18.1 VPLS parameters overview

This section describes the parameters on the VPLS creation form and child forms.

Note: This section also describes parameters common to the Service Template form and child forms. Service templates are intended for use in the NFM-P GUI. Nokia does not recommend using the XML API XML classes and methods associated with service templates.

A.18.2 Clear Forced Switchover

The Clear Forced Switchover button allows you to clear a manual switchover from a redundant spoke SDP binding back to an active spoke SDP binding that was previously initiated by using the A.18.5 “Force Switchover” (p. 3280) button. You must clear any such manually forced switchovers by using the Clear Forced Switchover button after the active spoke SDP binding has been restored.

The system does not switch over automatically to other active spoke SDP bindings if this is not done, even if the redundant spoke SDP binding subsequently goes down.

The Active State read-only display indicates the change in status for the SDP binding when you press the Clear Forced Switchover button.

A.18.3 Disable Revert Time (Infinite)

The Disable Revert Time (Infinite) parameter specifies whether or not to disable the Revert Time (seconds) parameter indefinitely.

The options are:

- enabled
- disabled (default)

A.18.4 Enable

The Enable parameter specifies whether to enable or disable the configurability of the Enable Lease Populate parameter. The parameter is configurable when the Snooping parameter is enabled.

The options are:

- enabled
- disabled (default)

When the parameter is enabled, you can configure the Enable Lease Populate parameter. Disabling the parameter is equivalent to configuring the Enable Lease Populate parameter with a value of 0.

A.18.5 Force Switchover

The Force Switchover button allows you to force a switchover of the active SDP binding to a redundant SDP binding under an endpoint of the VPLS. When you do this, the redundant SDP binding becomes active and the Active State indicator displays the status change.

Note: You must clear a manually forced switchover using the A.18.2 “Clear Forced Switchover” (p. 3279) button after the active spoke SDP binding is restored. The NFM-P is unable to switch automatically to other active spoke SDP bindings if this is not done, even if the redundant spoke SDP binding subsequently goes down.

A.18.6 Maximum Number of Sources

The Maximum Number of Sources parameter specifies the maximum number of IGMP sources in each group that can be statically or dynamically learned. The default for all devices is 0, which means that no limit is imposed. Reducing the value of the parameter below the number of learned sources does not remove already-learned sources, but does prevent new sources from being learned. The range is 0 to 1000.

A.19 VPRN parameters

A.19.1 VPRN parameters overview

This section describes the parameters on the VPRN service creation forms.

Note: This section also describes parameters common to the Service Template form and child forms. Service templates are intended for use in the NFM-P GUI. Nokia does not recommend using the XML API XML classes and methods associated with service templates.

A.19.2 Enable DNS

The Enable DNS parameter specifies whether or not DNS is configured on a routing instance. This parameter must be enabled in order to configure primary, secondary, and tertiary DNS addresses on the routing instance.

The options are:

- disabled (default)
- enabled

A.19.3 Inherit from Network Element

The Inherit from Network Element check box specifies whether the interface inherits the value of the Operational State Transition Interval parameter from the NE.

The options are:

- Enabled (default)
- Disabled

When the check box is disabled, the Operational State Transition Interval parameter is configurable.

A.20 Bundles parameters

A.20.1 Show Only Compatible Channels

The Show Only Compatible Channels parameter specifies whether to filter the list of channels presented, by determining whether the channels can be configured as members of a multilink bundle.

The options are:

- Enabled (default)
- Disabled

A.21 Card Slot parameters

A.21.1 Administrative

The Administrative parameter is used to differentiate between an OS 6850 and OS 6850E NE for card slot configuration purposes at the administrative level.

The options are:

- OS 6850 (default)
- OS 6850E

A.21.2 Operational

The Operational parameter is used to differentiate between an OS 6850 and OS 6850E NE for card slot configuration purposes at the operational level.

The options are:

- OS 6850 (default)
- OS 6850E

A.22 Channel parameters

A.22.1 Ds3 Channel Payload Type

The Ds3 Channel Payload Type parameter specifies the type of payload that is configured for the channel. The parameter appears only for OC3 or OC12 ASAP ports when the Channel Type parameter is set to SONET Sts1 (Sdh Au3) and the Sts1 Channel Payload Type parameter is set to PDH Ds3.

The options are:

- None (default)
- DS1
- E1

A.22.2 Edit ATM button

Click on the Edit ATM button to configure the ATM Interface parameters for the channel.

A.22.3 Edit ILMI Link button

Click on the Edit ILMI Link button to configure the ILMI link parameters for the ATM interface.

A.22.4 Edit PPP button

Click on the Edit PPP button to configure the keep-alive Period and Drop Count parameters for the channel.

A.22.5 Keep Alive (seconds)

The Keep Alive (seconds) parameter specifies the interval, in seconds, used to send periodic keepalive packets. The receiver process expects to receive a keepalive packet at every keepalive interval. The link is declared down if the receiver process does not receive a keepalive packet within the timeout interval. The link is declared up when the number of continual keepalive packets received equals the up-count. The nodes at the two endpoints of the cHDLC link should be provisioned with the same values. The range is 0 to 300. The default is 10.

A.22.6 Restore Keep-Alive Defaults

Click on the Restore Keep-Alive Defaults button to restore the default values of the keep-alive parameters for the ILMI link.

A.22.7 STs1 Channel Payload Type

The STs1 Channel Payload Type parameter specifies the type of payload that is configured for the channel.

The options are:

- SONET VT15 (SDH Tu11)
- PDH Ds3 (default)

A.22.8 Time Slots per DS0 Channel Group

The Time Slots per DS0 Channel Group parameter specifies the timeslots from the selected TDM port to be assigned to the channel group. The range is 1 to 24 for DS1 channel groups and 1 to 31 for E1 channel groups. If you set the parameter option to “0”, a DS0 channel group is not created.

For DS1 channel types, the maximum number of timeslots is 24 (that is, TS1-TS24). For E1 channel types, the maximum number of timeslots is 31 (that is, TS2-TS32). Depending on the TDM port selected, the NFM-P automatically creates the DS0 channel groups with the appropriate type of timeslots.

Assigned DS0 timeslots are greyed out with a check mark against the assigned timeslot.

A.22.9 Vt15 Channel Payload Type

The Vt15 Channel Payload Type parameter specifies the type of payload that is configured for the channel. The parameter appears only for OC3 or OC12 ASAP ports when the Channel Type parameter is set to SONET Sts1 (Sdh Au3) and the Sts1 Channel Payload Type parameter is set to SONET VT15 (SDH Tu11). The only option is PDH Ds1.

A.23 Common equipment navigation tree parameters

A.23.1 Telnet Session button

Click on the Telnet Session button to open a Telnet session with the route. You can use the Telnet session to communicate directly with the managed objects.

A.24 Daughter Card and Daughter Card Slot parameters

A.24.1 Assigned MCM Card Type

The Assigned MCM Card Type parameter specifies the MDA carrier module type to be configured for the daughter card slot. The options depend on the settings of the unconfigurable Supported Daughter Card Types and Allowed Daughter Card Types parameters. You can configure the parameter when the In MDA Carrier Module Slot parameter is enabled.

A.25 Device parameters

A.25.1 Custom Property 1

The Custom Property 1 parameter specifies any custom user text you want to attach to an NE. You can add up to 80 characters of custom text. There is no default.

Note: This parameter name reflects the default name of the parameter on the NFM-P GUI. The name of this parameter can be changed using the System Preferences form.

A.25.2 Custom Property 2

The Custom Property 2 parameter specifies any custom user text you want to attach to an NE. You can add up to 80 characters of custom text. There is no default.

Note: This parameter name reflects the default name of the parameter on the NFM-P GUI. The name of this parameter can be changed using the System Preferences form.

A.25.3 Custom Property 3

The Custom Property 3 parameter specifies any custom user text you want to attach to an NE. You can add up to 80 characters of custom text. There is no default.

Note: This parameter name reflects the default name of the parameter on the NFM-P GUI. The name of this parameter can be changed using the System Preferences form.

A.25.4 Host Address

The Host Address parameter specifies the Cflowd collector host address. Specify an IPv4 address in dotted-decimal format

A.25.5 Ignore Timestamps

The Ignore Timestamps parameter specifies whether entries with unchanged last change timestamps are processed.

The options are:

- Enabled
- Disabled (default)

A.25.6 Port Number

The Port Number parameter specifies the Cflowd collector UDP port. The range is 1 to 65 535. The default is 2055.

A.25.7 Resource Group ID

CAUTION

Service Disruption

Changing the Resource Group ID parameter setting has serious consequences.

Do not configure the parameter without first contacting your Nokia technical-support representative.

The Resource Group ID parameter specifies the group to which the NE is assigned for the management of NFM-P system resources.

A.25.8 Template Re-transmit (seconds)

The Template Re-transmit (seconds) parameter specifies how often, in s, Cflowd sends Cflowd template definitions to collectors. The parameter is configurable when the Version parameter is set to version-9 or version-10. The range is 10 to 600. The default is 600.

A.25.9 Vendor-Specific ICMP Extensions

The Vendor-Specific ICMP Extensions parameter specifies whether vendor-specific ICMP functionality is enabled on the 7450 ESS, 7705 SAR, 7750 SR, and 7950 XRS device types.

The options are:

- Enabled
- Disabled (default)

A.26 Gateway parameters

A.26.1 Dual Stack Preference Cplane

The Dual Stack Preference Cplane parameter specifies the IP version that is used for the control plane for the S5/S8 path.

The options are:

- IPv4
- IPv6 (default)

A.26.2 Dual Stack Preference Uplane

The Dual Stack Preference Uplane parameter specifies the IP version that is used for the user plane for the S5/S8 path.

The options are:

- IPv4
- IPv6
- Control Plane

A.27 ISA-AA Group parameters

A.27.1 Collector Port

The Collector Port parameter specifies the UDP port of the AA Cflowd collector. The range is 1 to 65 535. The default is 4739.

A.27.2 Host Address

The Host Address parameter specifies the Cflowd collector host address. Specify an IPv4 address in dotted-decimal format

A.27.3 Template Re-transmit

The Template Re-transmit parameter specifies how often, in s, AA Cflowd sends Cflowd template definitions to collectors. The range is 10 to 600. The default is 600.

A.28 LAG parameters

A.28.1 Auto-Generate

The Auto Generate parameter specifies whether to automatically configure an Actor Administration Key parameter.

The options are:

- Enabled (default)
- Disabled

A.28.2 Hash

The Hash for Ethernet LAG enabled parameter specifies service-level hashing for Ethernet services on the Wavence SM.

The options are:

- L1
- L2
- L3

A.28.3 Show Only Compatible Ports

The Show Only Compatible Port Numbers parameter specifies whether to filter the list of ports presented, by determining whether the ports can be configured as LAGs.

The options are:

- Enabled (default)
- Disabled

When the parameter is enabled, several checks are performed.

Which of the following checks are performed depends on the type of NE:

- the port mode is network
- the port cannot be a mobile port
- the port cannot be POS
- the port cannot belong to another LAG
- there cannot be more than eight ports in a LAG
- the port cannot be bound to a Layer 3 interface
- the ports must have the same speed
- the port must be set to full duplex and auto negotiation must be turned off

A.28.4 View the newly created Port Termination

The View the newly created Port Termination parameter specifies that the Properties form for the newly created LAG opens when you close the configuration form.

A.28.5 Wait to Restore (ms)

The Wait to Restore (ms) parameter specifies the amount of time to wait after a fault clears before a traffic interface is restarted in the LAG. This parameter is specific to Wavence NEs. The range is 100 to 8000. The default is 1000.

A.29 MME parameters

A.29.1 Abort MME Load Balance button

The Abort MME Load Balance button cancels the load balancing operation.

A.29.2 Lock MME button

The Lock MME button prevents the MME from accepting new UE connections.

A.29.3 Unlock MME button

The Unlock MME button returns an MME instance to an unlocked state, allowing the MME to accept new UE connections.

A.30 Port parameters

A.30.1 Configured Alarms

The Configured Alarms parameter specifies the alarms that are monitored by the interface.

Table A-8 Configured Alarms (cfgAlarms): OTU Alarms

Configurable OTU Alarms	
OTU Backward Defect Indication	OTU Bit Error Rate Signal Degrade
OTU Bit Error Rate Signal Fail	OTU Alarm Indication Signal
Loss of Multi-frame	Loss of OTU Framing
Loss of Signal	Loss of Clock
ODU Alarm Indication Signal	Uncorrectable FEC errors
FEC Rx/Tx Mode Mismatch	FEC Signal Degrade
FEC Signal Failure	OTU Backward Incoming Alignment Error
OTU Incoming Alignment Error	OTU Trace ID Mismatch
PM Trace ID Mismatch	OPU PSI Payload Type Mismatch
OPU PSI Trace Mismatch	PM Backward Defect Indication
ODU Locked	ODU Open Connection Indication

Table A-9 Configured Alarms (cfgAlarms): Wave Tracker Alarms

Configurable Wave Tracker Alarms	
Power Control Low limit reached	Power Control High limit reached
Power Control Degrade	Power Control Failure
Encoder Degrade	Encoder Failure

Table A-10 Configured Alarms (ampcfgAlarms): Optical Amplifier Alarms

Configurable Optical Amplifier Alarms	
Amplifier Module communication failure	Amplifier Loss of output power
Amplifier Loss of input optical power	Amplifier Module Case temperature low
Amplifier Module Case temperature high	Amplifier Pump temperature
Amplifier Pump over-current	—

Table A-11 Configured Alarms (tdcmcfgAlarms): Optical Tunable Dispersion Compensation Module Alarms

Configurable Optical Tunable Dispersion Compensation Module Alarms	
Tdcm module communication failure	Tdcm EEPROM invalid
Tdcm thermal control temperature limit	Tdcm thermal control unlocked
Tdcm module temperature low	Tdcm module temperature high
Tdcm not ready	—

A.30.2 Expected Rx Bytes

The Expected Rx Bytes parameters specify the expected type of receiver (Rx) Trail Trace Identifier (TTI) in the OTU. The parameters appear only when the A.30.3 “Expected Rx Mode” (p. 3289) parameter is set to Bytes.

The value is a hexadecimal number.

Table A-12 Expected Rx Bytes parameters

Parameter	Specifies the TTI for
Expected Rx Bytes (pmTtiExp)	PM
Expected Rx Bytes (smTtiExp)	SM
Expected Rx Bytes (psiTtiExp)	PSI

A.30.3 Expected Rx Mode

The Expected Rx Mode parameters specify the expected type of TTI in the OTU overhead.

Table A-13 Expected Rx Mode parameters

Parameter	Specifies the TTI for	Options
Expected Rx Mode (pmTtiExpMode)	PM	Auto (default) String Bytes
Expected Rx Mode (smTtiExpMode)	SM	
Expected Rx Mode (psiTtiExpMode)	PSI	

A.30.4 Expected Rx String

The Expected Rx String parameters specify the expected receiver (Rx) TTI in the OTU overhead. The parameters are only configurable when the A.30.3 “Expected Rx Mode” (p. 3289) parameter is set to String.

The value is 0 to 192 bytes.

Table A-14 Expected Rx String parameters

Parameter	Specifies the TTI for
Expected Rx String (pmTtiExp)	PM
Expected Rx String (smTtiExp)	SM
Expected Rx String (psiTtiExp)	PSI

The auto-populated default sequence is the name of the NE, the IOM number, the MDA slot number, the port number, and the DWDM channel number.

A.30.5 J0 Byte

The J0 Byte parameter specifies a numeric value for a SONET section trace. This value is inserted at the source and is checked against the value expected by the receiver. The parameter is configurable when the Framing parameter is set to SONET and the SONET Section Trace Mode parameter is set to Byte. The range is a hexadecimal number from 00 to FF. The default is 01.

A.30.6 Receiver

These parameters specify the TTI in the received OPU overhead. The auto-populated default sequence is the name of the NE, the IOM number, the MDA slot number, the port number, and the DWDM channel number.

Table A-15 Receiver parameters

Parameter	Specifies the TTI for	Options
Receiver (pmTtiRx)	PM	0 to 192 bytes
Receiver (smTtiRx)	SM	0 to 192 bytes
Receiver (psiPayloadTypeRx)	PSI	0 to 254 bytes

A.30.7 Transmitter Bytes

The Transmitter Bytes parameters specify the type of transmit (Tx) TTI in the OTU. These parameter appears only when the A.30.8 “Transmitter Mode” (p. 3290) parameter is set to Bytes.

The value is a hexadecimal number.

Table A-16 Transmitter Bytes parameters

Parameter	Specifies the TTI for
Transmitter String (pmTtiTx)	PM
Transmitter String (smTtiTx)	SM
Transmitter String (psiTtiTx)	PSI

A.30.8 Transmitter Mode

The Transmitter Mode parameters specify the type of TTI in the OTU overhead.

Table A-17 Transmitter Mode parameters

Parameter	Specifies the TTI for	Options
Transmitter Mode (pmTtiTxMode)	PM	Auto (default) String Bytes
Transmitter Mode (smTtiTxMode)	SM	
Transmitter Mode (psiTtiTxMode)	PSI	

A.30.9 Transmitter String

These parameters allow specify the type of transmit TTI in the OTU overhead. These parameters are only configurable when the A.30.8 “Transmitter Mode” (p. 3290) parameter is set to String.

The value is 0 to 192 bytes.

Table A-18 Transmitter String parameters

Parameter	Specifies the TTI for
Transmitter String (pmTtiTx)	PM
Transmitter String (smTtiTx)	SM
Transmitter String (psiTtiTx)	PSI

The auto-populated default sequence is the name of the NE, the IOM number, the MDA slot number, the port number, and the DWDM channel number.

A.31 Shelf parameters

A.31.1 Interface Name

Click on the Select button beside the Interface Name parameter and select a timing reference.

A.31.2 Port or Channel Name

Click on the Select button beside the Port or Channel Name parameter and select a timing reference. When configuring Timing Reference One on a 7210 SAS-D ETR, only ports 1 to 4 can be selected. When configuring Timing Reference Two on a 7210 SAS-D ETR, only ports 5 and 6 can be selected. Ports 7 to 10 can be selected for any timing reference.

A.31.3 Quality Level Override

This parameter specifies the quality level used for SETS input selection. This value overrides any value received by the SSM process of that reference.

Table A-19 Quality Level Override parameters

Parameter	Description	Options
Quality Level Override (firstTimingReferenceQualityLevel)	Specifies the quality level used for the first timing reference for SETs input selection.	None Prs Stu St2 Tnc St3e St3 Prc Ssua Ssub Sec Eec1 Eec2
Quality Level Override (secondTimingReferenceQualityLevel)	Specifies the quality level used for the second timing reference for SETs input selection.	
Quality Level Override (bitsQualityLevel)	Specifies the quality level used for the reference for SETs input selection.	
Quality Level Override (ptpQualityLevel)	Specifies the quality level used for the reference for SETs input selection.	

A.31.4 Radio Name

The Radio Name parameter specifies specifies a description for the MW Link Member. The range is 0 to 32 characters.

A.32 TWAMP parameters

A.32.1 Conn Idle Time Periodic Threshold (seconds)

The Conn Idle Time Periodic Threshold (Seconds) parameter specifies the configurable threshold for the elapsed time, in seconds, for a TWAMP message to be received on this control connection. When the value of this parameter exceeds the value configured for Inactivity Timeout (Seconds), the connection will be closed.

The range is 0 to 9 223 372 036 854 775 807. The default is 0.

A.32.2 Conn Session Count Periodic Threshold

The Conn Session Count Periodic Threshold parameter specifies the configurable threshold for the number of test sessions conducted by the TWAMP server, for the connection specified by the index values.

The range is 0 to 9 223 372 036 854 775 807. The default is 0.

A.32.3 Conn Test Packets Rx Periodic Threshold

The Conn Test Packets Rx Periodic Threshold parameter specifies the configurable threshold for the number of TWAMP test packets received by the TWAMP server, for the connection specified by the index values.

The range is 0 to 9 223 372 036 854 775 807. The default is 0.

A.32.4 Conn Test Packets Tx Periodic Threshold

The Conn Test Packets Tx Periodic Threshold parameter specifies the configurable threshold for the number of TWAMP test packets sent by the TWAMP server, for the connection specified by the index values.

The range is 0 to 9 223 372 036 854 775 807. The default is 0.

A.32.5 Conn Test Sess Completed Periodic Threshold

The Conn Test Sess Completed Periodic Threshold parameter specifies the configurable threshold for the number of test sessions completed by the TWAMP server, for the connection specified by the index values.

The range is 0 to 9 223 372 036 854 775 807. The default is 0.

A.32.6 Conn Test Sess Rejected Periodic Threshold

The Conn Test Sess Rejected Periodic Threshold parameter specifies the configurable threshold for the number of test sessions rejected by the TWAMP server, for the connection specified by the index values.

The range is 0 to 9 223 372 036 854 775 807. The default is 0.

A.32.7 Srv Pfx Conn Count Periodic Threshold

The Srv Pfx Conn Count Periodic Threshold parameter specifies the configurable threshold for the number of control connections currently managed by the TWAMP server, for the prefix specified by the index values.

The range is 0 to 9 223 372 036 854 775 807. The default is 0.

A.32.8 Srv Pfx Conns Rejected Periodic Threshold

The Srv Pfx Conns Rejected Periodic Threshold parameter specifies the configurable threshold for the number of control connection requests which have been rejected by the TWAMP server, for the prefix specified by the index values.

The range is 0 to 9 223 372 036 854 775 807. The default is 0.

A.32.9 Srv Pfx Session Count Periodic Threshold

The Srv Pfx Session Count Periodic Threshold parameter specifies the configurable threshold for the number of currently in-progress TWAMP test sesssions, for the prefix specified by the index values.

The range is 0 to 9 223 372 036 854 775 807. The default is 0.

A.32.10 Srv Pfx Test Packets Rx Periodic Threshold

The Srv Pfx Test Packets Rx Periodic Threshold parameter specifies the configurable threshold for the number of TWAMP test packets received by the TWAMP server.

The range is 0 to 9 223 372 036 854 775 807. The default is 0.

A.32.11 Srv Pfx Test Packets Tx Periodic Threshold

The Srv Pfx Test Packets Tx Periodic Threshold parameter specifies the configurable threshold for the number of TWAMP test packets sent by the TWAMP server.

The range is 0 to 9 223 372 036 854 775 807. The default is 0.

A.32.12 Srv Pfx Test Sess Abort Periodic Threshold

The Srv Pfx Test Sess Abort Periodic Threshold parameter specifies the configurable threshold for the number of test sessions aborted by the TWAMP server, for the prefix specified by the index values.

The range is 0 to 9 223 372 036 854 775 807. The default is 0.

A.32.13 Srv Pfx Test Sess Completed Periodic Threshold

The Srv Pfx Test Sess Completed Periodic Threshold parameter specifies the configurable threshold for the number of test sessions completed by the TWAMP server, for the prefix specified by the index values.

The range is 0 to 9 223 372 036 854 775 807. The default is 0.

A.32.14 Srv Pfx Test Sess Rejected Periodic Threshold

The Srv Pfx Test Sess Rejected Periodic Threshold parameter specifies the configurable threshold for the number of test sessions rejected by the TWAMP server, for the prefix specified by the index values.

The range is 0 to 9 223 372 036 854 775 807. The default is 0.

A.33 Common Manage menu parameters

A.33.1 Common Manage menu parameters overview

This section describes the parameters that are common to the NFM-P Manage menus forms.

Note: This section also describes parameters common to the Service Template form and child forms. Service templates are intended for use in the NFM-P GUI. Nokia does not recommend using the XML API XML classes and methods associated with service templates.

A.33.2 Allow Binding Of Templates Not Associated With Any Subscriber

The Allow Binding Of Templates Not Associated With Any Subscriber parameter specifies whether you can bind templates even when they do not have a subscriber association.

The options are:

- enabled (default)
- disabled

A.33.3 SAP Administrative State

The SAP Administrative State parameter specifies whether the SAP is administratively enabled.

The options are:

- Up (default)
- Down

A.34 Customers parameters

A.34.1 Apdex Thresholds - Unacceptable

The Apdex scores below this threshold are unacceptable quality, the parameter range is 0.00 to 1.00 in 0.01 increments. The default value is 0.5.

A.34.2 Apdex Thresholds - Poor

The Apdex scores below this threshold are poor quality, the parameter range is 0.00 to 1.00 in 0.01 increments. The default value is 0.7.

A.34.3 Apdex Thresholds - Fair

The Apdex scores below this threshold are fair quality, the parameter range is 0.00 to 1.00 in 0.01 increments. The default value is 0.85.

A.34.4 Apdex Thresholds - Good

The Apdex scores below this threshold are good quality, the parameter range is 0.00 to 1.00 in 0.01 increments. The default value is 0.94.

A.34.5 MOS Thresholds - Unacceptable

The MOS scores below this threshold are unacceptable quality, the parameter range is 0.00 to 5.00 in 0.01 increments. The default value is 1.0.

A.34.6 MOS Thresholds - Poor

The MOS scores below this threshold are poor quality, the parameter range is 0.00 to 5.00 in 0.01 increments. The default value is 2.0.

A.34.7 MOS Thresholds - Fair

The MOS scores below this threshold are fair quality, the parameter range is 0.00 to 5.00 in 0.01 increments. The default value is 3.0.

A.34.8 MOS Thresholds - Good

The MOS scores below this threshold are good quality, the parameter range is 0.00 to 5.00 in 0.01 increments. The default value is 4.0.

A.35 IPsec VPN parameters

A.35.1 Security Policy ID

The Security Policy ID parameter specifies an ID for the IPsec security policy on the VPRN site. The range is 1 to 8192. The default is 0.

A.35.2 Tunnel Type

The Tunnel Type parameter specifies the tunnel type for the tunnel group.

The options are:

- Dynamic (Site-to-Site)
- Dynamic (Soft Client)
- Static

A.36 LSPs parameters

A.36.1 Auto Select Hop-less Path

The Auto Select Hop-less Path parameter specifies whether MPLS paths are explicitly specified during LSP creation or the LSP uses a completely loose path and the NFM-P selects the MPLS paths for the LSP.

Table A-20 Auto Select Hop-less Path parameter

Option	Option description
Disabled (default)	Specifies that you must manually choose or create the MPLS paths during LSP creation based on the source NE. IGP is used to identify the next hop.
Enabled	Specifies a loose path. The NFM-P chooses the MPLS paths for the LSP. If no hopless path to the destination exists, the NFM-P creates one.

Note: If the A.36.1 “Auto Select Hop-less Path” (p. 3296) parameter is enabled, the NFM-P automatically creates a hopless MPLS path for the dynamic LSP. This path will be named “HOP-LESS PATH <system_IP_adress>-<ID>”, where the system_IP_address is the source NE address and the ID is the unique identifier for the MPLS. If you want to create an MPLS path and use the A.36.1 “Auto Select Hop-less Path” (p. 3296) parameter to assign it to the LSP, it must follow this naming convention.

A.36.2 Exclude Node in ERO

The Exclude Node in ERO parameter specifies whether or not a device should be excluded from the manual bypass LSP path.

When this parameter is enabled, you can enter an IPv4 address for the Exclude Node IP Address parameter.

The options are:

- enabled
- disabled (default)

A.36.3 View the newly created Bypass Only Lsp

The View the newly created Bypass Only Lsp parameter specifies whether you want to view the configuration information about the newly created LSP. The Bypass Only LSP child form displays the service tunnel configuration information.

The options are:

- Enabled
- Disabled (default)

A.36.4 View the newly created Dynamic LSP

The View the newly created Dynamic LSP parameter specifies whether you want to view the configuration information about the newly created LSP. The Dynamic LSP child form displays the service tunnel configuration information.

The options are:

- Enabled
- Disabled (default)

A.37 Mirror Services parameters

A.37.1 Mirror Services parameters overview

This section describes the unique parameters on the Manage Mirror Service Templates form and child forms.

Note: The mirror service templates are intended for use in the NFM-P GUI. Nokia recommends that you do not use the XML API XML classes and methods that are associated with the service templates.

A.37.2 Template Description

The Template Description parameter specifies a description for the template type. The range is an interface name of 0 to 80 characters. The default is an empty string.

A.38 MPLS Paths parameters

A.38.1 Insert Hop

Click the Insert Hop button to insert a hop in the MPLS provisioned path. A hop can be an interface on an Nokia-managed NE or a third-party device.

A.38.2 Specify Site

The Specify Site parameter specifies the method for configuring the destination site of the MPLS path.

Table A-21 Specify Site parameter

Option	Option description	Dependencies
Manually	Specifies that you must select the destination site for the MPLS path by manually entering the IP address.	—
By Selection	Specifies that you must select the destination site for the MPLS path by: • listing and choosing the network element site ID or IP address using the Select buttons • manually entering the IP address	

A.38.3 Starting Network Element

Click the Select button to specify the starting network element for the MPLS path.

A.39 Services parameters

A.39.1 Number of SAPs

The Number of SAPs parameter displays the total number of SAPs present under a service site.

A.39.2 What type of interface would you like to create?

The What type of interface would you like to create? parameter specifies the:

- type of multicast interface that is added to an existing IES
- type of protocol that is applied to an existing IES or IES SAP

Table A-22 What type of interface would you like to create? parameter

Object	Options
IES	PIM (default) IGMP

Table A-22 What type of interface would you like to create? parameter (continued)

Object	Options
IES or IES SAP	OSPFv2 (default) OSPFv3 RIP ISIS

A.40 Service Tunnel parameters

A.40.1 No VLAN VC Ethertype

The No VLAN VC Ethertype parameter specifies whether a VLAN VC Ethertype parameter can be specified. When the No VLAN VC Ethertype parameter is enabled the VLAN VC Ethertype parameter cannot be set.

The options are:

- enabled (default)
- disabled

A.40.2 Order

The Order parameter specifies whether the group is ordered or unordered.

The options are:

- unordered (default)
- ordered

A.40.3 View the newly created tunnel

The View the newly created Dynamic LSP parameter specifies whether you want to view the configuration information about the newly created LSP. The Dynamic LSP child form displays the service tunnel configuration information.

The options are:

- Enabled
- Disabled (default)

A.40.4 VPLS

The VPLS parameter specifies whether Ethernet ring element interconnection is enabled through VPLS. The VPLS parameter is configurable when the Type parameter is set to Non Virtual Link. When the VPLS parameter is set to True, the Ethernet Ring ID parameter is set to 4294967295. The default is False.

A.41 Templates parameters

A.41.1 Command Type

The Command Type parameter specifies the command type for the template.

The options are:

- Create (default)
- Modify

When you choose the Create option, the template is used to create new objects. When you choose the Modify option, the template is used to modify an existing object.

A.41.2 Generate First (Base) Version

The Generate First (Base) Version parameter specifies whether a Velocity UI header is generated in the XML API configuration template script at template creation.

The options are:

- Enabled (default)
- Disabled

A.41.3 Generate Velocity Properties

The Generate Velocity Properties parameter specifies whether a Velocity UI header is generated in the XML API configuration template script.

The options are:

- Enabled (default)
- Disabled

A.41.4 Mode

The Mode parameter is used to specify the state of the template.

The options are:

- Draft (default)
- Released

A.41.5 Show Created Object

The Show Created Object parameter specifies whether to open the properties form for the object that you are creating from the template.

The options are:

- Enabled
- Disabled (default)

A.41.6 Type

The Type parameter specifies a user-defined description of the XML API configuration templated category. The range is 0 to 255 characters.

A.42 VLAN group and path parameters

A.42.1 Destination Network Element

The Destination Network Element parameter specifies the IP address of the Wavence SM at the end of the VLAN path. There is no default.

A.42.2 Has Tail

The Has Tail parameter specifies whether a tail node is attached to a ring element.

The options are:

- Disabled (default)
- Enabled

A.42.3 Head End

The Head End parameter specifies the IP address of the Wavence SM at the head end of the VLAN group.

A.42.4 Is Point to Multipoint

The Point to Multipoint parameter specifies whether the VLAN path is a P2P (dot1q) VLAN path or a P2MP (dot1q) VLAN path.

The options are:

- Disabled -- P2P (default)
- Enabled -- P2MP

Note: The P2P (dot1q) VLAN services is for users that need to restrict a dot1q VLAN service to two sites.

The P2MP (dot1q) VLAN services is for users who need a dot1q VLAN service with two or more sites.

Services must be deleted to change from P2P to P2MP and P2MP to P2P.

A.42.5 Link

The Link parameter specifies the link for the VLAN path to traverse.

A.42.6 Minimum Bandwidth (kbps)

The Minimum Bandwidth (kbps) parameter specifies the guaranteed bandwidth that is available across all network ports that have to be selected during creation of a VLAN path. This parameter is optional.

A.42.7 Network Element

The Network Element parameter specifies which hops the VLAN paths traverses.

A.42.8 Starting Network Element

The Starting Network Element parameter specifies the IP address of the Wavence SM at the start of the VLAN path.

A.43 7705 SAR Fabric parameters

A.43.1 Rate To MDA (destRateTo1<card#>

The Rate To MDA parameter specifies the rate, in kb/s, to each daughter card slot. You can configure the rates individually for each daughter card slot on the 7705 SAR. There is a rate for each slot identified by IOMslot/daughter card slot; for example, Rate to MDA 1/1, Rate to MDA 1/2, and so on. You can configure each of the rates in the range 1 to 1 000 000 kb/s and 200 000 kb/s is the default value.

A.44 Wavence NE QoS parameters

A.44.1 DSCP

The DSCP (DiffServ) parameter specifies a QoS classification that uses the DS field of the IPv4 or IPv6 packet header defined in RFC2474. The priority values in the DSCP (Differentiated Service Code Point) field are not directly mapped to queues but are mapped to the internal forwarding classes.

The Priority values are mapped to eight forwarding classes from 0 (lowest priority) to 7 (highest priority). When an incoming packet is not IPv4 or IPv6, the packet is assigned to the lowest priority queue.

A.45 Application Assurance parameters

A.45.1 Add Factor

The Add Factor parameter specifies that the Factor Value parameter value is to be added to each application filter entry ID to be renumbered.

A.45.2 Multiply Factor

The Multiply Factor parameter specifies that each application filter entry ID to be renumbered is to be multiplied by the Factor Value parameter value.

A.45.3 Port Value Type

The Port Value Type parameter specifies the destination port value type.

The options are:

- Single (default)

- Range

A.45.4 Port Value Type

The Port Value Type parameter specifies the source port value type.

The options are:

- Single (default)
- Range

A.46 Access Egress parameters

A.46.1 Port Redirect Queue Group

Table A-23 Port Redirect Queue Group parameter

Parameter	OSS equivalent name	Description
Port Redirect Queue Group	portRedirectGroupQueue	Specifies that packets are redirected to a queue in a SAP egress port queue group. The forwarding class queue ID is explicitly specified in the SAP egress QoS policy.
Port Redirect Queue Group (for HSMDA queues)	portRedirectHsmdaQueuePortGrpQ	Specifies that packets are redirected to an HSMDA queue in a SAP egress port queue group. The forwarding class HSMDA queue ID is explicitly specified in the SAP egress QoS policy.

The choices for either version of this parameter are:

- disabled (default)
- enabled

A.46.2 Traffic Control

The Traffic Control parameter specifies the type of object used in the forwarding class.

The options are:

- Use Policer
- Use Queue Group
- Use Queue (default)

The Use Policer option specifies whether a policer is used in the forwarding class. You can assign a policer to a forwarding class for Unicast traffic. When you assign a policer, you must select a Policer ID in the Policers panel.

The Use Queue Group option specifies whether a queue from an egress queue group template is used in the forwarding class. You must select an egress queue from the specified queue group template policy in the Queue panel.

The Use Queue option specifies whether a queue configured locally within the policy is used in the forwarding class. You must select a Queue ID in the Queue panel.

A.47 Access Ingress parameters

A.47.1 Use Policer

The Use Policer parameter specifies whether a policer is used in the forwarding class.

You can assign a policer to a forwarding class for the following traffic types:

- Unicast
- Multicast
- Broadcast
- Unknown

When you assign a policer for one or more of the traffic types, you must select a policer ID for each traffic type in the Policers panel.

A.47.2 Use Queue Group

The Use Queue Group parameter specifies whether a queue from an ingress queue group template is used in the forwarding class, and if so, the type of queue.

The options are:

- Unicast Queue
- Multicast Queue
- Broadcast Queue
- Unknown Queue

When you enable one or more of the options, you must select a ingress queue from the specified queue group template policy in the Queues panel. If you do not enable the parameter options, the ingress queues that are listed for each queue type are queues that are configured locally within the policy.

A.48 Auto Tunnels parameters

A.48.1 Order

The Order parameter specifies whether the group is ordered or unordered.

The options are:

- unordered (default)
- ordered

A.48.2 View the newly created tunnel

The View the newly created Dynamic LSP parameter specifies whether you want to view the configuration information for the newly created LSP. The Dynamic LSP child form displays the service tunnel configuration details.

The options are:

- Enabled
- Disabled (default)

A.49 Common Policies menu parameters

A.49.1 Default

The Default parameter specifies whether a parameter is set to the default value or can be configured.

The options are:

- disabled
- enabled (default)

When the Default parameter is set to enabled, you cannot configure the associated parameters.

A.49.2 Destination IP Prefix

The Destination IP Prefix parameter specifies a list of IP prefixes to use as destinations for the filter policy. When the parameter is enabled, click on the Select button and choose a prefix list.

A.49.3 Log ID

The Log ID parameter specifies the filter log for the filter entry. Click on the Select button beside the parameter to choose a filter, or type in a value. The range is 101 to 199. The default is 0, which means that the parameter is not configured.

A.49.4 New Entry ID

The New Entry ID parameter specifies the new identifier of the filter entry. The parameter value becomes the Entry ID of the filter entry. A filter policy compares the contents of a packet to each filter entry until it finds a match, beginning with the lowest Entry ID. The range is 1 to 65535. There is no default.

A.49.5 Override CIR

The Override CIR parameter specifies the override value for the administrative committed information rate for the queue or the policer. The default is MAX which specifies the maximum available CIR.

The CIR override is configured in kbps if the Rate Type for the queue or policer was originally set to kbps. The CIR override is configured as a Percent (%) if the Rate Type for the queue or policer was originally set to either Percent Port Limit (queues only) or Percent Local Limit.

The range depends on the type of object being configured.

Table A-24 Override CIR parameter

Object type	Range
Queue	The range is 0 to 100 000 000 kbps (0 to 100%), depending on the line rate of the object to which the policy is applied. A value of -2 specifies that no override is applied. A value of -1 specifies that the maximum override is applied.
Policer	The range is 0 to 20 000 000 kbps (0 to 100%), depending on the line rate of the object to which the policer is applied. A value of -2 specifies that no override is applied. A value of -1 specifies that the maximum override is applied.

A.49.6 Override CIR Adaptation

The Override CIR Adaptation parameter specifies the override value for the method used by the device to derive the operational CIR setting when the queue is provisioned in hardware

You can also choose the Default option, which specifies that the operational CIR for the queue is the rate closest to the rate specified by the CIR (kbps) parameter.

Table A-25 Override CIR Adaptation parameter

Option	Option description	Dependencies
Closest (default)	The operational CIR for the queue is the rate closest to the rate specified by the CIR (kbps) parameter.	—
Min	The operational CIR for the queue is equal to or greater than the administrative rate specified by the CIR (kbps) parameter.	
Max	The operational CIR for the queue is equal to or less than the administrative rate specified by the CIR (kbps) parameter.	

A.49.7 Override Committed Burst Size

The Override Committed Burst Size parameter specifies the override value for the Committed burst pool size for a queue.

The range is -1 to 4 194 304, with -1 indicating default. Default specifies that the device calculates committed burst pool size based on the CIR and the PIR. The default is default.

A.49.8 Override High Priority Reserved

The Override High Priority Reserved parameter specifies the override value for the percentage of buffer pool space for the queue that is only used by high-priority packets.

The range is -1 to 100, with -1 indicating default. The default is default, which means that the device calculates the high priority reserved pool size based on the CIR and the PIR values.

A.49.9 Override Maximum Burst Size

The Override Maximum Burst Size parameter specifies the override value for the maximum burst pool size for a queue.

The range is -1 to 4 194 304, with -1 indicating default. Default specifies that the device calculates the committed burst pool size based on the CIR and PIR.

A.49.10 Override Packet Offset

The Override Packet Offset parameter specifies the number of offset bytes to add to (or remove from) a packet handled by a policer. A positive number adds bytes. A negative number removes bytes. The range is -128 and -32 to 31. The -128 value indicates that no override is applied. The default is -1.

A.49.11 Override PIR

The Override PIR parameter specifies the override value for the administrative peak information rate for the queue or the policer. The default is MAX which specifies the maximum available PIR.

For policers and non-HSMDA queues, the PIR override is configured in kbps if the Rate Type for the queue or policer was originally set to kbps. The PIR override is configured as a Percent (%) if the Rate Type for the non-HSMDA queue or policer was originally set to either Percent Port Limit (queues only) or Percent Local Limit.

The range depends on the type of object being configured.

Table A-26 Override PIR parameter

Object type	Range
HSMDA queue	The range is 0 to 100 000 000 kbps, depending on the line rate of the object to which the policy is applied. A value of -2 specifies that no override is applied. A value of -1 specifies that the maximum override is applied.
Queue	The range is 0 to 100 000 000 kbps (0 to 100%), depending on the line rate of the object to which the policy is applied. A value of -2 specifies that no override is applied. A value of -1 specifies that the maximum override is applied.
Policer	The range is 0 to 20 000 000 kbps (0 to 100%), depending on the line rate of the object to which the policer is applied. A value of -2 specifies that no override is applied. A value of -1 specifies that the maximum override is applied.

A.49.12 Override PIR Adaptation

The Override PIR Adaptation parameter specifies the override value for the method used by the device to derive the operational PIR setting when the queue is provisioned in hardware

You can also choose the Default option, which specifies that the operational PIR for the queue is the rate closest to the rate specified by the PIR (kbps) parameter.

Table A-27 Override PIR Adaptation parameter

Option	Option description	Dependencies
Closest (default)	The operational PIR for the queue is the rate closest to the rate specified by the PIR (kbps) parameter.	—
Min	The operational PIR for the queue is equal to or greater than the administrative rate specified by the PIR (kbps) parameter.	
Max	The operational PIR for the queue is equal to or less than the administrative rate specified by the PIR (kbps) parameter.	

A.49.13 Override Port Average Overhead

The Override Port Average Overhead parameter specifies the override value for the average percentage that the offered load to a queue is expected to expand during the frame encapsulation process before sending traffic on queues that egress a SONET or SDH port or channel.

The range is 0 to 100. Default specifies that the egress QoS policy for the queue is applied.

A.49.14 Override Queue CIR Weight

The Override Queue CIR Weight parameter specifies the override value for the weight that should be assigned to this queue by the parent scheduler among all the entities feeding into the parent when the traffic is conforming to the committed rate.

The range is -2 to 100. Default specifies that the egress or ingress QoS policy for the queue is applied. A value of '0' specifies that the queue will not receive bandwidth for the 'within-cir' pass on its parent scheduler.

A.49.15 Override Queue Weight

The Override Queue Weight parameter specifies the weight that needs to be used by the scheduler to which this queue would be feeding.

The range is -2 to 100. Default specifies that the egress or ingress QoS policy for the queue is applied.

A.49.16 Override Summed CIR

The Override Summed CIR parameter specifies the override value for the summed CIR.

The options are:

- true
- false (default)

A.49.17 Value

The following table lists the variations in the Value parameter for the Advanced Configuration Policy. These values will be assigned to whatever entity the Advanced Configuration Policy is applied to, unless the associated Default parameter is enabled.

Table A-28 Value parameter

Applicability	XML reference	Description	Range
Above Offered Cap (kbps)	aboveOfferedCapRate	Specifies the explicit number of kilobits per second that should be used as the limit to the applicable entity's fair share increase to the operational PIR. This is capped by the entity's configured PIR.	0 to 100 000 000, and also -1. Default = 0 -1 represents the maximum value.
Above Offered Cap (%)	aboveOfferedCapPirPercent	Specifies the percentage of the administrative PIR that should be used as the limit to the applicable entity's fair share increase to the operational PIR. This is capped by the entity's configured PIR.	0 to 100 Default = 100
Granularity (of Bandwidth Distribution) (kbps)	bwdGranularityRate	Specifies the explicit number of kilobits per second that should be used as the rounding step value for the applicable entity's administrative PIR.	0 to 100 000 000 Default = 0
Granularity (of Bandwidth Distribution) (%)	bwdGranularityPirPercent	Specifies the granularity percentage of the applicable entity’s administrative PIR that should be used as the rounding step value.	0 to 100 Default = 0
Granularity (of Measured Offered Rate) (kbps)	omGranularityRate	Specifies the explicit number of kilobits per second that should be used as the offered rate change sensitivity value for the applicable entity's administrative PIR.	0 to 100 000 000 Default = 0
Granularity (of Measured Offered Rate) (%)	omGranularityPirPercent	Specifies the granularity percentage of the applicable entity’s administrative PIR that should be used as the threshold sensitivity to the offered rate.	0 to 100 Default = 0
Measured Offered Rate Increase (kbps)	childAdminRate	Specifies the explicit number of kilobits per second of the applicable entity’s administrative PIR that should be added to the entity's offered rate. This is capped by the entity's configured PIR.	0 to 100 000 000 Default = 0
Measured Offered Rate Increase (%)	childAdminPirPercent	Specifies the percentage of the applicable entity’s administrative PIR that should be added to the entity's offered rate. This is capped by the entity's configured PIR.	0 to 100 Default = 0

Table A-28 Value parameter (continued)

Applicability	XML reference	Description	Range
Max Decrement (kbps)	maxDecrementRate	Specifies the explicit number of kilobits per second of the applicable entity's administrative PIR that should be used as the decrement limit to the offered rate change.	0 to 100 000 000 Default = 0
Max Decrement (%)	maxDecrementPirPercent	Specifies the percentage of the applicable entity's administrative PIR that should be used as the decrement limit to the offered rate change.	0 to 100 Default = 100

A.50 Format and Range Policies parameters

A.50.1 Auto Assign By Default

The Auto Assign By Default parameter specifies whether the Auto-Assign ID check box is enabled by default.

The options are:

- enabled
- disabled

A.50.2 Auto Assignment Enabled

The Auto Assignment Enabled parameter specifies whether the Auto-Assign ID parameter is enabled by default.

The options are:

- enabled
- disabled

A.50.3 Copy Text From Position

The Copy Text From Position parameter specifies the source attribute text that is copied. This parameter is configurable when you choose the Auto-Filled option for the text block format parameters. The range is 1 to 1000 characters.

A.50.4 Default Value

The Default Value parameter specifies the default of the text field. The parameter is configurable when the text block format option is Text Parameter. The range is 0 to 250 characters.

A.50.5 Mask

The Mask parameter specifies the text that is entered for a parameter value when the parameter value is configured by a format policy. For example, when a format policy is created for a service description, you can configure the text that automatically populates the description field. You cannot enter values that do not comply with the mask. The range is 0 to 250 characters.

The following table lists the special formatting characters available for the Mask parameter.

Table A-29 Special formatting characters

Character	Source object property options
‘	Used to escape any of the special formatting characters
#	Any valid number
U	Any letter, where lowercase characters are mapped to uppercase characters
L	Any letter, where uppercase characters are mapped to lowercase characters
A	Any letter or number
?	Any letter
*	Anything
H	Any hexidecimal character: • 0 to 9 • a to f • A to F

A.50.6 Maximum

The Maximum parameter specifies the highest number in the ID range for a range policy. The range is 0 to 1000000999999. The default is automatically set when the range policy is created. You can click on the Reset to Default button to reset the value.

A.50.7 Max. Length

The Max. Length parameter specifies the maximum length of a text field parameter that is configured in a format policy text block. The range is 1 to 250 characters.

A.50.8 Minimum

The Minimum parameter specifies the lowest number that can be used in the ID range for a range policy. The range is 0 to 1000000999999. The default is automatically set when the range policy is created. You can click on the Reset to Default button to reset the value.

A.50.9 Min. Length

The Min. Length parameter specifies the minimum length of a field text parameter that is configured in a format policy text block. The range is 0 to 250 characters.

A.50.10 Object Type

The Object Type parameter specifies the object class that is configured in the format or range policy. Choose an object type by clicking on the Select button.

A.50.11 Priority

The Priority parameter specifies the sequence in which multiple instances of a policy are sorted. The range is 1 to 1000 (lowest priority). The list of policies returned by the policy that matches a query is listed using the priority value.

A.50.12 Property Name

The Property Name parameter specifies the parameter to which the format or range policy applies.

The options are:

- Name
- Service Name
- Description
- Service ID
- ID
- Interface ID
- Outer Encapsulation Value

A.50.13 Read Only

The Read Only parameter specifies when the A.50.9 “Min. Length” (p. 3311) and A.50.7 “Max. Length” (p. 3311) parameters are read-only. The Read Only parameter is configured in the Text Format option of the Text Block Format form.

The options are:

- Enabled
- Disabled (default)

A.50.14 Source Object Name

The Source Object Name parameter specifies the object type to be used as the source to create the text string. This parameter is set during Auto-Filled Parameter configuration.

A.50.15 Source Property Name

The Source Property Name parameter specifies the object attributes to be used as the source to create the text string. This parameter is configured when the Auto-Filled Parameter option is configured.

A.50.16 Tooltip Text

The Tooltip Text parameter allows the operator to create a description for the parameter value to inform users that a format policy is applied to the parameter. The range is 0 to 1000 characters.

A.50.17 Through To Position

The Through To Position parameter copies the text of the source parameter up to the position that is configured by this parameter. This parameter is configurable when the auto-filled option is selected for the text block format and the A.50.18 “Unlimited” (p. 3312) parameter is disabled. The range is 1 to 1000.

A.50.18 Unlimited

The Unlimited parameter specifies the amount of source attribute text to be copied. The parameter is configurable when the auto-filled option is selected for the text block format. When the parameter is enabled, the source attribute text is copied from the A.50.3 “Copy Text From Position” (p. 3310) parameter value to the end. When the parameter is disabled you can copy the source parameter text to a specified position.

The options are:

- enabled
- disabled

A.51 HSMDA WRED Slope parameters

A.51.1 HSMDA High Slope

The High Slope parameter specifies how the high-priority packets, also known as in-profile packets, access the shared portion of the buffer pool. The probability of the buffer pools discarding packets is determined by the RED slope. The RED slope is indicated on the client GUI in a graph.

The Start Depth, Max Depth, and Max Prob. parameters specify the values of the RED slope.

In general, packets that are in-profile fall within the configured CIR and PIR ranges. This means that the packets are more likely to gain access to the shared buffer pool, and not be discarded because of a buffer overflow.

A.51.2 HSMDA Low Slope

The Low Slope parameter specifies how the low-priority packets, also known as out-of-profile packets, access the shared portion of the buffer pool. The probability of the buffer pools discarding packets is determined by the RED slope. The RED slop is indicated on the client GUI in a graph.

The Start Depth, Max Depth, and Max Prob. parameters specify the values of the RED slope.

In general, packets that are out-of-profile fall outside configured CIR and PIR ranges. This means that the packets should not be allowed to cause a buffer overflow in the shared buffer pool, and are more likely to be discarded because of a buffer overflow.

A.52 Ingress Multicast Path Management parameters

A.52.1 Administrative BW (kbps)

The Administrative BW parameter specifies the multicast channel's administrative bandwidth in kilo-bits per second. The range is from 0 to 40 000 000 kbps. The default is 0.

The XML property name for this parameter varies depending on where it is set, namely at the bundle, channel range, or channel override level.

Table A-30 Administrative BW (kbps) parameter variations

Parameter configuration level	XML property name
Channel bundle	defaultAdminBw
Channel range	adminBw
Channel override	adminBw

A.52.2 Black Hole Rate (kbps)

The Black Hole Rate parameter specifies at which current rate a channel (including channels within a channel range or bundle) should be placed in the black-hole state (packets are dropped). This value can only be set when the A.52.3 “BW Decision” (p. 3314) parameter is set to Dynamic. The range is 0 to 40 000 000. The default is 0, which means never.

The XML property name for this parameter varies depending on where it is set, namely at the bundle, channel range, or channel override level.

Table A-31 Black Hole Rate (kbps) parameter variations

Parameter configuration level	XML property name
Channel bundle	defaultBlackHoleRate
Channel range	blackHoleRate
Channel override	blackHoleRate

A.52.3 BW Decision

The BW Decision parameter specifies how the multicast ingress path manager determines the amount of bandwidth required by a multicast channel, including channels within a channel range or bundle.

The XML property name and default value for this parameter varies depending on where it is set, namely at the bundle, channel range, or channel override level.

Table A-32 BW Decision parameter variations

Parameter configuration level	XML property name	Default value
Channel bundle	defaultBwDecision	Dynamic
Channel range	bwDecision	unspecified
Channel override	bwDecision	unspecified

A.52.4 Explicit Path

The Explicit Path parameter specifies an explicit ingress switch fabric multicast path for the channels (including those in a range or a bundle). If the parameter is set to None, the Multicast Path Manager dynamically places channels on the most optimal switch fabric paths.

The options are:

- None (default)
- Ancillary
- Primary
- Secondary

The XML property name for this parameter varies depending on where it is set, namely at the bundle, channel range, or channel override level.

Table A-33 Explicit Path parameter variations

Parameter configuration level	XML property name
Channel bundle	defaultExplicitPath
Channel range	explicitPath
Channel override	explicitPath

A.52.5 Falling Delay (seconds)

The Falling Delay parameter specifies the value the bandwidth manager uses as a threshold to hold on to the previous highest bandwidth until the delay time has expired, while operating in dynamic bandwidth mode. This allows the bandwidth manager to ignore momentary drops in channel bandwidth. This value can only be set if A.52.3 “BW Decision” (p. 3314) is set to Dynamic. A value of 0 specifies that a non-zero value of the parent is applied.

The XML property name for this parameter varies depending on where it is set, namely at the bundle, channel range, or channel override level.

Table A-34 Falling Delay (seconds) parameter variations

Parameter configuration level	XML property name	Default value	Range	Parent
Channel bundle	defaultFallingDelay	30	10 to 3600s	—
Channel range	fallingDelay	0	0 | 10 to 3600	Channel bundle
Channel override	fallingDelay	0	0 | 10 to 3600	Channel bundle Channel range

A.52.6 Preference Level

The Preference Level parameter specifies the relative preference level for multicast channels. The preference of a channel (including those in a bundle or range) specifies its relative importance over other multicast channels. Eight levels of preference are supported: 0 through 7. Preference value 7 indicates the highest preference level.

The XML property name and default value for this parameter varies depending on where it is set, namely at the bundle, channel range, or channel override level.

Table A-35 Preference Level parameter variations

Parameter configuration level	XML property name	Default value
Channel bundle	defaultPrefLevel	7
Channel range	prefLevel	0
Channel override	prefLevel	0

A.53 Named buffer pool parameters

A.53.1 Default Reserved CBS

The Default Reserved CBS parameter specifies whether the default percent for reserved CBS is used.

The options are:

- Enabled
- Disabled

A.54 NAT Policy parameters

A.54.1 Default

The Default parameter specifies whether the IPFIX Collector Source Address parameter is included in IPFIX messages. Enabling this parameter allows you to configure the A.54.3 “IPFIX Collector Source Address” (p. 3316) parameter.

The options are:

- Enabled
- Disabled (default)

A.54.2 IPFIX Collector Address

The IPFIX Collector Address parameter specifies the IPv4 address of the IPFIX collector to which IP flow information is sent. Specify an IPv4 address in dotted-decimal format.

A.54.3 IPFIX Collector Source Address

The IPFIX Collector Source Address parameter specifies the IPv4 address from which IP flow information is sent to an IPFIX collector. When this parameter is not set, the IPFIX collector identifies sources by the IP address from which the IPFIX message is sent; if the source uses a proxy, this is the IP address of the proxy. Use this parameter to specify a different IP address. This parameter cannot be configured unless the A.54.1 “Default” (p. 3316) parameter is enabled. Specify an IPv4 address in dotted-decimal format.

A.54.4 IPFIX Export Policy

The IPFIX Export Policy parameter specifies the IPFIX export policy for the NAT policy. Click on the Select button to choose an IPFIX export policy.

A.54.5 MTU

The MTU parameter specifies the MTU size, in bytes, for IPFIX messages sent to the IPFIX collector. The range is 512 to 9212. The default is 1500.

A.54.6 Refresh Timeout

The Refresh Timeout parameter specifies the refresh rate of the IPFIX source, in hours, minutes, and seconds. After this time, the IPFIX source resends the IPFIX template information to the IPFIX collector. The range is 0 seconds to 24 hours, 59 minutes, and 59 seconds. The default is 10 minutes.

A.54.7 Router Instance Type

The Router Instance Type parameter specifies the type of router instance that is used as a collector source.

The options are:

- Base (default)
- VPRN

A.55 Network parameters

A.55.1 Use Queue Group

The Use Queue Group parameter specifies whether a queue from an egress queue group template is used in the egress forwarding class of a network policy.

The options are:

- Enabled
- Disabled (default)

When you set the Use Queue Group to Enabled, you must enter the egress queue ID specified in the queue group template policy in the Queue panel when applied to an IP interface.

A.56 Policer Control parameters

A.56.1 Cumulative MBS Contribution

The Cumulative MBS Contribution parameter specifies the maximum amount of cumulative buffer space (in bytes) allowed for a specific priority level by a policer control policy. The range is 1 to 134217728. The default is the maximum value.

A.56.2 Fixed MBS contribution

The Fixed MBS Contribution parameter specifies if the cumulative buffer space is fixed for a specific priority level. When this parameter is set to True for a priority level, the system treats the defined Cumulative MBS Contribution value as an explicit MBS definition for the priority level.

A.57 RADIUS Based Accounting parameters

A.57.1 Enable

The Enable parameter specifies whether the interval for updating subscriber host information is enabled.

The options are:

- enabled
- disabled (default)

When the Enable parameter is set to disabled, the subscriber host information is not updated. When the parameter is set to enabled, you can configure the Value (minutes) parameter.

A.58 Residential Subscriber parameters

A.58.1 Assign Aggregate Rate Limit

The Assign Aggregate Rate Limit parameter specifies whether or not to use the aggregate rate limit to you set using the associated Aggregate Rate Limit (kbps) parameter.

The options are:

- Disabled (default)
- Enabled

A.58.2 Keep-Alive - Default

The Keep-Alive - Default parameter specifies whether default setting are used for the Keep-Alive-Interval (seconds), Keep-Alive-Timeout (seconds), and Keep-Alive-Retries (seconds) parameters. The Default parameter must be disabled in order to specify non-default settings for the Keep-Alive parameters.

The options are:

- Disabled
- Enabled (default)

A.58.3 Message-Retransmit - Default

The Message-Retransmit - Default parameter specifies whether default setting are used for the Message-Retransmit-Retries and Message-Retransmit-Timeout (seconds) parameters. The Default parameter must be disabled in order to specify non-default settings for the Message-Retransmit parameters.

The options are:

- Disabled
- Enabled (default)

A.58.4 No Constraint

The No Constraint parameter specifies whether the Mandatory Bandwidth (kbps) or Unconstrained Bandwidth (kbps) parameters are set to their default values, or can be configured.

The options are:

- disabled
- enabled (default)

When the No Constraint parameter is set to enabled, you cannot configure the associated parameters.

A.58.5 Use Ingress L2TP DSCP

The Use Ingress L2TP DSCP parameter specifies whether the DSCP value found in the L2TP header of ingress traffic of PPP subscribers is used for egress classification. When this parameter is enabled, egress traffic is assigned to a forwarding class based on the L2TP DSCP information.

The options are:

- enabled
- disabled (default)

A.59 Routing parameters

A.59.1 View the newly created Policy Statement

The View the newly created Policy Statement parameter specifies whether the properties form for the policy is displayed when the current configuration form is closed.

The options are:

- Enabled
- Disabled (default)

A.60 Service PW Template parameters

A.60.1 Egress Filter Type

The Egress Filter Type parameter specifies the type of egress filter to be used.

The options are:

- No filter defined (default)
- Egress IP
- Egress IPv6
- Egress MAC

A.60.2 Ingress Filter Type

The Ingress Filter Type parameter specifies the type of ingress filter to be used.

The options are:

- No filter defined (default)
- Ingress IP
- Ingress IPv6
- Ingress MAC

A.61 Time of Day parameters

A.61.1 Priority

The Priority parameter specifies the priority of the time of day suite entry. If there are overlapping time range entries within a time of day suite entry, the time range entry with the highest priority is run first. The range is 1 to 10, where 1 is the highest priority, and 10 is the lowest. The default is 5.

The Priority parameter value must be unique within a same policy type.

A.62 WRED Slope parameters

A.62.1 High Slope

The High Slope parameter specifies how the high-priority packets, also known as in-profile packets, access the shared portion of the buffer pool. The probability of the buffer pools discarding packets is determined by the RED slope. The RED slope is indicated on the client GUI using a graph.

The Start Avg., Max Avg., and Max Prob. parameters specify the values of the RED slope.

In general, packets that are in-profile fall within the configured CIR and PIR ranges. This means the packets are more likely to gain access to the shared buffer pool, and not be discarded because of a buffer overflow.

A.62.2 Low Slope

The Low Slope parameter specifies how the low-priority packets, also known as out-of-profile packets, access the shared portion of the buffer pool. The probability of the buffer pools discarding packets is determined by the RED slope. The RED slop is indicated on the client GUI using a graph.

The Start Avg., Max Avg., and Max Prob. parameters specify the values of the RED slope.

In general, packets that are out-of-profile fall outside configured CIR and PIR ranges. This means the packets should not be allowed to cause a buffer overflow in the shared buffer pool, and should be more likely to be discarded because of a buffer overflow.

A.62.3 Max Avg.

(maxAverage)

The Max Avg. parameter specifies the maximum average of the RED slope position. The parameter indicates that the packet discard probability has increased to 1, and packets are discarded. The range is 0 to 100%. The default is 75% buffer pool utilization before the packet discard probability is 100% for the low slope and 90% for the high slope. The parameter must be greater than or equal to the Start Avg. parameter.

For example, when out-of-profile packets arrive on an interface configured with a low slope policy that has the parameter set to 75% and the Start Avg. parameter set to 50%, out-of-profile packets may start to be discarded by the buffer when it reaches 50% full, and all packets are dropped when the buffer reaches 75% full. The probability of the packets being discarded before the Max Avg. parameter is reached is determined by the Max Prob. parameter.

A.63 Routing Instance parameters

A.63.1 Infinite

The Infinite parameter specifies whether or not the static port forward will have an infinite lifetime.

The options are:

- Enabled (default)
- Disabled

A.63.2 Notify When Pool Is Depleted

The Notify When Pool Is Depleted parameter specifies whether an alarm is raised when there are no IP addresses available in the IP address pool.

The options are:

- Enabled (default)
- Disabled

A.63.3 Suppress Duplicate Error

The Suppress Duplicate Error parameter specifies whether an error message appears when the NFM-P attempts to synchronize a static port forward that already exists on the backup router.

The options are:

- Enabled
- Disabled (default)

A.64 Interface parameters

A.64.1 Inherit from Network Element

The Inherit from Network Element check box specifies whether the interface inherits the value of the Operational State Transition Interval parameter from the NE.

The options are:

- Enabled (default)
- Disabled

When the check box is disabled, the Operational State Transition Interval parameter is configurable.

A.64.2 View the newly created Network Interface

The View the newly created Network Interface parameter specifies whether the properties form for the interface is displayed when the current configuration form is closed.

The options are:

- Enabled
- Disabled (default)

A.64.3 What type of interface would you like to create?

The What type of interface would you like to create? parameter specifies the type of network interface that you are creating.

The options are:

- MPLS (default)
- OSPFv2
- OSPFv3
- RIP
- ISIS
- LDP

A.65 IS-IS parameters

A.65.1 Remove Key button

The Remove Key button deletes the MD5 key.

A.66 L2TP parameters

A.66.1 Load Balance Method

The Load Balance Method parameter specifies whether the NFM-P performs load balancing on an LT2P tunnel group on a per-session, or per-tunnel basis.

Table A-36 Load Balance Method parameter

Option	Description
No	Do not perform load balancing. This option is available only for tunnel profiles.
Per Session	Perform load balancing on a per-session basis.
Per Tunnel	Terminate all L2TP sessions with the same local tunnel ID on one MS-ISA, and perform load balancing on a per-tunnel basis.

A.67 MPLS parameters

A.67.1 View the newly created MPLS path

The View the newly created MPLS path parameter specifies whether you want to view the configuration information for the newly created MPLS path using the MPLS Path form.

The options are:

- Enabled
- Disabled (default)

A.68 Network Domain parameters

A.68.1 Interface Association Count

The Interface Association Count parameter specifies the number of interfaces associated with the domain.

A.68.2 Routing Instance ID

The Routing Instance ID displays the ID of the routing instance in the site.

A.68.3 SDP Association Count

The SDP Association Count lists the number of SDP and tunnels associated with the domain.

A.68.4 Site ID

The Site ID is the ID in which the network domain was configured.

A.68.5 Network Interfaces tab

The Network Interfaces tab lists the details of all the interfaces associated with the network domain. You can enter details in each of the options or select an option from the dropdown menu to filter your criteria.

A.68.6 Service Tunnels tab

The Service Tunnels tab lists the details of all service tunnels and SDP associated with the network domain. You can enter details in each of the options or select an option from the dropdown menu to filter your criteria.

A.69 OSPF parameters

A.69.1 Change Password button

You can use the Change Password button to change the text password used to validate OSPF messages between neighbors. The button is enabled when the Authentication Type parameter is set to the Simple Password option.

A.70 RSVP parameters

A.70.1 Down Threshold (%)

The Down Threshold (%) parameters (1 through 16) specify the Down Threshold level percentages for reserved bandwidth per interface. Any reserved bandwidth change per interface is compared to the configured threshold levels. An IGP TE update is triggered if the configured threshold levels are crossed, as a result of either an LSP setup or teardown. Threshold levels configured for the NE at the RSVP level can also be inherited by all configured RSVP interfaces under the NE.

You can configure from one to sixteen Down Threshold percentage levels. If you configure one or more thresholds to a non-default value, then the configured Down Thresholds will be rearranged in descending order. The range is -1, 0 to 100, where -1 indicates that the threshold level is disabled.

Table A-37 Down Threshold (%) parameters

Down Threshold (%) parameter name	XML string	Default value
Down Threshold 1 (%)	teThresholdLevelDown1	100
Down Threshold 2(%)	teThresholdLevelDown2	99
Down Threshold 3 (%)	teThresholdLevelDown3	98
Down Threshold 4 (%)	teThresholdLevelDown4	97
Down Threshold 5 (%)	teThresholdLevelDown5	96
Down Threshold 6(%)	teThresholdLevelDown6	95

Table A-37 Down Threshold (%) parameters (continued)

Down Threshold (%) parameter name	XML string	Default value
Down Threshold 7 (%)	teThresholdLevelDown7	90
Down Threshold 8 (%)	teThresholdLevelDown8	85
Down Threshold 9 (%)	teThresholdLevelDown9	80
Down Threshold 10(%)	teThresholdLevelDown10	75
Down Threshold 11 (%)	teThresholdLevelDown11	60
Down Threshold 12 (%)	teThresholdLevelDown12	45
Down Threshold 13 (%)	teThresholdLevelDown13	30
Down Threshold 14 (%)	teThresholdLevelDown14	15
Down Threshold 15 (%)	teThresholdLevelDown15	0
Down Threshold 16 (%)	teThresholdLevelDown16	-1

A.70.2 Up Threshold (%)

The Up Threshold (%) parameters (1 through 16) specify the Up Threshold level percentages for reserved bandwidth per interface. Any reserved bandwidth change per interface is compared to the configured threshold levels. An IGP TE update is triggered if the configured threshold levels are crossed, as a result of either an LSP setup or teardown. Threshold levels configured for the NE at the RSVP level can also be inherited by all configured RSVP interfaces under the NE.

You can configure from one to sixteen Up Threshold percentage levels. If you configure one or more thresholds to a non-default value, then the configured Up Thresholds will be rearranged in ascending order. The range is -1, 0 to 100, where -1 indicates that the threshold level is disabled.

Table A-38 Up Threshold (%) parameters

Up Threshold (%) parameter name	XML string	Default value
Up Threshold 1 (%)	teThresholdLevelUp1	0
Up Threshold 2(%)	teThresholdLevelUp2	15
Up Threshold 3 (%)	teThresholdLevelUp3	30
Up Threshold 4 (%)	teThresholdLevelUp4	45
Up Threshold 5 (%)	teThresholdLevelUp5	60
Up Threshold 6(%)	teThresholdLevelUp6	75
Up Threshold 7 (%)	teThresholdLevelUp7	80
Up Threshold 8 (%)	teThresholdLevelUp8	85
Up Threshold 9 (%)	teThresholdLevelUp9	90
Up Threshold 10(%)	teThresholdLevelUp10	95
Up Threshold 11 (%)	teThresholdLevelUp11	96

Table A-38 Up Threshold (%) parameters (continued)

Up Threshold (%) parameter name	XML string	Default value
Up Threshold 12 (%)	teThresholdLevelUp12	97
Up Threshold 13 (%)	teThresholdLevelUp13	98
Up Threshold 14 (%)	teThresholdLevelUp14	99
Up Threshold 15 (%)	teThresholdLevelUp15	100
Up Threshold 16 (%)	teThresholdLevelUp16	-1

A.71 Static Routes parameters

A.71.1 Enable CPE Check

The Enable CPE parameter allows configuration of the CPE check parameters when it is enabled. The CPE check parameters are hidden when it is disabled. The default is disabled.

A.72 Accounting Policies parameters

A.72.1 Counters

The Counters parameter in the Egress panel of the CustomQueueConfig or CustomOverrideConfig form specifies the ingress statistics counters or override queue counters to monitor. See the Egress Counters parameter in this section for the parameter options.

A.72.2 Counters

The Counters parameter in the Ingress panel of the CustomQueueConfig or CustomOverrideConfig form specifies the ingress statistics counters or override queue counters to monitor. See the Ingress Counters parameter in this section.

A.73 Auto-Provision Profiles parameters

A.73.1 Network Element Type

The Network Element Type parameter specifies the type of NE that supports auto provisioning.

A.73.2 Network Element Version Information

The Network Element Version Information parameter specifies the release of the NE that supports auto provisioning.

A.73.3 View the newly created Auto-Provisioning

The View the newly created Auto-Provisioning parameter specifies whether you need to view the configuration details of the newly created Auto-Provision.

The options are:

- Enabled
- Disabled (default)

A.74 Bulk Operations parameters

A.74.1 Batch Size

The Batch Size parameter specifies the size of each batch. The range is 100 to 5000. The default is 2000.

A.74.2 Batch Status

The Batch Status parameter displays the bulk change status of all of the batch items. The value is not configurable.

If all of the batch items have the same bulk change status, the Batch Status parameter displays that status. If one or more of the batch items has a different bulk change status, the Batch Status parameter displays the Mixed status.

Table A-39 Batch Status descriptions

Status	Description
Cancelled	The operation has been manually stopped.
DB Failures	A database error occurred with the batch change.
Deployment Failure [1]	Deployment to the node failed.
Exception	An internal error occurred during the batch execution.
Execution Failures	An error occurred with the operation.
In Progress	The operation is executing.
Mixed	One or more of the batch items has a different bulk change status.
No Change	No objects were changed.
Not Applicable	—
Not Executed	The operation has never been executed before.
Not in User Span	Objects were not in the user span.
Object Not Found	The object to modify no longer exists in the NFM-P.
Queued	The operation is queued to execute.
Successful	The operation completed successfully.

Notes:

1. This status does not update automatically if or when the deployment failure clears.

A.74.3 Batch Status Summary

The Batch Status Summary parameter displays the status of all of the batches. The value is not configurable.

If all of the batches have the same batch status, the Batch Status Summary parameter displays that status. If one or more of the batches has a different batch status, the Batch Status Summary parameter displays the Mixed status.

See Table A-39, “Batch Status descriptions” (p. 3327) for a list of generated statuses and their descriptions.

A.74.4 Changed

The Changed parameter displays the number of objects that were modified in the batch. The value is not configurable.

A.74.5 Continue on Failure

The Continue on Failure parameter specifies whether the operation stops if a failure occurs or if the operation continues until the operation is complete regardless of failures.

The options are:

- Enabled
- Disabled (default)

A.74.6 Creator

The Creator parameter displays the name of the NFM-P user that created the last operation. The value is not configurable.

A.74.7 Duration

The Duration parameter specifies how long the last operation took to execute. The value is not configurable.

A.74.8 Execution Status

The Execution Status parameter displays the status of the bulk change operation. The value is not configurable.

Table A-40 Execution Status descriptions

Status	Description
Cancelled	The operation has been manually stopped.
Completed	The operation has been executed.

Table A-40 Execution Status descriptions (continued)

Status	Description
Generating...	Batch generation is in progress.
Generation Complete	Batch generation is complete.
In Progress	The operation is executing.
No Deployers Available	All available deployers are busy, or the deployment failed.
Not Applicable	—
Not Executed	The operation has never been executed.
Queued	The operation is queued for execution.

A.74.9 Failures

The Failures parameter displays the number of objects in the batch that failed to be changed. The value is not configurable.

A.74.10 Last Total Changed

The Last Total Changed parameter displays the number of objects that were changed by the last executed operation. The value is not configurable.

A.74.11 Not Changed

The Not Changed parameter displays the number of objects in the batch that did not change. The value is not configurable.

A.74.12 Not Found

The Not Found parameter displays the number of objects in the executed batches that could not be changed because they no longer exist in the NFM-P. The value is not configurable.

A.74.13 Not in Span

The Not in Span parameter displays the number of objects in the executed batches that could not be changed because they are not in the user span of control. The value is not configurable.

A.74.14 Object Type

The Object Type parameter specifies the object class to which the bulk change applies. Choose an object type using the pull-down list.

A.74.15 Operation ID

The Operation ID parameter specifies a unique numeric identifier for the operation. The parameter is configurable when the Auto-Assign ID parameter is disabled. The range is 1 to 65 535. The default is 0, which means that a value is not specified.

A.74.16 Range

The Range parameter displays the range of objects that are included in the batch. The range is not configurable.

A.74.17 Time Last Started

The Time Last Started parameter specifies the time that the last operation execution started. The value is not configurable.

A.74.18 Time Last Finished

The Time Last Finished parameter specifies the time that the last operation execution finished. The value is not configurable.

A.75 Card Migration Event Manager parameters

A.75.1 Auto Reboot

The Auto Reboot parameter specifies whether the NFM-P reboots a target NE automatically after the migration tasks on the NE are complete. The parameter is configurable at the card migration event level, which applies to each target NE, and at the target NE level, which applies only to the selected NEs.

The options are:

- Enabled
- Disabled (default)

A.75.2 New Type

The New Type parameter specifies the new IOM or MDA type, depending on which panel contains the parameter, and on the Current Type value in the panel.

The parameter options for IOMs are:

- No Change (default)
- 2 x XP MDA IOM 3

The following table lists the parameter options for MDAs. The default is No Change.

Table A-41 New Type parameter

Current Type	New Type
10 x 1-Gig Ethernet SFP	10 x 1Gig Extended Performance SFP 20 x 10/100/1000 Ethernet Extended Performance SFP 20 x 10/100/1000 Ethernet Extended Performance TX
5 x 1-Gig Ethernet SFP	10 x 1Gig Extended Performance SFP 20 x 10/100/1000 Ethernet Extended Performance SFP 20 x 10/100/1000 Ethernet Extended Performance TX

Table A-41 New Type parameter (continued)

Current Type	New Type
1 x 10-Gig Ethernet	4 x 10Gig Extended Performance XFP 2 x 10Gig Extended Performance XFP 1 x 10Gig Extended Performance SFP
20 x 100 Ethernet Fx	20 x 10/100/1000 Ethernet Extended Performance SFP 20 x 10/100/1000 Ethernet Extended Performance TX
20 x 10/100/1000 Ethernet Tx	20 x 10/100/1000 Ethernet Extended Performance SFP 20 x 10/100/1000 Ethernet Extended Performance TX
2 x 10-Gig Ethernet XFP	2 x 10Gig Extended Performance XFP 4 x 10Gig Extended Performance XFP
20 x 10/100/1000 Ethernet SFP	20 x 10/100/1000 Ethernet Extended Performance SFP 20 x 10/100/1000 Ethernet Extended Performance TX
1 x 10-gig Ethernet XFP	4 x 10GigExtended Performance XFP 2 x 10Gig Extended Performance XFP 1 x 10Gig Extended Performance XFP
5 x 10/100/1000	10 x 1Gig Extended Performance SFP 20 x 10/100/1000 Ethernet Extended Performance SFP 20 x 10/100/1000 Ethernet Extended Performance TX
10 x 10/100/1000 Ethernet SFP	10 x 1Gig Extended Performance SFP 20 x 10/100/1000 Ethernet Extended Performance SFP 20 x 10/100/1000 Ethernet Extended Performance TX

A.76 Copy/Move SAPs parameters

A.76.1 Continue on individual Failure

The Continue on individual Failure parameter specifies the action to be taken if a SAP copy or move operation fails. When the parameter is disabled, the operation stops after the first failure and all successful SAP copy or move operations are reversed. When the parameter is enabled, the operation continues until all SAP copy or move operations that can be completed successfully are finished.

The options are:

- Disabled (default)
- Enabled

A.76.2 Inner Encap Value End

The Inner Encap Value End parameter specifies the ending value of the inner encapsulation label. The range is 1 to 65 535 (default is 1) for ATM channels. Otherwise, the range is 0 to 4095 (default is 0).

A.76.3 Inner Encap Value Start

The Inner Encap Value Start parameter specifies the starting value of the inner encapsulation label. The range is 1 to 65 535 (default is 1) for ATM channels. Otherwise, the range is 0 to 4095 (default is 0).

A.76.4 Outer Encap Value End

The Outer Encap Value End parameter specifies the end value of the outer encapsulation label. The range is 0 to 4094. The default is 4094.

A.76.5 Outer Encap Value Start

The Outer Encap Value Start parameter specifies the start value of the outer encapsulation label. The range is 0 to 4094. The default is 0.

A.76.6 Service Type

The Service Type parameter specifies the type of service for the source interface SAPs.

When the Current Mode parameter is L2 Access Interface, the options are:

- All L2 Services (default)
- Apipe
- Epipe
- Ipipe
- VPLSs
- MVPLS

When the Current Mode parameter is L3 Access Interface or L3 Subscriber Interface SAP, the options are:

- All L3 Services (default)
- IES
- VPRN

A.77 NE Sessions parameters

A.77.1 Append to file

The Append to file parameter specifies whether the NFM-P appends the console output to the file specified by the A.77.7 “Log File Location” (p. 3334) parameter.

The parameter is configurable when the A.77.9 “Send Console To a File” (p. 3334) parameter is enabled.

Table A-42 Append to file parameter

Option	Description
disabled (default)	The NFM-P overwrites the file specified by the A.77.7 “Log File Location” (p. 3334) parameter using the console output.
enabled	The NFM-P appends the console output to the file specified by the A.77.7 “Log File Location” (p. 3334) parameter.

A.77.2 Background color

The Background color parameter specifies the background color of the console window. Click on the Set color button beside the parameter to choose a color using a palette form. The default is black.

A.77.3 Bold

The Bold parameter specifies whether the console window displays text in boldface type.

The options are:

- disabled (default)
- enabled

A.77.4 Font Name

The Font Name parameter specifies the typeface of the text in the console window.

The options are:

- Monospaced (default)
- DialogInput
- Lucida Console
- Lucida Sans Typewriter

A.77.5 Foreground color

The Foreground color parameter specifies the color of the text in the console window. Click on the Set color button beside the parameter to choose a color using a palette form. The default is white.

A.77.6 Italic

The Italic parameter specifies whether the text in the console window is italicized.

The options are:

- disabled (default)
- enabled

A.77.7 Log File Location

The Log File Location parameter specifies the path and name of the file that is to contain the console output. The NFM-P creates the file if it does not exist.

You can configure the parameter using one of the following methods.

- Manually type a file name.
- Click on the Change button and use the form that opens to specify a file.
- Click on the Set Default button to restore the default path and file name.

The default is *install_dir*/nms/log/client/*user_name*/cli_output.txt on a RHEL client station, and *install_dir*\nms\log\client*user_name*\cli_output.txt on a Windows client station

where

install_dir is the client installation directory, typically /opt/nsp/client on RHEL, and C:\nsp\client on Windows

user_name is the RHEL or Windows user name

The parameter is configurable when the A.77.9 “Send Console To a File” (p. 3333) parameter is enabled.

A.77.8 Minimum number of scrolling lines

The Minimum number of scrolling lines parameter specifies the maximum number of text lines that the console scroll buffer can contain. When the number of lines exceeds the parameter value, the NFM-P removes the oldest line from the buffer and the line is no longer displayed in the console window.

A.77.9 Send Console To a File

The Send Console To a File parameter specifies whether the NFM-P records the console output in a file.

The options are:

- disabled (default)
- enabled

A.78 Schedules parameters

A.78.1 Change Current User To

The Change Current User To parameter specifies the NFM-P user to which the NFM-P scheduled task is to be assigned. The options are all configured user accounts. The default is admin, which is the default NFM-P account.

A.78.2 Enable

The Enable parameter specifies whether to enable or disable the configurability of the Delay Time (seconds) parameter.

The options are:

- Enable
- Disable (default)

A.78.3 Run Every Days

The Run Every Days parameter specifies whether the NFM-P schedule runs every *n* days, where *n* is a numerical value that you set using the up and down arrows. The parameter is configurable when the Frequency parameter is set to Per Day. The range is 1 to 2 147 483 647. The default is 1.

A.78.4 Run Every Hours

The Run Every Hours parameter specifies whether the NFM-P schedule runs every *n* hours, where *n* is a numerical value set using the up and down arrows. The parameter is configurable when the Run Every Hour parameter is disabled. The range is 1 to 2 147 483 647. The default is 1.

A.78.5 Run Every Minutes

The Run Every Minutes parameter specifies that the NFM-P schedule runs every *n* minutes, where *n* is a numerical value set using the up and down arrows. The parameter is configurable when the Run Every Minute parameter is disabled.

A.78.6 Run Every Months

The Run Every Months parameter specifies that the NFM-P schedule runs every *n* months, where *n* is a numerical value set using the up and down arrows. The parameter is configurable when the Frequency parameter is set to Per Month. The range is 1 to 2 147 483 647. The default is 1.

A month is based on a 30-day interval.

A.78.7 Run Every Seconds

The Run Every Seconds parameter specifies that the NFM-P schedule runs every *n* seconds, where *n* is a numerical value set using the up and down arrows. The parameter is configurable when the Run Every Second parameter is disabled. The range is 1 to 2 147 483 647. The default is 1.

A.78.8 Time Alignment Setting

The Time Alignment Setting parameter specifies the base minute with which the NFM-P schedule aligns. The parameter is used with the A.78.5 “Run Every Minutes” (p. 3335) parameter. The range is 0 to 59. The default is 0.

A.79 Scripts parameters

A.79.1 Answer

The Answer parameter specifies the answer to a command sent by the system in response to a question intervention tag.

A.80 Scripts parameters

A.80.1 Default Value

The Default Value parameter specifies the default value that is associated with the parameter tag or intervention tag in the CLI script. The range is 0 to 255 characters. The characters ‘ ( ) ? / are not allowed.

A.80.2 Label

The Label parameter specifies the CLI script parameter tag in a CLI script. The range is 1 to 255 characters. Only alphanumeric characters, underscores, and dashes are allowed.

A.80.3 Question

The Question parameter specifies a question that is expected in response to a command in a script. The system responds to the question with the answer specified by the A.79.1 “Answer” (p. 3336) parameter.

A.80.4 Type

The Type parameter specifies the category of the script. The range is 0 to 255 characters.

A.81 Server Performance Statistics parameters

A.81.1 Accounting Stats Failure Periodic Threshold

The Accounting Stats Failure Periodic Threshold parameter specifies the number of accounting statistics failures that the Stats Collection counter records during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. Accounting statistics failures can be caused by conditions such as failed file transfers. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.2 Accounting Stats Pending Periodic Threshold

The Accounting Stats Pending Periodic Threshold parameter specifies the number of accounting statistics that are pending to be processed that the Stats Collection counter records during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.3 Accounting Stats Processed Periodic Threshold

The Accounting Stats Processed Periodic Threshold parameter specifies the number of accounting statistics processed that the Stats Collection counter records during the interval specified by the A.81.8 “Collection Interval” (p. 3336) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.4 Accounting Stats Total Periodic Threshold

The Accounting Stats Total Periodic Threshold parameter specifies the number of accounting statistics received that the Stats Collection counter records during the interval specified by the A.81.8 “Collection Interval” (p. 3336) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.5 Alarm Total Periodic Threshold

The Alarm Total Periodic Threshold parameter specifies the number of alarms that the Alarm Rate counter records during the interval specified by the A.81.8 “Collection Interval” (p. 3336) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.6 Average Processing Time Periodic Threshold

The Average Processing Time Periodic Threshold parameter specifies the average processing time for AA statistics files during the interval specified by the A.81.8 “Collection Interval” (p. 3336) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.7 Cleared Periodic Threshold

The Cleared Periodic Threshold parameter specifies the number of cleared alarms that the Alarm Rate counter records during the interval specified by the A.81.8 “Collection Interval” (p. 3336) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.8 Collection Interval

(pollingInterval)

The Collection Interval parameter specifies the frequency with which the statistics counters for the selected statistics class are logged. The default is 15 minutes.

A.81.9 Condition Periodic Threshold

The Condition Periodic Threshold parameter specifies the number of condition alarms that the Alarm Rate counter records during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.10 Critical Periodic Threshold

The Critical Periodic Threshold parameter specifies the number of critical alarms that the Alarm Rate counter records during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.11 Dropped Backpressure Periodic Threshold

The Dropped Backpressure Periodic Threshold parameter specifies the number of traps dropped because of backpressure during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. Backpressure conditions occur when the NFM-P server is very busy processing other traps. When the SNMP Trap counter reaches this number, a threshold-crossing alarm is raised.

A.81.12 Dropped Duplicate Periodic Threshold

The Dropped Duplicate Periodic Threshold parameter specifies the number of duplicate SNMP traps dropped during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the SNMP Trap counter reaches this number, a threshold-crossing alarm is raised.

A.81.13 Dropped Full Resync Periodic Threshold

The Dropped Full Resync Periodic Threshold parameter specifies the number of SNMP traps that are not processed because of a pending full resync during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the SNMP Trap counter reaches this number, a threshold-crossing alarm is raised.

A.81.14 Dropped Not Managed Periodic Threshold

The Dropped Not Managed Periodic Threshold parameter specifies the number of SNMP traps associated with an unmanaged NE dropped during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the SNMP Trap counter reaches this number, a threshold-crossing alarm is raised.

A.81.15 Dropped Out Of Sequence Periodic Threshold

The Dropped Out Of Sequence Periodic Threshold parameter specifies the number of SNMP traps with non-sequential trap IDs dropped during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the SNMP Trap counter reaches this number, a threshold-crossing alarm is raised.

A.81.16 File Accounting Stats Pending Periodic Threshold

The File Accounting Stats Pending Periodic Threshold parameter specifies the number of accounting files transferred from NEs that are waiting to be processed. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.17 File Accounting Stats Processed Periodic Threshold

The File Accounting Stats Processed Periodic Threshold parameter specifies the number of accounting statistics files that have been read and processed into statistics records. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.18 File Accounting Stats Total Periodic Threshold

The File Accounting Stats Total Periodic Threshold parameter specifies the number of accounting statistics files that have been transferred from NEs. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.19 Incoming Periodic Threshold

The Incoming Periodic Threshold parameter specifies the number of SNMP traps received during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the SNMP Trap counter reaches this number, a threshold-crossing alarm is raised.

A.81.20 Indeterminate Periodic Threshold

The Indeterminate Periodic Threshold parameter specifies the number of indeterminate alarms that the Alarm Rate counter records during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.21 Info Periodic Threshold

The Info Periodic Threshold parameter specifies the number of log entries for info alarms that the Alarm Rate counter records during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.22 Major Periodic Threshold

The Major Periodic Threshold parameter specifies the number of major alarms that the Alarm Rate counter records during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.23 Maximum Processing Time Periodic Threshold

The Maximum Processing Time Periodic Threshold parameter specifies the maximum processing time for AA statistics files during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.24 Minimum Processing Time Periodic Threshold

The Minimum Processing Time Periodic Threshold parameter specifies the minimum processing time for AA statistics files during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.25 Minor Periodic Threshold

The Minor Periodic Threshold parameter specifies the number of minor alarms that the Alarm Rate counter records during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.26 Scheduled Polling Stats Pending Periodic Threshold

The Scheduled Polling Stats Pending Periodic Threshold parameter specifies the number of scheduled SNMP statistics awaiting processing that the Stats Collection counter records during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.27 Scheduled Polling Stats Processed Periodic Threshold

The Scheduled Polling Stats Processed Periodic Threshold parameter specifies the number of processed scheduled SNMP statistics that the Stats Collection counter records during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.28 Scheduled Polling Stats Total Periodic Threshold

The Scheduled Polling Stats Total Periodic Threshold parameter specifies the number of scheduled SNMP statistics received that the Stats Collection counter records during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.29 Scheduled Resync Failure Periodic Threshold

The Scheduled Resync Failure Periodic Threshold parameter specifies the number of scheduled node resync failures that the Node Resync counter records during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.30 Scheduled Resync Processed Periodic Threshold

The Scheduled Resync Processed Periodic Threshold parameter specifies the number of scheduled processed node resyncs that the Node Resync counter records during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.31 Scheduled Resync Received Periodic Threshold

The Scheduled Resync Received Periodic Threshold parameter specifies the number of scheduled node resyncs that the Node Resync counter records during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.32 Scheduled Stats Failure Periodic Threshold

The Scheduled Stats Failure Periodic Threshold parameter specifies the number of scheduled SNMP statistics processing failures that the Stats Collection counter records during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. Statistics failures may occur if an NE is unreachable or if collection takes longer than the collection interval time. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.33 Total Processing Time Periodic Threshold

The Total Processing Time Periodic Threshold parameter specifies the total processing time for AA statistics files during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.34 Unscheduled Resync Failure Periodic Threshold

The Unscheduled Resync Failure Periodic Threshold parameter specifies the number of unscheduled node resync failures that the Node Resync counter records during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.35 Unscheduled Resync Processed Periodic Threshold

The Unscheduled Resync Processed Periodic Threshold parameter specifies the number of unscheduled processed node resyncs that the Node Resync counter records during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.36 Unscheduled Resync Received Periodic Threshold

The Unscheduled Resync Received Periodic Threshold parameter specifies the number of unscheduled node resyncs that the Node Resync counter records during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.37 Used Heap Memory Periodic Threshold

The Used Heap Memory Periodic Threshold parameter specifies the amount of heap memory currently in use that the NFM-P Memory counter records during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.38 Unscheduled Polling Stats Pending Periodic Threshold

The Unscheduled Polling Stats Pending Periodic Threshold parameter specifies the number of unscheduled SNMP statistics awaiting processing that the Stats Collection counter records during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.39 Unscheduled Polling Stats Processed Periodic Threshold

The Unscheduled Polling Stats Processed Periodic Threshold parameter specifies the number of processed unscheduled SNMP statistics that the Stats Collection counter records during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.40 Unscheduled Polling Stats Total Periodic Threshold

The Unscheduled Polling Stats Total Periodic Threshold parameter specifies the number of unscheduled SNMP statistics received that the Stats Collection counter records during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.41 Unscheduled Stats Failure Periodic Threshold

The Unscheduled Stats Failure Periodic Threshold parameter specifies the number of unscheduled SNMP statistics processing failures that the Stats Collection counter records during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.42 Used Non Heap Memory Periodic Threshold

The Used Non Heap Memory Periodic Threshold parameter specifies the amount of non-heap memory currently in use that the NFM-P Memory counter records during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.81.43 Warning Periodic Threshold

The Warning Periodic Threshold parameter specifies the number of warning alarms that the Alarm Rate counter records during the interval specified by the A.81.8 “Collection Interval” (p. 3337) parameter. When the counter reaches this number, a threshold-crossing alarm is raised.

A.82 Statistics Manager parameters

A.82.1 Default Polling Interval (seconds)

The Default Polling Interval (seconds) parameter specifies the default interval, in seconds, for the polling interval for real-time statistics in the Statistics Plotter form.

A.82.2 Maximum Data Retention Time (seconds)

The Maximum Data Retention Time (seconds) parameter specifies the number of seconds to keep statistics data in the Statistics Plotter form.

A.82.3 Retention Time (hours)

The Retention Time (hours) parameter specifies the time, in hours, that the database stores the statistics associated with a statistics policy.

A.82.4 Statistics Type

The Statistics Type parameter specifies the type of logged data that is displayed in the search list.

Table A-43 Statistics Type parameter

Option	Description
Current Data (default)	The most recent available statistics record
Statistics Policy	The statistics policy configured for the statistics class
Statistics Record	All available records for the statistics class

Note: Following an upgrade to NSP Release 24.8, all historical CPU Utilization Statistics will be deleted from the NFM-P system/database.

A.82.5 Threshold Reporting State

The Threshold Reporting State parameter specifies whether to generate threshold alarms when the number of log entries exceeds the Max Log Records parameter value. The options are:

- Up (default)
- Down

A.83 Service Test Manager parameters

A.83.1 Count

The Count parameter specifies the number of frames to be sent during an OmniSwitch ping. The range is 0 to 2 147 483 647. The default is 6.

A.83.2 Include Falling Threshold

The Include Falling Threshold parameter specifies whether to generate a threshold-crossing alarm for an OAM test if the value falls below a specified level.

The options are:

- Enabled
- Disabled (default)

A.83.3 Interval (seconds)

The Interval (seconds) parameter specifies the polling interval that is used for the ping. The range is 1 to 10 000. The default is 1.

A.83.4 Maximum Hop

The Maximum Hop parameter specifies the maximum number of hops in the path to the target OmniSwitch. The range is 0 to 2 147 483 647. The default is 5.

A.83.5 Source Site ID

The Source Site ID parameter specifies the IP address of the service tunnel origin. Specify an IP address in dotted-decimal format. The default is 0.0.0.0, which means that the parameter is not configured.

A.83.6 Test Interval (minutes)

The Test Interval (minutes) parameter specifies the time delay, in minutes, between contiguous tests. The range is 10 to 1500. The default is 10.

A.83.7 Timeout (seconds)

The Timeout (seconds) parameter specifies the time, in s, to wait for a message response. All reply messages that arrive after the specified time are silently discarded. The range is 1 to 100. The default is 5.

A.83.8 Timeout (minutes)

The Timeout (seconds) parameter specifies the number of minutes to wait for the test suite completion. The range is 1 to 600. The default is 15.

A.84 Time Range Entry Assignment parameters

A.84.1 End Date

The End Date parameter specifies the end date and time of the time range entry assignment analysis. You can use the up and down arrows to change the year, month, day, hour, or minute. The default value is the current system time of the NFM-P server.

A.84.2 Search by Time Of Day Entry Type

The Search by Time Of Day Entry Type parameter specifies whether the time range entry assignment analysis tool uses the A.7.2 “Password Change Required” (p. 3264) parameter as an input criterion.

The options are:

- enabled
- disabled (default)

A.84.3 Start Date

The Start Date parameter specifies the start date and time of the time range entry assignment analysis. You can use the up and down arrows to change the year, month, day, hour, or minute. The default value is the current system time of the NFM-P server.

A.84.4 Time Of Day Entry Policy Type

The Time Of Day Entry Policy Type parameter specifies the type of time of day entry policy that the time range entry assignment analysis tool uses as an input criterion. The options are:

- Ingress IPV6 Filter
- Egress MAC Filter
- Egress QoS Scheduler Policy
- Ingress IP Filter
- Egress IPV6 Filter
- Ingress QoS Scheduler Policy
- Egress QoS Policy
- Ingress QoS Policy

A.84.5 Time Range Entry Container Type

The Time Range Entry Container Type parameter specifies the type of policy string that the time range entry assignment analysis tool uses as an input criterion.

The options are:

- L2 Access Interface
- L3 Access Interface
- Aggregation Suite
- Time Of Day Suite

A.85 CPAM parameters

A.85.1 Destination FEC

The Destination FEC parameter specifies the IP address and subnet mask of the destination router or link in a CSPF calculation. Enter an IPv4 address in dotted decimal format or use the Select button to list and choose a destination router or link.

A.85.2 Ethernet Error

The Ethernet Error parameter specifies whether the audit verifies the error rate of the IP link against a specified threshold. The options are:

- Enabled (default)
- Disabled

A.85.3 First IP

The First IP parameter specifies the IP address of the source router. Enter the IPv4 address of the router in dotted-decimal format or use the Select button to list and choose a router.

A.85.4 Group IP

The Group IP parameter specifies the IP address of a multicast group to be highlighted.

A.85.5 In Profile Drop

The In Profile Drop parameter specifies whether the audit verifies the in profile drop rate for FC queues 1 to 8 against a specified threshold. The options are:

- Enabled
- Disabled (default)

A.85.6 Interface Error

The Interface Error parameter specifies whether the audit verifies the error rate of the network interface against a specified threshold. The options are:

- Enabled (default)
- Disabled

A.85.7 Least Fill Min Threshold %

The Least Fill Min Threshold % parameter specifies the minimum threshold of least-utilized links that can be used in the ECMP tie-breaking process.

The Least Fill Min Threshold % parameter is configurable only when the A.85.14 “Request Type” (p. 3347) parameter is set to Least_Fill.

A.85.8 Line - Severely Errored Seconds

The Line - Severely Errored Seconds parameter specifies whether the audit verifies the counter associated with the number of severely errored framing seconds found by a SONET/SDH line in the current 15 minute interval. The options are:

- Enabled
- Disabled (default)

A.85.9 Mask

The Mask parameter specifies the subnet mask length for the multicast group prefix. This parameter works in conjunction with the Multicast Group Prefix parameter. The range is 0 to 32. The default is 0.

A.85.10 Multicast Group Prefix

The Multicast Group Prefix parameter specifies the prefix for a multicast group.

A.85.11 Out of Profile Drop

The Out of Profile Drop parameter specifies whether the audit verifies the out of profile drop rate for FC queues 1 to 8 against a specified threshold. The options are:

- Enabled
- Disabled (default)

A.85.12 Prefix Length

The Prefix Length parameter, when combined with an IP address value, specifies the local IP prefix. The range is 0 to 32. The default is 24.

A.85.13 Protocol

The Protocol parameter specifies the multicast protocol of the routers to be highlighted. The options are:

- PIM
- IGMP (default)
- PIM or IGMP

A.85.14 Request Type

The Request Type parameter specifies how CSPF selects a path in the tie-breaking process for ECMP if there are several equal cost paths. The parameter options are described in the following table:

Table A-44 Request Type parameter

Option	Description	Dependencies
All	Traffic is sent over all of the matching paths.	—
Random	Traffic is sent over one randomly selected path.	—
Least_Fill	Traffic is sent over the path with the least-utilized links. The CPAM considers the value of the A.85.7 “Least Fill Min Threshold %” (p. 3346) only when this option is selected.	—

A.85.15 Required Bandwidth

The Required Bandwidth parameter specifies the minimum available bandwidth of the calculated CSPF. The range is 0, or 1 to 4 294 967 295. A value of zero means that the CSPF calculation includes no minimum bandwidth requirements.

A.85.16 Second IP

The Second IP parameter specifies the IP address of the destination router. Enter the IPv4 address of the router in dotted-decimal format or use the Select button to list and choose a router. On an ISIS topology map, an IPv6 router address can be entered in colon-hexadecimal format.

A.85.17 Section - Severely Errored Framing Seconds

The Section - Severely Errored Framing Seconds parameter specifies whether the audit verifies the counter associated with the number of severely errored framing seconds found by a SONET/SDH section in the current 15 minute interval. The options are:

- Enabled
- Disabled (default)

A.85.18 Section - Severely Errored Seconds

The Section - Severely Errored Seconds parameter specifies whether the audit verifies the counter associated with the number of severely errored seconds found by a SONET/SDH section in the current 15 minute interval. The options are:

- Enabled
- Disabled (default)

A.85.19 Source IP

The Source IP parameter specifies the IP address of the source router or link in a CSPF calculation. Enter an IPv4 address in dotted decimal format or use the Select button to list and choose a source router or link.

A.85.20 SRLG Strict

The SRLG Strict parameter specifies whether the CSPF highlight is calculated if the CPAM does not find path with SRLG. If the SRLG Strict parameter is enabled, CSPF tries to find paths with excluded SRLG. If no paths are found, CSPF returns an empty result.

If the SRLG Strict parameter is disabled, CSPF tries to find paths with excluded SRLG. If no paths are found, CSPF returns paths that ignore the SRLG constraint, if any.

The options are:

- Enabled
- Disabled (default)

A.85.21 SRLG Value

The SRLG Value parameter specifies the SRLG value that must be excluded from a CSPF calculation. The range is 1 to 4 294 967 295.

A.85.22 Stats Capture Delay

The Stats Capture Delay parameter specifies the delay, in seconds, between first capture and the second capture of the statistics. The range is 15 to 300. The default is 30.

A.85.23 Total Drop

The Total Drop parameter specifies whether the audit verifies the drop rate for FC queues 1 to 8 against a specified threshold. The options are:

- Enabled (default)
- Disabled

A.85.24 Threshold

The Threshold parameter specifies the threshold against which the audit parameter is compared. The files that enable customization of the default Threshold values can be found in /opt/nsp/nfmp/server/nms/config/audit/params on an NFM-P main server. The following table lists the defaults for each audit parameter:

Table A-45 Threshold parameter default values

Audit parameter	Default	Measure
A.85.2 “Ethernet Error” (p. 3345)	0.5	%
A.85.5 “In Profile Drop” (p. 3345)	2.5	%
A.85.6 “Interface Error” (p. 3346)	0.5	%
A.85.8 “Line - Severely Errored Seconds” (p. 3346)	0	seconds
A.85.11 “Out of Profile Drop” (p. 3346)	2.5	%
A.85.18 “Section - Severely Errored Seconds” (p. 3348)	0	seconds
A.85.17 “Section - Severely Errored Framing Seconds” (p. 3347)	0	seconds
A.85.23 “Total Drop” (p. 3348)	2.5	%
A.85.25 “Utilization” (p. 3349)	97.5	%

A.85.25 Utilization

The Utilization parameter specifies whether the audit verifies the utilization rate of the network interface or IP link against a specified threshold. The options are:

- Enabled (default)
- Disabled
